Abstract

In response to the limitations of manual ad creation, significant research has been conducted in the field of automatic ad text generation (ATG). However, the lack of comprehensive benchmarks and well-defined problem sets has made comparing different methods challenging. To tackle these challenges, we standardize the task of ATG and propose a first benchmark dataset, CAMERA, carefully designed and enabling the utilization of multi-modal information and facilitating industry-wise evaluations. Our extensive experiments with a variety of nine baselines, from classical methods to state-of-the-art models including large language models (LLMs), show the current state and the remaining challenges. We also explore how existing metrics in ATG and an LLM-based evaluator align with human evaluations.

1 Introduction

The global online advertising market has witnessed significant growth and quadrupled over the last decade, particularly in the domain of search ads (Meeker and Wu, 2018). Search ads are designed to accompany search engine results and are tailored to be relevant to users' queries (search queries). These ads are displayed alongside a landing page (LP), providing further details about the advertised product or service. Therefore, ad creators must create compelling ad texts that captivate users and encourage them to visit the LP. However, the increasing volume of search queries, which is growing at a rate of approximately 8% annually (Djuraskovic, 2022), poses challenges for manual ad creation.

The growing demand in the industry has fueled research on the automatic generation of ad texts. Researchers have explored various approaches, starting with *template-based* methods that generate ad text by inserting relevant keywords into predefined templates (Bartz et al., 2008; Fujita et al., 2010; Thomaidou et al., 2013). Recently, neural language generation (NLG) techniques based on encoder-decoder models, which are widely employed in machine translation and automatic summarization, have been applied to ad text generation (ATG) (Hughes et al., 2019; Mishra et al., 2020; Kamigaito et al., 2021).

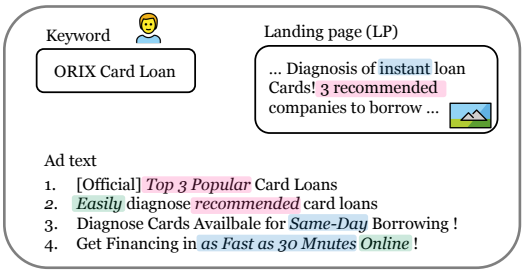

Figure 1: Examples of our dataset, translated into English for visibility. The highlighted areas indicate the aspects of advertising appeals: *Speed*, *Trend*, and *User-friendliness*

However, the automated evaluation of ATG models presents significant challenges. Previous research has been constrained to conducting individual experiments using proprietary datasets that are not publicly available (Murakami et al., 2023). This limitation arises from the absence of a shared dataset (i.e., a benchmark) that can be universally applied across the field. Moreover, the absence of benchmarks has resulted in a lack of consensus regarding task settings such as the models' input/output formats. While some studies use keywords as input (Bartz et al., 2008; Fukuda, 2019), others employ existing advertisements (Mishra et al., 2020) or LPs (Hughes et al., 2019; Kanungo et al., 2022; Golobokov et al., 2022). This variation in the task setting indicates that the field as a whole has yet to establish a standardized problem setting, which hinders the generalization and comparability of ATG techniques.

This study aims to advance ATG technology by

Proceedings of the 62nd Annual Meeting of the Association for Computational Linguistics (Volume 1: Long Papers), pages 955–972

standardizing the task setup, transforming it into a format accessible to potential players by providing a shared dataset, and exploring the current status and limitations. Standardizing problem settings common to a variety of advertising applications as tasks allows for focused exploration of core issues in an academic context while maintaining the flexibility to be applied to a wide variety of applications (§3). To engage a broader community of researchers beyond those who possess ad data, we construct the first publicly available benchmark, **CAMERA** (**C**yber**A**gent **M**ultimodal **E**valuation for Ad Text Gene**RA**tion)(Figure 1), which is meticulously developed a comprehensive dataset (§4).[1] Our dataset comprises actual data sourced from Japanese search ads and incorporates annotations encompassing multi-modal information such as the LP images. To explore the current state and future challenges, we conducted extensive experiments using nine diverse baselines, including multimodal models and large language models (LLMs), as well as the dominant approaches in existing studies (§5). Furthermore, we also conducted a meta-evaluation of how well the existing metrics and LLM-based evaluators reproduced human evaluations (§6.1).

Our major contributions are:

- Establishing the standardized task and creating open data have paved the way for reproducible research and lowered barriers to entry.
- Benchmarking experiments with nine diverse models, including classical, standard, and state-of-the-art LLM-based models, demonstrated the current state and future challenges.
- The first meta-evaluation highlighted the reliability and limitations of automatic evaluations.

We observed the following:

- Fine-tuned encoder-decoder models play an important role in maximizing automatic evaluation scores and improving quality in intrinsic evaluations such as faithfulness and fluency.
- Few-shots with strong LLMs have great potential for quality improvement in extrinsic evaluations such as human preference.
- Using multimodal information like LP images improves ad quality, but methods for model integration require further exploration.
- Model performance and rankings vary by industry domain.
- Existing metrics work as intrinsic evaluations, but it is still difficult to use them as a substitute for extrinsic evaluations.
- Human preference serves as a rough estimation of performance values in online evaluation such as CTR.

2 Background

Various types of online advertising exist, including search ads, display ads [2], and slogans [3]. However, since most existing studies are related to search ads (Murakami et al., 2023), this study also focuses on search ads and provides an overview of ATG research and its current limitations.

2.1 A quick retrospective

Early ATG systems predominantly relied on template-based approaches (Bartz et al., 2008; Fujita et al., 2010; Thomaidou et al., 2013). These approaches involved filling appropriate words (i.e., keywords) into predefined templates, resulting in the generation of ad texts. Although this method ensured grammatically correct ad texts, it has limitations in diversity and scalability because it could only accommodate variations determined by the number of templates, which are expensive to create. To address these constraints, alternative approaches have been explored, including reusing existing promotional text (Fujita et al., 2010) and extracting keywords from LPs to populate template slots (Thomaidou et al., 2013).

Encoder-decoder models, which have demonstrated their utility in NLG tasks such as machine translation and summarization (Sutskever et al., 2014), have been applied to ATG research (Hughes et al., 2019; Youngmann et al., 2020; Kamigaito et al., 2021; Golobokov et al., 2022). These models have been employed in various approaches, including *translating* low click-through-rate (CTR) sentences into high CTR sentences (Mishra et al., 2020), *summarizing* crucial information extracted from the LPs (Hughes et al., 2019; Kamigaito et al., 2021), and combining these techniques by first summarizing the LPs and subsequently translating them

[1] https://github.com/CyberAgentAILab/camera; https://huggingface.co/datasets/cyberagent/camera

[2] Display ads typically take the form of banner ads strategically placed within designated advertising spaces on websites or applications.

[3] Slogans are catchy phrases designed to captivate the attention of internet users and generate interest in products, services, or campaigns.

into more effective ad texts based on CTR (Youngmann et al., 2020).[4] Recently, transfer learning approaches using pre-trained language models have become mainstream, allowing for more fluent and diverse ATG (Wang et al., 2021; Zhang et al., 2021; Golobokov et al., 2022; Kanungo et al., 2022; Wei et al., 2022; Li et al., 2022; Murakami et al., 2022a).

2.2 Current limitations

ATG has experienced remarkable growth in recent years, garnering significant attention as a valuable application of natural language processing (NLP). However, the automated evaluation of models presents substantial challenges. Existing studies, validated only on *non-public* datasets, hinder fair comparisons and discussions across studies, posing challenges in generalizing ATG technology. Related to this, the problem settings for ATG, such as input/output, are not shared among the studies because there are variations depending on the advertising medium (e.g., search ads and display ads) and platform (e.g., Google and Bing). These challenges are primarily due to the absence of a shared benchmark dataset that can benefit the entire research community. The reason behind the reluctance to share ad datasets is that they usually contain performance values such as CTR, which are confidential data for companies. Table 6 summarizes the existing studies in the field and shows that this field is led by companies operating advertising-related businesses. Moreover, it stands out as a valuable research subject contributing to the development of user-centered NLP techniques. As a confluence of these trends, this study aims to establish ATG as an NLP task by standardizing the task and building a benchmark dataset.

3 Standardization of ad text generation

One of the goals of this study is to develop a task that is not specific to a particular platform or advertising medium but focuses on universal core problems common to these applications, to facilitate the generalization of ATG technology. To meet these requirements, we standardize the ATG task as follows: Let $\boldsymbol{x}$ be a source document that describes advertised products or services, $\boldsymbol{a}$ a user signal reflecting the user's latent needs or interests, and $\boldsymbol{y}$ an ad text. ATG aims is to model $\boldsymbol{p(y|a, x)}$. User signals, such as search keywords for search ads and user browsing and action history for display ads, can vary based on the application and domain. The specific data to be selected for each $\boldsymbol{x}$, $\boldsymbol{a}$, and $\boldsymbol{y}$ will be left to future dataset designers and providers. This standardization of ATG allows a focused exploration of core issues in an academic context while maintaining flexibility for diverse applications in an industrial context.

The requirements of ad text The purpose of advertising is to influence consumers' (users) attitudes and behaviors towards a particular product or service. Therefore, the goal of ATG is to create text that encourages users' purchasing behaviors. Based on this, the following two requirements for ad text were defined: (1) The information provided by the ad text is consistent with the content of the source document; and (2) the information is carefully curated and filtered based on the users' potential needs, considering the specific details of the merchandise. Requirement 1 relates to *hallucinations*, which is currently a highly prominent topic in the field of NLG (Wiseman et al., 2017; Parikh et al., 2020; Maynez et al., 2020). This requirement can be considered crucial for practical implementation since the inclusion of *non-factual hallucination* in ad texts can cause business damage to advertisers. Regarding requirement 2, it is necessary to successfully convey the features and attractiveness of a product within a limited space and immediately capture the user's interest. Therefore, ad text must selectively include information from inputs that can appeal to users.

Differences from existing tasks The ATG task is closely related to the conventional document summarization task in that it performs information compression while maintaining consistency with the input document's content. Particularly, *query-focused summarization (QFS)* (Dang, 2005), a type of document summarization, is the closest in problem setting because it takes the user's query as the input; however, there are some differences. The task of QFS aims to create a summary from one or multiple document(s) that answers a specific query (*explicit needs*). In contrast, ATG is required to extract not only surface information from user signals but also the *latent needs* behind them and then return a summary. For example, when a user's query is "used cars," the goal of QFS is to provide information about used cars. On the other hand, for users seeking higher-priced items like cars, factors such as quality become important even if they are

[4] CTR is a widely-used indicator of advertising effectiveness in the online advertising domain.

used. Therefore, the task of ATG aims to present ads that include expressions appealing to high quality and reassurance, such as *"All cars come with a free warranty!"*.

Another notable difference is that while summarization aims to deliver accurate text that fulfills task-specific requirements, ATG surpasses mere accuracy and aims to influence user attitudes and behavior. Consequently, unconventional and/or ungrammatical text may be intentionally used in ad-specific expressions to achieve this objective (refer to details in §4.2). Therefore, QFS is a subset of ATG (QFS $\subset$ ATG). One of the technical challenges unique to ATG is capturing users' latent needs based on such user signals $\boldsymbol{a}$ and generating appealing sentences that lead to advertising effectiveness, which depends significantly on the psychological characteristics of the recipient users. Therefore, realizing more advanced ATG will also require a connection with advertising psychology (Scott, 1903) based on cognitive and social psychology. The ATG is an excellent research topic for advancing user-centered NLP technologies.

4 Construction of CAMERA

4.1 Dataset design

In this study, the following two design policies were first established: the benchmark should be able to (1) utilize multimodal information and (2) evaluate by industry domain. In terms of **Design Policy 1**, various advertising formats use textual and visual elements to communicate product features and appeal to users effectively. It is well-recognized that aligning content with visual information is crucial in capturing user attention and driving CTR. **Design Policy 2** highlights the significance of incorporating specific *advertising appeals* to create impactful ad texts. In general, ad creators must consider various aspects of advertising appeals such as the *price*, *product features*, and *quality*. For instance, advertising appeals in terms of *price* such as *"get an extra 10% off"* captivate users by emphasizing cost savings through discounts and competitive prices. Previous studies revealed that the effectiveness of these advertising appeals varies depending on the target product and industry type (Murakami et al., 2022b).

4.2 Construction procedure

We utilized Japanese search ads from our company involved in the online advertising business.[5] In these source data, the components of user queries, ad texts, and LPs (URLs) are allocated accordingly. Search ads comprise a *title* and *description* as shown in Figure 8. Description in search ads has a larger display area compared to titles. It is typically written in natural sentences but may also include advertising appeals. In contrast, titles in search ads often include unique wording specific to the advertisements. They may deliberately break or compress grammar to the extent acceptable to humans because their primary role is immediately capturing a user's attention. For instance, the sentence *"If you're looking to sell your brand-name merchandise, why not get a free valuation at XX right now?"* is transformed into an ad-specific expression: *"Sell your brand-name goods / free valuation now"*. Studies in advertising psychology have reported that these seemingly ungrammatical expressions, unique to advertisements, not only do not hinder human comprehension but also capture their attention (Wang et al., 2013). We extracted only titles as ad texts $\boldsymbol{y}$ to create a benchmark focusing on ad-specific linguistic phenomena.

In our dataset, we extracted `meta description` from the HTML-associated LPs, which served as a description document (*LP description*) $\boldsymbol{x}$ for each product. Furthermore, in line with **Design Policy 1**, we processed a screenshot of the entire LP to obtain an LP image, allowing us to leverage multi-modal information. Through this process, we obtained images $\boldsymbol{I}$, layout information $\boldsymbol{C}$, and text $\{x_i^{\texttt{ocr}}\}_{i=1}^{|\boldsymbol{R}|}$ for the rectangular region set $\boldsymbol{R}$ using the OCR function of the Cloud Vision API.[6]

4.3 Annotation

The source data is assigned a delivered gold reference ad text, but because of the variety of appeals in the ads, there is a wide range of valid references for the same product or service. Therefore, three additional gold reference ad texts were created for the test set by three expert annotators who are native Japanese speakers with expertise in ad annotation. The test set was obtained by randomly sampling about 1000 sentences (about 5% of the total) of the source data set, considering the annota-

[5] We take great care to ensure that advertisers are not disadvantaged by the release of data.

# tokens per an LP OCR	4649.6	4610.4	3510.3
industry-wise			✓

Table 1: Statistics of our dataset. Tokens are character units. *# tokens per an reference* in the test set shows the mean and standard deviation of the four references. *Industry-wise* (✓) indicates whether the data is separable by industry.

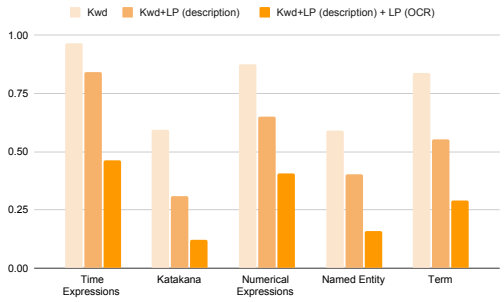

Figure 2: Percentages of novel entities included in our dataset when input information is increased.

tion cost and the need to ensure a minimum amount of data for evaluation purposes.[7] The detailed annotation guidelines are presented in Appendix C. During the data collection process for evaluation annotations, data were randomly selected based on keywords manually mapped to industry labels, such as *"designer jobs"* mapped to the human resource industry, following **Design Policy 2**. Here, we used the following four industry domain labels: human resources (HR), e-commerce (EC), finance (Fin), and education (Edu). The dataset was partitioned into training, development, and test sets to prevent data duplication between the training (development) and test sets, which was achieved through filtering processes.

Table 1 provides the statistics of our dataset. It is worth noting that more information can be taken into account, including not only the text information (*LP desc.*) of the LP, but also the text written on the image by applying OCR processing to the LP image (*LP OCR*). Figure 1 presents examples from the test set of this dataset. Although the annotator was not given explicit instructions regarding the advertising appeal, we confirmed that the annotator created an ad text (#2-4) that featured a variety of advertising appeals different from the original ad text (#1) that considered latent needs based on keywords. This suggests that our test set captures a certain level of diversity in expressing advertisements. To emphasize the multimodal nature of this dataset, we provide examples of ad texts that are difficult to generate without understanding the LP's image information in Appendix D.

4.4 Understanding of human ad creation

To gain more insight into the dynamics of human ad creation, we investigated the extent to which ad creators are making their ads extractive (or abstractive). This exploration would be also useful as a guideline for future model development.

Figure 2 illustrates the percentage of *novel* entities in the target ad texts not found in their respective source documents. Here, we focused on five distinct entity types as outlined in Table 2 to conduct a more comprehensive analysis.[8] By incorporating additional input information such as the LP description and OCR-processed text of the LP full view, the percentage of novel entities in the target ad text was effectively reduced. Furthermore, the analysis based on entity type reveals a wide range of variations in *Time Expressions* and *Numerical Expressions*. In the example of *Numerical Expressions* as shown in Table 2, the source document x mentioned the price range as *6,800 yen - 8,000 yen*, while the target ad text y only included the lower limit of the range as *6,800 yen*. This rewording may be intended to make the price more appealing to users by presenting the lowest price, or to make it more straightforward to fit into a limited display area.

5 Benchmarking of ATG models

To clarify the current state and remaining challenges, we conduct benchmark experiments using the dataset constructed in §4 and various ATG models. Specifically, we investigate the following research questions:

RQ1 *How do differences in the use of pre-trained language models (i.e., finetuning vs. few-shot) affect overall performance?*

RQ2 *Is multimodal information useful for ad text generation?*

[7] Excluded cases where LP URL was invalid after sampling.

[8] The procedure for calculating the ratio of novel entities is described in Appendix E.

Entity type	Input	Output
Time Expression	2022年9月（*September 2022*）	2022年 (*2022*)
Katakana	サイト (site)	ホームページ (homepage)
Numerical Expressions	6,800円 - 8,000円 (*6,800 yen - 8,000 yen*)	6,800円 (*6,800 yen*)
Named Entity	イシダ (*Ishida*)	株式会社イシダ (*Ishida Corporation*)
Terms	求人情報 (*Job Openings*)	求人紹介 (*Job Introductions*)

Table 2: The novel entity types used in our analysis and their corresponding examples. Katakana is a Japanese syllabary.

RQ3 *Do trends in model performance vary by industry domain?*

RQ4 *What are the qualitative differences between generated ad text compared to human-produced ad text?*

5.1 Models

As outlined in §2.2, existing studies use non-public data with performance values, such as CTRs, and therefore cannot be replicated on the CAMERA data set, which does not include performance values. Therefore, this experiment will focus on a simplified replication of previous studies and follow-up on the dominant approach.

- **BM25** is a model of an extractive approach using the BM25 algorithm (Robertson et al., 2009). The BM25 algorithm is used to generate ad texts by extracting one query-related sentence from the input document.
- **BART** is a fine-tuned model using BART (Lewis et al., 2020). We used the following pre-trained model: `japanese_bart_base_2.0` [9]
- **T5** is a fine-tuned model using T5 (Raffel et al., 2022). We used the following pre-trained model: `sonoisa/t5-base-japanese` [10].
- **GPT-3.5** is a few-shot model using GPT-3.5 (`gpt-3.5-turbo-0613`) (Ouyang et al., 2022). We built the model using the API provided by OpenAI [11].
- **GPT-4** is a few-shot model using GPT-4 (`gpt-4-0613`) (OpenAI, 2023). As with GPT-3.5, we constructed the model using the API provided by OpenAI.
- **Llama2** is a few-shot model using Llama2 (Touvron et al., 2023). We used the following pre-trained model: `ELYZA-japanese-Llama-2-7b-instruct` [12].

For BART and T5, we fine-tuned each pre-trained model on the train split of CAMERA. For GPT-3.5, GPT-4, and Llama2, the baseline models were constructed by 3-shot in-context learning, respectively. To investigate the effectiveness of incorporating multi-modal features such as images and layout in the LPs and their impact on the overall performance, we built various settings for the T5-based model that considered LP image information, following Murakami et al. (2022a). Specifically, we incorporated the following three types of multi-modal information into the model architecture: LP OCR text (`lp_ocr;o`), LP layout information (`lp_layout;l`), and LP BBox image features (`lp_visual;v`). See Appendix F for details on the experimental setup for each baseline model, including the prompt template.

5.2 Evaluation

Automatic evaluation To evaluate the generated texts quality, we employed two widely used metrics in ATG: BLEU-4 (B-4)[13] (Papineni et al., 2002) and ROUGE-1 (R-1) (Lin, 2004). These metrics assess the similarity between the generated text and reference based on n-gram overlap. Since paraphrases are commonly used in ad texts, BERTScore (BS) (Zhang et al., 2020), an embedding-based metric, was also used to handle their semantic similarity. Additionally, as task-specific guardrails, we introduce keyword insertion rates (KWD) (Mishra et al., 2020) and sentence length regulation compliance rates (REG). KWD represents the percentage of cases where the specified keyword is included in the generated text for evaluating the relevance

	Faithfulness	Fluency	Attractiveness
All (= 3)	0.3	0.25	0.17
Majority (≧ 2)	-	-	0.84

Table 3: Inter annotator agreement.

of the LP and the ad text. REG indicates the percentage of compliance with the character count regulation (15 characters or less).

Manual evaluation To answer RQ4, we conducted a manual evaluation. Three human raters who are native Japanese speakers with expertise in ad annotation evaluate each of the 10 ad texts of the 9 models (§5.1) and one original reference for each of the three evaluation aspects of *faithfulness*, *fluency*, and *attractiveness*. The faithfulness and fluency evaluations were conducted using an *absolute* evaluation of whether the input document implies or does not imply the ad text, and whether the content of the ad text is understandable and natural, respectively. Given the challenge of providing an absolute evaluation of each ad text's attractiveness, we conducted a pairwise evaluation comparing the human reference and each model output, considering cases where the attractiveness was equal (*Tie*). For faithfulness and fluency, we sampled 200 cases from the test data and conducted manual evaluations for a total of 2000 ad texts. For attractiveness, we sampled 100 cases, created pairs of the human reference and each model output, and performed manual evaluations for a total of 900 ad texts. Details of the instructions in the manual evaluation are provided in Appendix G.

Table 3 shows the inter-annotator agreement (IAA)[14]. As expected, the IAA for attractiveness is the lowest, but when loosened to more than a majority, it is outstandingly high (0.84). This suggests that, while achieving unanimous favorability is challenging, there is a considerable level of consensus on attractiveness.

5.3 Result

The answers corresponding to the RQs listed in §5 are provided below:

A1: Finetuning and few-shot are good performers in intrinsic and extrinsic evaluations, respectively In automatic evaluation, we observe that few-shot learning falls behind finetuning (Table 4). A similar trend can also be observed in the manual evaluation, except for attractiveness (Figure 4 and Figure 5). These series of results highlight the high potential of LLM few-shot for improving quality in *extrinsic* evaluation such as attractiveness and human preference, while finetuning can play an important role in maximizing quality in *intrinsic* evaluation such as automatic scores, faithfulness, and fluency.

[14]It is based on majority vote and counted as a Tie if they are all split for attractiveness

	B-4	R-1	BS	KWD	REG
Unimodal model:					
BM25	5.4	16.1	70.1	**97.0**	45.0
BART	**14.4**	21.4	73.4	75.8	81.0
T5	13.6	**23.0**	**73.8**	89.8	78.5
GPT-3.5	3.5	14.2	64.2	73.9	84.5
GPT-4	4.4	16.4	65.1	78.6	**87.0**
Llama2	4.6	13.6	55.4	72.2	60.0
Multimodal models:					
T5 + {o}	**16.0**	**24.7**	**74.9**	**85.7**	70.0
T5 + {o,l}	15.6	23.3	74.1	84.4	67.5
T5 + {o,l,v}	13.2	23.5	74.1	84.5	**74.0**

Table 4: Results: a **bold** value indicates the best result in each column.

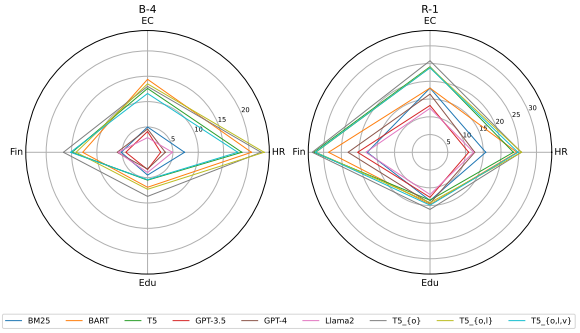

Figure 3: Industry-wise evaluation results.

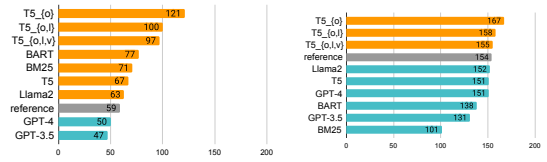
A2: Multimodal information contributes to the quality of generated ad text We observe that incorporating additional features such as OCR-processed text (+ {o}), the LP layout information (+ {o,l}), and LP image features (+ {o,l,v}) improved the quality of generated sentences in terms of faithfulness (4a) and fluency (4b). On the other hand, the incorporation of layout information and visual features into the models does not necessarily improve performance, so methods for model integration require further exploration. Nevertheless, we also confirmed cases where the use of multimodal information in LPs improves the quality of the generated ad text as shown in Figure 6. The performance drop may be due to image information acting as noise when using the LP Full View directly in this experiment. Therefore, the devel-



(a) Faithfulness (b) Fluency

Figure 4: Human ranking in terms of faithfulness and fluency, respectively.

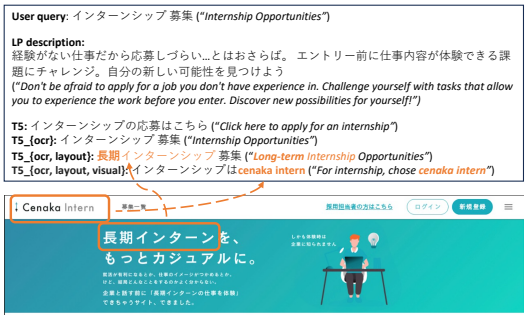

Figure 6: Example of how multimodal information in an LP contributed to the quality of the generated ad text.

	Faithfulness		Fluency		Attractivenss	
Metrics	r	ρ	r	ρ	r	ρ
B-4	0.88	0.83	0.53	0.30	-0.12	-0.68
R-1	0.83	0.75	**0.70**	**0.55**	**0.35**	**0.03**
BS	**0.90**	**0.85**	0.67	0.50	0.20	-0.20
GPT-4	0.20	-0.48	-0.22	0.10	-0.47	-1.20

Table 5: System-level meta-evaluation results with Pearson (r) and Spearman (ρ)

opment of a multimodal system that adaptively accesses only important information from LPs will be a straightforward future work.

A3: Model performance and model rankings vary by industry domain Figure 3 shows the industry-wise evaluation results in each metric[15]. We observe the model performance and rankings vary by industry. This suggests that the performance of ATG models is sensitive to the industry domain and highlights the need for industry-wise evaluation to develop robust models.

A4: Some baselines have already reached human-level performers In **faithfulness**, the outputs of the baseline models, except GPT-3.5 and GPT-4, are more faithful to the input than the human reference (Figure 4a). Note, however, that low faithfulness in human reference does not necessarily mean low quality, since it is known that ad creators use expressions based on their external knowledge to the extent that they can ensure factual consistency with the input to enhance fluency and appeal. Non-factual, fake ads can be fatal to advertisers in terms of legal compliance and corporate branding, but it is difficult for a model to perfectly capture real-time product-specific information, such as discount prices and campaign periods. Therefore, one important direction is the development of models with guaranteed faithfulness as a step toward achieving an ATG system with guaranteed factual consistency.

In **fluency**, we can confirm that the human reference has high fluency as a trade-off for low faithfulness, while GPT-4, T5, and Llama2 are almost at the same level as the human reference (Figure 4b). It should also be noted that integrating multimodal information from LP images into the model contributes to generating more fluent ad text.

In **attractiveness**, GPT-4 is already able to generate more attractive ad text for humans than reference (Figure 5). If equivalent (Tie) cases are included, T5 and T5+ {o} also reach the same level as humans. GPT-4 also achieves a sentence-length regulation compliance rate (REG in Table 4), making it a model with high real-world applicability.

6 Analysis

6.1 How well can automated evaluations replicate human evaluations?

To clarify the limitations and possibilities of automatic evaluation, we performed a meta-evaluation by adding a GPT-4 based evaluator to the set of the metrics used in the experiment in §5. The GPT-4 based evaluator was constructed by giving the same instructions as those given to the human raters in the manual evaluation §5.2.[16]

[15] We provide the details of the results in Appendix I

[16] The prompts used are presented in Appendix H.

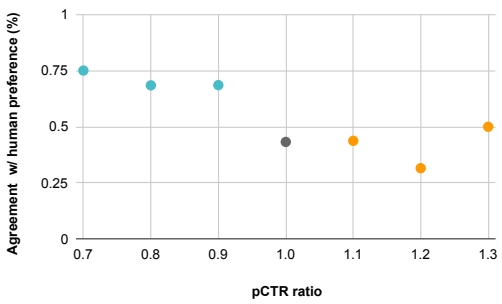

Figure 7: Agreement rate between human preference and pCTR.

Table 5 shows that the system-level meta-evaluation results with Pearson (r) and Spearman (ρ). BS and R-1 correlate best with humans for faithfulness and fluency, respectively. On the other hand, it was difficult to replicate the human ranking for attractiveness. This suggests that existing metrics work as intrinsic evaluations, but it is still difficult to use them as a substitute for extrinsic evaluations. The GPT-4 based evaluator had the lowest correlation in any evaluation aspect. This result is inconsistent with the existing studies (Chiang and Lee, 2023; Zheng et al., 2023)'s report that LLM evaluations produce results similar to those of expert human evaluations. One reason for this may be due to domain mismatch, as most of the datasets in the GPT-4 pre-training are general or non-advertising domains (OpenAI, 2023).

6.2 How well does human preference align with advertising performance?

To clarify the extent to which the human preference in Figure 5 is aligned with advertising performance such as CTR, we investigate the rate of agreement between human preference and CTR. Measuring CTR requires deploying the system output obtained in §5 as online advertisements, which is impractical. Therefore, we follow methodologies established in previous studies(Rennie et al., 2017; Hughes et al., 2019) and approximate it using a CTR prediction model (i.e., predicted CTR; *pCTR*).[17]

Table 7 shows the agreement rate between human preference and pCTR when divided into bins according to the size of the ratio of pCTR (henceforth, *pCTR ratio*) between reference and system, which is calculated as pCTR ratio = pCTR (system) / pCTR (reference). The results suggest that as the pCTR ratio decreases (indicating greater expected effectiveness of the reference over the system), humans find the reference more appealing. Conversely, when the pCTR ratio exceeds 1.0 (indicating the system outperforms the reference in expected advertising effectiveness), human preference and pCTR are less likely to align. This suggests that in the band of performance where there's room for improvement, indicated by the generated ad text quality falling below the human reference, leveraging human preferences as an estimate of ad performance values like CTR is effective. Conversely, as the quality of the generated ad text approaches saturation and surpasses the human reference, it's advisable to incorporate online evaluation such as CTR measurement alongside offline evaluation to verify advertising effectiveness.

[17]We utilized 極予測TD (Kiwami Yosoku TD), our company's off-the-shelf model for pCTR calculation, which aligns with CTR. cf. https://cyberagent.ai/products/

7 Discussion for reproducible research

We want to situate our findings in the context of the broader NLP community, in line with our goal of discussion on increased transparency in the field. Examples of data that are challenging to open include proprietary datasets primarily owned by companies, housing sensitive information for maintaining a competitive advantage (e.g., datasets managed by OpenAI). Ad data, the primary focus of this study, also exemplified this scenario. One of the reasons why ad data has not been shared with the community in the past is that CTRs and other performance data are confidential. Also, measuring CTR is difficult except for a few companies in the advertising business. Therefore, as an incentive mechanism to promote the creation of open research within the research community, there is a direction for the community to accept secondary information (e.g., pCTR or human preference in §6.2) that is guaranteed to be consistent to some extent with sensitive primary data (e.g., CTR).

8 Conclusion

We standardized ATG as a cross-application task and developed the first benchmark dataset. Through evaluation experiments using our dataset, we demonstrated the current status and remaining challenges. ATG is a promising application of NLP and a critical and complex research area for advancing user-centric language technology. We hope that the research infrastructure we established will drive the progress and development of ATG technology.

Acknowledgements

We thank the anonymous reviewers for their helpful comments and suggestions. We are also thankful to Ukyo Honda, Shota Sasaki, Sho Hoshino and the other members of CyberAgent for their insightful comments and suggestions.

Limitations

One of the limitations of this study is that the dataset is only available in Japanese. In particular, the community should also enjoy benchmark datasets in English that are more accessible to researchers and developers around the world. We hope that advertising-related companies who share our vision of building on common datasets to build on the technologies in the field of ATG will follow this research and provide public datasets to the community for reproducible NLP research.

A Example of search ads

We provide an example of search ads in Figure 8.

B Summary of existing studies

A summary of existing studies of ad text generation is shown in Table 6. From this, we can see that (1) the field is primarily led by companies related to the online advertising business, (2) there is no consensus on inputs and outputs, and (3) research has begun to flourish in the ACL community in recent years.

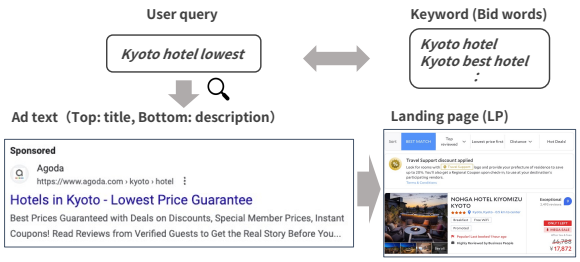

Figure 8: An example of search ads.

C Annotation guideline

The main instructions given to the annotators were as follows:

1. Consider the search keyword as the user's intent.
2. Create an advertisement that is consistent with the product/service description in the LP.
3. Ensure that the length of the advertisement is within 15 full-width characters [18].
4. These instructions were provided to guide the annotators in creating the additional reference advertisements.

As explained in §3, since it is important for ad creation to consider latent needs behind user signals, we instructed the annotators to explicitly consider search keywords as user intentions.

D Examples of ad texts that are difficult to generate without considering LP image information

We provide an actual example observed in our dataset in Table 7, which is difficult to generate without considering LP image information. Based on the hypothesis that advertisements generally use visual information in addition to text to more effectively promote their products to users, we decided to include LP image information in the data set (i.e., Design Policy 1 in §4.1). In the dataset we constructed, we observed that the LP description alone was not sufficient and that the ad texts text required a deep understanding of the textual information embedded and the table data in the LP image.

[18] This follows the guidelines for headline text in Google Responsive Search Ads (https://support.google.com/google-ads/answer/12437745).

E Calculation of ratio of novel entities

In this section, we describe the procedure for calculating the ratio of novel entities, that is, entities that appear only on the output side. The target entity types are the following five types: (1) named entities, (2) terms, (3) katakana, (4) time expressions, and (5) numerical expressions. Let x denote the input and y the output ad sentence. Then, a procedure for calculating the ratio of novel entities is described as follows.

1. We perform NFKC normalization and lowercasing for each sentence in x and y.

2. In each instance (x,y), we perform the following (a)-(c) for each entity type t_i.

   (a) We extract entity mentions of type t_i from x and y (we call them $S_x^{(i)}$ and $S_y^{(i)}$, respectively) [19]. Regarding time expressions, we perform not only entity mention extraction, but also entity linking (e.g., "decade" and "10 years" are linked to the same time expression entity) thanks to the ja-timex library.

   (b) We get novel entity mentions $S_{novel}^{(i)}$ by the following procedure. The following (i) or (ii) is used as the criterion to judge whether a given entity mention is novel or not. (i) In

[19] We use GiNZA in spacy (ja_ginza) for named entities, pytermextract (http://gensen.dl.itc.u-tokyo.ac.jp/pytermextract) for term extraction, regular expression for katakana, ja_timex (https://github.com/yagays/ja-timex) for time expressions, and pynormalizenumexp(https://pypi.org/project/pynormalizenumexp) for numerical expressions.

the case of the perfect match criterion (for katakana, time expressions, and numerical expressions): $S^{(i)}_{novel} = S^{(i)}_y / S^{(i)}_x$ (ii) For partial matching criteria (for named entities and terms): if each mentions in $S^{(i)}_y$ is not a full or partial match with any mentions in $S^{(i)}_x$, it is judged as a novel entity mention and added to $S^{(i)}_y$. As for named entities and terms, we adopt the partial matching criterion (ii), because there are many cases in which most of the entity mentions are identical, such as "Sendai" and "Sendai-city" in our initial exploration for sampled 100 instances from our dataset.

(c) If $S^{(i)}_y$ is not an empty set, then the ratio of novel entities for type t_i for a given instance is calculated by $|S^{(i)}_{novel}|/|S^{(i)}_y|$.

3. Finally, for each entity type t_i, we compute the macro-averages of the above ratios for the set of instances in which entity mentions of type t_i occur at least once in y.

F Details on experimental setup for each baseline models

F.1 BM25

We used the BM25 to rank sentences of the source document given a query and took the most relevant sentence as the generated ad text. For implementation, we used the `rank_bm25` toolkit [20].

F.2 T5 and BART

We fine-tuned each pre-trained model on the training dataset to create our baseline models. Specifically, we used a pre-trained model `japanese_bart_base_2.0` from Kyoto University's Japanese version of BART [21] as the basis for our BART-based baseline model. For the T5-based baseline model, we used a pre-trained model `sonoisa/t5-base-japanese` [22]. The specific hyperparameters and other experimental details are reflected in Table 8.

F.3 Multimodal models

Figure 10 presents an overview of incorporating the LP information into the T5-based model. [23]. As an input, we used three sets of token sequences, the LP descriptions x^{des}, user queries x^{qry}, and each OCR token sequence x^{ocr}_i of the rectangular region set $R = \{r_i\}^{|R|}_{i=1}$ obtained by OCR from the LPs, where each token sequence x^* is $x^* = (x^*_i)^{|R|}_{t=i}$. Furthermore, the layout $C = c_i{}^{|R|}_{i=1}$ and image information $I = I_i{}^{|R|}_{i=1}$ for the rectangular region set R was used. Here, c_i denotes $(x^{\mathsf{min}}_i, x^{\mathsf{max}}_i, y^{\mathsf{min}}_i, y^{\mathsf{max}}_i) \in \mathbb{R}^4$ as shown in Figure 10.

Next, we explicitly describe each embedding (Figure 10) as follows:

Token embedding Each token sequence x^* was transformed into an embedding sequence t^* before being fed into the encoder. Here, D denotes the embedding dimension.

Segment embedding The encoder distinguishes the region of each token sequence x^*. For example, for a token sequence x^{des}, we introduced $s^{des} \in \mathbb{R}^D$.

Visual embedding We introduced an image I_i for each rectangular region r_i to incorporate visual information from the LP, such as text color and font. More specifically, the obtained image I_i was resized to 128 $\times$ 32 (width $\times$ height). The CNN-based feature extraction was employed to create visual features $v_i \in \mathbb{R}^D$.

Layout embedding In the LP, the position and size of the letters played crucial roles. We input the layout c_i of a rectangular region r_i into the MLP to obtain $l_i \in \mathbb{R}^D$.

Using the above embeddings, we generated the encoder inputs, as shown in Figure 10. This study investigated the contribution of each type of multimodal information to the overall performance. We incorporated the following three types of multimodal information into the model architecture in Figure 10: LP OCR text (`lp_ocr;o`), LP layout

[20] https://github.com/dorianbrown/rank_bm25

[21] https://github.com/utanaka2000/fairseq/tree/japanese_bart_pretrained_model

[22] https://huggingface.co/sonoisa/t5-base-japanese

[23] Note that the model constructed for this experiment, shown in Figure 10, is not the proposed model, but a baseline model created according to Murakami et al. (2022a)

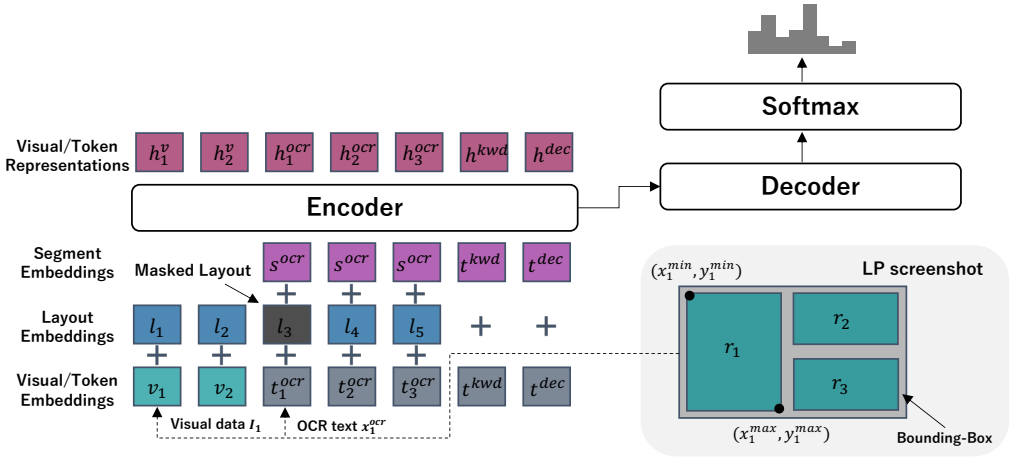

Figure 10: An overview of the model incorporating LP information, following Murakami et al. (2022a).

LP description:
[A calm daily life starts from daily diet] Self-care for common women's problems / Regular delivery costs about 81 yen per day.

information (`lp_layout;l`), and LP BBox image features (`lp_visual;v`).

Hyperparameters We present the hyperparameters used during the training of both models in Table 8. For the maximum sequence length in T5, it was set to 712 only for the model using LP bounding box image features (`+{o,l,v}`), while all other models were set to 512. Furthermore, early stopping was applied if the loss on the development set deteriorated for 3 consecutive epochs in the case of T5, and 5 consecutive epochs in the case of BART.

F.4 GPT-3.5, GPT-4, and Llama2

For GPT-3.5, GPT-4, and Llama2, the baseline models were constructed by 3-shot in-context learning, respectively. The prompts used to build these models are provided in Table 9.

G Details on experimental setup for manual evaluation

Three native Japanese speakers and advertising annotation experts were recruited from our in-house annotation center. As an overview of the annotation, we instructed that a human evaluation of the quality of the ad text be conducted for each of the following three evaluation perspectives.

Please select all sentences whose content is understandable and natural.
- ❑ Ad text0
- ❑ Ad text1
- ❑ Ad text2
- ❑ Ad text3
- ❑ :

Figure 12: An example of annotation task in the fluency evaluation.

Keyword:
Trial Cleansing

When searching for the above keywords, which ad text is of more interest to you
- ❑ Ad text0
- ❑ Ad text1
- ❑ The attractiveness level is the same

Figure 13: An example of annotation task in the attractiveness evaluation.

- **faithfulness:** *Does the LP description imply the ad text?*
- **fluency:** *Is the content understandable and natural as an ad text?*
- **attractiveness:** *Is it an attractive ad text?*

When conducting the annotation, the following tasks were created for each evaluation perspective: faithfulness (Figure 11), fluency (Figure 12), and attractiveness (Figure 13), using `Label Studio`[24], an open-source annotation tool.[25] Since faithfulness and fluency are absolute evaluations, 10 ad texts

Table 9: Prompts used for the ATG model based on LLMs (GPT-3.5, GPT-4, and Llama2), were translated into English for visibility.

(9 systems + 1 reference) were evaluated together as shown in Figure 11 and Figure 12 to reduce annotation costs. To ensure the quality of the annotations, a training phase was established before the test phase, and the annotators were trained with a total of 60 ad texts, 20 for each task. The entire annotation process took roughly 6 hours.

H Prompts for GPT-4 evaluator

The GPT-4-based evaluator was constructed by giving the same instructions as those given to the human raters in the manual evaluation §5.2. We present the prompts we used for faithfulness, fluency, and attractiveness in Tables 10, Table 11, and Table 12, respectively.

I Details of industry-wise evaluation

Details of the results of the evaluation of the ATG model by industry are presented in Table 13.

Please answer "1" if the question text implies the ad text and "0" if it does not.

Question text: [A calm daily life begins with a regular diet] Self-care for common female problems/regular delivery costs about 81 yen a day.
Ad text: Peaceful everyday life
Answer: 1

Question text: [A calm daily life begins with a regular diet] Self-care for common female problems/regular delivery costs about 81 yen a day.
Ad text: [Official] Daily diet
Answer: 0
