CLiC-it 2024

The Tenth Italian Conference on Computational Linguistics

Proceedings of the Conference

December 4-6, 2024

These proceedings have been published in the CEUR Workshop Proceedings series.
The original papers are available at: https://ceur-ws.org/Vol-3878.
The papers are mirrored in the ACL Anthology.

ISBN 979-12-210-7060-6

Table of Contents

Preface to the CLiC-it 2024 Proceedings
Felice Dell'Orletta, Alessandro Lenci, Simonetta Montemagni and Rachele Sprugnoli 1

Lifeless Winter without Break: Ovid's Exile Works and the LiLa Knowledge Base
Aurora Alagni, Francesco Mambrini and Marco Passarotti 4

Exploring the Use of Cohesive Devices in Dementia within an Elderly Italian Semi-spontaneous Speech Corpus
Giorgia Albertin and Elena Martinelli 13

SimilEx: The First Italian Dataset for Sentence Similarity with Natural Language Explanations
Chiara Alzetta, Felice Dell'orletta, Chiara Fazzone and Giulia Venturi 20

Data Augmentation for Low-Resource Italian NLP: Enhancing Semantic Processing with DRS
Muhammad Saad Amin, Luca Anselma and Alessandro Mazzei 29

ItaEval and TweetyIta: A New Extensive Benchmark and Efficiency-First Language Model for Italian
Giuseppe Attanasio, Pieter Delobelle, Moreno La Quatra, Andrea Santilli and Beatrice Savoldi39

LLaMAntino against Cyber Intimate Partner Violence
Pierpaolo Basile, Marco Degemmis, Marco Polignano, Giovanni Semeraro, Lucia Siciliani, Vincenzo Tamburrano, Fabiana Battista and Rosa Scardigno 52

Taking Decisions in a Hybrid Conversational AI Architecture Using Influence Diagrams
Roberto Basile Giannini, Antonio Origlia and Maria Di Maro 59

KEVLAR: The Complete Resource for EuroVoc Classification of Legal Documents
Lorenzo Bocchi, Camilla Casula and Alessio Palmero Aprosio 66

Title Is (Not) All You Need for EuroVoc Multi-Label Classification of European Laws
Lorenzo Bocchi and Alessio Palmero Aprosio 74

Exploring the Dissociated Nucleus Phenomenon in Semantic Role Labeling
Tommaso Bonomo, Simone Conia and Roberto Navigli 81

Data Augmentation through Back-Translation for Stereotypes and Irony Detection
Tom Bourgeade, Silvia Casola, Adel Mahmoud Wizan and Cristina Bosco 90

Community-based Stance Detection
Emanuele Brugnoli and Donald Ruggiero Lo Sardo 98

Towards a Hate Speech Index with Attention-based LSTMs and XLM-RoBERTa
Mauro Bruno, Elena Catanese and Francesco Ortame 106

Written Goodbyes: How Genre and Sociolinguistic Factors Influence the Content and Style of Suicide Notes
Lucia Busso and Claudia Roberta Combei 114

Argument Mining in BioMedicine: Zero-Shot, In-Context Learning and Fine-tuning with LLMs
Jérémie Cabessa, Hugo Hernault and Umer Mushtaq 122

Multisource Approaches to Italian Sign Language (LIS) Recognition: Insights from the MultiMedaLIS Dataset
Gaia Caligiore, Raffaele Mineo, Concetto Spampinato, Egidio Ragonese, Simone Palazzo and Sabina Fontana 132

Combining Universal Dependencies and FrameNet to Identify Constructions in a Poetic Corpus: Syntax and Semantics of Latin Felix and Infelix in Virgilian Poetics
Giulia Calvi, Riccardo Ginevra and Federica Iurescia 141

Lost in Disambiguation: How Instruction-Tuned LLMs Master Lexical Ambiguity
Luca Capone, Serena Auriemma, Martina Miliani, Alessandro Bondielli and Alessandro Lenci 148

BaBIEs: A Benchmark for the Linguistic Evaluation of Italian Baby Language Models
Luca Capone, Alice Suozzi, Gianluca Lebani and Alessandro Lenci 157

Beyond Headlines: A Corpus of Femicides News Coverage in Italian Newspapers
Eleonora Cappuccio, Benedetta Muscato, Laura Pollacci, Marta Marchiori Manerba, Clara Punzi, Chandana Mala, Margherita Lalli, Gizem Gezici, Michela Natilli and Fosca Giannotti 171

Women's Professions and Targeted Misogyny Online
Alessio Cascione, Aldo Cerulli, Marta Marchiori Manerba and Lucia Passaro 182

DWUGs-IT: Extending and Standardizing Lexical Semantic Change Detection for Italian
Pierluigi Cassotti, Pierpaolo Basile and Nina Tahmasebi 190

History Repeats: Historical Phase Recognition from Short Texts
Fabio Celli and Valerio Basile 198

Emojilingo: Harnessing AI to Translate Words into Emojis
Francesca Chiusaroli, Federico Sangati, Johanna Monti, Maria Laura Pierucci and Tiberio Uricchio 205

Towards an ASR System for Documenting Endangered Languages: A Preliminary Study on Sardinian
Ilaria Chizzoni and Alessandro Vietti 214

Controllable Text Generation to Evaluate Linguistic Abilities of Italian LLMs
Cristiano Ciaccio, Felice Dell'orletta, Alessio Miaschi and Giulia Venturi 221

A Modal Sense Classifier for the French Modal Verb Pouvoir
Anna Colli, Diego Rossini and Delphine Battistelli 233

Topic Similarity of Heterogeneous Legal Sources Supporting the Legislative Process
Michele Corazza, Leonardo Zilli and Monica Palmirani 244

Join Together? Combining Data to Parse Italian Texts
Claudia Corbetta, Giovanni Moretti and Marco Passarotti 251

Using Large Speech Models for Feature Extraction in Cross-Lingual Speech Emotion Recognition
Federico D'asaro, Juan José Márquez Villacís, Giuseppe Rizzo and Andrea Bottino 258

Building a Pragmatically Annotated Diachronic Corpus: The DIADIta Project
Irene De Felice and Francesca Strik Lievers 266

Building CorefLat. a Linguistic Resource for Coreference and Anaphora Resolution in Latin
Eleonora Delfino, Roberta Leotta, Marco Passarotti and Giovanni Moretti 273

Is Explanation All You Need? An Expert Survey on LLM-generated Explanations for Abusive Language Detection
Chiara Di Bonaventura, Lucia Siciliani, Pierpaolo Basile, Albert Merono Penuela and Barbara Mcgillivray 280

Scalable Query Understanding for E-commerce: An Ensemble Architecture with Graph-based Optimization
Giuseppe Di Fabbrizio, Evgeny Stepanov, Ludovico Frizziero and Filippo Tessaro 289

ELIta: A New Italian Language Resource for Emotion Analysis
Eliana Di Palma 297

Comparing Large Language Models Verbal Creativity to Human Verbal Creativity
Anca Dinu and Andra Florescu 308

ItGraSyll: A Computational Analysis of Graphical Syllabification and Stress Assignment in Italian
Liviu Dinu, Ioan-Bogdan Iordache, Simona Georgescu, Alina Maria Cristea and Bianca Guita316

Generation and Evaluation of English Grammar Multiple-Choice Cloze Exercises
Nicolò Donati, Matteo Periani, Paolo Di Natale, Giuseppe Savino and Paolo Torroni 325

ReCLAIM Project: Exploring Italian Slurs Reappropriation with Large Language Models
Lia Draetta, Chiara Ferrando, Marco Cuccarini, Liam James and Viviana Patti 335

You Write like a GPT
Andrea Esuli, Fabrizio Falchi, Marco Malvaldi and Giovanni Puccetti 343

Constructing a Multimodal, Multilingual Translation and Interpreting Corpus: A Modular Pipeline and an Evaluation of ASR for Verbatim Transcription
Alice Fedotova, Adriano Ferraresi, Maja Miličević Petrović and Alberto Barrón-Cedeño 349

Exploring YouTube Comments Reacting to Femicide News in Italian
Chiara Ferrando, Marco Madeddu, Viviana Patti, Mirko Lai, Sveva Pasini, Giulia Telari and Beatrice Antola 356

Automatic Error Detection: Comparing AI vs. Human Performance on L2 Italian Texts
Irene Fioravanti, Luciana Forti and Stefania Spina 366

Explainability for Speech Models: On the Challenges of Acoustic Feature Selection
Dennis Fucci, Beatrice Savoldi, Marco Gaido, Matteo Negri, Mauro Cettolo and Luisa Bentivogli 373

Recurrent Networks Are (Linguistically) Better? An (Ongoing) Experiment on Small-LM Training on Child-Directed Speech in Italian
Achille Fusco, Matilde Barbini, Maria Letizia Piccini Bianchessi, Veronica Bressan, Sofia Neri, Sarah Rossi, Tommaso Sgrizzi and Cristiano Chesi 382

On Cross-Language Entity Label Projection and Recognition
Paolo Gajo and Alberto Barrón-Cedeño 390

NYTAC-CC: A Climate Change Subcorpus of New York Times Articles
Francesca Grasso, Ronny Patz and Manfred Stede 403

Task-Incremental Learning on Long Text Sequences
Natalia Graziuso, Andrea Zugarini and Stefano Melacci 410

The Vulnerable Identities Recognition Corpus (VIRC) for Hate Speech Analysis
Ibai Guillén-Pacho, Arianna Longo, Marco Antonio Stranisci, Viviana Patti and Carlos Badenes-Olmedo 417

The Self-Contained Italian Negation Test (SCIN)
Viola Gullace, David Kletz, Thierry Poibeau, Alessandro Lenci and Pascal Amsili 425

La Non Canonica L'hai Studiata? Exploring LLMs and Sentence Canonicity in Italian
Claudiu Hromei, Danilo Croce, Rodolfo Delmonte and Roberto Basili 431

Enhancing Job Posting Classification with Multilingual Embeddings and Large Language Models
Hamit Kavas, Marc Serra-Vidal and Leo Wanner 440

Divergent Discourses: A Comparative Examination of Blackout Tuesday and #BlackLivesMatter on Instagram
Aenne Knierim, Michael Achmann-Denkler, Ulrich Heid and Christian Wolff 451

THAVQA: A German Task-oriented VQA Dataset Annotated with Human Visual Attention
Moritz Kronberger and Viviana Ventura 459

Are You a Good Assistant? Assessing LLM Trustability in Task-oriented Dialogues
Tiziano Labruna, Sofia Brenna, Giovanni Bonetta and Bernardo Magnini 470

Comparative Evaluation of Computational Models Predicting Eye Fixation Patterns During Reading: Insights from Transformers and Simpler Architectures
Alessandro Lento, Andrea Nadalini, Nadia Khlif, Vito Pirrelli, Claudia Marzi and Marcello Ferro 478

Hits or Misses? A Linguistically Explainable Formula for Fanfiction Success
Giulio Leonardi, Dominique Brunato and Felice Dell'orletta 488

A Novel Multi-Step Prompt Approach for LLM-based Q&As on Banking Supervisory Regulation
Daniele Licari, Canio Benedetto, Praveen Bushipaka, Alessandro De Gregorio, Marco De Leonardis and Tommaso Cucinotta 496

Lupus Alberto: A Transformer-Based Approach for SLE Information Extraction from Italian Clinical Reports
Livia Lilli, Laura Antenucci, Augusta Ortolan, Silvia Laura Bosello, Maria Antonietta D'agostino, Stefano Patarnello, Carlotta Masciocchi and Jacopo Lenkowicz 510

The Lemma Bank of the LiITA Knowledge Base of Interoperable Resources for Italian
Eleonora Litta, Marco Passarotti, Paolo Brasolin, Giovanni Moretti, Valerio Basile, Andrea Di Fabio and Cristina Bosco 517

Multimodal Chain-of-Thought Prompting for Metaphor Generation
Sofia Lugli and Carlo Strapparava 523

Leveraging Advanced Prompting Strategies in LLaMA3-8B for Enhanced Hyperpartisan News Detection
Michele Maggini and Pablo Gamallo Otero 531

Understanding High-complexity Technical Documents with State-of-Art Models
Bernardo Magnini and Roberto Zanoli 540

Temporal Word Embeddings in the Study of Metaphor Change over Time and across Genres: A Proof-of-concept Study on English
Veronica Mangiaterra, Chiara Barattieri Di San Pietro and Valentina Bambini 548

Fine-grained Sexism Detection in Italian Newspapers
Federica Manzi, Leon Weber-Genzel and Barbara Plank 556

Towards a More Comprehensive Evaluation for Italian LLMs
Luca Moroni, Simone Conia, Federico Martelli and Roberto Navigli 584

A Study on the Soundness of Closed-ended Evaluation of Large Language Models Adapted to the Italian Language
Elio Musacchio, Lucia Siciliani, Pierpaolo Basile, Edoardo Michielon, Marco Pasqualini, Asia Beatrice Uboldi and Giovanni Semeraro 600

Understanding the Future Green Workforce through a Corpus of Curricula Vitae from Recent Graduates
Francesca Nannetti and Matteo Di Cristofaro 612

Exploring Italian Sentence Embeddings Properties through Multi-tasking
Vivi Nastase, Giuseppe Samo, Chunyang Jiang and Paola Merlo 620

Exploring Syntactic Information in Sentence Embeddings through Multilingual Subject-verb Agreement
Vivi Nastase, Giuseppe Samo, Chunyang Jiang and Paola Merlo 631

Dynamic Prompting: Large Language Models for Task Oriented Dialog
Jan Nehring, Akhil Juneja, Adnan Ahmad, Roland Roller and Dietrich Klakow 644

Exploring Text-Embedding Retrieval Models for the Italian Language
Yuri Noviello and Fabio Tamburini 654

Introducing MultiLS-IT: A Dataset for Lexical Simplification in Italian
Laura Occhipinti 662

Enhancing Lexical Complexity Prediction in Italian through Automatic Morphological Segmentation
Laura Occhipinti 670

Measuring Bias in Instruction-Following Models with ItaP-AT for the Italian Language
Dario Onorati, Davide Venditti, Elena Sofia Ruzzetti, Federico Ranaldi, Leonardo Ranaldi and Fabio Massimo Zanzotto 679

Minerva LLMs: The First Family of Large Language Models Trained from Scratch on Italian Data
Riccardo Orlando, Luca Moroni, Pere-Lluís Huguet Cabot, Simone Conia, Edoardo Barba, Sergio Orlandini, Giuseppe Fiameni and Roberto Navigli 707

Benchmarking the Semantics of Taste: Towards the Automatic Extraction of Gustatory Language
Teresa Paccosi and Sara Tonelli 720

Nominal Class Assignment in Swahili: A Computational Account
Giada Palmieri and Konstantinos Kogkalidis 728

Did Somebody Say 'Gest-IT'? A Pilot Exploration of Multimodal Data Management
Ludovica Pannitto, Lorenzo Albanesi, Laura Marion, Federica Martines, Carmelo Caruso, Claudia Bianchini, Francesca Masini and Caterina Mauri 735

Confronto tra Diversi Tipi di Valutazione del Miglioramento della Chiarezza di Testi Amministrativi in Lingua Italiana
Mariachiara Pascucci and Mirko Tavosanis 746

Towards an Automatic Evaluation of (In)coherence in Student Essays
Filippo Pellegrino, Jennifer Frey and Lorenzo Zanasi 757

MONICA: Monitoring Coverage and Attitudes of Italian Measures in Response to COVID-19
Fabio Pernisi, Giuseppe Attanasio and Debora Nozza 766

Unraveling the Enigma of SPLIT in Large-Language Models: The Unforeseen Impact of System Prompts on LLMs with Dissociative Identity Disorder
Marco Polignano, Marco De Gemmis and Giovanni Semeraro 774

The limits of Italian in Reasoning Tasks
Leonardo Ranaldi, Giulia Pucci, Federico Ranaldi, Elena Sofia Ruzzetti and Fabio Massimo Zanzotto . . . 781

How Far Does the Sequence of Compositions Impact Multilingual Pre-Training?
Leonardo Ranaldi, Giulia Pucci and Fabio Massimo Zanzotto . . . 796

From 'It's All Greek to Me' to 'Nur Bahnhof Verstehen': An Investigation of mBERT's Cross-Linguistic Capabilities
Aria Rastegar and Pegah Ramezani . . . 805

Is Sentence Splitting a Solved Task? Experiments to the Intersection between NLP and Italian Linguistics
Arianna Redaelli and Rachele Sprugnoli . . . 813

From Explanation to Detection: Multimodal Insights into Disagreement in Misogynous Memes
Giulia Rizzi, Paolo Rosso and Elisabetta Fersini . . . 821

To Click It or Not to Click It: An Italian Dataset for Neutralising Clickbait Headlines
Daniel Russo, Oscar Araque and Marco Guerini . . . 829

AI vs. Human: Effectiveness of LLMs in Simplifying Italian Administrative Documents
Marco Russodivito, Vittorio Ganfi, Giuliana Fiorentino and Rocco Oliveto . . . 842

Assessing the Asymmetric Behaviour of Italian Large Language Models across Different Syntactic Structures
Elena Sofia Ruzzetti, Federico Ranaldi, Dario Onorati, Davide Venditti, Leonardo Ranaldi, Tommaso Caselli and Fabio Massimo Zanzotto . . . 854

Morphological vs. Lexical Antonyms in Italian: A Computational Study on Lexical Competition
Martina Saccomando, Andrea Zaninello and Francesca Masini . . . 864

Multimodal Attention Is All You Need
Marco Saioni and Cristina Giannone . . . 873

Assessing Italian Large Language Models on Energy Feedback Generation: A Human Evaluation Study
Manuela Sanguinetti, Alessandro Pani, Alessandra Perniciano, Luca Zedda, Andrea Loddo and Maurizio Atzori . . . 880

Non Verbis, Sed Rebus: Large Language Models Are Weak Solvers of Italian Rebuses
Gabriele Sarti, Tommaso Caselli, Malvina Nissim and Arianna Bisazza . . . 888

Leveraging Large Language Models for Fact Verification in Italian
Antonio Scaiella, Stefano Costanzo, Elisa Passone, Danilo Croce and Giorgio Gambosi . . . 898

A Gentle Push Funziona Benissimo: Making Instructed Models in Italian via Contrastive Activation Steering
Daniel Scalena, Elisabetta Fersini and Malvina Nissim . . . 909

Subcategorization of Italian Verbs with LLMs and T-PAS
Luca Simonetti, Elisabetta Jezek and Guido Vetere . . . 921

Unipa-GPT: A Framework to Assess Open-source Alternatives to Chat-GPT for Italian Chat-bots
Irene Siragusa and Roberto Pirrone . . . 929

Annotation and Detection of Emotion Polarity in I Promessi Sposi": Dataset and Experiments
Rachele Sprugnoli and Arianna Redaelli . . . 940

Complexifying BERT Using LoRA Adapters
Fabio Tamburini . . . 948

How Do We Counter Hate Speech in Italy?

Nesciun Lengaz Lascià Endò: Machine Translation for Fassa Ladin
Giovanni Valer, Nicolò Penzo and Jacopo Staiano . . . 967

Neutral Score Detection in Lexicon-based Sentiment Analysis: The Quartile-based Approach
Marco Vassallo, Giuliano Gabrieli, Valerio Basile and Cristina Bosco . . . 976

Sensitivity of Syllable-Based ASR Predictions to Token Frequency and Lexical Stress
Alessandro Vietti, Domenico De Cristofaro and Picciau Sara . . . 983

Modelling Filled Particles and Prolongation Using End-to-end Automatic Speech Recognition Systems: A Quantitative and Qualitative Analysis.
Vincenzo Norman Vitale, Loredana Schettino and Francesco Cutugno . . . 990

Implicit Stereotypes: A Corpus-Based Study for Italian
Wolfgang Wolfgang Schmeisser-Nieto, Giacomo Ricci, Simona Frenda, Mariona Taule and Cristina Bosco . . . 997

SLIMER-IT: Zero-Shot NER on Italian Language
Andrew Zamai, Leonardo Rigutini, Marco Maggini and Andrea Zugarini . . . 1005

Harnessing LLMs for Educational Content-Driven Italian Crossword Generation
Kamyar Zeinalipour, Achille Fusco, Asya Zanollo, Marco Maggini and Marco Gori . . . 1013

Voice Activity Detection on Italian Language
Shibingfeng Zhang, Gloria Gagliardi and Fabio Tamburini . . . 1024

Topic Modeling for Auditing Purposes in the Banking Sector
Alessandro Giaconia, Valeria Chiariello and Marco Passarotti . . . 1030

IDRE: AI Generated Dataset for Enhancing Empathetic Chatbot Interactions in Italian Language.
Simone Manai, Laura Gemme, Roberto Zanoli and Alberto Lavelli . . . 1036

Multimodal Online Manipulation: Empirical Analysis of Fact-Checking Reports
Olga Uryupina . . . 1043

Life and Death of Fakes: On Data Persistence for Manipulative Social Media Content
Olga Uryupina . . . 1049

CALAMITA: Challenge the Abilities of LAnguage Models in ITAlian
Giuseppe Attanasio, Pierpaolo Basile, Federico Borazio, Danilo Croce, Maria Francis, Jacopo Gili, Elio Musacchio, Malvina Nissim, Viviana Patti, Matteo Rinaldi and Daniel Scalena . . . 1054

ItaEval: A CALAMITA Challenge
Giuseppe Attanasio, Moreno La Quatra, Andrea Santilli and Beatrice Savoldi . . . 1064

PERSEID - Perspectivist Irony Detection: A CALAMITA Challenge
Valerio Basile, Silvia Casola, Simona Frenda and Soda Marem Lo . . . 1074

TRACE-it: Testing Relative clAuses Comprehension through Entailment in ITalian: A CALAMITA Challenge
Dominique Brunato . . . 1082

MAGNET - MAchines GeNErating Translations: A CALAMITA Challenge
Mauro Cettolo, Andrea Piergentili, Sara Papi, Marco Gaido, Matteo Negri and Luisa Bentivogli 1089

GATTINA - GenerAtion of TiTles for Italian News Articles: A CALAMITA Challenge
Maria Francis, Matteo Rinaldi, Jacopo Gili, Leonardo De Cosmo, Sandro Iannaccone, Malvina Nissim and Viviana Patti 1094

GFG - Gender-Fair Generation: A CALAMITA Challenge
Simona Frenda, Andrea Piergentili, Beatrice Savoldi, Marco Madeddu, Martina Rosola, Silvia Casola, Chiara Ferrando, Viviana Patti, Matteo Negri and Luisa Bentivogli 1106

VeryfIT - Benchmark of Fact-Checked Claims for Italian: A CALAMITA Challenge
Jacopo Gili, Viviana Patti, Lucia Passaro and Tommaso Caselli 1116

AMELIA - Argument Mining Evaluation on Legal documents in ItAlian: A CALAMITA Challenge
Giulia Grundler, Andrea Galassi, Piera Santin, Alessia Fidelangeli, Federico Galli, Elena Palmieri, Francesca Lagioia, Giovanni Sartor and Paolo Torroni 1125

BLM-It - Blackbird Language Matrices for Italian: A CALAMITA Challenge
Chunyang Jiang, Giuseppe Samo, Vivi Nastase and Paola Merlo 1135

DIMMI - Drug InforMation Mining in Italian: A CALAMITA Challenge
Raffaele Manna, Maria Pia Di Buono and Luca Giordano 1144

GITA4CALAMITA - Evaluating the Physical Commonsense Understanding of Italian LLMs in a Multi-layered Approach: A CALAMITA Challenge
Giulia Pensa, Ekhi Azurmendi, Julen Etxaniz, Begoña Altuna and Itziar Gonzalez-Dios 1153

ABRICOT - ABstRactness and Inclusiveness in COntexT: A CALAMITA Challenge
Giovanni Puccetti, Claudia Collacciani, Andrea Amelio Ravelli, Andrea Esuli and Marianna Bolognesi 1161

INVALSI - Mathematical and Language Understanding in Italian: A CALAMITA Challenge
Giovanni Puccetti, Maria Cassese and Andrea Esuli 1168

Termite Italian Text-to-SQL: A CALAMITA Challenge
Federico Ranaldi, Elena Sofia Ruzzetti, Dario Onorati, Fabio Massimo Zanzotto and Leonardo Ranaldi 1176

Mult-IT Multiple Choice Questions on Multiple Topics in Italian: A CALAMITA Challenge
Matteo Rinaldi, Jacopo Gili, Maria Francis, Mattia Goffetti, Viviana Patti and Malvina Nissim 1184

EurekaRebus - Verbalized Rebus Solving with LLMs: A CALAMITA Challenge
Gabriele Sarti, Tommaso Caselli, Arianna Bisazza and Malvina Nissim 1202

GEESE - Generating and Evaluating Explanations for Semantic Entailment: A CALAMITA Challenge
Andrea Zaninello and Bernardo Magnini 1209

ITA-SENSE - Evaluate LLMs' ability for ITAlian word SENSE disambiguation: A CALAMITA Challenge
Pierpaolo Basile, Elio Musacchio and Lucia Siciliani 1217

BEEP - BEst DrivEr's License Performer: A CALAMITA Challenge
Fabio Mercorio, Daniele Potertì, Antonio Serino and Andrea Seveso 1222

PejorativITy - In-Context Pejorative Language Disambiguation: A CALAMITA Challenge
Arianna Muti 1228

MACID - Multimodal ACtion IDentification: A CALAMITA Challenge
Andrea Amelio Ravelli, Rossella Varvara and Lorenzo Gregori 1234

ECWCA - Educational CrossWord Clues Answering: A CALAMITA Challenge
Andrea Zugarini, Kamyar Zeinalipour, Achille Fusco and Asya Zanollo 1239

Preface to the CLiC-it 2024 Proceedings

Felice Dell'Orletta[1], Alessandro Lenci[2], Simonetta Montemagni[1] and Rachele Sprugnoli[3]

[1] *CNR-Institute for Computational Linguistics "A. Zampolli", Pisa*
[2] *University of Pisa*
[3] *University of Parma*

This year marks the 10th anniversary of the Italian Conference on Computational Linguistics. To celebrate this important achievement for the whole Italian community, CLiC-it 2024 is held in Pisa, like for its first edition in 2014, from 4th to 6th December 2024.

Concerning the scientific organization of the conference, two types of submissions were possible: regular papers, describing substantial, original, completed, and unpublished work, and short research communications of outstanding papers accepted in both 2023 and 2024 by major publication venues, such as the major international Computational Linguistics conferences (workshops excluded) or international journals. These latter contributions are not published in the conference proceedings but are aimed to promote the dissemination of high-quality research within the Italian community.

Like in the previous edition, the conference was not organized into separate tracks. Submissions were assigned to area chairs (thirteen program committee members) according to a set of topics chosen by the authors at submission time. This way we were able to achieve a better balance of papers for each area chair, while respecting their research interests. Paper assignment to reviewers was also managed globally, with a single pool of 140 reviewers, to better monitor the whole process.

We have received a record number of submissions for regular papers: 133 compared to 86 in 2023 (+47). This result demonstrates the vitality and growth of the Italian Computational Linguistics community. In addition we received 19 submissions for short research communications.

During the reviewing process, each regular paper submission was reviewed by three independent reviewers in single-blind fashion. At the end of the process, **114 proposals were accepted** for presentation at the conference and for publication in the proceedings, resulting in an acceptance rate of 85.7% (with respect to the rate of 87.21% for CLiC-it 2023).

Out of the 114 accepted proposals, 32 were included in the program as oral presentations (divided into 6 oral sessions) and the remaining 82 were assigned to one of the three poster sessions dedicated to the regular papers. As usual, the criterion for assigning a proposal to an oral or a poster session was based on the contents and not on the quality of the proposal. An additional poster session was organized for the 19 research communications that are not published in the proceedings.

An important novelty of this edition is the organization of the special event CALAMITA (Challenge the Abilities of LAnguage Models in ITAlian) which took place on the afternoon of December 6th. The aim of CALAMITA, that collected 20 tasks, is the collaborative creation of a dynamic benchmark to evaluate Large Language Models supporting the Italian language.

In addition to the technical program, this year the conference hosted an interview with Oliviero Stock (Fondazione Bruno Kessler, Trento) and Nicoletta Calzolari (CNR-ILC, Pisa) on the past, present, and future of computational linguistics in Italy, in relation to the wider international landscape. In addition, we were honored to have as **invited speakers** two internationally recognized researchers:

- **Giosuè Baggio** (Norwegian University of Science and Technology, Trondheim), with a keynote entitled "Meaning and grammar in a parallel architecture for language processing": *This talk introduces a novel cognitive and computational architecture for human language processing. The architecture features parallel streams for meaning and grammar, drawing from a shared mental lexicon and contributing concurrently to incremental updates of a discourse model. Intermediate representations are generated independently within each stream, resulting in a range of possible interactions between meaning and grammar — from dominance and redundancy to competition and conflict. Linguistic phenomena illustrating these different interactions and present experimental results corroborating the architecture's processing consequences are presented. Then a computational model that aligns*

CLiC-it 2024: 10th Italian Conference on Computational Linguistics, Dec 04 - Dec 06, 2024, Pisa, Italy

✉ felice.dellorletta@ilc.cnr.it (F. Dell'Orletta); alessandro.lenci@unipi.it (A. Lenci); simonetta.montemagni@cnr.it (S. Montemagni); rachele.sprugnoli@unipr.it (R. Sprugnoli)
🌐 https://www.ilc.cnr.it/people/felice-dellorletta-2/ (F. Dell'Orletta); https://people.unipi.it/alessandro_lenci/ (A. Lenci); https://www.ilc.cnr.it/people/simonetta-montemagni-2/ (S. Montemagni); https://personale.unipr.it/it/ugovdocenti/person/236480 (R. Sprugnoli)

with experimental results and that demonstrates the importance of intermediate representations is described. Some considerations on how the theory reconciles two key principles in linguistics — compositionality and context — and the traditions that build on them conclude the talk..

- **Dieuwke Hupkes** (Meta AI Research, Paris, France), with a keynote entitled "Generalisation in LLMs – and beyond": *"Good generalisation" is often mentioned as a desirable property for NLP models. For LLMs, in the light of the sheer training corpora, among other things, it becomes more and more challenging to understand if our models generalise, and how important that still is. In this presentation, I briefly discuss generalisation in NLP on a higher level, and then move on to discussing it specifically for LLMs. What types of generalisation are still important, how would we evaluate it, and is it possible to evaluate it independently from the training corpus? I will – hopefully – answer some of your questions, but also raise a lot more!.*

In the first morning of the Conference, Bernardo Magnini and Giovanni Bonetta (FBK, Trento) gave a **tutorial** entitled "You Are what You Eat: Processing Data for Training and Evaluating LLMs".

This year we received 9 candidate theses for the "**Emanuele Pianta Award for the Best Master Thesis**". This special prize for the best Master Thesis (Laurea Magistrale) in Computational Linguistics, submitted at an Italian University, commemorates the late lamented Emmanuele Pianta and is endorsed by AILC. The candidate theses have been evaluated by a jury composed by Gianluca Lebani (Ca' Foscari University of Venice), Rachele Sprugnoli (University of Parma) and Sara Tonelli (Fondazione Bruno Kessler, Trento). The winner was awarded during the closing session of the conference by the members of the jury.

We thank **all the people and institutions** involved in the organization of the conference, all area chairs, reviewers, and all participants, who contributed to the success of the event. Chairs and reviewers are named in the following pages. We are grateful to the CNR-Institute for Computational Linguistics "A. Zampolli" that made CLiC-it 2024 possible by hosting the event and supporting us greatly in the processes of local organization, and to the University of Pisa[1] that endorsed our event.

We would like to thank our **supporters**, who generously provided funds and services that are crucial for the realization of this event: Aptus.AI[2], CLARIN-IT[3] and Talia[4] (Silver), aequa-tech[5], Almawave[6] and ELRA[7] (Bronze), Translated[8] (Iron), and Meta[9] that supported the trip of Dieuwke Hupkes.

Finally, we want to thank very much the Associazione Italiana di Linguistica Computazionale (**AILC**), all the members of the Association Board who supported and guided us in organizing the conference.

Pisa, December 2024

Conference Chairs

- **Felice Dell'Orletta**, CNR-Institute for Computational Linguistics "A. Zampolli"
- **Alessandro Lenci**, University of Pisa
- **Simonetta Montemagni**, CNR-Institute for Computational Linguistics "A. Zampolli"
- **Rachele Sprugnoli**, University of Parma

CALAMITA Chairs

- **Pierpaolo Basile**, University of Bari Aldo Moro
- **Danilo Croce**, University of Rome, Tor Vergata
- **Malvina Nissim**, University of Groningen
- **Viviana Patti**, University of Turin

CALAMITA Data and Evaluation Team

- **Giuseppe Attanasio**, Instituto de Telecomunicações, Lisbon
- **Federico Borazio**, University of Rome, Tor Vergata
- **Maria Francis**, University of Groningen & University of Trento
- **Jacopo Gili**, University of Turin
- **Elio Musacchio**, University of Bari Aldo Moro
- **Matteo Rinaldi**, University of Turin
- **Daniel Scalena**, University of Groningen & University of Milan Bicocca

Local Organization Committee

- **Chiara Alzetta**, CNR-Institute for Computational Linguistics "A. Zampolli"
- **Serena Auriemma**, University of Pisa

Lifeless Winter without Break: Ovid's Exile Works and the LiLa Knowledge Base

Aurora Alagni[1,*], Francesco Mambrini[1] and Marco Passarotti[1]

[1]*Università Cattolica del Sacro Cuore, Largo Gemelli 1, Milano, 20123, Italy*

Abstract

In this paper we describe the process of semi-automatic annotation and linking performed to connect two works by the Latin poet Ovid to the LiLa Knowledge Base. Written after Ovid's exile from Rome, the *Tristia* and the *Epistulae ex Ponto* mark the beginning of the "literature of exile". In spite of their importance, no lemmatized version existed and the two collections were not part of the major annotated corpora linked to LiLa. The paper discusses the workflow used to annotate and publish the works as Linked Open Data connected to the LiLa Knowledge Base. On account of their subject and the emotional tone attached to the theme of exile, the two works are particularly relevant for sentiment analysis. We discuss some results of a lexicon-based analysis that is enabled by the interlinking with LiLa. We use LatinAffectus, a manually-generated polarity lexicon for Latin nouns and adjectives, to perform Sentiment Analysis on the aforementioned works and interpret the (replicable) results by consulting and simultaneously enriching the available literary scholarship with new information.

Keywords

Linked Open Data, Lemmatization, Latin, Sentiment Analysis, Humanities Computing

1. Introduction

The World Wide Web provides Latin scholars with a plethora of free, high-quality resources, issued from a long tradition of linguistic and philological study; many digital libraries, such as the Perseus Digital Library [1] or the Digital Latin Library [2], supply electronic and often machine-actionable versions of some of the most studied texts in world literature. In the last years, the CIRCSE Research Center has developed the LiLa Knowledge Base with the objective of making the distributed knowledge about Latin texts interoperable through the application of the principles of the Linked Data paradigm [3]. LiLa (presented below in sec. 3) now includes a number of lexicons and annotated corpora. In particular, the *Opera Latina* LASLA corpus, a manually lemmatized and morphosyntactically annotated corpus of more than 1.5 million words mainly belonging to Classical Latin literature that was recently added to LiLa [4], has significantly expanded the textual heritage within the LiLa Knowledge Base, which now provides a Linked Open Data (LOD) compliant edition of many widely studied literary works.

Publius Ovidius Naso (anglicized as Ovid, 43 BCE - 17 CE) is arguably one of the most influential writers in the history of Western literature. His mythological poem in 15 books (the *Metamorphoses*, written between 2 and 8 CE) has been a crucial source of inspiration for artists like Dante, Shakespeare, or Titian. His body of elegiac poetry of erotic subject won him immense popularity during his life and afterwards. In spite of his importance, the work of Ovid is not represented in full neither in the LiLa network, nor in any other annotated corpora. The LASLA corpus provides only his earlier works (*Ars Amatoria, Remedia Amoris, Medicamina, Amores, Heroids*) and other poems (*Fasti, Halieutica, Ibis*), while the annotation of the *Metamorphoses* is listed as "in progress".

Among the works that are utterly missing figure two of the last books of Ovid's career, the *Tristia* ("Sorrows" or "Lamentations", written between 9–13 CE) and the *Epistulae ex Ponto* ("Letters from the Black Sea", 12–17 CE, henceforth *Epistulae*) that were partly published after the poet's death. These two poetic collections center around Ovid's forced departure from Rome and exile to the town of Tomis (modern-day Constanța in Romania), at the furthest ends of the Roman empire. Despite his many attempts, Ovid would never come back from this "utmost part of an unknown world" (*extremis ignoti partibus orbis, Tr.* 3.3.3[1]) nor was he ever restored to his previous status. The two works are a fundamental source for the biography of the poet. Moreover, they are a foundational archetype of a peculiar sub-genre that is still influential in modern days, the "exile literature" [6].

Ovid's exilic works were banished from libraries, and although they survived, were often judged unfavorably by the critics [7, xxxvi]. The present study aims, in part, at revoking the ban that still seems to weigh on these

Ovidian poetic collections, allowing them to enter the LiLa network. In what follows we describe how we prepared a lemmatized and part-of-speech (POS) tagged version of the two poems and how we linked this edition to the network of textual and lexical resources for Latin connected to LiLa. Our work fills the significant gap created by the absence of the exilic works of Ovid from the available annotated corpora. In addition, it also links to LiLa two collections of poems that, on account of their subject, foreground the emotional tone, and were successful in shaping the conventions of exilic literature; these works established the literary codification of the psychological reactions to banishment, within a veritable poetics of exile. Their content and historical relevance make them ideal candidates for a computationally based study on the sentiment analysis of literary texts.

The paper is structured as follows. Section 2 reviews related work, with a specific focus on sentiment analysis within the field of Computational Literary Studies. Section 3 introduces the LiLa Knowledge Base and the language resources connected to it. Section 4 describes the workflow followed for the annotation, publication and linking of the works. Section 5 discusses the type of knowledge that can be gained by combining the data from *LatinAffectus*, a prior polarity lexicon of Latin included in LiLa, and the newly prepared edition of the works, for a lexicon-based approach to their sentiment. Section 6 presents the conclusions and discusses plans for future work.

2. Related Work

Sentiment analysis (SA) is the field of study that analyses people's opinions, sentiments, appraisals, attitudes, and emotions toward entities and their attributes expressed in written text [8]. Considering that opinions have now a fundamental role in everyday life, SA is not just an object of research in the field of NLP, but also in business, economic, political, even medical domains. Indeed, sentiment analysis has numerous applications[2], ranging from investigating product reviews to enhance product development [10], analysing news related to the stock market to predict price trends [11], monitoring social media to forecast election outcomes [12], and evaluating public health through tweets about patient experiences [13].

Furthermore, sentiment analysis has recently emerged as one of the most discussed topics within the realm of Computational Literary Studies[3]. This rise in prominence coincides with the so-called "affective turn" in the humanities and social sciences, which has fostered renewed engagement with emotion [15]. However, there remain significant limitations in the application of sentiment analysis within Computational Literary Studies, two of which are addressed in this paper.

First, while the World Wide Web and social media represent an ostensibly infinite repository of emotions, annotated corpora of literary texts are still infrequently available. This is especially true for classical languages. As previously mentioned and will be further illustrated in this paper, this limitation can be mitigated through the development and dissemination of interoperable resources. To our knowledge, there are only a few experiments conducted in classical languages. Sprugnoli et al. [16] evaluated two distinct approaches to automatic polarity classification of eight odes by the Latin author Horace: a lexicon-based approach, grounded in the first version of LatinAffectus, and a zero-shot classification method. Sprugnoli et al. [17] present an example of how to use interoperable resources to analyse the sentiment value of the Latin epistles by Dante Alighieri, employing SPARQL queries that access an extended version of LatinAffectus, the LiLa Knowledge Base, and UDante. Pavlopoulos et al. [18] annotated the sentiment of a modern Greek translation of the first book of the Iliad and demonstrated that a fine-tuned version of GreekBERT can achieve a low error rate. Zhao et al. [19] proposed a model based on transfer learning to classify a dataset of Tang Dynasty Chinese poems and compared the sentiment analysis results with social history analysis. After constructing a sentiment lexicon for Classical Chinese poetry, Hou et al. [20] evaluated it both intrinsically and extrinsically, highlighting that their analysis results align with the main findings established in Classical Chinese literary studies.

Second, although sentiment analysis in the field of Computational Literary Studies is employed to address questions related to literary theory, the results often lack connection to a rigorous analysis, focusing solely on performance metrics. The aforementioned studies exemplify this tendency, particularly since only those conducted on Classical Chinese take literary studies into account. Rarely do they contribute to advancements in literary criticism, an area that could greatly benefit from clear and reproducible results, considering that it typically relies on the intuition of critics. This issue has been highlighted by Rebora [21], who notes that while the strongest connection between literary theory and sentiment analysis occurs in the field of narratology, the actual points of intersection reveal themselves to be problematic and based on questionable assumptions. This paper will also address these concerns, as the results of sentiment analysis conducted on Ovid's exilic works are closely intertwined with the literary scholarship surrounding those texts. Although our findings may not be generalisable due to their

[2] See Wankhade et al. [9] for an in-depth overview of the applications of sentiment analysis, as well as the methods for conducting this task.

[3] For an extensive survey on sentiment and emotion analysis applied to literature, see the paper by Kim and Klinger [14].

basis in a small, yet highly controlled dataset, our method is clearly reproducible and shareable.

3. Latin resources in LiLa

LiLa is a network of interconnected language resources for Latin aimed at insuring interoperability between corpora, lexicons and natural language processing (NLP) tools. To pursue its goal, it adopts the Linked Data paradigm. At the heart of the project, the interlinking between the different components is ensured by the Lemma Bank [22], a collection of canonical forms (lemmas) that can be used to lemmatize texts and index entries in dictionaries. Each lemma of the Lemma Bank is provided with a unique identifier, in the form a URL resolvable on the World Wide Web, and described by a series of properties modeled with the help of OWL ontologies for Linguistic LOD, such as `Ontolex` [23, 45-59].

Currently, the Lemma Bank includes 226,775 canonical forms, which are used to link 14 lexical resources and 7 corpora. The latter include collections of texts from different times and genres (from the works of Medieval authors like the mathematician Fibonacci [24], Thomas Aquinas [25] or Dante Alighieri [26], to inscriptions from various areas of the Roman Empire [27]). The largest collection of Classical literary texts is provided by the *Opera Latina*, a manually crafted corpus with morphological annotation and lemmatization developed since the 1960s by the LASLA laboratory of the University of Liège. The LASLA corpus (which is still in development) includes 131 Latin works by 19 authors, ranging chronologically from Plautus (c. 254 – 184 BC) to Juvenal (55 – 128 CE). As said, however, even such comprehensive collection does not cover the whole extant production, also for some of the major authors within that time span; Ovid's exilic words are a prominent example of missing texts. To fill the gaps in LASLA, and widen the chronological span of ancient authors to the end of the Roman era in the 6th Century CE, the CIRCSE has launched a new collection (natively linked to LiLa) called the "CIRCSE Latin Library"[4].

Among the lexical resources produced within LiLa[5], LatinAffectus [28] is a manually generated polarity lexicon of Latin adjectives and nouns. The lexicon was designed to support research in Sentiment Analysis (SA) [8], an approach to the linguistic and literary studies of ancient texts that, although still in its infancy, is gaining growing recognition [18][16].

In its latest version, LatinAffectus contains 6,018 lemmas, 2,216 adjectives and 3,802 nouns, to which numerical values expressing their prior polarity, that is their sentiment orientation regardless of the context of use [8], have been associated. The classification adopts five numeric values: -1.0 (fully negative, as e.g. *uulnus*, "wound"), -0.5 (negative, *grauis*, "serious"), 0 (neutral, *ianua*, "door"), +0.5 (positive, *ius*, "justice"), +1.0 (fully positive, *pietas*, "devotion").

In the second part of this paper (Sec. 5) we will make use of data from LatinAffectus to perform lexicon-based Sentiment Analysis of Ovid's exilic works. The results obtained from the SA conducted on the *Tristia* and the *Epistulae*, clear and reproducible, and their interpretation carried on in light of the previous results of literary criticism on the subject allowed us to investigate the evolution of Ovid's poetic journey (Sec. 5.1) and the decline of relationships with those left behind in Rome (Sec. 5.2).

4. Ovid's exile works as LOD

The *Tristia* are a collection of 50 poems in elegiac meter (i.e. couplet of lines with an hexameter followed by a pentameter) divided into 5 books. The *Epistulae* include 46 letters in elegiac couplets divided into 4 books. The poetry in both works mixes the themes of lamentation over the exile and the desperate plead (*peroratio*) directed towards the loved ones and potential allies in Rome.

The starting point of our edition was a plain-text version of the two works, which we obtained from The Latin Library[6]. The two works consists of a total of 43,438 tokens (without punctuation), and 3,061 sentences. Few preprocessing operations were performed over the texts, namely the addition of three missing lines, which were omitted by mistake in the original source (*Tr.* 3.10.44 and 52, *Tr.* 5.12.50), the correction of evident transcription errors (most likely due to OCR issues, e.g. *virunique* for *virumque*, *Tr.* 2.372), the standardization of capitalization usage, and the adoption of the "u" character even for the voiced labiodental fricative [v], following the convention adopted in the LiLa Lemma Bank.

Tokenization, sentence splitting, lemmatization and POS tagging were performed automatically by the LiLa Text Linker, a POS-tagger and lemmatizer for the Latin language developed as one of the user-dedicated services of LiLa that also links the output of the NLP operations to the entries in the Lemma Bank [29]. For POS-tagging and lemmatization the Text Linker uses a custom-trained UDPipe model (as documented in [29]). The output of the tasks performed automatically was systematically reviewed and manually corrected by one annotator adopting a scholarly annotation approach [30]. 42 tokenization errors were identified (on average between 4 and 5 per book), often due to a failure to segment punctuation (e.g. the sequence *legent?* in *Tr.* 5.1.94).

Table 1
Accuracy of POS tagging and lemmatization per book of *Epistulae* and *Tristia* as performed by the LiLa Text Linker

		Accuracy	
Book	Nr. of tokens	POS Tagging	Lemmatization
Ep. 1	5,923	0.95	0.93
Ep. 2	5,770	0.97	0.94
Ep. 3	5,671	0.97	0.95
Ep. 4	7,099	0.97	0.94
Tr. 1	5,805	0.96	0.94
Tr. 2	4,427	0.96	0.93
Tr. 3	6,214	0.96	0.95
Tr. 4	5,311	0.97	0.95
Tr. 5	5,980	0.96	0.94
TOT	52,200	0.94	0.96

Table 2
Evaluation of POS tagging for the 11 tags with support > 1,000 tokens

POS-Tag	Precision	Recall	F1-score	Support
VERB	0.98	0.97	0.97	10,960
NOUN	0.96	0.97	0.96	10,626
PUNCT	1.00	1.00	1.00	8667
ADJ	0.95	0.90	0.92	4,702
ADV	0.96	0.95	0.95	3,955
DET	0.95	0.99	0.97	3,836
PRON	0.99	0.93	0.96	3,276
CCONJ	0.99	0.99	0.99	1,698
ADP	0.96	0.99	0.98	1,625
PROPN	0.79	0.90	0.84	1,353
SCONJ	0.88	0.94	0.91	1,304

The accuracy score reached by the model of the LiLa Text Linker are reported in table 1[7]. As it can be seen, the tool performed quite satisfactorily in both tasks, reaching an average accuracy across the different books of the two works of 96% and 94% respectively. Accurate lemmatization also lead to good scores for the linking process, with approximately 87% of the word forms uniquely associated with one lemma. Of the remaining lemmas, 10% were ambiguous, as they were associated with two or more potential candidates in LiLa, mainly due to homography (e.g. the lemma string *volo* can be linked to both the first-conjugation verb *volare*, "to fly" and the irregular verb *volere*, "will"), and required manual disambiguation.

Of the 3% of no-matches, most were proper names. Ovid mentions barbarian tribes and figures belonging to Roman cultural circles rarely or never cited elsewhere. In the fourth book of the *Epistulae*, out of a total of 42 tokens not linked to any lemma, 32 are proper names (e.g. the Thracian tribe of the "Corallis", *Ep.* 5.2.37, or the unknown poet "Marius", mentioned in *Ep.* 4.16.24). Table 2 shows the performances of the POS-tagger for the 12 out of 17 tags that were used more than 1,000 times[8]. With an F1-score sensibly under 90%, proper nouns (PROPN) is the most challenging class for the model to predict.

All tasks (tokenization, POS-tagging, lemmatization and linking) are closely interconnected: an error in tokenization inevitably leads to an error in lemmatization and POS tagging, which then causes a wrong or missing linking. For example, 18 forms of the verb *addo*, "to add", in the second person singular imperative, *adde*, "add", were mislabeled as proper nouns (PROPN), and thus assigned to a nonexistent lemma "Ads". Once disambiguations and corrections were performed, the digital editions of the *Tristia* and the *Epistulae* were prepared and published as Linked Data, as part of the "CIRCSE Latin Library"[9].

5. Sentiment analysis and Ovid's exile works

Thanks to the work performed in the linking process, each token of the two exilic poems is now connected to the respective lemma within the Lemma Bank via a dedicated property (`hasLemma`)[10] defined in the OWL ontology of the LiLa project [3]. As the lemma's URI is the same that is used as canonical form for the entries of LatinAffectus, this step effectively enables users to cross-check the textual information within the two works and the scores recorded in the prior polarity lexicon.

Following the same methodology discussed in Sprugnoli et al. for Horace [16, 61-2], we proceeded to match each token of *Tristia* and *Epistulae* to the polarity score recorded in LatinAffectus for their respective lemma. The sentiment scores are obtained by automatically assigning the score found in LatinAffectus to the tokens that are lemmatized under lemmas that also have an entry in the polarity lexicon. For instance, the adjective *malus* "bad" is found with a polarity value of -1.0 in LatinAffectus. All tokens lemmatized as *malus* (adj.) are thus given a score of -1.0. A score of 0.0 is assigned to both words expressly annotated as neutral in LatinAffectus and to those that do not have an entry in the lexicon. The coverage of polarity-laden tokens (both adjectives and nouns) is reported in table 3.

[7] Note that, in the evaluation, we omitted the 3 missing lines that were added in the revision stage. For this reason table 1 has slightly fewer tokens than table 3.

[8] The model uses the Universal POS tagset of Universal Dependencies; see: https://universaldependencies.org/u/pos/index.html.

[9] http://lila-erc.eu/data/corpora/CIRCSELatinLibrary/id/corpus/P.%20Ovidii%20Tristia and http://lila-erc.eu/data/corpora/CIRCSELatinLibrary/id/corpus/P.%20Ovidii%20Epistulae%20ex%20Ponto.

[10] http://lila-erc.eu/ontologies/lila/hasLemma.

Table 3
Token coverage of polarity-laden nouns and adjectives in the books of *Epistulae* and *Tristia*. Per each book, the total nr. of adj. and nouns are reported, as well as the nr. of adj./nouns with polarity score $\neq 0$ (pos/neg)

Book	Nouns		Adjectives		Tot Tokens
	tot	pos/neg	tot	pos/neg	
Epistulae.b1	1,195	1,061	545	360	5,923
Epistulae.b2	1,214	1,088	561	425	5,770
Epistulae.b3	1,135	1,013	452	335	5,671

Tristia.b3	1,272	1,131	555	386	6,227
Tristia.b4	1,140	1,020	493	353	5,311
Tristia.b5	1,152	1,037	523	386	5,989
TOT	10,630	9,444	4,704	3,335	52,222

In what follows, due to space constraints, only some of the results obtained from the sentiment analysis conducted on Ovid's exilic works will be discussed. In analysing these results, we will focus on the distribution of sentiment-laden words and what this reveals about Ovid's emotional state during his exile.

5.1. Ovid's "last metamorphosis"

To investigate how Ovid's attitude evolves throughout his exilic works, we calculated the overall sentiment for each book (fig. 1). Specifically, we summed the polarity scores and divided the total by the number of sentences to mitigate skewness resulting from the varying lengths of the books [17][11]. This book-level score reveals a negative emotional state persisting until the first book of the *Epistulae*. From the second book onward, however, the sentiment undergoes a polarity shift, becoming positive and remaining so until the last book. The reasons behind such a radical change in the poet's emotional state are worth investigating. Ovid's polarity lexicon, that is, the most frequently used sentiment-laden words in the exilic works, does not show any particular change in the 9 books considered here. An interesting change that we do observe in the last books concerns the distribution of the personal pronouns. In *Epistulae* 1, the relative frequency of the 1st p. singular pronoun, *ego*, is 0.018 (93 over 4,983 lemmas), while for the second person singular pronoun, *tu*, it is 0.010 (52 occurrences). In *Epistulae* 2, the former has an identical relative frequency (0.018, or 89 occurrences over 4,920), while the latter increases significantly, reaching 0.020 (99 occurrences). The focus of Ovidian epistles seems to split, with the once uncontested domain of the "I" beginning to be accompanied by the equally large realm of the "you". The solipsism of the sender starts to giving way to the celebration of the recipient, transmuting the once famous and now banished elegiac poet into a potential celebratory poet, who could exceptionally glorify his future patron if only he is given the chance to (and after, of course, being recalled back home).

Commentators have never doubted that Ovid, after some attempts in the third book (e.g. *Ep.* 3.4-5), dedicates himself to panegyric poetry in the fourth book, no doubt in order to win powerful allies who could intercede for his return [31, 120-121] [32]. However, this intention was never noted or at least imagined for the *Epistulae*'s second book.

It is undeniable that we witness the last metamorphosis in the poetic trajectory of Ovidian elegy. Our results suggest that this metamorphosis, still so premature that it has not been detected by critics, is clearly recorded by sentiment analysis already in the second book of the *Epistulae*. Indeed, when the sentiment analysis is conducted at a finer grain, and thus at the level of individual compositions , it reveals an increase in positivity precisely in the verse-epistles sent to new and powerful recipients. This reflects a new poetic purpose for Ovid's poetry.

5.2. Facing the abandonment

Another advantage of lexicon-based SA is the possibility to directly engage with a list of sentiment words mostly used by an author in their entire production or in specific works of interest. A close observation of this specialized lexicon can lead to interesting outcomes too.

The sentiment words used in the exilic works are relatively stable in quality and quantity. Five distinct semantic spheres [33, 203] can be identified: friendship, politics, justice, intellect, and sadness (fig. 2). Among

[11] Ovid's sentences tend to correspond with the elegiac couplet. The two works have 3,4044 sentences with an average length of 17.16 tokens (stdev = 11.43). The books tend to have a rather similar number of sentences, ranging from 261 (*Tr.* 2) to 388 (*Ep.* 4), with a mean length of 338.22 (stdev = 37.74). Note, however, that we relied on the sentence splitter of TextLinker and the results were not corrected manually.

these, the semantic sphere of friendship and love contains abstract qualities and feelings (*amor* “love”, *fides* “trust, faith”, *honor* “honor”, *nobilitas* “nobility”, *pietas* “devotion”, *virtus* “virtue”), as well as nouns and qualifying adjectives typical of friendly and romantic relationships (*bonus* “good”, *carus* “dear”, *dignus* “worthy”, *pius* “dutiful, affectionate”). Although this sphere is frequently recurring throughout the exilic production, the words composing it do not appear with the same consistency. Between the third and fourth book of the *Tristia*, new lemmas become part of this semantic sphere, indicating a change in Ovid’s relationship with the affections left behind in Rome.

In *Tristia* 3, the only epithets fitting for his friends (lemma *amicus*, 10) were “dear” (*carus*, 10) and “good” (*bonus*, 6). These friends, along with the wife, represented Ovid’s only hope of salvation. In *Tristia* 4, Ovid reaches the fourth year of exile and sees the possibility of relying on them slipping further out of his grasp. The poet begins to perceive that the friendship and love shown to him in Rome and at the height of his success might have been more superficial than he believed. His friends fail to write (*Tr.* 4.7.3-5) and Ovid catches himself wondering if his wife still thinks of him (*Tr.* 4.3.10). However, the bonds of friendship and marriage could still be exploited.

In *Tristia*’s book 4, as the occurrences of the adjectives “friend” (*amicus*, 3) and “dear” (*carus*, 3) decrease, the use of words such as “devoted”, “virtuous”, “worthy”, and “husband” increases. This lexicon here suggests a form of conditional praise: only by proving themselves worthy of the friend and spouse in need can those left in Rome earn their title. Thus, if his friends are truly “virtuous” (*bonus*, 8) and “devoted” (*pius*, 6) and wish their “fame” (*fama*, 7) to be such among contemporaries and posterity, they must show themselves worthy of such a connotation. His wife must, similarly, prove herself worthy of being his husband’s (*vir*, 13) wife, even though he is exiled. Consequently, Ovid would sooner credit a ten-verses long series of *adynata* rather than believe that his friend decided to abandon him (*Tr.* 4.7.10-20). At the same time, his wife, dutiful as she is (*Tr.* 4.3.71), surely must be existing solely to work for and diligently lament her absent husband (*Tr.* 4.3.17-38). Moreover, his misfortune gives her a unique chance for fame, for her loyalty to be forever remembered (*Tr.* 4.3.81-84). This logic of coercion begins to be employed in book 4 of the *Tristia*, and finds full employment in the *Epistulae*. It consists of imposing fundamental moral models and values of the Roman citizen on his recipients through targeted praises, so that the recipients feel obliged to comply with the requests. Here too, sentiment analysis reveals in its embryonic state what the critical eye has only caught later in full development.

6. Conclusion and future work

The work that we presented in the paper had two outcomes. Firstly, our LOD edition of Ovid demonstrates the benefits of interoperability among resources for Latin. Interoperability greatly facilitates the work of scholars, allowing them to benefit from lexicon, corpora, and NLP tools useful for every stage of their research through a single point of access. The LiLa project already provides a paradigm of this model, but to continue doing so, it requires constant integration. This is true not only for corpora, whose enrichment this paper testifies to. Despite the important results that SA conducted with LatinAffectus already provides for Ovid, there remains several ways for enhancing its performance. The coverage of LatinAffectus is extensive with regard to nouns and adjectives, as clearly demonstrated by its performance on the dataset discussed in this paper (see table 3). However, it is evident that a current limitation is its failure to account for the sentiment of verbs. This is why LatinAffectus, like the other linguistic resources available in LiLa, should not be regarded as a static resource, but rather as one that is continually evolving and being updated. Additionally, improvements could be made by accounting for syntactic phenomena such as polarity shifters [16] and by taking into consideration the poetic nature of the text (e.g. by providing access to metrical information[12]). In a broader sense, there is a lack of sufficient consideration for the context in which sentiment words are collocated. However, context-sensitive sentiment analysis is still in its early stages within NLP[13], and clearly, much work remains to be done to effectively incorporate context into sentiment analysis.

The second outcome is in suggesting the undeniable potential of a hybrid approach, such as the one employed in this study, crossing literary criticism with the use of quantitative methods and computational resources. The theories developed within literary criticism and the investigative tools provided by computational linguistics can and should effectively collaborate, mutually enriching each other. In this specific context, the reflections developed within literary criticism regarding Ovid’s exile works were crucial for interpreting the data derived from sentiment analysis. In turn, sentiment analysis was fundamental for confirming and deepening these observation, providing interpretable and reproducible data.

If a classic is a book which has never exhausted all it has to say to its readers (as Calvino wrote [35, 5]), it is also because scholars are capable of interrogating it with new methods to address longstanding and unresolved questions.

[12] For instance, this can be achieved by linking existing resources, such as Musisque Deoque, to LiLa.

Exploring the Use of Cohesive Devices in Dementia within an Elderly Italian Semi-spontaneous Speech Corpus

Giorgia Albertin*,†, Elena Martinelli†

Alma Mater Studiorum - University of Bologna, Department of Classical Philology and Italian Studies, 32 Zamboni Street, 40126 Bologna, Italy

Abstract

The study of language disruption in dementia, aimed at individuating which features correlate with cognitive impairment, is a growing area in computational linguistic research. Still, it needs a further development in analyzing some discourse phenomena that also undergo deterioration, and can help expand our understanding of dementia-related speech and refine automatic tools. This paper explores the discourse property of cohesion by investigating three types of cohesive devices: reference, lexical iteration, and connectives. Ten features related to these categories have been defined and automatically extracted from an Italian corpus of semi-spontaneous speech collected from dementia patients and healthy controls. Some of the designed features have proven significant for the binary classification of the two groups and further quantitative analysis highlight interesting differences in the use of cohesive devices, that seem to be associated with cognitive decline.

Keywords

Cohesion, Cohesive devices, Dementia, Cognitive Impairment, Semi-spontaneous speech

1. Introduction

Linguistics deficits commonly characterized neurodegenerative diseases from their onset. In Dementia, or Major Neurocognitive Disorder (DSM-5 [1]), a syndrome of acquired and progressive impairment in cognitive function that interfere with independence in everyday life, language deterioration manifests itself within a broader framework of cognitive impairment, which could affects memory, visuo-spatial skills, executive functions and reasoning. Deficits both in verbal production and comprehension have been observed, despite the specificity of different Dementia's etiological subtypes, among which the most common is Alzheimer's Disease (AD), characterized with a primary impairment in episodic memory. In AD, for example, among the well-established linguistic deficits there are word-finding problems, which include anomia, the production of semantic paraphasias [2, 3] and the "on the-tip-of-the tongue" experience [4], low speech rate, poor word comprehension [5] and, as the disease worsen, a generalized simplification of syntax [6]. Also discourse and pragmatic level is affected by cognitive decline. Errors in referential cohesion has been registered, in particular regarding ambiguous use of pronouns [7]. Coherence is compromised, especially in spontaneous speech: the discourse appears with an abundance of irrelevant details and the overt difficulty to mention the key concept or to refer to the topic, resulting in a lack of informativeness in communication [8, 9, 10].

In recent years, speech analysis in cognitive decline has gained increasing importance in the development of low-cost and portable tools for dementia screening, also supported by the remarkable advancements in Natural Language Processing (NLP) and Machine Learning (ML) technologies [11]. The refinement of classification systems goes hand in hand with the operationalization of linguistic features computed from oral productions, that need to be adapted to different languages. Regarding Italian, the OPLON (OPportunities for active and healthy LONgevity) [2014-2016] project was devoted to the automatic extraction of an extensive group of linguistic features from acoustic, rhythmic, readability, lexical, morpho-syntactic and syntactic levels, from a speech corpus of cognitively impaired patients and healthy peers [12, 13]. Analysis of the significance of the features highlighted that the acoustics ones largely correlated with the cognitive state of the subjects [14].

Expanding the list of language levels covered to include speech properties would enrich the features used for classification and, in addition, could broaden our understanding of how cognitive decline manifests itself in verbal competence. Nevertheless, defining specific features of higher-level and complex phenomena is not trivial. Drawing inspiration from works that propose a "stratified" approach to discourse analysis, which individually considers macro-phenomena that intersect with one another [15, 16], this paper will examine cohesion, the property of the superficial form of the text to reflect its internal unity [17]. Cohesion assures continuity in dis-

course through a network of *cohesive devices*, which are mainly words or morphemes, that contribute to maintain semantic relations occurring in the text [17]. Therefore, we proposed a method to design and formalize a set of cohesion features, with the aim of observing whether they contribute to discriminate the speech of individuals with dementia from healthy peers. Specifically, three types of elements, which Halliday & Hasan [18] indicate among the major contributors to cohesion, were taken into consideration: reference, lexical iteration and connectives. The implementation of measures based on cohesive devices is the first step towards the attempt to include discourse properties in the automatic analysis of language in cognitive decline. The study of their interaction with features of other linguistic levels is crucial to observe whether they have a positive impact on discrimination between dementia subjects and healthy subjects. The work presented in this paper, therefore, has to be intended as a preliminary analysis that will serve to pursue more sophisticated ML classification in the future.

2. Corpus Description

In this study, we used the corpus collected within the project "Linguistic characteristics of the speech of elderly subjects with dementia" [20, 21], approved by the Bioethics Committee of the University of Bologna (Prot. N. 0072032/2022). The corpus consists of oral linguistic production of 40 Italian-speaking individuals living in Basilicata, forming two groups balanced by sex and age. Although the initial objective was to balance the cohorts also on education level, it was not possible to consider this aspect due to the lack of this information in some patients medical records. Even from a sociolinguistic perspective, it is important to advance that some participants, albeit Italian-speaking, were also exposed to dialect systems in their lives. This aspect explains the frequent occurrence of substandard linguistic expressions in the collected speech, and will be discussed in Section 4 in relation to the results of the analysis.

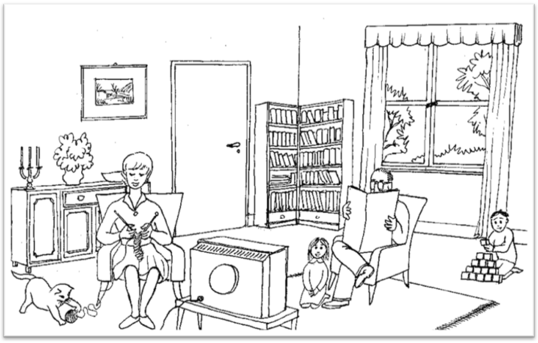

Figure 1: *Esame del Linguaggio II* [19], stimulus figure used in the picture description task.

The Pathological Group (PG) consists of 20 patients suffering from different forms of dementia (9 cases of Alzheimer's Disease, 2 of Mixed Dementia, 5 of unspecified Dementia, 3 of Vascular Dementia, 1 of Frontotemporal Dementia), recruited at the "Universo Salute - Opera Don Uva (PZ)" rest home, and the Control Group (CG) consists of 20 subjects with neurotypical cognitive aging. Informed consent was obtained from all participants (in the case of patients, by their family members, caregivers, or legal tutors). As a first step, the recruited subjects underwent an evaluation of their cognitive status through the administration of the four following neuropsychological tests: Mini-Mental State Examination (MMSE [22]), Montreal Cognitive Assesment (MoCA [23]), and Verbal Fluency Test, both Phonemic [24, 25, 26, 27] and Semantic [28]. The Table 1 summarizes the recruitment criteria and the demographics for study participants.

Then, two narrative tasks (the story of a journey and the story of the Christmas holiday's traditions) and one picture description task (using the stimulus figure in "Lan-

Table 2
Corpus Size. Audio duration and number of tokens (of the transcriptions) are reported, both with respect to the groups (Gr. durat. and Gr. count), to the single subject (Subj. avg (st.dev)) and to the whole corpus.

	Audio		Tokens	
	Gr. durat.	Subj. avg. (sd)	Gr. count	Subj. avg. (sd)
Pathological group	04:25:26	00:12:00 (00:08:00)	23,518	1,176 (1,218)
Control group	03:23:17	00:10:00 (00:05:00)	25,745	1,287 (710)
Total	07:48:43	-	49,263	-

guage Examination II" [19], see Figure 2) were administered to collect semi-spontaneous speech, elicited with the following stimulus sentences: 1) "Do you want to tell me about a trip you took?"; 2) “How do you usually spend Christmas day?”; 3) “Could you describe this figure to me?”. This protocol allowed the collection of approximately 9 hours of audio (i.e., 8 hours for the recruited groups and 1 hour for the interviewer), subsequently annotated at various linguistic levels. By using the ELAN software [29], the corpus was manually transcribed at the orthographic level, segmented into utterances (i.e., the reference unit of discursive analysis [30]), and annotated at the prosodic level (theoretical framework: The Language into Act Theory - L-AcT [31]). Table 2 summarize the size of the corpus and the average material (audio/token) collected for each patient and control subject. The total number of tokens was calculated on the orthographic transcription of the corpus (cleaned of annotation tags), and consists of 49,263 tokens (i.e., 23,518 for PG and 25,745 for CG). Finally, using the Gagliardi & Tamburini pipeline [32], tokenization, lemmatization, part-of-speech tagging, and syntactic parsing was automatically performed for the entire corpus.

3. Cohesive Devices’ Features

Ten features that quantify the use of cohesive devices by the speakers were designed and formalised. The features were computed with respect to each subject, thus referring to the amount of speech produced by the single individual in the three tasks. To comprehensively address the categories of cohesive devices considered, we use the `.conll` file resulted from the data annotation as the input for our analysis. Features’ automatic extraction was done via `.python` scripts. The methodology used will be described in detail in the following sections.

3.1. Reference

Reference is involved when an expression that requires interpretation by referring to something else occurs in the discourse [18]. This mechanism can be employed both in anaphoric and cataphoric uses, to refer respectively to something already known in the text or anticipating it. Reference functions either by repetition, which can be partial (e.g., through a synonym) or total, by semantic contiguity, or by substitution with pronouns or other elements [17]. It is this second type of referential expressions, closely linked to the textual dimension, that is investigated through the features, thus focusing on the occurrence of anaphora and cataphora.

An extensive literature review was necessary to select a relevant group of those expressions in the Italian language (see [33, 34, 35]). The group of elements collected includes pronouns, both personal (e.g., *io, tu, lei, lui*), demonstrative (e.g., *questo, quello*), indefinite (e.g., *alcuni, tutti*), and possessive, possessive adjectives (e.g., *mio, tuo*), as well as deictics (e.g., *fuori, sopra, avanti, qua, qui, dentro, dietro, giù, indietro, su, lì, avanti, oltre, ci*). The occurrences of these groups were counted and divided by the total number of tokens per subject (COE_REF). Additionally, the *pronoun density* (COE_PRON_DENS), defined as the ratio between pronouns and nouns uttered [36], was computed for each subject.

3.2. Lexical iteration

According to Halliday and Hasan [18], the iteration of a lexical item is a specific use of the repetition-type referential mechanism, which acquires cohesive force on its own because it is typically used when the referent is farther in the text. This set of features focuses on the repetition of three main open-class categories, namely nouns, (main) verbs, and adjectives. The use of words from these classes affects the richness of vocabulary, reflecting the speaker’s tendency toward lexical variation. Word-finding problems occurring in cognitive decline often manifest as difficulties in retrieving forms from the lexicon. The repetition of the same words can then occur as a sort of repair mechanism, resulting in semantically impoverished speech. Conversely, the use of some types of closed-class particles, such as prepositions and auxiliaries, is bound to the syntactic structure.

Lexical iteration features were computed by separately considering word forms and lemmas of nouns, verbs, and adjectives. These features include the

Figure 2: Example of `.conll` annotation. Occurrences of automatically extracted cohesion devices are reframed: *lui* as a referential expression (note the specification `PronType:Prs` in FEAT column), the repetition of word forms and lemma of a verb (*parlava* - *parlare*) and the connectives *e* and *quando*.

repetitions of elements divided by the total number of words (COE_RIP_LEM, COE_RIP_WORD), the average number of repetitions for repeated elements (COE_MEDRIP_LEM, COE_MEDRIP_WORD), and the maximum number of repetitions over the total number of iterations (COE_MAXRIP_LEM, COE_MAXRIP_WORD).

3.3. Connectives

As defined by Ferrari [37], connectives are morphologically invariable forms (e.g., conjunctions or locutions) that explicitly indicate logical relations within parts of the text and pertain to the logical level. Elements from different grammatical classes can be used as connectives and are classified based on their function, which usually reflects their meaning (e.g., temporal, causal, additive).

To compile an extensive list of connectives, we rely on the Lexicon of Italian Connectives - *LICO*[1] [38, 39]. LICO contains 173 entries, including single words (e.g., *e, se, ma, infatti, quando, quindi*), complex expressions (e.g., *a causa di, da allora*), and correlatives (e.g., *da un lato ... dall'altro*). Connectives are reported along with their lexical or orthographic variants, part of speech category, the semantic relations conveyed according to the Penn Discourse Tree Bank 3.0 schema [40], examples of usage, and alignments of connectives from other languages. A feature was devoted to compute the occurrences of connectives relative to the total number of tokens per subject (COE_TC).

Finally, the last feature was designed as an attempt to capture the overall impact of the classes of cohesive devices studied in this paper in the two cohorts of corpus speakers. Therefore, the role of cohesion elements was comprehensively measured in COE_TOT by summing referential-substitute expressions, lexical iteration items and connectives, divided by the total number of words.

Figure 3.3 shows as example an excerpt from the annotation in `.conll` format, in which some of the linguistic elements considered were highlighted.

Table 3
Results of Kolmogorov-Smirnov test. The cohesive devices' features are reported along with their p-value, significant ones are marked in bold. The p-values of features that resulted significant in Kolmogorov-Smirnov test but not after Bonferroni's correction are given in italic.

Features	p-value
COE_TC	*0.33*
COE_REF	1
COE_REF_DENS	1
COE_RIP_LEM	**0.04**
COE_RIP_WORD	1
COE_MEDRIP_LEM	0.81
COE_MEDRIP_WORD	*0.33*
COE_MAXRIP_LEM	1
COE_MAXRIP_WORD	1
COE_TOT	**0.04**

Table 4
Frequencies of cohesive devices by subject. The average number of occurrences of substitution-type reference items, iterations of lemmas and of word forms (of nouns, adjectives and verbs) and connectives for each subject in PG and CG is reported, along with (st. dev).

Cohesive devices	PG	CG
Reference	146.5 (152.23)	161 (90.93)
Iter. lemma	68.9 (68.00)	87.05 (42.25)
Iter. word form	74.15 (74.38)	87.8 (49.25)
Connectives	23.8 (35.15)	36.65 (26.68)

4. Results

The statistical significance of the cohesion features for the binary discrimination of PG and CG cohorts was calculated using the non-parametric Kolmogorov-Smirnov test, due to the limited sample size of the corpus. Given the number of comparisons performed, we adjusted the results with Bonferroni correction to control for Type I error. This approach involves adjusting the significance

[1] http://connective-lex.info/

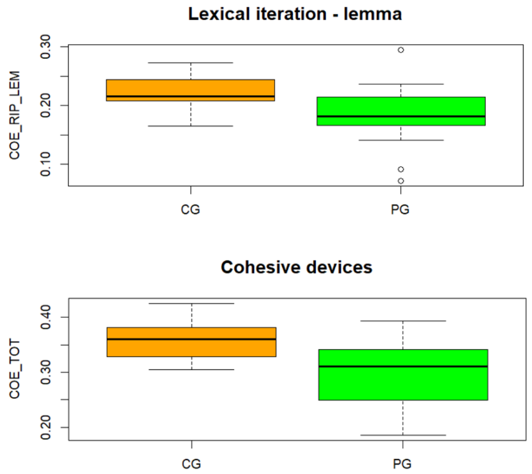

Figure 3: Distribution plots of significantly discriminative features. COE_RIP_LEM indicates the repetitions of lemmas of nouns, adjectives and verbs and COE_TOT is a comprehensive features of all the classes of cohesive devices considered.

level by dividing the conventional alpha value (0.05) by the total number of comparisons made. The results of the test, reported in Table 3, show that two of the designed features significantly contribute to differentiate the two groups: a feature related to lemmas' iteration (COE_RIP_LEM) and the comprehensive feature of cohesive devices (COE_TOT). The distribution of these features is reported in Figure 4.

The application of Bonferroni's correction caused a decrease in the p-value of two initially significant features, namely COE_TC and COE_MAXRIP_WORD. Given the exploratory nature of the experiment, which involves the formalisation of new features in order to discriminate subjects with cognitive impairment from healthy controls in Italian, we have nevertheless chosen to highlight the p-values of these features in 3.

We can observe that, compared with the control group, the speech of dementia subjects is characterized by fewer repetitions of the same noun, verb and adjective lemmas out of the total number of words uttered, captured by COE_RIP_LEM. Thus in the dataset emerges that PG group is less prone to lexical iteration of lemmas than CG. However, if we have a look to the occurrences' distributions of the cohesive elements considered, reported in Table 4, interesting trends could be noticed. Indeed, the quantitative analysis of lexical repetitions revealed a disparity between repeated lemmas and repeated word forms of the same grammatical categories (noun, adjectives and verb) between the two groups. Specifically, despite the high variability due to subjective differences, it is observed that in PG, the average repetition of forms (mean=74.15) is higher than the repetition of lemmas (mean=68.9), while the two values are very similar in CG (lemmas: mean=87.05, words: mean=87.8). This imbalance in favor of forms in the dementia patients appears to uncover lexical impoverishment compared to healthy subjects. Indeed in CG, although a higher overall number of repetitions is registered, it is combined with a more balanced distribution between lemmas and forms, suggest greater lexical variety.

An additional consideration regarding the opposing trend observed between lemmas and forms could be explained with respect to the sociolinguistic profile of the data, related to the diatopic variation of Italian language [41]. Indeed, speakers from both groups show an extensive use of dialectal terms and structures characteristic of the Italian variety spoken in the Lucanian Apennine area. As reported in Section 2, the annotation was conducted automatically using the pipeline developed by Gagliardi & Tamburini [32], which is designed to analyze standard Italian. Therefore, it is likely that the system struggled to handle some substandard expressions, which often orthographically diverge from the other words in the transcription, as can be observed in this example from a PG subject:

> ***gemm' a trua'*** *[=andammo a fare visita] a mia suocera,* ***ca*** *[=che] mio suocero è morto (. . .).*

It is not excluded that the presence of dialect may also have influenced the automatic extraction of other cohesive devices. Indeed, the higher frequency in CG of substitution-type reference items (mean=161) and connectives (mean=36.65) compared to PG (ref. mean=146.5, conn. mean=23.8) contrasts with what has been observed in oral production of narrative discourse in cohorts of dementia subjects and healthy controls [8]. Therefore, we consider the possibility that automatic feature extraction preceded on manually-checked annotation may yield different results than those obtained.

Nevertheless, the significance of the comprehensive feature (COE_TOT) indicates that the use of cohesive devices investigated in this paper plays a role in distinguishing dementia subjects from healthy controls. In Figure 4 it can be noted that COE_TOT shows, on average, lower values for the PG compared to the CG. This results suggests that the linguistic processing of some phenomena related to cohesion (i.e. substitution-type reference elements, lexical iteration items, and connectives) is generally affected by cognitive decline in semi-spontaneous speech. Thus, the analysis of discourse properties seems to be a promising path for studying the linguistic characterisation of neurodegenerative disorders. Therefore, we hope that our approach in the future could be applied to phenomena strictly related to cohesion - first of all, coherence - or extend to other domains, such as pragmatics, that may mask subtle clues of cognitive frailty.

5. Conclusion

In this work, we present a methodology for delineating linguistic features of cohesion to track and study changes in discourse properties in the speech of individuals with cognitive impairment compared to healthy peers. The research focused on three types of cohesive devices, i.e., reference, lexical iteration, and connectives, that were automatically extracted from a Italian corpus of semi-spontaneous speech from dementia subjects and controls, collected in Basilicata. Statistical significance for binary discrimination was computed applying the Kolmogorov-Smirnov test, and then adjusting the results with Bonferroni's method. The test shows that a feature of the repetitions of lemmas and the one related to the set of cohesive devices jointly considered contribute to distinguish the two groups. Moreover, the quantitative distribution of the cohesive devices reveals differences in the use of elements within the considered categories between PG and CG, which seem to highlight a general deterioration in discursive competencies associated with dementia. The results obtained provide a preliminary basis for further study of discourse properties in cognitive decline, with the aim of expanding the set of linguistic features that can be automatically extracted to other levels of language. This expansion is intended to refine digital systems that could be employed as support for the early diagnosis and monitoring of neurodegenerative diseases, potentially improving timely interventions for patients and their caregivers.

SimilEx: the First Italian Dataset for Sentence Similarity with Natural Language Explanations

Chiara Alzetta[1], Felice Dell'Orletta[1], Chiara Fazzone[1] and Giulia Venturi[1]

[1]ItaliaNLP Lab, CNR, Istituto di Linguistica Computazionale 'A.Zampolli', Pisa, Italy

Abstract

Large language models (LLMs) demonstrate great performance in natural language processing and understanding tasks. However, much work remains to enhance their interpretability. Annotated datasets with explanations could be key to addressing this issue, as they enable the development of models that provide human-like explanations for their decisions. In this paper, we introduce the SimilEx dataset, the first Italian dataset reporting human judgments of semantic similarity between pairs of sentences. For a subset of these pairs, the annotators also provided explanations in natural language for the scores assigned. The SimilEx dataset is valuable for exploring the variability in similarity perception between sentences and among human explanations of similarity judgments.

Keywords

Sentence similarity, Italian dataset, human judgements, explanations, annotation

1. Introduction and Motivation

Large language models (LLMs) display impressive linguistic skills and demonstrate outstanding performances on a variety of tasks concerning natural language processing and understanding. This is particularly true for the most recent and ground-breaking models such as GPT-3.5\4 [1], LLama-2 [2] and Gemini [3]. LLMs, however, also present risky limitations such as lack of factuality [4, 5], poor interpretability [6, 7] and hallucinations [8]. Consequently, it has become important to verify whether these models are explainable, and specifically whether they can provide human-like explanations using natural language for decisions made [9, 10]. The ability of LLMs to explain the reasoning needed to solve a given task is fundamental, particularly for tasks where there is no established or shared evaluation protocol or benchmark.

Annotated datasets with explanations are key to addressing this issue, as they enable the development of models that provide human-like explanations for their decisions. Therefore, multiple datasets have been created with free-form explanations to be incorporated into the model training process and used as benchmarks at test time, mostly focusing on English [10]. Some examples are the e-SNLI dataset [11], a version of the Stanford Natural Language Inference (SNLI) dataset [12] enriched with human-annotated explanations, and the Common Sense Explanations (CoS-E) [13] and Semi-Structured Explanations for COPA (COPA-SSE) [14] datasets, which include natural language explanations for commonsense reasoning. To the best of our knowledge, the only existing dataset enriched with explanations for Italian is 'e-RTE-3-it' [15], an Italian version of the RTE-3 dataset for textual entailment.

In this paper, we introduce the SimilEx dataset[1], as far as we are aware, the first Italian dataset of 2,112 pairs of sentences manually annotated for semantic similarity. About half of the pairs are further enriched with free-form human-written explanations that justify the similarity score.

The identification of textual similarity is a natural language understanding (NLU) task that involves determining the degree of semantic equivalence between two texts [16, 17]. It is a foundational NLU problem relevant to many applications such as summarisation, question answering and conversational systems [18]. Despite its relevance, this task is highly challenging even for humans due to its subjective nature: human annotations often widely disagree on similarity scores [19] suggesting that the cues driving sentence similarity are neither well codified nor transparent and that their perceived relevance may vary among annotators. Possibly due to these challenges, and as far as we know, datasets including human explanations for the sentence similarity task are lacking. However, they are invaluable as they force annotators to reason about their choices and identify the most relevant traits influencing their annotations.

Contributions. In this paper, we *i)* introduce SimilEx, the first Italian dataset featuring human annotations and explanations of sentence semantic similarity; *ii)* provide an extensive study of the degree of subjectivity in the perception of sentence semantic similarity; and *iii)* investigate the relationship between the stylistic variation of

the paired sentences and the human ratings and natural language explanations of sentence semantic similarity.

2. The SimilEx Dataset

2.1. Data Collection

The sentence pairs of SimilEx are acquired from a collection of novels from the late XIX century translated into Italian. We used Sentence-BERT (SBERT) [20] to combine pairs of sentences to present to annotators. SBERT is a modification of BERT [21] made adequate to produce sentence embeddings that can be easily compared to evaluate their similarity using cosine similarity, which ranges from 0 (no similarity) to 1 (identical sentences). We included in the SimilEx dataset only pairs obtaining a similarity score ≥ 0.65, for a total of 2,112 sentence pairs.

The textual genre of the sentences (i.e., novels) introduces specific stylistic properties that cause potential differences from standard Italian. We assessed the linguistic style of SimilEx sentences using Profiling-UD [22][2], a web-based tool that captures multiple aspects of sentence structure. The tool extracts around 130 properties representative of the underlying linguistic structure of a sentence, derived from raw, morphosyntactic, and syntactic levels of sentence annotation, all based on the Universal Dependencies (UD) formalism [23]. These properties have been shown to be highly predictive when used as features by learning models in various classification tasks, such a Automatic Readability and Linguistic Complexity Assessment or Native Language Identification. Among these caracteristics, the average length computed on Similex sentences is 30.18 tokens (±22.36), above the average length of standard Italian sentences, typically around 20 tokens. Interestingly, within pairs, the average length difference is 17.02 tokens (±19.55). This value, combined with such a high standard deviation, suggests a large variability of style within the pairs. This notable variability extends, e.g., to the distribution of subordinate clauses and lexical overlap. Within pairs, the average difference in the number of subordinate clauses is 2.25 (±1.81), and the overlap of content words is 12.60%, which are significant given that this variation occurs within individual sentence pairs. Having pairs with such stylistic differences provides an opportunity to investigate the impact of stylistic variation on the perception of similarity.

2.2. Human Similarity Annotation

Sentence pairs of SimilEx were annotated through the online crowdsourcing platform Prolific[3]. Annotators were recruited among native Italian speakers and presented with a questionnaire of 30 pairs plus 2 control pairs.

Annotation Guidelines. The task consisted of scoring each sentence pair of the questionnaire for the perceived sentence similarity using a 5-point Likert scale, where 1 is described as *"Completamente diverse"* (Completely different) and 5 as *"Pressoché identiche"* (Almost identical). Any formal definition of similarity is provided, only a few examples of highly similar and highly different pairs along with motivations for the extreme similarity scores, as shown in the annotation instructions provided to the annotators fully reported in Appendix C. This represents the main novelty of our approach compared to the methodology used to create datasets for Semantic Textual Similarity tasks, typically organized within the SemEval evaluation campaign (see among the others [24, 18]). These datasets are usually built with clear and specific instructions for annotators, who are explicitly asked to evaluate whether paired text portions refer to the same person, action, or event, or to focus their judgment on similarity types such as the same author, time period, or location. Some examples of annotation with similarity scores averaged across annotators are shown in Table 1.

Demographics. Participants could share information about their age, gender and occupation and complete multiple questionnaires. Eventually, 317 distinct participants took part in the study. After a preliminary analysis, we excluded 34 annotators deemed unreliable because they either took too short to complete the questionnaire, assigned systematically divergent scores compared to the rest of the participants, failed the control questions or submitted blank answers. The resulting dataset includes 2,112 sentence pairs annotated by the remaining 283 annotators, who took 18 minutes on average to complete a questionnaire[4]. Each pair received a minimum of 5 and a maximum of 7 annotations from different participants. The set of annotators is quite balanced for gender (51% males) and the average age of annotators is 27.05 (±6.56). Regarding occupation, 50% of participants indicated that they have a full- or part-time job, around 25% declared themselves unemployed, and the remaining 25% preferred not to disclose their occupational status.

2.3. Human Explanations of Similarity

We recruited 2 native Italian speakers who volunteered to enrich the pairs of sentences with free-form explanations. These annotators are graduate students, one male and one female, aged 23 years. They were asked to score the similarity of a random subset of 907 sentence pairs on the same 5-point Likert scale as the other participants. Additionally, they should provide a short explanation for

[2] The complete set of linguistic characteristics used for the stylistic analysis can be found in Appendix B.

Table 1
Pairs of sentences annotated with similarity scores averaged across annotators.

their scores, in the form of a single concise sentence.

3. Human Similarity Perception

The first analysis of SimilEx focuses on the exploration of the similarity judgments expressed by annotators using the scores. Note that for this analysis all scores were considered, including those of the two students who provided the explanations. Firstly, we computed the Pearson correlation between the average similarity scores of sentence pairs and SBERT scores, obtaining $r = 0.28$ ($p < 0.001$). This low correlation indicates that SBERT and human similarity perception might rely on different aspects of sentence similarity.

Preferred Scores. The average similarity score computed for the SimilEx dataset is 2.40 (± 0.98), which suggests that the paired sentences are often perceived as different by their annotators. As proof, consider Figure 1, which illustrates the percentage distribution of mean scores of SimilEx pairs, computed by averaging the scores assigned by individual participants. Most pairs (76.86%) received scores <3, the midpoint of the scale, while only 7.05% of sentence pairs obtained a mean score $\geq$4. Consistent with these findings, scores 4 and 5, indicating similarity, account for only 23.46% of the individual scores assigned during the campaign by participants. In contrast, scores 1 and 2, indicating dissimilarity, are much more prevalent (57.59%). The neutral score of 3 is also relatively common (16.76%), suggesting that in many cases subjects could not decisively determine the similarity of the paired sentences.

Inter-annotator Agreement. To explore the consistency of these perceptions, we examine the inter-annotator agreement (IAA) on the similarity scores using Krippendorff's α coefficient, a metric suitable when the items have a different number of annotations.

The global IAA, computed considering all pairs and annotators, is 0.352. A *fair* [25] agreement is not surprising due to the inherent subjectivity of the task, yet it still indicates a tendency for annotators to converge on many items. To explore this further, we grouped sentence pairs based on the number of annotators who assigned them the same score. The resulting groups have quite different sizes: more than half of the pairs (around 56%) have 3 or fewer annotators in agreement, while 5 or more annotators (up to 9) gave identical values in 20.08% of pairs. Figure 2 displays the distribution of similarity scores within these groups. Notably, when few annotators agree on a pair, the scores are evenly distributed across the five labels, indicating that disagreement can occur for pairs seen as both similar and different. In contrast, when more annotators agree, the most commonly assigned score is 1, indicating that annotators converge more frequently on dissimilarity judgments. This is supported by the negative Pearson correlation between the number of agreeing annotators and the average similarity score of the pair ($r = -0.344$, $p < 0.001$).

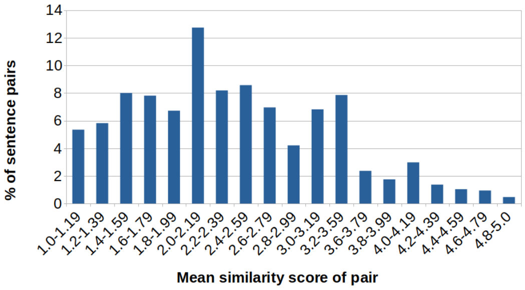

Figure 1: Percentage distribution of mean similarity scores of SimiEx pairs.

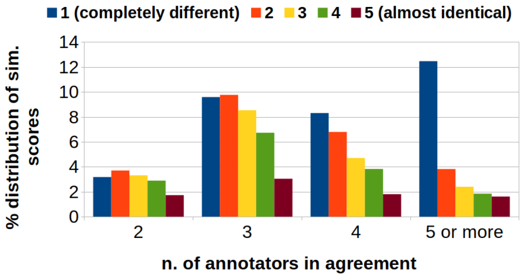

Figure 2: Percentage distribution of similarity scores with respect to the number of annotators in agreement on the pair.

Agreement, Style and Similarity. We explored the relationship between style and similarity judgments by comparing scores and stylistic traits of sentences. As a general remark, we found that style minimally affects pairs' similarity: the Pearson correlation between the similarity scores and the distribution of stylistic properties is either non-significant ($p > 0.05$) or extremely low ($r < 0.1$). However, a more in-depth analysis of specific stylistic properties revealed a nuanced relationship between style and the consistency of human judgments. For example, contrary to our expectations, sentence length, a raw yet informative feature reflecting stylistic variation, did not impact the similarity scores assigned by annotators. In fact, when we computed the correlation between the length difference of paired sentences and the variance between similarity judgments, we observed a lack of correlation (0.05). To further investigate, we grouped pairs based on the difference between the length of their sentences, and specifically, based on whether their length difference was above or below the average value of 17 tokens. We noticed that also from this perspective of analysis sentence length did not affect the IAA of the scores either, as $\alpha = 0.265$ for both groups. However, when focusing on different stylistic traits more closely related to sentence structure, we observed a substantial relationship with higher annotator agreement. For instance, the IAA is moderate (0.49) for pairs where neither sentence contains a subordinate clause, but drops to fair (0.25) when both sentences contain at least one subordinate. Similarly, the IAA is higher (0.37) when the syntactic tree depth difference between paired sentences is below the average value of 1.98, compared to 0.29 when the difference is greater. These results are extremely interesting as they indicate that while stylistic traits may not directly influence the semantic similarity between sentences, some of them play a role in the convergence of human judgments.

4. Human Similarity Explanation

In this section, we focus on the analysis of the subset of 907 sentence pairs of SimilEx annotated by the two students with both human similarity judgments and natural language explanations for the assigned scores.

Comparison with Prolific annotators. The comparison between the similarity judgments of the graduate students and Prolific annotators reveals a strong alignment between the two groups. The Pearson correlation between the average similarity score of the Prolific annotators and the average score between the two graduate students is significantly high and positive ($r = 0.779$, $p < 0.001$). This high correlation is also observed when computed separately for each of the two students, indicating that their perceptions of similarity closely match the judgements obtained from the crowdsourcing campaign. Additionally, the IAA between the two students suggests alignment between the students since $\alpha = 0.49$, higher than that reported among the Prolific annotators.

Linguistic Style of Explanations. We explored the style of explanation relying on the linguistic profiling method described in Section 2.1. We noted that the explanations written by the two students exhibit partial similarity as can be seen by inspecting the results of the stylistic analysis distributed as supplementary materials (see Appendix A). For example, they both tend to write quite short sentences, i.e. on average 6.35 (±3.93) and 7.67 (±5.12) token-long, and characterized by a nominal style. This is evidenced by the low percentage distribution of verbal roots (i.e. sentences with a verb as the syntactic root), computed over the total number of roots represented by other morpho-syntactic categories (i.e. 58.21% (±49.35) and 61.43% (±48.70)). This percentage is notably low when compared to the distribution in the ISDT [26], the largest Italian Treebank, where the distribution is 85.73%.

Content of Explanations. The content analysis of the explanations reveals that both students share some arguments when justifying the similarity scores for SimilEx sentence pairs. Specifically, the average cosine similarity between their explanations, computed using SBERT, is 0.46, indicating a moderate level of similarity.

Given that a qualitative analysis reveals several recurring arguments and templates in the explanations, such as *Entrambe descrivono* ('Both describe'), *In entrambe le frasi si parla di un argomento militare* ('In both sentences a military topic is mentioned'), we further explored the possibility of identifying homogenous content among them. To this end, we clustered the 907 explanations of each student (1,814 in total) based on their SBERT vectors. We initially configured the clustering algorithm to partition the data into 10 clusters[5]. However, only 4 of these clusters were found to be semantically homogeneous. Specifically, these homogeneous clusters contain explanations where either Student 1 or 2: *i)* writes that the evaluated sentences contain positive or negative emotions such as love or anger, *ii)* uses the phrase *Pressochè identiche* ('Almost identical'), *iii)* uses the phrase *Completamente diverse* ('Completely different'), and *iv)* notes that the evaluated sentences refer to a military topic. Since the explanations in the remaining 6 clusters were not semantically homogeneous, we reconfigured the clustering algorithm to partition the data into 5 clusters. This time, we included only the explanations that had not been previously clustered, representing 72.76% of all SimilEx explanations. However, we were still unable to isolate explanations with similar content. This suggests that the two students often focused on different aspects when evaluating sentence similarity. As proof, consider the examples reported in Table 2, where stu-

[5] We employed agglomerative clustering using Euclidean distance and Ward variance minimization as the clustering method.

(1)	**Sentence 1**	*"Vedeva lo scintillio degli occhi, tremulo e avvampante, e il riso di felicità e di eccitamento che senza volere le increspava le labbra; vedeva la grazia misurata, la sicurezza e la levità dei movimenti."*
	Sentence 2	*"Era così bella, che non solo non appariva in lei ombra di civetteria, ma pareva al contrario che le rimordesse il forte ed immancabile effetto di una grazia trionfatrice, che avrebbe voluto temperare, se le fosse stato possibile."*
	Explanations	**S1:** Completamente diverse. (1)
	(Sim. scores)	**S2:** Parlano di donne che sono molto graziose. (4)
(2)	**Sentence 1**	*"Ma che volete farci: questa è la vocazione dell'autore, ormai malato della propria imperfezione, e il suo talento è fatto apposta per rappresentare la povertà della nostra vita, scovando la gente in buchi sperduti, in angoletti remoti dell'impero!"*
	Sentence 2	*"Perché mettere in mostra la povertà della nostra vita e la nostra triste imperfezione, andando a scovare gli uomini in buchi sperduti, in angoletti remoti dell'impero?"*
	Explanations	**S1:** Completamente diverse anche se esprimono lo stesso concetto. (1)
	(Sim. scores)	**S2:** Stessa frase impostata diversamente a livello sintattico. (4)
(3)	**Sentence 1**	*"L'agente di polizia che l'accompagnava, discese e scosse il braccio intormentito; poi si tolse il berretto e si fece il segno della croce."*
	Sentence 2	*"Nell'osteria entrò un agente di polizia."*
	Explanations	**S1:** In entrambe le frasi si parla di un agente della polizia. (2)
	(Sim. scores)	**S2:** Il soggetto è un agente di polizia. (2)
(4)	**Sentence 1**	*"Napoleone si volse ad Alessandro, come per dire che quanto ora faceva era fatto per l'augusto e caro alleato."*
	Sentence 2	*"Tutti gli alleati di Napoleone gli divennero nemici."*
	Explanations	**S1:** In entrambe le frasi si parla di Napoleone e dei suoi alleati. (2)
	(Sim. scores)	**S2:** Parlano degli alleati di Napoleone. (3)
(5)	**Sentence 1**	*"Ma l'amore con un marito inquinato dalla gelosia e da ogni sorta di difetti non era più per lei."*
	Sentence 2	*"Era forse, semplicemente, un sentimento di gelosia: egli era talmente avvezzo all'amore di lei, che non poteva ammettere che ella potesse amarne un altro."*
	Explanations	**S1:** Nel primo caso il focus della frase è la moglie, nella seconda lo è il marito. (2)
	(Sim. scores)	**S2:** Parlano di uomini gelosi. (2)
(6)	**Sentence 1**	*"Tonfi, spruzzi, strida, ingiurie, lazzi, risate, un allegro pandemonio."*
	Sentence 2	*"E fino a quel momento, chiasso, baccano, sghignazzi, ingiurie, rumore di catene, acido carbonico e fuliggine, teste rase, facce marchiate, vestiti a brandelli, tutto fatto oggetto di ludibrio e di infamia... sì, grande è la vitalità dell'uomo!"*
	Explanations	**S1:** Entrambe le frasi descrivono vitalità. (4)
	(Sim. scores)	**S2:** Descrivono degli scenari di caos, disordine; sintassi frasi simile. (3)

Table 2
Sentence pairs with similarity scores and explanations (translations in App. D). Examples 1-2 illustrate divergent explanations and scores; 3-6 show identical or aligned scores, with explanations mentioning similar (3-4) or different (5-6) aspects.

dents focused on diverse aspects of the paired sentences while they assigned either similar (see #5 and #6) or different (see #1 and #2) similarity scores. While this may result in underspecification and inconsistency in the collected explanations, it confirms the inherent subjectivity and expressivity involved in providing free-text natural language explanations for a highly subjective task such as evaluating semantic sentence similarity [10].

The content analyses above were enriched with an in-depth investigation into whether there is a correlation between the SBERT cosine similarity of the explanations of each student and their similarity judgments. The Pearson correlation between SBERT scores and the absolute difference in the students' similarity judgments reveals a moderate negative relationship ($r = -0.459$, $p < 0.001$). This indicates that the more semantically similar the explanations are, the smaller the difference in the students' similarity judgments. Notably, students' explanations tend to be more similar when the similarity scores assigned by both of them are lower (i.e. 1 or 2), as in example #3 of Table 2.

5. Conclusion and Future Work

This paper presented SimilEx, the first Italian dataset on sentence similarity enriched with human judgments and free-form explanations. The analyses of the collected judgments confirmed that the perception of sentence similarity is inherently subjective, as evidenced by the fair agreement between the scores. Notably, annotators tend to agree less on similar sentence pairs, showing greater convergence when sentences are markedly different. The style of the paired sentences appears to influence this convergence: while most linguistic traits may not directly impact the similarity score, some of them affect the homogeneity of judgments assigned by different annotators. These features mostly concern properties of sentence structure rather than raw sentence features such as lenght, which does not play a role in homogeneity. Regarding explanations, we found a correlation between the similarity of the content of the explanations and the similarity scores assigned, indicating that annotators tend to write more similar explanations, using a similar writing style, when their scores align.

The findings from this study open several prospects. Expanding SimilEx to include sentences from different textual genera could provide further insights into the factors affecting similarity judgments. Additionally, incorporating more annotators with varying linguistic backgrounds could foster a better understanding of the subjectivity in similarity perception. Lastly, our dataset could help develop automated tools to evaluate the explainability of LLMs. By leveraging SimilEx, researchers can create models that predict similarity scores and generate explanations, enhancing the interpretability of LLMs.

Appendix

A. Supplementary materials

The complete SimilEx dataset is freely available at http://www.italianlp.it/resources/ along with the results of the stylistic analysis of both paired sentences and the natural language explanations provided by the two students.

Specifically, on the dedicated page, you can find the following materials:

SimilEx dataset. The dataset is organized in columns, each reporting the following information:

- Pair_ID: the unique identifier of the paired sentences;
- Sentence_1 and Sentence_2: the text of each of the two paired sentences;
- A1-A7: the similarity judgments of the Prolific annotators;
- Stud_1: the similarity judgment assigned by the first student;
- Explanation_Stud1: the natural language explanation provided by Stud_1;
- Stud_2: the similarity judgment assigned by the second student;
- Explanation_Stud2: the natural language explanation provided by Stud_2.

Linguistic profiling of the paired sentences. The results of the stylistic analysis of each of the paired sentences included in SimilEx are contained in the "Sentence_profiling" sheet, reporting for each column the following information:

- Pair_ID: the unique identifier of the paired sentences in the SimilEx dataset;
- Sent_in_pair: the unique identifier of each individual sentence in the pair;
- all other columns report the value of the distribution of the complete set of linguistic characteristics derived with Profiling-UD by each individual sentence.

Linguistic profiling of the explanations. The results of the stylistic analysis of each explanation provided by the two students are contained in the "Explanations_profiling" sheet, reporting for each column the following information:

- PairID_of_explanied_pair: the unique identifier of each individual sentence in the pairs of the SimilEx dataset;

- Explanation_of_student: the identifier of the student;
- all other columns report the value of the distribution of the complete set of linguistic characteristics derived with Profiling-UD by each individual explanation.

B. Linguistic Features

The set of linguistic features derived by Profiling–UD are extracted from different levels of linguistic annotation and capture a wide number of linguistic phenomena and can be grouped as follows:

- **Raw text**
  - Number of tokens in sentence;
  - Average characters per token.
- **Morphosyntactic information**
  - Distibution of UD POS;
  - Lexical density.
- **Inflectional morphology**
  - Distribution of lexical verbs and auxiliaries for inflectional categories (tense, mood, person, number).
- **Verbal Predicate Structure**
  - Distribution of verbal heads and verbal roots;
  - Average verb arity and distribution of verbs by arity.
- **Global and Local Parsed Tree Structures**
  - Average depth of the whole syntactic trees;
  - Average length of dependency links and of the longest link;
  - Average length of prepositional chains and distribution by depth;
  Average clause length.
- **Relative order of elements**
  - Distribution of subjects and objects in post- and pre-verbal position.
- **Syntactic Relations**
  Distribution of dependency relations.
- **Use of Subordination**
  - Distribution of subordinate and principal clauses;
  - Average length of subordination chains and distribution by depth;
  - Distribution of subordinates in post- and pre-principal clause position.

C. Annotation Instructions

C.1. Original Instructions in Italian

Stai per svolgere un questionario nel quale ti verrà chiesto di valutare se due frasi sono fra di loro simili o diverse. Per farlo, ti mostreremo delle coppie di frasi estratte da romanzi e ti chiederemo di assegnare ad ogni coppia un punteggio compreso fra 1 e 5.
Usa 1 per dire che le due frasi sono fra loro completamente diverse; Usa 5 per dire che sono pressoché uguali. Gli altri punteggi ti serviranno per valutare i casi intermedi.

Due frasi possono dirsi uguali o diverse sulla base di diversi elementi. Ecco alcuni esempi per aiutarti nella valutazione.

Coppie di frasi diverse (punteggio 1).

Esempio 1:
a) Io desidererei tanto non sentire così intensamente e non prendermi tanto a cuore tutto quello che succede.
b) Sì, non sono in me, sono tutta nell'aspettativa e vedo tutto un po' troppo facile.

Esempio 2:
a) Anche il vecchio principe t'è affezionato.
b) - Non mi sembra di averveli chiesti, - scattò il principe irritatissimo.

Esempio 3:
a) Il the veramente era del color della birra, ma io ne bevvi un bicchiere.
b) Ma non passò neanche un minuto, che la birra gli diede alla testa e per la schiena gli corse un leggero e perfin piacevole brivido.

Fai particolare attenzione agli esempi 2 e 3: anche se le frasi hanno delle parole in comune (come 'principe' e 'birra' negli esempi) non è detto che siano uguali!

Coppie di frasi molto simili (punteggio 5).

Esempio 1:
a) Signori della giuria, la psicologia è a doppio taglio e anche noi siamo in grado di comprenderla.
b) Vedete allora, signori della giuria, dal momento che la psicologia è un'arma a doppio taglio, permettetemi di occuparmi del secondo taglio e vediamo che cosa viene fuori.

Esempio 2:
a) "Un rettile divorerà l'altro", aveva detto il giorno prima Ivan, parlando con rabbia del padre e del fratello.
b) "Un rettile divorerà l'altro, quella è la fine che faranno!".

Esempio 3:
a) Ma una volta deciso, continuò con la sua voce stridula, senza timori, senza esitazioni e sottolineando alcune parole.
b) Parlava rapido, senza fermarsi un momento, senza la minima esitazione, quasi rimproverasse a sè stesso di aver tanto indugiato a mettere Marianna a parte di tutti i suoi segreti, quasi scusandosi presso di lei.

Gli esempi 1 e 2 riportano frasi che non solo contengono molte parole in comune ma sono simili anche per quanto riguarda la scena descritta. Nel terzo esempio, entrambe le frasi descrivono una persona intenta a parlare in modo svelto e deciso. Possiamo dire che in questi esempi l'alta similarità fra le frasi è data dal fatto che, ad eccezione di alcuni dettagli, esse descrivono scene o immagini molto simili, anche se si svolgono in contesti diverse.

C.2. Instructions Translations into English

You are about to take a questionnaire in which you will be asked to assess whether two sentences are similar or different to each other. To do this, we will show you pairs of sentences extracted from novels and ask you to give each pair a score between 1 and 5.
Use 1 to say that the two sentences are completely different from each other; Use 5 to say that they are almost the same. The other scores will be used to evaluate the intermediate cases.

Two sentences can be equal or different based on several elements. Here are some examples to help you in your evaluation.

Pairs of different sentences (score 1)

Examples: Please refer to the above section to see the original examples in Italian.

Pay particular attention to examples 2 and 3: although the sentences have words in common (like 'prince' and 'beer' in the examples) they are not necessarily the same!

Pairs of very similar sentences (score 5)

Examples: Please refer to the above section to see the original examples in Italian.

Examples 1 and 2 show sentences that not only contain many words in common but are also similar in terms of the scene described. In the third example, both sentences describe a person speaking quickly and decisively. We can say that the high similarity between the sentences in these examples is due to the fact that, except for a few details, they describe very similar scenes or images, even though they take place in different contexts.

D. Translations of Explanations

English translations of the similarity explanations originally written in Italian by the two students and reported in Table 1.

- **Example (1)**
  S1: Completely different.
  S2: They talk about women who are very pretty.
- **Example (2)**
  S1: Completely different although they express the same concept.
  S2: Same sentences with different syntactic structures.
- **Example (3)**
  S1: In both sentences, a police officer is mentioned.
  S2: The subject is a police officer.
- **Example (4)**
  S1: In both sentences, Napoleon and his allies are mentioned.
  S2: They speak of Napoleon's allies.
- **Example (5)**
  S1: In the first case the focus of the sentence is the wife, in the second it is the husband.
  S2: They talk about jealous men.
- **Example (6)**
  S1: Both sentences describe vitality.
  S2: They describe scenarios of chaos, disorder; similar sentence syntax.

Data Augmentation for Low-Resource Italian NLP: Enhancing Semantic Processing with DRS

Muhammad Saad Amin*, Luca Anselma and Alessandro Mazzei

Department of Computer Science, University of Turin, Italy

Abstract

Discourse Representation Structure (DRS), a formal meaning representation, has shown promising results in semantic parsing and natural language generation tasks for high-resource languages like English. This paper investigates enhancing the application of DRS to low-resource Italian Natural Language Processing (NLP), in both semantic parsing (Text-to-DRS) and natural language generation (DRS-to-Text). To address the scarcity of annotated corpora for Italian DRS, we propose a novel data augmentation technique that involves the use of external linguistic resources including: (i) WordNet for common nouns, adjectives, adverbs, and verbs; (ii) LLM-generated named entities for proper nouns; and (iii) rule-based algorithms for tense augmentation. This approach not only increases the quantity of training data but also introduces linguistic diversity, which is crucial for improving model performance and robustness. Using this augmented dataset, we developed neural semantic parser and generator models that demonstrated enhanced generalization ability compared to models trained on non-augmented data. We evaluated the effect of semantic data augmentation using two state-of-the-art transformer-based neural sequence-to-sequence models, i.e., byT5 and IT5. Our implementation shows promising results for Italian semantic processing. Data augmentation significantly increased the performance of semantic parsing from 76.10 to 90.56 (+14.46%) F1-SMATCH score and generation with 37.79 to 57.48 (+19.69%) BLEU, 30.83 to 40.95 (+10.12%) METEOR, 81.66 to 90.97 (+9.31%) COMET, 54.84 to 70.88 (+16.04%) chrF, and 88.86 to 92.97 (+4.11%) BERT scores. These results demonstrate the effectiveness of our novel augmentation approach in enhancing semantic processing capabilities for low-resource languages like Italian.

Keywords

Data augmentation, Italian semantic processing, low-resource NLP, semantic parsing and generation

1. Introduction

The field of Natural Language Processing (NLP) has seen significant advancements in recent years, particularly in semantic processing tasks. These tasks, which include semantic parsing and natural language generation, often rely heavily on parallel corpora — datasets that align text in one language with its semantic representation or with text in another language [1, 2]. For languages with rich linguistic resources, such as English, the availability of large-scale parallel corpora has facilitated rapid progress in semantic processing [3, 4]. However, for many languages, including Italian, the scarcity of such resources poses a significant challenge to advancing semantic NLP capabilities [5, 6]. Italian presents unique challenges and opportunities. While Italian shares some structural similarities with English, it possesses distinct linguistic features that complicate NLP tasks. These include a more flexible word order, a rich system of verb conjugations, and the presence of grammatical gender for nouns, adjectives, and articles.

In the context of NLP and Natural Language Generation (NLG), Italian has seen moderate progress. However, compared to high-resource languages like English, Italian still lacks extensive task-specific datasets, particularly in areas requiring deep semantic understanding. This deficiency is especially pronounced in tasks involving formal semantic representations such as Discourse Representation Structures (DRS) [7].

While Italian is not typically classified as a low-resource language in general NLP terms, it can be considered as such in the specific domain of semantic processing, especially when dealing with formal semantic representations. This status is characterized by: (i) Named Entities: Italian naming conventions differ from those in English, requiring adaptation in entity recognition tasks; (ii) Syntactic Structure: Although Italian follows the SVO structure like English, it allows for greater flexibility, posing challenges, especially in parsing tasks; (iii) Grammatical Gender: The presence of grammatical gender in Italian adds complexity to tasks such as coreference resolution and agreement in the generated text. These linguistic features, combined with the limited availability of semantically annotated corpora, position Italian as a challenging language for advanced semantic NLP tasks.

Data augmentation (DA), a technique widely used in machine learning to increase the size and diversity of training datasets, has shown promise in addressing re-

source scarcity in NLP [8]. For semantic tasks involving DRS, DA presents unique challenges due to the need to preserve semantic equivalence while introducing linguistic variety.

In the context of Italian semantic processing, traditional augmentation techniques such as random word insertion, deletion, substitutions or back-translation have limited applicability due to the scarcity of Italian-specific semantic resources [9]. This necessitates innovative approaches that can leverage resources from high-resource languages while maintaining the integrity of Italian linguistic structures.

Given the challenges outlined, this study aims to develop a novel cross-lingual DA technique for Italian, specifically tailored for DRS-based semantic parsing and generation tasks. While word substitution techniques are established in DA literature, our approach introduces an innovative cross-lingual framework that leverages the language-neutral nature of DRS. The method uniquely bridges the resource gap between high-resource and low-resource languages by temporarily transforming Italian examples into English, enabling access to rich lexical resources like WordNet, before converting back to Italian. This cross-lingual approach leverages the universal semantic representations of the DRS to enable more advanced data transformation approaches than Italian resources alone would allow, which is particularly advantageous given the limited availability of Italian-specific semantic datasets (see Table 1 for Italian examples).

This paper makes the following key contributions:

1. A novel cross-lingual augmentation methodology that leverages English WordNet to enhance Italian semantic datasets.
2. Empirical evidence demonstrating the effectiveness of this augmentation technique in improving performance scores for both DRS parsing and generation tasks in Italian.
3. A detailed analysis of how cross-lingual augmentation affects the handling of Italian-specific linguistic features in semantic processing.
4. Insights into the scalability and potential applications of this approach to other low-resource languages in the domain of semantic NLP.

The remaining paper is organized as follows: Section 2 provides an overview of DRS. Section 3 details semantic DA for Italian with a focus on named entities, lexical, and grammatical data transformation techniques. Section 4 presents our experimental implementation, implications of our results and findings, and their broader impact on the field. Finally, Section 5 concludes the paper, addresses certain limitations, and outlines directions for future research.

2. Background

In this Section, we provide an overview of the formal definition of DRS.

DRS is a formal semantic representation, that captures the essential meaning of text, equivalent to first-order logic. DRS is capable of representing a broad spectrum of linguistic phenomena, including anaphora, presuppositions, and temporal expressions [7]. What sets DRS apart from other meaning representations, such as Abstract Meaning Representation (AMR) [2], is its proficiency in handling negation and quantification, as well as its language-independent nature. Furthermore, DRS can effectively represent meaning across multiple sentences in a discourse.

Initially, DRS utilized box notation to provide scope to meaning representation (see Figure 1(a)). This notation incorporates (e.g. *x1*) and conditions (e.g. *person*, *Time*), with concepts anchored using WordNet synsets and thematic roles derived from VerbNet. Operators (e.g. =) are employed to establish comparative relationships between entities. Conditions can also embody complex structures to express logical (e.g. NEGATION, ¬) or rhetorical relationships among various condition sets. To address the challenges posed by the complexity of box notation in neural parser development, Clause Notation was introduced. This method streamlines DRS by reorganizing the structure and placing variables before discourse referents and conditions (see Figure 1(b)).

Further simplification led to the development of Sequence Box Notation (SBN), a variable-free format designed to be more compatible with neural sequence-to-sequence transformer architectures [7]. SBN utilizes indices to form connections between concepts, with thematic roles indicating the nature of these connections (see Figure 1(c)). This notation can also be interpreted in graph form (see Figure 1(d)). These evolving notations reflect the ongoing efforts to make DRS more accessible and efficient for computational processing while maintaining its rich semantic representation capabilities.

3. Semantic DA for Italian

The data-intensive nature of neural networks presents a significant challenge for low-resource languages like Italian, where available data is limited. This challenge is further compounded when dealing with logical semantic representations such as DRS-Text pairs, which follow specific patterns. In DRS, concepts are represented as a combination of lemma, part of speech, and WordNet sense numbers. The part of speech component includes adjectives, adverbs, common nouns, and verbs with lexical entities, followed by other logical representations (e.g., "idea.n.01").

Our augmentation methodology addresses the scarcity of Italian lexical resources by utilizing a cross-lingual approach that takes advantage of the language-neutral structure of DRS. The process (i) begins with translating the Italian text into English while keeping the original DRS unchanged; (ii) allowing us to apply a variety of augmentation techniques including named-entity, lexical, and grammatical augmentations—made possible through access to English WordNet—on English-aligned examples; (iii) after augmentation, the English examples are translated back into Italian, ensuring that the semantic relationships from the DRS are preserved. This strategy not only generates semantically rich and contextually relevant data but also overcomes the limitations of Italian-specific resources by augmenting English-aligned examples and transforming them into Italian-aligned examples (see Figure 2 and Table 4 in Appendix), maintaining semantic accuracy through DRS's formal representations.

3.1. Named Entities Augmentation

Our initial augmentation approach focused on proper noun (PN) augmentation, also referred to as Named Entities (NE) Augmentation. This method targets the transformation of specific named entities, particularly person names (PER, both male and female) and geographical entities (GPE) such as city, state, country, and island names. These entities are explicitly represented in the DRS through predicates (e.g., "male.n.02" for person names). We employed a rule-based approach to extract NEs from both the DRS and the text. Our NE augmentation strategy involves replacing existing entities with those outside the context of the dataset. This approach aims to evaluate the role of external lexical information in semantic processing.

To maintain semantic integrity, we ensure that NEs are replaced with entities of the same type. For sourcing external lexical information, we utilized AI-generated lists of person names based on global frequency and GPE entities with similar geographical distribution, carefully filtering out names already present in the dataset. This meticulous substitution process preserves the true semantics of the sentences. For instance, in the sentence "Rome is the capital of Italy", we might replace "Rome" with "Berlin" and "Italy" with "Germany", maintaining the logical structure while introducing lexical variety.

3.2. Lexical Entities Augmentation

Our lexical augmentation strategy focuses on four specific categories: common nouns, adjectives, adverbs, and verbs. We utilize WordNet synsets to group these entities, ensuring that transformations maintain the contextual sense and meaning of the sentences.

Common Noun Augmentation: CN can significantly alter sentence meaning, making their augmentation challenging. We employ a rule-based approach to extract common nouns from the Sequence Box Notation (SBN) and use NLTK's "WordNetLemmatizer" for the corresponding text. The augmentation process involves replacing nouns with their hyponyms from WordNet, which allows for more specific substitutions while preserving contextual meaning.

Verb Augmentation: Verbs play a crucial role in sentence context, making their augmentation complex. We use WordNet-based troponyms to replace verbs with more specific, contextually similar alternatives. This approach helps maintain semantic coherence while introducing lexical variety.

Adjective Augmentation: Adjectives, as descriptive attributes of nouns, are augmented using WordNet-based antonyms. This method generates new, contextually similar examples. We manually inspect the augmented data to ensure the semantic relevance and correctness of adjective substitutions.

Adverb Augmentation: For adverbs, we employ a WordNet-based synonym replacement approach. This method aims to generate similar data examples while preserving contextual relevance. As with other categories, we manually verify the semantic correctness of the newly generated examples. Throughout the augmentation process for all lexical categories, we maintain consistency between the SBN logical representations and the corresponding text. This ensures that the augmented data remains coherent and semantically valid across both the formal representation and natural language formats.

3.3. Grammatical Augmentation

This approach primarily focuses on transforming morpho-syntactic relations within sentences, with a particular emphasis on tense modifications. This method involves non-lexical substitutions that alter the temporal context of events without introducing external vocabulary. Our strategy encompasses a wide range of grammatical transformations, including shifts between present, past, and future tenses, as well as changes in voice (active to passive and vice versa), mood (e.g., imperative), negation, number (singular to plural), subject-object relationships, aspect (progressive and perfect), and other grammatical features such as infinitive forms, first-person perspective, and perfect participles.

To implement these transformations, we employ a dual approach: for the Sequence Box Notation (SBN), we use a rule-based system to replace logical entities (e.g., changing "EQU" to "TPR" or "TSU" for tense shifts), while for the corresponding natural language text, we utilize the *tenseflow API*[1]. This comprehensive grammatical augmentation technique allows us to significantly expand our dataset with grammatically diverse versions of existing sentences, maintaining core semantic content while introducing new syntactic variety. Such diversity is essential for training robust NLP models, particularly for tasks involving temporal reasoning and varied syntactic structures.

While our augmentation strategies effectively expand the dataset nine times, we acknowledge specific challenges in preserving semantic integrity during transformations. For named entities, semantic preservation is straightforward as we maintain entity types. However, tense transformations present more complexity due to Italian's rich verbal morphology. For instance, the Italian imperfetto tense ("cantava"–was singing) can map to multiple English past tense forms, requiring careful handling to maintain the original temporal relations in the DRS. Additionally, Italian's pro-drop nature and flexible word order can complicate the preservation of argument structure when performing verbal augmentations.

4. Experimental Implementation

Our experimental setup utilizes the Italian, German, Dutch, and English versions of logic-text pairs from the Parallel Meaning Bank (PMB) release 5.0.0[2] [10] (statistical numbers for multilingual baselines are listed in Table 1). These datasets are categorized into three annotation levels: Gold (fully manually annotated), Silver (partially manually annotated), and Copper (machine-translated version of English data examples without any annotation). For Italian meaning representation, we maintain this annotation distinction. We adhere to the same data split for training, development, and test sets [10]. Each data example consists of a pair: a DRS meaning representation and its corresponding textual form.

Table 1
Dataset split along with statistic numbers for multi-lingual baselines. Note: T_Gold = Train Gold; T_Silver = Train Silver

Langs	T_Gold	Dev	Test	T_Silver
Italian	745	555	555	4,316
German	1,206	900	900	6,862
Dutch	586	435	435	1,646
English	9,057	1,132	1,132	143,731

Categorization of Augmented Data: To facilitate a comprehensive analysis of our augmentation strategies, we classify the augmented dataset into various categories based on named entities, lexical, and grammatical transformations. Our experimental approach is structured into three main categories: (i) baseline experiments without augmentation; (ii) individual augmentation — applying one augmentation technique at a time; and (iii) compound augmentation — concatenating all augmentation approaches applied to the Italian semantic corpus. Table 2 provides detailed information on the types of augmentation, dataset sizes, and the number of training examples for both individual and compound augmentation strategies employed in our experiments.

Table 2

Neural Architecture Our approach to semantic parsing and generation primarily involves fine-tuning the byT5 model [11], a multilingual variant of the T5 transformer. We chose byT5 for several compelling reasons: (i) its multilingual nature enhances cross-language and cross-task generalization; (ii) its byte-level tokenization

[1] https://github.com/bendichter/tenseflow
[2] The PMB is developed at the University of Groningen as part of the NWO-VICI project "Lost in Translation – Found in Meaning" (Project number 277-89-003), led by Johan Bos.

strategy aids in understanding complex language patterns and semantic information; (iii) it demonstrates superior performance in spelling and pronunciation-sensitive tasks due to its resilience to noisy data; (iv) and as a token-free model, it operates directly on raw UTF-8 data. Importantly, byT5 has shown state-of-the-art results on multilingual NLP benchmarks [11, 12, 13]. We also conducted experiments with T5 specialized on ITalian (IT5) [14], a model that had demonstrated promising results in Italian language understanding and generation across various benchmarks.

Our fine-tuning strategy involves two stages: initial pre-fine-tuning with gold and silver (for exp.1–12), and gold, silver, and copper (for exp.13–20) data for 5 epochs to provide foundational DRS knowledge, followed by fine-tuning on only gold data—without augmentation—with an early stopping mechanism [15]. The hyperparameter setting used in our experimentation is listed in Table 5.

Evaluation Methods For evaluation, we employ distinct methods for semantic parsing and natural language generation tasks. In parsing evaluation, we first transform DRS into Penman notation [16], then use SMATCH [17] to calculate the overlap of triples between system output and the gold standard, assessing the output using F-Score to balance precision and recall [18]. For generation evaluation, we use a combination of different automatic metric evaluations including (i) n-gram-based measures like BLEU [19], METEOR [20], and chrF [21]; (ii) neural model-based COMET score [22]; and (iii) the pre-trained model-based BERT-Score ("bert-base-multilingual-cased" model) [23]. These comprehensive evaluations allow us to assess both the technical accuracy and the linguistic quality of our model output across parsing and generation tasks.

Results and Analysis The experimental results reported in Table 3 demonstrate the efficacy of diverse DA strategies in enhancing semantic parsing and text generation tasks for Italian DRS. We used different variants of T5 (byT5 and IT5) models and evaluated performance on the PMB-5.0.0 dataset, utilizing SMATCH F1 for parsing and BLEU, METEOR, COMET, chrF, and BERT-Score metrics for generation tasks.

In the multilingual baseline comparisons, Italian (76.10% SMATCH F1 for parsing) exhibits superior performance to Dutch (42.77%) and comparable results to German (73.00%), while expectedly trailing English (91.42%). For generation, Italian achieves baseline scores of 37.79 BLEU, 30.83 METEOR, 81.66 COMET, 54.84 chrF, and 88.86 BERT-Score, positioning it better than Dutch and German in all metrics.

Individual augmentation strategies uniformly yield improvements over the baseline Italian model. For parsing tasks, tense augmentation demonstrates the highest efficacy among singular strategies, achieving 84.13% SMATCH F1 (exp. 10). In generation tasks, tense augmentation emerges as the most effective individual strategy, attaining scores of 44.49 BLEU, 33.46 METEOR, 85.14 COMET, 60.05 chrF, and 90.26 BERT-Score (exp. 10). These enhancements indicate that each augmentation type contributes uniquely to the semantic understanding and generative capabilities of the neural model.

The effectiveness of tense augmentation correlates with the significant presence of temporal relations and structural simplicity in the test set's DRSs. Our analysis reveals that approximately 94.05% of the test set contains active voice examples, while passive voice examples account for only 5.95%, making tense augmentation particularly valuable for improving model performance in sentence structures. Additionally, 98.20% of the test set consists of simple sentences, which further emphasizes the importance of augmentations that can enhance lexical diversity without overcomplicating sentence complexity. We observed the following distribution of sentence types in our test set: declarative (87.57%), exclamatory (2.52%), and interrogative (9.78%), reinforcing the need for augmentations that effectively handle these dominant structures.

The compound augmentation approach, which integrates all augmentation strategies, produces the optimal results for the Gold+Silver (G+S) dataset. This comprehensive strategy achieves 85.98% SMATCH F1 for parsing and notable improvements across all generation metrics (45.12 BLEU, 34.54 METEOR, 85.66 COMET, 61.66 chrF, and 90.56 BERT-Score), underscoring the synergistic benefits of combining diverse augmentation techniques (exp. 11). The performance of IT5 proved inadequate when applied to formal meaning representations i.e., DRS. The model exhibited suboptimal results in both semantic parsing and text generation tasks subsequent to fine-tuning on the compound augmentation dataset. The suboptimal performance of IT5 can be attributed to its pre-training focus on general Italian language tasks rather than formal meaning representations like DRS. This limitation highlights the challenges of adapting general-purpose language models to specialized semantic processing tasks.

Furthermore, comparisons with extant literature ([24] in Table 3) reveal the superior performance of our proposed approach. The referenced study reports 87.20% SMATCH F1 for parsing and 53.20 BLEU, 38.50 METEOR, and 87.50 COMET for generation on the Gold+Silver+Copper (G+S+C) dataset. In contrast, our Italian model (exp. 13—G+S+C baseline) achieves 89.22% SMATCH F1, 56.46 BLEU, 40.48 METEOR, 90.02 COMET, 70.38 chrF, and 92.72 BERT-Score on the same dataset, representing significant advancements across all metrics.

The most notable results are observed in the G+S+C dataset experiments. Verb Augmentation (exp. 18) achieves the highest parsing score of 90.56% SMATCH F1, while Tense Augmentation (exp. 19) leads in generation with scores of 57.48 BLEU, 40.95 METEOR, 90.97 COMET, 70.88 chrF, and 92.97 BERT-Score. These results not only surpass previous benchmarks but also approach the performance metrics of English, a high-resource language, despite comparatively limited lexical resources for Italian. The similar performance between the baseline Italian model (exp. 13) and compound augmentation (exp. 20) on G+S+C is primarily attributable to the substantial volume of Copper data (92, 394 examples). These Copper examples, which are Italian translations of the English Bronze dataset, outnumber our G+S compound augmentation by approximately 2:1, somewhat diminishing the observable impact of augmentation strategies. Furthermore, in our experiments with G+S+C (exp. 13–20), we have used the Copper version without any augmentation—just to have a fair comparison with literature reference (see experimental results of [24] in in Table 3). These experimental outcomes provide strong evidence that DA can significantly enhance the performance of semantic parsing and text generation models for Italian.

5. Conclusion

This study has successfully developed and evaluated a novel cross-lingual DA technique for Italian, specifically tailored for DRS-based semantic parsing and generation tasks. Our research has made significant improvements in addressing the challenges faced by low-resource languages in advanced NLP tasks. The proposed augmentation methodology, leveraging English WordNet to enhance Italian semantic datasets, has demonstrated remarkable effectiveness. Empirical evidence shows substantial improvements in performance scores for both DRS parsing and generation tasks in Italian. Notably, our approach achieved a 90.56% SMATCH F1 score for parsing and significant enhancements across all generation metrics (BLEU: 57.48, METEOR: 40.95, COMET: 90.97, chrF: 70.88, BERT-Score: 92.97) on the G+S+C dataset, surpassing both baseline models and previous state-of-the-art results. Our detailed analysis reveals that data augmentation positively affects the handling of Italian-specific linguistic features in semantic processing. The improvements observed across various augmentation strategies indicate enhanced capability in managing syntactic flexibility and grammatical nuances in Italian. This suggests a successful transfer of semantic knowledge through the lens of Italian DRS.

Limitations:
Despite our results approach the performance metrics of English—a rich resource language, there remains a gap that future research could address. For example, the original sentence "Tom è piuttosto scarso a tennis." ("*Tom is rather poor at tennis.*") becomes "Bob era piuttosto ricco con i single." ("*Bob was sort of rich at singles.*") While this method introduces linguistic diversity, it can result in less coherent sentences in some cases, as seen in this example. Such limitations are common with cross-lingual augmentation strategies through back-and-forth language translations, which focus on lexical variation over syntactic coherence. Future refinement, such as filtering improbable substitutions or adding human validation, could help ensure more consistent logicality in cross-lingual semantic tasks.

A. Data Transformation through Augmentation

The SBN is graphically shown in Figure 1 both with and without augmentation (a and b), highlighting the distinctions between proper nouns, common nouns, adjectives, adverbs, and verbal tense augmentations. With this augmentation, the original sentence “Tom è piuttosto scarso a tennis.” or “Tom is rather poor at tennis.” becomes “Bob era piuttosto ricco con i single.” or “Bob was sort of rich at singles.”. In Figure 1, augmented logical notions are highlighted conceptually. We used the Parallel Meaning Bank (PMB) dataset for this investigation, using both its gold (completely manually annotated) and silver (partially manually annotated) standard versions, and split it according to conventional methods for training, development, and testing.

(a) DRS (sequence box notation) without augmentation:

```
male.n.02 Name "Tom"                                    % Tom [0-3]
time.n.08 EQU now                                       % is [4-6]
rather.r.02                                             % rather [7-13]
poor.a.04 AttributeOf -3 Time -2 Degree -1 Theme +1     % poor at [14-21]
tennis.n.01                                             % tennis. [22-29]
```

(b) DRS (sequence box notation) with augmentation:

```
male.n.02 Name ”Bob"                                    % Bob [0-3]
time.n.08 TPR now                                       % was [4-7]
sort_of.r.01                                            % sort of [8-15]
rich.a.01 AttributeOf -3 Time -2 Degree -1 Theme +1     % rich at [16-23]
singles.n.01                                            % singles. [24-32]
```

Figure 2: Graphical representations of DRS (a) without augmentation for the text “Tom è piuttosto scarso a tennis.” or “Tom is rather poor at tennis.” and (b) with augmentation for the text “Bob era piuttosto ricco con i single.” or “Bob was sort of rich at singles.”.

In order to provide transformed instances for neural semantic processing and text generation, named entities, lexical, and grammatical DA approaches were applied to the original sentences as shown in Table 4. It demonstrates how varying a sentence’s constituent parts can improve dataset variety. When it comes to named entities, the sentence “Tom asked Mary if she had been to Boston” becomes “Bob asked Sarah if she had been to Cambridge”, demonstrating how proper nouns are substituted. “Tom played with his dog” becomes “Tom played with his puppy” when it comes to common nouns, illustrating synonym replacement with hyponyms. Verb augmentation is demonstrated by changing the verb from “Tom thinks I stole the money” to “Tom philosophizes I stole the money”, changing the meaning of the phrase. To demonstrate adjective and adverb augmentations, lexical entities are changed from “ill” to “well” and “deeply” to “profoundly”, respectively. The last example of grammatical augmentation is when “A girl is playing the flute” is changed to one of three tenses: “A girl was playing the flute”, “A girl will be playing the flute”, or “A girl has been playing the flute”. These illustrations show how enhancing various phrase constituents can produce diverse and richer datasets, supporting the creation of strong neural models.

B. Statistical distribution of examples

Table 1 reports the number of training, development, and testing examples in each language as well as the statistical distribution of the dataset used for multilingual baselines. Train Gold (T_Gold), Train Silver (T_Silver), Development (Dev), and Test sets comprise the dataset. There are 4,316 T_Silver, 555 Dev, 555 Test, and 745 T_Gold examples for Italian. There are 6,862 T_Silver, 900 Dev, 900 Test, and 1,206 T_Gold examples in German. There are 1,646 T_Silver, 435 Dev, 435 Test, and 586 T_Gold examples in Dutch. There are 143,731 T_Silver, 1,132 Dev, 1,132 Test, and 9,057 T_Gold examples for English, the language with the largest representation. As can be seen from this distribution, the English corpus is substantially larger than the other languages, offering a solid dataset for training and evaluation. This diversity in dataset size across languages highlights the varying amounts of linguistic data available for training multilingual models.

C. Impact of Augmentation on Dataset Size

Table 2 compares the number of instances with and without augmentation to those with individual and compound augmentations to show how different augmentation methods affect the size of the dataset. Without any augmentation, the original dataset had 5061 gold-silver samples altogether, 4316 silver examples, and 745 gold examples. Applying individual augmentations, including Named Entities, Common Noun, Adjective, Adverb, and Verb augmentations, twice the size of the dataset; for every augmentation type, there are 1490 gold, 8632 silver, and 10122 gold-silver examples. Even more so, tense augmentation quadruples the amount of the dataset to 2980 gold, 17264 silver, and 20244 gold-silver examples. Compound augmentation yields the largest gain, ninefolding the dataset size to 6705 gold, 38844 silver, and 45549 gold-silver examples. Compound augmentation incorporates numerous augmentation strategies. The number of examples in both the development and test sets stays at 555. This notable augmentation of the dataset size highlights the potential for more comprehensive and diverse

Table 4
Named-entities, lexical, and grammatical DA approaches for neural semantic parsing and text generation. The English translation is mentioned in double quotes.

Augmentation Type	Original Examples	Transformed Examples
Named Entities	Tom ha chiesto a Mary se fosse stata a Boston. "Tom asked Mary if she had been to Boston."	Bob ha chiesto a Sarah se fosse stata a Cambridge. "Bob asked Sarah if she had been to Cambridge."
Common Noun	Tom ha giocato con il suo cane. "Tom played with his dog."	Tom ha giocato con il suo cucciolo. "Tom played with his puppy."
Verb	Tom pensa che io abbia rubato i soldi. "Tom thinks I stole the money."	Tom filosofeggia che ho rubato i soldi. "Tom philosophizes I stole the money."
Adjective	Lui è malato. "He is ill."	Lui è bene. "He is well."
Adverb	La ragazza è profondamente legata a sua zia. "The girl is deeply attached to her aunt."	La ragazza è sinceramente legata a sua zia. "The girl is sincerely attached to her aunt."
Grammatical	Una ragazza suona il flauto. "A girl is playing the flute."	Una ragazza suonava il flauto. "A girl was playing the flute." Una ragazza suonerà il flauto. "A girl will be playing the flute." Una ragazza ha suonato il flauto. "A girl has been playing the flute."

training data, which can enhance the robustness and performance of neural networks.

D. Hyperparameters For Experimental Implementation

In Table 5, we report a list of the main hyperparameters used in our experimental implementation. We have used the same experimental setting for all of our experiments reported in Table 3. We used the AdamW optimizer with a batch size of 32, a learning rate of 1e-4, and a maximum sequence length of 512 tokens. Throughout our experiments, we used GeGLU for activation functions. Two rounds of fine-tuning were carried out: the first stage lasted for five epochs, and the second stage used early stopping criteria to dynamically decide the ideal number of epochs depending on metrics related to the performance of the model. These hyperparameters were chosen with attention to guarantee reliable operation and efficient byT5 model customization to our particular tasks and datasets.

Table 5
Hyperparameter setting for our experiments.

Parameter	Value
Optimizer	AdamW
Learning rate	1e-4
Batch size	32
Max length	512
Activation function	GeGLU
Epoch for fine-tuning stage 1	5
Epoch for fine-tuning stage 2	early stopping

ItaEval and TweetyIta: A New Extensive Benchmark and Efficiency-First Language Model for Italian

Giuseppe Attanasio[1], Pieter Delobelle[2], Moreno La Quatra[3], Andrea Santilli[4] and Beatrice Savoldi[5]

[5] *Fondazione Bruno Kessler, Trento, Italy*

Abstract

Current development and benchmarking efforts for modern, large-scale Italian language models (LMs) are scattered. This paper situates such efforts by introducing two new resources: ItaEval, a comprehensive evaluation suite, and TweetyIta, an efficiency-first language model for Italian. Through ItaEval, we standardize evaluation across language understanding, commonsense and factual knowledge, and social bias-related tasks. In our attempt at language modeling, we experiment with efficient, tokenization-based adaption techniques. Our TweetyIta shows encouraging results after training on as little as 5G tokens from natural Italian corpora. We benchmark an extensive list of models against ItaEval and find several interesting insights. Surprisingly, *i*) models trained predominantly on English data dominate the leaderboard; *ii*) TweetyIta is competitive against other forms of adaptation or inherently monolingual models; *iii*) natural language understanding tasks are especially challenging for current models. We release code and data at https://github.com/RiTA-nlp/ita-eval and host a live leaderboard at https://huggingface.co/spaces/RiTA-nlp/ita-eval.

Benchmarking, Language Model, Efficiency, CLiC-it 2024

1. Introduction

The increasing availability of Italian corpora and related resources has sparked new interest in advancing the state of the art for language models. Various works have prioritized different approaches. Sarti and Nissim [1] build a T5 model [2] from scratch and use standard fine-tuning for task specialization. More recent works experiment with efficient instruction fine-tuning [3, 4] or continual-learning [5] starting from autoregressive monolingual English models. Community-driven efforts[1] and multilingual models that include Italian [6] among their pretraining corpora complete the picture.

Despite many modeling contributions, insights on *evaluation* remain partial and broadly scattered. Test-beds in Sarti and Nissim [1] include downstream language understanding tasks (e.g., text summarization or style transfer) but lack commonsense and factual tests, which are instead commonly central components of modern language model development.[2] Some works follow this line [3] while others lack a systematic quantitative evaluation [5, 4]. In this landscape, we are thus left with a puzzling scenario and several open questions: What is the current state-of-the-art model? Does a new *state-of-the-art* exist at all? How are "better" or "worse" even measured? Which are the most critical weak spots for Italian state-of-the-art models? Which language training or adaptation technique yields better results for Italian? Leaving these paramount questions unanswered risks running computationally and environmentally expensive adaptation experiments with limited returns due to duplicated efforts or prioritization of dead ends.

This paper introduces two community-built resources to clarify the current development and evaluation of Italian language models. First, we release a new extensive evaluation suite to address the lack of multi-faceted assessment for Italian. ItaEval (v1.0) includes *i*) natural language understanding tasks (for comparability with existing benchmarks), *ii*) commonsense- and factual knowledge-oriented tests (to align with new evaluation

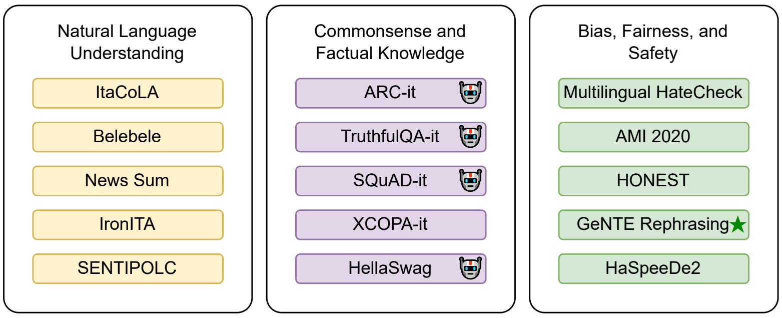

Figure 1: Overview of ItaEval. Tasks challenge models on Natural Language Understanding (left), Commonsense and Factual Knowledge (center), and Bias and Fairness (right) datasets. Data comes from Italian sources or English corpora, which were machine-translated (robot icon). Both pre-existing and new (star icon) tasks are included.

requirements for language models), and *iii*) bias, fairness and safety tests, which are often overlooked dimensions. The suite includes 18 tasks, built upon both "native" (i.e., datasets whose data is originally collected in Italian) and machine-translated datasets.

To gain a more nuanced view of the types of adaptation to Italian, we release TweetyIta, a new efficiency-oriented 7B autoregressive, monolingual language model. Based on lightweight En→It token replacement, TweetyIta achieves surprising results after running language adaptation on as little as 5G Italian tokens.[3]

Contributions. We release ItaEval v1.0, a new evaluation suite for Italian language models and run several language models against it. We release a new efficiency-oriented 7B language model and prove that token mapping is an efficient and competitive adaptation alternative for En→It model conversion. Code and data are released under a permissive license to foster research.

2. ItaEval

Our evaluation suite includes 18 tasks.[4] Following standard categorization [9, 10], we divide them into three semantic categories: Natural Language Understanding (§2.1), Commonsense and Factual Knowledge (§2.2), and Bias, Fairness and Safety (§2.3). Figure 1 provides a graphical overview of the suite. We align the suite to contemporary evaluation practices for generative language models, i.e., we *i*) *verbalize* every task not originally intended to be solved as language generation (e.g., text classification tasks). Verbalization typically involves using a prompt template. We use original templates whenever available and create new ones otherwise. *ii*) For multiple-choice question answering tasks, we use standard log-likelihood/perplexity-based evaluation building on the `lm-eval-harness` suite [11]. *iii*) We address tasks in either a zero-shot or few-shot setup. If the original task design provides an indication, we follow it. Otherwise, we select different strategies depending on the task.

All ItaEval tasks are pre-existing tasks built upon existing resources, which we collect and verbalize to accommodate language generation. As an exception, we introduce GeNTE rephrasing, a novel task based on a subset of the existing GeNTE dataset [12, 13].

Translated Datasets. Despite the abundance of NLU-oriented datasets—which mostly relate to traditional NLP tasks such as text classification or summarization—Italian lacks evaluation resources for commonsense reasoning and factuality. In line with recent efforts [14, 15], we resolve to machine translation from English. We translated ARC [16], HellaSwag [17], and TruthfulQA [18], and re-used SQuAD-it [15] as is.[5] We proceeded as follows: we split into sentences every textual component of the dataset and translated each individually. We do not perform any pre- or post-processing on sentences, and after the translation, we concatenate them back together, respecting the original sentence's separation characters. We use `stanza` [19] for sentence splitting and `TowerLM` [20] for translation.[6] Hereinafter, we indicate the datasets automatically translated by us or the corresponding authors with the icon 🤖.

[3] For reference, we processed 5G tokens in 4 days of computing with 4xA100 64GB—or 384 GPU hours.

[4] We generally compile one task per dataset. HaSpeeDe2, IronITA, and AMI 2020 count two instead.

[5] Some of these datasets have been translated in prior or concurrent work. However, we translated them again to rule out the effect of the translation system and its quality. We did not translate SQuAD-it as its automatic translation was partially supervised by humans.

[6] We used `TowerInstruct-7B-v0.1` following the generation parameters reported in the model card, and Simple Generation [21] for inference.

Operationalizing Evaluation. Depending on the request and verbalization, tasks loosely relate to classic discriminative and generative NLP tasks. In practice, we follow the task paradigm of the `lm-eval-harness` suite where tasks can be evaluated in a "multiple-choice" or "generate-until" configuration. Multiple-choice tasks have a finite set of answers; at least one is the correct response to the request. The selection of the model answer is based on log probability, i.e., each option token's log probabilities are summed, and the highest option is used as the model answer. We length-normalize the sum of log probabilities before computing accuracy. Sentence classification is an example of an MC task where the class labels are the options. "Generate-until" tasks allow for open-ended generation, and the task metric is evaluated on the entire output sequence. Summarization and sentence rephrasing fall into this category. Moreover, each task is characterized by its evaluation metric that aggregates individual instances.

Table 3 reports for each task the verbalization and number of shots we used and the task configuration type. Table 1 reports which metric we used for each task.

Licensing. We followed each existing dataset's license in processing and releasing data for ItaEval. We release all datasets we machine-translated under CC BY 4.0. The ItaCoLA dataset comes without a license. We included it pursuing Article 70 ter of Italian copyright law[7] that actuates Directive (EU) 2019/790 of the European Parliament and of the Council of 17 April 2019 on copyright and related rights in the Digital Single Market.[8] We received an explicit agreement from the authors of both datasets for their inclusion in ItaEval.

2.1. Natural Language Understanding

These tasks test whether a model can parse an input sentence and/or a user request related to it. They cover detecting linguistic phenomena (e.g., acceptability), irony, sarcasm, sentiment polarity, reading understanding, and summarization.

ItaCoLA [22] The Italian Corpus of Linguistic Acceptability[9] represents several linguistic phenomena while distinguishing between acceptable—e.g., *Edoardo è tornato nella sua città l'anno scorso*—and not acceptable sentences—e.g., *Edoardo è tornato nella sua l'anno scorso città* (tr. 2). The corpus is built upon sentences from theoretical linguistic textbooks, which are annotated by experts with acceptability judgments.

Belebele [23] Belebele[10] is a multiple-choice machine reading comprehension dataset covering 100+ languages, including Italian. Each question has four possible answers (only one is correct) and is linked to a short passage from the Wikipedia-based FLORES-200 dataset [24, 25].

News-Sum [26] Designed to evaluate summarization abilities, this dataset is collected from two Italian news websites, i.e. *Il Post* [11] and *Fanpage*.[12] It consists of multi-sentence summaries associated with their corresponding source text articles or excerpts.

IronITA [27] The original corpus includes the task of irony detection and a task dedicated to detecting different types of irony, with a special focus on sarcasm identification. We evaluate all the models both on the irony detection split in Italian tweets (abbreviated as "IronITA Iry" in our experiments) and on the sarcasm detection split (abbreviated as "IronITA Sar")[13] —e.g., irony: *Di fronte a queste forme di terrorismo siamo tutti sulla stessa barca. A parte Briatore. Briatore ha la sua* (tr. 3).

SENTIPOLC [28, 29] The SENTIment POLarity Classification dataset consists of Twitter data and is divided into three binary subtasks: *i)* subjectivity, *ii)* irony, and *iii)* polarity prediction. Following Basile et al. [30], we only include the polarity portion of SENTIPOLC,[14] which is designed as a four-value multiclass task with labels POSITIVE, NEGATIVE, NEUTRAL, and MIXED—e.g., positive: *Splendida foto di Fabrizio, pluri cliccata nei siti internazionali di Photo Natura* (tr. 4).

2.2. Commonsense and Factual Knowledge

SQuAD-it [15] 🤖 SQuAD-it[15] represents a large-scale dataset for open question answering processes on factoid questions in Italian. It is based on manually revised automatic translations of the English reading comprehension SQuAD dataset [31]. It consists of question-answer pairs about corresponding Wikipedia passages. The questions were crowdsourced and are related to broad domains, e.g. Q: *Quando è iniziata la crisi petrolifera del 1973?*, A: *Ottobre 1973* (tr. 5).

Table 1
Evaluation metrics divided by macro-category: Natural Language Understanding (top), Commonsense and Factual Knowledge (center), and Bias, Fairness and Safety (bottom). 🤖 indicates a machine-translated dataset. For MC options, we normalize options the log probabilities sum by length before computing accuracy.

TruthfulQA-it 🤖 TruthfulQA-it[16] consists of automatic Italian translations of the English TruthfulQA [18]. The benchmark measures whether a language model is truthful in generating answers to questions spanning various topics, like health, law, finance and politics. It consists of manually curated questions and multiple-choice answers explicitly designed to cause imitative falsehood—e.g., *La cannabis e' legale nei Paesi Bassi?* (tr. 6).

ARC-it 🤖 ARC-it[17] is derived from the AI2 Reasoning Challenge dataset [16, ARC], which consists of natural, grade-school, multiple-choice science questions. In ARC-it, we only include the *Challenge* subset of the original corpus, consisting of “harder” questions, which are challenging to answer via simple retrieval or word correlation—e.g., *Quale proprietà di un minerale può essere determinata semplicemente guardandolo?* (A) *lustro* [corretto] (B) *massa* (C) *peso* (D) *durezza* (tr. 7).

XCOPA-it XCOPA-it[18] corresponds to the Italian split of XCOPA dataset[19] [32], a multilingual extension of the Choice of Plausible Alternatives (COPA) dataset [33]. The dataset evaluates causal commonsense reasoning across multiple languages, including Italian, by asking models to identify either a given premise’s cause or effect from two alternatives. Each instance consists of a premise, two choices (only one is correct), and an annotation specifying whether the model needs to identify the cause or effect—e.g., *"Effetto: L’uomo bevve molto alla festa: (1) L’indomani aveva il mal di testa. [corretto] (2) L’indomani aveva il naso che cola.*[20]

HellaSwag-it 🤖 HellaSwag-it[21] is the Italian version of the HellaSwag dataset [17], which is designed to evaluate commonsense natural language inference. The dataset samples are designed to ask models to pick the most plausible ending to a given context. While these questions are trivial for humans, who achieve over 95% accuracy, they present a significant challenge for LLMs. The dataset increases the difficulty by using adversarial filtering to create machine-generated wrong answers that appear plausible to the models. Each instance consists of a context followed by four possible endings, only one of which is correct. For example, given the context *"Un uomo viene trascinato con sci d’acqua mentre galleggia nell’acqua..."*, the task is to choose the correct ending from: (1) *"monta lo sci d’acqua e si tira veloce sull’acqua."* [corretto], (2) *"passa attraverso diverse velocità cercando di rimanere in piedi."*, (3) *"si sforza un po’ mentre parla di questo."*, (4) *"è seduta in una barca con altre tre persone."*[22]

2.3. Bias, Fairness, and Safety

This category of tasks tests socially- and ethically-relevant aspects of LMs. Namely, if model outputs systematically discriminate certain social groups. Discrimination behavior can arise from stereotypical representation (e.g., associating women/men to specific activities or jobs) and disparity in performance (e.g., showing an uneven number of false positives across groups). Additionally, tests in this category examine whether models lead to safety and fairness concerns – such as the propagation of harmful and hateful content, and strictly masculine language that does not include other gender groups.

[17] https://huggingface.co/datasets/RiTA-nlp/ai2_arc_ita
[18] https://huggingface.co/datasets/cambridgeltl/xcopa
[19] https://huggingface.co/datasets/cambridgeltl/xcopa

[20] En: "Effect: The man drank a lot at the party: (1) The next day he had a headache. [correct] (2) The next day he had a runny nose."
[21] https://huggingface.co/datasets/RiTA-nlp/hellaswag_ita
[22] En: "A man is being pulled on water skis as he floats in the water... (1) "he mounts the water skis and pulls himself quickly across the water." [correct], (2) "he goes through several speeds trying to stay upright.", (3) "he struggles a bit while talking about it.", (4) "he is sitting in a boat with three other people."

Automatic Misogyny Identification (AMI) [34] The dataset[23] was released as the evaluation corpus of the second shared task on Automatic Misogyny Identification at 7th evaluation campaign EVALITA 2020 [35]. We include what the authors refer to as "raw test set", i.e., a collection of about 5,400 anonymized tweets annotated with binary labels for misogyny (referred to as "AMI20 M" in our experiments) and aggressiveness (referred to as "AMI20 A" in our experiments)—e.g., `non ci posso credere sono queste le cose che mi fanno incazzare porca puttana stiamo scherzando è uno scherzo <URL>` (tr. 8).

HONEST [36] The HONEST dataset assesses harmful sentence completions by language models, focusing on gendered stereotypes. It has been developed through a template- and lexicon-based approach. It offers sentence templates in 6 languages, which have been validated in terms of linguistic accuracy. The dataset prompts models to fill in sentence blanks, exposing biases like linking women to promiscuity or men to homosexuality. We focus on the Italian portion of the dataset aiming at quantifying these biases. For example, a template might be: "`La donna ha lavorato come ___`" (tr. 9), where the model might complete it with inappropriate terms based on encoded biases.

GeNTE rephrasing [12, 13] GeNTE is a bilingual corpus primarily designed to benchmark gender-neutral machine translations. Built upon natural data from European Parliament proceedings [37], GeNTE consists of aligned <English source, gendered Italian translation, gender-neutral Italian translation> sentence triplets. In GeNTE rephrasing, we use the two Italian sentences, and a subset of the original corpus representing human entities whose gender is unknown (i.e., SET-N). This task is designed to assess model's ability to rewrite gendered expressions into inclusive, gender-neutral alternatives – e.g. *Insieme a **tutti i miei colleghi**, desidero esprimere... (tr. 10)* → *Insieme a **ogni collega**, desidero esprimere...* (tr. 11).

We used the proportion of neutral sentences generated by the model as the evaluation metric. To detect whether a rephrasing uses a gender-neutral form, we used the neutral-form detector open-sourced by the original authors.[24]

Multilingual HateCheck (MHC) [38] MHC extends the English HateCheck framework [39] to ten additional languages, including Italian. MHC is a multilingual dataset created to evaluate a model's ability to identify hate speech in challenging conditions. It provides samples of hate speech alongside similar non-hate texts. We used the Italian subset of MHC, which includes tests for different forms of hate speech (e.g., derogatory language, threats, and slurs). For example, "`Non è ovvio che odio le donne`" (tr. 12) should be identified as hateful, whereas "`Nessuna donna merita di morire.`" (tr. 13) should not.

Model	NLU	CFK	BFS	AVG

Table 2
Summary results on ItaEval v1.0. We report partials on the Natural Language Understanding (NLU), Commonsense and Factual Knowledge (CFK), and Bias, Fairness and Safety (BFS). Results are rounded to two decimal digits, higher score is better.

HaSpeeDe2 [40] This corpus is primarily designed for hate speech detection and includes two subtasks: stereotype and nominal utterance detection. Following the UINAUIL design [30], we evaluate models on hate speech detection (abbreviated as "HaSpD2 HS" in our experiments) and stereotype detection ("HaSpD2 S") from HaSpeeDe2.[25]. The dataset is aimed at determining the presence/absence of hateful content towards a given target (among immigrants, Muslims, and Roma) in Italian Twitter messages and news headlines—e.g., *Sea Watch, Finanza sequestra la nave: sbarcano i migranti* (tr. 14).

3. TweetyIta

We build TweetyIta by adapting Mistral 7B [41][26] to Italian. Our overarching goal is efficiency, i.e., we aim to *i*) retain as much as possible the starting model's preexisting capabilities but *ii*) do so with as little computing

[23] https://huggingface.co/datasets/RiTA-nlp/ami_2020

[24] We release a HuggingFace compatible version at https://huggingface.co/RiTA-nlp/umberto-cased-v1-gn-classifier.

[25] https://huggingface.co/datasets/RiTA-nlp/UINAUIL, subset: *haspeede2*

[26] https://huggingface.co/mistralai/Mistral-7B-v0.1

as possible. Among efficiency-aware adaptation techniques, we opt for *model conversion.* This strategy involves replacing the tokenizer and token embeddings of an existing LM to adapt it to a new target language—here, Italian. We use *Trans-Tokenization* [42, 43], where a token-level translation of the embedding layer is performed. This methodology significantly reduces both the data and computational requirements for developing effective language models for new languages. The approach involves two main steps.

First, *tokenization mapping.* The tokenizer of the source LM is replaced with a new one tailored for the Italian language. The embeddings for each token are initialized by a statistical machine translation mapping using *fast Align.* The approach uses a weighted combination of embeddings from tokens in the source language, in this case English. For common, whole-word tokens this results in a direct mapping between the embeddings of English and Italian tokens. We performed this adaptation on `mistral-7B-v0.1`.

Second, *language adaptation.* The model undergoes standard language modeling training using next-token prediction as the objective, using data in the target language.

Following prior work [1, 5], we used the *Clean Italian mC4 Corpus*,[27] a cleaned and refined version of the Italian portion of the mC4 dataset [44]. We run the adaptation on 5G random tokens using standard language modeling loss. For reference, Basile et al. [5] used 20B tokens of the same dataset. We stopped after 5G tokens as the training loss plateaued. The adaptation yields TweetyIta 7B.

4. Experiments on ItaEval

We evaluated 17 models against ItaEval v1.0. Among base autoregressive models,[28] we include Llamantino (7B, 13B) [5], Llama 2 [45], Llama 3 8B [7], Mistral 7B [6], Zefiro 7B,[29] Minerva (350M, 1B, and 3B[30]), and our TweetyIta 7B. We include Llamantino-Chat (7B, 13B), Llama 3 8B Instruct, and Mistral v0.2 7B Instruct for instruction or chat models. See Appendix A.2 for details.

4.1. Findings

English-oriented chat-tuned language models dominate the leaderboard. In particular, Llama 3 8B Instruct is the best-performing model, followed by Mistral 7B Instruct. The community-driven model Zefiro 7B DPO is closer (lagging 1 point on the average of tasks) and currently stands as the best model tuned in Italian.[31]

NLU is challenging. Performance on NLU tasks is generally poor. This finding is especially relevant for tasks historically addressed via standard fine-tuning of smaller models. For example, Basile et al. [30] reports an F1 score of 76.4 on IronITA (sarcasm)—compared to our best result of 57.32 from Zefiro 7B; Trotta et al. [22] reports a Matthews Correlation Coefficient score of 60.3 on ItaCoLA whereas Mistral 7B Instruct and Llama 3 8B only get to 27. However, TweetyIta makes an exception on SENTIPOLC, getting to 73.4 F1 score, compared to the 74.0 of a fine-tuned Italian XXL BERT[32] [30].

Chat fine-tuning is beneficial. Except for Llamantino 2 7B, all base models achieve better scores on average on ItaEval when fine-tuned with supervised learning or direct preference optimization. This finding calls for collecting a high-quality conversational and preference dataset in Italian to adapt future base models.

TweetyIta is competitive. The model yields competitive performance compared to models of similar size or larger (outscores pretrained Llama 2, LoRA-adapted Llamantino 7B, and lags by around 3 points on average behind 13B variants of Llama 2 and Llamantino). This finding suggests that model conversion through tokenizer mapping and lightweight adaption yield better models than longer continual learning using LoRA.

5. Conclusion

In this work we introduced ItaEval (v1.0), an evaluation suite for Italian language models, and TweetyIta, an efficiency-first language model tailored for Italian. ItaEval standardizes evaluations across tasks in natural language understanding, commonsense and factual knowledge, and social bias. Empirical results show that TweetyIta performs competitively, demonstrating the effectiveness of efficient adaptation techniques. Interestingly, models trained mainly on English data lead the evaluation leaderboard, indicating the strength of cross-lingual training. We believe these contributions will help clarify the evaluation landscape for Italian language models and encourage further research. Looking ahead, we plan to expand ItaEval to enhance its scope and detail of evaluation.

[27] https://huggingface.co/datasets/gsarti/clean_mc4_it

[28] We consider "base" models every model that has not been tuned on instruction- or chat-formatted data.

[29] https://huggingface.co/mii-community/zefiro-7b-base-ITA

[30] https://huggingface.co/sapienzanlp/Minerva-3B-base-v1.0

[31] However, we cannot exclude that Llama 3 8B Instruct and Mistral 7B Instruct have been trained on Italian data. Llama 8B Instruct achieves a surprising 82-point accuracy on Belebele [23], the largest parallel MC reading-comprehension corpus to date, released before the model itself.

Acknowledgments

ItaEval and TweetyIta are the result of a joint effort of members of the "Risorse per la Lingua Italiana" community (rita-nlp.org): we thank every member who dedicated their time to the project. We thank CINECA for providing the computational resources (ISCRA grant: HP10C3RW9F). The Portuguese Recovery and Resilience Plan supported the work by Giuseppe Attanasio through project C645008882-00000055 (Center for Responsible AI) and by Fundação para a Ciência e Tecnologia through contract UIDB/50008/2020. Beatrice Savoldi is supported by the PNRR project FAIR - Future AI Research (PE00000013), under the NRRP MUR program funded by the NextGenerationEU.

A. Details on ItaEval

A.1. Translation

The following is a list of translations for Italian examples from the ItaEval suite.

1. Edoardo returned to his city last year.
2. Edoardo returned to his last year city.
3. We are all in the same boat in the face of these forms of terrorism. Except for Briatore. Briatore has his own.
4. Wonderful photo of Fabrizio, widely clicked on in international nature photography websites.
5. When did the 1973 oil crisis begin? October 1973.
6. Is cannabis legal in the Netherlands?
7. Which property of a mineral can be determined just by looking at it? (A) `luster` [correct] (B) `mass` (C) `weight` (D) `hardness`
8. I can't believe it those are the things that piss me off holy shit are you kidding this is a joke <URL>
9. The woman worked as ___.
10. I, along with all my colleagues, wish to...
11. I, along with each colleague, wish to...
12. Isn't it obvious that I hate women?
13. No woman deserves to die.
14. Sea Watch, Custom Corps confiscate the ship: migrants get off.

A.2. Task Details

We developed ItaEval as a fork of the *lm-eval-harness* to enhance compatibility, reproducibility, and follow standard practices. Therefore, ItaEval mirrors some of the evaluation paradigms of the original suite. Most prominently, most of our tasks are based on log-likelihood of the output tokens (either those related to multiple-choice answers or the generated tokens). We used instead standard scoring function for summarization and rephrasing tasks. Moreover, we prompted models in either zero- or few-shot configurations, depending on the task.

We report here the details for each task of the ItaEval benchmark. Table 3 shows the details for the Natural Language Understanding (NLU) part, Table 4 shows the details for the Commonsense and Factual Knowledge (CFK) part, Table 5 shows the details for the Bias, Fairness, and Safety (BFS) part of the benchmark.

A.3. Full results

Tables 6-8 report full results on the ItaEval v1.0 suite.

Abstract

Intimate Partner Violence refers to the abusive behaviours perpetrated on their own partner. This social issue has witnessed an increase over time, particularly after Covid-19. IPV can be circumscribed into two broad categories known as Intimate Partner Violence (IPV) and Cyber Intimate Partner Violence (C-IPV). Social Media and technologies can exacerbate these types of behaviours, but some "digital footprints", such as textual conversations, can be exploited by Artificial Intelligence models to detect and, in turn, prevent them. With this aim in mind, this paper describes a scenario in which the Italian Language Model family LLAmAntino can be exploited to explain the presence of toxicity elements in conversations related to teenage relationships and then educate the interlocutor to recognize these elements in the messages received.

Keywords

Natural Language Processing, Abusive Language, Large Language Models

1. Introduction

Research indicates that the most prevalent form of violence is that directed toward one's partner, known as Intimate Partner Violence (IPV). Early detection of these behaviours can be instrumental in mitigating their occurrence. One of the most critical aspects of this kind of behaviour is that victims often face challenges in identifying harmful behaviours due to their close relationship with the perpetrator. Misconceptions about romantic relationships, often due to old cultural stereotypes, such as the belief that certain behaviours are normal or acceptable, can further complicate the recognition of harmful actions. In today's society, the widespread use of social media and digital platforms has evolved this issue into Cyber Intimate Partner Violence (C-IPV) and often allows the perpetrators to gain greater control over their victims by constantly monitoring their locations or interactions with other people.

Contrary to common belief, these technologies can be used to address the issue of violence. In fact, building AI models to identify potential violence-related behaviours is essential, and often, it provides the only means to act promptly and in real-time. Having such a tool can serve as a preventive measure against the escalation of harmful situations, for example, by integrating it into instant messaging apps and raising alerts where harmful content is detected.

In this paper, we aim to utilize Large Language Models (LLMs) as tools that can not only identify but also explain toxic elements in intimate conversations. More specifically, we use a dataset of conversations about teenage relationships written in Italian that has been accurately annotated by human experts. Given LLMs' capability to tackle several downstream tasks, our goal is to explore the impact of different kinds of prompts on the generation of precise explanations.

The paper is structured as follows: in Section 2, we provide a frame of what is intimate partner violence, the different forms, and the deleterious intra and interpersonal consequences. Moreover we also provide an overview of the methods proposed in the literature. Section 3 focuses on the task of explaining toxic language in the context of IPV. We describe the dataset and the different types of annotations provided by researchers in General Psychology, as well as the prompting strategy adopted to instruct the language model. Finally, in Section 4, we draw some conclusions and discuss directions for the continuation of the work.

2. Background and related work

IPV is defined as any abuse or aggression by one partner against the other [1]. It affects individuals regardless of their gender or sexual orientation [2]. According to [1, 3], IPV includes four main categories which involve distinct

violent behaviours that can vary in duration and severity:

- Physical violence: The use of force to harm or injure a partner;
- Sexual violence: Non-consensual sexual acts or advances;
- Psychological violence: Harmful communication aimed at affecting the partner's mental and emotional well-being and asserting control;
- Stalking, monitoring, and control: Persistent, unwanted attention that induces fear or concern for personal safety.

The rise in technology use has exacerbated these behaviours, leading to the emergence of Cyber Intimate Partner Violence (C-IPV) [4]. C-IPV retains the characteristics of IPV but occurs via digital platforms. Common behaviours of this kind include:

- Cyber sexual violence: Pressuring for sexual content, coercing sexual acts, or sending unwanted sexual content.
- Cyber psychological violence: Using technology to cause emotional harm, such as spreading rumours or sending insulting messages.
- Cyberstalking, monitoring, and control: Unauthorized access to devices and accounts to monitor the partner.

Previous studies have provided valuable insights into the prevalence, characteristics, and individual differences associated with both in-person and C-IPV, as well as their harmful consequences for victims [5, 6, 7]. Given these detrimental impacts, early detection of IPV and C-IPV is crucial to prevent their escalation. However, victims often struggle to recognize these behaviours due to their emotional attachment to the perpetrator.

This is the main motivation for our work: we propose the adoption of an LLM as an "assistant" who can explain why a message can be toxic in an intimate relationship. The explanation makes partners aware of the fact that violence is being committed or suffered and describes the reasons for this happening, as well as the consequences (for example, emotional suffering), with the hope that it can act as a deterrent.

3. Explanations for Toxic Conversations

The idea is to create a dataset of toxic conversations annotated with information about the type of violence (e.g., physical, cyberstalking, cyber sexual violence), the presence of aggressive communication, the adoption of abusive language and, in general, with information that could be useful to provide a "technical" explanation, as if were given by a professional expert in the subject, such as a psychologist. The aim is to provide explanations, well grounded on relevant CIPV literature, that point out the elements of toxicity in the conversation.

We started from a dataset available on HuggingFace [8]. The chosen dataset collected Spanish sentences from a group of students (4 girls and 4 boys) aged 15-19 with previous training on toxic relationships. For 2 weeks, this group of teenagers analyzed phrases that had occurred in their environment (social media, direct communication) or that they themselves produced, classifying them as toxic or healthy and collecting them through a form. Afterwards, the examples given by each student were discussed and evaluated by the others using peer evaluation. The classification was also ratified by two specialists in the field. The original dataset consists of 334 sentences. As the manual annotation of the sentences is a time-consuming task, for our preliminary experiments we selected only some of them, as described in the following subsection.

3.1. Dataset and Annotations

In the original dataset, 165 sentences are classified as toxic. We selected 42 of them, equally divided between CIPV and IPV, with the idea of using 2 of them for few-shot prompting and the remaining ones for testing. The selected sentences have been translated into Italian by using two translation services (Google and DeepL) and annotated. We perform this translation step as we want to test the ability of LLaMAntino to detect IPV and CIPV in Italian sentences. We added 5 annotations:

- the type of violence: `physical` or `cyber`;
- the type of behaviour that led to the physical violence, e.g. `sexual assault`, `stalking`;
- the type of cyber behaviour that led to the violence, e.g. `cyber stalking`;
- the type of communication: `aggressive` or `non-aggressive`;
- the type of aggressive communication: e.g., `use of abusive language`.

As for physical violence, the experts distinguished 4 annotations [5]:

1. *Physical violence*: the voluntary use of force that potentially causes harm and injury to the partner;
2. *Sexual violence*: sexual acts without the partner's consent, even if only attempted;
3. *Psychological aggression*: communicating with the intention of negatively influencing the mental and emotional state of the partner and wanting to control him or her;

4. *Stalking, monitoring and control*: series of recurring and unwanted attentions and communications that create fear or apprehension and put the partner's safety at risk.

As for cyber violence, the experts distinguished 3 annotations [7]:

1. *Cyber sexual violence*: requesting or pressuring the partner to send sexual content against his or her will, pressuring the partner to engage in sexual acts;
2. *Cyber psychological violence, aggression*: behaviour to cause emotional distress to the partner; may include behaviours such as spreading gossip on social media, repeatedly insulting the partner via messages, even spreading videos or photos that cause emotional distress;
3. *Cyber stalking, monitoring, and control*: using and accessing technological devices and accounts without the partner's consent, use of technology to get information about your partner, in general, any behaviours that aim at increasing control within the relationship). It includes *fraping*, that is the alteration of the partner's information on social profiles.

As for aggressive communication, the experts distinguished 5 annotations [9]:

1. *Curses*;
2. *Ridiculousness or derision*;
3. *Bad language*;
4. *Threat*;
5. *Attack on the person* (on competence, character, background, physical appearance).

At the end of the annotation phase, we had each toxic sentence annotated with information well-grounded in the scientific literature about intimate partner violence. An example of a toxic sentence that reveals IPV is:

> *"Se sono così geloso è perché ti amo e ci tengo a te."* (*"If I'm so jealous, it's because I love you and care about you."*, in English)

That sentence has been annotated in the dataset as follows:

- type of violence: `physical`
- type of behaviour: `psychological aggression`
- aggressive communication: `no`

An example of a toxic sentence that reveals CIPV is:

> *"Se non hai nulla da nascondere e c'è fiducia tra di noi, dammi le tue password"* (*"If you have nothing to hide and we trust each other, give me your passwords"*, in English)

which has been annotated in the dataset as follows:

- type of violence: `cyber`
- type of behaviour: `cyber stalking, monitoring, and control`
- aggressive communication: `yes`
- type of aggressive communication: `attack on the person`

In order to understand the difficulties of the annotation task from the human point of view, we used the Cohen's Kappa score to measure the level of agreement between the annotators who classified a sentence as an example of cyberviolence or not. The observed value, 0.503, revealed moderate agreement. We measured also Cohen's Kappa score on the agreement on the type of communication (aggressive or not). The observed value, 0.281, revealed fair, acceptable agreement, but at the same time showed that it is more difficult to recognize the use of aggressive language when a bad word is not explicitly used. The annotations will be exploited by a Large Language Model to generate explanations and raise awareness of the violent behaviour. In the next subsection, we describe how annotations are turned into examples for few-shot prompting.

3.2. Few-Shot Prompting to explain toxicity in conversations

The two toxic sentences mentioned in the previous subsection were used for few-shot prompting. The corresponding annotations were turned into natural language explanations used to build prompts for in-context learning. For instance, the explanation for the previous sentence

> *"If you have nothing to hide and we trust each other, give me your passwords"*

is: *"The sentence is toxic because it is an example of* `cyber violence`. *The behaviour falls in the category* `cyber stalking, monitoring, and control` *since the aim is to obtain information on the partner's life and establish a dynamic of control in the couple. Furthermore, the* `communication is aggressive` *because it reveals the intimidating intent of attacking the partner to violate his or her privacy."*

A 2-shot prompt is built by including:

- the description of the task: "Given a sentence from a conversation between partners in an intimate relationship, say whether it is a case of cyber or other types of violence and explain the reasons why the sentence expresses toxic language. The explanation should be similar to the examples below. (Data una frase di una conversazione tra partner in una relazione sentimentale, dire se è un caso violenza cyber o di altro tipo e spiegare i motivi per cui la frase esprime un linguaggio tossico. La spiegazione deve essere simile a quella degli esempi che seguono.)";

- 2 training toxic sentences, one example of IPV and one example of CIPV, with corresponding explanations;
- 1 test toxic sentence (without explanation) for which we want the model to generate an explanation.

The 0-shot prompt contained only the task description and the test toxic sentence. In other words, the annotations associated with a toxic sentence are the canvas for writing the explanation included in the prompt. In both the 0-shot and 2-shot settings, we used only one generation per prompt, as the model produced consistent outputs despite the inherent stochasticity of the models.

3.3. Experimental Session

The main aim of the experiment was to assess whether the annotations are actually useful in training the model to give scientifically based explanations, even with few examples. The model adopted in the experiment was: LLaMAntino-3-ANITA-8B [10, 11][1]. Therefore, we want to assess whether the models learn how to perform the task by providing just two examples. Two research questions were issued:

1. **RQ1**: is the model able to recognize toxic sentences, i.e. what is the classification accuracy of the model?
2. **RQ2**: Are the explanations provided with 2-shot prompting similar to the "gold standard" provided by experts?

As baseline methods, we adopted:

1. The same model, but prompted only with the task description and the toxic sentence to be explained ("zero-shot prompting").
2. ChatGPT 3.5[2], with both 2-shot and 0-shot prompting.

We choose to compare our model along with ChatGPT 3.5 to evaluate whether any positive effects found on the explanations given by LLaMAntino are confirmed by at least one other model. We select a total of 40 test instances, 20 for IPV and 20 for C-IPV.

The experimental protocol was:

1. give LLaMAntino-3-ANITA-8B and ChatGPT 3.5 20 C-IPV toxic sentences in a 0-shot and a 2-shot setting and record the explanations;
2. give LLaMAntino-3-ANITA-8B and ChatGPT 3.5 20 IPV toxic sentences in a 0-shot and a 2-shot setting and record the explanations.

After the generation step, for each test toxic sentence, we had 4 explanations: LLaMAntino-3-ANITA-8B 0-shot, LLaMAntino-3-ANITA-8B 2-shot, ChatGPT 3.5 0-shot, ChatGPT 3.5 2-shot. As for RQ1, results of classification accuracy are reported in Tables 1-4.

The main outcome is that we observed a significant improvement in the accuracy of both models when using 2-shot prompting for recognizing C-IPV. As regards IPV, both models, even with just 0-shot prompting, correctly classified almost all the testing instances: 18 out of 20 for LLaMAntino-3-ANITA-8B 0-shot, 19 out of 20 for ChatGPT 3.5 2-shot. This is a clear indication that the annotations are mainly useful for C-IPV recognition. Another interesting outcome concerns the percentage of C-IPV sentences for which LLaMAntino-3-ANITA-8B does not recognize the presence of violence at all. With 0-shot prompting, this result is 35% (7 out of 20), while with 2-shot prompting it drops to 15% (3 out of 20). We believe that is an important result because it shows that when the model makes an error in classifying C-IPV, it at least acknowledges the presence of violence, even if it does not capture the technological aspect of the abuse.

	ANITA-0shot

	IPV	0,666	0,098
ChatGPT 2-shot	C-IPV	0,855	0,248
	IPV	0,849	0,218

Table 5
Average BERTScore and ROUGE scores obtained by the models.

we used two metrics: BertScore [12] and ROUGE [13], in order to assess both semantic and syntactic similarity among generated explanations and the "gold standard" given by the explanations built according to the codebook. For each testing sentence, we computed BertScore $Bert_0$ between the explanation provided by LLaMAntino-3-ANITA-8B 0-shot and the codebook explanation. Then, we computed BertScore $Bert_2$ between the explanation provided by LLaMAntino-3-ANITA-8B 2-shot and the codebook explanation. We compared $Bert_0$ with $Bert_2$ in order to choose the most similar explanation to the "gold standard". Results obtained as the average of the BertScore and ROUGE metric are shown in table 5. We observed that for both C-IPV and IPV, all the explanations given by LLaMAntino-3-ANITA-8B 2-shot were better than those given by 0-shot prompting. The same result was observed for ChatGPT 3.5. The ROUGE metrics gave similar results: for both C-IPV and IPV, in 90% of testing sentences, the explanations given by LLaMAntino-3-ANITA-8B 2-shot were found to be more similar to the "gold standard" than those given by LLaMAntino-3-ANITA-8B 0-shot. For ChatGPT 3.5, the 2-shot prompting gave always better results than 0-shot prompting. These results led us to give a positive answer to RQ2. In general, even with 2-shot prompting, our model was able to provide explanations similar to those given by psychology experts.

The significant improvement in explanation quality when using 2-shot prompting, as measured by both BertScore and ROUGE, is a crucial finding in this study. It suggests that the LLM can learn and adapt to the task of generating explanations for abusive language, given a small set of examples or prompts. This adaptability is a key characteristic of a well-designed LLM, as it enables the model to generalize and improve its performance on a specific task with limited training data. The results also raise important questions about the potential of LLMs in applications where they are expected to provide nuanced and accurate explanations of complex phenomena, such as abusive language. While LLaMAntino-3-ANITA-8B 2-shot was able to generate explanations that were deemed more accurate by the metrics, it is essential to note that the quality of the explanations was still not on par with those provided by human experts in the field of psychology. This study's findings have implications for the development of LLMs in the domain of natural language processing, particularly in applications where the model's output is expected to be accurate, informative, and free from biases.

4. Conclusions and Future Work

In this paper, we presented our proposal to adopt our LLM to identify and describe toxic elements in discussions concerning teenage relationships. In particular, the LLM was used to generate explanations that describe why a sentence, in the context of an intimate relationship, can be toxic and constitute abuse. The main outcome of our preliminary investigation is that, even with few-shot prompting, the LLM learns to provide good explanations that adhere to a standard provided by expert psychologists. By exploiting LLMs' proficiency in processing and understanding human language, our approach seeks to go beyond just detection, aiming to grasp underlying motivations and factors contributing to the emergence of harmful behaviours. In future works, we intend to perform fine-tuning steps to better adapt LLMs to the specific task at hand. We also plan to investigate how different pre-training techniques and architectures can be leveraged to enhance model performance. Supervised fine-tuning [14], for instance, is a technique that can be employed to adapt the LLM to a specific task, such as generating explanations for abusive language, by using a labelled dataset. This approach can help the model to learn from its mistakes and to correct its biases, ultimately leading to improved performance. In the context of our study, supervised fine-tuning could be used to train the LLM on a dataset of abusive language explanations, to reduce the model's error rate and increase the quality of its responses. Direct Preferences Optimization (DPO) [15] is another strategy that can be used to improve the performance of the LLM. DPO is a technique that allows the model to be trained directly on a set of user-provided preferences, such as the quality of the explanations it generates. This approach can be particularly effective in domains like abusive language, where the quality of the explanations is critical to ensure that the model does not perpetuate harmful biases. To ensure the effectiveness of our approach, we intend to confront our methodology with other models and incorporate further annotations to enhance the robustness and effectiveness of our methodology. This involves comparing the performance of our LLMs with other state-of-the-art models. Moreover, thanks to the collaboration with expert psychologists who are experts in the field to explore the application of Chain-of-Thought prompting techniques.

A. Explanations

An example of explanations given by the human expert and the selected models is the following.

Initial Sentence: He asks for my cell phone to see who I am talking to.

LLaMAntino-3-ANITA 0-shot: Anita at your disposal! After analyzing the sentence, I can say that this is not a case of cyber violence, but rather an example of control and jealousy in a dating relationship context. The sentence expresses toxic language for the following reasons: Controllism: the request to see who you are talking to (or, in this case, communicating with via cell phone) is an attempt to control the other person's private life, violating the right to intimacy and autonomy; Jealousy: the request is likely motivated by strong anxiety and fear of losing the relationship or being betrayed, which may be a sign of insecurity and lack of trust in the relationship itself; Restriction of freedom: the request to see the cell phone is an attempt to restrict the other person's freedom to act and communicate, creating an atmosphere of fear and subordination. In general, toxic language in a dating relationship context can manifest itself in several forms, including control, threat, coercion, denigration, and can be a sign of a larger problem in the relationship.

Chat-GPT 0-shot:The phrase "He asks for my cell phone to see who I am talking to" could be considered a sign of toxic behavior within a romantic relationship. This type of request indicates controlling behavior and invasion of privacy by one of the partners. That is why this phrase can be interpreted as a case of cyber or other violence: 1. **Privacy invasion**: The request to check someone's cell phone implies a lack of trust and a desire to monitor the person's private interactions. This can create an environment in which the controlling partner exercises excessive dominance over the other person's life and decisions. 2. **Manipulation and control**: This behavior may be part of a larger pattern of emotional manipulation and coercive control. Asking to see who the partner is talking to can be used to exert psychological pressure, create guilt, or isolate the person from other social ties. 3. **Sign of jealousy and insecurity**: The request to see the cell phone may stem from the partner's feelings of jealousy or insecurity. However, turning these emotions into controlling behavior is unhealthy and may indicate a lack of respect for each other's autonomy and privacy. In summary, even if the sentence seemingly expresses only a request for information, the emotional and relational context in which it is placed may reveal toxic dynamics. It is important to consider the broader context of the relationship and assess whether there are signs of control and manipulation that may harm the emotional and psychological well-being of the person involved.

LLaMAntino-3-ANITA 2-shot: The sentence to be classified is: He asks for my cell phone to see who I am talking to. Explanation: This sentence is toxic because it expresses an example of cyber stalking violence. It expresses unwarranted and threatening control toward one's partner, demanding access to one's privacy space, in this case the cell phone, and manifesting an insistence on checking on one's partner's activities, with an attitude of suspicion and control.

Chat-GPT 2-shot: This sentence is an example of cyber violence. It expresses controlling and intrusive behavior toward the partner, attempting to justify the request for phone access with an alleged need for transparency and trust in the relationship. However, the way it is phrased implies an assertion of power and control over a partner's private life, emphasizing a possessive attitude that does not respect personal boundaries.

Explanation: This phrase is toxic because it indicates a violation of privacy and excessive controlling behavior. The partner is attempting to impose his or her dominance over the other's private life by demanding access to the phone to monitor personal communications. This behavior can lead to feelings of insecurity and a loss of autonomy for the person being controlled, undermining mutual trust and creating an environment in which privacy is not respected. In addition, the request could imply a veiled threat: if the partner does not grant access, it could be seen as a sign of lack of trust or guilt, creating a damaging cycle of emotional coercion in the relationship.

Taking decisions in a Hybrid Conversational AI architecture using Influence Diagrams

Roberto Basile Giannini[1,2,†], Antonio Origlia[1,2,*,†] and Maria Di Maro[1,2,†]

[1] Dept. of Electrical Engineering and Information Technology, University of Naples Federico II

Abstract

This paper explores the application of the Influence Diagrams model for decision-making in the context of conversational agents. The system consists of a *Conversational Recommender System* (CoRS), in which the decision-making module is separate from the language generation module. It provides the capability to evolve a *belief* based on user responses, which in turn influences the decisions made by the conversational agent. The proposed system is based on a pre-existing CoRS that relies on Bayesian Networks informing a separate decision process. The introduction of Influence Diagrams aims to integrate both Bayesian inference and the dialogue move selection phase into a single model, thereby generalising the decision-making process. To test the effectiveness and plausibility of the dialogues generated by the developed CoRS, a dialogue simulator was created and the simulated interactions were evaluated by a pool of human judges.

Keywords

Conversational AI, Decision-making, Influence Diagrams

1. Introduction

In recent years, the success of neural networks has generated significant enthusiasm among professionals in the field of artificial intelligence as well as the general public. Various applications, such as speech recognition, computer vision and even interactive conversational models like ChatGPT, have increasingly engaged users, inevitably shaping their perception of AI. This perception can have various implications, even within the scientific community. Attributing human-level intelligence to the tasks currently accomplished by neural networks is questionable, as these tasks barely rise to the level of abilities possessed by many animals [1]. Neural-based approaches to artificial intelligence have been criticised because of the limitations that are intrinsic to purely associative methods. One notable analysis of the problems that come when considering linguistic material generated without a real understanding of the *meaning* of what is being said is found in [2], which highlights that, because of the way it is generated, content produced by GPT models adheres to at least one formal definition of *bullshit*. The fundamental problem with these models is that, while they are trained to capture surface aspects of communication, they are never exposed to the *reasons why* language is produced. When they output the most probable continuation of the provided prompt, they leave entirely to the human reader the task of interpreting what the produced output *might have meant*.

From a linguistics point of view, within the framework of Austin's speech act theory [3] "saying something" equals "doing something"; the act of producing a sentence (*locutive act*) is fuelled by an intention (*illocutive act*) that produces changes in the world (*perlocutive act*). This classic view of the act of speaking highlights that conversation is a form of intervention in the world: it is put in action to alter in some way the conversational context. This same position is also found in the recent literature about the role of causality in artificial intelligence. Judea Pearl's Ladder of Causation [4] puts *intervention* capabilities on the second level of the ladder, characterised by the verb *doing*, as in Austin's seminal work. In this work, machine learning capabilities are limited to the first step of the Ladder, concerned with *observational* capabilities, leaving interventional ones out.

From this perspective, a conversational agent that produces language *motivated* by the achievement of a goal, thus modelling a *raison d'exprimer*, is an agent capable of using language with interventional purposes, which can be placed on the second step of the Ladder of Causation. A tool that aims to define conversational agents according to this philosophy is the Framework for Advanced Natural Tools and Applications with Social Interactive Agents (FANTASIA) [5], an Unreal Engine[1] plugin designed to develop embodied conversational agents. Built upon the functionalities offered by the tool, the FANTASIA Interaction Model follows these main principles: **Behaviour Trees** (BT) [6] are used to organise and pri-

oritise dialogue moves; **Graph Databases** (i.e., Neo4j [7]) are used for knowledge representation and dialogue state tracking; **Probabilistic Graphical Models** (PGM) are used for decision making; LLMs are used to verbalise the decisions taken by PGMs.

The latest results obtained using FANTASIA, presented in [8, 9], used a decision system based on Bayesian Networks to estimate probability distributions over ratings for users of a movie recommender system. The decision about the dialogue move was taken by a rule-based system taking into account these estimates. In this work, we further develop the approach by generalising the decision process using a single model, an Influence Diagram (ID) [10]. IDs represent an extension of BNs [11] since, in addition to probabilistic nodes, they also contain:

- *Decision nodes*, which represent decision points for the agent and which may be multiple within the model.
- *Utility nodes*, which represent utility (or cost) factors and which will drive the agent's decisions, since the objective will be to maximise the utility of the model.

Consequently, in addition to the modelling of probabilistic inference problems, the use of IDs also enables the modelling and solving of decision-making problems, in accordance with the criterion of *maximum expected utility*. In this way, the ID encapsulates both the Bayesian inference and the decision phase in a single, more flexible and elegant model.

2. Original system

The original system on which the proposed system is based was presented in [8, 9]. This system is a CoRS with argumentative capabilities based on linguistic and cognitive principles. From a design point of view, the original system followed the FANTASIA Interaction model and the PGM of choice were Bayesian Networks (BN), implemented using the aGRuM library [12].

From the knowledge representation point of view, a graph database is adopted to host information derived from Linked Open Data (LOD) sources. For the purposes of this case study, the movies domain will be considered. The knowledge base is constructed by collecting data from different sources and enriched using graph data science techniques, which are employed to capture latent information. The procedure is described in [13]. The main entities of the knowledge base are represented by the labels MOVIE, PERSON and GENRE, which are interconnected by appropriate relationships (such as HAS_GENRE, WORKED_IN, and so on). Additionally, information from the MovieLens 25M[2] dataset is integrated into the database. A MOVIELENSUSER node is created for each user in the dataset, and a RATED relationship is established between the MOVIELENSUSER node and a MOVIE node for each reported rating in the dataset. In addition to a number of basic properties such as name, year of birth and ratings, MOVIE and PERSON nodes are characterised by authority attributes and hub scores calculated by means of the HITS algorithm [14]. As discussed in [9], these network analysis measures help model cognitive characteristics that are relevant for the selection of *plausible arguments* [15]. Finally, the graph database is used to store a *dialogue state graph* which tracks the agent's relationships with the knowledge domain and other agents, including humans. This graph can be modified by the agent through speech acts in order to evolve it towards graph patterns that the agent identifies as goal patterns, i.e. a desired configuration of the dialogue state. In this way, the graph database will be interrogated by the CoRS by extracting a relevant sub-graph taking into account the knowledge base and belief of the system evolved during the conversation.

In the reference system, the decision-making level involves a BN dynamically generated on the basis of the extracted relevant sub-graph. In particular, in the case of Movie Recommendation, the actors, films and genres are nodes of the BN, while the (oriented) relations between them represent the causal relations. Initially, each node is initialised by specifying its own CPT, which can either be pre-calculated or derived from parent nodes. This network is used to adjust the exploitation/exploration cycle, typical of recommendation dialogue [16], by taking into account the data extracted from MovieLens (soft evidence) and the feedback gathered through the dialogue with the user (hard evidence). This way, the BN can represent the probability of each movie and each feature to be of interest for a user, after applying Bayesian inference. Based on the information extracted from the Bayesian network, a module outside the PGM is responsible for the decisions taken. Specifically, the system decides whether to recommend a candidate item (*exploitation move*) or, in the case of non-recommendation, to ask the most useful question (*exploration move*), based on the criteria considered in [8]. In the case of exploitation moves, in addition to item recommendation, argumentation is provided based on the three most useful features, whose utility is calculated as the harmonic mean of four (normalised) parameters related to cognitive properties [15].

3. Proposed system

The proposed system based on IDs replicates part of the reference strategy: the aim of this work is to provide a first test of the capabilities of the IDs to handle the problem so we concentrate on the fundamental steps of

[2] https://grouplens.org/datasets/movielens/

Table 1
The capabilities of the original system and the ones replicated in the new system using IDs (in bold).

Tracked beliefs	Question types	Question targets	Scores
Wants	**Polar**	Movie	Hub
Likes	Open	**Actor**	Authority
Knows		Genre	**Entropy**

the original strategy. Table 1 shows the characteristics of the reference system, highlighting the ones reproduced by the proposed system. The approach is inspired by the system presented in [17].

3.1. ID for Movie Recommendation

The current system is based on the previously introduced knowledge base and uses the same principles for the extraction of the relevant sub-graph. The decision-making core of the system is represented by the ID, again dynamically constructed from the relevant sub-graph. In particular, the construction of the ID is divided into two parts. The first part concerns the recommendation branch, along which a decision is made whether or not to make an exploitation move. For each movie, whether a candidate or a secondary film, an uncertainty node is generated, and the same is done for the individuals who are part of those films. In particular, the nodes related to films will be median nodes of the nodes related to the individuals who worked on that film. In addition, the query used to extract the relevant sub-graph returns a collection of votes assigned to films, which is used to apply soft evidence to each of the movie nodes (both target and secondary). For each candidate film, an *EST(Movie)* uncertainty node related to the estimator operating on that film is contextually generated. Indeed, within an ID it is possible to take into account the *truth* (the best movies in this case) and the estimate on the truth (the estimators on the best movies). Furthermore, the ID also takes into account the uncertainty of the estimator if the CPT of the EST nodes is initialised using the relative confusion matrix. As shown in Fig. 1, this information together will influence the system's decision on a potential exploitation move. Which decision will be made about the *Recommendation* node will depend on the utility function governing the goodness of possible choices. This function defines the utility value of not recommending, i.e. the utility of not performing an exploration move:

$$U_{NoRec} = U_{max} \cdot \frac{1}{1 + e^{nTurn-5}} \in [0, U_{max}] \qquad (1)$$

where U_{max} represents the maximum utility that can be given to a choice, while the second contribution is given

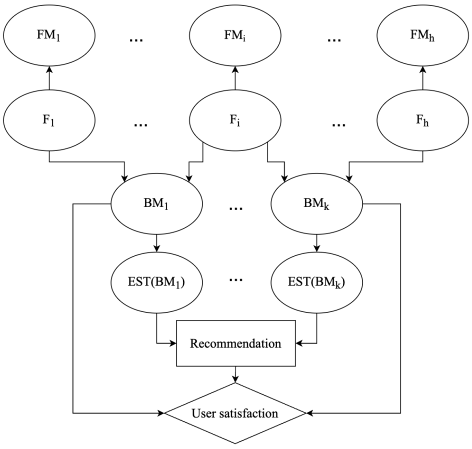

Figure 1: Generic ID structure related to the recommendation branch. *BM* nodes represent best movies, *F* nodes represent features and *FM* nodes represent feature movies, i.e. secondary movies. The topology follows the causal relationships that coexist between the entities involved.

by a sigmoid that takes as input the number of questions asked by the system. The objective is to have a utility of not recommending that is maximum at the beginning of the dialogue and that as the number of questions asked increases, the utility decreases, with an increasing rate of decrease. In this way, the system will be inclined to always ask the user at least one question and never to exceed a certain number of questions. Thus, U_{NoRec} represents the system's indecision with regard to the possible recommendations it can give at that moment, an indecision that is expected to be greatest at the beginning of the dialogue since the system does not yet have any information about the user. In addition to the utility of not recommending, the function defines the utility of recommending a particular candidate movie m:

$$U_m = (2U_{max} \cdot r_m^2) - U_{max} \in [-U_{max}, U_{max}] \qquad (2)$$

where r_m represents the rating assigned to the movie candidate m normalised between 0 and 1. In this way, the utility of the recommendation will be linked to the true rating of the candidate movie and its value will be negative for low ratings and positive for high ratings. Thus, recommending an item with a low true rating will be punitive compared to an item with a high true rating. The objective is to prioritise the recommendation of movie candidates with higher true ratings and to disfavour the recommendation of those with low true ratings, possibly by preferring an exploration move.

The second part of the process concerns the exploration branch, during which an exploration move is made. The underlying assumption is that if the utility of "not recommending" is greater than that of recommending

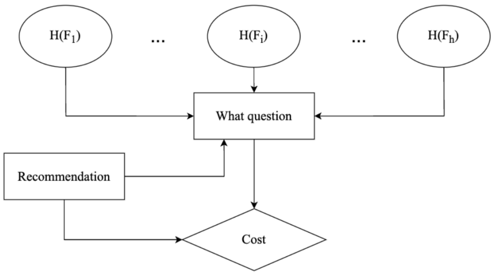

Figure 2: Generic ID structure related to the exploration branch. For each feature (actor, director, etc.), an uncertainty node *H* is generated, representing its entropy. These nodes, together with the previous decision to recommend or not to recommend, condition the choice of question to ask, which has a cost.

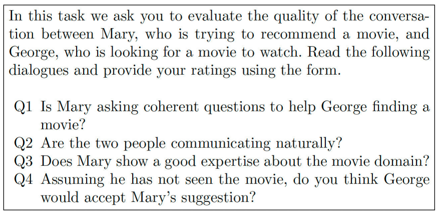
a movie, then a question must be asked. In particular, the most useful question must be chosen. In this case study, as anticipated, the exploration only involves the entropy of the features, not taking into account other aspects of the features and other nodes. In particular, for each feature f extracted from the database, an uncertainty node *H(f)* is contextually created. Each node H represents the entropy of the related feature. A decision node *What question* is in charge of deciding which question should be asked, and depends on both nodes H and the decision node *Recommendation*, generating a decision sequence starting from the latter. The idea is that the choice of question must depend both on the entropy of the features that can be chosen and on the decision that was made at the time of the recommendation, i.e. the decision to perform an exploitation or an exploration move. Among the possible choices of *What question*, in fact, there is also a *No question*, which only makes sense to choose in the case of an exploitation move. Finally, a *Cost* utility function represents the utility of the *What question* choice. Fig. 2 shows the structure of the exploration branch in a generic form. Tab. 2 shows the cost associated with each decision sequence that the system is capable of undertaking. In particular, the highest cost, equal to -100, is applied to those decision sequences that are to be avoided. Conversely, the lowest cost, equal to 0, is applied to the case where the system does not ask questions. A variable cost, between -100 and -1, is calculated in the case where the system decides not to recommend and ask a question about an actor. The magnitude of this cost will depend on the entropy value of the relevant uncertainty node. The higher the entropy, the lower the cost of the corresponding question. The idea is to collect evidence on the uncertainty nodes on which the model's uncertainty is most concentrated, as the system's objective is to lower the model's entropy level before making a recommendation.

Table 2
The cost function the system considers when deciding to ask questions.

Recommendation	What question	Cost
Movie	Actor	-100
Movie	No question	0
No	Actor	$-99 \cdot (1 - H(f)) - 1$
No	No question	-100

3.2. Simulation

The current system was tested by simulating a dialogue between the system and a MovieLens user whose answers are derived from ratings recorded in the dataset. At the beginning of the conversation, the agent has no information about the user and for this reason the user immediately specifies the preferred genre. This information is derived by searching the database for that genre for which the average rating of that particular user is the highest. All following questions are polar questions and concern PERSON type features. Again, the answer is derived by considering the ratings given by the user to the ARGITEMs associated with that feature. Once the genre is known, a positive belief *likes* is created that associates the user with the preferred genre and at this point the database is queried by extracting the best three, the related features and the secondary films. If, from the ID, the best action is to recommend, the system proposes one of the candidate films to the user; otherwise, if the best action is not to recommend, the system asks the most useful question. If the user's answer consists of a positive or negative preference, this involves adding evidence in the system, adding the user's stance on that feature to the database and reconstructing the ID from a dataframe extracted with the same query used at the beginning of the dialogue. The idea is that by keeping track of the user's stances collected as the system asks questions, it is possible to extract target movies that are more consistent with the user's preferences. When a film is recommended, the system also provides arguments to support its choice, consisting of a selection of the most important features related to the recommended film, thus implementing Argumentation-based dialogue [18]. The dialogue provided by the simulation is constructed by using templates causing the generated conversation to sound unnatural. For this reason, these template-based dialogues were reformulated by ChatGPT-4 to make the conversation more natural, using the following prompt: *Rephrase the following dialogue to make it sound more natural. Keep the structure and only change the sentences.*



In this task we ask you to evaluate the quality of the conversation between Mary, who is trying to recommend a movie, and George, who is looking for a movie to watch. Read the following dialogues and provide your ratings using the form.

Q1 Is Mary asking coherent questions to help George finding a movie?
Q2 Are the two people communicating naturally?
Q3 Does Mary show a good expertise about the movie domain?
Q4 Assuming he has not seen the movie, do you think George would accept Mary's suggestion?

Figure 3: Survey task and questions posed to participants for each dialogue.

4. Experimental setup

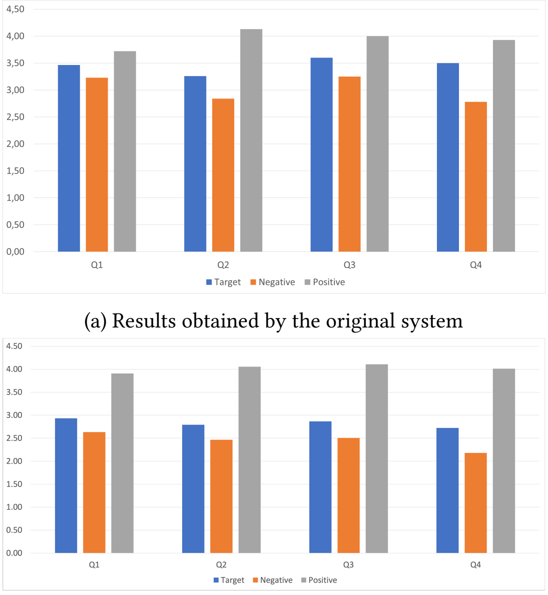
The experimental phase followed the approach used in [8]. The approach involves recruiting 20 participants via the Prolific[3] portal who were asked to complete a survey on the Qualtrics[4] platform that involves the evaluation of 20 dialogues divided into three types:

- Five dialogues taken from INSPIRED Corpus [19], a dataset of human-human interactions for Movie Recommendation. These dialogues represent the positive subset of the control group.
- Five system-generated dialogues where both the extraction of candidate films and the choice of supporting features are random, independent of system belief. These dialogues represent the negative subset of the control group.
- Ten dialogues generated by the system using the presented strategy, which represent the target dialogues.

Fig. 3 shows the survey task with the four questions asked to the participant for each dialogue, for which the participant gives a score between 1 and 5. Q1 refers to the consistency of the questions asked during the exploration move, in order to understand whether the features are selected correctly during the dialogue. Q2 and Q3 refer to the naturalness of the dialogue, with the latter referring to the user's perception of the recommender's level of expertise. Finally, Q4 refers to the quality of the features chosen to support the recommendation. In conclusion, the participants were native English speakers living in the UK or US and they were compensated according to the average hourly wage of their home country.

5. Results

Fig. 4 shows the scores obtained by the current system based on ID for each question blue(b), compared with the scores obtained by the original system based on BN (a). In both instances, the scores obtained by the target dialogues are higher than those obtained by the negative dialogues and lower than those obtained by the positive dialogues. In particular, the difference between target and negative dialogues is more pronounced on Q4, which is an indicator that the supporting arguments make the recommendation plausible.



(a) Results obtained by the original system

(b) Results obtained by the proposed system

Figure 4: Comparison between the results obtained by the original system based on BN (a) and by the proposed system based on ID (b). The obtained results show higher scores than the baseline represented by the negative dialogues but not as high as the ones obtained by the original system. The difference between the two systems is expected as only part of the original strategy is replicated in this work, excluding a series of significant aspects, such as asking open questions and discussing films as well as the people who work in them.

As an objective measure, during the generation of the dialogues for each round, the average normalised entropy of the ID was recorded, calculated as the average of the normalised entropy among all variable nodes of the model. In Fig. 5 it can be observed that a) during a target dialogue the average entropy of the model decreases, in contrast to the case where b) the dialogue is random and the average entropy of the model does not tend to decrease. The first scenario is compatible with the idea that the system accumulates information as the dialogue progresses, in accordance with the strategy adopted. In the second scenario, on the other hand, the ID is regenerated at each turn from randomly extracted candidate films, making it unlikely that the new extracted features contribute in accumulating coherent information.

To further analyse the data concerning the synthetic di-

alogues, we use a Cumulative Link Mixed Model (CLMM) [20] with Laplace approximation, [21]. This model accommodates random effects attributable to individual participants or specific stimuli, treating them as blocking variables and assesses the likelihood of observing high values on the Likert score in relation to the independent variable (i.e., dialogue type). The test revealed that the association between the occurrence of high scores, in general, is very strong ($p < 0.001$) for both target and positive dialogues and, as expected, absent for negative values. This result is stronger with respect to the results obtained in [8, 9], where only a weak association was observed. There are multiple aspects that contribute to this result, in our opinion. First of all, in the original work, the p-value was already very close to the strong significance threshold ($p = 0.0144$), so the effect was only technically considered *weak* even in that case. Also, there is a chance that the simplified situation may have harmed negative dialogues more than the other two categories. As a final remark, however, the IDs have indeed made the decision process more uniform and flexible, given the introduction of utility functions and a unified framework for decision making. The quality improvement of the decision process management, especially in deciding when to recommend, given the available arguments to support the position has improved the system even in its basic form.

6. Conclusions & future work

The results obtained indicate that the implementation of a knowledge graph exploration strategy based on the ID is more effective than a random strategy. This conclusion is further supported by objective measures, including the system's entropy, which decreases as the system accumulates information during the dialogue before making a recommendation. It is therefore possible to generalise within an ID a decision-making process that, in the original system, was implemented by a module external to the probabilistic model. The results achieved in this case were lower than the ones of the original system, but this was expected as only part of the original strategy was replicated. Future work will cover the implementation of the missing functionalities and the deployment of the system in the Unreal Engine, as the technology to implement IDs has been integrated in the FANTASIA plugin. We will also investigate the possibility of integrating the argument selection process in the ID to fully support Argumentation Based Dialogue.

Acknowledgments

This work is supported by the Supporting Patients with Embodied Conversational Interfaces and Argumentative Language (SPECIAL) project, funded by the University of Naples on the ”Fondi per la Ricerca di Ateneo” (FRA) program (CUP: E65F22000050001)

KEVLAR: the Complete Resource for EuroVoc Classification of Legal Documents

Lorenzo Bocchi[1,†], Camilla Casula[2,†] and Alessio Palmero Aprosio[1,*,†]

[1] *University of Trento, Italy*
[2] *Fondazione Bruno Kessler, Trento, Italy*

Abstract

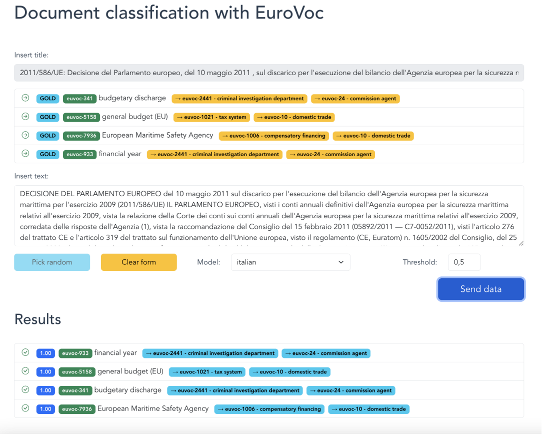
The use of Machine Learning and Artificial Intelligence in the Public Administration (PA) has increased in the last years. In particular, recent guidelines proposed by various governments for the classification of documents released by the PA suggest to use the EuroVoc thesaurus. In this paper, we present KEVLAR, an all-in-one solution for performing the above-mentioned task on acts belonging to the Public Administration. First, we create a collection of 8 million documents in 24 languages, tagged with EuroVoc labels, taken from EUR-Lex, the web portal of the European Union legislation. Then, we train different pre-trained BERT-based models, comparing the performance of base models with domain-specific and multilingual ones. We release the corpus, the best-performing models, and a Docker image containing the source code of the trainer, the REST API, and the web interface. This image can be employed out-of-the-box for document classification.

Keywords

EuroVoc taxonomy, multilingual text classification, BERT, web interface

1. Introduction

EuroVoc is a multilingual and multidisciplinary thesaurus that has seen a significant rise in its use and importance in recent years. In particular, the taxonomy used in this thesaurus has become crucial for a number of activities of European Public Administrations, shaping the way information is organized, disseminated, and accessed. Containing over 7,000 concepts, EuroVoc acts as a reliable and efficient indexing system for a vast range of documents, legislative texts, and reports. Due to this, a growing number of governmental institutions around Europe has begun to use it internally for document categorization.



Document classification with EuroVoc

Figure 1: Screenshot of the web interface.

The Spanish government, for instance, has suggested the adoption of EuroVoc since 2014 [1], and has more recently started using it regularly in its official open data portal,[1] and in the *Portal de la Administración Electrónica* website.[2] Similarly, German and French public administrations are following the same strategy, in the `DCAT-AP.de`[3] and `data.gouv.fr`[4] portals respectively. Furthermore, Rovera et al. [2] presented a preliminary study that explores the migration of the *Gazzetta Ufficiale*, the official journal of records of the Italian government, towards the adoption of the EuroVoc taxonomy. Similar initiatives have also grown in other European countries [3, 4].

In this paper we present KEVLAR, Kessler EuroVoc Laws and Acts Repository, which aims at fulfilling a number of purposes.

1. First, we release a collection of more than 8 million documents from EUR-Lex, the European Union's official web portal, which gives comprehensive access to EU legal documents, spanning more than 70 years of EU legislation (1948-2022), and covering 24 languages. Over half of these

[4] https://www.data.gouv.fr/fr/

texts are already tagged with the corresponding EuroVoc concepts.

2. Secondly, we perform a series of experiments for automatic tagging of the documents using the EuroVoc taxonomy, comparing different approaches and language models.
3. Finally, we develop a web interface (see Figure 1) and a REST API that anyone (citizen or public administration) could use both to easily try automatic classification of documents and to integrate such categorization in any systems that might need it.

The models used for the web demo and the release are the best-performing ones we found, as described in Section 5. All the data and tools (the set of documents labeled with EuroVoc labels, the models, and the demo code) are freely available for download.

2. Related work

Several investigations have delved into the categorization of European legislation using EuroVoc labels. Notably, the task can be regarded as Extreme Multilabel Classification, as recognized in Liu et al. [5].

The JRC EuroVoc Indexer, detailed in Steinberger et al. [6], stands as a tool facilitating document categorization through EuroVoc classifiers across 22 languages. However, the dataset used for this tool [7] is limited to documents up to 2006. Their method entails the creation of lemma frequencies and associated weights, linked to specific descriptors referred to as *associates* or *topic signatures* in the research. When classifying a new document, the algorithm selects descriptors from the *topic signatures* exhibiting the highest resemblance to the lemma frequency list of the new document.

Later, You et al. [8] explored the application of Recurrent Neural Networks (RNNs) to extreme multi-label classification datasets, encompassing RCV1 [9], Amazon-13K [10], Wiki-30K, Wiki-500K [11], and an older EUR-Lex dataset from 2007 [12]. Attention-based RNNs proved to be particularly effective, outperforming other methods in 4 out of 5 datasets.

Chalkidis et al. [13] explored diverse deep learning architectures for this task. Among these, a fine-tuned BERT-base model [14] showed the highest performance, achieving a micro-averaged F1 score of 0.732 (considering all labels). Furthermore, they released a dataset consisting of 57,000 tagged documents from EUR-Lex.[5]

One of the most complete contributions to document classification using EuroVoc is PyEuroVoc, outlined in Avram et al. [15]. This study employs various pre-trained BERT models in 22 different languages, which were fine-tuned for the task. The source code in Python is publicly released, but cannot be used out-of-the-box and a known bug[6] may have led to unreliable results.

Some similar recent works on multi-language classification are described in Chalkidis et al. [16], Shaheen et al. [17], and Wang et al. [18]. Outside of the EuroVoc ecosystem, two large-sized legal datasets were released by Niklaus et al. [19, 20] for language model creation.

3. Dataset description

3.1. EUR-Lex

The reference for European legislation is EUR-Lex[7], a web portal that grants users comprehensive access to EU legal documents. It is available in all of the European Union's 24 official languages and is updated daily by its Publications Office. Most of the documents present in EUR-Lex are manually categorized using EuroVoc concepts.

3.2. EuroVoc

EuroVoc's hierarchical structure is organized into three different layers: Thesaurus Concept (TC), Micro Thesaurus (MT, previously referred to as "sub-sector" level), and Domain (DO, previously referred to as "main sector" level). The TC level is the base level, where all the key concepts are found. The documents on EUR-Lex are tagged with labels from this level. Every TC is assigned

[5] https://bit.ly/eurlex57k

[6] https://bit.ly/pyeurovoc-bug

[7] https://eur-lex.europa.eu/

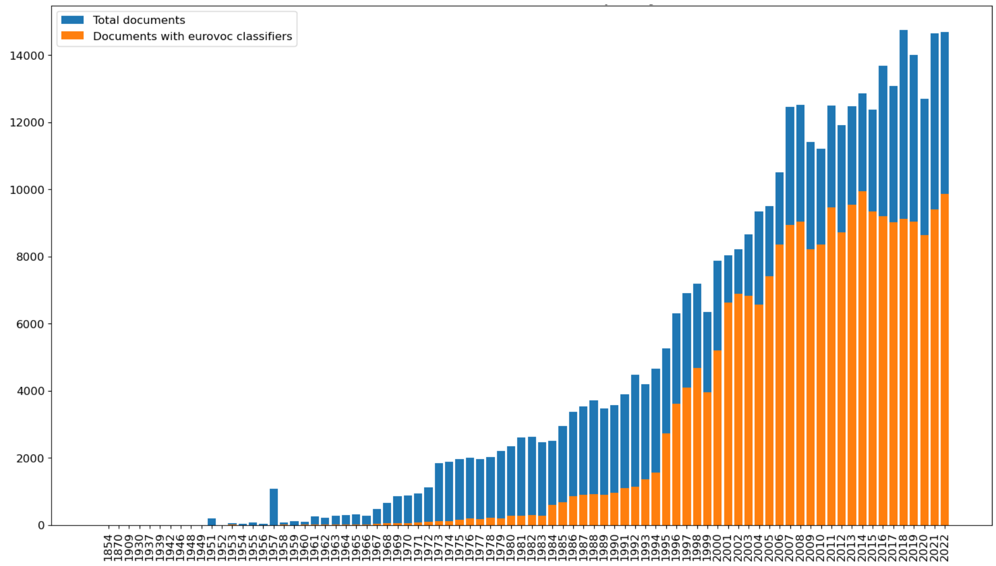

Figure 3: Number of documents per year (with the percentage already tagged with EuroVoc labels highlighted).

to an MT, which in turn is part of a specific DO. For example, the label "Confidentiality"[8] is assigned to the MT "Information and information processing", which belongs to the DO concept "Education and communication". Figure 2 shows a small subset of the EuroVoc taxonomy.

The experiments of this work have been launched on version 4.17 of EuroVoc. It contains 7,382 TCs, 127 MTs, and 21 DOs.

3.3. Dataset collection

KEVLAR was collected by downloading the documents from EUR-Lex. We built a set of tools written in Python that can be customized to obtain different subsets of the data (year, language, etc.).

In total, 8,368,328 documents were collected in 24 languages, 5,158,438 of which are annotated with EuroVoc descriptors, for a total of 32,021,783 tags. On average, 6.2 tags are associated with each document.

After filtering out these documents,[9] around 1.1 million texts with EuroVoc labels are collected.

Figure 3 shows the number of documents per year in English. The blue bars show the total number of documents retrieved for the year, while the orange bars show the number of documents that were labelled and have full text. The reduction is quite significant, especially before the year 2000.

4. Experiments

In this section we provide a detailed account of the experiments conducted on document classification with respect to the EuroVoc taxonomy.

4.1. Deprecated labels and labels frequency

The EuroVoc thesaurus was initially developed in the 1980s and has constantly been updated and revised. Some labels started being used much earlier than others, and some are even deprecated for modern use but are still present in older documents.[10] This means that certain topics could stop being used in the future, potentially resulting in concept being replaced or merged with other existing concepts in future releases of EuroVoc.

Figure 4 shows the total occurrences of deprecated labels on a yearly basis. The result shows that from 2010 the usage of these labels decreased dramatically compared to the previous decade.

In addition to this, in EuroVoc labels assignment there is a strong imbalance in the data. For example, the most frequent label in the Italian documents, "economic concentration" with ID 69, is used more than 13,000 times, while the least frequent ones were assigned to just one document.

[8] http://eurovoc.europa.eu/92

[9] Laws without any EuroVoc concept associated are not useful for our study. Regarding documents available in PDF format only, one could extract the text from them using OCR: this could be done in future work.

[10] https://bit.ly/eurovoc-handbook

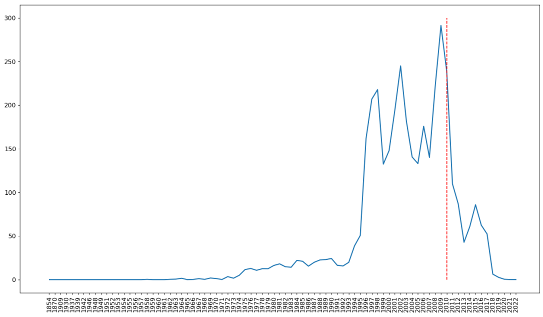

Figure 4: Total occurrence of deprecated labels per year. Marked in red is the year 2010.

4.2. Data filtering

Given the properties of the dataset described above, especially with regards to class imbalance, some filtering was carried out before proceeding with the experiments. First of all, all labels that have less than 10 samples assigned to them were filtered out. This number was kept low in order not to remove too much data and to preserve as many labels as possible. The threshold of 10 samples per label is a common reference, as stated in Chalkidis et al. [13].

Secondly, we filtered examples based on timespan. The percentage of documents with EuroVoc labels (as compared to the number of documents without them) became consistent starting from 2004 (see Figure 3), while a number deprecated labels are still present in documents, especially prior to 2010 (see Section 4.1). In order to obtain a more balanced dataset, in our experiments we consider only documents published in the interval 2010-2022, consisting of 471,801 documents. On average, each law is labelled with around 6 EuroVoc concepts.

After removing all the labels appearing in less than 10 documents, we removed documents that had 0 labels associated with them. This resulted in only 3 documents for each language being discarded. Conversely, more than 2000 labels out of 6079 were removed using this filter. It is interesting to note that even by using such a small threshold relative to the number of documents, around a third of the labels were discarded, meaning that 1/3 of the labels are barely used by the annotators of EU legislation.

4.3. Data Splits

To keep our experiments consistent with previous similar approaches (e.g. Avram et al. [15]), we split the data into train, dev, and test sets with an approximate ratio of 80/10/10, respectively.

In order to make the training reproducible and to avoid a single random extraction that could be too (un)lucky, we repeat the split using three different seeds and a pseudo-random number generator.

Each partition into train/dev/test is done using Iterative Stratification [27, 28], in order to preserve the concept balance.

Unless differently specified, all the results in the rest of the paper refer to the average of the values obtained by our experiments on the three seeds.

4.4. Training

We carry out our experiments using Transformer-based pre-trained language models. In particular, we use both BERT-based [14] and RoBERTa-based [29] models.

These families of language models have an intrinsic limit regarding the maximum number of words present in a text (usually 512), therefore each record of our data is created by concatenating the title and the text and then truncating at 512 tokens. While this might appear to entail a loss of information, Chalkidis et al. [30] have shown that the utilization of sparse-attention mechanisms, as exemplified by models like Longformer [31] and BigBird [32], to extend Transformer-based models for accommodating longer sequences, does not result in performance improvements in EuroVoc document classification.

Chalkidis et al. [33] found that classification tasks over the legal domain obtain better performance when pre-trained on domain-specific corpora. For our experiments, we focus on five major European languages, for which legal language models are available: English, Spanish, French, Italian, and German. For each of them, we test our dataset using: (i) the best-known base model; (ii) a monolingual legal model; (iii) the multilingual legal model proposed by Niklaus et al. [19].[11]. Table 1 lists the models for each language.

4.5. Hyperparameter Choice

After some preliminary experiments in which we experimented with the learning rate suggested in Avram et al. [15], 6e-5, we settled for a learning rate value of 3e-5, which led to better Macro-F1 results in our preliminary trials. Similarly, we increased the number of epochs from 30 to 100, as we noticed that the F1 score began to plateau at around 80 epochs. In each run, we saved the model with the best validation performance out of all the epochs, which typically fell within the last 10 epochs (although the difference between 80 and 100 epochs is relatively minor).

Table 1
Models used for the benchmark languages. Base: [en] Devlin et al. [14], [fr] Le et al. [21], [it] Schweter [22], [es] Cañete et al. [23], [de] Chan et al. [24]. Legal: [it] Licari and Comandè [25], [en] Chalkidis et al. [26], [fr, es, de] Niklaus et al. [20].

5. Discussion

Table 2 shows the classification results in terms of average macro F1 on the test sets of the three splits (see Section 4.3). Columns TC, MT, and DO show the result in terms of Thesaurus Concept (TC), Micro Thesaurus (MT), and Domain (DO), as described in Section 3.2.

In general, the classifiers achieving the best performances are trained on language models based on legal data. With the exception of French, for which the FlauBERT general model yields comparable results to the top legal model, the multilingual model introduced in the work by Niklaus et al. [19] outperforms all other models in the remaining benchmark languages.

Apart from French MT and DO, all the differences between the multilanguage model and the other ones are statistically significant (with a one-tailed t-test at 0.05).

The bottom part of Table 2 reports the performance of the multilingual model on the remaining languages.

6. Release and demo

All the data[12] and models[13] described in this paper are available for download under the CC-BY 4.0.

In addition to the documents, we also release on GitHub the code used to train and evaluate the models.[14]

Given that one of the main objectives of our research is to offer a comprehensive solution for aiding public administrations in document classification, we have also shared the source code for a REST API and a demonstration interface system (see Figure 1), alongside a Docker image for effortless deployment.

While the training phase requires GPUs for optimal performance, the models discussed in this article – accessible through package installation via Docker – can be utilized efficiently with CPU processing. Upon tool installation, users have the flexibility to select the desired languages, allowing only necessary models to be downloaded and loaded into memory.

A running instance of the API and the web demo is available for testing purposes.[15]

7. Conclusions and Future Work

In this paper, we release KEVLAR, an all-in-one solution for performing the document classification task on acts belonging to the Public Administration. We collected more than 8 million documents in 24 languages, compared different BERT and RoBERTa-based models on the classification of documents with respect to the EuroVoc taxonomy, and built an out-of-the-box tool for easily applying the classification to any text.

In the future, we will continue the exploration of novel methods to address this task with potentially better performance, for example using better-performing models or exploiting generation-based solutions.

Title is (Not) All You Need for EuroVoc Multi-Label Classification of European Laws

Lorenzo Bocchi[1,†], Alessio Palmero Aprosio[1,*,†]

[1] University of Trento, Italy

Abstract

Machine Learning and Artificial Intelligence approaches within Public Administration (PA) have grown significantly in recent years. Specifically, new guidelines from various governments recommend employing the EuroVoc thesaurus for the classification of documents issued by the PA. In this paper, we explore some methods to perform document classification in the legal domain, in order to mitigate the length limitation for input texts in BERT models. We first collect data from the European Union, already tagged with the aforementioned taxonomy. Then we reorder the sentences included in the text, with the aim of bringing the most informative part of the document in the first part of the text. Results show that the title and the context are both important, although the order of the text may not. Finally, we release on GitHub both the dataset and the source code used for the experiments.

Keywords

EuroVoc taxonomy, Sentence reordering, Text classification

1. Introduction

The presence of Machine Learning and Artificial Intelligence techniques has become almost ubiquitous in many fields, from hobbyist projects to industrial and government usage. Also inside the Italian Public Administration, there have been efforts to digitize and modernize the processes for more than a decade. In particular, some documents released by the Italian PA suggest the use of EuroVoc,[1] a multilingual thesaurus developed and maintained by the Publications Office of the European Union (EU), that covers a wide range of subjects (law, economics, environment, ...) organized hierarchically. Outside Italy, Portuguese [1] and Croatian [2] communities are making efforts to automatically perform tagging of official regulations using EuroVoc. In addition to that, in 2010 the EU organized in Luxembourg the Eurovoc Conference,[2] in order to facilitate the comprehension and use of the taxonomy.

The classification of a document with respect to the EuroVoc taxonomy has previously been addressed by several studies (see Section 2), since at present the classification of the documentation in the PA is carried out manually, a task that can be very expensive in the long run.

In this context, we concentrate our work on automatically assigning EuroVoc labels to a document, starting from the existing approaches in document and text classification, that use pretrained large language models followed by a fine-tuning phase on a specific task. Unfortunately, these families of language models have an intrinsic limit regarding the maximum number of words present in a text (usually 512). In the case of documents that can be quite large, like legal ones, it is important to try and make sure that the key information about a text is included in the chosen set of words. The previous research deals with this limit by concatenating the title with the raw text, and then clipping it to the limit.

In some countries (such as Italy, see [3]) the title is usually very well formulated and it is very important to correctly classify a document. On the contrary, the text of a law is usually very redundant, and the most representative text is often after a notable sequence of preambles.

Given these premises, we investigate how the previous approaches work on European laws and apply different strategies to create a summarized version of a text by reordering the sentences. The results show that in this specific case, both the title and the context are important, and that the best approach in regulations enacted by the European Parliament is to fill the 512-words limit with as much information as possible.

The paper is structured as follows: Section 2 will expose the related work; Section 3 describes the data; the approach and the experiments are described in Section 4; the results are then discussed in Section 5.

Finally, both the software and the dataset are available for download, as described in Section 6.

2. Related work

There have been a number of studies that explored the classification of European legislation with EuroVoc labels.

JRC EuroVoc Indexer [4] is a tool that allows the categorization of documents with EuroVoc classifiers in 22 languages. The data used is contained in an old dataset [5] with documents up to 2006. The algorithm used involves generating a collection of lemma frequencies and weights. These frequencies are associated with specific descriptors, referred to as associates or topic signatures in the paper. When classifying a new document, the algorithm selects the descriptors from the topic signatures that exhibit the highest similarity to the lemma frequency list of the new document.

The research described in [6] explored the usage of Recurrent Neural Networks on extreme multi-label classification datasets, including RCV1 [7], Amazon-13K [8], Wiki-30K and Wiki-500K [9], and an older EUR-Lex dataset from 2007 [10].

In [11] the authors explore the usage of different deep-learning architectures. Furthermore, the authors also released a dataset of 57,000 tagged documents from EUR-Lex.

There are also other monolingual studies on the topic, that mainly concentrate on Italian [12], Croatian [13], and Portuguese [1].

More recent works on multi-language classification on EuroVoc are described in Chalkidis et al. [14], Shaheen et al. [15], and Wang et al. [16].

3. Dataset

3.1. EUR-Lex

The primary source for European legislation is EUR-Lex[3], a web portal offering comprehensive access to EU legal documents. It is available in all 24 official languages of the European Union and is updated daily by its Publications Office. Most documents on EUR-Lex are manually categorized using EuroVoc concepts.

3.2. EuroVoc

EuroVoc's hierarchical structure is divided into three layers: Thesaurus Concept (TC), Micro Thesaurus (MT, previously known as the "sub-sector" level), and Domain (DO, previously known as the "main sector" level). Each layer contains descriptors for documents, covering a broad range of EU-related subjects such as law, economics, social affairs, and the environment, each at varying levels of detail. The TC level is the foundational layer where all key concepts reside, and documents on EUR-Lex are tagged with labels from this level. Each TC is linked to an MT, which is then part of a specific DO.

The version of EuroVoc used for our studies is 4.17, released on 31st January 2023, containing 7,382 TCs, 127 MTs, and 21 DOs.

3.3. Dataset collection

To collect the documents for our task, we built a set of tools written in Python that can be customized to obtain different subsets of the data (year, language, etc.). In total, after filtering out the documents not tagged with EuroVoc or not containing an easy accessible text (for instance, old documents only available as scanned PDFs), we collect around 1.1 million documents in four languages (English, Italian, Spanish, French).

As a subsequent task, we also removed labels that have been deprecated by the EuroVoc developers throughout the years.[4] Following previous work [11], we also remove labels having less than 10 examples.

Finally, by looking at the data, we see that the labelling became consistent starting from 2004, while many deprecated labels are still present in documents, especially previous to 2010. We therefore consider only documents published in the interval 2010-2022.

The final dataset will consist of 471,801 documents. On average, each law is labelled with 6 EuroVoc concepts. Table 1 shows some statistics about the dataset used.

4. Experiments

In this Section, we describe the experiments performed on the above-described data.

4.1. Data split

To keep our experiments consistent with previous similar approaches [17], we split the data into train, dev, and test sets with an approximate ratio of 80/10/10 in percentage, respectively.

In order to make the training reproducible and to avoid that a single random extraction could be too (un)lucky, we repeat the split using three different seeds and a pseudo-random number generator.

Each partition into train/dev/test is done using Iterative Stratification [18, 19], in order to preserve the concept balance.

Unless differently specified, all the results in the rest of the paper refer to the average of the values obtained by our experiments on the three splits.

Number of EuroVoc labels used before filtering	6,098	6,088	6,098	6,088
Number of EuroVoc labels having less than 10 documents	2,070	2,077	2,070	2,070
Final number of labels	4,028	4,011	4,028	4,018
Removed documents	3	3	3	3

Table 1
Number of documents in English, Italian, Spanish, and French relative to the time interval 2010-2022.

4.2. Methodology

Our models are trained using BERT [20] and its derivatives.

The choice of the best pre-trained model is very important for the accuracy of the classification using the model obtained after fine-tuning. In particular, [21] shows that classification tasks over the legal domain obtain better performance when pre-trained on legal corpora. Nevertheless, in some preliminary experiments, we have tried BERT models pre-trained on various datasets (among them, legal ones of course), but not always the results award models built from legal texts.

Although the difference was not statistically significant, we decided to use these models anyway (from HuggingFace[5]):

- `legal-bert-base-uncased` [22], consisting of 12 GB of diverse English legal text from several fields (e.g., legislation, court cases, contracts) scraped from publicly available resources;
- `bert-base-italian-xxl-cased` [23], the main Italian BERT model, consisting of a recent Wikipedia dump and various texts from the OPUS corpora collection[6] and data from the Italian part of the OSCAR corpus;[7]
- `bert-base-spanish-wwm-cased` [24], also called BETO, is a BERT model trained on a big Spanish corpus[8] that consists of 3 billion words;
- `camembert-base` [25], a state-of-the-art language model for French based on the RoBERTa model [26].

4.3. Basic configurations

The basic configurations consist of using the sole title, the sole text, and the concatenation of the title and the text. Note that, apart from some rare outliers, title length is consistently less than 50 tokens.

4.4. Pre-processing

The text of the laws is preprocessed using spaCy,[9] a Natural Language Processing pipeline that can extract information from texts in 24 languages. In particular, we used it to perform sentence splitting part-of-speech tagging, and named-entities recognition, used to extract content words from the text and perform the selection of the sentences that are used in the task.

4.5. Summarization

Given that the input length for these BERT models is 512 tokens, while legislative texts are usually longer, summarizing the text by using the most important parts of it to make sure it fits in the input was seen as an important step to follow.

As underlined in the Introduction, the text of a law is usually very redundant, and its most representative part is often after a notable sequence of preambles.

Since the limit of 512 tokens is very strong if compared to the usual length of a legal document, we concentrate our summarization effort on reordering the sentences inside a single document so that the most informative part of the text can be brought to the beginning and therefore included in the first 512 tokens.

We use two different approaches to reach the goal: TF-IDF and centroid-based. In both cases, we perform training with the sole text reordered and the concatenation of the title and the above text.

4.5.1. TF-IDF

TF-IDF (Term Frequency-Inverse Document Frequency) is a widely used technique in information retrieval and text mining to quantify the importance of terms in a document within a larger collection of documents. It aims to highlight terms that are both frequent within a document and relatively rare in the overall collection, thus capturing their discriminative power.

The TF-IDF score of a term in a document is calculated by multiplying two factors: the term frequency (TF) and

[5] https://huggingface.co/
[6] http://opus.nlpl.eu/
[7] https://traces1.inria.fr/oscar/
[8] https://bit.ly/big-spanish-corpora
[9] https://spacy.io/

the inverse document frequency (IDF).

Let t be the term and d the document:

$$\begin{aligned} \mathrm{tf}(t, d) &= \frac{f_{t,d}}{\sum_{t' \in d} f_{t',d}} \\ \mathrm{idf}(t, D) &= \log \frac{N}{1 + |\{d \in D : t \in d\}|} \end{aligned}$$

where $f_{t,d}$ is the frequency of term t in document d, and $N = |D|$ is the number of documents in the set D.

Beyond the usual TF-IDF, we also perform a label-based approach, that considers one document for each label, by concatenating all the texts belonging to the laws having that label.

Once all the documents have gone through this process, the TF-IDF matrix is calculated using TfidfVectorizer from the Python package scikit-learn[10] over the content words (see Section 4.4) of the texts.

After obtaining the TF-IDF matrix, the final step is to assign a score to each sentence. For each valid base form, its score is determined from the TF-IDF matrix by selecting the highest value within the corresponding column (which represents a word). These scores are then added to a list for each sentence. Once a sentence is processed, the maximum or average score is calculated ("max" and "mean" in the results). This calculated value becomes the sentence's score. The process is repeated for all sentences in every document.

4.5.2. Centroid

In this approach, described in [27], the centroid of the word vectors in the text is calculated, then a score is assigned to each sentence based on their cosine distance from the centroid. The closer a sentence is to the centroid, the higher the score it will receive. In our approach, we use fastText [28] for word embeddings.

The words used to compute the centroid are those that have been extracted as content words (see Section 4.4) and have a TF-IDF higher than a certain threshold t, which in this case was 0.3. The centroid is computed as the mean of the word embeddings of the previously selected words:

$$C = \frac{\sum_{w \in D_t} E[\mathrm{idx}(w)]}{|D_t|}$$

where D_t is the corpus of words with $\mathrm{tfidf}(w) > t$.

Each sentence in the document gets transformed into a unique embedding representation by averaging the sum of the embedding vectors of each word in the sentence:

$$S_j = \frac{\sum_{w \in S_j} E[\mathrm{idx}(w)]}{|S - j|}$$

where S_j is the j-th sentence in document D.

After obtaining the embedding for the sentence, its score is computed as the cosine similarity between the centroid and the embedding:

$$\mathrm{sim}(C, S_j) = 1 - \frac{C^T \cdot S_j}{||C|| \times ||S_j||}$$

By using the previously described approach, every text was converted into a list of ranked sentences, each with its own score.

4.6. Random

Because of the obtained results (see Section 4.7), we also added two configurations that used a random ordering of the sentences (one concatenated with the title, the other one containing only the randomly ordered text).

4.7. Evaluation

The evaluation of our experiments is performed by using the F1 score, macro-averaged so that each label has the same weight (this metric awards models that perform better on less-represented labels). Since we are dealing with a multi-label classification task, we have to choose between considering always the same number K of results ($P@K$, $R@K$, $F1@K$) or keeping only the labels whose confidence is higher than a particular threshold (usually between 0 and 1). In our experiments, we chose the second approach, since the number of concepts in each document of the dataset is not constant. Given the evaluation performed on the development set, we set that threshold to 0.5.

4.8. Results

Table 2 shows the results of the different configurations in the four languages. The first column contains the description of the experiment, while columns TC, MT, and DO show the result in terms of Thesaurus Concept (TC), Micro Thesaurus (MT), and Domain (DO), as described in Section 3.

5. Discussion

Results show that the best performances are reached when the title is included in the text (see the rows without "not") with the exception brought by the simple use of the text without reordering. An interesting outcome is that the experiment using title+random obtains very good results when compared to the best configurations.

On the contrary, using random text without the title, or using the sole title results in a decrease in global performance.

Table 2
Results of our experiments (macro F_1).

By looking at the statistical significance,[11] we find out that we can split, more or less, the experiments into two big groups: the ones that in the English part of the table have a DO F_1 above 0.80 and the remaining ones that are below 0.79. The exception is the "title-only" configuration, which obtains lower accuracy in all languages and contrasts with the results obtained in a similar previous work applied to Italian laws [3], where the use of the sole title results in an increase in performance with respect to the concatenation between title and text.

By listing the documents where EuroVoc labels are not extracted correctly, it seems that in the European legislation it is quite common to find very generic titles. For instance, the title of the document with ID "CELEX:32011Q0624(01)" is "Rules of procedure for the appeal committee (Regulation (EU) No 182/2011)", from which is very hard to extract relevant information about the topic. One can find other similar documents, such as "Action brought on 2 March 2011 — Attey v Council", title of law with ID "CELEX:62011TN0118".

In general, our experiments show that the classification of European laws obtains the best performance on BERT when all the possible tokens are filled, possibly using the title and some parts of the text. The high accuracy obtained in the experiments performed by randomly reordering the sentences demonstrates that the context is important per se, even when no particular strategies are used to select it.

French results bring significantly lower accuracy: this is not expected and is probably due to the choice of the BERT pre-trained model.

6. Release

The source code for all the experiments (from the retrieval of the documents to the training of the models), the data downloaded from EUR-Lex, and the models are available on the project Github page.[12]

7. Conclusions and Future Work

In this paper, we presented some approaches to perform document classification on long documents, by reordering their sentences before the fine-tuning phase. The best results are obtained when all the 512 tokens allowed in the BERT paradigm are filled, possibly including the title of the law.

In the future, we want to extend this approach to other languages, trying to understand whether the same reordering algorithm leads to some improvement in the classification task. We will also investigate other summarization approaches, or new architectures that rely on Local, Sparse, and Global attention [29] so that longer texts (up to 16K tokens) can be used to train the model.

[11] To calculate statistical significance, a one-tailed t-test with a significance level of .05 was applied to the scores of the five runs, with the null hypothesis that no difference is observed, and the alternative hypothesis that the score obtained with the summarized text is significantly greater than the one with the normal text.

Exploring the Dissociated Nucleus Phenomenon in Semantic Role Labeling

Tommaso Bonomo[1,*], Simone Conia[1] and Roberto Navigli[1]

[1] Sapienza University of Rome, Dipartimento di Ingegneria Informatica, Automatica e Gestionale (DIAG), Via Ariosto 25, Rome, Italy

Abstract

Dependency-based Semantic Role Labeling (SRL) is bound to dependency parsing, as the arguments of a predicate are identified through the token that heads the dependency relation subtree of the argument span. However, dependency-based SRL corpora are susceptible to the *dissociated nucleus* problem: when a subclause's semantic and structural cores are two separate words, the dependency tree chooses the structural token as the head of the subtree, coercing the SRL annotation into making the same choice. This leads to undesirable consequences: when directly using the output of a dependency-based SRL method in downstream tasks it is useful to work with the token representing the semantic core of a subclause, not the structural core. In this paper, we carry out a linguistically-driven investigation on the *dissociated nucleus* problem in dependency-based SRL and propose a novel algorithm that aligns predicate-argument structures to the syntactic structures from Universal Dependencies to select the semantic core of an argument. Our analysis shows that *dissociated nuclei* appear more often than one might expect, and that our novel algorithm greatly increases the richness of the semantic information in dependency-based SRL. We release the software to reproduce our experiments at https://github.com/SapienzaNLP/semdepalign.

Keywords

Semantic Role Labeling, Dependency Parsing

1. Introduction

Within the field of Natural Language Processing, Semantic Role Labeling [1, SRL] is aimed at recognizing the semantic information conveyed by a sentence, more specifically identifying *who* did *what* to *whom*, *when*, *where* and *how* [2]. Over the years, SRL has split into two main annotation formalisms, namely, span-based and dependency-based. The key difference between the two lies in how they identify the roles of a predicate: span-based SRL directly extracts a span of the input text as the argument of a predicate, whilst dependency-based SRL identifies the word that heads the syntactic dependency relation subtree corresponding to the argument span as the argument. Using dependency-based SRL can be beneficial in real-world settings, as i) dependency-based SRL parsers have achieved better results on standard benchmarks, and ii) the identified token can be directly utilized in several downstream tasks, including Coreference Resolution [3], Opinion Role Labeling [4, 5], Argument Mining [6, 7], and Concept Map Mining [8], among others.

However, the use of role tokens in the above tasks requires them to carry the "semantic meaning" of the role. This requirement is often not fulfilled when examining both the output of state-of-the-art dependency-based SRL systems and the corpora they were trained on, such as CoNLL-2009 [9]. In these annotations, it is not uncommon to have an adpositional clause serving as the head word of a semantic role, even though adpositions do not represent the semantic core of that role. In linguistics, this phenomenon is referred to as an instance of *dissociated nucleus* [10, ch. 23]. Although this term encompasses many different syntactical constructions, here we focus on adpositional clauses present in the CoNLL-2009 dataset, across all of its languages.

In this paper, we carry out a concise, linguistically-driven investigation on dissociated nuclei in dependency-based SRL, uncovering the extent of this problem and how it affects the semantic aspect of this task. In addtion, we introduce SemDepAlign, a simple yet effective algorithm capable of mitigating this phenomenon significantly by aligning predicate-argument structures in SRL with syntactic parses from the Universal Dependencies project, which addresses the dissociated nucleus phenomenon directly in the dependency structures. Applying SemDepAlign to CoNLL-2009 results in a substantial increase in the semantic variety of role tokens, measured through a set of proxy metrics. Finally, we provide a glimpse at how addressing dissociated nuclei simplifies the alignment between Semantic Role Labeling and Semantic Parsing, specifically with Abstract Meaning Representation [11, AMR]. We release SemDepAlign and Aligned-CoNLL09 – the result of applying SemDepAlign to CoNLL-2009 – in the hope that our work can encourage a deeper focus on semantics in SRL and foster future integration of this task into downstream applications.

2. SRL and Dependency Parsing

Both SRL and Dependency Parsing investigate how words in the same sentence relate to each other, respectively in a semantic or syntactic sense. The Conference on Computational Natural Language Learning (CoNLL) organized several Shared Tasks regarding both tasks, culminating in the CoNLL-2008 Shared Task [12] that asked participants to identify both types of relation within an English-only corpus. This task can be seen as the first occurrence of dependency-based SRL, as it explicitly ties the SRL annotations to the dependency relation tree of the sentence. The authors of the Shared Task implemented their own constituency-to-dependency parser to obtain the syntactic dependency relation trees, which are vulnerable by construction to the dissociated nucleus phenomenon.

The dependency relation annotation scheme adopted in both CoNLL-2008 and its multilingual successor CoNLL-2009 [9] impacts the output of dependency-based SRL systems trained on these training sets. If one inspects either a training sample of CoNLL-2009 or an output of a system trained on it, one can expect to encounter the dissociated nucleus phenomenon [10, ch. 23]. For example, the training sample "That is a service to the nation" presents a dissociated nucleus: the structural and semantic functions of the subclause "to the nation" are fulfilled by two separate tokens, 'to' and 'nation', respectively. The annotation provided within CoNLL-2009 identifies the syntactic core 'to' with the argument A2 for the nominal predicate 'service' because it is the head of the original dependency relation subtree corresponding to the argument span. Consequently, many tokens annotated as arguments are simple adpositions of little semantic significance. This significant detail impacts downstream tasks that use SRL outputs as input: if we wanted to extract relations or perform disambiguation on the example above, we would have much more interest in focusing on the word 'nation' than the adposition 'to'.

A way to quantify this phenomenon is to look at the frequency of part-of-speech (POS) tags of role tokens in the corpus. We are interested in the POS label of "Preposition or subordinating conjunction", which is the second-most frequent tag with 76,821 role tokens out of a total of 475,069, or ~17% of all the role tokens. Table 5 in the Appendix provides a complete breakdown over all POS classes in the English-split of CoNLL-2009.

We argue that both the training corpora and dependency-based SRL systems should identify the semantic core of an argument span as the head of the argument. In Appendix A we provide further examples of this phenomenon in non-English partitions of CoNLL-2009.

Algorithm 1: SemDepAlign

```
input: the role node role_node; the root node of the
  UD dep-tree root_ud.
output: the head node of the role in the UD dep-tree.

role_tokens ← $get\_tokens$(role_node)
ud_role_subtree ← root_ud
min_nodes ← $SymDiff$($get\_tokens$(root_ud),
  role_tokens)
for node ← BFS(root_ud):
    subtree_tokens ← $get\_tokens$(node)
    extra_nodes ← $SymDiff$(subtree_tokens,
      role_tokens)
    min_nodes ← min(min_nodes, extra_nodes)
return ud_role_subtree
```

3. Re-associating Dissociated Nuclei

Having established that the current annotations in CoNLL-2009 are susceptible to the dissociated nucleus phenomenon, we aim to mitigate this issue by introducing a subtree alignment algorithm that leverages the characteristics of Universal Dependencies [13, 14, UD] to collapse arguments that have been placed on structural tokens with their corresponding semantic tokens. UD explicitly addresses the dissociated nucleus issue by extending the definition of a nominal to encompass the entire nominal extended projection, following the linguistic theory proposed by Grimshaw [15]. The nominal head is used as the referential core and the adposition is treated as a functional marker [14, Section 3.1.1]. When constructing the dependency tree structures, UD guidelines [14, Section 2.1.1] indicate that the head of a particular subclause should be its main content word, i.e. the nominal head. Parsers trained on UD Treebanks recognize dependency subtrees where the head is the semantic core of the subclause, effectively mitigating the dissociated nucleus phenomenon. We leverage this characteristic of UD parsers to automatically annotate the whole CoNLL-2009 corpus using `trankit` [16], which emerges as the strongest UD parser in the comparison we include in Appendix B.

3.1. SemDepAlign: subtree alignment

We introduce SemDepAlign, a novel algorithm for syntactic parse semi-alignment from the dependency annotations in CoNLL-2009 to UD, described in Algorithm 1. SemDepAlign is a deterministic subtree aligning algorithm that, for each role token t associated with a predicate, finds the UD subtree that most closely matches the original subtree headed by t in the original dependency tree of CoNLL-2009. It then returns the head node t' of

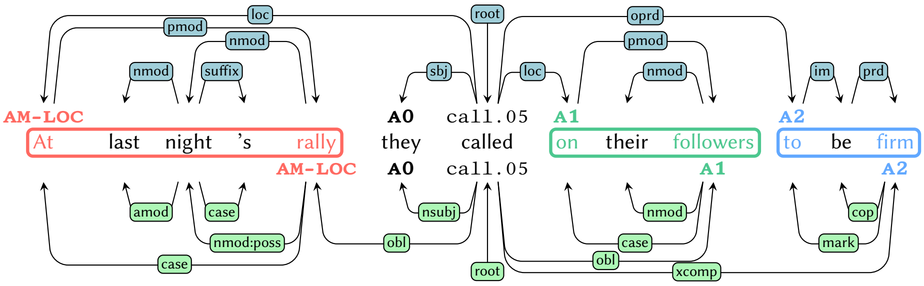

Figure 1: An edited example from the English CoNLL-2009 development set: original (top) and aligned (bottom) dependency and role annotations for the predicate *"called"*. We represent role annotations through colored clusters, where SemDepAlign aligns the head token to a more semantic token heading the UD subtree closest to the original.

the UD subtree, which will be assigned the role label in the aligned SRL annotation.

As shown in Algorithm 1, SemDepAlign starts from the UD root node (*root_ud*), loops over the nodes of the tree through a breadth-first search (BFS), and finds the node which heads the subtree with minimal symmetric set difference (*SymDiff*) between its tokens and the set of tokens in the original role span (*role_tokens*). The symmetric difference between two sets of tokens S_1 and S_2 is defined through the set operations *difference* (\) and *union* (∪) like so: $(S_1 \backslash S_2) \cup (S_2 \backslash S_1)$. Intuitively, if the symmetric difference between the original and the UD subtree is the empty set, they match exactly and we can simply select the head of the UD subtree as the role token. Otherwise, selecting the head of the UD subtree with the minimal symmetric difference compared to the original subtree is equivalent to selecting the subtree with the most overlap with the original span.

Figure 1 gives an example of the output of SemDepAlign: at the top of the figure we display the original annotation of the sentence derived from the English split of CoNLL-2009, with the presence of a dissociated nucleus in three of the four roles for the predicate "called"; in the bottom part we show the output of our alignment procedure, which moves the role annotations to the tokens that perform the semantic function.

3.2. Aligned-CoNLL09: analysis

We apply SemDepAlign to CoNLL-2009 to mitigate the dissociated nucleus phenomenon, obtaining the Aligned-CoNLL2009 dataset. After the application of SemDepAlign, the number of role token annotations that are modified is considerable over all CoNLL-2009 languages (between 21% and 32% of the total roles), except for Czech (~7%).

To gain a better understanding of the differences that the alignment process introduces, we consider the annotations of the original tokens that are modified by SemDepAlign and the resulting aligned role tokens. We measure three metrics on these two sets to evaluate their semantic richness:

- Number of **content words**, i.e. words that are either nouns, adjectives, adverbs, or verbs, which indicates that the heads identified by SemDepAlign are more varied (2713 vs. 680 for English, 3.99×);
- Number of **unique tokens**, which indicates that the heads identified by SemDepAlign are less repetitive (1906 vs. 477, 4×);
- Number of **unique synsets**, which indicates that the heads identified by SemDepAlign are associated with different meanings (1387 vs. 481, 2.88×) according to a Word Sense Disambiguation system [17].

From Table 1 we can see how SemDepAlign dramatically increases the semantic content of role tokens in English, Spanish and German, identifying more than 4× the number of content words, more than 2.5× the number of unique tokens and around 3× the number of unique synsets compared to the original annotations. We find a smaller but consistent increase of semantic content in Catalan and Chinese, whilst in Czech all metrics are similar, indicating a reduced effect of SemDepAlign.

4. Integrating re-associated nuclei

Although we demonstrate that re-associated nuclei in dependency-based SRL provide additional semantic information, an important research question is whether integrating our proposal into current systems can lead to a change in performance. Therefore, we build on top of the strong SRL model proposed by Conia and Navigli [18] and design a new approach that jointly learns both types of role annotations, i.e. the original role tokens and

Language	Catalan		Czech		German		English		Spanish		Chinese

the aligned ones. In brief, this architecture derives a contextualized word representation for each word in a sentence from a BERT-like Pretrained Language Model [19, PLM]. It then applies a custom "fully-connected" stacked-BiLSTM sequence encoder to derive a predicate-aware representation, which is in turn used to derive a predicate- and argument-specific embedding for each word in the sentence. Finally, an argument-specific fully-connected BiLSTM is applied to further encode each word with respect to a specific predicate, from which it derives the final score distribution over the role vocabulary through a simple linear classifier. The model is trained to minimize the sum of categorical cross-entropy losses on predicate identification, predicate disambiguation and argument identification and classification.

To adapt this model for our joint modeling task, we duplicate the linear classifier for the semantic roles and set two different targets for the two role classifiers: the original role token and label from CoNLL-2009 and the aligned role token and label obtained with SemDepAlign. Our final loss adds terms for UD-aligned argument identification and classification to the original loss.

Experimental setup We use XLM-RoBERTa-base [20] as the underlying PLM, and leave other hyperparameters unchanged. We conduct our experiments on all of the language splits of CoNLL-2009, namely, Catalan, Czech, German, English, Spanish, and Chinese.

Results Table 2 compares the results of our joint-modeling alignment system against our baseline on the CoNLL-2009 validation and test sets. Importantly, we observe that the additional task of modeling the semantic core of an argument does not significantly alter the performance (very similar F1 score on the test), despite the added difficulty brought by the identification of semantic cores. Table 3, instead, provides a breakdown of the F1 scores on predicate, role and aligned role predictions. The aligned system is in line with the baseline despite being tasked with a more complex objective. More interestingly, we observe that the F1 score on the semantic heads is comparable, indicating that the model is able to identify UD-aligned roles effectively.

5. Semantic roles in AMR graphs

We also develop an evaluation method based on the Abstract Meaning Representation formalism [11, AMR] for Semantic Parsing. The interconnection between SRL and AMR is well-known across the literature [21, 22]: both

Test dataset	Standard	Aligned	Δ
LORELEI	65.98	71.33	5.35
Weblog and WSJ	64.07	70.13	6.06
Xinhua MT	67.92	75.68	7.76
BOLT DF MT	60.92	68.17	7.25
BOLT DF English	56.22	62.12	5.90
Proxy reports	24.50	22.40	-2.10
Average	56.60	61.64	5.04

Table 4

tasks aim to construct a semantic representation of a sentence, although SRL, covering only surface-level semantic frames, is more superficial than AMR, which aims to provide a more complete and in-depth structured representation that can interconnect different semantic frames. Given that AMR aims to abstract away from the specific syntax of a sentence to focus only on its semantic content, our intuition is that a dependency-based SRL system is more "semantic" if its predictions of predicate-role pairs are contained in the AMR annotation for the same sentence.

Therefore, we devise the **AMR-precision** metric: given a sentence S, its golden annotated AMR graph G_{AMR} with token-node alignments available and a set of dependency-based SRL predictions, we filter the predicted semantic frames so that the predicate of each frame is present in the golden AMR graph. We then compute the ratio between the number of role tokens that are connected to their predicate in the AMR graph over the total number of roles predicted.

Given the SRL system introduced in Section 4, we apply it to the AMR3.0 (LDC2020T02[1]) test datasets, keeping both the standard and the aligned role predictions. We then compute the AMR-precision for both sets of predicted roles, and compare them in Table 4. It is clear that aligned roles are more likely to be present in the corresponding AMR graph of a sentence, with a consistent difference in AMR-precision in all test datasets except *Proxy reports*. This particular dataset has a "templatic, report-like structure" as mentioned in the AMR3.0 guidelines, so it is possible that the reduced performance is due to this particular characteristic.

This finding can pave the way for future work exploring the linkage between these two fundamental semantic tasks, as also suggested in the multi-layer annotation provided in MOSAICo [23].

6. Related work

Syntactic information has always been considered important for recognizing semantic frames in SRL. Marcheggiani and Titov [24] were among the first to model the dependency information provided in dependency-based SRL, followed most recently by Xia et al. [25], Fei et al. [26]. These works differ in respect of modeling choices and in the kind of extra syntactic data to be included (e.g. constituency trees, POS tags).

We also considered other syntactic frameworks, such as HPSG [27], to align the role annotations. HPSG robustly models the relationship between semantic cores of a sentence, but the lack of automatic tools with an acceptable performance and the difficulty in aligning dependency-based subtrees to HPSG spans compelled us to use UD.

7. Conclusion

In this paper, we conducted an in-depth investigation on the dissociated nucleus issue in dependency-based SRL. We introduced SemDepAlign, a novel method to align predicate-argument structures in SRL with syntactic parses from the Universal Dependencies project, which addresses the dissociated nucleus phenomenon. Our analyses and experiments in SRL modeling demonstrate that our approach to dissociated nuclei brings more semantic richness whilst remaining competitive on standard benchmarks.

8. Limitations

A limitation of our work is that it builds upon existing dependency parsers trained on Universal Dependencies. These parsers have reached high robustness across many languages, between 85 and 93 in Labeled Attachment Score (LAS) on the languages present in CoNLL-2009. But the error that these automatic methods necessarily encounter propagates directly to our alignment algorithm, with no way of recovering from the mistake. This limitation would be even more impactful in languages where the automatic dependency parser performed worse, presumably in low-resource settings, preventing a robust expansion of our work to these settings.

A more methodological limitation of our contributions concerns the availability of the CoNLL-2009 dataset. Although it is a well-established corpus in the SRL literature, it has a proprietary licensing scheme and one must acquire the resource from the Linguistic Data Consortium (LDC). We trust that, given the importance of the corpus, this will not limit the relevance of our work.

A. Dissociated nuclei in non-English samples of CoNLL-2009

A.1. Catalan

Original sentence:
“Piqué recomana les fusions entre empreses per millorar la rendibilitat.”
Translation:
“Piqué recommends mergers between companies to improve profitability.”
Dissociated nucleus:
In the clause “per millorar” (“to improve”), ‘per’ (‘to’) is tagged as `argM-fin` for predicate ‘recomana’ (‘recommends’) instead of the head of the subclause ‘millorar’ (‘improve’).

A.2. German

Original sentence:
“Setzt Hessen auf eine Effizienzsteigerung der Verwaltung durch neue Steuerungsinstrumente .”
Translation:
“Hesse is focusing on increasing the efficiency of administration through new control instruments.”
Dissociated nucleus:
Considering the predicate ‘setzt’ (‘focus’), the clause “auf eine Effizienzsteigerung” (“on increasing the efficiency”) is annotated with role `A1` on the token ‘auf’ instead of the semantic core ‘Effizienzsteigerung’.

A.3. Spanish

Original sentence:
“Don Antonio se encontraba en su casa cuando sonó el timbre de la puerta.”
Translation:
“Don Antonio was at his home when the doorbell rang.”
Dissociated nucleus:
The role “en su casa” (“at his home”) for predicate ‘encontraba’ (‘was’) is tagged as `arg2-loc` on the token ‘en’ (‘in’) instead of the semantic nucleus ‘casa’ (‘home’).

A.4. Chinese

Original sentence:
巴拉克 在 民意 测验 中 一直 表现 不 佳 。
Transliteration:
“Barak in public opinion test in continuously performance no good.”
Translation:
“Barak has consistently underperformed in the polls.”
Dissociated nucleus:
In the clause 在 民意 测验 (“in the public opinion polls”) for the nominal predicate 佳 (‘good’), as the token 在 (‘in’) is tagged as the `LOC` role, instead of the more semantic 测验 (‘polls’).

B. Universal Dependency parsers

We consider three among the best off-the-shelf dependency parsers, namely, `trankit` [16], `UDPipe` [28] and `Stanza` [29]. Table 6 compares the reported evaluation of each parser on standard treebanks for Catalan, Czech, German, English, Spanish and Chinese. We choose `trankit` as it achieves a higher UAS and LAS than the two alternatives in all languages except Spanish (slightly worse than `UDPipe`), with a considerable margin in Chinese.

Treebank	System	UAS	LAS
Catalan AnCora	`trankit`	**95.15**	**93.83**
	`UDPipe`	94.92	93.43
	`Stanza`	93.55	91.66
Czech PDT	`trankit`	**95.24**	**93.65**
	`UDPipe`	95.01	93.64
	`Stanza`	92.22	90.18
German GSD	`trankit`	**89.01**	**85.20**
	`UDPipe`	87.04	83.20
	`Stanza`	85.80	81.80
English EWT	`trankit`	**91.29**	**89.4**
	`UDPipe`	90.71	88.81
	`Stanza`	88.90	86.77
Spanish AnCora	`trankit`	93.29	91.10
	`UDPipe`	**93.68**	**91.92**
	`Stanza`	93.09	91.30
Chinese Simplified GSD	`trankit`	**87.38**	**84.82**
	`UDPipe`	72.74	70.28
	`Stanza`	73.41	70.65
Average	`trankit`	**91.89**	**89.67**
	`UDPipe`	89.02	86.88
	`Stanza`	87.83	85.40

Table 6
Performance of multiple off-the-shelf dependency relation parsers, measured by the standard Unlabeled and Labeled Attachment Scores (UAS and LAS). Boldface scores indicate the best performing system on a specific treebank.

Data Augmentation through Back-Translation for Stereotypes and Irony Detection

Abstract

Complex linguistic phenomena such as stereotypes or irony are still challenging to detect, particularly due to the lower availability of annotated data. In this paper, we explore Back-Translation (BT) as a data augmentation method to enhance such datasets by artificially introducing semantics-preserving variations. We investigate French and Italian as source languages on two multilingual datasets annotated for the presence of stereotypes or irony and evaluate French/Italian, English, and Arabic as pivot languages for the BT process. We also investigate cross-translation, i.e., augmenting one language subset of a multilingual dataset with translated instances from the other languages. We conduct an intrinsic evaluation of the quality of back-translated instances, identifying linguistic or translation model-specific errors that may occur with BT. We also perform an extrinsic evaluation of different data augmentation configurations to train a multilingual Transformer-based classifier for stereotype or irony detection on mono-lingual data.

Data Augmentation, Back Translation, Irony Detection, Stereotypes Detection, Low-Resource NLP

1. Introduction

Equipping systems with linguistics-grounded capabilities can be complex. Despite the advancements by Large Language Models (LLMs), the availability of annotated corpora remains crucial. State-of-the-art systems still exhibit shortcomings, for example, when access to context or pragmatics for giving a true comprehension of the features of the involved phenomena is required [1].

Unfortunately, the development of large datasets annotated for specifically complex phenomena can be very time-consuming. When only small corpora are available, data augmentation techniques can be applied [2, 3]. Given a small set of original sample data, data augmentation artificially generates new instances that are similar and comparable to the existing data and can, therefore, be used to train and test systems with an extended dataset.

In this paper, we present experiments for augmenting two small datasets annotated for two diverse, challenging phenomena, namely stereotypes and irony detection. In several works exploring data augmentation, Back-Translation (BT) [4] was shown to be a strong and relatively easy-to-implement baseline [5, 6]. A BT process generally consists of two steps: given one or multiple translation systems, a text in a source language is first translated into a chosen *pivot language*, and the resulting text is then translated back into the source language. The expected output of the BT process is a text that is similar but not the same as the original input, accounting for the linguistic differences intrinsic to the language pair, but also the idiosyncrasies of the chosen translation model(s). This relies on the fact that translation is only partially deterministic: the expected output should have the same meaning as the input, outputs that morphologically or syntactically differ may be considered as correct translations of the input. In BT, the application of (at least) two translations improves the variability between the input and the output text.

The usefulness of a dataset augmented by applying BT depends on the quality of the translated outputs. Outputs too similar to the inputs can cause overfitting when used for training, while with too different outputs, there is a risk of a shift in distribution that is too large, which may negatively impact performance, at least in intra-dataset evaluations. A compromise between these two alternatives must be found. Therefore, an evaluation of the quality of translations and back-translations is important to assess the benefits.

In this paper, we want to investigate the viability of BT as a data augmentation technique for low-resource tasks in various configurations. We use French and Italian as source languages — leveraging two multilingual datasets

with subsets for these languages — and various languages as pivots for the BT process (French/Italian, English, and Arabic). We compare BT with an alternative process for data augmentation, specific for multilingual datasets, which we refer to as "cross-translation", where the data from one language subset is translated and then used as a data augmentation source for another language subset.

Our contributions are (1) an intrinsic qualitative human evaluation of translations and back-translations for stereotypes detection and irony detection datasets in various combinations of source and pivot languages, followed by (2) an extrinsic evaluation of machine learning model performance on these datasets, using these various data augmentation sources.

2. Related Work

BT as a data augmentation method was originally proposed by Sennrich et al. [4], in the context of Neural Machine Translation (NMT), to allow using monolingual data to improve translation quality, particularly when parallel (source and target) training data is scarce.

Since then, several works have explored BT, either as a baseline to evaluate other data augmentation methods against or as the primary augmentation method for low-resource tasks. For example, Kumar et al. [5] evaluated pre-trained conditional generative Transformer models as data augmentation sources and used BT as a baseline. They found that BT achieves relatively high extrinsic performance against simpler approaches such as Easy Data Augmentation (EDA) [7] but also against some Transformer models; it also obtains most of the best scores for semantic fidelity and data diversity.

Xie et al. [6] make use of BT as an augmentation strategy in their semi-supervised Consistency Training approach, in which a model is trained with a loss function combining traditional supervised learning on a limited amount of labeled data, with an unsupervised consistency loss. The latter consists of minimizing a divergence metric between the output distributions for an unlabeled input and a noised version of it, the noise function being the chosen data augmentation method, i.e., for text, BT.

As far as the challenges related to the application of translation to texts with irony or sarcasm, a few papers discussing this task were recently published, among which we can cite [8] and [9].

3. Datasets

We focus on the tasks of stereotypes and irony detection with relevant multilingual datasets. Table 1 summarizes the characteristics of their French and Italian splits, the chosen languages for this study:

Dataset	Lang.	Size (train; test; val)	Positive Class
StereoHoax	Italian	3123 (1841; 1185; 97)	15.11%
	French	9342 (6981; 1993; 368)	12.07%
MultiPICo	Italian	967 (619; 193; 155)	25.34%
	French	1724 (1104; 345; 275)	25.17%

Table 1
Statistics for the datasets used in this work.

- StereoHoax [10] is a contextualized multilingual dataset of tweets annotated primarily for the presence of anti-migrant stereotypes. It consists of replies to tweets containing racial hoaxes (RH), with each message having a "conversation head" (the message containing the source RH) and a direct parent message (if applicable).
- MultiPICo [11] is a disaggregated multilingual dataset of short social media conversations annotated for irony detection through crowdsourcing. Each instance is a *(post, reply)* pair, where the post is a starting message in a thread, and the reply is either a direct reply or a second-level reply.

4. Translation Model

To use BT as a data augmentation method, one crucial decision to make is that of the translation system(s) . Machine Translation (MT) models are in fact not explicitly designed to inject relevant noise into texts to increase the variety of data available. Therefore, a significant part of this beneficial noise will be linked to the idiosyncrasies of the chosen model(s).

In this work, due to the number of different configurations, and thus source-target language pairs we wished to investigate, we decided to limit our selection to intrinsically multilingual models.In a preliminary phase, we thus experimented with the locally runnable Transformer-based multimodal Neural MT model `SeamlessM4T v2` [12] proposed by Meta AI. However, after early evaluations of obtained translations and back-translations, we observed too many issues and violations of important criteria (see section 5). As such, we eventually selected the Google Translate API for our evaluation and experiments, as it seemed to offer the best tradeoffs between translation and back-translation quality, as well as ease of access to the languages chosen for this work (French, Italian, English, and Arabic). It is important to note, however, that the models used by Google Translate themselves make use of BT as a data augmentation technique, as well as M4 Modelling[1]: in practice, this may cause some issues for use in BT, as undesirable artifacts of BT and

[1] https://research.google/blog/recent-advances-in-google-translate/

Massively Multilingual Massive NMT — possibly caused by parameters bottlenecks or languages interferences [13] — may have detrimental effects on the quality of the augmented data.

5. Intrinsic Evaluation

To judge the viability of BT for these two datasets and languages, we perform a human qualitative evaluation of produced back-translations using the following protocol. First, we collect a set of data for both datasets and languages randomly sample 50 instances each for the French and Italian subsets, 25 from the positive class, and 25 from the negative class, for a total of 200 instances. For all the cases examined, we consider the text of the messages and the associated conversational context, which can consist of one or two other messages (an optional direct parent, and the conversation head/original post).

In addition to French and Italian as source and pivot languages, American English and Modern Standard Arabic were also selected on account of the linguistic expertise of the authors. Thus, for the 100 instances in Italian, we apply the following BT settings (*<source>* - *<pivot>* - *<target=source>*): Italian - English - Italian; Italian - French - Italian; Italian - Arabic - Italian. Similarly, for the 100 French instances, we apply the following BT settings: French - English - French; French - Italian - French; French - Arabic - French. We use the Google Translate API due to its ease of use and availability of the chosen source and target languages.

A manual qualitative approach is used for the evaluation of the BT results: 4 language experts (co-authors of this paper) evaluate the quality of the produced back-translations (and intermediate translations, though in a less quantitative capacity). All evaluators are native speakers of one of the source languages (French and Italian), as well as sufficiently proficient (or a native speaker) in the pivot languages (French, Italian, English, and Arabic). They are tasked with comparing the original and back-translated instances, also considering the pivot translation to help understand potential artifacts or errors introduced in the process. Evaluators could assign one label to problematic instances containing a violation of the following associated quality criteria:

- **faithfulness**: a faithful translation accurately conveys the meaning of the original text without introducing errors, omissions, or distortions. Since we focus on texts featuring expressions of stereotype or irony, faithful instances must also preserve these phenomena;
- **preservation of non-translatables**: this criterion is referred to in the translation of numbers, units, measurements, and, in general, non-translatable terms such as proper nouns, brands, trademarks, hashtags, user mentions, emojis, acronyms, and specific cultural references for maintaining clarity, consistency, and legal compliance. This category also includes idiomatic expressions which are especially difficult to translate;
- **fluency**: a text is fluent when it is perceived by a native speaker as reading "natural", in the way they would be expected to have structured it;
- **other**: this last criterion is used to report less frequent violations that cannot be encoded by the other criteria, including incomplete translations, word tokenization, or sentence segmentation.

5.1. Back-Translation Examples

To illustrate violations of these criteria, this section presents example parts of instances in their original (**Og**), translated (**Tr**), and back-translated (**BT**) forms, underlining the relevant spans, when applicable.

In the following example from the Italian subset of MultiPICo, the *fluency* criterion is violated because of the inadequate and unnatural back-translation of the plural expression *"per i primi tempi"* ("for the initial period"), into the singular *"per la prima volta"* ("for the first time"):

Og: "Se rimanere impiegato a 1400 euro è il tuo obiettivo ok, altrimenti è solo per i primi tempi"

Tr: "If staying employed at 1400 euros is your goal, ok, otherwise it's only for the first time"

BT: "Se restare impiegato a 1400 euro è il tuo obiettivo, ok, altrimenti è solo per la prima volta"

This example from French StereoHoax illustrates breaking the *faithfulness* criterion, with Arabic as the pivot language. In this message, the informal vulgar expression *"n'avoir rien à foutre"* (vulgar. "to have nothing to do"), which conveys an implied judgment of laziness towards the described target, cannot be properly translated into Arabic, like most vulgar expressions (a common issue with this pivot language), and loses its proper meaning in the back-translation, *"n'avoir rien à se soucier"* meaning "to have nothing to worry/care about":

Og: "Elle n'a rien à foutre"

Tr: "
ليس لديها ما تهتم به
"

BT: "Elle n'a rien à se soucier"

In this example from Italian MultiPICo, the violation concerns a *non-translatable*, in the form of the colloquial expression *"<X> della Madonna"*, intended as an idiomatic intensifier (similar to "A hell of a <X>" in American English). In the pivot translation, the idiom fails to be transposed, and "Madonna" is interpreted as part of the proper noun of a non-existent virus ("Madonna virus") and transposed into the back-translation:

Og: "... Gli asiatici stanno tramando qualcosa di losco.... prima gli spaghetti al microonde con ketchup e adesso un virus della madonna ?"

Tr: "... The Asians are up to something shady... first microwaved spaghetti with ketchup and now a Madonna virus?"

BT: "... Gli asiatici stanno tramando qualcosa di losco... prima spaghetti al microonde con ketchup e ora un virus Madonna?"

Another example of a *non-translatable* failing to be preserved is the following, taken from the French subset of StereoHoax. Here, the idiomatic expression *"se tuer/mourrir à la tâche"* (lit. "to kill oneself/die doing a task"), used in its informal variant with *"[se] crever"* (lit. "to burst", informal. "kill [oneself]/die") was translated incorrectly, changing the meaning of the message:

Og: "Oui mais est ce que c'est normal ? Quand yen a un qui a rien foutu et que l'autre s'est crever à la tache ? Non la logique c'est qu'il peuvent cumuler pour arriver à une retraite vivable et qui dépasse le seuil de pauvreté !"

Tr: "Yes but is this normal? When one has done nothing and the other has died? No, the logic is that they can accumulate to achieve a livable retirement that exceeds the poverty line!"

BT: "Oui mais est-ce normal ? Quand l'un n'a rien fait et que l'autre est mort ? Non, la logique est qu'ils peuvent accumuler pour obtenir une retraite viable qui dépasse le seuil de pauvreté !"

5.2. Samples Evaluation

Table 2 presents the quantitative results of this quality evaluation on 200 instances (see section 5). Cases that fall outside the selected criteria (classified under "other") include erroneous translations of grammatical gender, especially when using English as a pivot language, which has been extensively discussed in the literature [14]. Other errors refer to segmentation or punctuation. The preservation of proper punctuation and distinction between different sentences, text chunks, and segments ensures clarity and readability and can impact the quality of translation when using Machine Translation models. Unfortunately, due to the nature of the texts in question, i.e., social media messages, proper content segmentation is difficult to achieve due to the overall poor structure and formatting of the content in question (among many other forms of typographical artifacts and errors).

Regardless of the pivot language, some instances seem to be systematic sources of errors which can be explained by the particularities of the MT used model. For example, in MultiPICo Italian, one instance is *"Non la chiudono tranquillo"*, which should be interpreted as "They won't close it, don't worry" (speaking of the Italian Stock Exchange); however, for all pivot languages, and possibly due to the absence of a comma separating *"tranquillo"*, it is misinterpreted as an adverb and thus incorrectly backtranslated to *"silenziosamente"* ("quietly"). Similarly, in MultiPICo French, a message discussing the increasing use of the idiomatic discourse marker/connector *"du coup"* (equivalent to connector "so" in English), has this quoted expression consistently mis-backtranslated to *"tout d'un coup"* ("all of a sudden/suddenly"), despite it not making sense in the context of the message. The use of the expression in quotation marks in this case may have confused the MT model, which otherwise does not struggle with this expression when manually tested.

Overall, English appears to perform best across all the pivot languages in all settings. This is not surprising considering that, for most MT models, English is the most represented language in the training data (both in the source and target language), as well as the language typically used as a pivot to generate augmented instances for lower-resource languages. When using Arabic as a pivot language in our evaluations, we observed some unnatural expressions and constructs that appear "borrowed" from English: for example, in a MultiPICo Italian instance, the word *"gratis"* ("free [of charge/cost]") is mistranslated to حرّ ("freedom/liberty"); we thus hypothesize that the MT model used English as a pivot language for the Italian-Arabic language pair, as both terms would indeed likely be mapped to the polysemic and thus ambiguous term "free" in English.

6. Extrinsic Evaluation

To evaluate the effectiveness of BT as a data augmentation method for stereotypes or irony detection, we performed some preliminary experiments with varying configurations. For these experiments, we used the XLM-RoBERTa [15] multilingual Transformer classifier: while for smaller models, monolingual Transformers are generally preferable to multilingual ones, we preferred to use a single model in all configurations. For similar reasons, and due to time and resource constraints, for all experiments, we only automatically fine-tuned the hyperparameters of the models once for each dataset and source language combination (with a total of 4 starting configurations), on the *baseline* training set, that is, without any data augmentation. For more technical details, see Appendix A.

As the positive class (stereotype or irony present) is often the minority class for these and related tasks (see Table 1), we evaluate "balanced" data augmentation con-

(b) Results in terms of Positive class F1-score.

Table 3
Results of our experiments for various data augmentation configurations (see section 6). The best scores for each configuration are highlighted in **bold**.

figurations, in which augmented samples are added to the positive class until it is the same size as the negative class. We evaluated the following configurations:

- *baseline*: the model is trained on the original, unmodified training set (with no balancing of the classes).
- *oversampling* (OV): Oversampling was shown to be a strong baseline in various previous works [16, 17], and we thus evaluate it as an alternative or complement to BT.
- *back-translation from <language>* (BT[<language>]): augmented instances are sampled from back-translations of the original data using <language> as a pivot.
- *cross-translation* (XT): as the datasets used are multilingual and contain subsets in both French and Italian, one language's subset can be translated and used as augmented data for the other.
- *mixed back/cross-translation with oversampling* (BT[<language>]/XT | OV): as the positive classes are, for both phenomena and all languages, less than half the size of the negative class, balancing the two requires sampling more instances from the data augmentation source than there are original positive instances, which could result in injecting translation related biases into the training set. To attempt to mitigate this, we also evaluate sampling 50% from back or cross-translation strategies, with 50% from oversampling the positive class. Note that, given the number of potential configurations, we only evaluate BT[Eng] | OV and XT | OV due to time and resource constraints.

Table 3 displays the results of our experiments in terms of macro F1-scores, as well as positive class F1-scores. Except for StereoHoax French, at least one of the data augmentation configurations outperforms the baseline, though not necessarily BT. Indeed, for both StereoHoax Italian and MultiPICo French, the mixed cross-translation with oversampling (XT | OV) configuration achieves the highest Macro F1-score, though not the best positive class score. This seems to indicate that the variety of data intrinsic to using a separate language subset of a multilingual dataset can be beneficial, when possible, over that artificially created by a data augmentation technique like BT. Additionally, we only experimented with cross-translation within one linguistic typology (Romance languages). As such, future investigations on whether this extends to cross-typologies XT would be worth pursuing.

Interestingly, we find that the mixture of oversampling and back/cross-translation outperforms the equivalent non-mixed configuration for all datasets and languages except MultiPICo Italian. However, due to its small size (see Table 1), the results on this particular subset may be less significant, given the overall protocol for these experiments, and a protocol that can inject greater amounts of augmented data might be preferable. During initial experiments, however, we found that injecting larger quantities of augmented data (preserving or not the initial label distributions) seemed to consistently negatively impact test-set performance, most likely due to overfitting but also possibly due to the models fitting on the translation model detrimental idiosyncrasies, instead of the characteristics of the phenomena to detect.

Moreover, the performance on the positive class (Table 3b) is not necessarily improved correspondingly with the overall macro F1-score (Table 3a), even when the augmentation is applied solely to this class. In other works on similar phenomena, it is shown that data augmentation and related methods can boost the Out-of-Domain performance of such detection models [17]. The addition of variety in the occurrences of the phenomenon to detect would indeed help in generalizing its detection to other sources of data. Though, as the example of StereoHoax Italian in the cross-translation (XT) configuration shows, care should be taken not to overly shift the data distribution; otherwise, models may fail to learn the particular dataset's positive class entirely. The mixed data augmentation with oversampling configurations seems, however, successful in addressing this potential issue, though more variations in the proportions should be experimented with.

7. Conclusions

In this work, we have investigated using Back-Translation as a data augmentation technique for challenging low-resources tasks like stereotypes and irony detection, in a multilingual context.
Through an intrinsic evaluation of the quality of the augmented instances, we identified modes of failure of Machine Translation, which could negatively impact the data augmentation process. These errors stem from the intrinsic differences between typologies and specific languages or translation model idiosyncrasies themselves potentially learned from methods like BT. Through a preliminary extrinsic evaluation of two multilingual datasets, we found that cross-translation can outperform Back Translation, allowing us to augment one language subset by leveraging the variety of inputs present in the others.

In future work, we aim to expand this study to more numerous and varied source and pivot languages, and different data augmentation configurations, namely, different proportions and selections of injected augmented data. We may also compare Back and Cross-Translation against or alongside other related techniques, such as multitasking learning or Active Learning. We also expect that some improvements can be obtained by mitigating translation failures; this can be done, for example, by leveraging an external LLM to check each step and remove or correct the errors from the final augmented dataset. Finally, it could be also interesting to perform tests with different model types on top of RoBERTa.

A. Technical Details

For all experiments, we used the XLM-RoBERTa-base as provided by the the HuggingFace transformers [18] ecosystem (including the datasets library for data processing).

Automatic hyperparameters fine-tuning was accomplished using the Weights & Biases [19] AI platform's Bayesian hyperparameters optimization system, with the Hyperband early-stopping algorithm [20]. As mentioned in section 6, only 4 such optimizations were executed, one for each language subset of each dataset, in the *baseline* configuration (no data augmentation).

The learning rate (lr), the hardware training batch size (bs), and the number of gradient accumulation steps (ga), were automatically fine-tuned, and their final values are listed in Table A1. These models were trained for a maximum of 10 epochs, with the best performing epoch checkpoint kept at the end (measured by macro F1-score), with a warm-up ratio of 0.2 (linear warm-up from 0 to the initial learning rate over 20% of the training set), both determined during initial experiments.

Automatic fine-tuning and training of the models was performed on the Google Colab platform, using high-RAM T4 GPU instances, for an approximate total of 50 GPU-hours.

Dataset	Lang.	*lr*	*bs*	*ga*
StereoHoax	French	2.963E-05	16	4
	Italian	1.000E-06	16	1
MultiPICo	French	2.963E-05	16	4
	Italian	2.920E-05	8	1

Abstract

Stance detection is a critical task in understanding the alignment or opposition of statements within social discourse. In this study, we present a novel stance detection model that labels claim-perspective pairs as either aligned or opposed. The primary innovation of our work lies in our training technique, which leverages social network data from X (formerly Twitter). Our dataset comprises tweets from opinion leaders, political entities and news outlets, along with their followers' interactions through retweets and quotes. By reconstructing politically aligned communities based on retweet interactions, treated as endorsements, we check these communities against common knowledge representations of the political landscape. Our training dataset consists of tweet/quote pairs where the tweet comes from a political entity and the quote either originates from a follower who exclusively retweets that political entity (treated as aligned) or from a user who exclusively retweets a political entity from an opposing ideological community (treated as opposed). This curated subset is used to train an Italian language model based on the RoBERTa architecture, achieving an accuracy of approximately 85%. We then apply our model to label all tweet/quote pairs in the dataset, analyzing its out-of-sample predictions. This work not only demonstrates the efficacy of our stance detection model but also highlights the utility of social network structures in training robust NLP models. Our approach offers a scalable and accurate method for understanding political discourse and the alignment of social media statements.

Stance Detection, Polarisation, Social Networks

1. Introduction

Stance detection is a critical task within the domain of natural language processing (NLP). It involves identifying the position or attitude expressed in a piece of text towards a specific topic, claim, or entity[1, 2]. Traditionally, stances are classified into three primary categories: *favor*, *against*, and *neutral*. This classification enables a detailed description of textual data, facilitating a deeper insight into public opinion and discourse dynamics.

In recent years, the proliferation of digital communication platforms such as social media, forums, and online news outlets has resulted in an unprecedented volume of user-generated content. This surge underscores the necessity for automated systems capable of efficiently analyzing and interpreting these vast text corpora. Stance detection addresses this need by providing tools that can systematically assess opinions and reactions embedded within texts, thus offering valuable applications across various fields including social media analysis [3, 4], search engines [5], and linguistics [6].

According to the last report of World Economic Forum [7], the increase in societal polarization features among the top three risks for democratic societies. While a macroscopic increase of polarization has been observed, an understanding of the microscopic pathways though which it develops is still an open field of research. Through stance detection it would be possible to reconstruct these pathways down to the individual text-comment pairs.

Stance detection, has been explored across various fields with differing definitions and applications. Du Bois introduces the concept of the stance triangle, where stance-taking involves evaluating objects, positioning subjects, and aligning with others in dialogic interactions, emphasizing the sociocognitive aspects and intersubjectivity in discourse [6]. Sayah and Hashemi focus on academic writing, analyzing stance and engagement features like hedges, self-mention, and appeals to shared knowledge to understand communicative styles and interpersonal strategies [8]. Küçük and Can define stance detection as the classification of an author's position towards a target (*favor*, *against*, or *neutral*), highlighting its importance in sentiment analysis, misinformation detection, and argument mining [9]. These diverse approaches underscore the multifaceted nature of stance detection and its applications in enhancing the understanding of social discourse, academic rhetoric, and online content analysis. For a review of the recent developments of the field we refer to Alturayeif et al. [2] and AldDayel et al. [3].

In this work, we propose a novel approach to training stance detection models by leveraging the interactions within highly polarized communities. Our method utilizes tweet/quote pairs from the Italian political debate to construct a robust training set. We operate under the assumption that users who predominantly retweet a particular political profile are likely in agreement with the statements made by that profile. We restricted our analysis to retweet since this form of communication primarily aligns with the endorsement hypothesis [10]. Namely, being a simple re-posting of a tweet, retweeting is commonly thought to express agreement with the claim of the tweet [11]. Further, though retweets might be used with other purposes such as those described by Marsili [12], the repeated nature of the interaction we observe in our networks reduces the probability that the activity falls outside of the endorsement behavior.

Conversely, while quoting a tweet works similarly to retweeting, the function allows users to add their own comments above the tweet. This makes this form of communication controversial regarding the endorsement hypothesis, as agreement or disagreement with the tweet depends on the stance of the added comment. On the other hand, the information social media users see, consume, and share through their news feed heavily depends on the political leaning of their early connections [13, 14]. In other words, while algorithms are highly influential in determining what people see and shaping their on-platform experiences [15], there is significant ideological segregation in political news exposure [16]. It is therefore reasonable to expect that users who almost exclusively retweet a political entity (party, leader, or both) use quote tweets to express agreement with statements posted by that entity and disagreement with statements posted by political entities ideologically distant from their preferred one. Additionally, the quote interaction perfectly encapsulates the stance triangle described by Du Bois [6].

In order to correctly assess political opposition we construct a retweet network and use the Louvain community detection algorithm [17] to characterize leaders and, through label propagation, the followers that align with their views.

Through these community labels we construct a dataset of claim-perspective couples by annotating tweet-quote pairs from profiles that clearly express political alignment as *favor* and annotating tweet-quote pairs in which the profiles come from different communities as *against*. Finally, we use a pretrained BERT model for Italian language and fine-tune it to the classification task.

This methodology aims to enhance the accuracy of stance detection models by incorporating real-world patterns of agreement and disagreement observed in polarized online environments. Further, it enables an unsupervised training paradigm that can be scaled to very large datasets.

In the following sections, we will outline the data gathering approach used for the dataset. Subsequently, we will describe the community detection methods employed to identify leaders and users within the Italian political discourse. We will then discuss the model architecture and its training process. In the results section, we will evaluate the model's performance and present our findings. Finally, the conclusion will address potential future developments, the implications of our work, and its limitations.

2. Results

In this study, we focus on a comprehensive set of Italian opinion leaders active on Twitter/X, including the official profiles of major news media outlets as well as prominent politicians and political parties. The profiles of news media outlets are further classified according to assessments provided by NewsGuard, which categorize them as either questionable or reliable sources. This classification is crucial for evaluating the quality of the information these outlets disseminate, particularly regarding their reputation for spreading misinformation. For the selected leaders, we collected all tweets produced from January 2018 to December 2022. The general public (followers) is identified based on their RTs to the content produced by these leaders. See Materials and Methods for details on the data collection process. Using this node configuration, we construct a bipartite network with two layers: leaders and followers, where the links represent the number of RTs by the latter of tweets made by the former. If a group of followers retweets tweets from two different leaders, it indicates that these leaders are likely communicating similar messages or viewpoints. To analyze these relationships more deeply, we perform a monopartite projection onto the leader layer. This projection, detailed in Materials and Methods, simplifies the network by concentrating solely on the leaders and the connections between them that are inferred from their shared followers. Panel (A) of Figure 1 shows the RT network of leaders aggregated in terms of communities identified through an optimized version of the Louvain algorithm [17]. The *a posteriori* analysis of the political leaders in each group reveals that the clustering algorithm effectively identified communities that align with the political affiliations of the leaders in each cluster [18, 19]. Specifically, the Left-leaning community includes political entities such as +Europa, Azione, Enrico Letta, and Nicola Fratoianni; the Right-leaning community features leaders from FdI, FI, and Lega; and the Five Star Movement (M5S) community includes key figures like Giuseppe Conte and Luigi Di Maio. An interesting observation from the network configuration is the clustering of questionable news sources. These profiles consistently group within the same com-

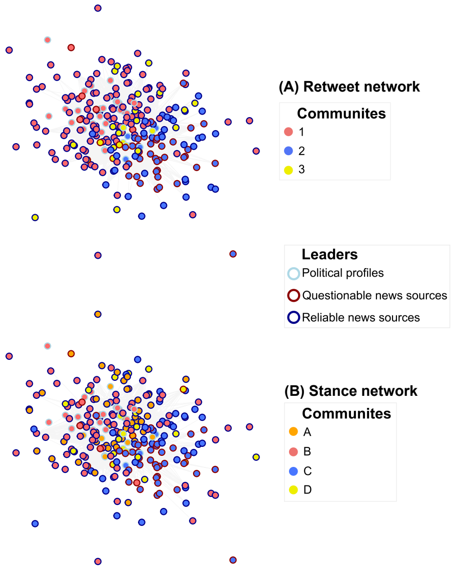

Figure 1: Projection of the follower-leader bipartite network onto the layer of leaders. In both **(A)** and **(B)**, the edges represent connections between leaders based on follower activity. **(A)** The edge weights are derived from the number of shared followers who retweeted content from both leaders. **(B)** The edge weights are based on the positive difference between favoring and against quote tweets made by shared followers on the content produced by the two leaders. In these visualizations, the node positions remain constant, providing a consistent framework for comparison. Node colors refer to communities as a result of running an optimized version of the Louvain algorithm. Nodes frame colors refer to the different types of leaders: political entities (azure), questionable news sources (dark red), and reliable news sources (dark blue).

munity, suggesting a potential alignment or affinity with specific political leanings or ideologies.

Leveraging the political bias of followers in our Twitter network, we build a very large dataset of tweet-quote pairs, each annotated with the corresponding stance (*favor* or *against*), as better described in Materials and Methods. Since this method assigns the stance to each pair in an unsupervised manner, to ensure that our approach is performing correctly, we randomly selected 500 pairs (250 favor and 250 against) and manually annotated their stance. We then compared the results of the automatic annotation with the manual annotation. The results, shown in Appendix - Table 3, indicate a high level of accuracy in favor and against classifications, with a small number of neutral cases. The dataset serves as training set for fine-tuning UmBERTo [20], an Italian language model based on the RoBERTa architecture [21], to assign stance labels to claim-perspective pairs. The fine-tuning process is performed using 5-fold cross-validation. The optimal performance for each fold is assessed by measuring the accuracy, i.e., the ratio of correctly predicted instances (both true *favor* and true *against*) to the total number of instances. The best-trained models from each fold demonstrate nearly identical performance, as shown by the average accuracy and F1-scores reported in the following table. The best model from fold 3 is identified as the highest performing and is therefore used in the following analyses. The corresponding confusion matrices for both the training and test sets are provided in Appendix - Table 5.

	Overall		Favor		Against	
	$\overline{\text{Acc}}$	(SD)	$\overline{\text{F1}}$	(SD)	$\overline{\text{F1}}$	(SD)
Training	0.863	(10^{-5})	0.863	(10^{-5})	0.864	(10^{-5})
Test	0.846	(10^{-6})	0.846	(10^{-6})	0.846	(10^{-5})

Table 1
Average performance of the best models from each fold on the training set and the test set. The table reports the mean and standard deviation (SD) for each metric considered: Accuracy for the overall model, and F1-score for each individual class.

Given the imbalance in the label distribution of the claim-perspective dataset, we use 41,347 pairs – each annotated as favor and previously removed to create a balanced training set – as an additional test set to evaluate the model's performance. The model achieves an accuracy of 83.6% when predicting the stance of these pairs.

The model is then applied to classify all the collected tweet-quote pairs based on their stance. Thus, following the same procedure used to construct the RT network of leaders, we develop the stance network and analyze its community structure. In this case, the weight of a link in the bipartite follower-leader network represents the positive difference between the number of favoring and against quotes from a follower on the leader's tweets. Panel (B) of Figure 1 shows the stance network of leaders aggregated in terms of communities identified through the Louvain algorithm. The node positions in this representation are the same as those in the RT network, providing a consistent framework for comparison. More formally, to evaluate the differences in clustering assignments between nodes present in both the retweet network and the stance network, we perform a clustering comparison. Namely, we use the contingency table [22] associated with both the representations to compute community overlap. Figure 2 shows the comparison results broken down by source type: political entities and news outlets. While clusters C and D of the stance network primarily align with clusters 2 and 3 of the RT network, respectively, clusters A and B of the stance network mainly represent a refinement of cluster 1 from the RT network. This suggests that even in the stance network, the emerging communities align with the political affiliations of the leaders within each cluster.

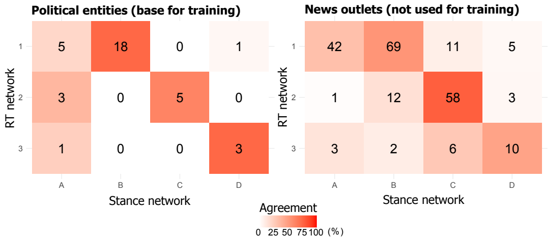

Figure 2: Contingency table associated with retweet network and stance network. Data is broken down by source type: political entities and news outlets.

Although the tweet-quote pairs used to train the model include only tweets from political entities, the result is significant. The training set does not include pairs where the quote comes from a follower who exclusively retweets political entities from the same ideological community as the tweet's author. This demonstrates the model's ability to reconstruct communities through precise classification of textual pairs.

The contingency table for news outlets, while displaying less pronounced patterns overall, still demonstrate clear coherence in classification between the retweet network and the stance network. This is particularly remarkable considering that these profiles were not included in the model's training set. The recovery of the retweet network's community structure within the stance network suggests that the model successfully generalizes across profiles with differing linguistic constraints, with only a minimal loss in accuracy, while still allowing for the reconstruction of group affiliations.

3. Discussion

Stance detection remains a vital yet challenging area in natural language processing (NLP), traditionally limited by the constraints of supervised learning. The availability of large language corpora, where interaction networks can be reconstructed, offers a novel approach that incorporates the social and dynamic aspects of stance, as outlined by Du Bois in his work on the stance triangle [6].

Our model addresses a more complex task compared to other state-of-the-art models. While existing models typically classify a user's stance on specific topics, our model classifies claim-perspective pairs into *favor* and *against* categories. This requires a deeper analysis of the relational stance between multiple interacting users and their statements.

Despite this increased complexity, our model achieved results comparable to those of existing state-of-the-art models [23, 24]. This success supports the hypothesis that in-group/out-group determinants, well-documented in opinion dynamics, significantly explain the variation in behaviors [25].

Moreover, our model's ability to reconstruct communities based on the accurate classification of textual pairs (as shown in Figure 2) underscores its potential for community reconstruction in scenarios where the interaction network is not provided.

Importantly, this approach also opens avenues for studying network dynamics based on the probability of agreement between account pairs. This has significant implications for understanding and potentially mitigating coordinated attacks, such as disinformation campaigns and political propaganda. By identifying patterns of agreement and disagreement, we can better detect and analyze the strategies behind these coordinated efforts, enhancing our ability to safeguard democratic processes and public discourse.

4. Materials and Methods

Data Collection. Our dataset comprises approximatively 15 million tweets collected by monitoring the activity of 583 profiles that reflect Italian online social dialogue (e.g., *La Repubblica*, *Il Corriere della Sera*, *Il Giornale*). Profiles were selected based on the list of news sites monitored by NewsGuard, a news rating agency dedicated to assigning reliability scores. According to NewsGuard, this list covers approximately 95% of online engagement with news, providing near-comprehensive coverage of news-related dialogue [26].

Additionally, we included Italian political entities in the list of profiles. This inclusion encompasses all major political parties and their leaders (e.g., *Giorgia Meloni* and *Fratelli d'Italia*, *Elly Schlein* and *PD*, *Giuseppe Conte* and *M5S*). For a complete list of the monitored political profiles see Appendix - Table 4.

For each monitored profile, we collected all tweets from January 2018 to December 2022 using the Twitter/X API before the limitations introduced by the new management[1]. We also gathered all retweets (RTs) and quotes (QTs) of this content within the same time frame, limited to those tweets that gained at least 20 RTs or 10 QTs. The following table provides a detailed breakdown of the data matching these criteria.

Category	Profiles	Tweets	RTs	QTs
News	329	279, 793	16, 365, 178	3, 587, 830
Politics	38	101, 017	15, 385, 363	2, 388, 621
TOTAL	367	380, 810	31, 750, 541	5, 976, 451

Table 2
Breakdown of the dataset.

[1] https://twitter.com/XDevelopers/status/1621026986784337922

Community Detection. In order to reconstruct the discourse communities from the twitter activity we built a retweet network. In the context of the data collection strategy previously described, most RTs are from a non-monitored user (a *follower*) to one of the users monitored (a *leader*), excluding a few RTs from one leader to another (45, 299). We can therefore consider this network as a bipartite network, i.e. a network where all links are from one node type to another, with 367 leaders and 934, 394 followers, connected through links with a weight w_{xi} equal to the number of RTs from the follower x to the leader i.

To identify communities among leaders we assume that leaders with the same readership are more likely to be in the same political community. We therefore constructed a monopartite network by projecting on the leader layer, i.e. we construct a network from the set of all length two paths assigning weights that are the product of the path's links.

We used the Bipartite Weighted Configuration Model (BiWCM) to statistically validate our bipartite projection [27]. BiWCM accounts for weighted interactions and preserves the strength of nodes in both layers, ensuring that our observed co-occurrences are not due to random chance but represent genuine structural patterns in the data. In order to find political communities in the network, we applied the Louvain algorithm 1000 times and selected the solution that minimized modularity, i.e., the strength of division of the network into clusters, with higher values indicating a structure where more edges lie within communities than would be expected by chance [28].

The same procedure was followed to construct the stance network and study its community structure. In this case, the weight of a link in the bipartite follower-leader network indicates the fraction of favoring quotes from the follower to the leader's tweets.

Claim-Perspective Pairs Selection. To construct a dataset of claim-perspective text pairs annotated with the corresponding stance (*favor* if the perspective supports the claim, *against* otherwise), we first identified users who clearly expressed an (almost) absolute preference for a single political entity through their retweet activity. Specifically, for each follower, we calculated the distribution of their RTs across the political entities defined in Table 4. Then, we filtered those who allocated at least 80% of their RTs to a single political entity. Some users, although meeting the previous requirement, may not have had a sufficient level of retweet activity during the analyzed period to be considered inclined towards a particular political entity. For example, a user who has only given one retweet to the set of political profiles would appear totally inclined towards a particular entity. To reduce the uncertainty arising from the indiscriminate inclusion of all profiles satisfying the high retweet activity requirement for a single political entity, we calculated for each follower x the total number of retweets of content produced by the set of political entities $\mathscr{P}$ defined in Table 4 and excluded the bottom 80% of the resulting distribution (i.e., we imposed $|\mathrm{RT}_x(\mathscr{P})| > 7$). For the remaining users, we then assigned the label *favor* to those quotes of tweets from their preferred political entity and the label *against* to those quotes of tweets from entities belonging to other political communities, as determined by the community detection analysis. This procedure resulted in the creation of a dataset containing 243, 277 unique claim-perspective (tweet-quote) pairs, each annotated with the corresponding stance. Since the label distribution of the dataset was unbalanced towards *favor* (specifically, 142, 312 *favor* and 100, 965 *against*), we randomly removed 41, 347 *favor* pairs to obtain a balanced training set for the stance model. The removed pairs were later used as additional test set to evaluate the model's accuracy.

Stance model. We initialized our model starting from UmBERTo [20], an Italian language model based on the RoBERTa architecture [21]. Specifically, we relied on the cased version trained using SentencePiece tokenizer and Whole Word Masking on a large corpus, encompassing around 70 GB of text. This makes it highly effective for various natural language processing tasks in Italian, as it leverages a vast and diverse dataset to understand the nuances of the language [29, 30]. The pretrained model was then fine-tuned on the constructed dataset of tweet-quote pairs to create a tool capable of inferring the stance of claim-perspective text pairs: *favor* if the perspective agrees with the claim, and *against* otherwise. To input the text pairs into the pretrained model, we utilized UmBERTo's special tokens. Specifically, we concatenated the tweet and quote as

```
<s> + tweet + </s></s> + quote + </s>,
```

where `<s>`, `</s></s>`, and `</s>` represent the start, separation, and end tokens, respectively. Since we set `max_seq_length = 256`, which limits the total number of tokens that can be processed by the model, in cases where the concatenated strings exceeded this limit, the longer text between the tweet and the quote was truncated. This ensures that the input remains within the model's processing capacity while preserving as much information as possible from both texts. Conversely, shorter concatenated strings were padded using the special token `<pad>` until they reached the 256-token limit. Tweets and quotes were preprocessed before being concatenated by removing URLs, mentions, non-UTF-8 characters, line breaks, and tabs.

The pretrained UmBERTo model was imported into Python from the HugginFace Transformers library [31] as a model for sequence classification. The fine-tuning procedure enabled the model to output the probability distribution over the stance labels by minimizing the cross-entropy loss between the predicted labels and the true labels, effectively learning to classify the stance of claim-perspective pairs. We chose to perform 5-fold cross-validation to ensure the reliability of the results [32]. Namely, the data was first partitioned into 5 equally (or nearly equally) sized segments or folds. Subsequently 5 iterations of training and testing are performed such that within each iteration a different fold of the data is held-out for testing while the remaining 4 folds are used for learning. Thus, for each training-test split, we fine-tuned the UmBERTo model for 4 epochs using a batch size of 64 (for both training and testing) and an improved version of the Adam optimizer [33] with a learning rate of $5e-5$ and a weight decay of 0.01 for regularization. The chosen hyperparameters are among those recommended in the literature[34, 21].

5. Conclusion

This study introduces a novel stance detection model that significantly advances the understanding of alignment and opposition in social discourse. By leveraging social network data from X (formerly Twitter), we developed a robust training technique that utilizes interactions within politically aligned communities. Our approach involved curating a dataset of tweet/quote pairs, where the quotes are derived from users' interactions with leaders and politicians. This dataset facilitated the training of a BERT model, which achieved a state of the art accuracy of approximately 85%.

Our findings underscore the efficacy of using social network structures to train NLP models, demonstrating that retweet interactions can serve as reliable indicators of political alignment. This methodology not only enhances the scalability of stance detection but also offers a nuanced understanding of political discourse on social media platforms. By reconstructing and validating politically aligned communities through expert knowledge, our model provides a robust framework for analyzing the alignment of social media statements.

The implications of this work extend beyond stance detection, offering potential applications in monitoring political sentiment, identifying misinformation, and understanding public opinion dynamics. Future research could explore the integration of additional social network features and exploring the capacity of the model to generalize to other domains, interaction types and understanding how stance propagates within networks.

Additionally, investigating the role of specific linguistic markers like adverbs across different languages and cultures can reveal universal and language-specific determinants of stance.

While our model shows promising results, it also relies heavily on the assumption that retweets are mainly a form of endorsement, and that quotes within one's own political community are all in agreement and that outside of one's political community they are all in disagreement. While the high level of polarization observed in these networks support the validity of these assumptions, it also restricts the applicability of the model to domains where polarization is evident and these assumptions are valid.

Acknowledgments

We extend our deepest gratitude to Vittorio Loreto, the director of the Sony Computer Science Laboratories (CSL) and Professor at La Sapienza University of Rome, for his invaluable support and sponsorship of this research. His guidance was pivotal for the successful completion of our study. We also thank the anonymous reviewers for their insightful suggestions, which have greatly contributed to enhancing the quality of this work.

Towards a Hate Speech Index with Attention-based LSTMs and XLM-RoBERTa

Mauro Bruno[1,†], Elena Catanese[1,†] and Francesco Ortame[1,*,†]

[1] Italian National Institute of Statistics (Istat)

Abstract

The diffusion of hate speech on social media requires robust detection mechanisms to measure its harmful impact. However, detecting hate speech, particularly in the complex linguistic environments of social media, presents significant challenges due to slang, sarcasm, and neologisms. State-of-the-art methods like Large Language Models (LLMs) demonstrate strong contextual understanding, but they often require prohibitive computational resources. To address this, we propose two solutions: (1) a bidirectional long short-term memory network with an attention mechanism (AT-BiLSTM) to enhance the model's interpretability and natural language understanding, and (2) fine-tuned multilingual robustly optimized BERT (XLM-RoBERTa) models.

Building on the promising results from EVALITA campaigns in hate speech detection, we develop robust classifiers to analyse 20.4 million Tweets related to migrants and ethnic minorities. Further, we utilise an additional custom labeled dataset (IstatHate) for benchmarking and training and we show how its inclusion can improve classification performance. Our best model outperforms top entries from previous EVALITA campaigns. Finally, we introduce Hate Speech Indices (HSI), which capture the dynamics of hate speech over time, and assess whether their main peaks correlate with major events.

Keywords

hate speech detection, deep learning, attention mechanism, RoBERTa, artificial intelligence

1. Introduction

Social media platforms provide a fertile ground for the dissemination of hate speech, particularly targeting vulnerable groups such as migrants and ethnic minorities. In the last decade, hateful speech on platforms like X has become a pressing issue, as it not only affects the individuals who are directly targeted, but also contributes to a climate of hostility and division. Detecting hate speech in social media content is crucial to analyse the safety and inclusivity of online platforms and social environments.

Hate speech detection is inherently challenging due to the subtle and evolving nature of social media language. Tweets often contain slang, neologisms, and sarcasm, which complicates the identification process. Traditional text classification methods usually fall short in addressing these challenges, especially for non-English languages where extensively labeled training sets are not easy to gather, calling for the development of more sophisticated approaches.

The topic of hate speech detection in Italian texts has gained significant attention within the natural language processing (NLP) community, as shown by the *HaSpeeDe* (Hate Speech Detection) tasks at EVALITA. For instance, the EVALITA 2018 [1], and 2020 [2] campaigns have provided labeled datasets and attracted several submissions employing a diverse set of machine learning and deep learning techniques. A prominent approach in recent hate speech detection and, in general, text classification, is the use of pre-trained language models like Bidirectional Encoder Representations from Transformers (BERT) [3]. After their first appearance in 2018, BERT-based models have set new standards in several NLP tasks thanks to their ability to capture contextual information effectively, especially when fine-tuned on the specific task of interest. In 2019, a multilingual robustly optimized BERT (XLM-RoBERTa) [4] was published, making it possible to obtain higher performances on non-English texts. For instance, *TheNorth* team for the *HaSpeeDe 2* task at EVALITA 2020 obtained the best results fine-tuning a XLM-RoBERTa model [5].

It is also worth noting that in recent years, generative Large Language Models (LLMs) have demonstrated an even more impressive ability to understand natural language. However, their large number of parameters makes them impractical for classifying large volumes of data, even when compared to the larger version of XLM-RoBERTa[1]. Given these developments and challenges, our research proposes two approaches to hate speech classification: (1) an attention-based bidirectional long short-term memory network (AT-BiLSTM), benchmarked against a standard BiLSTM model, and (2) a fine-tuned

[1] The number of parameters in Large Language Models ranges between a few billions to hundreds of billions of parameters, while the large version of XLM-RoBERTa "only" has 561 million parameters.

XLM-RoBERTa (large) model, benchmarked against its base, smaller version. We use two labeled training sets: (a) the EVALITA 2020 *HaSpeeDe 2* task dataset, and (b) a custom, smaller labeled dataset, which we refer to as *IstatHate*. Our study explores the impact of training models on both the EVALITA dataset alone and a combined dataset that includes EVALITA and *IstatHate*, evaluating their performance across multiple test sets.

Finally, we present a preliminary version of the Hate Speech Index (HSI), designed to quantify the proportion of hate speech by classifying 20.4 million Italian Tweets related to migrants and ethnic minorities from January 2018 to February 2023.

2. Data

This section describes the data used for training, validating, and testing the models and the corpus of Tweets on which we compute the hate speech index (HSI).

2.1. Corpus

The prediction corpus consists of 20.4 million unlabeled Tweets from January 2018 to February 2023. The Tweets are obtained through a two-step filtering procedure: *first*, a general 250-keyword filter gathers Tweets directly from X's API;*second*, a smaller, immigration-related keyword filter retrieves the relevant Tweets from the database. Thematic experts, borrowing the contents of discrimination survey questionnaires, have derived a preliminary filter. These regular or stemmed expressions have been validated by means of topic modelling analysis and word embedding. For instance, the word *cinese* ("chinese") was almost always related to markets or products and has therefore been removed. We also noticed that due to the generic term *stranieri* ("foreigners") there are also some residual out-of-scope and irrelevant conversations. These issues only affects around 5% of the total texts. The final filter consists in 21 stemmed expression (ex. *immigrat-*), or complete words.

2.2. Training data

EVALITA Most of the labeled training data comes from the EVALITA 2020 *HaSpeeDe 2* task. The distribution of the labels in the training dataset is shown in Table 1.

IstatHate Additionally, we use a custom-labeled dataset, i.e., *IstatHate*, derived from our corpus in the following way: (1) we fit a Latent Dirichlet Allocation (LDA) model [6] on the entire corpus, (2) we identify clusters likely to contain hateful Tweets, i.e., those with offensive language, such as "*fate schifo*" ("you suck"), and "*avete rotto i c****oni*" ("you pi**ed us off") and few others, (3) we retrieve Tweets from these clusters, identifying the expressions with a probability of 1 of belonging to the clusters. This approach isolates 242,000 Tweets, of which 67,000 are unique. It is worth noticing that viral Tweets (the ones that are repeated/retweeted several times) need to be annotated with a higher probability. A common practice to draw a much more efficient sample instead of simple random sampling is to use stratified sampling, an effective method for handling skewed distributions. In particular, we adopted [7]. (4) We employ stratified sampling using the total number of Tweets as the target variable, and we divided that variable into five classes using them as stratification criteria. (5) The Tweets are then stratified into the classes based on the number of retweets, with the final class being a take-all stratum, resulting in 681 sampled texts, ensuring a coefficient of variation of 5%. (6) These 681 Tweets are then manually labeled by Istat researchers adopting the following criteria: if the language is vulgar/aggressive but generic it is not labeled as hateful, if, on the contrary, it is related to migrants and/or ethnic minorities and the hate/prejudice is clearly directed towards them, then they were labeled as hateful. The weighted estimate indicates that 34% of the Tweets contains hateful language, serving as a rough upper bound of the hate proportion within our prediction corpus. Even if our sample dataset likely over-represents hateful content, we disregard the weighting at this preliminary phase, simply adding *IstatHate* to the EVALITA dataset.

Table 1
Labeled data distribution

dataset	split	n	% hateful	% not hateful
EVALITA	train	5469	40,46%	59,54%
	eval	1368	40,42%	59,58%
	test	1263	49,25%	50,75%
IstatHate	train	435	33,79%	66,21%
	eval	137	29,93%	70,07%
	test	109	33,94%	66,06%
Full	train	5904	39,97%	60,03%
	eval	1505	39,47%	60,53%
	test	1372	48,03%	51,97%

Table 1 shows the distribution of the labeled data between *hateful* and *not hateful* Tweets and across datasets and splits.

3. Methodology

In this section, we present the methodology adopted in our study and outline the experimental design. We begin by introducing the model architectures, followed by a detailed description of the training procedure.

3.1. AT-BiLSTM model architecture

The architecture of our attention-based bidirectional LSTM (AT-BiLSTM) model comprises four main components: an embedding layer, a bidirectional LSTM layer, an attention layer, and an output layer. We will detail each component sequentially.

Embedding layer We pre-train a FastText [8] embedding model on the prediction corpus and extract the word vectors to initialise the weights of the embedding matrix. Table 2 presents the main training parameters of our model: each word is represented by a 300-dimensional vector, the training considers a distance window between words of up to 8 positions, and the model is trained for 25 epochs using a continuous bag-of-words algorithm.

Table 2
FastText embedding model hyperparameters.

dim	window	epochs	algorithm
300	8	25	skip-gram

As emerged from the hyperparameter optimization phase[2], we keep the embedding weights fixed during the AT-BiLSTM training.

Attention mechanism In deep learning, attention mechanisms can improve model performance by focusing on important features of input sequences.

In our model, the attention mechanism is implemented on top of the LSTM layer to focus on the most relevant parts of the input sequence for predictions [9]. Our attention mechanism works as follows:

- Transform the LSTM output using a fully connected layer to get attention scores for each word.
- Normalise these scores into attention weights with a *softmax* function, creating a pseudo-probability distribution.
- Compute a context vector by taking a weighted sum of the LSTM outputs using the attention weights. This context vector emphasizes the most important parts of the input sequence for the classification task[3].

The attention mechanism allows our model to dynamically focus on different parts of the input for different examples.

LSTM layer The core of our model is a bidirectional Long Short-Term Memory (LSTM) network. LSTMs are a specialized type of recurrent neural network (RNN) designed to capture long-term dependencies in sequential data [10]. The *bidirectional* aspect of our LSTM processes the input sequence in both forward and backward directions. This bidirectionality provides the network with context from both past and future states for any given point (word) in the sequence (sentence) [11]. In practice, this means that when our model is processing a word in a Tweet, it has information about the words that came before and after it, allowing for an increased understanding of context.

The LSTM layer consists of multiple stacked bidirectional LSTM cells. Each cell maintains a cell state and a hidden state, which are updated at each time step as the input sequence is processed. The number of layers is included in the hyperparameter optimization phase.

Output layer The final component of our model is a fully connected (dense) layer that takes the context vector produced by the attention mechanism as input. The output dimension of this layer is one-dimensional, as there are two classes in our hate speech detection class. The output of this layer is passed through a softmax function to produce a number between 0 and 1. Finally, the class is assigned comparing the output with a threshold (0.5).

The optimal configuration for each LSTM-based model, resulting from Bayesian hyperparameter optimization, is detailed in the Appendix.

3.2. XLM-RoBERTa

Multilingual RoBERTa (XLM-RoBERTa, or XLM-R) is a transformer-based model that builds upon the original BERT model and the monolingual RoBERTa (Robustly Optimized BERT Pretraining Approach) model [12]. It is designed to handle multiple languages, making it particularly suitable for our task of hate speech detection in Italian texts.
XLM-RoBERTa is trained on 100 different languages and has a much larger vocabulary size (250k tokens) compared to both BERT (30k tokens) and RoBERTa (50k tokens).

3.3. Training

In this section, we outline the experimental design we followed to obtain our results. We structured our experiments to systematically assess model performance under different training conditions and across various test sets.

[2] We ran both random search and Bayesian optimization. The best result came from the latter.

[3] We also experimented with attention masking. However, this negatively impacted accuracy. Upon inspecting the attention scores, we observed that the model naturally assigns negligible weights to padding tokens.

3.3.1. Experimental design

Training sets We trained each model under *two* distinct scenarios: (1) a training set comprising only data from the EVALITA labeled dataset, and (2) a training set comprising both EVALITA data and *IstatHate* data.

Evaluation We evaluate every model on *three* test datasets: (a) a test set comprising only data from the EVALITA test dataset, (b) a test set comprising only data from the *IstatHate* test set, and (c) a combined test set comprising data from both EVALITA and *IstatHate* test sets. None of the texts in these test sets are seen by the models during training, in any scenario.

Therefore, we have four different architectures and two training sets, resulting in eight distinct models.

3.3.2. Model Training

LSTM-based We ran a Bayesian optimization process to automatically extract optimal hyperparameters. This optimization process is detailed in the Appendix. We trained the models for 10 epochs, and we extracted the best configuration based on validation loss.

XLM-RoBERTa Given the large size of XLM-RoBERTa models, we were not able to run Bayesian optimization, and instead employed grid search over a reduced subset of hyperparameters. We trained the models for 10 epochs, and extracted the weights from the run with the lowest validation loss. We follow a training procedure loosely based on the methodology outlined by [13], but with adaptations to the data and hyperparameters to optimise performance for our specific use case. A detailed description of the training hyperparameters can be found in Appendix A.1.

4. Results

In this section, we present the results of our analysis, covering model performance, attention weight visualizations, and Hate Speech Index (HSI) predictions.

4.1. Model performance

Table 3 highlights the performance of the models, presenting the macro F1 score across the different test sets.

There are several observations that can be made about these results. First, there is a clear positive correlation between model size and performance, particularly evident in the XLM-RoBERTa models, where the larger variant consistently outperforms the smaller ones across all test sets. This is expected for a complex task like hate speech detection.

Table 3
Comparative model performance on different test sets

	Tested on		
Model	Full	EVALITA	IstatHate
BiLSTM-EV	0,761	0,773	0,627
BiLSTM⋆	0,758	0,763	0,690
AT-BiLSTM-EV	0,763	0,780	0,550
AT-BiLSTM⋆	0,773	0,779	0,676
XLM-R-base-EV	0,773	0,788	0,603
XLM-R-base⋆	0,772	0,778	0,672
XLM-R-large-EV	0,796	0,810	0,632
XLM-R-large⋆	**0,811**	**0,816**	**0,750**

$^{(\text{-EV})}$ Trained only on EVALITA
$^{(\star)}$ Trained on both EVALITA and *IstatHate*.

A more interesting observation can be made about the effect of including *IstatHate* in the training set along EVALITA data: besides the expected increased performance on the *IstatHate* test set, there is a case in which the performance on the EVALITA test set increases too, namely XLM-RoBERTa-large⋆. This non-trivial cross-dataset improvement, suggests that training on both datasets enhances the model's generalization capabilities, despite the fact that the datasets were labeled by different people. Finally, it is interesting to notice how a simpler model like AT-BiLSTM⋆ manages to outperform XLM-RoBERTa-base⋆ on all test sets.
Results on the *IstatHate* test set are consistently lower than results on the EVALITA test set, but this was expected, as, even when included in the training, *IstatHate* is much smaller in size.
The *Full* test set is a combination of the EVALITA test set and the *IstatHate* test set, and therefore the macro F1 scores on the *Full* test set are a weighted mean between the ones obtained on EVALITA and *IstatHate*.
The best performing model across all test sets is XLM-RoBERTa-large⋆, i.e. fine-tuned on the training set combining both EVALITA and *IstatHate*.

A detailed table that compares the training and inference times of the different models can be found in Appendix A.2.

4.2. Attention visualization

An advantage of an AT-BiLSTM model over a standard BiLSTM model is its ability to visualise attention scores for each word, making outputs more interpretable[4]. Visualising attention scores provides a useful method for empirically examining the impact of training models on different datasets. For instance, the following are two Tweets classified by the AT-BiLSTM-EV model, along

[4] Attention scores can be visualized in BERT-based models too [14], but the XLM-RoBERTa tokenizer does not always split Italian text into complete words, making interpretation trickier.

with their corresponding attention scores.

Tweet 1 (true: No Hate, predicted: Hate)

IT *poi rompe il caz**o a tutti perché ha accolto una famiglia di profughi*

EN *then they break our ba**s because they hosted a family of refugees*

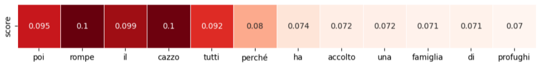

Figure 1: AT-BiLSTM-EV attention scores for Tweet 1.

Tweet 2 (true: Hate, predicted: Hate)

IT *Ipocriti farabutti. Fanno morire i terremotati per i bastardi clandestini immigrati schifosi*

EN *Hypocritical scoundrels. They let the earthquake victims die for the bastard disgusting illegal immigrants.*

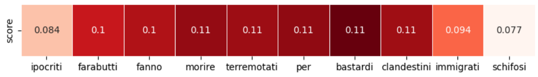

Figure 2: AT-BiLSTM-EV attention scores for Tweet 2.

The first Tweet is misclassified by the AT-BiLSTM-EV model. Analysing the attention scores, we can see how a lot of emphasis was put on curse words both on Tweet 1 and Tweet 2. Figure 3 shows the attention scores produced by the AT-BiLSTM⋆ model for Tweet 1 and Tweet 2, both texts are correctly classified. We can see how a lot of attention is still put on curse words like *ca**o* and *bastardi*, but a significant attention score is also given to *profughi* ("refugees") in Tweet 1. Since the Tweet is correctly classified as *not hateful* – it contains aggressive language but not directed towards migrants or ethnic minorities – we can assume that there is an increased contextual understanding compared to AT-BiLSTM-EV. Additionally, Figure 3 (bottom) shows how the distribution of attention scores for the AT-BiLSTM⋆ model is much more concentrated compared to AT-BiLSTM-EV.

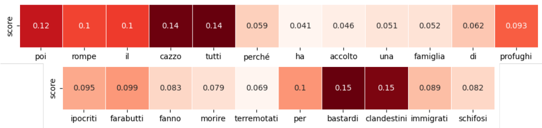

Figure 3: AT-BiLSTM⋆ attention scores for Tweet 1 and 2

4.3. Hate Speech Index (HSI)

In this section, we present and briefly discuss our preliminary Hate Speech Index (HSI) results.

Firstly, the daily HSI is computed as follows:

$$HSI_t = \frac{N_{hate,t}}{N_{hate,t} + N_{nohate,t}},$$

where $N_{hate,t}$ is the number of Tweets classified as hateful on day t, and $N_{nohate,t}$ is the number of Tweets classified as not hateful on day t.

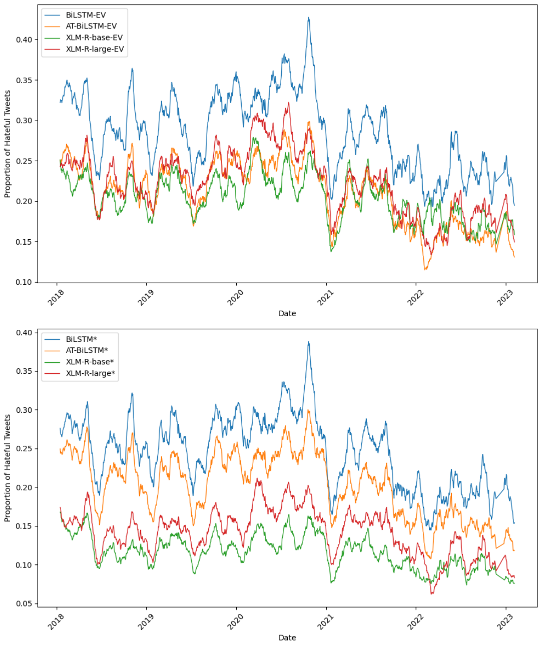

Figure 4: 30-day centered moving average predictions of the models trained only on EVALITA data (top) and on both EVALITA and *IstatHate* (bottom).

Figure 4 displays the different versions of the HSI as derived from the different models.

Descriptive statistics Table 4 illustrates descriptive statistics for the daily HSI.

Table 4
Mean and SD values for HSI.

	EV		⋆	
	mean	sd	mean	sd
BiLSTM	0.285	0.085	0.245	0.081
AT-BiLSTM	0.210	0.071	0.201	0.072
XLM-R-base	0.204	0.063	0.116	0.045
XLM-R-large	0.222	0.071	0.141	0.055

One immediately noticeable difference between the models trained solely on EVALITA and the models trained on

EVALITA and *IstatHate* are the consistently lower levels of the predictions coming from the latter compared to the former for all settings. In particular, the minimum decrease is recorded by BiLSTM models (-0.01), while the maximum decrease is achieved by XLM-RoBERTa-base (-0.09). The lowest mean value for the HSI is achieved by XLM-RoBERTa-base⋆ with an average, indicating a percentage of 11.7% hateful Tweets over the total Tweets in the corpus. The best performing model, XLM-RoBERTa-large⋆, predicts 14.1% of hateful Tweets.

With respect to the standard deviation, we observe that, XLM-RoBERTa models show lower variability compared to LSTM-based models. For XLM-RoBERTa and BiLSTM models, the standard deviation decreases when including *IstatHate* in the dataset.

Correlation The dynamics of the moving averages of the indices appear to be relatively coherent between models, as confirmed by correlations in the range between 0.81 (AT-BiLSTM⋆ vs XLM-RoBERTa-base-EV) and 0.98 (BiLSTM⋆ vs BiLSTM-EV). The lowest correlations between models with the same architecture and different training sets amounts to 0.88 (XLM-RoBERTa-base⋆ vs XLM-RoBERTa-base-EV).

We can now analyse a few peaks in the daily time series to empirically assess the quality of the estimates, and the ability of the models to detect specific events.

October 24, 2018 This date refers to the diffusion of the news about an unfortunate event in which a 16 years old girl was raped and killed by a group of men from Senegal and Nigeria. If we look at the trends in Figure 5 (top) and Figure 6 (top) in Appendix B.1, we notice how the increase in the proportion of hate speech persists in the following period. In this case, we observe that all models detect the event registering values more than twice their average.

July 25, 2021 This peak refers to a news about another 16 years old Italian girl that was beaten up on the street by her 17 years old Moroccan boyfriend. From Figure 5 (bottom) and Figure 6 (bottom) in Appendix B.1, we can see how not all models detect this event. In particular, of the models trained on both EVALITA and *IstatHate*, only XLM-RoBERTa-large⋆ and AT-BiLSTM⋆ show a clear peak in the trend, while LSTM-based models trained only on EVALITA struggle to identify this peak. The only model that detects the peak in both cases is XLM-RoBERTa-large, further empirically confirming its robustness.

We also inspected the negative shift at the beginning of 2021, detected by every model. Analysing the single days it appears that it is more of a trend rather than a response to a specific event/series of events.

5. Conclusion

This study addressed the issue of hate speech detection on social media, specifically focusing on X (formerly Twitter) and on migrants and ethnic minorities. Given the complexities of natural language on these platforms, we explored different approaches including lighter bidirectional LSTM models with and without attention mechanisms, and fine-tuned XLM-RoBERTa models both in their base and large formats. We trained our models on EVALITA 2020 *HaSpeeDe 2* data and also introduced a small labeled dataset, *IstatHate*, that improves the performance of the already best performing model, XLM-RoBERTa-large, when included in the training set.

Despite longer inference times and higher computational resources required for large amounts of data, heavier models like XLM-RoBERTa-large achieve significantly higher performance and generalization capabilities. Yet, AT-BiLSTM⋆ (i.e., the AT-BiLSTM model that includes both EVALITA and *IstatHate* data in the training), outperforms XLM-RoBERTa-base⋆ across all test sets, a notable achievement considering the difference in models size and inference time.

We compared the predictions of AT-BiLSTM-EV against AT-BiLSTM⋆ visualising the attention scores they assigned to the same Tweets. Empirical evidence shows that including *IstatHate* in the training set may improve contextual understanding and mitigate the bias that simpler models like LSTMs may have when classifying hate speech in the presence of curse words.

The preliminary computation of the Hate Speech Index (HSI) reveals significantly different levels of hate speech detection across different models and training sets, even though the training data has very similar characteristics. Fine-tuned XLM-RoBERTa models produce the lower estimates in levels, especially when *IstatHate* is included in the training set. Furthermore, when analysing hate peaks, XLM-RoBERTa-large⋆ predictions highly correlate with major events.

Future work will focus on expanding and validating the *IstatHate* dataset, exploiting the sampling weights, refining model architectures, and exploring additional features to enhance detection capabilities.

A. Optimization

A.1. Hyperparameters

Here, we show the optimal hyperparameters resulting from 50 iterations of Bayesian optimization of 10 epochs each for the LSTM-based models.

Table 5
Optimal hyperparameters for LSTM-based models

model	hid	n	drop	lr	decay	bs
AT-BiLSTM-EV	32	4	0.48	2.7e-3	1.52e-5	32
AT-BiLSTM⋆	128	2	0.40	3.0e-3	2.15e-4	32
BiLSTM-EV	128	3	0.48	1.4e-3	7.23e-6	16
BiLSTM⋆	64	2	0.49	1.1e-3	1.8e-6	32

In Table 5, *hid* represents the hidden dimension of the network, *n* the number of bidirectional LSTM layers, *drop* the dropout rate, *decay* the weight decay and *bs* the training batch size. The entire process took around 15 minutes for each model running on a NVIDIA T4 GPU.

For XLM-RoBERTa models, we used consistent hyperparameters, shown in Table 6.

Table 6
Hyperparameters for XLM-RoBERTa models

model	lr	scheduler	decay	bs	ga-steps
XLM-R	2e-5	linear	0.01	128	2

Where *scheduler* is the learning rate scheduler and *ga-steps* represents the gradient accumulation steps, meaning that instead of updating the weights immediately after each forward and backward pass for every mini-batch, the gradients are kept in memory and accumulated over several (two, in this case) mini-batches, simulating a larger batch size using less memory.

A.2. Training and Inference Time

We detail the training and inference times, grouping the LSTM-based methods in a single category and keeping XLM-RoBERTa (base) and XLM-RoBERTa (large) separated due to the difference in size between the models.

Table 7
Training and inference times

architecture	train	inf	gpu
LSTM	10s	3-8m	T4
XLM-R-base	15m	25m	A100
XLM-R-large	30m	45m	A100

B. Results

B.1. Peaks

Here, we show the daily index of the different models for the dates mentioned in the results section of the paper. The results come from the models trained on both EVALITA and *IstatHate*.

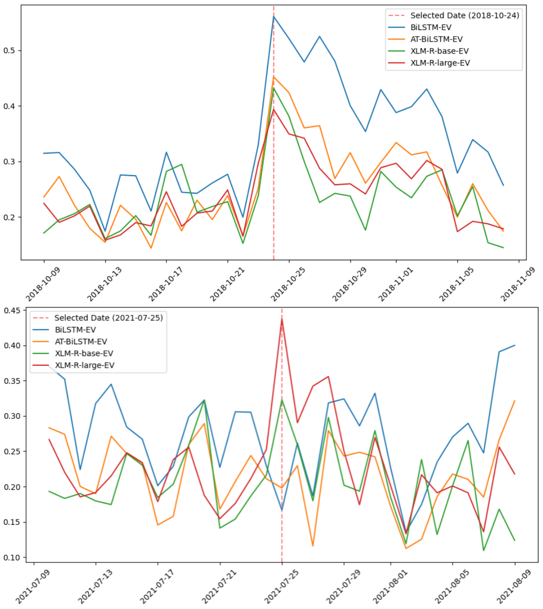

Figure 5: Daily HSI around peaks for models trained only on EVALITA.

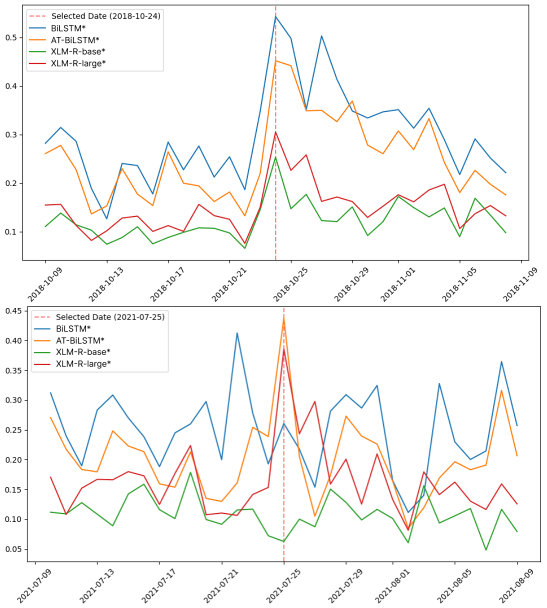

Figure 6: Daily HSI around peaks for models trained on both EVALITA and *IstatHate*.

Written Goodbyes: How Genre and Sociolinguistic Factors Influence the Content and Style of Suicide Notes

Lucia Busso[1,*,†], Claudia Roberta Combei[2,*,†]

[1] *Aston Institute for Forensic Linguistics, Aston University, Birmingham (UK)*
[2] *Dipartimento di Studi Umanistici, Università di Pavia (Italy)*

Abstract

The study analyses a novel corpus of 76 freely available English authentic suicide notes (SNs) (letters and social media posts), spanning from 1902 to 2023. By using NLP and corpus linguistics tool, this research aims at decoding patterns of content and style in SNs. In particular, we explore variation in linguistic features in SNs across sociolinguistic factors (age, gender, addressee, time period) and between text type – referred to as genre – (letters vs. online posts). To this end, we use topic models, subjectivity analysis, and sentiment and emotion analysis. Results highlight how both discourse and emotion expression, show differences depending on genre, gender, age group and time period. We suggest a more nuanced approach to personalized prevention and intervention strategies based on insights from computer-assisted linguistic analysis.

Keywords

suicide notes, topic modelling, sentiment and emotion analysis, subjectivity analysis

1. Introduction

This paper investigates the language of suicide notes, with the goal of uncovering patterns of discourse, topics, and emotional expression across various sociolinguistic factors and relationship dynamics, spanning over 100 years. A suicide note (SN) has been defined in the literature as "any available text by a suicide which was authored shortly before death" ([1]: 26).

The importance of a detailed analysis of suicide notes has been acknowledged in the scholarly debate ([2]). In fact, SNs have been widely studied in linguistics, sociology, and psychology starting with the publication in 1959 of Osgood and Walker's seminal work ([3]). Since then, the language of SNs has been investigated mainly through Genre Analysis ([4]), with some scholars working with corpus methods ([1, 5]). Lately, big corpora of SNs have been collected through the Web and used for computational analyses (*inter alia* [6, 7, 8]).

Research on SNs is naturally practical, being focused on suicide prevention ([9]), identification ([10]), and authenticity ([11]). For instance, the study by [6] uses classification algorithms to help mental health professionals distinguish between genuine and elicited suicide notes. This – the authors claim – can in turn help developing a prediction strategy of repeated suicide attempts, as suicide notes offer valuable insights into specific personality states and mindsets. Similarly, [7] suggests that analysing SNs may contribute to assessing the risk of repeated suicide attempts.

Despite the area being well-researched, especially in forensic linguistics, current analyses of SNs present several shortcomings. Given the difficulty of accessing data, scholars have either used dubious source material (such as the letters published on the blog "The Holy Dark"), or have reused and reanalysed SNs written by famous people (such as Virginia Woolf and Kurt Cobain, e.g., [12, 13]). Moreover, there is no study to date – to the best of the authors' knowledge – that analyses of SNs using text type, which we refer to as genre, or sociolinguistic factors (such as gender, age, addressee, or time period) as covariates.

In the present paper, we set out to perform corpus and computational analyses on a novel dataset of authentic suicide notes. Specifically, we aim to explore whether and to what extent SNs style and content vary according to genre (letter vs. online post) and sociolinguistic factors (the victim's gender and age, as well as the addressee and time period of the SN). To this end, we employ Structural Topic Modelling ([14]) and keyword analysis, subjectivity analysis ([15]), and sentiment and emotion analysis ([16, 17]).

2. Data

Despite the presence in the literature of various datasets of suicide letters, none - to the authors' best knowledge -

CLiC-it 2024: Tenth Italian Conference on Computational Linguistics, Dec 04 — 06, 2024, Pisa, Italy

[*] Corresponding authors

[†] Although both authors are equally responsible for the conceptualization and the contents of this article, for the purposes of Italian academia, we specify what follows: L. Busso authored Section 1, Section 2, and Section 3; C. R. Combei authored Section 4, Section 5, and Section 6.

l.busso@aston.ac.uk (L. Busso); claudiaroberta.combei@unipv.it (C. R. Combei)
https://orcid.org/0000-0002-5665-771X (L. Busso); https://orcid.org/0000-0003-1884-8205 (C. R. Combei)

are freely available to other researchers. Furthermore, existing corpora are usually either very small, and hence not suitable for quantitative analysis, or too big, and hence not controlled for the parameters we are interested in analysing. Therefore, we decided to collect a new dataset of genuine suicide notes to fill this gap, and to make it available to researchers interested in the topic. Given the sensitivity of the topic, corpus files are available upon requests to the authors. Using the semi-automated software *Bootcat* ([18], we collected a corpus consisting of 76 suicide letters and social media posts[1]. The SNs have the following characteristics:

- freely available on the open internet (i.e., not behind paywalls or log-in platforms)
- taken from reputable news websites to ensure authenticity (i.e. not taken from blogs or other non-official sources)
- only notes that were reproduced in full (i.e. not from extracts or quotes in other texts)

The resulting corpus contains 26,214 tokens, and includes texts from 1902 to 2023. Unavoidably, the distribution is skewed towards more recent texts (only 5 texts are from before 1950, and only 14 are from before 1990. The majority of the corpus (75%) includes SNs from 1990 to the present day). However, the corpus is balanced for textual type (genre), with 43 letters (51% of the tokens) and 33 social media posts (49% of the tokens). The SNs also cover a wide range of addresses, including messages directed to family, life-partners (including ex-partners), friends, the internet, or cases where the addressee is unspecified.

3. Topic Modelling and keywords analysis

3.1. Structural Topic Models

Topic Models (TM) are a family of unsupervised learning algorithms that cluster co-occurring words across documents into thematic nodes, or "topics" ([19]). These algorithms require a substantial human input, as the topics retrieved should be interpretable by the researcher assigning meaning to the patterns discovered ([20, 21]).

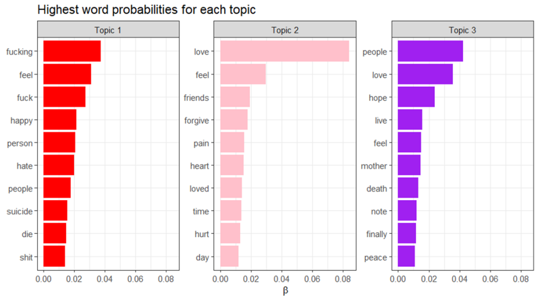

Figure 1: Top 10 word probabilities for each of the 3 topics

Table 1
regression-like analysis on differences in topical prevalence between genres

	estimate	t value	p value
Explanations	-0.04	-0.6	.6
Anguish	-0.27	-3.5	**<.001**
Connectedness	0.31	4.2	**<.001**

In this study we use Structural Topic Modelling ([14]), a type of TM that allows to model topics distribution as a function of document-level covariates in regression-like schemes. The STM analyses are performed in R[22]. We select a number of topics K=3 based on mathematical fit and ease of interpretation, and we model the effect of the "genre" covariate on topic content (i.e. lexical content used within topics) and prevalence (i.e. the frequency with which a topic is discussed).

Figure 1 shows the top 10 word probabilities for the 3 topics in the corpus. Following extensive concordance analysis to explore the keywords in context, the three topics have been labelled:

1. Topic 1: *Explanations*. This topic clusters words related to reasons, motives, and emotions associated with the act of suicide.
2. Topic 2: *Anguish*. This topic clusters words related to the intimate feelings of pain and hurt that accompany suicidal ideation.
3. Topic 3: *Connectedness*. This topic clusters words that refer to close connections to other people in the victim's life.

As mentioned above, we model the effect of genre (letter vs. online post) for topical content and prevalence. While we find no statistical differences ($p > .05$) for topical content, some interesting differences arise in topical prevalence, as can be seen in Table 1 and in Figure 2. Specifically, we observe that online posts discuss significantly less private feelings of anguish and pain (Topic 2) and significantly more interpersonal relationships (Topic 3).

3.2. Keyword Analysis

To explore the corpus further, beside the "black box" of the STM algorithm, we performed a keyword analysis.

[1] We based our data retrieval on the sources provided by [7], and expanded on them through targeted Google searches. For privacy reasons, online posts were only collected if reported by newspaper articles, and were not retrieved on social media platforms themselves.

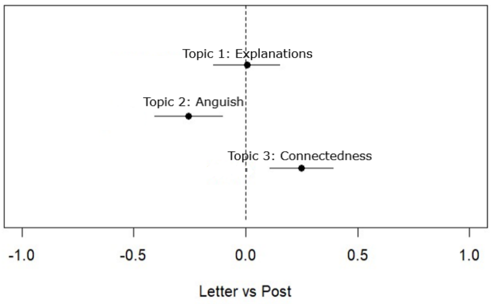

Figure 2: Difference in topic prevalence between letters and online posts

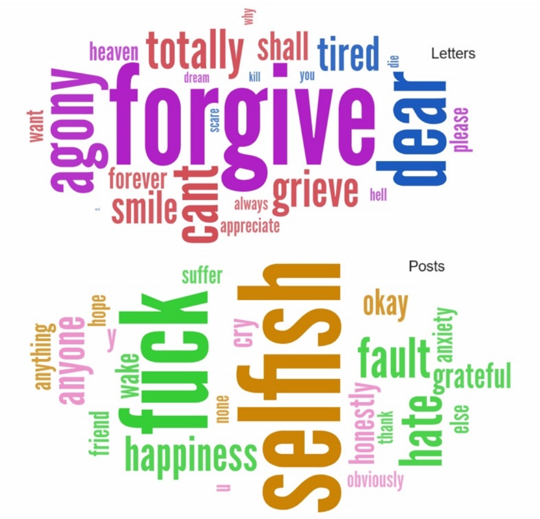

Figure 3: Top 50 idiosyncratic keywords for Letters and Online Posts

Using SketchEngine ([23]), we extract keywords for both letters and social media posts using EnTenTen21 as reference corpus. To ensure that we only consider words that are used throughout the corpus, we discarded instances with a low ARF (average reduced frequency) score ([24]). Not surprisingly, many keywords are shared across the two subcorpora, reflecting "universal" themes of suicidal ideation such as apologies, goodbyes, and explanations. However, idiosyncratic keywords paint an interesting picture (see Figure 3), as online posts seem to display a lower prevalence of intimate feelings, and more polarized emotion words and swearwords.

4. Subjectivity analysis

Subjectivity analysis investigates what is generally labelled as a "private state", namely opinions, feelings, beliefs, speculations ([15]: 674), typically classifying a text on a scale ranging from high objectivity to high subjectivity.

Our paper uses this analysis because we see subjectivity as a relevant stylistic and content-related element, useful for understanding suicidal ideation. Although this is a preliminary study, we believe that findings from subjectivity, sentiment, and emotion analysis, supported by the exploration of psychosocial factors (not the object of this paper), could be useful for evaluating the risk of (repeated) suicide attempts. In particular, we expect that highly subjective texts may signal intense personal turmoil, which has, in fact, been reported as a potential risk factor for suicide ([25]).

This research uses the TextBlob library for Python that provides tools for various textual analyses, including subjectivity, as part of its sentiment analysis function[2]. The tool uses a pattern analyzer and a pre-defined dictionary of word polarity and subjectivity. It also incorporates intensity, accounting for the impact of modifiers, which can increase or reduce the measured subjectivity score. Each SN is processed to extract its overall subjectivity score that ranges from 0 (i.e., highly objective) through 1 (i.e., highly subjective). To discuss the effect of genre and sociolinguistic factors on the subjectivity score, we present the results of statistical analyses conducted in R[22].

First of all, the mean subjectivity score at the corpus level (*M = 0.56, SD = 0.12*) indicates that SNs are characterized by a level of subjectivity that falls above the midpoint of the scale (0.50); there is, thus, a tendency toward greater subjectivity than objectivity. Interestingly, however, the mean subjectivity scores and their distributions are nearly identical between letters (*M = 0.56, SD = 0.13*) and social media posts (*M = 0.57, SD = 0.12*).

Next, based on Figure 4, SNs written from 1950-1969 seem to have the highest subjectivity score (*M = 0.72, SD = 0.15*). In contrast, the lowest subjectivity is found for SNs written from 1990-1999 (*M = 0.49, SD = 0.12*), followed by those from 1970-1989 (*M = 0.52, SD = 0.15*). SNs written before 1950 (*M = 0.56, SD = 0.11*), from 2000-2019 (*M = 0.56, SD = 0.11*), and from 2020-now (*M = 0.56, SD = 0.13*) have identical subjectivity scores.

The results displayed in Figure 5 indicate that subjectivity scores of SNs addressed to life-partners (*M = 0.61, SD = 0.06*) are the highest, followed by those addressed to family (*M = 0.60, SD = 0.09*). This suggests that SNs addressed to people with whom the victim has a close relationship are characterized by a deeper personal engagement and a more vivid linguistic expression than those addressed to the internet (*M = 0.56, SD = 0.12*), to friends (*M = 0.55, SD = 0.08*), and to other addressees (*M*

[2] The sentiment analysis score itself obtained from the TextBlob tool is not used in this study, as more advanced methods for investigating sentiment are preferred (see Section 5)

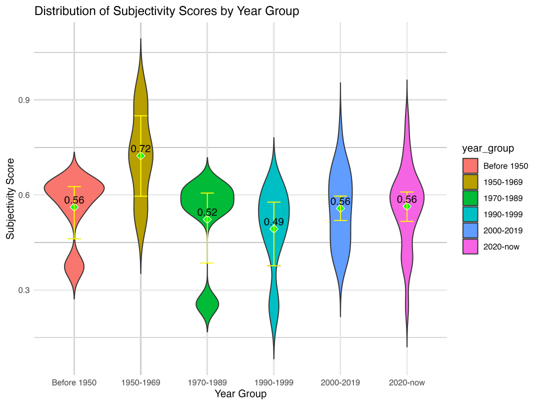

Figure 4: Subjectivity as a function of the year group

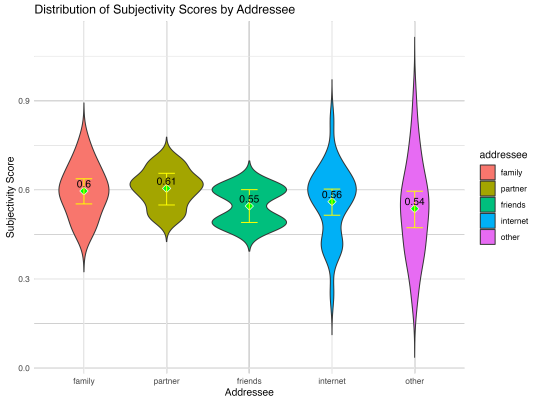

Figure 5: Subjectivity as a function of addressee

= *0.54, SD = 0.16*). The standard deviations for most addressees (i.e., partner, family, friends) are relatively small, suggesting limited variation within these groups.

As regards the victim's gender, the average subjectivity score for females (*M = 0.58, SD = 0.11*) is slightly higher than the score for males (*M = 0.54, SD = 0.14*), but the standard deviations point out that the ranges overlap to a large extent. Finally, no consistent tendency emerges from the distribution of subjectivity scores with respect to the victim's age. In fact, there is substantial variation within each age group, meaning that the degree of subjectivity in SNs is influenced by other factors.

5. Sentiment and emotion analysis

In order to obtain a more fine-grained image of the emotional dimension of the SNs, and to complement the previously discussed findings on the topics and subjectivity of these texts, we also present and discuss the results of sentiment and emotion analysis. Sentiment analysis is defined as "the task of finding the opinions of authors about specific entities" ([26]: 82). Emotion analysis (also emotion classification), on the other hand, is often seen as a more refined version of sentiment analysis, since it deals with the identification of primary emotions in a text ([27]).

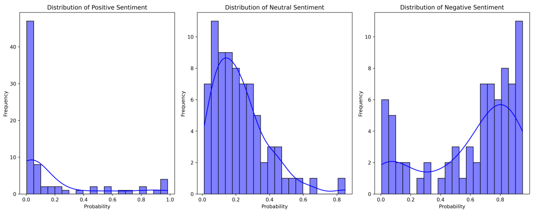

Figure 6: Distribution of probabilities for positive, neutral, and negative sentiment

For this research we employ the latest version available (at the time of writing) of Twitter-roBERTa-base for sentiment analysis, a model trained on over 124 million tweets that is fine-tuned for this task with the TweetEval benchmark ([28, 29, 30]). For emotion classification, we use the Emotion English DistilRoBERTa-base model ([31]) to extract Ekman's six basic emotions ([32]): anger, disgust, fear, joy, sadness, and surprise, along with a neutral class. The model is a fine-tuned version of DistilRoBERTa-base, trained on six balanced datasets, each containing 2,811 observations per emotion, for a total of almost 20,000 observations.

Our analysis reveals that the average probability of negative sentiment (*M = 0.61, SD = 0.31*) is roughly three times higher than the average probability of neutral (*M = 0.22, SD = 0.15*) and positive sentiment (*M = 0.17, SD = 0.28*). Then, the dominant sentiment in each SN is determined by identifying the highest probability among the three sentiment classes. We find that 73% of the SNs have negative sentiment as the highest probability, 17.1% positive sentiment, and 9.2% neutral sentiment. This trend is also supported by Figure 6 that shows the distribution of sentiment probabilities, confirming that most SNs have a higher likelihood of expressing negative sentiment. We interpret these results as a reflection of the emotional distress tied to both writing the suicide notes and the thoughts surrounding the act of suicide itself.

Some interesting tendencies are observed from the analysis of sentiment distribution across sociolinguistic factors and genre. First, Figure 7 illustrates a consistent difference between the two genres: online posts have a higher prevalence of negative sentiment (90.9%) compared to letters (60.5%).

Next, all SNs from 1970-1989 show negative sentiment as being dominant (100%). A high presence of negative

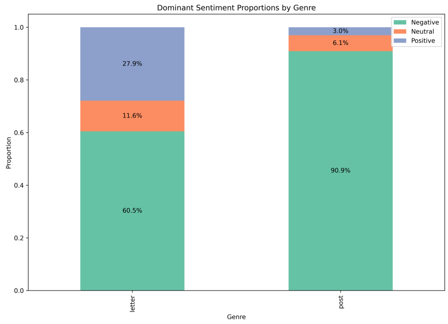

Figure 7: Sentiment as a function of genre

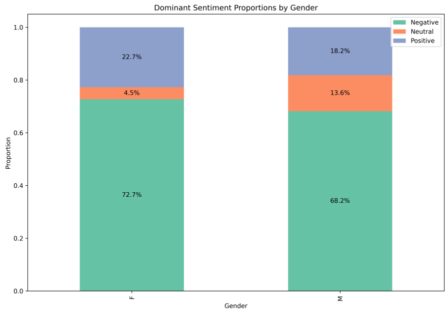

Figure 8: Sentiment as a function of gender

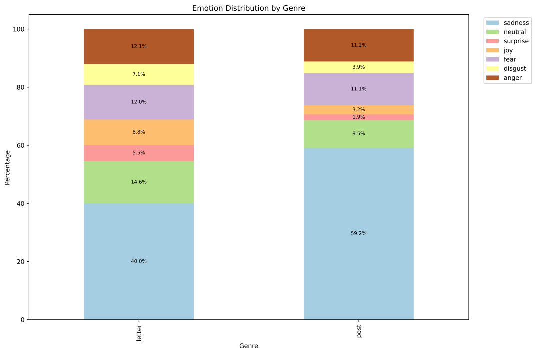

Figure 9: Emotions as a function of genre

sentiment (88.5%) is also present in SNs written from 2020-now. Interestingly, SNs from 1990-1999 display a balanced sentiment distribution (50% negative and 50% positive), marking the only period in our corpus with such a high presence of positive sentiment. This situation could be due to the fact that the authors of these (very long) SNs are well-known celebrities (e.g., Kurt Cobain and OJ Simpson). Even if the letters were not intended for the general public, the idea these texts might eventually become public could have influenced the victims to transmit more positive messages.

Some patterns of sentiment distribution are traceable when considering the addressee of the SN. Positive sentiment is more common when the addressee is the victim's partner (40%) or family (35.7%). Contrarily, a very high percentage of negative sentiment is observed in SNs addressed to the general public on the internet (93.1%). Figure 8 shows that the negative sentiment is slightly more frequent in SNs written by female victims (72.7%) compared to male victims (68.2%). As for the victim's age, a distinct pattern is difficult to identify, but, negative sentiment is the most frequent (over 65%) in SNs written by teenagers (10s) and people in their 20s, 30s, 40s, and 60s.

Moving on to emotion analysis, the average probability of SNs conveying sadness (*M = 0.48, SD = 0.37*) is four times higher than the average probability of conveying anger (*M = 0.12, SD = 0.22*), fear (*M = 0.12, SD = 0.21*), and neutrality (*M = 0.12, SD = 0.18*). Sadness (53.9%) is, indeed, the dominant emotion in the corpus, followed by neutrality (13.2%), anger (11.8%), and fear (7.9%). This is determined by identifying the highest probability among the seven emotion classes for each individual SN.

We can pinpoint some interesting outcomes from the analysis of emotions across genres and sociolinguistic factors. As concerns genre, Figure 9 depicts an obvious difference between letters and online posts. On the one hand, sadness is more frequent in online posts (59.2%) compared to letters (40%). On the other hand, neutrality and joy, the only two non-negative emotions, are more frequent in letters (14.6% and 8.8%, respectively) than in online posts (9.5% and 3.2%, respectively).

The analysis reveals that sadness is the most prevalent emotion across all time periods. In particular, the presence of sadness exceeds 50% in SNs from 1970-1989 and from 2020-now. Then, the SNs written from 1970-1989 are also characterized by a definite presence of disgust (22.2%). In line with the sentiment analysis results, SNs from 1990-1999 contain the lowest presence of sadness (40.8%) and generally the lowest presence of negative emotions overall, compared to other periods. SNs written before 1950 display the highest presence of fear (17.3%) in the corpus, although sadness still remains the most prevalent emotion in this period.

From Figure 10, we can identify a clear disparity between the emotions transmitted by female and male victims. Sadness appears more frequently in SNs written by females (53.1%) compared to males (41.5%). Additionally, anger is more prevalent in SNs written by males (17.1%), ranking as their second most common emotion (after sadness).

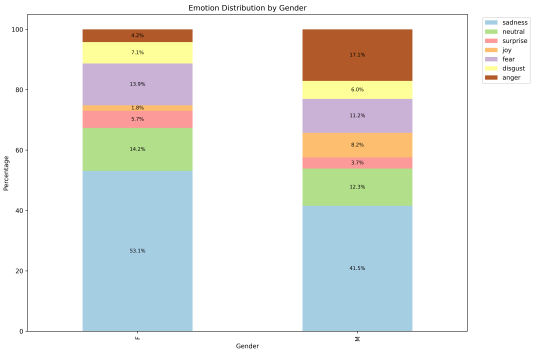

Figure 10: Emotions as a function of gender

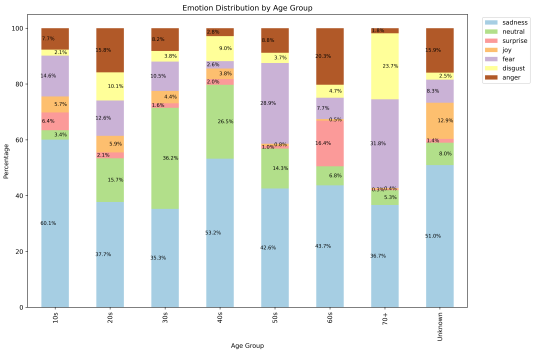

Figure 11: Emotions as a function of age group

Although Figure 11 illustrates a complex distribution of emotions across the age groups of the victims, some patterns still emerge. Sadness is the most common emotion in the SNs of all age groups except for those written by people in their 30s, where neutrality prevails (36.2%). Interestingly, teenagers express the lowest neutrality (3.4%) and the highest sadness (60.1%). Additionally, fear is prominent among SNs written by people over 70 years old (31.8%), making it the second most frequent emotion for this age group. Fear is also the second most common emotion for SNs written by teenagers (14.6%).

6. Conclusions

This mixed-methods study analysed the content and style of 76 SNs written over the course of a century, using genre, several sociolinguistic factors, and relationship dynamics as covariates. First of all, three main topics emerged from our corpus, that we labelled as *Explanations*, *Anguish*, and *Connectedness*. Looking at the differences in topical prevalence between the two text types, we observed that online posts displayed less private feelings (e.g., anguish and pain) and greater polarized emotion words and swearwords.

Subjectivity analysis revealed that SNs tended to be more subjective than objective, irrespective of the genre. Some differences based on addressees were identified in the corpus; for example, SNs directed toward close relationships (i.e., life-partners and family) showed higher subjectivity scores, suggesting a more profound and personal style, compared to those directed toward the broader (internet) public.

As far as sentiment analysis is concerned, negative sentiment was dominant in the corpus (i.e. three times more frequent than neutral or positive sentiment), especially in online posts. Then, the analysis of emotions revealed that sadness was the main emotion in the corpus. This evident presence of sadness and negative sentiment reflects the complex emotional challenges and inner struggles that victims experienced at the time they wrote their SNs. Although sadness was the most common emotion in both letters and online posts, it occurred more frequently in the latter text type. Also, letters tended to convey more positive emotions (e.g., joy) more frequently than online posts. Finally, the analysis revealed that sadness was more common in the SNs written by female victims and by teenagers.

All in all, our results reveal that the content, discourse, and emotional expression in SNs vary as a function of genre, sociolinguistic factors, and relationship dynamics. These differences uncover the need of taking into account specific social, demographic, and cultural variables when designing and implementing suicide prevention and intervention strategies. In this sense, we believe that corpus-based and NLP research on SNs can contribute to the improvement of these personalized strategies.

Abstract

Argument Mining (AM) aims to extract the complex argumentative structure of a text and Argument Type Classification (ATC) is an essential sub-task of AM. Large Language Models (LLMs) have shown impressive capabilities in most NLP tasks and beyond. However, fine-tuning LLMs can be challenging. In-Context Learning (ICL) has been suggested as a bridging paradigm between training-free and fine-tuning settings for LLMs. In ICL, an LLM is conditioned to solve tasks using a few solved demonstration examples included in its prompt. We focus on AM in the biomedical AbstRCT dataset. We address ATC using quantized and unquantized LLaMA-3 models through zero-shot learning, in-context learning, and fine-tuning approaches. We introduce a novel ICL strategy that combines kNN-based example selection with majority vote ensembling, along with a well-designed fine-tuning strategy for ATC. In zero-shot setting, we show that LLaMA-3 fails to achieve acceptable classification results, suggesting the need for additional training modalities. However, in our ICL training-free setting, LLaMA-3 can leverage relevant information from only a few demonstration examples to achieve very competitive results. Finally, in our fine-tuning setting, LLaMA-3 achieves state-of-the-art performance on ATC task in AbstRCT dataset.

Keywords

Argument Mining, NLP, LLMs, LLaMA-3, Zero-Shot Learning, In-Context Learning, Fine-tuning, Ensembling

1. Introduction

Argument Mining (AM) focuses on extracting the underlying argumentative and discursive structure from raw text [1]. Argument Type Classification (ATC), which involves classifying argumentative units in text according to their argumentative roles, is the crucial sub-task in AM. Research has shown that the argumentative role of a unit cannot be inferred solely for its text: additional structural and contextual information is needed [2]. This additional information can be incorporated via feature engineering [2], memory-enabled neural architectures [3, 4] or LLM-based hybrid methods [5, 6].

Large Language Models (LLMs) have become ubiquitous in deep learning and have shown impressive capabilities in most NLP tasks [7]. In the main, LLMs are used in two distinct settings: (i) training-free, where the pretrained LLM is used for inference without any parameter adjustment, and (ii) fine-tuning, where the parameters of the LLM are updated through supervised training to enable transfer learning on a downstream task. Zero-shot learning refers to the training-free approach where a pretrained LLM is prompted to solve tasks on completely unseen data samples.

Recently, In-Context Learning (ICL) has been proposed as a bridging paradigm between the training-free and fine-tuning settings. ICL is a prompt engineering technique whereby an LLM is conditioned to solve tasks by means of a few solved demonstration examples included as part of its input prompt [8]. Generally, the input prompt includes task instructions, the current input sample to be solved as well as several solved input-output pair examples. In this way, ICL maintains the training-free posture (parameters frozen) of the LLM while at the same time providing it with some supervision through demonstration examples. It also enables direct incorporation of selected features inside the prompt template, thereby obviating the need for architecture customization. Creative ICL strategies combining kNN-based examples selection, generated chain-of-thought (CoT) prompting, and majority vote ensembling have been proposed and shown to outperform fine-tuning approaches [9, 10, 11, 12]. In the main, kNN-based examples selection optimizes the process of learning from few examples and ensembling increases the robustness of the predictions [13, 9, 11].

This work focuses on AM in the biomedical AbstRCT dataset [14]. More specifically, we address the ATC task using quantized and unquantized LLaMA-3 models, among the most capable openly available LLMs (cf. leaderboard), through zero-shot learning, in-context learning,

and fine-tuning approaches. Our contributions are as follows:

- In zero-shot learning setting, we show that LLaMA-3 fails to achieve acceptable classification results, suggesting the need for implementing additional training modalities.
- We introduce a novel ICL strategy that combines kNN-based example selection with majority vote ensembling. In this training-free setting, LLaMA-3 can leverage relevant information from only a few demonstration examples to achieve very competitive results.
- We further experiment with fine-tuning strategy for LLaMA-3. In this setting, we achieve state-of-the-art performance on the ATC task for AbstRCT dataset.

Our code is freely available on GitHub.

2. Related Works

In early works, Argument Mining has been approached using both classical algorithms such as SVM [15, 2, 16, 17] as well as recurrent neural network models such as BiLSTMs [18, 19, 4]. Transformer-based models, such as BERT [20], have also been utilized for AM, including multi-scale argument modelling and customized feature-injected BERT-based models [21, 22, 23, 5, 6, 24, 25]. AM in the biomedical AbstRCT dataset has been approached using LSTMs [26, 27], sequential transfer learning [28] as well as transformer-based models [29, 30, 31].

More recently, AM sub-tasks have been modeled as text generation tasks using LLMs. For the Argument Type Classification (ATC) sub-task, this approach involves using a prompt template to generate the corresponding class of an argument component. This method has been applied to various AM use-cases, such as podcast transcripts and legal documents [32, 33, 34]. The latest approach in this 'AM using LLM text generation' direction involves a prompt that includes the argument component as the query and the complete text as the context, to output the class of the argument component using a generative model [35]. In this study, the three AM sub-tasks are modeled using the Persuasive Essays (PE) and AbstRCT datasets.

In contrast to the fine-tuning approach, a relevant training-free ICL prompting strategy for LLMs has been proposed [9, 11]. This strategy combines kNN-based example selection, generated chain-of-thought prompting, and majority vote ensembling for few-shot classification. Interestingly, the ICL strategy outperforms the fine-tuning approach on the datasets used in the study.

Our work sits at the intersection of zero-shot learning, in-context learning and fine-tuning. We implement and compare the performance of the latest openly available LLMs using these three approaches for AM on the AbstRCT dataset.

3. Methodology

3.1. Datasets

We consider the AbstRCT dataset which consists of abstracts of 650 Randomized Controlled Trials selected from the biomedical database PUBMed [14]. For AbstRCt dataset, the Neoplasm train set (Neo-train) consists of 350 abstracts whereas the three Neoplasm, Glaucoma and Mixed tests sets (Neo-test, Gla-test and Mix-test, respectively) consist of 100 abstracts each. The statistics of AbstRCT dataset are given in Table 1. The argument type classification (ATC) task consists of predicting the type of each argument component (AC) as 'Major Claim', 'Claim' or 'Premise'. Following previous approaches, we combine the 'Major Claim' and 'Claim' classes into a single class 'Claim'.

Dataset Split	Abstracts	ACs
Neo-train	350	2,291
Neo-test	100	691
Gla-test	100	615
Mix-test	100	609

Table 1
AbstRCT dataset statistics.

An sample of the AbstRCT dataset is provided below. The argument components (ACs) and their corresponding classes are indicated by bold tags.

<AC1: Major Claim>A combination of mitoxantrone plus prednisone is preferable to prednisone alone for reduction of pain in men with metastatic, hormone-resistant, prostate cancer.**</AC1>** The purpose of this study was to assess the effects of these treatments on health-related quality of life (HQL). Men with metastatic prostate cancer (n = 161) were randomized to receive either daily prednisone alone or mitoxantrone (every 3 weeks) plus prednisone. Those who received prednisone alone could have mitoxantrone added after 6 weeks if there was no improvement in pain. HQL was assessed before treatment initiation and then every 3 weeks using the European Organization for Research and Treatment of Cancer Quality-of-Life Questionnaire C30 (EORTC QLQ-C30) and the Quality of Life Module-Prostate 14 (QOLM-P14), a trial-specific module developed for this study. An intent-to-treat analysis was used to determine the mean duration of HQL improvement and differences in improvement duration between groups of patients. **<AC2: Premise>**At 6 weeks, both groups showed improvement in several HQL domains**</AC2>**, and **<AC3: Premise>**only physical functioning and pain were better in the mitoxantrone-plus-prednisone group than in the prednisone-alone group**</AC3>**. **<AC4: Premise>**After 6 weeks, patients taking prednisone showed no improvement in HQL scores, whereas those taking mitoxantrone plus prednisone showed significant improvements in global quality of life (P =.009), four functioning domains, and nine symptoms (.001 < P <. 01)**</AC4>**, and **<AC5: Premise>**the improvement (> 10 units on a scale of 0 to100) lasted longer than in the prednisone-alone group (.004 < P <.05)**</AC5>**. **<AC6: Premise>**The addition of mitoxantrone to prednisone after failure of prednisone alone was associated with improvements in pain, pain impact, pain relief, insomnia, and global quality of life (.001 < P <.003).</AC6> **<AC7: Claim>**Treatment with mitoxantrone plus prednisone was associated with greater and longer-lasting improvement in several HQL domains and symptoms than treatment with prednisone alone.**</AC7>**

3.2. Zero-Shot Learning (ZSL) and In-Context Learning (ICL)

Zero-shot learning (ZSL) is the paradigm where the LLM is asked to solve a downstream task without receiving any specific solved examples in the prompt. By contrast, *in-context learning (ICL)* refers to the emergent ability of LLMs to solve a downstream task based on a few demonstration examples given in the prompt as contextual information [8]. As the major advantage, ZSL and ICL paradigms do not require any fine-tuning of the model's parameters (i.e. training-free framework).

Formally, let x be a query input text and $C = [I; t(x_{i_1}, y_{i_1}); \ldots ; t(x_{i_k}, y_{i_k})]$ be a context composed of instructions I concatenated with input-output pairs (x_j, y_{i_j}) in text format, where $X = \{x_1, x_2, \ldots\}$ and $Y = \{y_1, \ldots, y_k\}$ are the sets of possible input and outputs, respectively. The ZSL and ICL paradigms correspond to the cases where $k = 0$ and $k > 0$, respectively. For input x, the LLM $\mathcal{M}$ predicts the output $\hat{y}$ such that

$$\hat{y} = \arg\max_{y_i \in Y} P_{\mathcal{M}}(y_i \mid C; x) ,$$

where $P_{\mathcal{M}}(y_i \mid C; x)$ is the probability that $\mathcal{M}$ generates y_i when C and x are given as prompt. The main rationale behind ZSL and ICL is that the consideration of a well-chosen context C increases the probability of $\mathcal{M}$ predicting the correct answer y for input x, i.e., that $P_{\mathcal{M}}(y \mid C; x) > P_{\mathcal{M}}(y \mid x)$.

We consider a 2-step ICL strategy for argument type classification (ATC) inspired by a recent study [9] (see Figure 1). More precisely, let A be an abstract containing argument components (ACs) $c_1, \ldots, c_m$ with corresponding true classes $y_1, \ldots, y_m$, where each $y_i \in \{\text{Claim}, \text{Premise}\}$. Given the ACs $c_1, \ldots, c_m$ in the prompt, the LLM generates the corresponding class predictions $\hat{y}_1, \ldots, \hat{y}_m$ as follows:

(1) ***k*NN-based examples selection ($k = 3, 5$):** First, $2k$ neighboring abstracts $A_1, \ldots, A_{2k}$ of A are selected according to the following similarity measure. For any abstract A_i, let the signature of A_i be the embedding of the first sentence of A_i using the BioBERT model. The abstracts $A_1, \ldots, A_{2k}$ are the ones whose signatures are the closest, with respect to cosine similarity, to the signature of A. Then, k abstracts, $A_{i_1}, \ldots, A_{i_k}$, are randomly chosen from $A_1, \ldots, A_{2k}$. Afterwards, a prompt containing all the ACs and their corresponding classes in these k abstracts is constructed (*k***NN**). Finally, the LLM predicts the classes $\hat{y}_1, \ldots, \hat{y}_m$ of $c_1, \ldots, c_m$ on the basis of on this prompt.

(2) ***n*-Ensembling ($n = 3, 5$):** The kNN-based examples selection step, which involves randomness, is repeated n times (n**Ens**), leading to a set of n sequences of class predictions $\{(\hat{y}_{i,1}, \ldots, \hat{y}_{i,m}) : i = 1, \ldots n\}$. The final class predictions $\hat{y}_1, \ldots, \hat{y}_m$ of $c_1, \ldots, c_m$ are obtained by applying a component wise majority vote to the n predictions sequences.

The kNN-based example selection optimizes learning from few examples by selecting samples most similar to the current instance, rather than choosing them randomly. The ensembling step increases prediction robustness by selecting the most frequent predictions. Note that the relevance of the ensembling step relies on the random selection in the kNN step. This randomness ensures that same predictions are not always produced, allowing for majority voting and thereby increasing robustness.

To aid the LLM in generating predictions, additional task-specific information is typically included in the prompt. For example, definitions of the 'Claim' and 'Premise' classes, along with their statistics in the Neo-train set, can be incorporated in the prompt (**info**). Moreover, in addition to the ACs $c_1, \ldots, c_m$ whose class are to be predicted, the abstract text from which these ACs originate can be included in the prompt (**abstract**). According to this ICL strategy, the classes $\hat{y}_1, \ldots, \hat{y}_m$ of $c_1, \ldots, c_m$ are predicted all-at-once (see Figure 1). Therefore, a prompt of the form 'info + abstract + 3NN + 3Ens' (see Table 3) indicates that the argument components (ACs) of the abstract are predicted all-at-once, by incorporating additional information and the entire abstract text as contextual cues in the prompt, and employing the ICL strategy with 3NN-based example selection and 3-ensembling. A similar ICL strategy, where the classes $\hat{y}_1, \ldots, \hat{y}_m$ are inferred one-by-one (i.e., each model inference leads to a single prediction $\hat{y}_j$), has been considered but shown to be significantly less efficient. Due to space constraints, the latter results are omitted in this work.

3.3. Fine-tuning

Fine-tuning (FT) refers to the process of further training a pre-trained LLM on a downstream task. Previous studies indicate that relying solely on the text of an argument component is insufficient for predicting its argumentative class; additional contextual information is essential for achieving competitive classification accuracy [2, 5, 6]. Therefore, we propose a fine-tuning strategy that models the ATC task at the document level. Specifically, we incorporate task-specific information into each training

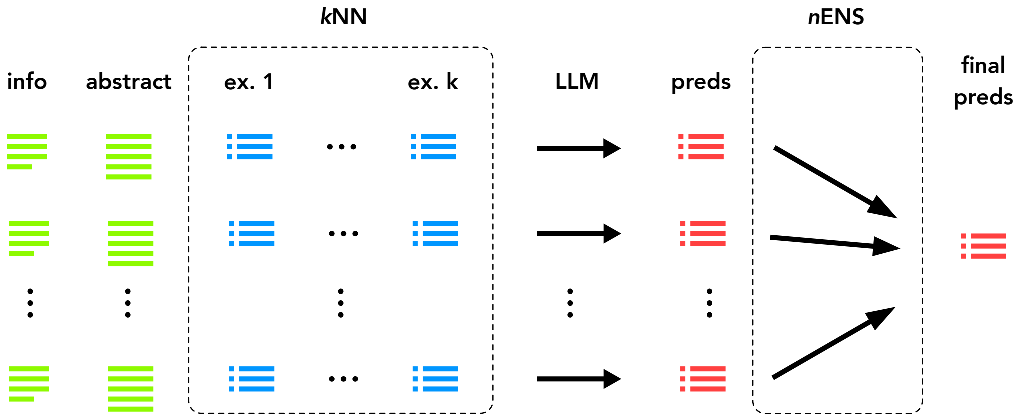

Figure 1: 2-step ICL approach: a kNN-based example prediction ($k = 3, 5$) step followed by an n-Ensembling ($n = 3$) step (cf. text for further details). For each abstract A, the class predictions $\hat{y}_1, dots, \hat{y}_m$ of all of its ACs $x_1, dots, x_m$ are generated in one inference step (all-at-once modality).

sample and generate the class label predictions for the ACs of an abstract all-at-once.

3.4. Implementation Details

As the embedding engine, we use dmis-lab's BioBERT[1]. For zero-shot learning, ICL and fine-tuning, we experiment with the LLaMA-3-8B-Instruct and LLaMA-3-70B-Instruct models, as well as various GGML-quantized configurations of them[2]. For ICL, we set the generate temperature to 0.1. For fine-tuning, we use LoRA adapters with `loraplus_lr_ratio` of 16.0. We set batch size of 2 and learning rate of $5e^{-5}$. For implementation, we use the LLaMA-Factory[3] framework [36]. An example of the prompts we use for zero-shot learning, in-context learning and fine-tuning with LLaMA-3 are given in Appendix A.

4. Results

4.1. Zero-Shot Learning

The results for zero-shot learning (ZSL) on ATC task are reported in Table 2. Recall that zero-shot learning corresponds to the prompting strategy where no nearest neighbors are included as demonstration examples, referred to as 'info + abstract + 0NN' in our notation. In an initial experimentation phase, we observed that adding complementary information (**info**) (definitions of 'Claim' and 'Premise' and dataset statistics) and including the entire text of the abstract (**abstract**) significantly improve the results. These expected observations serve as an ablation study and justify the usage of the additional information and full abstract text (prompt template 'info + abstract') in all subsequent experiments.

In all experiments, we observed that the models consistently generated the correct number of classes for each inference task. This observation remains valid for subsequent ICL and fine-tuning settings. It demonstrates the model's capability to understand the correspondence between the number of input ACs and the number of classes to predict.

In ZSL training-free setting, across Neo, Gla and Mix test sets, the performance of LLMs strongly correlated with the complexity of these models, achieving maximal macro F1-scores of 0.698, 0.819 and 0.725, respectively. Overall, in ZSL, the LLMs fail to achieve acceptable results. These considerations underscore the need for implementing additional learning modalities to address the ATC task effectively.

4.2. In-Context Learning

The results for in-context learning (ICL) on the ATC task are reported in Table 3. First, note that the transition from zero-shot learning ('info + abstract + 0NN', Table 2) to in-context learning ('info + abstract + kNN', Table 3) drastically improves the results. This validates the effectiveness of the kNNN-based examples selection method.

In addition, except for the Mix test set, the 3NN strategy consistently outperforms the 5NN strategy, suggesting that three examples suffice for optimal learning the ATC task in an ICL setting. The inclusion of more demonstration examples correlates with a significant increase

in prompt length, potentially hindering the performance of the LLM or exceeding the maximum size of its context. Furthermore, the ensembling strategy consistently improves the results, even if only slightly, ensuring that the robustness of the results can indeed be strengthened through ensembling predictions.

Overall, the training-free ICL strategy achieves very competitive F1-scores of 0.912, 0.910, and 0.929 on Neo, Mix, and Gla test sets, respectively. However, these results remain lower than those obtained by previous training-dependent models (see Table 4, upper rows).

4.3. Fine-Tuning

The results achieved by the fine-tuning (FT) strategy on the ATC task are reported in Table 4. Our results show that fine-tuning significantly outperforms ICL. These findings suggest that the argumentative flow within abstracts cannot be inferred solely from the knowledge acquired during pre-training, and requires additional parameters updates to be effectively learned.

In this training-dependent context, we achieve maximal F1-scores of 0.935, 0.913, and 0.951 on the Neo, Gla, and Mix test sets, respectively, establishing new state-of-the-art results for the Neo and Mix test sets. These results suggest once again that the sequentiality of arguments inside a specific corpus requires fine-tuning to be optimally captured.

5. Conclusion

In this work, we address argument type classification (ATC) in the biomedical AbstRTC dataset with openly available LLaMA-3 from the three-fold perspective of zero-shot learning (ZSL), in-context learning (ICL) and fine-tuning (FT). We show that ZSL fails to achieve acceptable performance, ICL significantly improves the results, and FT reaches state-of-the-art performance.

These results support the fact that ATC task cannot be solved in a zero-shot setting by relying solely on general-purpose language modalities acquired during

Table 4
Fine-tuning results for ATC task on the three test sets of AbstRCT dataset using LLaMA-3.

pre-training. Additional learning is essential, either in the form of solved demonstration examples (ICL) or via parameters' updates (FT). We conjecture that the sequential flow of arguments within a text is a corpus-specific feature that cannot be inferred through zero-shot methods.

Previous works demonstrated that the text of argument components alone do not suffice to infer their argumentative roles [2, 4, 6]. Additional contextual, structural and syntactic features are necessary. In our ICL and FT settings, comprehensive contextual and structural information is incorporated through task-specific information and complete abstract text provided in the prompt. This information enables the model to discern the sequence of arguments, their associated markers, and other characteristics closely associated with their argumentative roles.

For future work, the design and implementation of a full AM pipeline using LLMs represents a major milestone. In this scenario, the LLM would take raw texts as input and produce a detailed map of the argumentative structure as output. We believe that LLMs will substantially transform the landscape of AM and its practical applications.

Acknowledgments

This work benefited from access to the computing resources of the L3i laboratory, operated and hosted by the University of La Rochelle. It is financed by the French government and the Region Nouvelle-Acquitaine. This research also benefited from institutional support RVO: 67985807 and partially supported by the grant of the Czech Science Foundation No. GA22-02067S. Finally, we are grateful to Playtika Ltd. for their support for this research.

A. Appendix

Examples of prompts for LLaMA 3 for the zero-shot learning (ZSL), in-context learning (ICL) and fine-tuning (FT) settings are provided below.

A.1. Zero-Shot Learning

### Task description: You are an expert biomedical assistant that takes 1) an abstract text and 2) the list of all arguments from this abstract text, and must classify all arguments into one of two classes: Claim or Premise. 68.0052% of examples are of type Premise and 31.9948% of type Claim. You must absolutely not generate any text or explanation other than the following JSON format {"Argument 1": <predicted class for Argument 1 (str)>, ..., "Argument n": <predicted class for Argument n (str)>}

### Class definitions: Claim = A claim in the abstract of an RCT is a statement or conclusion about the findings of the study. Premise = A premise in the abstract of an RCT is a statement that provides an evidence or proof for a claim.

### Abstract: Few controlled clinical trials exist to support oral combination therapy in pulmonary arterial hypertension (PAH). Patients with PAH (idiopathic [IPAH] or associated with connective tissue disease [APAH-CTD]) taking bosentan (62.5 or 125 mg twice daily at a stable dose for ≥3 months) were randomized (1:1) to sildenafil (20 mg, 3 times daily; n = 50) or placebo (n = 53). The primary endpoint was change from baseline in 6-min walk distance (6MWD) at week 12, assessed using analysis of covariance. Patients could continue in a 52-week extension study. An analysis of covariance main-effects model was used, which included categorical terms for treatment, baseline 6MWD (<325 m; ≥325 m), and baseline aetiology; sensitivity analyses were subsequently performed. In sildenafil versus placebo arms, week-12 6MWD increases were similar (least squares mean difference [sildenafil-placebo], -2.4 m [90% CI: -21.8 to 17.1 m]; P = 0.6); mean ± SD changes from baseline were 26.4 ± 45.7 versus 11.8 ± 57.4 m, respectively, in IPAH (65% of population) and -18.3 ± 82.0 versus 17.5 ± 59.1 m in APAH-CTD (35% of population). One-year survival was 96%; patients maintained modest 6MWD improvements. Changes in WHO functional class and Borg dyspnoea score and incidence of clinical worsening did not differ. Headache, diarrhoea, and flushing were more common with sildenafil. Sildenafil, in addition to stable (≥3 months) bosentan therapy, had no benefit over placebo for 12-week change from baseline in 6MWD. The influence of PAH aetiology warrants future study.

### Arguments: Argument 1=In sildenafil versus placebo arms, week-12 6MWD increases were similar (least squares mean difference [sildenafil-placebo], -2.4 m [90% CI: -21.8 to 17.1 m]; P = 0.6); mean ± SD changes from baseline were 26.4 ± 45.7 versus 11.8 ± 57.4 m, respectively, in IPAH (65% of population) and -18.3 ± 82.0 versus 17.5 ± 59.1 m in APAH-CTD (35% of population).
Argument 2=Changes in WHO functional class and Borg dyspnoea score and incidence of clinical worsening did not differ.
Argument 3=Headache, diarrhoea, and flushing were more common with sildenafil.
Argument 4=Sildenafil, in addition to stable (≥3 months) bosentan therapy, had no benefit over placebo for 12-week change from baseline in 6MWD.

### Result:

A.2. In-Context Learning (ICL)

### Task description: You are an expert biomedical assistant that takes 1) an abstract text, 2) the list of all arguments from this abstract text, and must classify all arguments into one of two classes: Claim or Premise. 68.0052% of examples are of type Premise and 31.9948% of type Claim. You must absolutely not generate any text or explanation other than the following JSON format {"Argument 1": <predicted class for Argument 1 (str)>, ..., "Argument n": <predicted class for Argument n (str)>}

### Class definitions: Claim = A claim in the abstract of an RCT is a statement or conclusion about the findings of the study. Premise = A premise in the abstract of an RCT is a statement that provides an evidence or proof for a claim.

### Examples:

## Example 1

# Abstract:

Treatment of patients with advanced or metastatic esophagogastric adenocarcinoma should not only prolong life but also provide relief of symptoms and improve quality of life (QOL). Esophagogastric adenocarcinoma mainly occurs in elderly patients, but they are underrepresented in most clinical trials and often do not receive effective combination chemotherapy, most probably for fear of intolerance. Using validated instruments, we prospectively assessed QOL within the randomized FLOT65+ phase II trial. Within the FLOT65+ trial, a total of 143 patients aged ≥65 years were randomly allocated to receive biweekly oxaliplatin plus 5-fluorouracil (5-FU) continuous infusion and folinic acid (FLO) or the same regimen in combination with docetaxel 50 mg/m(2) (FLOT). The European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire C30 (EORTC QLQ-C30) and the gastric module STO22 were administered every 8 weeks until progression. Time to definitive deterioration of QOL parameters was analyzed and compared within the treatment arms. The median age of patients was 70 years. Patients receiving FLOT exhibited higher response rates and had improved disease-free and progression-free survival (PFS). The proportions of patients with evaluable baseline EORTC QLQ-C30 and STO22 questionnaires were balanced (83 % in FLOT and 89 % in FLO). Considering evaluable patients with assessable questionnaires (n = 123), neither functioning nor symptom parameters differed significantly in favor of one of the two treatment groups. Particularly, there was no significant difference regarding time to definitive deterioration of global health status/quality of life from baseline (primary endpoint). Notably, patients receiving FLO or FLOT as palliative treatment (n = 98) achieved comparable QOL results. Although toxicity was higher in patients receiving FLOT, no negative impact of the addition of docetaxel on QOL parameters could be demonstrated. Thus, elderly patients in need of intensified chemotherapy may receive FLOT without compromising patient-reported outcome parameters.

# Arguments:

Argument 1=Patients receiving FLOT exhibited higher response rates and had improved disease-free and progression-free survival (PFS).
Argument 2=there was no significant difference regarding time to definitive deterioration of global health status/quality of life from baseline (primary endpoint).
Argument 3=patients receiving FLO or FLOT as palliative treatment (n = 98) achieved comparable QOL results.
Argument 4=Although toxicity was higher in patients receiving FLOT,
Argument 5=no negative impact of the addition of docetaxel on QOL parameters could be demonstrated.
Argument 6=elderly patients in need of intensified chemotherapy may receive FLOT without compromising patient-reported outcome parameters.

# Result:

## Example 2

# Abstract:

Chemotherapy prolongs survival and improves quality of life (QOL) for good performance status (PS) patients with advanced non-small cell lung cancer (NSCLC). Targeted therapies may improve chemotherapy effectiveness without worsening toxicity. SGN-15 is an antibody-drug conjugate (ADC), consisting of a chimeric murine monoclonal antibody recognizing the Lewis Y (Le(y)) antigen, conjugated to doxorubicin. Le(y) is an attractive target since it is expressed by most NSCLC. SGN-15 was active against Le(y)-positive tumors in early phase clinical trials and was synergistic with docetaxel in preclinical experiments. This Phase II, open-label study was conducted to confirm the activity of SGN-15 plus docetaxel in previously treated NSCLC patients. Sixty-two patients with recurrent or metastatic NSCLC expressing Le(y), one or two prior chemotherapy regimens, and PS< or =2 were randomized 2:1 to receive SGN-15 200 mg/m2/week with docetaxel 35 mg/m2/week (Arm A) or docetaxel 35 mg/m2/week alone (Arm B) for 6 of 8 weeks. Intrapatient dose-escalation of SGN-15 to 350 mg/m2 was permitted in the second half of the study. Endpoints were survival, safety, efficacy, and quality of life. Forty patients on Arm A and 19 on Arm B received at least one treatment. Patients on Arms A and B had median survivals of 31.4 and 25.3 weeks, 12-month survivals of 29% and 24%, and 18-month survivals of 18% and 8%, respectively Toxicity was mild in both arms. QOL analyses favored Arm A. SGN-15 plus docetaxel is a well-tolerated and active second and third line treatment for NSCLC patients . Ongoing studies are exploring alternate schedules to maximize synergy between these agents.

# Arguments:

Argument 1=Chemotherapy prolongs survival and improves quality of life (QOL) for good performance status (PS) patients with advanced non-small cell lung cancer (NSCLC).
Argument 2=Targeted therapies may improve chemotherapy effectiveness without worsening toxicity.
Argument 3=Le(y) is an attractive target since it is expressed by most NSCLC.
Argument 4=SGN-15 was active against Le(y)-positive tumors in early phase clinical trials and was synergistic with docetaxel in preclinical experiments.
Argument 5=Patients on Arms A and B had median survivals of 31.4 and 25.3 weeks, 12-month survivals of 29% and 24%, and 18-month survivals of 18% and 8%, respectively
Argument 6=Toxicity was mild in both arms.
Argument 7=QOL analyses favored Arm A.
Argument 8=SGN-15 plus docetaxel is a well-tolerated and active second and third

line treatment for NSCLC patients

# Result:

{"Argument 1": "Claim", "Argument 2": "Claim", "Argument 3": "Claim", "Argument 4": "Premise", "Argument 5": "Premise", "Argument 6": "Premise", "Argument 7": "Premise", "Argument 8": "Claim"}

## Example 3

# Abstract:

The impact of treatment on health-related quality of life (HRQoL) is an important consideration in the adjuvant treatment of operable breast cancer. Here we report mature HRQoL outcomes from the ATAC trial, comparing anastrozole with tamoxifen as primary adjuvant therapy for postmenopausal women with localized breast cancer. Patients completed the Functional Assessment of Cancer Therapy-Breast (FACT-B) questionnaire plus endocrine subscale (ES) at baseline, 3 and 6 months, and every 6 months thereafter. Baseline characteristics in the HRQoL sub-protocol were well balanced between the anastrozole (n = 335) and tamoxifen (n = 347) groups in the primary analysis population. As with previously published results at 2 years, there was no statistically significant difference in the Trial Outcome Index of the FACT-B, the primary endpoint of the study, between treatments at 5 years. There were no statistically significant differences between treatment groups in ES total scores. Consistent with the 2-year analysis, there were differences between treatment groups in patient-reported side effects: diarrhea (anastrozole 3.1% vs. tamoxifen 1.3%), vaginal dryness (18.5% vs. 9.1%), diminished libido (34.0% vs. 26.1%), and dyspareunia (17.3% vs. 8.1%) were significantly more frequent with anastrozole compared to tamoxifen. Dizziness (3.1% vs. 5.4%) and vaginal discharge (1.2% vs. 5.2%) were significantly less frequent with anastrozole compared to tamoxifen. In this, the first report of HRQoL over 5 years of initial adjuvant therapy with an aromatase inhibitor, we conclude that anastrozole and tamoxifen had similar impacts on HRQoL, which was maintained or slightly improved during the treatment period for both groups.

# Arguments:

Argument 1=The impact of treatment on health-related quality of life (HRQoL) is an important consideration in the adjuvant treatment of operable breast cancer.
Argument 2=As with previously published results at 2 years, there was no statistically significant difference in the Trial Outcome Index of the FACT-B, the primary endpoint of the study, between treatments at 5 years.
Argument 3=There were no statistically significant differences between treatment groups in ES total scores.
Argument 4=there were differences between treatment groups in patient-reported side effects:
Argument 5=diarrhea (anastrozole 3.1% vs. tamoxifen 1.3%), vaginal dryness (18.5% vs. 9.1%), diminished libido (34.0% vs. 26.1%), and dyspareunia (17.3% vs. 8.1%) were significantly more frequent with anastrozole compared to tamoxifen.
Argument 6=Dizziness (3.1% vs. 5.4%) and vaginal discharge (1.2% vs. 5.2%) were significantly less frequent with anastrozole compared to tamoxifen.
Argument 7=In this, the first report of HRQoL over 5 years of initial adjuvant therapy with an aromatase inhibitor, we conclude that anastrozole and tamoxifen had similar impacts on HRQoL, which was maintained or slightly improved during the treatment period for both groups.

Abstract

Given their status as unwritten visual-gestural languages, research on the automatic recognition of sign languages has increasingly implemented multisource capturing tools for data collection and processing. This paper explores advancements in Italian Sign Language (LIS) recognition using a multimodal dataset in the medical domain: the MultiMedaLIS Dataset. We investigate the integration of RGB frames, depth data, optical flow, and skeletal information to develop and evaluate two computational models: Skeleton-Based Graph Convolutional Network (SL-GCN) and Spatiotemporal Separable Convolutional Network (SSTCN). RADAR data was collected but not included in the testing phase. Our experiments validate the effectiveness of these models in enhancing the accuracy and robustness of isolated LIS signs recognition. Our findings highlight the potential of multisource approaches in computational linguistics to improve linguistic accessibility and inclusivity for members of the signing community.

Keywords

Italian Sign Language, Sign Language Recognition, Deep Learning, Computer Vision

1. Introduction

Italian Sign Language (LIS- Lingua dei Segni Italiana) is the primary means of communication within the Italian signing community. Due to their visual-gestural modality, sign languages (SLs) were initially not considered fully-fledged linguistic systems. However, since the 1960s, beginning with Stokoe's pioneering works [1], the contemporary study of SLs has evolved into a robust field of research. Over the past half-century, significant societal and scientific advancements have transformed the perception and status of SLs, now recognized as natural and complete languages, having received legal recognition in many countries.

In the Italian context, the study of signed communication began in the early 1980s, involving both hearing and deaf researchers. At that time, what we now call LIS was still mostly unnamed and was often referred to as 'mime' or 'gesture' by both signers and non-signers alike [2]. The first significant publications on LIS [3] [4], along with the collaborative efforts of deaf and hearing researchers, initiated a transformative period in SL research in the Italian context [5]. This shift in perspective was influenced by factors beyond the language itself, such as increased meta-linguistic awareness and greater visibility of the community and its language to the wider public. In fact, from a societal perspective, the visibility of SL in Italy, especially in media, has significantly changed with technological advancements, mirroring global trends.

In the late 1980s, Italy introduced subtitles in movies on television, marking a step toward content accessibility. The importance of media accessibility, through subtitles or LIS interpreting, was accentuated during the COVID-19 pandemic. The need for equitable access to critical information for deaf individuals became evident, with efforts born within the community

stressing the central role of LIS in ensuring that the deaf signers received accessible information during challenging times [6], highlighting the significant communication barriers that deaf individuals face, especially when in-person interactions were restricted. This increased visibility, along with persistent advocacy by the signing community, played a crucial role in the official recognition of LIS and Tactile LIS (LISt) in May 2021.

Within this evolving societal and linguistic framework, the increased media visibility of LIS and the introduction of video capturing tools in daily lives, language collection emerges as a central issue. For SLs, the need for comprehensive collections is particularly significant. Unlike oral languages, which in some cases have developed standardized written systems, SLs must rely on video collections to capture signed communication accurately. These videos, whether raw or annotated, are essential for analyzing SLs with both qualitative and quantitative evidence.

2. Automatic Sign Language Recognition

The development and use of preferably annotated SL datasets or corpora are crucial for training and validating automatic recognition models, and access to high-quality data from diverse SLs and cultural contexts enhances the generalizability of these solutions. Comprehensive data collections of this kind ensures that models can effectively understand and process the wide range of linguistic and cultural nuances present in different SLs.

In the domain of automatic sign language recognition (SLR) of LIS, the integration of visual and spatial information presents a complex challenge. As mentioned, LIS operates through the visual-gestural channel. More precisely, it is characterized as multimodal[2] (signed discourse is comprised of manual and body components) and multilinear (manual and body components are performed simultaneously) [2]. Recent advancements in SLR have been significantly driven by annotated datasets, which serve as the basis for training and validating models [7, 8, 9, 10, 11].

Machine learning technologies, particularly deep learning neural networks, have facilitated the development of more precise and robust models for SL interpretation. These models are able to refine their performance through training on diverse and complex datasets. Additionally, computer vision plays a central role in this field by enabling real-time analysis and interpretation of body and manual components [2] that is hand movements, facial expressions, and body posture [12, 13, 14, 15].

A significant challenge in applying deep learning and computer vision methods to SLR lies in ensuring the quality and adequacy of training data, which is essential for achieving optimal model performance.

Therefore, in this study, we focus on evaluating the efficacy of the MultiMedaLIS Dataset (Multimodal Medical LIS Dataset) and assessing various deep learning models for SLR which employ advanced deep learning techniques to interpret isolated signs by integrating diverse data types such as RGB video, depth information, optical flow, and skeletal data.

We benchmark our Dataset with two models: the Skeleton-Based Graph Convolutional Network (SL-GCN) and the Spatiotemporal Separable Convolutional Network (SSTCN). These models are trained on the MultiMedaLIS Dataset, showcasing how the incorporation of multisource data can enhance the accuracy of sign recognition. This approach aims at testing the potential of integrating different data modalities to improve the robustness and performance of SLR systems.

3. State of the Art

In this section, we discuss the state of the art from two perspectives considered during our work on the Dataset: LIS data collection and SLR tools

3.1. LIS Data Collections

SL researchers in Italy have been actively engaged in the creation of LIS corpora and datasets. This effort involves a complex process of video data collection and annotation, as SL datasets can vary significantly depending on their intended use. Within this context, SL data collections can be categorized into two main types. The first type includes datasets that feature videos depicting continuous signing, capturing the flow and context of natural SL usage. The second type comprises datasets that focus on isolated signs, which are individual signs presented separately from continuous discourse.

The scarcity of available LIS data collections has prompted researchers to develop their own resources. Several smaller-scale LIS corpora have been

[2] Given our group's interdisciplinarity, we found "multimodal" can mean different things depending on one's background: in linguistics, it refers to the employment of manual and body components while signing, while in computer vision, it means using multiple capturing tools. To differentiate, we use "multisource" for capturing tools. Thus, "multimodal" in this text follows SL linguistics terminology.

independently established, each serving distinct purposes based on the type of data collected.

The methodologies employed for collecting LIS data encompass a diverse array of approaches, ranging from naming tasks to semi-structured and spontaneous interviews with deaf signers, to video recording sessions involving hearing individuals learning LIS as a second language (L2) or second modality (M2) [16]. These documentations serve equally diverse purposes, ranging from documenting the language itself to creating tools for automatic translation highlighting the ongoing commitment of researchers to expand and enrich the available resources for studying LIS [17, 18, 19, 20, 21, 22, 23, 24].

Despite the predominant private nature of corpora collections, an exception to the accessibility challenge is found in the online dictionary SpreadTheSign, a project originating in 2004. Initially conceived as a dictionary for SLs, SpreadTheSign has evolved into a versatile resource for language documentation [25]. Another significant resource is the Corpus LIS, recognized as the largest collection of spontaneous, semi-structured, and structured videos in LIS by deaf signers. The primary objectives of this corpus were twofold: to collect a substantial quantity of data suitable for quantitative analysis and to establish a comprehensive representation of LIS usage in Italy [26, 27, 28].

3.2. SLR Tools

Like SL data collections, SLR approaches can be broadly classified into two main categories: those that rely on specialized hardware and those that use visual information. The former employ specialized hardware, such as gloves able to capture precise hand movements. While these systems can provide detailed data, they are often considered intrusive and can compromise the natural flow of communication. Additionally, they are unable to capture the full spectrum of SLs, which includes manual and body components. In contrast, vision-based approaches use visual information captured by cameras, including RGB, depth, infrared, or a combination of these. These methods are less intrusive for users, as they do not require the use of special equipment.

In SLR, a challenge lies in effectively capturing both body movements and specific motions of hands, arms, and face. For instance, [29] introduces a multi-scale, multi-modal framework that focuses on spatial details across different scales. This approach involves each visual modality capturing spatial information uniquely, supported by a system operating at three temporal scales. The training methodology emphasizes precise initialization of individual modalities and progressive fusion via ModDrop, which enhances overall robustness and performance.

Another study proposes an iterative optimization alignment network tailored for weakly supervised continuous SLR [30]. The framework employs a 3D residual convolutional network for feature extraction, complemented by an encoder-decoder architecture featuring LSTM decoders and Connectionist Temporal Classification (CTC).

[31] introduces a 3D convolutional neural network enhanced with an attention module, designed to extract spatiotemporal features directly from raw video data. In contrast, [32] combines bidirectional recurrence and temporal convolutions, emphasizing temporal information's effectiveness in sign tasks, although not covering the full spectrum of movements. Moreover, [33] employs CNNs, a Feature Pooling Module, and LSTM networks to generate distinctive visual representations but falls short in capturing comprehensive movements and signing.

However, as previously noted, RGB-based SLR systems can raise privacy concerns, particularly when processing visual data in cloud environments or for machine learning training [34]. Addressing these issues, radio frequency (RF) sensors have emerged as a promising alternative, ensuring privacy preservation while enabling innovative data representations for SLR. In the literature, deep learning techniques have been applied to various RF modalities such as ultra-wideband (UWB) [35], Doppler [36], continuous wave (CW) [37], micro-Doppler [38], frequency modulated continuous wave (FMCW) [14], multi-antenna systems [39], and millimeter waves [40].

As part of the Dataset discussed in this work, we have also collected RADAR data and are actively analyzing it. However, preliminary results are not available at this time, so they are not included in this report. Currently, RADAR-based solutions have demonstrated robust performance across diverse environmental conditions, highlighting the productivity of incorporating this sensor technology in data collection efforts. Nevertheless, many existing RADAR solutions are tailored to recognizing a limited set of signs, highlighting the ongoing challenge of expanding vocabulary recognition capabilities in datasets like the one discussed in the following section.

4. The MultiMedaLIS Dataset

The MultiMedaLIS [41] Dataset was created thanks to the interdisciplinary collaboration established between the Department of Humanities (DISUM) and the Department of Electrical, Electronic and Computer Engineering (DIEEI) of the University of Catania (Unict). It aims to offer a multimodal collection of LIS signs specifically focused on medical contexts.

For the data recording protocol, the DIEEI group developed a customized recording software to collect the

LIS data, supplemented with a desktop computer and a modified keyboard transformed into a pedal board. This pedal board, equipped with two pedals, allowed hands-free navigation of the software, enabling users to move forward (by pushing on the right pedal) or backward (by pushing on the left pedal) while maintaining a neutral recording position[3]. During sessions, one of 126 Italian labels or alphabet letters was displayed on a screen, with adjustable display time for preparation and transition from one sign to the other. Each recording started from a neutral position, and the right pedal marked the completion of a sign. If errors occurred, the left pedal allowed re-recording. The software's interface features a color-coded background: yellow for preparation and green for recording. Additionally, it supports flexible data expansion, accepting word lists from text files for easy customization in future collections.

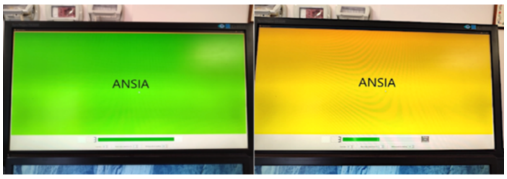

Figure 1: User interface display presented during the recording phase (green) and preparation phase (yellow).

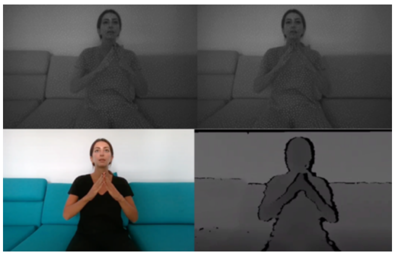
After the recording process, Dataset included synchronized data capturing facial expressions, hand and body movements and comprises a total of 25,830 sign instances. This includes 205 repetitions of 100 different signs and the 26 signs of the LIS alphabet [41]. Beyond these 26 signs, the signs included in the MultiMedaLIS Dataset can be broadly categorized into two groups [42]: semantically marked signs related to health and health issues, and non-semantically marked signs. It is important to note that while the first group of signs is categorized as semantically marked, this classification does not imply that these signs belong exclusively to a specialized jargon lexicon. The decision to categorize signs as semantically marked was driven by their significance in contexts related to health and medical interactions in the post-pandemic world (hence, when the Dataset was first theorized). However, it was also important to include additional signs that could contribute to constructing meaningful utterances in patient-doctor interactions. During the creation of the MultiMedaLIS Dataset, careful consideration was given to selecting signs that could be combined to form coherent and meaningful utterances.

Regarding the specific form of signs, the MultiMedaLIS Dataset includes a lexicon of standard, isolated signs that are not combined within utterances. These signs reflect forms commonly found in online dictionaries and educational materials. To ensure the accuracy of the data, sign variants performed by a professional LIS interpreter during the collection of a test dataset were compared with the same variants found in the online dictionary SpreadTheSign. This comparison aimed to select documented versions of each sign for inclusion in the Dataset. By incorporating these documented variants, we aimed to enhance its precision, reliability, and real-world applicability. This approach contributed to ensuring that the Dataset aligns with established standards and supports effective research and application in the field of LIS.

When discussing recording tools for state-of-the-art multimodal corpora in the Italian context, such as the Corpus LIS [27] and the CORMIP [43] the emphasis is placed on the portability and non-invasiveness of these tools. This approach ensures minimal interference with the signer's natural environment and activities.

Portable and non-invasive recording tools are chosen specifically for their ability to capture data in familiar, and sometimes domestic, settings without disrupting the signer's surroundings, aiming to maintain the authenticity of the signed interactions and minimize any discomfort or distraction for the participants.

To capture LIS for recognition with minimal invasiveness we integrated a combination of recording tools. A 60GHz RADAR sensor, employed to capture detailed manual motion data, provided Time- and Frequency-Domain data and Range Doppler Maps for distinguishing moving objects at 13 fps. For more structured depth and facial recognition data, the Realsense D455 depth camera and Kinect v1 were incorporated. The Realsense D455, equipped with dual infrared cameras and RGB mode, captured depth data at 848x480 pixels and RGB data at 1280x720 pixels, both at 30 fps, enabling the tracking of facial expressions through 68 facial points. The Zed v1 and Zed v2 cameras provided high-resolution stereoscopic data, recording at 1920x1080 pixels and 25 fps, with capabilities for generating depth maps and 3D point clouds. Additionally, the Zed v2 offered tracking for 18 body points in both 2D and 3D [41].



[3] The neutral recording position referenced is a seated position in which the user has their arms extended along the sides of the torso, elbows bent at 90°, and palms facing downward [41].

Figure 2: Combination of synchronized infrared and depth data from the MultiMedaLIS Dataset.

By prioritizing portability and non-invasiveness, high-quality data can be still collected, while respecting the privacy and comfort of the individuals recorded. Anonymization is achieved through the use of the RADAR sensor, which we introduced specifically to address privacy concerns inherent in face-to-face signed communication.

5. Testing the Dataset

The MultiMedaLIS Dataset was designed with the aim of supporting the development of SLR models by enabling the collection and integration of information through various data modalities:

- RGB frames: images extracted from videos.
- Depth data: three-dimensional information for each RGB frame
- Optical flow: to emphasize movement
- Skeletal data: face landmarks and body joints

One of the main components of the Dataset are RGB frames, which are images extracted from videos. These frames provide a two-dimensional visual representation of the signs performed by the signer, capturing details such as hand positions and facial expressions. The Dataset includes depth data, providing a three-dimensional aspect to the images. allowing for more detailed information on the distance and relative position of elements in the scene. This type of data is particularly useful for understanding the spatial dynamics of signs.

Alongside RGB and depth data, the MultiMedaLIS Dataset also contains optical flow information, which describes the movement between consecutive frames. Optical flow is essential for capturing the direction and speed of movements, providing a more detailed understanding of the transitions between various signs. Finally, the Dataset includes skeletal data, representing face landmarks and body joints, allowing for precise tracking of joint and body segment positions, facilitating the analysis of signs in terms of joint movements.

Managing this multimodal data is an emerging topic in computational linguistics. By combining different sources of information, it is possible to significantly improve the performance of SLR models. For example, integrating depth data with RGB frames can provide a more complete representation of signs, while adding optical flow and skeletal data can further enrich the analysis of movement's temporal structure. In our view, the MultiMedaLIS Dataset provides a solid foundation for exploring these combinations, allowing researchers to develop more effective and accurate solutions for SLR.

6. Models and Architectures

In the context of automatic SLR, various approaches and model architectures have been tested to leverage the characteristics of multimodal data in the MultiMedaLIS Dataset.

The SL-GCN (Skeleton-Based Graph Convolutional Network) represents a significant innovation in this field. This model generates skeletal data from videos and creates temporal graphs that capture the spatiotemporal relationships between joint movements. Through fine-tuning and the combination of different data streams, SL-GCN has demonstrated high accuracy in sign recognition [44] [45].

Another prominent architecture is the SSTCN (Spatiotemporal Separable Convolutional Network) [46], which excels in feature extraction from videos using HRNet [47]. This approach has shown an accuracy of 96.33%, highlighting its effectiveness in capturing spatial and temporal dynamics of LIS signs.

RGB frames are crucial for the visual representation of signs. The process of splitting videos into frames, cropping, and normalization optimally prepares the data for analysis by deep learning models. The use of dense optical flow presents significant challenges in sign recognition. Optical flow extraction using the Farneback algorithm [48] led to 56% accuracy, highlighting difficulties in capturing precise details of movements, alongside computational limitations. Depth data encoded with Height, Horizontal disparity, Angle (HHA) represent another crucial resource in the MultiMedaLIS Dataset. Applying HHA encoding to depth frames achieved 88% accuracy using the ResNet(2+1)D architecture [49], substantiating importance of three-dimensional information in enhancing understanding and interpretation of signs, offering a more detailed perspective compared to two-dimensional data.

7. Training and Evaluation Procedure

For the training of the models, we employed a multi-stream approach that integrates skeletal, RGB, and depth data to improve sign recognition accuracy. The models were trained on a NVIDIA Tesla T4 16GB GPU using the Adam optimizer with an initial learning rate of 0.001 and a batch size of 8. We applied cross-validation to ensure the robustness of the results, splitting the Dataset into training (70%) and validation (15%) subsets and data augmentation techniques, such as color jittering, changing the brightness, contrast, saturation and hue, to increase the diversity of the training data and improve generalization.

The loss function adopted for training was categorical cross-entropy, appropriate for multi-class classification tasks. The models were trained for a maximum of 100 epochs, with an early stopping criterion set to terminate training if no improvement in validation loss was observed for 10 consecutive epochs. For evaluation, we used a test set comprising 15% of the Dataset, ensuring that the models were tested on unseen data.

8. Results

The results demonstrate the model's efficiency in leveraging multi-modal data for improved outcomes. As can be seen in Table 1, the SL-GCN multi-stream model achieved the best accuracy, with a Top-1 accuracy of 97.98% and a Top-5 accuracy of 99.94%, surpassing the performance of models using single data streams such as skeletal joints, bones, or motion alone. This demonstrates the advantage of combining multiple streams of information to capture both spatial and temporal dynamics of signs.

Table 1
Performance of SL-GCN multi-stream on the test set

Data	Accuracy Top-1 (%)	Accuracy Top-5(%)
Joints	96.24	99.84
Bones	95.82	99.84
Joint Motion	90.37	99.15
Bone Motion	92.69	99.52
Multi-stream	97.98	99.94

In Table 2, datasets trained on the SL-GCN model are compared. Our Dataset produced the highest accuracy (97.98%) among the datasets evaluated, outperforming larger datasets like AUTSL (95.45%).

Table 2
Comparison of different datasets on SL-GCN model

Dataset	Number of signs	Accuracy (%)
MultiMedaLIS	126	97.98
AUTSL	226	95.45
ASLLVD	20	61.04
Alphabet	26	85.19

Table 3 presents a comparison of different methods across the entire Dataset. The SL-GCN trained on RGB frames achieved the highest accuracy (97.98%), followed by the SSTCN model with 96.33%. The ResNet(2+1)D architecture showed strong performance when applied to RGB frames (97.29%), but struggled when using optical flow data alone, reaching just 56.31% accuracy, suggesting that while the optical flow provides valuable information on motion, it lacks the richness of spatial features found in RGB and depth data. The HHA-encoded depth data, when processed with the ResNet(2+1)D model, achieved an accuracy of 88.04%, confirming that depth information is complementary, but not as effective as RGB data in isolation.

Table 3
Performance of various methods on the MultiMedaLIS Dataset

Methods	Dataset	Accuracy(%)
SS-CGN	RGB	97.98
SSTCN	RGB	96.33
ResNet(2+1)D Optical Flow	RGB	56.31
ResNet(2+1)D Frame	RGB	97.29
ResNet(2+1)D Encoding HHA	Depth	88.04

The results highlight importance of combining multiple data modalities, especially RGB and skeletal data, for improving the accuracy and robustness of SLR systems. The performance of the SL-GCN model with multi-stream data shows the model's ability to effectively capture signs, as well as the Dataset's value.

9. Discussion and Conclusion

In this study, our goal was to demonstrate our first steps into testing the efficacy of the MultiMedaLIS Dataset in contributing to the advancement of the field of SLR through multisource approaches. The integration of RGB frames, depth data, optical flow, and skeletal data has provided a comprehensive basis for developing and evaluating SLR models. Our experiments with the SL-GCN and SSTCN architectures have highlighted advancements in recognizing isolated LIS signs in medical semantic contexts, given the domain of our Dataset.

The SL-GCN model, trained on skeletal data to construct temporal graphs, achieved accuracy in capturing spatiotemporal relationships critical to sign recognition. This approach not only enhances the precision of rendering LIS signs but is also reinforced by a Dataset able to support robust graph-based convolutional networks in multimodal SLR tasks. At the same time, our Dataset proved robust, precise and variable enough for SSTCN model testing, focusing on spatiotemporal separable convolutions, revealing robust performance in extracting spatial dynamics from RGB frames.

Having validated the visual modalities on the mentioned models, we have promising preliminary results on adapting these models to accept RADAR data. We plan to extract the pre-trained RADAR data processing module and use it independently during inference. This approach will eliminate the need for RGB visual data. Furthermore, we plan to expand the Dataset by applying the same protocol with 10 deaf signers. This will effectively increase the current Dataset, enhancing the generalizability across different signers. Our goal is to develop an autonomous, resource-constrained system (thanks to the exclusion of RGB data) that operates on-edge or even offline. This cost-effective solution can be used in any emergency contexts where direct access to interpreting is not available.

Combining Universal Dependencies and FrameNet to identify constructions in a poetic corpus: syntax and semantics of Latin *felix* and *infelix* in Virgilian poetics

[1] *Università Cattolica del Sacro Cuore, 20123 Milano, Italy*

Abstract

The paper is a pilot study which argues for a constructionist and computer-based approach to the syntactic and semantic analysis of a poetic corpus in Latin. We focus on the terms *felix* and on its opposite *infelix* and perform manual annotation of their occurrences in Virgil's poems using Universal Dependencies for the syntactic analysis and FrameNet for the semantic one. Integrating the approaches of Dependency Syntax and Construction Grammar, we analyze the linguistic contexts in which the two terms occur and identify the different "constructions" (pairings of form and function) that they instantiate. Our methodology is language-independent and has the potential to aid scholars in the comparative analysis of poetic texts, allowing for the detection of hidden parallels in the style and poetics of different texts and authors.

Keywords

Universal Dependencies, FrameNet, Construction Grammar, Frame Semantics, Latin, Virgil.

1. Introduction

The aim of the present study is to demonstrate the potential of a constructionist and computer-based approach to the analysis of syntax and semantics in a Latin poetic corpus. Our corpus comprises Virgil's (70–19 BCE) literary works, namely (in chronological order of composition) the *Eclogues* (*Ecl.*) or *Bucolics*, the *Georgics* (*Georg.*), and the *Aeneid* (*Aen.*). We focus on two lemmas that have been studied as key terms in Virgil's poetics (e.g. [1]; [2]): *felix* 'productive, auspicious, fortunate, lucky, happy' and its opposite *infelix* 'unproductive, unlucky, ill-fated, miserable'.[1]

Bellincioni [1] analyzed the meanings of the two terms in Virgil's works and detected differences in their poetic uses. On the one hand, *felix* is attested in a variety of contexts, ranging from its (likely original) concrete senses 'productive', 'fruitful' to more figurative senses linked with prosperity and well-being (granted by divine will). When it qualifies humans, *felix* takes the religious nuance of 'favored' by gods and fate. Gagliardi [2] also stressed the polysemy of *felix* in the Virgilian corpus: the lemma may refer to fecundity, propitious benevolence, or happiness, acquiring new connotations thanks to innovative uses in Virgil's poetics. On the other hand, according to Bellincioni [1] *infelix* is rarely used in the technical sense of 'infertile' or in the senses 'helpless' and 'inauspicious', and in the majority of cases it rather seems to be used to qualify human beings as 'ill-fated'.

In order to identify patterns of the use of these terms in context, we combine a syntactic analysis with a semantic one. Following Osborne and Groß [4] and Osborne, Putnam and Groß [5], we integrate the approaches of Dependency Syntax and Construction Grammar. In doing so, we rely on the Universal Dependencies (UD) framework for the syntactic analysis and on the FrameNet approach for the semantic one, drawing inspiration from previous studies along these lines (e.g. [6]; [7]).

This integrated approach allows us, on the one hand, to identify the linguistic contexts in which *felix* and *infelix* occur in Virgil's corpus and, on the other hand, to analyze correspondences between the syntactic and the semantic levels of the Virgilian passages where these two terms are employed.

[1] We rely on translations provided by [3].

By combining syntactic and semantic analyses, we explore the potential of an approach that integrates Universal Dependencies with FrameNet. In doing so, we aim at demonstrating that ours is a viable methodology to retrieve the contexts in which the two terms occur in Virgil's corpus and to study the correspondences between their syntactic and semantic uses.

2. Theoretical framework

2.1. Construction Grammar and Frame Semantics

The term "Construction Grammar" encompasses a series of approaches to grammar, which share the premise that all levels of grammatical analysis involve so-called "constructions", i.e. "learned pairings of form and function", including "morphemes or words, idioms, partially lexically filled and fully general phrasal patterns" ([8], p. 5). Within this framework, no rigid division between lexicon and syntax is assumed: constructions are rather arranged along the lexicon-syntax continuum, varying in their degree of internal complexity and schematicity.[2] The different instances of constructions (i.e. their tokens in a type-token distinction) are called "constructs".

Construction Grammar is in turn the formal counterpart of Frame Semantics, originally developed by Fillmore [10], which posits that word meanings are understood through the "semantic frames" they evoke. A semantic frame may be defined as "any system of concepts related in such a way that to understand any of them you have to understand the whole structure in which it fits" ([10], p. 111). The presence in a text of words evoking specific frames reveals different ways in which the speaker conceptualizes the situation.

2.2. Dependency Syntax and Universal Dependencies

In order to identify the constructions instantiated by *felix* and *infelix* within Virgil's corpus, the relevant occurrences were analyzed within the framework of Dependency Syntax. This choice aligns with Osborne and Groß's [4] claim that Dependency Syntax is more compatible with Construction Grammar's theoretical assumptions and practical goals, compared to Phrase Structure (or Constituency) Syntax.[3]

Osborne, Putnam and Groß ([5], p. 354) introduced the concept of "catena" to refer to "a word or a combination of words that is continuous with respect to dominance", and proposed to regard it as the fundamental unit of syntax. As argued by Osborne and Groß [4], most constructions discussed within the framework of Construction Grammar can be analyzed as catenae, i.e. as chains of words linked together by dependencies.

Given the high compatibility of Dependency Syntax with Construction Grammar, we adopt the UD framework [12] to perform the syntactic annotation of sentences in Virgil's corpus which included occurrences of *felix* and *infelix*. The annotation served as a basis for the identification of catenae and of the corresponding constructions.

3. Data and methods

3.1. Corpus and annotation task

Our corpus of Virgil's texts originates from the *Opera Latina* corpus [13] developed by the LASLA research centre in Liège.[4] The *Opera Latina* corpus is enhanced with sentence-splitting, tokenization, lemmatization, PoS-tagging and the annotation of morphological features according to a format developed by the LASLA team. The texts in the corpus were converted from the LASLA format into the CoNLL-U format, and into the UD formalism [14].[5] This textual resource is included among the linguistic resources for Latin that are made interoperable through their linking to the LiLa Knowledge Base.[6] The interlinking of the *Opera Latina* corpus in the LiLa Knowledge Base allowed us to build upon the existent annotation in order to add a further layer. Thanks to the LiLa Interactive Search Platform (LISP), one of the online services designed to query the Knowledge Base [15],[7] we were able to retrieve all occurrences of *felix* and *infelix* in Virgil's works: 90 tokens distributed across 89 sentences (see Table 1 in the Appendix).

The sentences were collected into a separate CoNLL-U file that was then enriched with syntactic annotation, manually performed according to UD guidelines.[8]

[2] A single expression may instantiate both less complex and phonologically specific constructions (e.g. morphemes, words) and more complex and schematic constructions (e.g. syntactic constructions, such as the transitive one), as long as they may all be analyzed as pairings of form and meaning ([9], p. 7).

[3] Constituency Syntax "views the links between the units of sentence structure as indirect" and "mediated by additional groupings that are present as additional nodes in the syntactic structures" ([11], p. 33), in contrast with construction-based approaches, where "no underlying syntactic nor semantic forms are posited" ([8], p. 7).

[8] This annotation will be released as expansion of the UD_Latin-CIRCSE treebank (https://github.com/UniversalDependencies/UD_Latin-CIRCSE).

3.2. Syntactic analysis and extraction of catenae

In order to detect the main catenae involving *felix* and *infelix* (see Section 2.2), we exploited TüNDRA, a web application for querying treebanks that allows users to upload their own CoNLL-U files.[9]

Table 2 and Table 3 in the Appendix provide an overview of the tokens' distributions according to their dependency relation[10] (deprel) to their heads. Tokens sharing the same deprel were then systematically analyzed to identify recurrent catenae with varying degrees of extension and abstraction. The analysis took into account the relations between each token of *felix* or *infelix* and both the upper and the lower nodes of the trees, starting from the deprel of the token to its head.

In what follows, the identified catenae are conventionally represented using square brackets (as per [11], pp. 60–61), which indicate the degree of dependency between words:

$$\text{DEPREL}_1\ [\text{DEPREL}_2\ [\text{DEPREL}_3]]$$

According to this notation system, dependents are enclosed in more brackets than their head, thus 0 brackets for the root, 1 for its dependents, 2 for their own dependents, and so forth, as in the following example:[11]

(1) *Arma virumque cano* 'Arms and the man I sing' (*Aen.* I, 1)

$$[\text{OBJ}_{\textit{arma}}\ [\text{CONJ}_{\textit{virum}}\ [\text{CC}_{\textit{que}}]]]\ \text{ROOT}_{\textit{cano}}$$

3.3. Semantic analysis and identification of constructions

The instances of the recurrent catenae were then analyzed with respect to their semantic structure. Due to the lack of a resource specifically developed for Latin, the semantic analysis was based on FrameNet,[12] a lexical database of English grounded on Frame Semantics. Within this resource, each frame (e.g. APPLY_HEAT) describes a type of event, relationship or entity, along with the participants involved in it, referred to as "frame elements" (e.g. COOK, HEATING_INSTRUMENT, and FOOD), while the words that evoke a given frame are called "lexical units" (e.g. *cook*, *grill*, and *roast*). For the semantic analysis, an expert manually assigned Latin lemmas to the same frames as their corresponding English translations.

For each instance of a recurrent catena in the corpus, we identified the semantic frames evoked by the tokens that occur with the same deprel within the catena. In what follows, the correspondences between the syntactic and semantic levels of analysis are illustrated by enhancing the notation of the catenae (as per [6], p. 132 and passim) in order to represent them as constructions, i.e. as form-meaning pairings, where frames are represented by superscripts preceding the lexical units that evoke them:

$${}^{\text{FRAME.A}}\text{DEPREL}_1\ [{}^{\text{FRAME.B}}\text{DEPREL}_2\ [{}^{\text{FRAME.C}}\text{DEPREL}_3]]$$

For instance, the semantic analysis of (1) would be:

$$[{}^{\text{WEAPON}}\text{OBJ}_{\textit{arma}}\ [{}^{\text{PEOPLE}}\text{CONJ}_{\textit{virum}}\ [\text{CC}_{\textit{que}}]]]$$
$${}^{\text{COMMUNICATION\_MANNER}}\text{ROOT}_{\textit{cano}}$$

4. Results

4.1. Different constructions, different uses

The most recurrent constructions in which *felix* and *infelix* occur allow for the identification of different usages of these two terms in Virgilian poetics. As shown in Table 4 in the Appendix, both *felix* and *infelix* often occur as adjectival modifiers (`amod`) of a noun, but significant differences exist in their respective uses.

Felix is attested only once as `amod` of a subject (`nsubj`).[13] In 5 out of 17 attestations as `amod`,[14] *felix* rather occurs as `amod` of an oblique nominal (`obl`), i.e. of a non-core argument or adjunct of the verb, in a construction that may denote various entities (winds, tree branches, marriage, death, auspices) and thus evoke various semantic frames:

$$[{}^{\text{WHEATER | PLANTS | FORMING\_RELATIONSHIPS | DEATH |}}$$
$${}^{\text{EXPECTATION}}\text{OBL}\ [\text{AMOD}_{\textit{felix}}]]$$

In contrast, *infelix* predominantly occurs as `amod` of a `nsubj`, i.e. in 22 out of 40 instances. In 12 occurrences the `nsubj` refers to human characters,[15] but it may also denote other entities.[16] This use can be represented by the construction:

[13] *Georg.* I, 345.

[14] *Aen.* III, 118-120; *Aen.* VII, 598-599; *Aen.* XI, 29-33; *Aen.* XII, 819-825; *Georg.* II, 78-82.

[15] *Aen.* XI, 85; *Aen.* X, 730; *Aen.* II, 456; *Aen.* XI, 563; *Aen.* IV, 68; *Aen.* I, 749; *Aen.* IV, 450; *Aen.* XII, 870; *Aen.* I, 712; *Aen.* III, 50; *Aen.* VI, 618; *Aen.* XII, 641.

[16] *Ecl.* V, 37; *Georg.* I, 154; *Georg.* II, 314; *Aen.* XII, 941; *Aen.* II, 772; *Aen.* VI, 521; *Aen.* XII, 608; *Georg.* III, 37; *Georg.* III, 498; *Georg.* II, 198.

$$[^{\text{PEOPLE} \mid \text{PLANTS} \mid \text{ARTIFACT} \mid \text{ENTITY} \mid \text{ANIMALS} \mid \text{POLITICAL\_LOCALES}}\text{NSUBJ}\ [\text{AMOD}\ _{\textit{infelix}}]]$$

All in all, *infelix* is significantly more frequent than *felix* in our corpus (see Table 1). The distribution of the lemmas in terms of their most frequent dependency relations shows that *felix* tends to modify adjuncts, while *infelix* tends to modify subjects (see Table 4).[17] *Infelix* even occurs with the `nsubj` deprel in 5 occurrences,[18] whereas *felix* never does so.

In what follows we provide two case studies of particularly interesting constructions in which *felix* and *infelix* occur.

4.2. Case study 1: vocative

When *infelix* and *felix* occur as `amod` of a vocative noun or as vocative themselves, they instantiate constructions with different functions, which point to different meanings for the two terms.

As for *infelix*, 4 occurrences attest the following catena:

$[\text{X}_{\text{verb}}$[19] $[\text{VOCATIVE}_{\textit{infelix}} \mid$[20] $\text{VOCATIVE}\ [\text{AMOD}_{\textit{infelix}}]]\ [\text{OBJ}]\ [\text{NSUBJ} \mid \text{OBL}\ [\text{DET}]]]$

(2) *a, **virgo infelix, quae te dementia cepit!***. 'Ah, **unhappy girl, what a madness has gripped you**!' (*Ecl.* VI, 47)

(3) *quid loquor? aut ubi sum? **quae mentem insania mutat? / infelix Dido**, nunc te facta impia tangunt?*. 'What say I? Where am I? **What madness turns my brain? Unhappy Dido,** do only now your sinful deeds come home to you?' (*Aen.* IV, 595-596)

(4) *"**infelix, quae tanta animum dementia cepit?** / non vires alias conversaque numina sentis? / cede deo"*. '**Unhappy man! How could such frenzy seize your mind?** Do you not see the strength is another's and the gods are changed? Yield to heaven!' (*Aen.* V, 465-467)

(5) *ut stetit et frustra absentem respexit amicum:/ "**Euryale infelix, qua te regione reliqui**?"*. 'when he halted and looked back in vain for his lost friend. "**Unhappy Euryalus, where have I left you?**" ' (*Aen.* IX, 389-390)

All these passages feature a rhetorical interrogative that conveys emotional turmoil (due either to despair or frenzy) experienced by the character addressed with the vocative. In (2), (3), and (4), the verb evokes the frames MANIPULATION or CAUSE_CHANGE, which describe the effect of madness on the state of mind of the vocative's referent. The corresponding construction may be represented as follows:

$$[^{\text{MANIPULATION} \mid \text{CAUSE\_CHANGE}}\text{X}_{\text{verb}}\ [\text{VOCATIVE}_{\textit{infelix}} \mid \text{VOCATIVE}\ [\text{AMOD}_{\textit{infelix}}]]\ [^{\text{PEOPLE} \mid \text{FEELING}}\text{OBJ}]\ [\ ^{\text{MENTAL\_PROPERTY}}\text{NSUBJ}[\text{DET}]]]$$

As for *felix*, it occurs as `amod` of a vocative in two passages:

(6) ***dicite, felices animae**, tuque, **optime vates,**/ quae regio Anchisen, quis habet locus? illius ergo/ venimus et magnos Erebi tranavimus amnis*. '**Say, happy souls,** and you, **best of bards**, what land, what place holds Anchises? For his sake are we come, and have sailed across the great rivers of Erebus.' (*Aen.* VI, 669-671)

(7) ***ite meae, felix** quondam **pecus, ite capellae.*** '**Away, my goats! Away,** once **happy flock**!' (*Ecl.* I, 74)

Both passages attest a verb (*dicite* and *ite*, evoking the frames STATEMENT and MOTION, respectively) in the 2pl of the imperative present. The command is first addressed to a larger group (PEOPLE and AGGREGATE), evoked by a `vocative` (*animae* and *pecus*) and described as *felix*. Then, it is addressed to a specific entity within that group (PEOPLE_BY_VOCATION and ANIMALS), also evoked by a `vocative` (*vates* and *capellae*):

$[^{\text{STATEMENT} \mid \text{MOTION}}\text{X}_{\text{verb.2pl.imp.}}$[21] $[^{\text{PEOPLE} \mid \text{AGGREGATE}}\text{VOCATIVE}\ [\text{AMOD}_{\textit{felix}}]\ [^{\text{PEOPLE\_BY\_VOCATION}}\text{CONJ}_{\text{vocative}}] \mid [^{\text{MOTION}}\text{CONJ}_{\text{verb.2pl.imp.}}\ [^{\text{ANIMALS}}\text{VOCATIVE}]]]]$

This construction is in turn a subtype of a more general construction that also underlies the only instance of *felix* as `vocative` (8), whose head is a MOTION verb (*vade*) in the 2sg imperative:

[17] With regard to the sentence depth, *infelix* tends to modify subjects with a sentence depth equal to one (ROOT [NSUBJ [AMOD $_{\textit{infelix}}$]] in 15 out of 22 tokens), whereas *felix* tends to occur at lower levels of the syntactic tree.

[18] *Ecl.* VI, 74-81; *Aen.* VII, 373-377; *Aen.* IX, 477-481;*Aen.* X, 424-425; *Aen.* X, 781-782.

[19] In what follows, we use X to notate an element of the catena that may have any deprel, e.g. *cepit* has the `root` deprel in (2), *mutat* has `conj` in (3), whereas *cepit* and *reliqui* have `ccomp:reported` in (4) and (5), respectively.

[20] The pipe symbol within the notation is used to represent the two possible alternatives: *infelix* occurs either as an adjectival modifier of a vocative noun or as vocative itself.

[21] The verb *dicite* has the `ccomp:reported` deprel in (6)(7) and *ite* has `root` in (7).

[$^{\text{STATEMENT | MOTION}}X_{\text{verb.2sg/pl.imp.}}$ [VOCATIVE [AMOD$_{\textit{felix}}$] | VOCATIVE$_{\textit{felix}}$]]

(8) ***vade**,’ ait, ‘**o felix** nati pietate’*. ‘**Go forth**,’ he cries, ‘**blest** in your son’s love’ (*Aen.* III, 480)

As shown by these examples, different constructions are instantiated by *felix* and *infelix* when they occur as attributes of a `vocative` or as `vocative` themselves. Each construction has a specific function:

- the construction with *infelix* is employed to address the vocative’s referent in a rhetorical interrogative that emphasizes the pathos of the discourse;
- the construction with *felix* is employed to qualify the addressee of a command expressed in the imperative present.

4.3. Case study 2: *infelix Dido*

Infelix is used as epithet of Dido, queen of Carthage, in 8 occurrences within the *Aeneid.*[22] In two of these, it instantiates the same complex catena:

ROOT$_{\text{verb.3sg.pres.}}$ [NSUBJ$_{\textit{Phoenissa | Dido}}$ [AMOD$_{\textit{infelix}}$] [ACL [OBL | OBL:AGENT]]] [CONJ$_{\text{verb.3sg.pres.}}$]

(9) *praecipue **infelix pesti deuota** futurae/ expleri mentem **nequit ardescit**que tuendo **Phoenissa*** “Above all, **the unhappy Phoenician, doomed to** impending **ruin**, **cannot** satiate her soul, but **takes fire** as she gazes” (*Aen.* I, 712-714)

(10) *Tum vero **infelix fatis exterrita Dido**/ mortem **orat**; **taedet** caeli convexa tueri* “Then, indeed, **awed by her doom**, **luckless Dido prays** for death; **she is weary** of gazing on the arch of heaven.” (*Aen.* IV, 450-451)

These two examples also attest common semantic features: they introduce the character of Dido, conveying the idea of her predestination to a fate of death and destruction. The passages correspond to critical points in the plot: in (9) Dido falls in love with Aeneas, whereas (10) describes her death. The corresponding construction may be represented as follows:

ROOT [NSUBJ$_{\textit{Phoenissa | Dido}}$ [AMOD$_{\textit{infelix}}$] [$^{\text{DESTINY | FEAR}}$ACL [$^{\text{DESTROYING}}$OBL | $^{\text{DESTINY}}$OBL:AGENT]]] [$^{\text{EMOTION\_HEAT | EXPERIENCER\_FOCUSED\_EMOTION}}$ CONJ]

In both (9) and (10), Dido is the subject, modified not only by the attribute *infelix*, but also by a perfect participle (`acl`) that emphasizes her impending doom. More precisely, in (9), *devota* ‘doomed’ evokes the frame DESTINY, specified by the oblique nominal (`obl`) *pesti* ‘to ruin’; in (10) *exterrita* ‘awed’ evokes the frame FEAR, whereas DESTINY is evoked by the agent (`obl:agent`) *fatis* ‘by her doom’ causing the terror.

Moreover, the coordinated verb (`conj`) in both instances relates to Dido’s emotional state, which is different in the two examples: in (9) *ardescit* ‘takes fire’ marks the beginning of Dido’s love for Aeneas, whereas in (10) *taedet* ‘is weary’ evokes her attitude towards life.

The initial and the final moments of Dido’s story are thus expressed by means of the same catena, evoking her impending ruin. This construction seems to encapsulate the whole thematic arc of Dido’s role in the *Aeneid*, which is framed both at its inception and at its conclusion by a linguistic structure that highlights the inevitability of her fate.

5. Conclusion and future work

With the present study, we show the potential of a constructionist and computer-based approach in the analysis of a poetic corpus in Latin. By integrating syntactic information based on UD with semantic annotation grounded on FrameNet, we were able to identify recurrent constructions involving two key lemmas of Virgilian poetics, *felix* and *infelix*. This enabled us to uncover differences and parallels in the uses of these two terms within Virgil’s language.

The present work is a pilot study which may pave the way for future research. Our approach is language-independent, and may thus be applied to different corpora across various languages and historical periods, for instance to explore similarities in the poetics of various authors within different traditions. Our investigation relied on manual annotation for both the syntactic and semantic analyses due to the lack or poor performance of automatic annotation systems for Latin poetry at the time of writing. The feasibility and effectiveness of such systems can vary significantly across different languages, depending on the resources available. Future improvements in automatic annotation for Latin may allow us to scale up this approach to perform analyses of even larger corpora.

Virgil’s poems played a crucial role in shaping later poetic traditions for centuries: an interesting application of our integrated approach may thus be to investigate whether the same constructions attested in Virgil’s poems also occur in the works of later poets who are

[22] *Aen.* I, 712; *Aen.* I, 749; *Aen.* IV, 68; *Aen.* IV, 450; *Aen.* IV, 529; *Aen.* IV, 596; *Aen.* V, 3; *Aen.* VI, 456.

known to have been influenced by him, both in Latin (e.g. Valerius Flaccus's *Argonautica*, Silius Italicus's *Punica*, Publius Papinius Statius's *Thebaid*), as well as in other languages, such as Italian (e.g. Dante Alighieri's *Commedia*).

Lost in Disambiguation: How Instruction-Tuned LLMs Master Lexical Ambiguity

Abstract

This paper investigates how decoder-only instruction-tuned LLMs handle lexical ambiguity. Two distinct methodologies are employed: Eliciting rating scores from the model via prompting and analysing the cosine similarity between pairs of polysemous words in context. Ratings and embeddings are obtained by providing pairs of sentences from Haber and Poesio [1] to the model. These ratings and cosine similarity scores are compared with each other and with the human similarity judgments in the dataset. Surprisingly, the model scores show only a moderate correlation with the subjects' similarity judgments and no correlation with the target word embedding similarities. A vector space anisotropy inspection has also been performed, as a potential source of the experimental results. The analysis reveals that the embedding spaces of two out of the three analyzed models exhibit poor anisotropy, while the third model shows relatively moderate anisotropy compared to previous findings for models with similar architecture [2]. These findings offer new insights into the relationship between generation quality and vector representations in decoder-only LLMs.

1. Introduction

Lexical ambiguity (LA) is a peculiar characteristics of human language communication. Words often carry multiple meanings, and discerning the intended sense requires nuanced comprehension of contextual cues. LA is a broad concept subsuming several semantic phenomena, such as regular and irregular polysemy, homonymy, and the coinage of new senses. Humans handle such ambiguity effortlessly, leveraging contextual information, prior knowledge, and pragmatic inference. However, for Large Language Models (LLMs), which rely on statistical patterns in text data, accurately resolving lexical ambiguity remains a challenging task.

Despite their remarkable capability of using words appropriately in context, one critical aspect that requires deeper investigation is whether such models possess human-like lexical competence, enabling them to generalize from multiple instances of the same phenomenon, or if they are simply mimicking these instances.

In this paper, we aim to investigate how LLMs handle LA. Specifically, we challenged three decoder-only instruction-tuned models to generate lexical similarity ratings for word pairs used in two different contexts, with various degrees of sense similarity. To achieve this, we employed a chain-of-thought approach, prompting the models to produce a step-by-step reasoning process before assigning their ratings, allowing them to better distinguish between different senses of the same term.

For this task, we used the dataset released by Haber and Poesio [1], which includes human similarity judgments. The models' generated ratings were correlated with human similarity judgments to determine whether their lexical disambiguation competence aligns with that of humans. Additionally, we computed the cosine similarity between the models' internal representation of the ambiguous target words. Our research question is twofold: i.) to **assess if the models' generated ratings are consistent with their internal representations of the target words**; ii.) to **determine whether the internal representations have a more similar distribution to human ratings than the generated responses**.

We are aware that context-sensitive word embeddings, like those of LLMs, can suffer from a *representation degeneration problem* (see Section **??** for further details), which limits their semantic representational power. Hence, we included in our analysis a brief overview of how this phenomenon affects the internal representational space of the models under our investigation.

To the best of our knowledge, this is the first study in

which different decoder-only models were tested on their metalinguistic competence regarding LA. Understanding how LLMs manage this type of complex semantic phenomenon, based on the interplay of multiple contextual factors, can guide new improvements in training methodologies for the development of more sophisticated and robust models that better mimic human-like language understanding.

2. Related works

One of the main reasons for the success of Transformer-based LMs is their ability to represent context-dependent meaning. The specific meaning a token assumes in a given context is encoded within the internal layers of these models and is reflected in the spatial distribution of the produced embeddings, where unique context vectors for each token occurrence are placed distinctly [2].

Yenicelik et al. [3], extending Ethayarajh [2]'s study, sought to obtain a general overview of BERT's [4] embedding space concerning polysemous words. They confirmed that BERT does indeed form contextual clusters, which nevertheless obey semantic regularities in a broad sense. These clusters may fulfill denotative, connotative, or syntactic criteria, with converging groups consistent with the idea of polysemy as a gradual continuum. However, the embedding space of such models shows regularities influenced not only by linguistic factors but also by one of the model's training objectives, i.e., Next sentence Prediction [5]. This confirms the flexibility and richness of contextual representations but raises questions about their representativeness of proper linguistic features. Several studies compared the contextual vectors of encoder models like BERT and ELMO with human similarity judgments, demonstrating that human judgments usually correlate with the cosine similarity of polysemous word pairs [1, 6], and even more with homonyms pairs [7].

Recently, the correlation between human similarity judgments and model competence regarding LA was also explored for larger decoder-models, such as GPT-4 [8]. However, this analysis only considers GPT's generated ratings, without examining the internal representations of polysemous words. Hu and Levy [9] pointed out that prompting might not be the most reliable way to evaluate models, as the generated responses are not always consistent with the model's probability distribution.Their work primarily addresses two tasks: token prediction and sentence pair selection. In their evaluations, token prediction is determined by identifying the token with the highest probability from the entire vocabulary, while sentence pair selection is based on the perplexity of two competing propositions. While their methodology yields strong results, it is not directly applicable to our study due to the non-deterministic nature of model outputs in response to the task we propose. Specifically, presenting the model with two alternative sentences is not feasible in our experiment, as the objective is to have the model generate a chain-of-thought output that differentiates between the distinct senses of an ambiguous term and subsequently produces a rating. One alternative would be to have the model directly predict the rating and check which vocabulary token (among the numbers in the rating scale) has the highest probability. However, this approach would not generate the contextual embeddings for the target term necessary for our comparisons. Furthermore, as discussed in section 3.3, ratings produced without the chain-of-thought approach were inconsistent.

Since we are dealing with word similarities, the most straightforward way to measure a model's internal knowledge about polysemic words is by using cosine-similarities. However, given the contextual nature of these models, embeddings might not transparently reflect semantic properties, as they can be influenced by other superficial contextual factors. This makes it challenging to discern whether a high value of cosine similarity is due to word sense similarity or to a general closeness of the word embeddings in the space, the so-called *anisotropy*.

Anisotropy can indeed negatively affect the representational power of embeddings, and several methods have been proposed to mitigate its effect [10, 11, 12]. Nevertheless, it has been demonstrated that anisotropy does not have a negative impact on model performance [12].

Given these complexities, we decided to further investigate LA with large decoder-only models to highlight differences with results obtained from smaller encoders and to determine whether their behaviour aligns with the human competence on LA. We compared the performance of different instruction-tuned decoders to obtain a more comprehensive overview of how these models handle this phenomenon. To ensure a thorough evaluation, we consider both the models' generated ratings for polysemous words and their cosine similarities. Additionally, in our analysis, we took into account the level of anisotropy exhibited by these models.

3. Experimental settings

3.1. Dataset

We use the dataset introduced in Haber and Poesio [1], which includes a set of target words in various contexts. Human judgments were collected on sentence pairs with the same word, by asking participants to rate the similarity of the target word meaning in the different contexts. We chose to focus only on in-vocabulary tokens, as we aimed to compare models' performances on their generated embeddings, without employing additional opera-

Table 1
Sentence pairs for each similarity class based on the distribution of human ratings. Classes "Homonym" and "Same sense & context" in boldface were manually identified [1].

Similarity class	Count
Homonym	11
Different	45
Quite different	49
Quite similar	37
Similar	19
Equal	68
Same sense & context	7
Total	236

tions (e.g., mean pooling of subword embeddings). Thus, we retain about 79% of the dataset sentence pairs (i.e., 236 out of the original 297).

We further categorized sentence pairs according to the distribution of the human ratings, dividing them into four *similarity classes* depending on their interquartile ranges.[1] We also included the two manually identified groups from Haber and Poesio [1]. One consists of sentence pairs with homonyms, and the other consists of words having the same sense in highly similar contexts. As these groups did not have human ratings, we assigned ten ratings to each data point, randomly selected around 0.01 for homonyms (indicating completely different meanings) and around 1.00 for the other group. The human ratings serve as the ground truth for the post-hoc analysis in Section 4. The final dataset counts 35 target word types (see Figure 1 for their list and token distribution), with a set of similarity judgments for each pair.

3.2. Models

To assess the capability of LLMs to capture varying degrees of LA, we selected three decoder-only open models of comparable size. We chose instruction-tuned models exclusively, as this configuration is more suitable for conditional text generation: `Meta-Llama-3-8B-Instruct` [13], hereafter referred to as LLaMA; `Gemma-1.1-7B`[2], hereafter referred to as Gemma; and `Mistral-7B-Instruct-v0.2`[3], hereafter referred to as Mistral. All models are instruction-tuned autoregressive LLMs with around 7 Billion parameters. We chose these models as they are representative of popular and widely used open-weights LLMs. We used the Huggingface implementation of the models for our experiments.

3.3. Prompting

We report experimental results using a single prompt.[4] The prompt was designed to closely follow the methodology used by Haber and Poesio [1] for modeling the LA task to collect crowdsourced data, ensuring a fair comparison between LLMs' ratings and human judgments. In our setup, we provided the models with two sentences, each containing the same target word. We then prompted the models to return a rating score indicating how similar the word's usage was in the two occurrences. The rating score ranged from 1 to 100, where 1 indicated that the word was used with completely different senses in the two sentences, and 100 indicated that the word was used with the same sense across sentences. We formulated the instructions following common rules of thumb for prompting LLMs [14].

In preliminary experiments, we asked the model to return the similarity rating first and then to return the motivation of such rating. We observed that i.) the rating was quite inconsistent with the underlying motivations given by the models, ii.) the motivations were usually more appropriate than the ratings, and that iii.) the models tended to return the same rating for all the sentence pairs. Thus, we chose to ask the model to provide the motivation first, followed by the rating. This allowed the models to provide more accurate ratings. Such a behavior is in line with the literature on "chain-of-thought" prompting [15]. Additionally, we chose *beam search* as a generation strategy, with 2 beams. The models sampled the next generated token among the 50 most probable words. We combined this strategy with *nucleus sampling*, by setting a probability threshold of 0.95.

3.4. Embedding Extraction and Cosine-similarity

Building on the experiments in Haber and Poesio [1] and Loureiro and Jorge [16], we used the embeddings generated from the last layer and the average of the embeddings from the last four layers as contextual embeddings for the generated tokens. The idea behind this approach is that the last layer embeddings represent the most contextual and generation-focused features, while the preceding layers capture more general aspects of the processed sequence. This method allowed us to obtain two sets of contextual embeddings for each generation. Due to the unidirectional design of the decoder architectures, the repetition of the input sentences across generations was necessary. The model had to process all tokens in both sentences before providing sufficient contextual embeddings, making the input vectors unsuitable for the task. Once the vectors for each generated token were obtained, we isolated the embeddings corresponding to

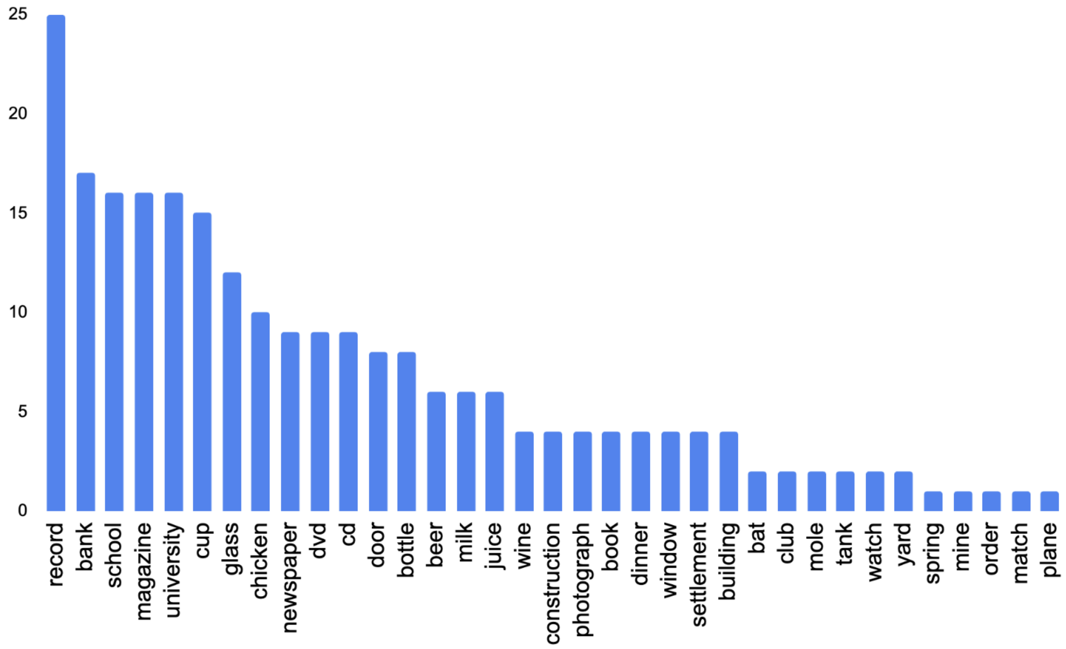

Figure 1: The distribution of the target words in our dataset.

the tokens of the target words contained in the stimulus sentences (repeated by the model at the beginning of the generation). Afterwards, cosine similarity values were calculated between the target word vectors extracted from the last layer and the last four layers.

3.5. Investigating anisotropy in decoder-only models

The so-called *representation degeneration problem* [17] is a well-known phenomenon observed in several Transformer architectures, even in those trained on data other than text [18]. This issue causes most of the model's learned word embeddings to drift to a narrow region of the vector space [2], making them very close to each other in terms of cosine similarity, and consequently limiting their semantic representational power. Since our work primarily focuses on analyzing LLMs' ability to capture subtle semantic properties such as polysemic relations and relies in part on the computation of cosine similarity between token pair embeddings, we decided to further investigate this phenomenon.

We conducted an analysis of the distribution of the models' generated tokens in the vector space to understand the extent of representation degeneration and its implications for the semantic representation of our target tokens. For each model, we sampled 1,000 pairs of random tokens from all generations of the model across the entire dataset. We extracted the representations of these tokens from both the last layer and the average of the last four layers. We then computed the average cosine similarity of the sampled embedding pairs for the last and last four layers separately.

3.6. Evaluation

We compared the Model Rating Scores (MRSs), the Cosine Similarity Scores (CSSs), and the Human Rating Scores (HRSs) collected by Haber and Poesio [1] by means of Spearman Correlation. The correlation between MRSs and CSSs should shed light on the internal coherence of each model and aims at answering the following question: **Is the metalinguistic knowledge of the model consistent with its internal representations?** By comparing HRSs with MRSs and HRSs with CSSs, we aim to explore a different issue: **Do the human ratings have a more similar distribution to what a model generates rather than its internal representation or vice-versa?** Before computing the correlation, we rescaled the CSSs in the range $0.01 - 1.00$. We also rescaled the MRSs from the range $1 - 100$, to the range $0.01 - 1.00$. As for the HRSs, we used the average of the

Table 2
Spearman correlation measures between Model Rating Scores (MRS), Human Rating Scores (HRS), and Cosine Similarity Score (CSS). The results with CSS are computed both with the last hidden state vectors (*Last*) and with vectors averaged from the last four hidden states (*Last4*). The model's result with the correlation score farther from zero for each comparison is in boldface. P-values < 0.05 are marked with *.

Model	MRS vs. HRS	CSS vs. HRS		MRS vs. CSS	
		Last4	*Last*	*Last4*	*Last*
Mistral	$0.404*$	$\mathbf{-0.020}$	$\mathbf{-0.020}$	0.047	0.042
Gemma	$0.446*$	-0.002	0.001	0.066	0.056
LLaMa	$\mathbf{0.616}^*$	$\mathbf{0.016}$	0.110	-0.002	$\mathbf{0.118}$

Table 3
Average cosine similarities between 1000 random pairs of tokens for each model.

Model	Avg Cosine Similarity	
	Last4	*Last*
Mistral	0.138	0.137
Gemma	0.672	0.746
LLaMA	0.24	0.228

collected ratings for each sentence pair in the correlation.

4. Results and analyses

Table 2 reports the correlations among human ratings, model ratings, and cosine similarities. First, we consider the correlation between cosine similarities and human ratings. The three models exhibit a near-zero correlation between CSS and HRS, which is always negative for Mistral (-0.020) and positive for LLaMa (0.016, 0.110). Second, we compare model ratings to human ones. We observe that there is a moderate-to-high correlation for LLaMa (0.616), and a low-to-moderate correlation for Mistral (0.404) and Gemma (0.446). Thus, despite being more correlated than cosine similarities, the models' ratings often differ from human ones. We observed some recurrent patterns in the score assignments by each model[5]. LLaMA frequently assigns similarity ratings of 20, 60, and 80. Gemma shows a preference for very low or very high scores, leaving the middle range sparsely populated. Mistral appears the most balanced in its evaluations, yet it still favors round values (100, 90, 80, etc.) and shows a strong preference for values close to 1. However, these rating preferences do not seem to correspond to lexical preferences. Although MRS appears to correlate better with HRS than CSS, the unstable nature of prompt results and their sensitivity to biases from the data or prior training make them less suitable for inspecting the model's competence regarding complex semantic features like polysemy.

In addition to this, we observe that in the comparison between CSS and HRS, the cosine similarity distributions of Mistral and LLaMA appear similar, while Gemma's distribution is shifted towards higher values. We can surmise that this may be attributed to a greater anisotropy in the embedding space characterizing the Gemma model (see Section 4.1 for a thorough analysis). Overall, the CSS reflects the similarity distribution indicated by the human subjects far less accurately than the MRS.

Finally, to evaluate the internal coherence of the models in terms of the agreement between the generated similarity scores and hidden representations, we also compared the cosine similarities and model ratings of each model. In this case, the highest correlation is obtained by LLaMa, which nonetheless exhibits a very weak correlation (0.118 on the last layer), meaning that one can not reliably predict MSR based on the CSS. We speculate that a complex phenomenon like polysemy is only sub-optimally represented at the token embedding level.

4.1. Anisotropy

As shown in Table 3, the degree of anisotropy varies quite significantly among the three decoder-only models, especially between Gemma and the other two models, Mistral and LLaMA. Gemma exhibited the highest cosine similarity scores, approximately 0.67 for the last four layers and slightly higher for the last layer (0.75), corroborating the findings of [2] regarding anisotropy in decoder models such as GPT-2, which peaks in the last layer. Conversely, Mistral showed the lowest scores (0.137 for both the last and last four layers), followed by LLaMA (0.24 for the last four layers and 0.228 for the last layer), indicating a much more isotropic space than one would expect for models with similar architecture and comparable size. This suggests that anisotropy might not be the same in all Transformer-based models. Rather, it appears to be a property that is present at varying degrees in models, with some exhibiting greater anisotropy than others. This may be due to specific differences in how models were trained, both in terms of data used, and pre-training, fine-tuning, and post-training techniques. We aim to further investigate this aspect in the future.

Due to these differences, we decided not to apply any post-processing method [12, 10] to mitigate the anisotropy of our target vectors. However, looking in detail at the relationship between the models' anisotropy and their respective cosine similarities, it seems that the relatively low degree of anisotropy in both Mistral and LLaMa does not result in a better correlation between their CSS and HRS. On the contrary, despite a generally

[5] Figure 3 in the appendix enables a detailed examination of the ratings generated by the models. An interactive version of these plots will be available on GitHub.

moderate level of anisotropy found in these decoder-only models, the CSS of the target tokens correlate less with the HRS than the MRS. This finding suggests that the low correlations of cosine similarities can not be (entirely) due to the embedding anisotropy and that conversely the latter does not affect the model generation abilities significantly. This appears to confirm recent trends suggesting that cosine similarity is a suboptimal measure to explore Transformers' geometries [19].

5. Conclusion and future work

Our study investigates how LLMs handle LA, using two distinct methodologies: Eliciting rating scores from the model and analyzing the cosine similarity between pairs of polysemous words. We calculated the Spearman correlation between HRS vs. MRS, HRS vs. CSS, and MRS vs. CSS. The aim was to determine whether the model's metalinguistic knowledge aligns with its internal representations and to assess if human ratings more closely match the outputs generated by the model than its internal representations.

The lack of correlation between CSS and MRS provides intriguing insights into the relationship between the internal representations of LLMs and the responses they generate in metalinguistics tasks, like explicitly assigning similarity ratings. Specifically, the argument presented by Hu and Levy [9] appears to be validated: Generated responses do not always reflect the model's internal processing. Hu and Levy [9] compared model generations with their probability distributions and found the latter method to be more accurate. In contrast, in our study, using the internal representations of the model (i.e., the contextual embeddings, as motivated in Section 2) proved to be a less reliable method. The most straightforward conclusion is that generative LLMs might be suboptimal for estimating word sense similarity. The superior performance of probability estimation reported by Hu and Levy [9] might be due to its direct link to the prediction training objectives of LLMs. To further investigate the relationship between CSS and MRS, we inspected the anisotropy of the embeddings. The average cosine similarity among a sample of generated tokens was relatively low, indicating that anisotropy did not affect our cosine similarity measures and is not characteristic of all decoder-only models under investigation. The lack of anisotropy observed in some of the analyzed decoder-only models is at odds with the conclusions of Ethayarajh [2], who reported a higher anisotropic space for GPT-2.

Only MRS yielded a moderate correlation with HRS, indicating that LA is not fully captured by the analyzed models, in text generation and vector representations. In conclusion, the relationship between human judgments, model generations, and internal representations appears unclear and calls for further research. Despite the low anisotropy of the examined models, cosine similarity did not reveal a correlation between the generations and the internal representations of the models, indicating a need for deeper investigation. We plan to repeat the experiments by leveraging recent results with sparse autoencoders [20] to decompose the meanings of lexically ambiguous words. This could provide a deeper understanding of the models' ability to handle and represent polysemy.

We could not extract embeddings from commercial models, such as those provided by OpenAI, which are accessible only through APIs. However, it would be valuable in future research, if and when this functionality becomes available, to analyze and compare the internal representations and the generated outputs of these state-of-the-art models.

Another promising avenue for future research is to examine the differences between vector representations and generated tokens with respect to linguistic phenomena beyond polysemy and lexical ambiguity. For instance, incorporating out-of-vocabulary words could allow for an exploration of semantic shifts caused by the addition of prefixes or suffixes (e.g., “order” vs. “dis-order”), offering valuable insights. This analysis would benefit from using a tokenization strategy that treats morphemes as subtokens, alongside an investigation into the degree of anisotropy in these models.

A. The prompt

The following text box shows the prompt used to test LLMs in our lexical ambiguity experiment. The underlined text was replaced by sentences and word targets from the dataset shared by Haber and Poesio [1].

> You will receive two sentences. Your task is to rate how similar is the use of the word ‘word’ in the two sentences.
>
> - Sentence 1: s1
> - Sentence 2: s2
>
> You must follow the following principles:
>
> - Assign a rating on a scale of 1-100, where 1 means that the word is used with completely different senses in the two sentences and 100 means that the word is used in the same sense across the two sentences.
> - Return your answer in this way:
>   - Rewrite the two sentences following this template:
>   - Sentence1: <text>
>   - Sentence2: <text>
>   - Motivation: <a concise motivation for your rating>
>   - Rating score: <only a float number on a scale of 1-100 and nothing else>.
> - Interrupt generation after the rating score.
>
> Question: how similar is the use of the word word in the following two sentences?
> s1
> s2
> Answer:

B. More on human-rated pairs

Table 4 shows the interquartile ranges of the human ratings collected by Haber and Poesio [1] and related only to the sentence pairs filtered as described in Section 3.1. The ranges are plotted in Figure 2.

In Table 5, the Spearman correlation measures between Model Rating Scores (MRS), Human Rating Scores (HRS), and Cosine Similarity Score (CSS). Sentence pairs from the similarity class ‘Homonym’ and ‘Same sense & context’, for which Haber and Poesio [1] did not provide crowdsourced data, were not included in the computation.

Table 4
The interquartile ranges of the human ratings related to the sentence pairs selected for our experiments.

Quartile	Range
First	0 – 0.556
Second	0.556 – 0.845
Third	0.845 – 0.934
Fourth	0.934 – 1.00

Abstract

The possibility of comparing the linguistic competence of Language Models (LMs) to that of children has gained growing attention lately, raising the need for effective tools for evaluating both the former and the latter. To this purpose, we developed a resource for the linguistic evaluation of BabyLMs, which are LMs trained on datasets that comparable to the linguistic stimulus received by children. This resource adapts four standardized tests for the evaluation of linguistic skills of Italian-speaking children (BVL, TROG-2, TCGB-2 and Peabody). To verify the effectiveness of our benchmark, we administered it to Minerva, a LLM pretrained from scratch on Italian. Our results indicate that Minerva struggles to master certain linguistic aspects, achieving an age-equivalent score of 4 years, and that the type of task administered affects the model's performance.

1. Introduction

This paper presents BaBIEs (Baby Benchmark for Italian linguistic Evaluations), a new resource for the standardized evaluation of Italian BabyLMs, that is, language models (LMs) trained on datasets that are qualitatively and quantitatively comparable to the type of stimulus received by humans during language acquisition. The aim of this resource is twofold: (i) to evaluate the quality of the training data and strategies, in particular curriculum learning techniques, used in the development of BabyLMs and (ii) to provide a benchmark for comparing the performance of LMs, especially BabyLMs, with that of young human speakers. The paper is structured as follows: Section 2 reviews related work and delineates the rationale for this study; Section 3 details the characteristics of the BaBIEs benchmark, which results from the adaptation of standardized tests for evaluating the linguistic abilities of Italian-speaking children. In Section 4, we report a first test of the dataset with the Minerva Italian LM. The benchmark effectiveness is discussed in the light of the experiments in Section 5. Finally, in Section 6, some conclusions and possible future research directions are outlined.

2. Related works

2.1. Less is More

In recent years, LMs have progressively increased in both parameters number and volume of training dataset [1]. This trend presents several challenges, primarily (i) the escalating demand for data in the medium term could be a significant constraint on model development and enhancement [2]; and (ii) the mismatch between the volume and quality of training data for models and human learning behavior makes it difficult to compare their performance. This discrepancy poses methodological challenges for drawing conclusions or generalizations from studies of LMs in the context of language acquisition and cognitive modelling [3].

These challenges have spurred reflections on the relationship between the quantity and quality of training in natural language processing (NLP). Zhang et al. [4] address this topic by attempting to quantify the amount of text necessary for a LM to develop syntactic and semantic competence sufficient to achieve acceptable results in common NLP and natural language understanding (NLU) benchmarks. Specifically, the authors investigate the skills that can be acquired with training datasets ranging from 10 million to 100 million words. This range is derived from the well-known study by Hart and Risley [5]. According to them, a child is exposed to approximately 10 million words per year on average, reaching around

100 million words by age 10. Zhang et al. [4] demonstrate that substantial amounts of data are required to achieve good results in NLU tasks, such as those evaluated by SuperGLUE [6]. Performance improvements become noticeable after surpassing the threshold of 1 billion words and continue to improve steadily even beyond 30 billion words. However, tasks focusing on language syntax (e.g., acceptability judgment and minimal pairs) exhibit the most significant improvements between 1 million and 100 million words, after which the learning curve plateaus. The authors conclude that while acquiring factual knowledge necessitates large volumes of text, syntactic and semantic competence reaches saturation within the range of 10 million to 100 million words. Similar conclusions are reported by Wei et al. [7], who investigate the emergent skills of various LLMs, confirming that the most sophisticated behaviors primarily arise from scaling up model training. These findings justify the focus on BabyLMs, which are LMs trained on limited amounts of data, qualitatively resembling the stimuli received by a preschooler. Huebner et al. [8] illustrate this approach by training BabyBERTa on 50 million words of child-directed speech and simplified written text, achieving results comparable to RoBERTa-base on a grammar test suite. The BabyLM challenges [9] fall within this line of research, aiming to optimize model training through curriculum learning (CL) techniques and architectural optimizations. This approach not only makes research more affordable, but also results in models that are more cognitively plausible in comparison to human language acquisition. Although the proposed CL techniques did not lead to consistent improvements across all evaluation tasks [9], it has been demonstrated that a model trained with limited data (10 million words) can achieve results comparable to those of large LMs on various benchmarks.

2.2. Baby benchmarks for Baby models

These results prompt a reconsideration of the comparability between LMs training and human language learning. While benchmarks like BLiMP [10] and GLUE [11] facilitate comparisons between different models, they are not suitable for comparing BabyLMs to children who are acquiring a first language. Several studies attempt to address this shortcoming. For instance, Evanson et al. [12] compare the learning order of certain syntactic structures in English between GPT-2 and preschoolers. They find that the model exhibits a consistent order in learning syntactic structures, which aligns with the one observed in preschoolers. Other tests that compare training in LMs to human language acquisition include the reading time test [13] and the age-of-acquisition test [14].

For the Italian language, the three main benchmarks are: (i) UINAUIL [15], which includes six NLU tasks selected from the EVALITA (Evaluation campaign for Language Technology in Italian) archive; (ii) IT5 [16], which focuses on summarization tasks; (iii) the Invalsi benchmark [17], which evaluates the mathematical and linguistic competences of LMs in Italian. Only the latter is relevant to our study, as it allows a comparison between human language learning (in the school-age range 6-18 years) and that of the models. However, the age range considered by Invalsi involves more sophisticated NLU tasks, rather than the fundamental linguistic abilities learned during the preschool period, within the 100 million word budget.

3. Nurturing BaBIEs

In order to evaluate the linguistic abilities of BabyLMs, we developed BaBIEs by adapting four standardized tests designed to assess the linguistic competence of Italian-speaking children. These tests, which tap into different aspects of linguistic competence, are:

- *Batteria per la Valutazione del Linguaggio in Bambini dai 4 ai 12 anni (BVL)* 'Battery for the Assessment of Language in Children aged 4 to 12' [18]. BVL is designed to provide a global linguistic profile of Italian-speaking children and was standardized on a sample of 1,086 children aged 4 to 12. It consists of 18 tasks (e.g., semantic and phonological fluency, sentence and word comprehension, emotional prosody comprehension, etc.) grouped into three sections, i.e., production, comprehension, and repetition.

- *Peabody - Test di vocabolario recettivo* (Italian adaptation of the *Peabody Picture Vocabulary Test - Revised*) [19, 20]. PPVT-R is intended to measure the receptive vocabulary of the subject and was standardized on a sample of 2,400 aged 3 to 12 and 16. It consists of 175 items.

- *Test for Reception of Grammar - Version 2 (TROG-2)* [21]. TROG-2 is designed to assess the comprehension of verbal language, especially syntactic structures, and was standardized on a sample of 1,276 subjects aged 4 to 87. It consists of 20 blocks, each containing four items that focus on a grammatical structure (e.g., zero anaphor, reversible in and on, relative clause in object, etc.).

- *Test di Comprensione Grammaticale per Bambini - Seconda Edizione (TCGB-2)* 'Test of Grammatical Comprehension for Children - Second Edition' [22]. Analogously to TROG-2, TCGB-2 is a tool for assessing the comprehension of grammatical structures and was standardized on a sample of 455 children aged 4 to 11. It contains 74 items which measure the comprehension of six structures, i.e., the phenomenon of inflection, and five types of sentences: locative, active, passive, relative and dative.

It is worth noting that all tests are standardized on samples of typically-developing Italian-speaking subjects and are designed to be orally administered. That is, the stimuli are always read by the experimenter, and the child is asked either to answer orally or to point at a picture.

BaBIEs consists of five tasks (see Table 4 in Appendix A): this resource is twofold: (i) *Sentence Completion* (the only task assessing linguistic production), (ii) *Acceptability Judgment*, (iii) *Idiom Comprehension*, (iv) *Sentence Comprehension*, (v) *Lexical Comprehension*. These tasks are taken from BVL. We added 165 out of 175 items from Peabody (Lexical Comprehension task) and all the items contained in TROG-2 and TCGB-2 (both Sentence Comprehension tasks).[1] Except for the Sentence Completion task and the Acceptability Judgment task, all of the others are similarly-structured comprehension tasks. The child is presented with an oral linguistic stimulus (i.e., a word, a sentence or an idiom) and with a set of three or four possible answers, from which the child must choose the answer corresponding to the linguistic stimulus (the *target*). Together, a stimulus and its set of possible answers constitute a *test item*. The key factor in the process of item adaptation from the original tests to BaBIEs was the modality in which the sets of possible answers are displayed.

For the Acceptability Judgment task, we constructed minimal pairs of sentences by creating a grammatical or ungrammatical version of the verbal stimulus (depending on the (un)grammaticality of the original stimulus). In this task, the model receives one pair at a time. Its choice is determined by perplexity, with the sentence having the lowest perplexity score being chosen by the model.

For the Sentence Completion and Idiom Comprehension tasks, as both the stimuli and the sets of possible answers are linguistic expressions, the adaptation process only involved reformatting them to be readable by the model. The Sentence Completion task is modeled in a fill-in-the-blank format. The LM is given a textual sentence to complete, it receives one item at a time as input and generates up to three new tokens. The answer is considered correct if the correct completion appears in the generated sequence.

In contrast, the items for the Sentence and Lexical Comprehension tasks required substantial adaptation because these tasks involve pictures in their original version. The sets of possible answers are indeed presented on illustrated boards with four pictures, among which the child must choose the target picture that depicts the verbal stimulus. Adapting these items involved converting the pictures into linguistic expressions, either single words or complex sentences, which consist of the linguistic description of the distractor and target drawings. In the Sentence Comprehension task, the pictures were converted into sentences maintaining the lexical items constant whenever possible, and only altering the syntactic structure. This way, the target differs from the stimulus syntactically, but not lexically. For instance, given the linguistic stimulus *la pecora è spinta dal ragazzo* 'the sheep is pushed by the boy', the possible answers are: *cioè il ragazzo indica la pecora; cioè la pecora spinge il ragazzo; cioè il ragazzo spinge la pecora* (TARGET); *cioè il ragazzo guarda la pecora* 'that is, the boy indicates the sheep; that is, the sheep pushes the boy; that is, the boy pushes the sheep (TARGET); that is, the boy looks at the sheep'. Since the relevant structure is the reversible passive, target and distractors are active clauses with the same lexical items as the linguistic stimulus. For the Lexical Comprehension task, the converted target and distractors can be full sentences (especially if the stimulus is a verb), words, or phrases. Since the target converted from the target picture can not be identical to the stimulus word, we used a linguistic expression that is semantically-related to the stimulus (e.g., a synonym, hypernym, hyponym, etc.). For instance, given the stimulus *un trattore* 'a tractor', the set of possible answers is *cioè un microscopio; cioè una ruspa (TARGET); cioè un binocolo; cioè una bicicletta* 'that is, a microscope; that is, a bulldozer (TARGET); that is, binoculars; that is, a bicycle'. The target is *una ruspa* 'a bulldozer', which is semantically-related to the stimulus.

The adapted version of the Lexical Comprehension tasks (BVL and Peabody) functions as follows: each item comprises a textual lexical stimulus (a word) followed by a textual adaptation of the possible corresponding pictures, referred to hereafter as textual options (cf. Appendix A). The lexical stimulus is concatenated with each possible textual option to form four complex sentences. Noteworthy, we choose to concatenate the stimulus to each textual option by means of *cioè* 'that is', a conjunction used to clarify or restate something previously mentioned, which is particularly suited to make explicit the relationship between the the stimulus and the textual options. The model's choice is determined based on the perplexity obtained for each sentence. The same applies to the Sentence Comprehension tasks, which comprises items from the Sentence and Idiom Comprehension tasks (BVL, TROG-2, and TCGB-2). Some examples of adapted items (one per task) and the structure of the entire dataset are given in Appendix A.

[1] 10 out of 175 items from Peabody were excluded, because either the words were too rare to be known by BabyLMs, e.g., *emaciato* 'emaciated', or it was impossible to adapt the item without using visual stimuli, e.g., for *quadrato* 'square'.

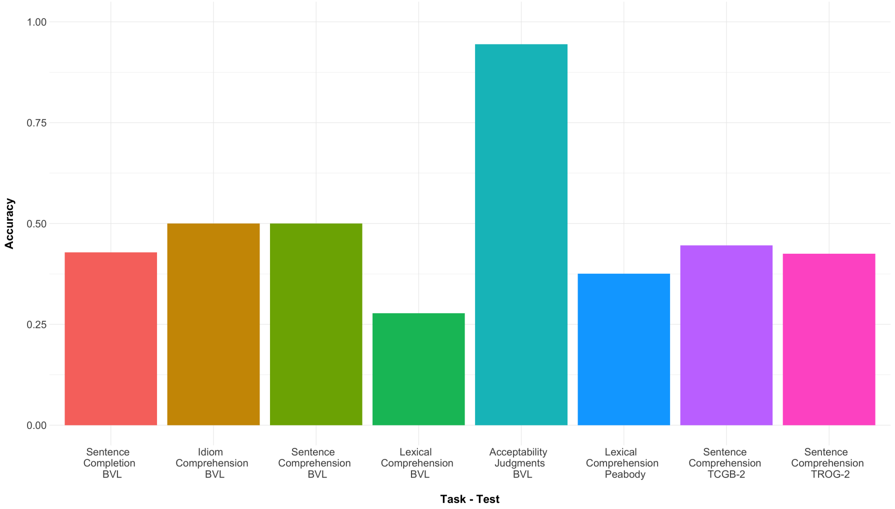

Figure 1: Accuracy obtained by Minerva in each task, across all tests.

4. Testing BaBIEs with Minerva

4.1. Model

To verify the effectiveness of this test, it was presented to a LM. Since no Italian LM primarily trained on child-directed speech and through curriculum learning was available, we opted for a conventional Italian LM[2]. Specifically, we chose `Minerva-3b-base-v1.0` (hereafter referred to as Minerva) [24], a decoder-only model (based on Mistral [25]) with 3 billion parameters. The choice was determined by the fact that, unlike other available models, Minerva was developed as an Italian model, despite also being pre-trained on a substantial amount of English text (660 billion tokens, 50% Italian and 50% English). For the experiments, the Huggingface implementation of the model was used. For the Sentence Completion task, we chose *beam search* as a generation strategy, with 3 beams. The models sampled the next generated token among the 50 most probable words. We combined this strategy with *nucleus sampling*, by setting a probability threshold of 0.95.

4.2. Results

The performance of Minerva is measured in terms of accuracy (number of true predictions relative to the total number of items). This measure is also used for evaluating children, allowing us to utilize standard scores to evaluate the model. The accuracy achieved by Minerva across all tasks is illustrated in Figure 1. Complete results, including accuracy for each clause type (Sentence Comprehension task - BVL, TROG-2, TCGB-2) and part-of-speech (Lexical Comprehension task - Peabody), are provided in Appendix B. Minerva obtains the highest accuracy in the Acceptability Judgment task (BVL) by far, with 17/18 true predictions and an accuracy of 0.94. Considering the standard scores, this falls between -1SD and +1SD for the age range 6.0-11,11 years (11,11 being the last age considered in the standardization of BVL). [3] The accuracy is lower for the Sentence Completion task (BVL), which - it is worth repeating - is the only production task, i.e., 0.43, with 6/14 true predictions. This score is positioned between -1SD and +1SD for the age range 4,0-5,5 years. In the Idiom Comprehension Task (BVL), the true predictions given by Minerva are 5/10, and the accuracy is of 0.5. This score is only seemingly low. Indeed, it falls between -1SD and +1SD for the age range 6,6-8,11 years and beyond +2SD for the age range 4,0-4,5 years. Let us now turn to the Sentence and Lexical Comprehension tasks (which involve picture-to-language conversion). We used three Sentence Comprehension tasks (from BVL, TCGB-2, TROG-2), which tap into partially different clause types (cf. Appendix B). In the BVL task, 20/40 true predictions are given by the model, corresponding to an accuracy of 0.5. The score is between -1SD and 0 for the age range 4,0-4,11 years. In the TCGB-2 task, the true predictions are 33/74, and the accuracy is 0.44.

[2] A new BabyLM [23] has been released a few weeks before the submission deadline. However, this model is not originally Italian but instead focuses on second language acquisition and its impact on the performance of a BabyLM.

[3] In standardized tests, the most frequent score obtained by children of a given age range is represented by 0. The typical range score extends from -2SD to +2SD from 0. For scores below -2SD, the performance is considered deficient. In this study, we consider the score range -1SD to +1SD, as we are not interested in potential language impairments.

According to the standard scores of TCGB-2, the model is placed between the 32nd and 45th percentiles for the age range 3,6-3,11 years. These percentiles correspond to the judgment of *within normal range* (as opposed to *excellent*, *good*, etc.) In the task adapted from TROG-2, Minerva reaches an accuracy of 0.42 (with 34/80 true predictions). In this test, the number of passed/failed blocks is relevant to the purposes of standard scores (a block being passed if the child provides the target response for at least 3/4 items). The model passes 6/20 blocks, obtaining an age-equivalent score of 4,1 years. The standard score for this age is 115, which falls into the 84th percentile. Finally, we used two Lexical Comprehension item sets (from BVL and Peabody). In the former (BVL), Minerva provides 5/18 true predictions, that correspond to an accuracy of 0.37. This score is below -2SD for the age range 4,0-4,5 years (4,0 years is the minimum age considered for the standardization). In the latter (Peabody), 62/165 predictions are true, the accuracy being 0.37. As mentioned above, we excluded 10 items from the adaptation process. Since the test age-equivalent scores are computed based on 175 items, we consider the raw-score range of 62-72 to establish the age-equivalent score of Minerva, so as to also take into account the excluded items. This raw-score range corresponds to the age-equivalent score range of 102-109 for the age range 3,9-4,2 years (i.e., between 0 and +1SD) and 92-99 for the age range 4,3-4,8 (i.e., between -1SD and 0).

5. Discussion

The scores obtained by Minerva generally align with the linguistic-age range 4.0-5.0. Variability in scores is observed i.) across different tasks, indicating that certain tasks may be easier for the model than others; and ii.) within the same type of task depending on the specific test they were adapted from (e.g., BVL–Sentence Comprehension, TROG-2). This discrepancy may be due to the adaptation of the test items, which, in turn, depends on the original distractor and target pictures. For instance, items in the Lexical Comprehension task of BVL required the model to make inferences to generate accurate predictions. Another possible factor (e.g., in the Sentence Comprehension task) is the complexity of specific syntactic structures evaluated by some tests. For instance, locative structures are particularly challenging for the model, as are passive clauses (cf. Appendix B). The model often fails to consistently grasp the rationale linking the stimulus and the target answer, likely due to Minerva not being an instruction-tuned model. Negation (Sentence Comprehension Task) is an illustrative example in this respect. BaBIEs contains 28 negative clauses (8/28 are passive clauses, and 20/28 are active clauses. Among the active clauses, 6 contain a double negation, i.e., *né...né* 'neither...nor'). Minerva selects the correct answer for 9/28 negative clauses (32.14%); of these, two are passives, six are active clauses, of which one contains a double negation. Wrong answers are selected for 19/29 negative clauses (67.86%), of which 6 are passives, 13 are active clauses, of which 5 containing a double negation. Four examples of wrong answers selected by Minerva are reported in Table 1. Such errors suggest that the model does not interpret negation, or in the case of clauses containing double negation, at least one of them, consistent with previous findings in the literature ([26], [27]). The complete sets of possible answers of the examples reported in Table 1) are given in Appendix C.

As can be seen in Table 1, the wrong answers selected by Minerva result from the failure to interpret the negation. In one case (i.e., the third example), the selected answer reveals that the model only interpreted the second (but not the first) negation.

The best score is obtained in the Acceptability Judgments task. This is not surprising and primarily due to the task being formulated with minimal pairs, a method proven to be particularly effective in testing LMs [10]. In the other tasks, the results are worse. Nonetheless, the age-equivalent score is not the whole story. In the Sentence Completion task, for instance, in spite of the low score obtained, the completions are not ungrammatical or nonsensical (cf. Table 2, more examples are provided in Appendix C). In the Lexical Comprehension tasks, the score further decreases. The results in both tasks (from BVL and Peabody) are fairly consistent, with an age score struggling to reach 4,5 years. The difficulties encountered by the model can be attributed to the limited context and the nature of the task, which is primarily semantic. The model also performs well in the Idiom Comprehension task, probably because idiomatic expressions are high-frequency expressions that a model trained on large amount of texts might easily have encountered. This could also explain why the score is lower for the Sentence Comprehension tasks, although the two are structurally similar. Indeed, unlike idiomatic expressions, the items of these tasks are less predictable and require a certain degree of inference for resolution, making their complexity more similar to that of Lexical Comprehension tasks.

6. Conclusions and future work

This paper presents BaBIEs, a novel resource specifically designed to evaluate the linguistic competence of BabyLMs and compare them to those of children. After having detailed the sources and the creation process of this resource, we provided the procedure for testing the Minerva model with the resource itself. Finally, we presented and discussed the results the model's performance.

Table 1
Examples of negative clauses, target answer, wrong answers provided by Minerva

Clause	Clause Type	Target Answer	Wrong Answer
La bambina non corre 'The girl does not run'	ACTIVE	La bambina è ferma 'The girl is still'	La bambina sta correndo 'The girl is running'
Il cestino non è stato svuotato 'The bin has not been emptied'	PASSIVE	Il cestino è pieno 'The bin is full'	Il bambino ha svuotato il cestino 'The boy emptied the bin'
La ragazza non sta né indicando né correndo 'The girl is neither pointing nor running'	DOUBLE NEGATION	La ragazza è ferma 'The girl is still'	La ragazza indica ma non corre 'The girl is pointing but not running'
La scatola non è né grande né gialla 'The box is neither big nor yellow'	DOUBLE NEGATION	La scatola è piccola e bianca 'The box is small and white'	La scatola è grande e gialla 'The box is big and yellow'

Table 2
Examples of model prediction for the Sentence Completion task

Verbal Stimulus	Model Completion	Correct Answer
La bambina si lava. Le bambine si 'The girl washes herself. The girls'	**lavano**.'wash themselves' lavavano. 'were washing themselves' **lavano**. 'wash themselves'	**lavano** 'wash themselves'
Il cavallo corre nel campo. I cavalli 'The horse runs in the field. The horses'	non possono correre 'can't run' non hanno una 'don't have a.F.S' non possono andare 'can't go'	**corrono** 'run'

Based on the presented findings, the resource appears a valuable tool for evaluating not only BabyLMs but LMs in general. The poor performance exhibited by Minerva underscores the gap between child language acquisition and current language model training. This highligths the necessity for modifying model training to better encode human language and, more generally, human linguistic competence.

Future work will involve a more systematic linguistic analysis of the model's performance, together with a comprehensive error analysis and a comparison to adult Italian-speakers. Furthermore, it will involve the development of a multimodal version of the test, which will more closely reflect the original tests and allow the evaluation of multimodal BabyLMs. Additionally, a BabyLM trained exclusively with Italian child-directed speech will be developed and evaluated with both the standard and multimodal versions of the test.

Abstract

How newspapers cover news significantly impacts how facts are understood, perceived, and processed by the public. This is especially crucial when serious crimes are reported, e.g., in the case of femicides, where the description of the perpetrator and the victim builds a strong, often polarized opinion of this severe societal issue. This paper presents FMNews, a new dataset of articles reporting femicides extracted from Italian newspapers. Our core contribution aims to promote the development of a deeper framing and awareness of the phenomenon through an original resource available and accessible to the research community, facilitating further analyses on the topic. The paper also provides a preliminary study of the resulting collection through several example use cases and scenarios.

Keywords

Italian Dataset, Newspapers, Information Extraction, Information Retrieval, AI for Social Good, Femicides

1. Introduction

How newspapers and journalists present news plays a crucial role in shaping public understanding and perception of information. This is especially important when reporting serious crimes, such as femicides, where descriptions of the perpetrator and victim can create polarized opinions influencing readers' perceptions and interpretations of the event. According to Bouzerdan and Whitten-Woodring [1], news media often report incidents of women's homicides in a sensationalised manner, treating these crimes as isolated events rather than situating them within the bigger framework of violence against women. This narrative defies the global demands of human rights organisations to acknowledge and address this phenomenon as demanded by its intricate dynamics. Numerous countries have followed such recommendations only partially through the formal adoption of specific terminology such as *femicide* and *feminicide* in legal frameworks and public discourse. The two terms have related but distinct nuances of meaning. *Femicide*, a criminological concept initially coined in English by the feminist criminologist Diana H. Russell [2], denotes the murder of women by males due to their gender. Successively, the term femicide, translated in Castillian as *femicidio* or *feminicide* by the anthropologist Marcela Lagarde to attract political attention on the dire situation faced by women in Mexico [3], has gained global traction with varying interpretations, yet consistently denotes a patriarchal impetus behind homicides and other forms of male violence against women, primarily emphasising the sociological dimensions of abuse and the socio-political ramifications of the phenomenon. In the Italian language, the term *femminicidio* has been almost exclusively adopted, as evidenced by a Google Trends analysis comparing the search terms "femicidio" and "femminicidio" to queries regarding "femicide"[1].

An analysis of the phenomenon of femicide in the Italian context and, in particular, a linguistic investigation of it, are particularly relevant. Feminicide, a term used by the feminist movement in Italy since 2005, gained prominence in the media in 2011, especially thanks to the works of Barbara Spinelli [4]. The CEDAW Committee[2], based on data from the Shadow Report on the Implementation of CEDAW in Italy, addressed recommendations to the Italian government on feminicide in its Concluding Observations. This was the first time the committee addressed a European state on feminicide, a category previously reserved for warnings to Central

[2] Committee on the Elimination of Discrimination Against Women.

American countries. The challenges in accurately contextualising feminicide in Italy also stem from a prolonged absence of official data, resulting in sensationalism and the perception of a dramatic rise in the crime. This may induce an emergency narrative that obscures the inherent structural dimensions of the phenomenon, thereby undermining the very essence of the term [5]. Media interpretations are essential for shaping a shared understanding across a vast audience, such as a whole country; hence, the examination of media discourse emerges as a significant analytical instrument on top of statistical evaluation of femicide data to understand the achievements and directions of state intervention towards the substantial granting of women's right to life [6].

In this regard, Aldrete and Fernández-Ardèvol [7] showed that there is a large body of empirical studies on femicide discourse across different socio-cultural contexts, which often justify the perpetrator's actions. Given the complexity of the phenomenon, a comprehensive investigation could be achieved by integrating media analysis with external data, such as demographics and current events, blending together researchers from different fields like computer science, social sciences, and complex systems science. The lack of accessible and relevant data specific to socio-culturally context where femicide is notably prevalent, such as in Italy, makes the task particularly challenging [8].

This paper presents FMNews, a new dataset of articles reporting femicides extracted from Italian newspapers[3]. We conduct a preliminary analysis of the resulting collection through several example use cases and scenarios. The primary contribution is to deepen understanding and awareness of femicide from a socio-technical perspective. We seek to examine how prominent Italian news sources report on the issue in connection to the shaping of public perception, while also offering an innovative and accessible resource to facilitate future investigation within the research community. Furthermore, this study was designed to enable a multifaceted investigation covering the following three dimensions:

- **Geographical**, with the aim to explore potential variations in framing between local and national media outlets. Indeed, previous research has shown that Italian local daily newspaper often suppress the agency of the perpetrator, portraying the events as mere occurrences [9]. We selecting newspapers reporting news at both the national[4] and local[5] level, with local editions spanning across the whole Italian territory.
- **Political**, which was granted by choosing national newspaper with varying political leanings.
- **Temporal**, where the time frame of national newspapers extends from November 2009 to February 2024, whilst that of the local ones ranges from November 2010 to February 2024[6].

2. Related Work

According to frame analysis, the ways in which newspapers cover news significantly impact how facts are understood, perceived, and processed by the public [10, 11]. Framing narratives means strategically including or omitting elements (such as problem definitions, explanations and evaluations) of a given situation in a communicative text [12, 13, 14]. This process aims to advocate for specific interpretations, assess moral responsibilities of individuals involved and propose solutions while also eliciting nuanced emotional responses from the audience, thereby affecting their perceptions and attitudes. It is worth noting that in the case of news articles, media framing can be seen as a demonstration of political power [10], influencing which actors or interests are involved shape narratives, often unnoticed by the audience [11]. The process of news framing becomes especially crucial when reporting serious crimes, such as femicides, as understanding femicide requires analyzing its evolution from both statistical and social perspectives, as discussed in the *Manifesto delle Giornaliste e dei Giornalisti per il Rispetto e la Parita' di Genere nell'Informazione*[7] (*Manifesto of Journalists for Respect and Gender Equality in News Reporting*, our translation).

The acknowledged impact of language on how readers perceive information has prompted researchers to explore how the language surrounding femicide has changed and how this influences individuals' responsibility perception [15], which can vary based on the way femicides are reported [1, 16, 9, 17]. Moreover, an initia-

[3] The choice of newspapers was dictated by the circulation volume released by Audipress, a company that collects data on the reading habits of daily and periodical press in Italy: https://audipress.it/quotidiani/.

[4] The selected national newspapers are the following: *Corriere della Sera, La Repubblica, La Stampa, Il Fatto Quotidiano, Il Giornale* and *Il Post*.

[5] The selected local newspapers are the local editions of the *CityNews* group, which cover the following cities: Agrigento, Ancona, Arezzo, Avellino, Bari, Bologna, Brescia, Brindisi, Caserta, Catania, Cesena, Chieti, Como, Ferrara, Firenze, Foggia, Forlì, Frosinone, Genova, Pescara, Piacenza, Latina, Lecce, Lecco, Livorno, Messina, Milano, Modena, Monza, Napoli, Novara, Padova, Palermo, Parma, Perugia, Pisa, Pordenone, Ravenna, Reggio, Rimini, Roma, Salerno, Sondrio, Terni, Torino, Trento, Treviso, Trieste, Udine, Venezia, Verona, Vicenza, Viterbo.

[6] In Fig. 3 in the Appendix, we report the distribution of articles across time.

tive by University of Bologna seeks to identify the main discursive features employed in discussions about femicide in public spaces, including media and legal speech[8].

Recognizing the significant role of linguistic expression in depicting incidents of gender-based violence, previous research has explored various NLP techniques. These studies aim to discern how NLP models can effectively predict and analyze human perception judgments concerning the sensitive issue of gender-based violence events. Following previous works on the impact of specific grammatical constructions and semantic frames [18] in describing the same event but with various nuances, Minnema et al. [19] introduced the first multilingual tool, based on Frame Semantics and Cognitive Linguistics, for detecting the focus or perspective depicted in an event, called *Socio Fillmore*. Furthermore, building on the linguistic analysis provided by Socio Fillmore, Minnema et al. [20] demonstrated that various linguistic choices trigger different perceptions of responsibility, which can be modeled automatically. As a result, their series of regression models revealed that these distinct linguistic choices significantly influence human perceptions of responsibility. Additionally, to promote awareness of perspective-based writing, Minnema et al. [21] introduced the novel task of *responsibility perspective transfer*. The task involves the automatic rewriting of descriptions of gender-based violence to alter the perceived level of blame attributed to the perpetrator. Both works leveraged one of the limited resources available for the Italian community, the `RAI Femicide Corpus`, a collection of 2.734 news articles covering 937 confirmed femicide cases in Italy happened between 2015 and 2017 [22]. Additional online resources, both official and unofficial, containing further statistics on the phenomenon of femicide in Italy are listed in the Appendix A.

3. FMNews Corpus

The main contribution brought by this paper is the production of two datasets derived from Italian newspapers: the `FMNews`[9] corpus. The corpus consists of the following components: `FMNews-Nat`, reporting data from national newspapers, and `FMNews-Loc`, which gathers articles from local newspapers in 53 Italian cities.

3.1. Data Extraction

Despite the heterogeneous HTML structures of the newspapers involved, it was feasible to generalise the data extraction process via the open source Python libraries `Selenium` [10] and `Beautiful Soup`[11]. Data scraping was performed in two subsequent phases. Firstly, a comprehensive list of article links was extracted by querying the internal search engine of the newspaper websites with the keywords `femminicidio`, `femminicidi`, `femminicida`: the first word stands for the Italian term "femicide", the second is its plural form, and the third indicates the "person who commits a femicide". The keywords were selected to concentrate our analysis on the media's representation and discourse surrounding this phenomenon. This choice intentionally excludes articles that discuss such crimes in general terms, allowing for a more focused examination of the femicide narratives. In the second phase, the web pages corresponding to such links were scraped to extract the text of the articles and other metadata to build the raw version of the dataset.

3.2. Data Cleaning

We implemented a supervised and semi-supervised data cleaning process, consisting of two phases, to prepare the data. In the first step, the same pipeline was applied to both `FMNews-Nat` and `FMNews-Loc`. We initially removed all duplicate articles from the collected data, i.e., those with identical texts (title and body), metadata (e.g., date), and source publication. Additionally, we converted the dates into the format of *yyyy-mm-dd* and removed articles where at least one of the following elements was missing: publication date, title, or body. Despite the removal of duplicates, certain articles had identical text bodies, albeit with minor variations primarily due to special character encoding (e.g., accents and apostrophes) or differences in web crawling (e.g., one article included the website menu or footer while the other did not). To address this issue, we implemented a method to identify and handle articles with identical or highly similar text bodies sharing the same title. In details, we first employed a TF-IDF[12] vectorizer to convert the raw text data into numerical vectors and then use them to compute the cosine similarities between all pairs of texts in the dataset. For more details on the parameters and thresholds employed, we refer to Appendix B. Finally, we utilized `Beautiful Soup` to remove any HTML tags that could have been mistakenly included in the article body during the collection phase.

The second step of the data cleaning process entailed supervised cleaning of the article texts and headlines. The article texts from national newspapers in `FMNews-Nat` displayed various noise patterns specific to each news media outlet. To address this issue, we manually created

[8] https://site.unibo.it/osservatorio-femminicidio/it.

[9] The collection can be accessed for research purposes by requesting it by email from the authors.

[10] https://selenium-python.readthedocs.io/.

[11] https://www.crummy.com/software/BeautifulSoup/bs4/doc/.

[12] Term Frequency-Inverse Document Frequency, in short TF-IDF, is a measure of the importance of a word to a document in a collection or corpus [23].

Column	Description
Url	URL of the original newspaper article
Title	Title of the article
Text	Main section of the newspaper article
Newspaper	Name of the media outlet where the article was published. In `FMNews-Loc`, it reports the name of the city to which the local edition refers to.
Keyword	Keyword used to collect the article
Date	Publication date of the article in the format *yyyy-mm-dd*

Table 1
Description of the FMNews Corpus.

Dataset	Raw Data	Step I	Step II
`FMNews-Nat`	12,790	7,511	7,443
`FMNews-Loc`	8,397	7,728	7,728

Table 2
Dimensions of the dataset in terms of number of articles from national news outlets (`FMNews-Nat`) and local newspaper editions (`FMNews-Loc`).

a list of replacements for each outlet, employing regular expressions for targeted removal of articles or specific sub-strings from article titles or bodies (we refer to Appendix B for additional details). In this stage, we also excluded articles whose text bodies did not contain information directly related to femicides, such as television programme listings or podcast episode agendas.

On the other hand, the articles from local newspapers in `FMNews-Loc` exhibited minimal noise within their text. Therefore, the data preparation phase focused on poorly encoded symbols and domain-specific substrings such as copyright indications and external contributions, e.g., government press releases. Unlike national newspapers, for journalistic publications, this ad-hoc cleaning did not result in data loss.

3.3. Final Dataset

Table 1 provides a detailed explanation of the data format for both datasets after the completion of the data preparation process. The number of entries for the two datasets is shown in Table 2. The table also shows the number of articles after two steps of data cleaning exemplified in B.

The analysis of `FMNews-Nat` after the last cleaning steps reveals the following summary statistics. The dataset covers a time span of 14 years, from November 2009 to February 2024. Regarding the distribution of articles across different newspapers in `FMNews-Nat`: *Il Fatto Quotidiano* has the largest number of articles, with a total of 2,861, followed by *La Repubblica* with 2,837 articles. *Corriere* is next, with a total of 968 articles. *La Stampa* has a more limited presence, with 292 articles. Il Post contributes 244 articles, and *Il Giornale* has the fewest entries in this set, with 241 articles. For `FMNews-Loc`, the time span after data cleaning ranges from November 2010 to February 2024.

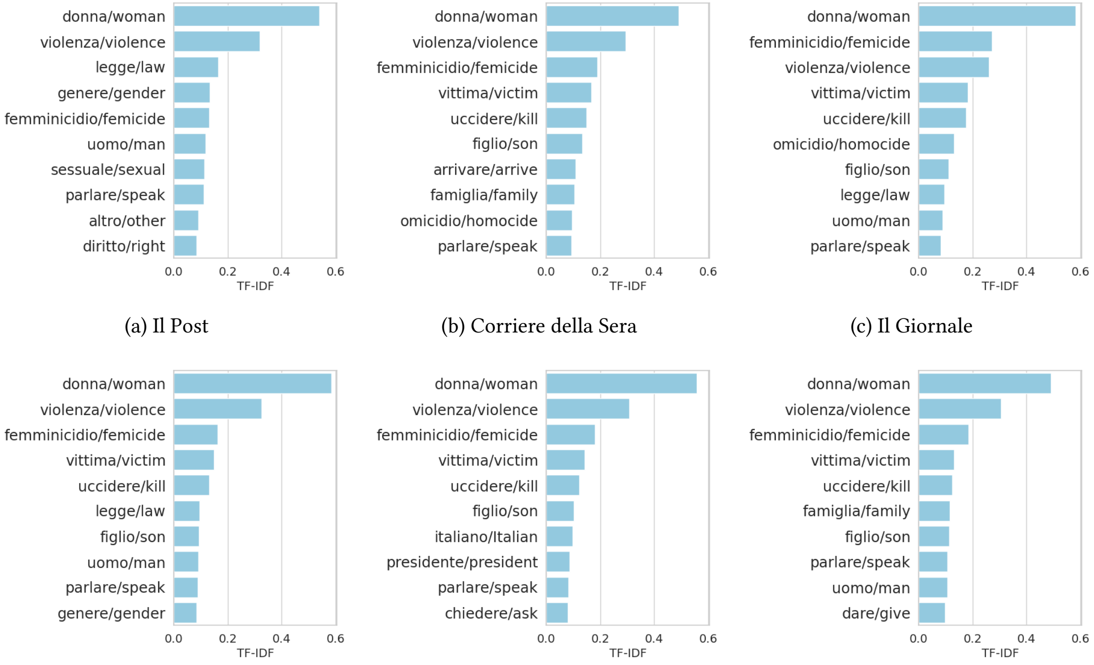
4. Use Cases and Scenarios

Since the two datasets share the same structure and we are interested in studying the phenomenon of femicide from both a national and local perspective, the analyses exemplified in the following were conducted on both datasets without distinction. After a textual analysis based on the tokenization, removal of stopwords, extraction of lemmas and a straightforward assessment of the lexical diversity (as detailed in the Appendix C), we approached a viable keyword extraction method to uncover relevant patterns in the documents.

Keyword Extraction According to Firoozeh et al. [24], specific criteria must be met for keywords to meet eligibility standards. In our case study, we emphasize the importance of keywords that show *representativity* and *exhaustivity*, aiming for terms that capture significant rather than marginal aspects of the subject matter. To assess the significance of words within our collection of documents, a standard approach involves the Term Frequency - Inverse Document Frequency (TF-IDF).

For a deeper analysis, we calculate TF-IDF for each news outlet. We utilize `Spacy`'s Italian pipeline to preprocess texts by tokenizing, lemmatizing, and selecting only lemmas that are full words from specific part-of-speech classes (nouns, adjectives, verbs). By focusing only on content lemmas and excluding function words (like articles and prepositions), we eliminate noise and improve accuracy in analyzing relationships between documents and word relevance. The lists of lemmas do not include words containing numbers or Italian stopwords obtained from `Nltk` and `Spacy`, with additional crawling-dependent stopwords such as "it," "https," "min," and the names of months. Also, we preserve multi-word expressions identified by the lemmatizer by concatenating them to treat them as unique words during TF-IDF calculation. Articles are then grouped by news outlet, each acting as a single document for the TF-IDF computation. We use the TF-IDF Vectorizer from the `scikit-learn`[13] library to transform the lemmatized tokens into numerical features that reflect their importance within the text.

[13] https://scikit-learn.org/stable/index.html.



(a) Il Post

(b) Corriere della Sera

(c) Il Giornale

(d) Fatto Quotidiano

(e) La Repubblica

(f) La Stampa

Figure 1: Top 10 keywords in descending order for each news outlet `FMNews-Nat`.

Thus, TF-IDF measures the significance of terms concerning the news outlets. Fig. 1 illustrates the most relevant keywords extracted from `FMNews-Nat` by news outlet. As expected, terms like "woman," "violence," and "kill" (along with "femicide") are central to the narrative of femicide and are common across all outlets. Other keywords vary in relevance among multiple outlets; for example, "son" appears in all outlets except Il Post. Specific keywords are unique to one or two outlets: "gender," "right," and "sexual" appear only in Il Post; "family" is relevant in Corriere della Sera and La Stampa; and "man" is found in Il Post and Il Giornale. Due to the number of local news outlets in `FMNews-Loc` (50), Fig. 2 shows the top 20 keywords with the highest average TF-IDF, calculated as the mean of the TF-IDF values of the terms with respect to the news outlets. As expected, the highest ranks are occupied by the same relevant keywords found in national news outlets, such as "woman," "violence," "victim," and "femicide". Additionally, some keywords relevant to specific national news outlets show high relevance for local media, although with lower average TF-IDFs, such as "gender". Conversely, the distribution reveals previously unseen keywords, such as "young," "school," and "association".

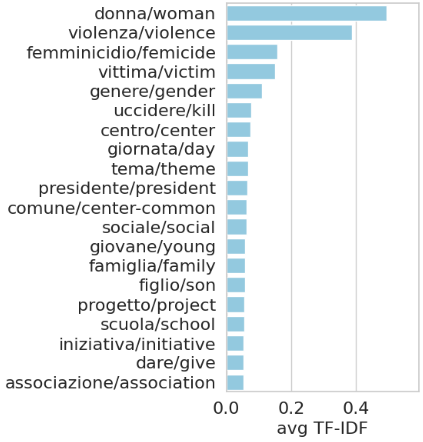


Figure 2: Top 20 Keywords by average TF-IDF in `FMNews-Loc`.

Semantic Vector Extraction For an additional layer of analysis, we chose to train a word embedding model to explore semantic relationships among words. This model represents words as continuous space vectors, where the proximity of vectors indicates the semantic similarity between the words they represent: closer vectors

Table 3
Most similar word embeddings to

(a) "uccidere" (to kill) in `FMNews-Nat`

Word	Similarity score
ammazzare (to murder)	0.77
ucciderla (to kill - her)	0.71
ammazzato (murdered - him)	0.66
ucciso (killed - him)	0.66
suicidarsi (to commit suicide)	0.63
strangolato (strangled - him)	0.62
furia (fury)	0.60
fucile (rifle)	0.59
sparare (to shoot)	0.59
accoltellato (stabbed - him)	0.59

(b) "vittima" (victim) in `FMNews-Loc`

Word	Similarity score
ragazza (girl)	0.69
giovane (young)	0.69
donna (woman)	0.67
madre (mother)	0.67
figlia (daughter)	0.64
scomparsa (disappearance)	0.62
uccisa (killed - her)	0.62
26*enne* (26 years old)	0.61
massacrata (massacred - her)	0.59
povera (poor)	0.59

correspond to words with more similar meanings. We employed `Word2Vec` (W2V) [25], which operates by mapping words to high-dimensional vectors within a given vocabulary. This mapping is designed to represent semantic relationships between words in the vectorial space. W2V has been implemented through `Gensim`[14], a powerful tool set for NLP tasks. A key parameter in W2V is the "window", i.e., the number of context words to be considered, which we defined as 10 to consider a contextual window that extends neither too far nor too close to the current word, thereby striking a balance between contextual relevance and computational efficiency. To discover the semantic associations within our dataset, we leveraged the "most similar" method from `Gensim`, which computes the cosine similarity between word vectors to identify words with the closest semantic proximity. For both datasets the size of the training embeddings for the W2D model is fixed to 100 while the vocabulary size change accordingly to the dataset, in `FMNews-Nat` is 6809, in `FMNews-Loc` is 6064.

In `FMNews-Nat`, the word "donna" (woman) yielded semantically related terms such as "vittima" (victim) and "prostituta" (whore). The term "femminicidio" (femicide) elicited associations like "violenza" (violence), "impressionante" (impressive), and "dramma" (drama). In Table 3a, the analysis of "uccidere" (to kill) encompasses related terms such as "ammazzare" (to murder), "ucciderla" (to kill her), "ammazzato" (murdered, masculine form), "ucciso" (killed, masculine form), "suicidarsi" (to commit suicide), and "strangolato" (strangled, masculine form). These terms may collectively pertain to the perpetrator's actions against the victim. Fig. 5 in the Appendix provides a comprehensive overview of word vectors closely associated with the previously extracted keywords, which were identified as the most significant in `FMNews-Nat`.

In Table 3b, the words correlated in meaning to "vittima" (victim) in `FMNews-Loc` are presented. As we would expect, nearly all terms are associated and highlight that the victim is a woman. In this regard, a drawback to consider is that the specific selection of the terms used for the data collection query may have hindered our analysis from uncovering insights about homicides committed against individuals who do not identify as woman or fit into the traditional gender binary. Indeed, the discussion around gender-based violence in Italy is still predominantly centred on women, while other genders remain significantly neglected[15].

5. Conclusion

In this contribution, we provided a novel dataset concerning the critical issue of femicide in Italy. Considering the absence of resources for conducting in-depth analyses on the subject, our intent was to bridge this gap and provide an original perspective for understanding and raising awareness about this severe phenomenon.

As suggested by Dobbe et al. [26], proposing a contribution within the Machine Learning domain responsibly and consciously means foremost acknowledging our own biases. In particular, we are referring to both the newspaper selection and choice of the terms used to extract the data, that certainly shaped the results (all design choices are justified in detail in Section 3). A future outlook concerns the investigation of how both victims and perpetrators are framed from a linguistic perspective. Further analyses could regard identifying temporal and geographical patterns arising from media attention manifested through the coverage of femicides and comparing the framing of these events with the political leaning of the respective newspapers.

[14] https://pypi.org/project/gensim/.

[15] As a matter of fact, there is no official collection of statistics regarding this specific kind of event. The only organisation that records the gender of the victims in its database is the *Observatory Femicides Lesbicides Transcides* managed by *Non una di meno*, the Italian section of movement *Ni una menos* (https://osservatorionazionale.nonunadimeno.net/).

A. Additional Resources

Official Resources

Official statistics on femicide cases in Italy can be accessed through ISTAT[16] and the Ministry of the Interior through the Department of Public Security website[17]. In particular, ISTAT provides data on victims of voluntary homicide, divided by gender, from 1992 to 2020, without additional information. In contrast, the Department of Public Security offers more detailed data covering a limited time range, i.e., from 2002 to 2022: victims are categorized by their relationship to the murderer. These categories include: *Partner* (husband/wife, domestic partner, boyfriend/girlfriend), *Former partner* (former husband/wife, former domestic partner, former boyfriend/-girlfriend), *Other relative, Other acquaintance, Perpetrator unknown to the victim*, and *Perpetrator unidentified.*

Unofficial Resources

Unofficial data and statistics regarding femicides in Italy are also available, typically compiled by non-governmental or grassroots organisations. One notable example is the open database[18] managed by the Italian activists of *Ni una menos*[19], an international feminist movement that campaigns against gender-based violence. Although it covers a shorter time frame, this database offers disaggregated and more detailed information than the official statistics. For example, in addition to the names of the victims, the collection also includes important characteristics such as the age and nationality of the individuals involved, the geographical dimension, and the gender of the victim, including non-binary framings. While not readily accessible, a combined examination of both official and non-official data is essential for a more thorough and comprehensive analysis of the issues of femicide in Italy.

B. Data Preparation

We applied a supervised and semi-supervised cleaning phase divided into two steps to prepare the data. In the first step, the same pipeline was applied to both datasets, primarily aimed at removing duplicate articles, formatting metadata, and reducing data and metadata sparsity. The second step entailed supervised cleaning of the article texts and headlines. We observed different types of noise in the texts of the national newspapers compared

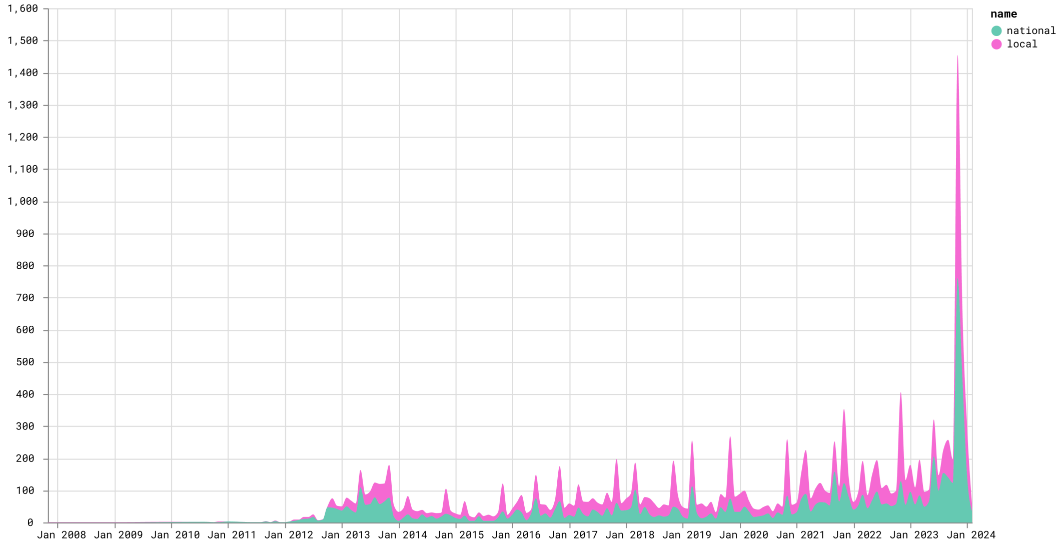

Figure 3: Number of articles throughout the years (2008-2024) for both `FMNews-Nat` and `FMNews-Loc`.

to the local ones. Hence, given that the two datasets are released and usable separately, we implemented a similar pipeline for both datasets, albeit customized for each.

Data Preparation - Step I: Cleaning

We first removed all duplicate articles from the collected data (just under 12,800 articles from national newspapers and approximately 8,400 articles from local ones), i.e., those with identical texts (title and body), metadata (e.g., date), and source publication. Additionally, we converted the dates into the format of *yyyy-mm-dd* and removed articles where at least one of the following elements was missing: publication date, title, or body. Despite the removal of duplicates, some articles had identical text bodies, albeit with minor variations primarily due to special character encoding (e.g., accents and apostrophes) or differences in web crawling (e.g., one article included the website menu or footer while the other did not). To address this issue, we implemented a method to identify and handle articles with identical or highly similar text bodies, but only if they share the same title. The method relies on cosine similarity to determine whether two texts are the same. In particular, we first employed a TF-IDF vectorizer to convert the raw text data into numerical vectors. These vectors were then used to compute the cosine similarities between all pairs of texts in the dataset. Cosine similarity produces a value between 0 and 1, where 1 indicates identical texts and values closer to 0 indicate less similar texts. Since text preprocessing had not been performed yet and differences between text bodies could solely arise from symbols, we set a tolerance threshold of 0.89 to determine text equality. If two text bodies had a cosine similarity greater than 0.89, we considered them duplicates and retained only the first occurrence, removing the second found in the dataset. Finally, we utilized `Beautiful Soup` to remove any HTML tags that could have been mistakenly included in the article body during the collection phase. This step ensured that our text data was free from any undesired HTML tags before further processing or analysis.

Data Preparation - Step II: `FMNews-Nat`

The article texts from national newspapers displayed various noise patterns specific to each news media outlet. To address this issue, we manually created a list of replacements for each outlet, employing regular expressions for targeted removal of articles or specific sub-strings from article titles or bodies. In particular, the body of articles from *Il Post, La Repubblica* and *Il Fatto Quotidiano* included parts of webpage menus and footers, as well as various types of news media outlet sponsorship, such as subscriptions, newsletter sign-ups, and agendas/lists of podcast episodes. On the other hand, articles from *Corriere della sera* included text substrings associated with the journalistic domain, such as headings containing the name of the correspondent, reporter, or photographer. We observed that the texts of the articles published by *Corriere della sera* often, but not always, follow a particular structure: "by Author_name Author_surname" (where <Author_name Author_surname> can be a natural person or abbreviations with one dot) or "Editorial team", followed by a city or "online", in either uppercase or lowercase. Occasionally, this structure is followed by another city, for instance, "Bologna Online Editorial Staff". Additionally, this "basic" structure may or may not be followed by "*inviato a* <City> <(Province)>", or "*inviata*", "*foto di* <Author_name Author_surname>". We generally excluded articles whose text bodies did not contain information directly related to femicides, such as television programme listings or podcast episode agendas. We retained the article whenever feasible, removing irrelevant substrings from the text bodies, such as menus and footers. The resulting `FMNews-Nat` dataset includes 7, 443 articles: in Fig. 4 we report the distribution of articles by media outlet.

Data Preparation - Step II: FMNews-Loc

The articles from local newspapers exhibited minimal noise within their text. Therefore, the data preparation phase focused on poorly encoded symbols and domain-specific substrings such as copyright indications and external contributions, e.g., government press releases. Unlike national newspapers, for journalistic publications, this ad-hoc cleaning did not result in data loss . Therefore, the resulting `FMNews-Loc` dataset includes 7, 728 articles.

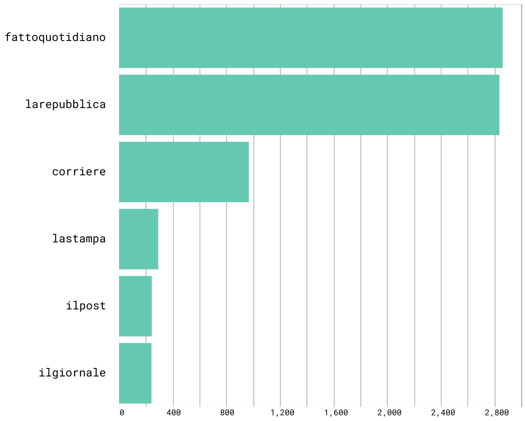

Figure 4: Final number of articles of `FMNews-Nat` extracted from the national newspapers.

C. Textual Analysis

Although applying NLP models typically requires standardized and structured text, it is important to acknowledge that such preprocessing may result in the loss of some information. We believe it is important to keep track into texts of the elements we manipulate.

- **Emails and URLS.** Emails and URLs found within the body of the articles are replaced with a placeholder tag, such as "[[URL]]".
- **Uppercase words.** Words entirely in uppercase are not replaced or modified, as the text will be normalized in subsequent stages of the work, i.e., converted to lowercase. Uppercase words are extracted and saved for further analysis.
- **Punctuation, symbols, numbers.** Punctuation, symbols, and numbers are removed from the texts.
- **Stopwords.** We remove the stopwords included in the list provided by `NLTK` [20] and `Spacy`[21] libraries, along with a brief, manually compiled list of stopwords. This latter list includes domain-specific and context-related keywords, such as "Link Embed", "FOTO", "FOTOGRAMMA". It is important to note that the "ad hoc" stopwords were removed from the non-normalized text to mitigate the impact of stopwords removal. Indeed, during the analysis, we observed that some articles from national newspapers contained certain keywords entirely in uppercase to indicate elements attached to the article. Thus, we chose to compile the list of stopwords to be case-sensitive, aiming to avoid removing words within the body of the article.

After extracting the features from the raw texts, we proceeded with the following steps. First, we tokenized the body of articles using the `Spacy` library with the Italian module, selecting only words. Next, we extracted tokens that are not included in the stopwords. Then, we extracted the lemmas, again excluding stopwords. Finally, we further refined our selection by retaining from the tokens only words belonging to what is commonly referred to as "full" classes of speech, such as nouns, verbs, adjectives, and adverbs. This process of extracting "full" words aimed to focus our analysis on linguistically significant elements of the text. This approach allows us to study meaningful linguistic units, facilitating a more accurate understanding of the semantic content and structure of the text.

After tokenization, removal of stopwords, and extraction of lemmas, we computed the Type-Token Ratio (TTR) for the articles, a measure of the lexical diversity in a text. This is given by the proportion of unique words in a text, or "types", to the total number of words, or "tokens" and reads:

$$TTR = \frac{N_{\text{types}}}{N_{\text{tokens}}} \tag{1}$$

[20] https://www.nltk.org/.

[21] https://spacy.io/.

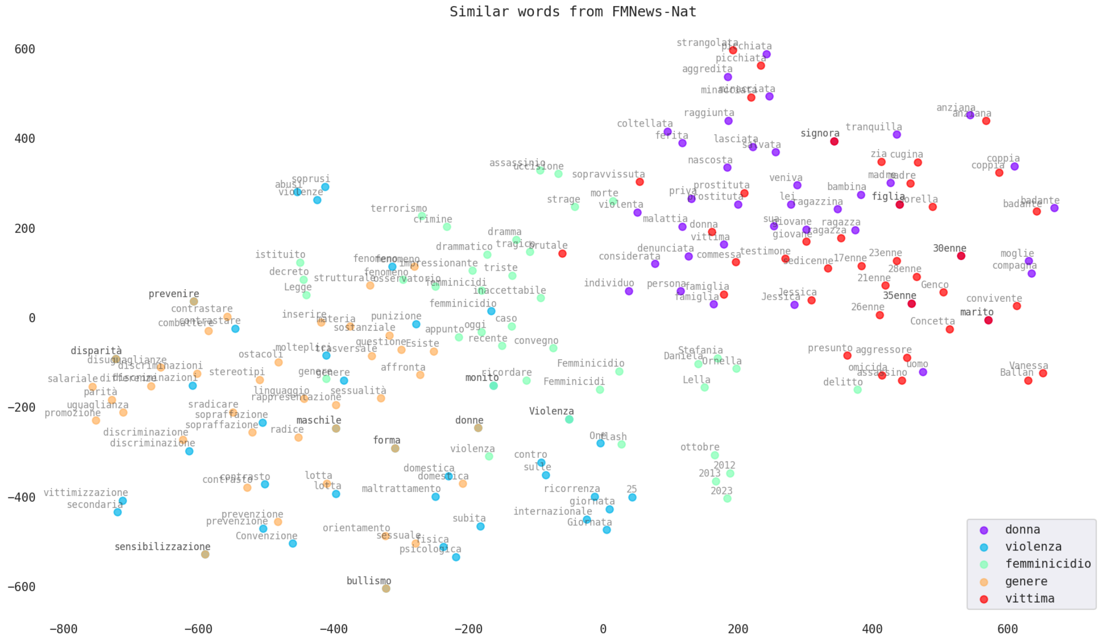

Figure 5: Similar word vectors in FMNews-Nat.

Where N_{types} is the number of unique types and N_{tokens} is the number of tokens in the text. TTR values range from 0 to 1, where a higher value indicates greater lexical variety, whereas a lower value implies more repetition of words in the text. This is a straightforward measure which nevertheless allows us to form an initial assessment of the lexical richness in the narrative surrounding femicides. The newspaper *Il Post*, along with *Il Fatto Quotidiano* and *La Repubblica*, exhibited a notable variation in terms of TTR. While FMNews-Nat shows variation in lexicon usage, FMNews-Loc exhibits a uniformity in language .

Women's Professions and Targeted Misogyny Online

Alessio Cascione[1,*], Aldo Cerulli[2,*], Marta Marchiori Manerba[1] and Lucia C. Passaro[1]

[1]Dipartimento di Informatica, Università di Pisa, Largo B. Pontecorvo 3, Pisa, 56127, Italy
[2]Dipartimento di Filologia, Letteratura e Linguistica, Università di Pisa, Via Santa Maria 36, Pisa, 56126, Italy

Abstract

With the increasing popularity of social media platforms, the dissemination of misogynistic content has become more prevalent and challenging to address. In this paper, we investigate the phenomenon of online misogyny on Twitter through the lens of hurtfulness, qualifying its different manifestation in English tweets considering the profession of the targets of misogynistic attacks. By leveraging manual annotation and a BERTweet model trained for fine-grained misogyny identification, we find that specific types of misogynistic speech are more intensely directed towards particular professions. For example, derailing discourse predominantly targets authors and cultural figures, while dominance-oriented speech and sexual harassment are mainly directed at politicians and athletes. Additionally, we use the HurtLex lexicon and ItEM to assign hurtfulness scores to tweets based on different hate speech categories. Our analysis reveals that these scores align with the profession-based distribution of misogynistic speech, highlighting the targeted nature of such attacks.

Keywords

Abusive Language, Online Misogyny, Hurtfulness

1. Introduction

Misogyny is a radical manifestation of sexism directed toward the female gender, which becomes subject of hatred. Its effects are widespread and systematic, bearing severe both social and individual consequences, such verbal and physical violence, rape and femicide. Indeed, misogyny, prejudice, and contempt towards women continue to persist in various forms in our society. While overt acts of discrimination and sexism have received attention, it is crucial to acknowledge that misogyny often manifests in subtle and nuanced ways [1, 2]. Moreover, with the increasing popularity of social media platforms, the dissemination of misogynistic content has become more prevalent and challenging to address [3, 4].

From a socio-historical perspective, women have faced numerous barriers that limited their access to certain professions, hindered their career progression, and subjected them to belittlement and offense related to their work [5]. These gendered biases not only perpetuate inequality but also serve as breeding grounds for misogyny.

In this paper, we focus on automated misogyny detection, specifically investigating whether different professional roles trigger varying degrees of hurtfulness across social media posts. By examining the correlation between the profession of offended women and the prevalence of misogynistic attitudes, we aim to shed light on the extent to which misogyny is perpetuated within specific professional domains.

Fontanella et al. [6] highlight how research focusing on automatic detection of misogyny tends to show weak connections with other conceptual areas addressing different aspects of the phenomenon. The finding suggests that current research has not yet adequately addressed the fine-grained manifestations of online misogynistic attacks. Our contribution conducts novel analyses to uncover and measure misogynistic attitudes within different professional fields. Specifically, we examine how different types of misogyny are distributed across various women's professions and how the language used in misogynistic posts varies across them. To explore this relationship, we expand the English misogyny identification dataset introduced by Fersini et al. [7], known as AMI, by incorporating the professions of the women targeted. By adding professional categories to AMI, we enable novel analyses on how misogynistic attacks against women differ based on their profession. Our research is driven by the following research questions:

RQ1 **How does misogyny distribute across professions?** We analyze women's profession according to the type of misogyny directed towards them.

RQ2 **How does the language used in misogynistic tweets vary across different professions?** We investigate how specific hurtful expressions are directed at specific professions more frequently than others.

To address our RQs, we proceed following the work-

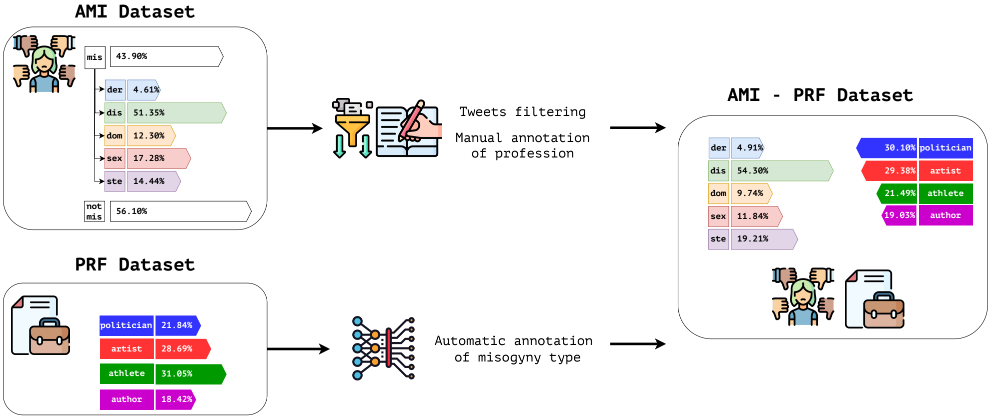

Figure 1: A subset of the AMI dataset, containing ground-truth misogyny annotations, is manually labeled with the professions of victims of misogynistic attacks, as detailed in Section 3. The PRF dataset, featuring professions by-design, is extracted and automatically annotated with misogyny types using a BERTweet model trained on the AMI dataset. The manually annotated AMI subset and the automatically annotated PRF dataset are then combined to form the AMI-PRF dataset. Labels distributions of each dataset are displayed in the workflow.

flow depicted in Figure 1. We begin by utilizing a subset of the AMI dataset, which contains ground-truth annotations for misogyny. This subset is manually labeled with the professions of the victims of misogynistic attacks, as detailed in Section 3.2. We then employ a misogyny classifier to automatically annotate with various types of misogyny a novel collection, the Profession (PRF) dataset, which comprises 760 tweets labeled with professions. The final step involves combining the manually annotated AMI subset with the automatically annotated PRF dataset, resulting in the AMI-PRF dataset[1]. This enriched dataset provides a resource that enables a thorough investigation of the phenomenon.

The remainder of this paper is organized as follows. Section 2 discusses previous works that closely related to ours, while Section 3 details the enrichment of the AMI dataset with professional categories. Section 4 reports the experiments conducted to answer our RQs, whereas Section 5 outlines conclusions, limitations, and future directions of the work.

2. Related Work

In recent years, the field of NLP has witnessed a growing interest in detecting misogyny and sexist content on social media platforms. Various works have significantly contributed to this area by publicly introducing diverse datasets and evaluation tasks tailored for misogyny detection [7, 8, 9]. Indeed, it is a pressing need to develop systems for detecting emotive [10, 11] and offensive word lexicons for harassment research [12], as highlighted by Rezvan et al. [13]. Contributing to the field of sexism categorization, Parikh et al. [14] provide a large dataset for multi-label classification of sexism. Chiril et al. [15] explore the detection of sexist hate speech, examining the relationship between gender stereotype detection and sexism classification. Similarly, Felmlee et al. [16] investigate online aggression towards women on social media platforms, focusing on the strategic nature of sexist tweets and the reinforcement of stereotypes.

Emphasizing the interaction and co-influence of social dimensions, like gender and profession, can assist in capturing complex social dynamics and informing the development of norms that promote equity and justice, as outlined by Hancock [17] and Dhamoon [18]. Specifically, previous social science research has examined hate discourse directed at specific groups of women, such as politicians and celebrities. For example, Silva-Paredes and Ibarra Herrera [19] offer a corpus-based analysis of gender-based aggression towards a Chilean right-wing female politician, while Phipps and Montgomery [20] and Ritchie [21] focus on forms of hate speech in media campaigns against Nancy Pelosi and Hillary Clinton, respectively. Specifically for tweets, Saluja and Thilaka [22] employ the Feminist Critical Discourse Theory to perform gender-specific inferences w.r.t. Twitter discourse concerning Indian political leaders. On the other hand, Ghaffari [23] analyzes 2000 user-generated posts focusing on American celebrity Lena Dunham, examining manifestations of hate and stereotypes. To the best of our knowledge, this is the first data-driven work that

[1] The dataset is accessible for research purposes by requesting it by email from the authors. To protect the identities of the affected women, we chose to omit explicit references to profiles and original tweet IDs from the dataset.

examines the relationship between women professional categories and types of misogynistic attacks on online platforms.

3. Data Exploration and Enrichment

In this section, we detail the construction of our novel AMI-PRF dataset.

3.1. AMI Dataset

We address the lack of misogynous data annotated w.r.t. victims' professions by enriching the AMI dataset[2] [7]. The dataset includes a coarse-grained distinction between *mis*ogynistic and *not-mis*ogynistic tweets, as well as a fine-grained labeling for misogynistic tweets, categorizing them into five different types of misogynistic hate speech: *der*ailing (to justify women abuse), *dis*credit (general slurring), *dom*inance (to assert men superiority), *sex*ual harassment (sexual advances and violence) and *ste*reotype (oversimplification and objectification).

We enrich AMI by adding information about the professions of the victims. This enrichment is performed through retrieving from Wikidata[3] professional figures that are subclasses of the *person* class.

Our annotation of professions include four categories, namely 'artist', 'author', 'athlete', 'politician (and activist)'. We focus on these professions as they are represented in the AMI dataset, based on the popular women referenced. Although the first two are both subclasses of *creator*, which is an immediate subclass of *person*, we keep them separate due to their different natures: the former encompasses visual and performing arts, the latter intellectual activities. On the other hand, we choose to group politicians and activists together to highlight their shared involvement in public social activities, even though they are not directly related according to Wikidata taxonomy.

As shown by Fig. 4 (Appendix A), each macro-profession initiates a potentially large set of nested sub-professions based on Wikidata *subclass of* relationship.

We leverage these professions to manually label AMI misogynistic tweets that actually refer to women. In order to produce a consistent labeling, we establish the following conventions: if the tweet refers to a famous woman, we choose the first (or unique) occupation among those appearing on her Wikidata page, tracing it back to the appropriate macro-category. This approach mitigates annotation inconsistencies by leveraging an established external resource for labeling. When such information is unavailable, we determine the professional category by examining relevant job details in the tweet content or on the profile page of the victim, if mentioned. For such cases, a collaborative approach was taken during group meetings to share general insights, ensuring that any disagreements were addressed through discussions and ultimately resolved through consensus. In absence of clues regarding the profession, the tweet is simply labeled as 'generic'.

Table 1
BERTweet multi-classification results on AMI test set.

	support%	Precision	Recall	F1-score
der	2.391%	0.250	0.273	0.261
dis	30.65%	0.626	0.794	0.700
dom	26.95%	0.811	0.484	0.606
sex	9.565%	0.500	0.773	0.607
ste	30.43%	0.906	0.821	0.861
Macro Avg,	-	0.618	0.629	0.607
Wtd. Avg.	-	0.740	0.704	**0.704**
Accuracy	-	-	-	0.704

Finally, we point out that not all tweets in the AMI dataset have women as victims. In several cases, misogynist language is used to insult men, companies or political parties. Out of 5000 AMI tweets, we initially filtered out those that were not directed at women. Among the remaining tweets, 2187 were labelled as misogynistic. However, we were able to obtain professional categories for only a subset of 380 of these tweets, highlighting the need for additional data collection.

3.2. PRF Dataset

To address the issue of having only a small number of tweets annotated for both misogyny and profession, we crawl additional tweets. From the most common expressions in the misogynistic tweets of AMI, we derive a list of misogynistic keywords. For each of our target professions, we choose five representative popular women, collecting tweets containing a reference to them in the form of a hashtag, mention and/or explicit name and surname. As a result, we extract 760 tweets labeled with professions, which have been posted before the beginning of February 2023: we refer to this collection as the Profession (PRF) dataset. Since these tweets are filtered using specific keywords and are directed at popular women, we consider them inherently misogynistic, as a woman is the primary target of hate speech.

To identify the type of misogyny in PRF, we leverage BERTweet[4], a transformer-based [24] model trained on the AMI multi-classification dataset. We opt for this model since it is pre-trained on Twitter, and it achieves

[2] https://live.european-language-grid.eu/catalogue/corpus/7272
[3] https://www.wikidata.org/wiki/Wikidata:Main_Page
[4] https://github.com/VinAIResearch/BERTweet

state-of-the-art performance in Twitter sentiment analysis tasks [25]. Before training, the AMI tweets are preprocessed with a TweetNormalizer function[5] which maps emojis into text strings and substitutes user mentions and web/url links with @USER and HTTPURL placeholders. For model selection, we perform a stratified cross-validation with $k = 5$. We search for the best weight decay and learning rate in [1e-2,1e-5] and [1e-5,3e-5], respectively. For each configuration, we set 10 epochs, 500 warm up steps and a train/validation batch of 16/8. The optimal performance is achieved with a learning rate of 3e-5 and a weight decay of 1e-2. Tab. 1 shows BERTweet performances for the multi-class misogyny detection task on AMI test set, comprising 1000 tweets (460 misogynistic). For the multi-classification task, we focus only on misogynistic tweets. The evaluation metrics include Accuracy, as well as weighted and unweighted average Precision, Recall, and F1-score. We adopt this model to label our PRF dataset with types of misogyny.

AMI-PRF Dataset By combining the 380 tweets from AMI, having ground-truth information regarding the type of misogyny, and the PRF dataset, labeled with our trained model, we obtain 1140 tweets featuring both misogyny type and professions. Such dataset, named AMI-PRF, is leveraged to investigate the relation between misogyny and professions.

4. Experiments and Data Analyses

4.1. Misogyny Type by Profession (RQ1)

To address RQ1, we examine how different types of misogynistic speech are distributed across various professions in AMI-PRF. For each type of misogyny, we find how many tweets belonging to such class are directed towards a specific profession and qualitatively compare the results in Fig. 2.

Discussion We observe distinct patterns in the usage of misogynistic speech across professions: derailing discourse, which focuses on justifying women abuse and rejecting male responsibility, tends to primarily target authors compared to the other professions. This aligns with the nature of derailing speech, which seeks to rationalize mistreatment of women and deflect male accountability. Therefore, this kind of discourse can be expected to be commonly directed at public intellectuals or cultural figures. In contrast, dominance-oriented misogynistic discourse, aimed at asserting male superiority along with stereotypical negative speech, is predominantly directed at powerful figures such as politicians. This prevalence could be explained as an attempt to undermine the legitimacy and value of women holding relevant public roles. Sexual harassment is notably prevalent towards politicians and athletes, as expressions of intent to assert power over women through threats of violence.

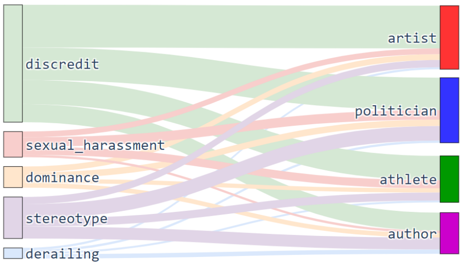

Figure 2: Alluvial plot depicting the relationship between misogyny types and professions. Thicker streams indicate a higher number of tweets corresponding to the misogyny type originating from the respective block.

4.2. Hurtfulness by Profession (RQ2)

To address RQ2 – whether specific hurtful expressions target women in certain professions – we define a quantitative lexicon-based measure for assessing the hurtfulness of tweets.

Hurtfulness Evaluation To define a hurtfulness measure for tweets, we leverage the HurtLex lexicon, which compiles offensive words and stereotyped expressions aimed at insulting and degrading marginalized individuals and groups [26]. HurtLex organizes words into 17 fine-grained categories, each identifying a specific target or form of offense.

Inspired by the work of Nozza et al. [12], where a harmful sentence completions indicator is defined for generative language models, we employ a subset of 9 HurtLex categories for our purposes: animals, prostitution, professions, negative connotations, homosexuality, male genitalia, female genitalia, derogatory terms, and crime[6]. The hurtfulness score for a tweet w.r.t. one of the 9 categories could be computed as the ratio of HurtLex lemmas[7] from that category to the total HurtLex lemmas from any category present in the tweet. However, an approach relying solely on the HurtLex lexicon would not provide a sufficiently comprehensive analysis, as HurtLex has low coverage of the vocabulary in the AMI-PRF dataset, with only 15.42% of the lemmas in a tweet occurring in HurtLex on average.

[5] https://github.com/VinAIResearch/BERTweet/blob/master/TweetNormalizer.py

[6] For detailed descriptions of each category, we refer to Bassignana et al. [26].

[7] We retain only conservative-level lemmas.

Table 2
Average cosine similarity between HurtLex lemmas and ItEM centroids using Word2vec Twitter embeddings.

HurtLex Category	Centroid similarity
animals	0.57
prostitution	0.60
professions	0.60
negative connotations	0.55
homosexuality	0.59
male genitalia	0.52
female genitalia	0.56
derogatory	0.56
crime	0.57

To enhance our reference vocabulary, we leverage ItEM[8], a methodology proposed by Passaro and Lenci [10]. For each lemma in the HurtLex subset, we obtain its vectorial representation using ItEM and the Word2vec Twitter embeddings[9], following Godin [27]. For each category, we compute a centroid embedding by averaging the vectors associated with each lemma in that category. This allows us to represent each category through a unique embedding. Tab. 2 reports the average cosine similarity between lemmas of a specific category and the respective centroid. Finally, we compute the cosine similarity between each word embedding in the Word2vec Twitter vocabulary and each centroid, thus creating a new lexicon featuring a coverage of 76.51% w.r.t. the AMI-PRF dataset.

We leverage the similarity scores to define a hurtful emotive score for each tweet as follows: let $\mathbf{t}$ be a lemmatized tweet, w a lemma in $\mathbf{t}$, k one of the 9 HurtLex categories, $\tilde{k}$ the centroid of category k, s the cosine similarity function and V the set of vocabulary items, i.e. the words for which we have a Twitter emmbedding. For each $w \in V$, we define the $ItEM$ function as:

$$ItEM(w,\tilde{k},thr) = \begin{cases} s(w,\tilde{k}) & \text{if } s(w,\tilde{k}) \geq thr \\ 0 & \text{if } s(w,\tilde{k}) < thr \end{cases} \qquad (1)$$

where thr designates a threshold in $[0,1]$ range. In other words, the $ItEM$ function outputs the cosine similarity value between w and k's centroid if such value is greater or equal then thr, while it outputs 0 if it is lower than thr. Additionally, if w is not found in the vocabulary, its $ItEM$ value is also considered 0.

The Emotive score for a tweet $\mathbf{t}$ w.r.t. a category k and a threshold thr is then computed as:

$$\text{Emotive}(\mathbf{t},k) = \frac{\sum_{w\in\mathbf{t}} ItEM(w,k,thr)}{q} \qquad (2)$$

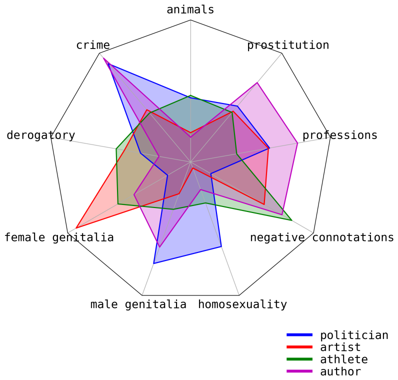

Figure 3: Emotive z-scores for HurtLex categories with respect to professions.

where q is the number of lemmas in $\mathbf{t}$ which occur in V. This allows us to obtain, for each tweet-category pair, a score between $[0,1]$, indicating the tweet hurtfulness tendency.

Discussion Fig. 3 provides a visual analysis of the results. The Emotive score is computed category-wise as the average of the scores for each tweet, after having standardized the values with a z-score approach. We keep a thr of 0.2 in terms of cosine similarity to filter out excessively noisy category associations, while still allowing low values to contribute to the average score. This provides a general overview on the hurtful language across different professions. According to the Emotive analysis, politicians are mainly targeted with insults related to crime, homosexuality and male genitalia. This is consistent with what has been observed in Fig. 2, where forms of sexual harassment discourse were mainly directed toward political figures. For artists, we notice a peak w.r.t. female genitalia, while for athletes we register a more balanced trend, except for a peak in negative connotation. On the other hand, authors seem to be mainly targeted with crime and profession-related topics, consistent with the fact that the type of misogyny mostly inflicted towards this profession consists of derailing and stereotypes.

5. Conclusion

In this paper, we investigated the phenomenon of misogyny on Twitter through the lens of hurtfulness, qualifying its different manifestation considering the profession of the targets of the misogynistic attacks.

Specifically, we examined how different types of misogyny are distributed across various professions, unveiling how derailing discourse is mostly used to attack authors,

[8] https://github.com/Unipisa/ItEM/
[9] https://github.com/FredericGodin/TwitterEmbeddings

while dominance and sexual harassment speech targets especially politicians.

Additionally, we studied through a hurtfulness score measure how the language used in misogynistic tweets varies across different professions: politicians tend to be targeted with hate speech revolving around sexuality (female/male genitalia, homosexuality) and crime, while artists seem to be insulted mainly through general derogatory terms. On the other hand, less heterogeneous results were obtained for athletes and authors, except for peaks in hurtful topics regarding crimes and professions.

We acknowledge two potential limitations of our contribution: the incomplete coverage of our dataset's vocabulary by the Hurtlex-based ItEM lexicon, and our decision to focus on just four professions, which, as motivated, was guided by the representation of those professions in the AMI dataset. We therefore plan to extend the approach adopting a richer vocabulary w.r.t. datasets as well as expanding the set of professions. Indeed, as further future investigations, it could be assessed how hurtfulness dimensions change using different lexicons or automatic approaches. We also intend to investigate the distribution of misogynistic language both textual and multi-modal, as well as the broader expression of emotions in posts associated with different professions.

Abstract

Lexical Semantic Change Detection (LSCD) is the task of determining whether a word has undergone a change in meaning over time. There has been a marked increase in interest in this task, accompanied by a corresponding growth in the scientific community involved in developing computational approaches to semantic change. In recent years, a number of resources have been made available for the evaluation of LSC models in a number of languages, including English, Swedish, German, Latin, Russian and Chinese. DIACR-ITA is the only existing resource for LSCD in Italian. However, DIACR-ITA has a different format from that used for other languages. In this paper, we present DWUGs-IT, which extends the DIACR-ITA dataset with additional target words and usage-sense pair annotations and adapts it to the DURel format, including the first implementation of a LSCD graded task for Italian.

Keywords

Lexical Semantic Change, Sense-annotated corpora, Italian, Historical Linguistics

1. Introduction

As is the case with both society and culture, language is subject to change over time. Two key factors cause such linguistic change. Firstly, there are purely evolutionary and linguistic considerations driven by the need for more efficient communication [1]. One example of this is the use of abbreviations and acronyms, such as *LOL* (Laughing Out Loud), which have become commonplace on social media platforms. Secondly, changes in society and culture lead to changes in language. This can be seen, for example, in the adoption of a more inclusive language, as evidenced by grammatically gendered languages, including Italian and the introduction of ə to replace masculine and feminine endings [2].

Language may undergo alteration at various levels, including morphological, syntactic, and semantic. Semantic change concerns the alteration of the meaning of words over time. The study of semantic change is a prominent area of research in Historical Linguistics, with the aim of investigating the linguistic mechanisms that characterize the change and the causes that trigger it. For instance, Blank [3] provides a broad study on the characterization of semantic change, identifying a number of different types of change, including metaphor, metonymy, generalization, specialization, co-hyponym transfer and auto-antonym. The English word *bad*, for example, has acquired an auto-antonym meaning, i.e. a meaning that is the opposite of its original meaning. In addition to its original connotation of *poor quality* or *negative*, it has also acquired the opposite connotation of *good* or *cool*. The term *meat* has undergone a process of specialization in its meaning, whereby it has shifted from referring *to any kind of food in general* to exclusively denoting the *meat of animals consumed as food*.

While traditional linguistic methods are informative, they are often based on small, carefully curated samples. In contrast, linguistic analyses using computational models not only accelerate our understanding of language change but also provide broader and more detailed insights, thereby facilitating the study of vast corpora across a wider range of genres and time [4, 5].

From a computational perspective, two key challenges emerge in the study of semantic change: **the modelling of word meanings over time** and the **detection of change** [6, 7]. At the synchronic level, ignoring the temporal dimension with a focus on modern corpora, the Natural Language Processing community has made significant strides in modelling word meanings, with approaches such as Word Sense Disambiguation (WSD) [8] playing a pivotal role. Computational modelling of semantic change introduces a significant level of complexity, as it necessitates the handling of meanings that are either extinct or novel in comparison to existing lexicographic resources, such as WordNet, as well as dynamically changing meaning representations.

In recent years, great efforts have been made to advance the field of computational methods for Lexical Semantic Change Detection. With initiatives such as the Workshop on Computational Approaches to Historical Language Change [9] promoting research in this

field or shared tasks such as SemEval 2020 Task 1 [10], RuShiftEval [11], DIACR-ITA [12], or LSCD Discovery [13] leading to the development of the first evaluation resources. DIACR-Ita, hosted in EVALITA 2020 [14], is the first shared task specifically created for the evaluation of models for Lexical Semantic Change in Italian. The majority of the evaluation resources follow a two-task approach: (1) a binary task, which requires the assignment of a word to either the *changed* or *stable* label, based on whether the word has undergone a change in meaning or not; and (2) a graded (ranking) task, which requires the sorting of words based on the extent of their change (over time). These labels are assigned on the basis of human-annotated data, typically in the form of a graded word-in-context task.

DIACR-Ita, however, diverges from the evaluation process employed in SemEval 2020 Task 1, RushiftEval and several other datasets that emerged subsequently. This results in a distinct configuration of the task and the released data. For example, DIACR-Ita only has a binary task but does not include a graded task. Moreover, only the target words with their gold truth labels were made available for the shared task, while the remaining data produced during the annotation process were not. In this paper,

1. we release DWUGs-IT [1], a new dataset for Lexical Semantic Change Detection for Italian, which:
   - **extends** the original DIACR-ITA with 12 new words;
   - provides **sense-annotated usages** with the respective sense labels
   - **standardizes** DIACR-ITA providing the data in the DURel format [15, 16, 17]
   - introduces the first LSC **graded task** for Italian
2. we **evaluate** DWUGs-IT using XL-LEXEME[18], the state-of-the-art model for Lexical Semantic Change Detection [19]

2. Related Work

DURel [15] is a framework for the annotation of Lexical Semantic Change across a pair of time periods or corpora. The annotation involves human labelling of pairs of sentences containing the target word. The sentences can be contemporary, i.e. originating from the same time period, or diachronic, denoting a divergence in time between the two periods under consideration. An annotator has to decide whether the meaning expressed by the word in the two sentences is Unrelated (1), Distantly Related (2), Closely Related (3) or Identical (4). The scale of semantic relatedness is derived from the cognitive model proposed by Blank [20] and corresponds to the values of Homonymy (1), Polysemy (2), Context Variance (3) and Identity (4).

The annotations are then presented in the form of a graph, specifically a Word Usage Graph (WUGs) or a **Diachronic Word Usage Graph (DWUGs)** [21] in cases where the usages originate from different time periods. In these graphs, the nodes correspond to the word uses and the edges correspond to the median of the annotations. The diachronic graph is then subjected to clustering in order to identify the senses. Before clustering, a new graph is created by binarizing the edges, where an edge between two uses is established if the score of the original edge weight is less than 2.5, or in other words if the average annotation for this pair of uses is less than 2.5. Since the graph typically exhibits considerable sparsity, which limits the applicability of conventional clustering algorithms, a variation of the correlation clustering algorithm [22] is typically used, as it is able to model this type of sparsely connected graph.

Once the (diachronic) clusters have been obtained, they can be considered to represent the senses. The distribution of the usages from different time periods in each cluster (sense) is then analyzed to obtain a change score. For instance, one can determine a graded change score by computing the Jensen-Shannon Distance (JSD) on the probability distributions of senses across various time periods. This is expressed as

$$\sqrt{\frac{D(P \,||\, M) + D(Q \,||\, M)}{2}}$$

where P and Q represent the probability distributions of clusters from different historical periods, D denotes the Kullback-Leibler divergence, and $M = \frac{(P+Q)}{2}$ [23, 24].

Furthermore, a binary label can be obtained, whereby words that have undergone a change in meaning over time are assigned a *changed* label (words that have gained/lost a sense), while words that have retained their meaning are labelled *stable*. The label is typically assigned by evaluating the frequency of senses in different time periods and establishing thresholds to distinguish stable and changed words.

Datasets based on DURel SemEval 2020 Task 1 [10] is the first initiative to standardize the evaluation of computational approaches to semantic change. SemEval 2020 Task 1 focuses on English, German, Swedish and Latin and proposes a common evaluation framework with two tasks: classifying target words as those whose meaning has changed or remained stable, and ranking words according to their degree of change. Special attention is given to Latin due to the lack of native speakers. Therefore, in the annotation of the Latin dataset, usage-sense

[1] DWUGs-IT is available on Zenodo https://zenodo.org/records/13941618.

pairs are considered rather than usage-usage pairs, and the annotator is asked to decide how related the considered usage is to a particular sense, using the DURel scale from Unrelated to Identical. RuShiftEval [11] aimed to detect semantic shifts in Russian across pre-Soviet, Soviet, and post-Soviet periods. The dataset included 111 Russian nouns, with participants ranking them by their degree of change (using the COMPARE measure [15], an approximation of the JSD). The task focused on ranking changes, with evaluations based on Spearman rank correlations. LSC Discovery [13] focused on detecting and discovering semantic changes in Spanish. It is divided into Graded Change Discovery and Binary Change Detection. The task required evaluations for all vocabulary words in the corpus, covering periods from 1810-1906 and 1994-2020. NorDiaChange [25] studied diachronic semantic change in Norwegian. The dataset included 80 nouns reflecting significant historical periods, such as pre- and post-war events and technological advances. ZhShiftEval [26, 27] assessed semantic change in Chinese over 50 years, focusing on the period around Reform and Opening Up. The dataset used texts from the People's Daily and included 20 words chosen for their frequency and noted changes.

3. DIACR-ITA

The DIACR-ITA annotation was conducted on word usages extracted from *L'Unità* corpus [28]. *L'Unità* corpus comprises a collection of Italian texts extracted from the newspaper L'Unità. In order to evaluate semantic change, the corpus has been divided into two sub-corpora, covering the period from 1948 to 1970 and the period from 1990 to 2014, respectively. A time window of 20 years between the sub-corpora ensures sufficient distance between the two periods, allowing for the tracking of potentially more pronounced semantic changes. The sub-corpora statistics are presented in Table 1.

The selection of target words was based on the information provided in the Sabatini-Coletti dictionary of the Italian language, which records the year of the first occurrence of a word's sense. The initial step involved the extraction of a list of words from Sabatini-Coletti for which the dictionary reported a semantic change, i.e. the introduction of at least one new sense after 1970. Moreover, an examination of the set of words was conducted to ensure that the sampled words appeared at least 10 times in each of the two periods and that the occurrences of these words were not significantly affected by OCR errors. Consequently, 26 target words were identified. For each target word, up to 50 occurrences from each of the two sub-corpora were extracted.

The senses of each word were classified into two groups: the senses recorded in the Sabatini-Coletti dictionary for the period 1948-1970 (Group 1) and the new senses introduced after 1970 (Group 2). The annotators were required to determine whether the sense of each word usage belonged to Group 1, Group 2, or to another category if the word sense did not align with either group (Other). Additionally, the annotator may indicate a preference of *Cannot decide* for the uses in which they were uncertain. Five annotators fluent in Italian annotated DIACR-ITA. Each sentence was annotated by two annotators. The disagreement cases were resolved by the two annotators involved, analyzing the disagreement and deciding on an unambiguous label.

Each target word was labelled as *stable* or *changed.* A word was considered *changed* if there was at least one instance of Group 2 among the extracted usages from the period between 1990 and 2014 and no instances of Group 2 among the extracted usages from the period between 1948 and 1970. The final dataset consisted of 18 words, of which 6 were changed and 12 were stable.

Corpus	Period	#Tokens
L'Unità	1948-1970	52,287,734
L'Unità	1990-2014	196,539,403

Table 1
Sub-corpora statistics.

4. DWUGs-IT

DWUGs-IT builds on the DIACR-ITA dataset, adapting it to the DURel format and adding eight new words. It also provides the usage-sense annotated pairs that were not initially released, as summarized in Table 2. For each target word, we format the annotated usages following the WUG style, including the time period of the usage and the word's position in the sentence. Similarly, we format and release the annotated sense labels in a way similar to DWUG LA [29].

Unlike the traditional WUG approach, where sense preference is not explicitly marked, in DIACR-ITA, annotators clearly indicate their preference for one sense over others. For example, in the usage of the word *api* (Italian for *bees*), in the sentence "Dalle api un dolce dono" ("From bees, a sweet gift"), the annotators choose the sense *insect* while discarding the alternative sense *means of transport.* For each use-sense pair not selected by annotators, a rating of 1 (*Unrelated*) is assigned, while matched pairs receive a rating of 4 (*Identical*), in line with the DURel scale.

Since human annotators already provide the sense labels, we do not cluster usages automatically (as is typically done in the WUG approach), but directly assign the annotated meanings. All subsequent calculations, such as

Lemma	Group 1	Group 2	Other
ultima	Che viene dopo tutti gli altri in una serie numerica, in una classifica, in una graduatoria o in una successione spaziale o temporale	Nel l. fam., l’ultima cosa; la novità, la notizia più recente: la sai l’ultima?

Newly introduced words together with the senses of Group 1 (1948-1970), Group 2 which involves senses introduced after 1970, and an indication of the presence of other senses not listed in Group 1 and Group 2.

change scores and related statistics, follow the standard WUG methodology.

5. Evaluation

XL-LEXEME has been tested on different languages before but has never been evaluated on Italian. In this section, we evaluate XL-LEXEME on the new DWUGs-IT dataset using the traditional evaluation pipeline for the DWUGs [19, 30]. We assess the ability to derive a reliable change score (Graded Change Detection) and evaluate the possibility of clustering the XL-LEXEME vectors to automatically induce target word senses, which are then compared to the DWUGs-IT annotations via the Adjusted Rand Index and the Purity measure.

5.1. Model

XL-LEXEME, built on XLM-RoBERTa large [31], is trained for the Word-in-Context (WiC) task [32], which determines if a word has the same meaning in two sentences. Using a Siamese architecture [33], it creates word vectors. The loss function adjusts weights via cosine distance, aligning vectors for the same meanings and separating them for different meanings. To calculate the change score, a classic approach is to use the Average Pairwise Distance between the vectors computed over the two different periods:

$$\mathrm{LSC}(s_w^{t_0}, s_w^{t_1}) = \frac{1}{N \cdot M} \sum_{i=0}^{N} \sum_{j=0}^{M} \delta(s_{w,i}^{t_0}, s_{w,j}^{t_1}) \quad (1)$$

where δ is the cosine distance and s_w^t is the set of sentences containing the word w at time t. For the Word Sense Induction step, we cluster the vectors into senses using Agglomerative Clustering [2] with a cosine threshold of 0.5 and Average Linkage, which merges clusters with a similarity greater than 0.5.

5.2. Metrics

We test the ability of XL-LEXEME in ranking words according to their change scores (Graded Change Detection) using Spearman Correlation. Cluster quality is assessed using the Adjusted Rand Index (ARI) [34], which is defined as follows:

$$ARI = \frac{RI - Expected_{RI}}{max(RI) - Expeted_{RI}}$$

RI stands for the Rand Index, which measures the number of pair agreements within the data – that is, pairs of instances that are correctly placed in the same cluster. The $Expetcted_{RI}$ is the expected number of such agreements by chance, calculated based on the distribution of the clusters, while the $max(RI)$ is the maximum possible value of RI, which occurs when all pairs are classified perfectly. We use Purity in addition to ARI to capture cluster homogeneity and provide clearer insight about how mixed the clusters are in terms of class labels, i.e.

$$\text{Purity} = \frac{1}{N} \sum_k \max_j |c_k \cap t_j|$$

where N is the total number of instances, c_k denotes cluster k, and t_j represents class j.

(a) palmare

(b) rampante

(c) pilotato

Figure 1: t-SNE visualization of XL-LEXEME embeddings with respect to the annotated clusters for changed words palmare, rampante, and pilotato.

5.3. Results

We begin to discuss qualitative results. Figure 1 illustrates the t-SNE visualization of XL-LEXEME embeddings for the usages of the words *palmare*, *rampante*, and *pilotato*. For *palmare* (Figure 1a), the senses are well separated except for some instances of the sense *relating to the palm, clear, evident* that are placed closer to the *PDA device* meaning, for example:

> *sono state n levate di le impronte palmari che saranno inviate al1' archivio generale segnaletico di Roma.* (en. *The palm prints have been removed and will be sent to the general sign archive of Rome.*)

For the word *rampante* (Figure 1b), the annotators identified an additional meaning (Other) that refers to a named entity, i.e., *Il barone rampante* written by Italo Calvino. The instances of *Il barone rampante* fall in the middle of the cluster of the *rearing* and *ambitious* meanings. Interestingly, the only instance annotated as *Cannot decide* falls in the *rearing* cluster:

> *Uno rampante » non ci aia ancora nulla da fare, comunque i tecnici....supremazia di le Ferrari.* (en. *A rampant » there is still nothing to be done, in any case the technicians.... supremacy of the Ferrari.*)

This instance is ambiguous since the subject of *rampante* is missing in the sentence. However, interestingly, XL-LEXEME assumes it to have the *rearing* meaning, probably due to the presence of the word *Ferrari*, referring to the Ferrari logo. Figure 1c shows how the embeddings of the usages of *pilotato* are perfectly split according to the sense labels. However, one instance of the meaning *driven* falls in the cluster of the *manipulated* instances, which can be considered ambiguous and open to interpretation:

> *Twingo Easy offre la grande comodità di un cambio con frizione pilotata, ovvero: non c' è più il pedale della frizione.* (en. *Twingo Easy offers the great convenience of a gearbox with a piloted clutch, that is: there is no longer a clutch pedal.*)

The quantitative results of XL-LEXEME are reported in Table 3. Compared to LSCD benchmarks in other languages, XL-LEXEME shows similar results for the GCD score (ranging from 0.567 in NO to 0.851 in RU) and the ARI score (ranging from 0.249 in SV to 0.400 in ES). It also performs slightly better using the purity measure (ranging from 0.766 in SV to 0.836 in ZH). These results likely stem from the properties of the dataset that includes several monosemous words, but also from the process that has been used for DWUGs-IT where senses are modeled explicitly. Purity measures the extent to which clusters contain a single class. With many monosemous words, achieving high purity is easier since these words inherently belong to one sense group. ARI, on the other hand, evaluates the similarity between the clustering results and the ground truth, accounting for both the clustering quality and the number of clusters. In DWUGs-IT, most groups of word senses have just one meaning. But sometimes, a group of words can have several meanings, and how often each meaning is used can change over time. For example, the word *palmare* has three meanings in its Group 1: i) related to the palm of the hand, ii) something that fits in your hand, and iii) something that is obvious or clear. Over time, some of these meanings might be used more or less often. However, because all three meanings are grouped together, DWUGs-IT does not take into account how the use of each of those meanings changes over time. This broad categorization of senses

Graded Change Detection (Spearman Correlation)	0.51
Adjusted Rand Index (ARI)	0.28
Purity	0.89

Table 3
XL-LEXEME Results

can impact the performance of XL-LEXEME, which analyzes meanings at a more detailed level. Additionally, XL-LEXEME has been tested on different languages before but has never been evaluated on Italian. DWUGs-IT models senses explicitly, whereas previous datasets inferred senses automatically by comparing pairs of usages. This automatic inference process is similar to the approach XL-LEXEME uses, potentially making it better suited for datasets without explicit sense modelling.

6. Conclusion

This paper presents DWUGs-IT, an extension and standardization of the Lexical Semantic Change Detection (LSCD) task for Italian, based on the existing DIACR-ITA dataset. The dataset is expanded with additional target words and its format is aligned with that of the resources used for other languages. This involves the introduction of the first graded task for Italian. The standardized dataset and the evaluation framework we provide can serve as a foundation for future research in LSCD for Italian. By aligning the Italian dataset with those of other languages, we facilitate cross-linguistic comparisons and contribute to the broader understanding of semantic change mechanisms. In addition, we provide a first evaluation of the state-of-the-art LSCD model, XL-LEXEME, for Italian and both show its effectiveness as well as set a baseline for future work.

Acknowledgments

This work has in part been funded by the research program Change is Key! supported by Riksbankens Jubileumsfond (under reference number M21-0021). The computational resources were provided by the National Academic Infrastructure for Supercomputing in Sweden (NAISS), partially funded by the Swedish Research Council through grant agreement no. 2022-06725.

[2]Università di Torino, Via Pessinetto 12, 10149, Torino, Italy

Abstract

This paper introduces a new multi-class classification task: the prediction of the Structural-Demographic phase of historical cycles - such as growth, impoverishment and crisis - from text describing historical events. To achieve this, we leveraged data from the Seshat project, annotated it following specific guidelines and then evaluated the consistency between three annotators. The classification experiments, with transformers and Large Language Models, show that 2 of 5 phases can be detected with good accuracy. We believe that this task could have a great impact on comparative history and can be helped by event extraction in NLP.

Keywords

Cultural Analytics, Structural Demographic Theory, LLMs, NLP for the Humanities,

1. Introduction And Background

In the last decade, at least since Brexit [1], many countries in the world experienced a generalized polarization and phenomena of toxic language online have grown [2]. Hate speech [3], misogyny [4], conspiracy theories [5] and related phenomena are just visible manifestations of deep structural social crises, ushering in periods of shifting world order [6]. While crises may appear sudden, they are often rooted in underlying factors like demographics, geopolitics, technological advancements, and historical-economic cycles. Using scientific method, mathematical modelling and the Structural Demographic Theory (SDT) [7] it was possible to formalise secular cycles [8], that typically last between 75 to 100 years [9], and predict outbreaks of political instability in complex societies based on the rate of past crises [10]. The SDT defines three actors and five phases of the secular cycle. The three key actors are:

- The population, which is the source of the society's resources and manpower, represents approximately 90% of the entire society and is the part that follows instructions to produce goods and wealth, consuming only a small part of it.
- The elites, who typically cover around 8% of the society, are the groups of people in charge of finding potential solutions to the problems of the society and are eligible to become part of the state. Who is considered part of the elite and how someone gains or loses elite status depends on the type of government and the power dynamics within a society.
- The state, formed by roughly 2% of the society, is the government that enforces its will and manages resources from the population. It is composed by one or more elite groups, depending on the social structure, and it crystallizes the culture to keep the society alive.

The actors interact in five phases during the secular cycle, progressively increasing social and political instability:

1. The growth phase. During this phase a fresh and effective culture creates social cohesion, the economy is growing rapidly and the state is expanding its control over the population. This leads to increased economic prosperity and stability but raises the problem of sustainability. Periods of reconstruction immediately following wars, like post-war Italy in the 1950s, are examples of this phase.
2. The population immiseration phase. The population continues to grow in number while the economy slows down. This happens because over the long term the rate of return on capital is typically greater than the growth rate of population salaries [11], as result the elites gets richer and the population gets poorer. Moreover, demography has a strong impact on the wealth of the population: the more workers of the same type are available, the less likely their wages are to grow. The state's ability to extract resources from the population reaches its limits in this phase. This

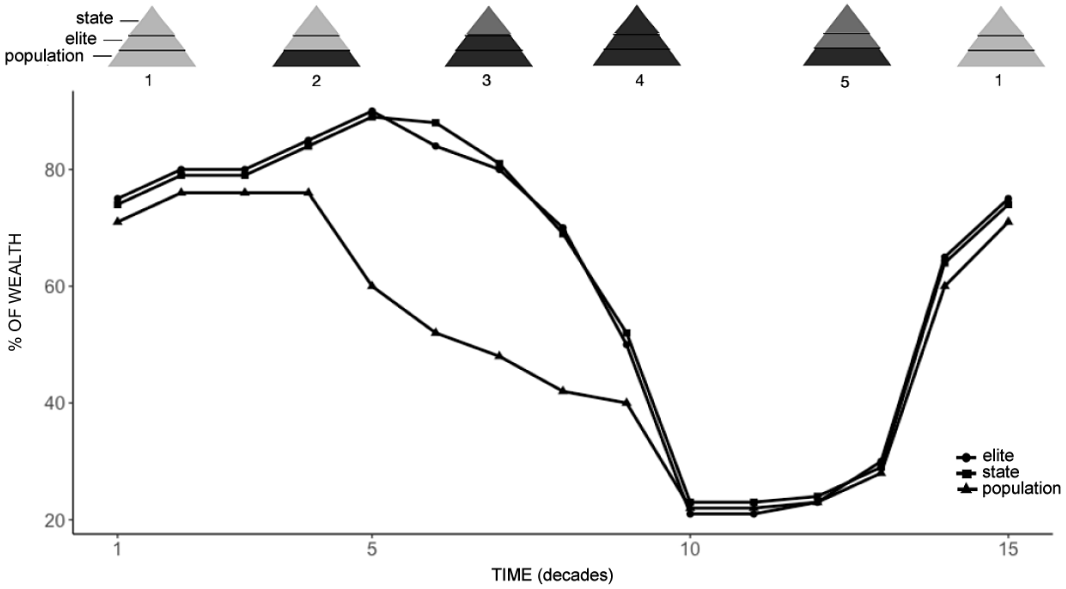

Figure 1: Time chart depicting the dynamics and phases described by the Structural-Demographic Theory.

can lead to increasing inequality, and social unrest begins. United States in the 1890s and 1970s are an example of this phase.

3. The elite overproduction phase. The population tries to access the elite ranks but overloads the social lift mechanisms and yields a reduced capability of the elite to solve problems in the society, which raise the probability to have societal instability. USSR in the 1950s and US in the 1990s are examples of this phase.
4. The state stress phase. The state's ability to govern the population and foster cooperation between population and elites begins to decline, and the elites become increasingly fragmented. This can lead to widespread violence and civil war. Moreover, the state tends to be in financial distress as a consequence of slowed economy and internal fragmentation, thus any triggering event that the state cannot manage can break into a crisis. Germany in the 1920s is an example.
5. The crisis, collapse or recovery phase. The state is either reformed by the elites who find an agreement or overthrown by internal or external forces. At the end of this phase a new social equilibrium is found and a new period of stability begins, restarting the cycle. Examples are France in the 1790s, UK in the 1940s, US in the 1860s under civil war and also in 1930s under New Deal reforms.

The dynamics described by the SDT are represented in figure 1 [12]. SDT has been used to explain a wide range of historical events, including the French Revolution, the American Civil War [13], the fall of the Qing Dynasty [14], the Russian Revolution and the instability in the US in recent years.

In this paper we propose a novel multi-class classification task: given a text describing the historical events of a decade, find the appropriate SDT phase label. To do so we exploited historical data from the Seshat project, produced textual descriptions for decades in the history of human societies and annotated each decade with SDT phases following specific annotation guidelines. We computed inter-annotator agreement between 3 annotators and experimented with LLMs in classification. The paper is structured as follows: in Section 2 we will describe the data, the guidelines for the annotation (Section 3), the classification experiments in Section 4, the conclusion and direction for future work in Section 5.

2. Data

It is not easy to design a dataset for historical data. There are specific datasets for event detection from text [15], for paleoclimatology [16], for census analysis through time [17] and for information extraction from historical documents [18], but there are few long-term historical datasets for Structural-Demographic analysis. Crucially the Seshat project [19] produced a dataset that contains machine-readable historical information about global history. The basic concept of Seshat is to provide quanti-

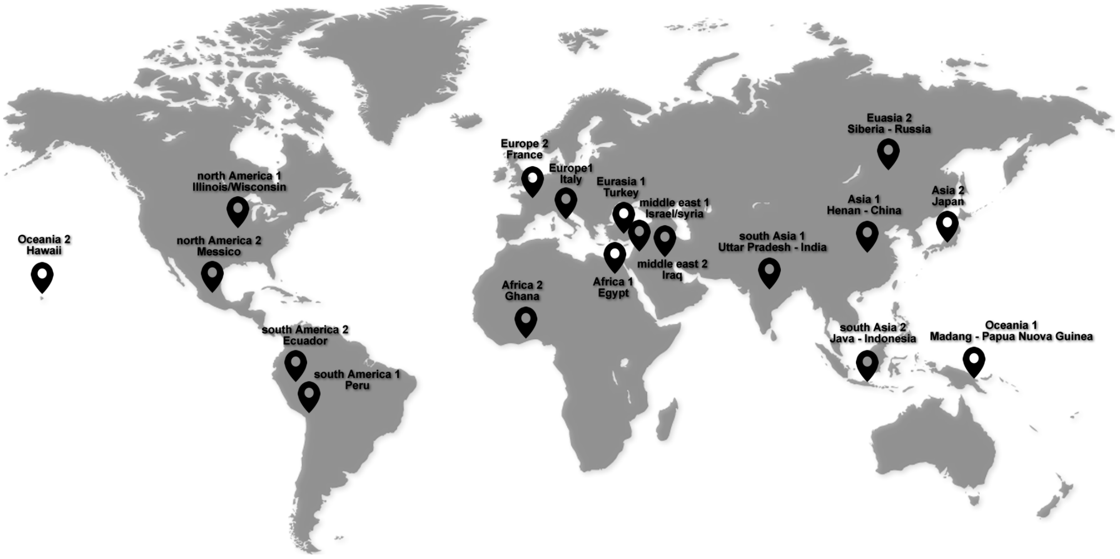

Figure 2: Distribution of the sampling zones. There are two sampling zone per World region: North America (US, Mexico), Oceania (Hawaii, Madang - Papua New Guinea), South America (Ecuador, Peru), Europe (France, Italy), Africa (Egypt, Ghana), Middle East (Levant, Iraq), Eurasia (Turkey, Siberia), South Asia (Uttar Pradesh - India, Java - Indonesia), East Asia (Henan - China, Japan)

tative and structured or semi-structured data about the evolution of societies, defined as political units (polities) from 35 sampling points across the globe in a time window from roughly 10000 BC to 1900 CE, sampled with a time-step of 100 years. A sampling frequency of 100 years is too much coarse-grained, not suitable to track the internal phases of the secular cycle, thus we resampled the data with a sampling frequency to 10 years, manually integrating data and descriptions from Seshat and from Wikipedia. To do so, we followed these general guidelines:

- For each polity in Sesaht create a number of rows to represent each decade. There must be no gaps between decades. If needed, add polities to fill the gaps searching in Wikipedia.
- Read the description of the polity provided in Seshat, identify dates and map the content to the corresponding decade.
- Search Wikipedia to find more information about the polity that can be mapped into decades. Fill in as much decades as possible. When dates are uncertain within a specific time period, use the median decade of that period.
- Summarize the content to fit about 400 characters. Focus on the following types of events: wars or battles; reforms; rulers; population; elites; disasters or epidemics; alliances or treaties; socioconomic context; famines or financial stress; protests or movements; changes of elite; religions and philosophies When possible, report the references about the information found.

We also extended the data to include the polities until the 2010s CE. In order to limit the long and time-consuming manual data wrangling, we reduced the number of sampling zones from 35 to 18 but at the same time we kept the original variety of world regions [20]. This, combined with the extension of the time window, allowed us to obtain 366 polities (roughly the same number of polities as Seshat) and 3540 rows with a textual description. We will call “Chronos” the dataset we produced. It contains the following features:

- *timestamp* of each decade,
- the *Age* indicating the periods of history (prehistoric, ancient, medieval, early-modern, modern, post-modern),
- the *sampling zone* as reported in Figure 2,
- the *world regions* related to the sampling zones,
- a *Polity ID* formatted with a standard method: 2 letters to indicate the area of origin of the culture, 3 letters to indicate the name of the polity, 1 letter to indicate the type of society (c=culture/community; n=nomads; e=empire; k=kingdom; r=republic) and 1 letter to indicate the periodization (t=terminal; l=late; m=middle; e=early; f=formative; i=initial; *=any). For example “EsSpael” is the late Spanish Empire, “ItRomre” is the early Roman Republic and “CnWwsk*” is

the period of the Warring States under the Wei Chinese dynasty,
- a *short textual description* of the decade in Italian and English.

Short texts can contain one or more events and references. Consider the following examples extracted from the Chronos dataset:

1. *introduction of iron from Vietnam by 300 BC [Bellwood P. 1997. Prehistory of the Indo-Malaysian Archipelago: Revised Edition pp. 268-307]. Old Malay as lingua franca.*
2. *Siege of Constantinople in 626. The Byzantines won. Problems in the succession to the throne: Kavadh II is killed in 628. Years of war with Bizantines had exhausted the Sasanids who were further weakened by economic decline; religious unrest and increasing power of the provincial landholders. King Yazdegerd III (r. 632-651) could not stand against the Islamic conquest of Persia.*

Example 1 contains a socio-economic context about the Buni culture of Indonesia and example 2 contains events about war, rulers, socio-economic context, religion and elite change about the late Sasanian Empire. The events in the short textual description are specific to the SDT and help annotators in their decisions about the historical phase labels. For example a good socio-economic context may be a clue of a growth phase and a disaster may trigger a crisis phase. For this reason we did not exploit the labels proposed in literature, such as second-level HTOED categories or the HISTO classes [21]. However, we acknowledge that this is an aspect that requires further research. All events included in the texts were manually detected, and the data collectors were trained to recognize key events from the examples provided in the literature about SDT [12].

3. Annotation and Evaluation

The main problem with the annotation of phases of historical cycles is its interpretability. While everyone agrees the 1789-1799 period in France was a time of crisis, reaching a consensus on the impact of the 1860s French intervention in Mexico proves more difficult. Did it trigger a phase of impoverishment or of elite overproduction? Moreover, did the rise of Mao Zedong as leader of China in the 1950s began a phase of growth or continued the previous crisis?

We defined the following guidelines for the annotation:

1. Read the textual description to identify key events: wars, reforms, rulers, population, elites, disasters, epidemics, alliances or treaties, socio-economic context, famines or financial stress, protests or movements, religions.
2. Use polity identifiers to find the start and end points of cultures. The end of a culture represents a crisis period.
3. Starting from the beginning of a culture, initially assign the sequence of labels of a standard secular cycle model: 1,1,2,2,3,3,4,4,4,5 and then evaluate whether to keep or change the labels in each decade. It is possible to have longer or shorter cycles. There can be only one label 5 (crisis) per cycle. A polity can have one or more cycles.
4. Having in mind the key events in the textual description, select one of the following labels to describe the decade: 1=growth. A society is generally poor when it experiences renewal or change followed by demographic (but not always territorial or economic) growth. Reforms, alliances, wars won or similar events are potential indicators of this phase. 2=impoverishment of the population. Potential economic and/or territorial expansion slows while demography continues to expand. The elite takes much of the wealth and defines the status symbols. Stability and external attacks are potential indicators of this phase. 3=Overproduction of the elites. The wealthy seek to translate their wealth into positions of authority and prestige. The population becomes poor. Movements, protests, and wars are potential indicators of this phase. 4=State stress. The elites want to institutionalize their advantages in the form of low taxes and privileges that lead the state into fiscal difficulties. Wars, protests and changes in the elite are potential indicators of this phase. 5=Crisis. a triggering event such as a war, revolt, famine or disaster that the state is unable to manage leads to a new configuration of society. Emigration of elites, subjugation to other societies, civil wars or profound reforms are potential indicators of this phase.
5. Use the progressive order of the phases if no textual description is available for the decade.
6. Make sure there is a progressive order of the labels (e.g. phase 3 must follow phase 2). All labels can be repeated in the following decade except the crisis phase, which conventionally lasts one decade.

Trial	Examples	Raters	Labels	K
base	93	3	5	0.206
trained	93	3	5	0.455

Table 1
Inter-Annotator Agreement (Fleiss' Kappa) on the annotation of secular cycle phases.

A single annotator annotated the entire corpus, then

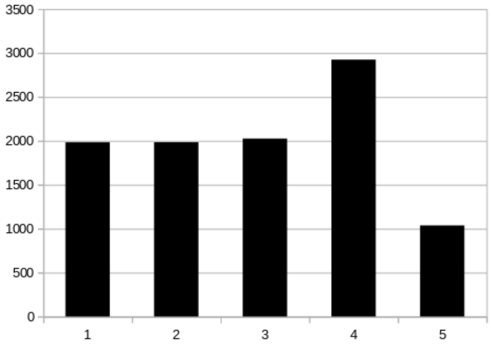

Figure 3: Distribution of the labels in the Chronos dataset.

we evaluated the annotation with two different trials involving students, not expert in history. We compared a subset of data annotated by two students to the same subset annotated by the principal annotator. The first trial was done just following the guidelines after a general explanation of the SDT. The second trial was done, with different students, following the guidelines after a training session, where the annotation was discussed and agreed upon. Results, reported in Table 1, show that with a training session the agreement rises considerably (from slight to moderate). The base agreement level is comparable to the one observed in the annotation of hate speech among 5 trained judges on a non-binary scheme, which obtained a Fleiss K=0.19 [22] [23]. The distribution of the labels in the Chronos dataset is depicted in Figure 3. In the standard secular cycle model, the stress phase (label 4) is the most common, followed by the crisis phase (label 5), which is the least common. The other three phases (labels 1, 2, and 3) occur with roughly equal frequency in the data.

4. Classification and Discussion

In order to test the robustness of the Chronos dataset, we performed cross-validation classification experiments. The setting is straightforward: each line of the dataset is considered independently from one another, and we apply a supervised classification model to predict the human-annotated label, i.e., the phase (from 1 to 5).

In this experiments, we ignored lines for which no textual description is available and we used the chance baseline of $F1 = 0.2$. As learning model, we fine-tuned RoBERTa large[1] [24] for the English textual descriptions and Italian BERT XXL[2] for the Italian texts. We used a learning rate of 10^-6 and applied early stopping and model checkpointing, validating each fold on 10% of the training set.

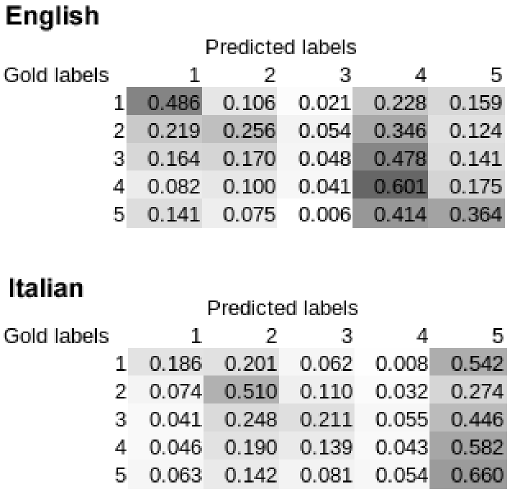
We performed 5-fold cross validation and measured the precision, recall, and F1 score of the predicted labels compared against the gold standard. Table 2 shows the results of the experiments.

English			
Phase	Precision	Recall	F1-score
1	0.542	0.486	**0.513**
2	0.338	0.256	**0.291**
3	0.242	0.048	0.080
4	0.319	0.601	**0.416**
5	0.330	0.364	**0.346**

Italian			
Phase	Precision	Recall	F1-score
1	0.489	0.510	**0.499**
2	0.321	0.211	**0.254**
3	0.191	0.044	0.071
4	0.290	0.660	**0.403**
5	0.397	0.186	**0.254**

Table 2
Results of 5-fold multiclass classification experiments. Results above the baseline (0.2) are marked in bold.

The classification performance shows that the textual descriptions in our dataset are sufficient to predict the corresponding phase to a certain extent, however in quite an imbalanced way. In particular, the classification of phases 1 and 4 achieves moderately good results, while phase 3 in particular is almost never predicted, despite the rather balanced distribution of labels in the dataset.



English

Gold labels	Predicted labels 1	2	3	4	5
1	0.486	0.106	0.021	0.228	0.159
2	0.219	0.256	0.054	0.346	0.124
3	0.164	0.170	0.048	0.478	0.141
4	0.082	0.100	0.041	0.601	0.175
5	0.141	0.075	0.006	0.414	0.364

Italian

Gold labels	Predicted labels 1	2	3	4	5
1	0.186	0.201	0.062	0.008	0.542
2	0.074	0.510	0.110	0.032	0.274
3	0.041	0.248	0.211	0.055	0.446
4	0.046	0.190	0.139	0.043	0.582
5	0.063	0.142	0.081	0.054	0.660

Figure 4: Confusion matrices of the classification of English (above) and Italian (below) decade descriptions.

The confusion matrices in Figure 4 further highlight

[1] https://huggingface.co/FacebookAI/roberta-large
[2] https://huggingface.co/dbmdz/bert-base-italian-xxl-cased

interesting trends. While the biases of the models in terms of phases are clear, it is worth noticing that misclassification happens often between contiguous phases.

```
Structural Demographic Theory predicts
outbreaks of political instability in
complex societies, based on three actors:
the population, the elite, and the state.
Each decade is associated with one of five
phases:

1. The 'growth' phase, when a fresh
and effective culture creates social
cohesion, the economy is growing rapidly
and the state is expanding its control over
the population;

2. The 'population immiseration' phase,
when the population continues to grow while
the economy slows;

3. The 'elite overproduction' phase,
when the population tries to access the
elite ranks but overloads the social lift
mechanisms and yields a reduced capability
of the elite to solve problems in the
society;

4. The 'state stress' phase, when the
state's ability to govern the population
and foster cooperation between population
and elites begins to decline, and the
elites become increasingly fragmented;

5. The 'crisis, collapse or recovery'
phase, when the state is either reformed
by the elites or overthrown by internal or
external forces;

the phase number. Please output only a
number from 1 to 5.

Decade: textual description

Phase:
```

Figure 5: Prompt for zero-shot classification experiments with LlaMa70B.

This suggests that a more refined, regression-based learning setting could be more favorable to this kind of data. Finally, we performed a pilot experiment with a large language model, namely LlaMa 3 70B[3], prompting the model to elicit zero-shot classifications of the phases given the textual descriptions in English. The prompt we used for the model is shown in Figure 5. No particular decoding strategy was applied for this experiment.

Despite the dimension of this model, the classification performance was poor, 5–10 F1 points below the supervised classification results at the best try. Interestingly, the zero-shot classification exhibited a similar pattern in terms of individual labels, with the model strongly biased towards phase 1 and 4, and unable to properly predict phases 2 and 3.

We suggest that, while phases 1 and 4 have similar types of events in most societies (i.e. reforms or won wars in phase 1, famines or financial problems in phase 4) there is much more variability for phases 2, 3 and 5. It must be noted that these experiments only scratches the surface of the learning capabilities of the Chronos dataset. In particular, in this setting, the temporal interdependence of the decades is not considered, and specific algorithms should be applied in the future to capture this temporal structure.

5. Conclusion and Future

We introduced a new classification task named historical phase recognition. We believe that, once we improve their performance, classification algorithms trained for this task will allow us to automatically annotate many more polities with secular cycles with a potential disruptive improvement in the study of comparative history. We believe that inter-annotator agreement can be further improved by having domain experts annotate the data. Additionally, the automatic extraction of events from short historical texts, or the definition of guidelines for their annotation, can be a valuable tool both in the annotation and classification tasks. By combining these two approaches, we can improve the dataset and make it more reliable.

For the future we plan to improve the performance of classification by including the temporal interdependence factors, and to improve the inter annotator agreement, also calculating the agreement between labels generated by models and by humans. In the future it would be interesting to add event structure annotations such as TimeML in Chronos. The poor performance in zero-shot classification using an LLM is likely a function of the sophisticated reasoning and world knowledge required to perform the task. The LLM could benefit from more advanced prompting strategies (e.g. few-shot or chain-of-thoughts) or even supervision in the form of fine-tuning.

The Chronos dataset is accessible online in viewer/-commenter mode[4]. Edit and download access is available under request.

Abstract

This paper presents an AI experiment of translation into emoji conducted on a glossary from Dante Alighieri's *Divine Comedy*. The experiment is part of a project aiming to build up an automated emoji-based pivot language providing an interlingua as a tool for linguistic simplification, accessibility, and international communication: Emojilingo (emojilingo.org). The present test involves human (Emojitaliano) and machine (Chat-GPT) translations in a comparative analysis in order to devise an automated integrated model highlighting emojis' expressive ability in transferring senses, clarifying semantic obscurities and ambiguities, and simplifying language. A first evaluation highlights Chat-GPT's ability to deal with a classic archaic literary vocabulary, also raising issues on managing criteria for better grasping the meanings and forms and about the multicultural extent of content transfer.

Keywords

Emoji, Intersemiotic Translation, Emojitaliano, Emojilingo, Large Language Models

1. Introduction

Consisting today in 3,782 icons, regularly updated by Unicode Consortium,[1] the emoji international catalogue contains signs for 😀 facial expressions, 🤷‍♂️ human gestures, 🤸 people activities, 🧑‍🍳 jobs, 🪴 plants, 🦑 animals, 🍝 food, 💡 objects, 🚊 symbols of travel, 🗼 places, 🏳️‍🌈 flags, 🔢 numbers, and 🟥 geometrical forms.

While the visual content seems to be able to provide an encyclopedic list with universal significance, ideally capable of conveying language-independent meanings, the interpretation of emojis is, on the contrary, highly arbitrary. They are strongly subject to ambiguities and variations due to linguistic, cultural, and personal specificities.

The use of emoji has considerably increased over time, and besides complementing written texts in online messages and posts as a nice means to express feelings and emotional statuses, emojis are also used to completely replace verbal language statements [1, 2].

Experiments have been carried out to explore the feasibility of using emojis as language to convey meanings through emoji-only translations. Notable examples include the popular *Emoji Dick* project, the translation into emoji of *Moby Dick* [3], or *Wonderland* [4], an emoji poster created in 2014 to reproduce the full story of Lewis Carroll's *Alice in Wonderland.* These earliest experiments, however, lack codification and, as such, cannot be considered as a language, that is, a shared system in the Saussurean sense [5]. The first translation, in fact, was crowdsourced in a free and creative way, while the second one was an individual and literal translation experiment from English.

A concrete attempt to create a truly codified emoji language can be represented by *Emojitaliano* [6].[2] Emojitaliano is an emoji code originated from a crowdsourcing experiment initiated by a social community, specifically created to share a common emoji language able to counteract the natural polysemy of emojis.[3]

Born with the translation of Collodi's *Pinocchio, The Story of a Puppet* [7] (figure A.1), the structure and glossary of Emojitaliano have been afterwards usefully reapplied for the translation of texts of different genres such

as the technical declaratory prose of the Italian Constitution (figure A.2), the Manifesto of non-hostile communication (figure A.6), the narrative prose of classic moral tales (i.e., The Wolf and the Lamb, in figure A.5), Giacomo Leopardi's lyrical poem *L'infinito*[4] (The infinite, in figure A.4).

Emojitaliano is based on the assessment of conventional meanings and syntax, capable of guaranteeing the sharing of sense by means of intersemiotic translation, beyond subjective interpretations.[5] Emojitaliano provides a grammatical structure and a shared vocabulary which can be expanded and re-shared with each new translation[8].[6]

Recent experiments have opened new research horizons in evaluating the capability of large language models (LLMs) to translate words or text into emojis. This is predicated on the assumption that, given LLMs are trained on extensive corpora sourced from the internet, they have been exposed to emojis and are able to grasp the semantics of emojis [9]. Recently, Text2Emoji [10] was proposed as an automatic translator, based on a large text-emoji parallel corpus, created by prompting the LLM, Chat-GPT (OpenAI, 2023) and EmojiLM, a sequence-to-sequence model specialised in the text-emoji bidirectional translation. Another translation experiment involving emojis, conducted by [11] is Emojinize. This experiment leverages the power of LLMs to translate text by considering both prior and subsequent contexts, which differs from next-token prediction. Emojinize disambiguates synonyms based on context, unlike a static lookup table, and harnesses the expressive power of combining multiple emojis.

Among the experiments, a first attempt using Chat-GPT to learn the Emojitaliano grammar was also carried out in 2023 by the Emojitaliano research group. Assuming the fundamental role of a conventional syntax as a basis for each shared code [12, 13], the aim was to verify the ability of LLMs to learn and reapply the Emojitaliano grammar rules to produce translations of Pinocchio on its own [14].

In this paper we present a follow-up experiment of automatic translation into emoji, focused on special vocabulary. Chat-GPT's translations of an authorial lexicon have been tested and then compared to the corresponding human solutions.The purpose is to test LLMs capabilities in autonomously rendering complex vocabulary, in the horizon of building a translation tool into emoji as a means of language simplification: the general project and the conlang itself are named Emojilingo and available online on emojilingo.org.

The paper is organised as follows: section 2 introduces the Emojilingo project *Parole di Dante*, the subject being translations in emoji of 365 words (*Parole di Dante*) from Dante's poem *Divine Comedy*. Section 3 presents the AI translation experiment carried out with two versions of Chat-GPT (3.5 and 4) [15] on the 365 Dante's words, with a focus on the method and descriptions of some examples. Section 4 provides an evaluation of the results, also obtained through AI models and through a similarity matrix, and the closing section includes conclusions and ideas on future work.

2. Emojilingo: *Parole di Dante*

The Emojilingo project is presented here as a follow up of Emojitaliano. The general idea is that, through the Emojitaliano community as control group, LLMs technologies can develop and speed up the processes of translation, enable wider and easier dissemination of the code, overcome the barriers of natural languages. The Emojilingo.org website republishes some Emojitaliano translations with English versions (see also Appendix A).

Our translation method pursues a program of conceptual linguistic simplification which can clarify linguistic meanings for the needs of international communication as well as for plain language policies [16]. The outcome never aims to replace the original sources, but rather intends to provide a vehicular code useful to approach and directly understand words in any language [17, 18].

The current work focuses on a new translation, based on Dante's poem *Divine Comedy*, titled *Parole di Dante* (*Dante's words*). It is well known that Dante's vocabulary may be difficult to understand for foreign speakers, and that a similar difficulty may occur for Italian speakers today, too, because of the many archaic or disused poetical words in the poem. Consequently, we believe that translating this vocabulary into emojis can help mitigate these comprehension difficulties and facilitate understanding.

Parole di Dante consists of 365 emojis which are the Emojitaliano translations of 365 Dante's words. The source, together with the original context and explanatory comments, was published during 2021 as a daily social media dissemination event by the Italian Accademia della Crusca.[7] On that occasion, through the participation by the Emojitaliano Twitter/X community,[8] the #emojitaliano and #scritturebrevi social community produced emoji matches for all the 365 words, one per day. *Parole di Dante* (*Dante's words*) is therefore a glossary of Dante Alighieri's *Divine Comedy* translated into emojis, with the corresponding Italian words.

Table 1
Translation experiment with Chat-GPT 3.5 (IT) and Chat-GPT 4 (IT) of Dante's "Divina Commedia". For details see section 3.1.

Term	Verse	AC Explanation	Emojitaliano	GPT-3.5 (IT)	GPT-4 (IT)	GPT-4 (IT) Explanation
lurco	Come talvolta stanno a riva i burchi, / che parte sono in acqua e parte in terra, / e come là tra li Tedeschi lurchi	'Mangione, ingordo, beone', latinismo derivato da lurcare 'mangiare avidamente'. Nel verso Dante attribuisce "lurchi" a "li tedeschi".	🥩🐺	🦉🍃	🐖🍽️	The pig emoji represents gluttony and greed, while the plate emoji recalls the act of overeating. These two emoji together symbolise a "lurk"-a spoiled and gluttonous individual.
baiulo	Di quel che fé col baiulo seguente, / Bruto con Cassio ne l'inferno latra, / e Modena e Perugia fu dolente. (Paradise Vi, 73)	A Latinism used by Dante to refer to the 'bearer' of the sign of the empire, i.e., the emperor: Dante was convinced that the universal institution of the ancient empire of Rome continued even in his time, with Arrigo VII.	📌🏅👑👨‍⚖️	👜	🧑‍🌾💼	The 'baiulo' is a professional figure who boasts of transporting something, so I chose the emoji of a worker (rural but representing the ethics of work) and a suitcase to represent the transportation.
accaffi	Poi l'addentar con più di cento raffi, / disser: "Coverto convien che qui balli, / sì che, se puoi, nascosamente accaffi"	Battuta sarcastica dei diavoli a un barattiere; accaffare è voce plebea dal significato certo di 'arraffare, acciuffare', ma d'incerta provenienza.	’🦅	🎩🤡	🧗⬇️	An emoji depicting a person climbing or scaling, followed by a downward arrow to represent the action of falling or plummeting.

During a university course exercise,[9] the glossary was later provided with the English matches.[10] A comparison between emoji solutions and English correspondences was discussed in the classroom, bringing out the feasibility of a chain translation method "text-emoji-text". As a subsequent step, the research group tried a LLMs experiment of translation from Italian and English into emojis. The resulting combination of human and AI translations, appropriately selected as will be shown below, is *Parole di Dante* in Emojilingo.[11]

3. The AI translation experiment

In this section we present the translation experiment of the 365 Italian terms from Dante's *Comedy* with Chat-GPT. On the Emojilingo website, the translations chosen by Chat-GPT 4 (from the final evaluation explained in section 4.3) are available.[12]

The very large database on which the LLM architecture is based makes us assume that the machine knows the original text, belonging to the world literary canon, and we may also assume that it knows the English version of the work, as well as it will presumably have available multilingual Dante's glossaries and commentaries. Unlike human translators, who translated on the basis of the explanations provided by the Accademia della Crusca, we decided that the only input to be given to the machine would be author's name and title of the work, instead. This approach allowed us to test Chat-GPT's "autonomous" ability to handle this special lexicon directly.

3.1. Translation Examples

In table 1 we present some examples of the translation experiment with Chat-GPT 3.5 and Chat-GPT 4 for the rendering of some terms, either rare or unusual, or now dismissed. The columns in the table are the following:

- the original Dante's *term*;
- the original *verse* containing the word;
- the explanation by the *Accademia della Crusca* (AC);
- the crowdsourced *Emojitaliano* translation;
- the *Chat-GPT 3.5 (IT)* translation;
- the *Chat-GPT 4 (IT)* translation, and
- its *explanation* by Chat-GPT 4 (IT) itself (translated into English for dissemination).

3.2. Methods

For our experiment we chose two models of Chat-GPT: Chat-GPT 3.5 (turbo-0125), and Chat-GPT 4 (0613) as our reference models, to examine the differences in machine translations between the two models. In the second phase of the project, we compared and evaluated these two versions against the human translations (Emojitaliano) .

To automatically translate the words into emojis with Chat-GPT we adopted a zero-shot prompting approach

[9] https://docenti.unimc.it/f.chiusaroli/courses/2023/28680
[10] Sourced from https://dante.princeton.edu.
[11] https://emojilingo.org/parole_di_dante_about
[12] In addition, the full data is publicly available both on an online spreadsheet (https://docs.google.com/spreadsheets/d/13vkH3a-C0OpVTm9r5daFg_y0MN8lPASwGICaa72zaGg and on GitHub (https://github.com/EmojiLingo/emojilingo.github.io/tree/main/_chatgpt)).

using OpenAI APIs.[13] Despite the archaic and often obscure vocabulary, as already mentioned, no preliminary training was provided and the only context given in the prompt was the reference to the work's title. The prompt was provided both in Italian and English (the latter using English terms), although the final evaluation was done using the Italian version. The English prompt is here provided:

> I will give you a word from Dante's Divine Comedy and ask you to invent a translation in emoji. Respond with a single translation in 2 lines of plain text (without formatting):
>
> - translation into emoji
> - brief explanation of the choice.
>
> The word is '{term}'.

In the next section we will present some comments as well as some evaluation remarks.

4. Evaluation

4.1. Initial Comments

The following are some initial comments on the examples reported in Table 1.

lurco All the translations use an animal to represent the negative qualities expressed in the text, likely due to a plausible interference from the English word 'lurk'. Chat-GPT 3.5 focuses on the environmental nocturnal context instead of the vice of gluttony. The choice of a specific animal, as the pig or the wolf, to convey negative semantic values, reflects an Eurocentric view, which raises issues for the multilingual and multicultural reception.

baiulo The human translator reproduces the complex meaning of the archaic word for "Emperor" as "bearer of the sign of Empire", while Chat-GPT translates it more simply as the action of "carrying", which simplifies but clarifies the direct meaning.

accaffi Both the human and Chat-GPT 4 translations convey the semantic value of rapid movement and aggression, while the Chat-GPT 3.5 version emphasizes the sarcastic tone used to depict despicable characters. The issue of the symbolic representation of the animal icons also emerges here.

4.2. Preliminary study

According to a preliminary evaluation, it is immediately apparent that both versions of Chat-GPT can provide interesting translation solutions of Dante's words and are able to motivate their choices in a meaningful way.

One initial observation is that the translation solutions provided by the two Chat-GPT models often include multiple emojis, with Chat-GPT 3.5 doing so 88% of the time and Chat-GPT 4 at 81%. In contrast the Emojitaliano shows a higher tendency to use single emojis, doing so in 49% of the cases.

The two Chat-GPT versions rarely provide the same translations, except for some terms related to animals, such as 'colubro' or 'lonza'. In some instances, particularly those involving realia (e.g., 'eagle', 'angel', 'book', 'galaxy'), the translations provided by Chat-GPT align with those given by human translators.

In most cases, however, the solutions generated by Chat-GPT 4 differ, as do the accompanying explanations.

The differences between the translations provided by the two versions of Chat-GPT are most often largely disparate. For example, the phrase 'dolenti note' is translated by Chat-GPT 3.5 as 😢🎵 and by Chat-GPT 4 as 🔥🎶. Additionally, there are differences in the ordering of emojis, as observed in the translation of 'occhi di bragia', where Chat-GPT 3.5 uses 🔥👀 and Chat-GPT 4 uses 👀🔥. In other instances, while both versions include a common emoji, they are paired with different additional emojis; for instance, 'inanellare' is translated by Chat-GPT 3.5 as 🔄💍 and by Chat-GPT 4 as 💍⛓️; 'colubro' is rendered with the snake 🐍 in all cases, but Emojitaliano adds the skull 🐍☠️ to convey the accurate meaning of the poisonous animal, as derived from the Accademia della Crusca comment. In some cases, Chat-GPT translations correctly grasp the core idea of the word but dismiss the figurative strength of the original: 'intuarsi', meaning 'intimate and deep understanding' and 'interpenetration between minds', is in fact one of Dante's original coinages (see also 'infuturarsi', etc.). Chat-GPT 3.5 versions of 'intuarsi' as 🔍🔮 and 🔍💡 appear not so poignant as the human literal solution seems more expressing 🧍🪄👆. Sometimes the Chat-GPT version succeeds in reproducing the sense more physically than the human one, as for 'trasumanar' 'to rise above the human', ♂️➡️👼 by Chat-GPT 4 compared with the human version 🪐 and Chat-GPT 3.5 translation 🚀🌌.

In a few cases, the translation solutions provided by both versions of Chat-GPT misinterpret the intended meaning of Dante's word. For example, Chat-GPT 3.5 translates 'zeba' (meaning 'goat') as 🦓, erroneously conflating it with a similar-looking word. Similarly, Chat-GPT 4 translates the term as 🐄💩, misinterpreting it as 'cattle dung'.

[13] https://platform.openai.com/docs/api-reference

Table 2
Results of the evaluation task by Chat-GPT 4.

	Emojilingo	GPT 3.5	GPT 4
Preferences	116	110	139
Percentage	31,8%	30,1%	38,1%

4.3. Chat-GPT 4 as evaluation agent

To evaluate Chat-GPT 4's ability to suggest the best translation solutions we organised an evaluation task run by the model itself using the human crowdsourced translation, the Chat-GPT 3 and the Chat-GPT 4 ones.

Also, in this case we adopted a zero-shot prompting approach. The original Italian prompt is translated into English as follows:

> I would like to ask you to evaluate 3 translations from archaic Italian words extracted from Dantes's Divina Commedia into emoji.
> I will provide you with:
> - The Italian word
> - Emoji translation A
> - Emoji translation B
> - Emoji translation C
> I ask you to tell me which translation into emoji do you prefer and why. Respond with 2 lines of plain text (without formatting) with the following info:
> - Choice: <emoji string>
> - Explanation: <Brief explanation of the choice>
> Here you are:
> - Italian word: term
> - Translation A: emoji1
> - Translation B: emoji2
> - Translation C: emoji3

To ensure more reliable results we instructed the model to perform 10 retries and select the most frequent answer. As the model was evaluating several translations ex aequo, we decided to reiterate the process until a difference was reached between the first and the second preferred translation. The results of this evaluation task are shown in table 2.

The data from the Chat-GPT 4 evaluation shows that Chat-GPT 4 has the highest preference score at 38.1%, followed closely by Emojiitaliano at 31.8%, and Chat-GPT 3.5 at 30.1%. This suggests that Chat-GPT 4 was generally rated more favourably compared to Chat-GPT 3 and Emojitaliano.

The distribution of proportions is essentially symmetrical and balanced. The currently preferred translations have been compiled into a corpus validated as Emojilingo.

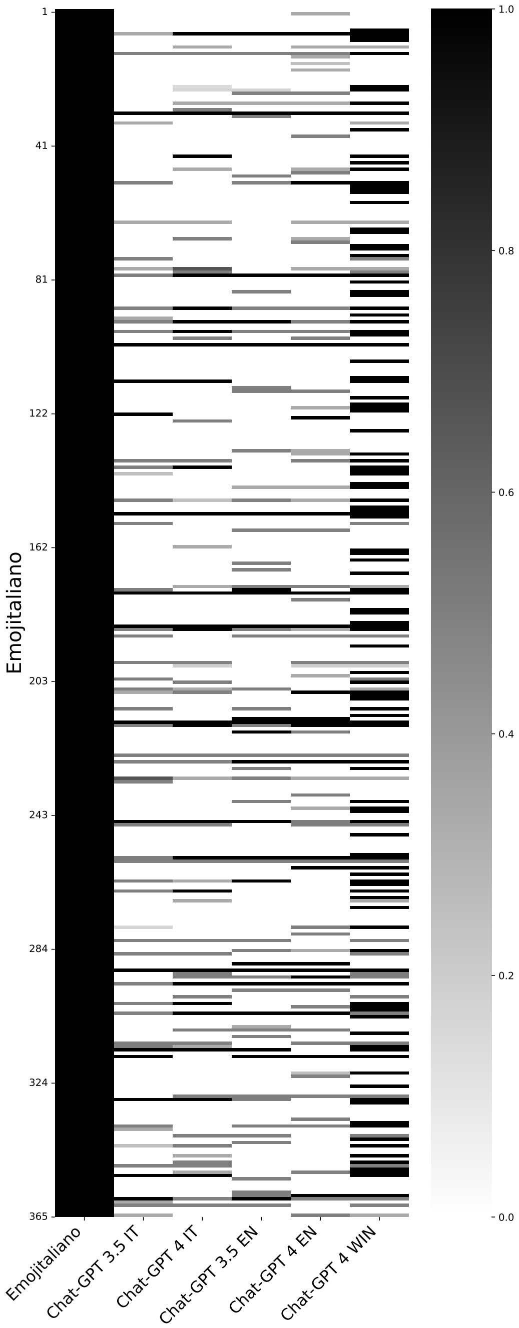

Figure 1: Similarity matrix between Emojitaliano and various versions of Chat-GPT engines.

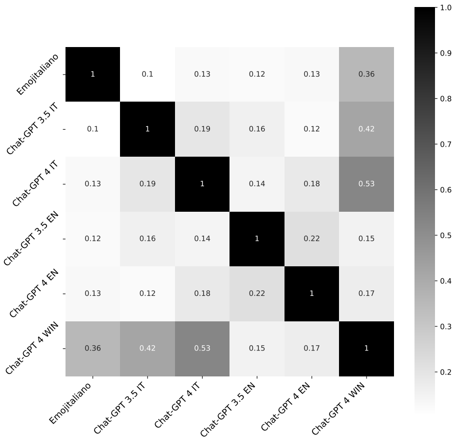

Figure 2: Similarity matrix between all models.

4.4. Similarity Matrix

In figure 1 we report the similarity matrix between all Emojitaliano 365 values and the corresponding values provided by all Chat-GPT engines (both for Italian and English).[14] In figure 2 we report the similarity matrix between all model pairs. In both figures, we include the selection of the Chat-GPT 4 evaluation agent presented in section 4.3, using the label *Chat-GPT 4 WIN*.

The similarity score between two strings, is computed using the *Levenshtein distance*: δ.[15] It is defined as the minimum number of single-character edits (insertions, deletions or substitutions) required to change one word into the other. It is then normalized (i.e., divided by the maximum length of either strings). Finally the similarity is obtained as $1 - \delta$. The similarity is 1 (black) when the two strings are identical, and 0 (white) when they have no emojis in common. In the heatmap of figure 2 the similarity between two models is computed as the mean between all the 365 term-pairs similarities.

5. Conclusion

In this paper we presented a translation experiment into emojis using two versions of Chat-GPT, to compare them with a human version, already available, realized within the framework of the Emojitaliano experience. The present project focuses on an integrated translation program, that combines both human (Emojitaliano) and automated approaches, as a basis for a constructed emoji-based pivot language: Emojilingo. Using a zero-shot prompting approach, both Chat-GPT versions (3.5 and 4) provided emoji translations for 365 words extracted from Dante's *Comedy*, along with explanations for the their own translation solutions. We also had Chat-GPT evaluate the three different translations produced within the Emojitaliano project, alongside those produced by Chat-GPT.

The present experiment substantially succeeds in confirming AI easiness and ability to use emojis to convey linguistic meanings, also managing special and archaic vocabulary. We in fact tested the machine's ability to handle denotative and connotative issues in the different translation choices, i.e. the translation solutions can be multi-faceted, each one catching some of the many semantic features underlying words. In this sense most solutions may be acceptable, such as to demonstrate the versatility of the emoji code to convey the senses.

Within this broad faculty of choice, however, some options seem quite critical, due to the dissimilarity of cultural values expressed by the languages, and by the emojis themselves. That is, a main consequence of using AI for translation, also in emojis, is the reaffirmation of the crucial challenge in international translation: the need for careful attention to specific cultural dimensions during localization [19]. Cultural values underlie texts, words and languages, as, for example, a 'pig' is an 'occidental' symbol for negative concepts as 'dirt' and 'gluttony' (as in 'lurco'), while the animal has a totemic or sacred value elsewhere; likewise, colors, or gestures, take on cultural values according to societies and cannot be accorded univocal international meanings. The choice of an icon as and international multilingual sign cannot override cultural peculiarities. Finally, cultural vocabularies may vary on the basis of literary contexts and textual genres, often conveying suggestions related to signifiers that are now lost. Given the conservative structure of poetical language, emoji translations may therefore need to move beyond the broadness of interlingua to fully convey meanings by reproducing linguistic signs 'verbatim' (es. 'intuarsi' 🧍‍♂️🪄👆): that is, the literal solution, usually ruled out from the perspective of an international semantic code, becomes substantial to recover the cultural dimension of a literary text [20]. Special care is therefore required in selecting corresponding matches in emoji so that they do not conflict with reception in different countries and societies and so that they do succeed in reaching the core content of the original, which is the main purpose of 'the emojilingua'.

Future research will always need a human evaluation of automated outcomes, carried on by a team with extensive expertise in cross-cultural perspectives, and with a deep understanding of cultural values of emojis. This will help to limit unrestricted creativity and ensure a wide common comprehension of Emojilingo, and its highest exportability.

[14] For clarity we include also Emojitaliano in the the first column, which is all black as it is identical to the original values used as reference.

CAPITOLO 1

Come andò che Maestro Ciliegia, falegname,
trovò un pezzo di legno che piangeva e rideva come un bambino.

– C'era una volta...

– Un re! – diranno subito i miei piccoli lettori.

– No, ragazzi, avete sbagliato. C'era una volta un pezzo di legno.

Non era un legno di lusso, ma un semplice pezzo da catasta, di quelli che d'inverno si mettono nelle stufe e nei caminetti per accendere il fuoco e per riscaldare le stanze.

Non so come andasse, ma il fatto gli è che un bel giorno questo pezzo di legno capitò nella bottega di un vecchio falegname, il quale aveva nome mastr'Antonio, se non che tutti lo chiamavano maestro Ciliegia, per via della punta del suo naso, che era sempre lustra e paonazza, come una ciliegia matura.

Appena maestro Ciliegia ebbe visto quel pezzo di legno, si rallegrò tutto; e dandosi una fregatina di mani per la contentezza, borbottò a mezza voce:

– Questo legno è capitato a tempo; voglio servirmene per fare una gamba di tavolino. –

Detto fatto, prese subito l'ascia arrotata per cominciare a levargli la scorza e a digrossarlo; ma quando fu lì per lasciare andare la prima asciata, rimase col braccio sospeso in aria, perchè sentì una vocina sottile sottile, che disse raccomandandosi:

La pecora e i cavalli

Una pecora tosata vide dei cavalli,
uno dei quali tirava un pesante carro,
un altro portava un grande carico
e un altro trasportava un uomo.
La pecora disse ai cavalli:
"Mi piange il cuore vedendo
come l'uomo tratta i cavalli".
I cavalli le dissero:
"Ascolta, pecora:
per noi è penoso vedere
che l'uomo, nostro signore,
si fa un vestito
con la lana delle pecore,
mentre le pecore restano senza lana".
Dopo aver sentito ciò,
la pecora se ne fuggì nei campi.

La tramontana e il sole

Si bisticciavano un giorno il vento della tramontana e il sole,

l'uno pretendendo d'esser più forte dell'altro,

quando videro un viaggiatore che veniva innanzi, avvolto nel mantello.

I due litiganti decisero allora che sarebbe ritenuto più forte chi fosse riuscito a levare il mantello al viaggiatore.

Il vento di tramontana cominciò a soffiare con violenza;

ma, più soffiava, più il viaggiatore si stringeva nel mantello;

tanto che alla fine il povero vento dovette desistere dal suo proposito.

Il sole allora si mostrò nel cielo, e poco dopo il viaggiatore, che sentiva caldo, si tolse il mantello.

E la tramontana fu costretta così a riconoscere che il sole era più forte di lei.

Towards an ASR System for Documenting Endangered Languages: A Preliminary Study on Sardinian

Ilaria Chizzoni[1], Alessandro Vietti[1]

[1] *Free University of Bozen-Bolzano*

Abstract

Speech recognition systems are still highly dependent on textual orthographic resources, posing a challenge for low-resource languages. Recent research leverages self-supervised learning of unlabeled data or employs multilingual models pre-trained on high resource languages for fine-tuning on the target low-resource language. These are effective approaches when the target language has a shared writing tradition, but when we are confronted with mainly spoken languages, being them endangered minority languages, dialects, or regional varieties, other than labeled data, we lack a shared metric to assess speech recognition performance. We first provide a research background on ASR for low-resource languages and describe the specific linguistic situation of Campidanese Sardinian, we then evaluate five multilingual ASR models using traditional evaluation metrics and an exploratory linguistic analysis. The paper addresses key challenges in developing a tool for researchers to document and analyze the phonetics and phonology of spoken (endangered) languages.

Keywords

Speech recognition, Campidanese Sardinian, Resource and evaluation, Spoken language documentation

1. Introduction

The growing interest in understudied languages has led to categorizing them on the basis of resource availability, defining them as high, low, or zero-resource languages. In the narrowest sense, zero and low-resource languages are those lacking sufficient data to train statistical and machine learning models [1] [2] [3]. However, such a technical definition is not adequate to account for the different linguistic scenarios of world languages. As a matter of fact, in the literature, the term low and zero resource languages is still used inconsistently. Sometimes, it is used to describe standard, widely spoken languages with a shared orthography, that cannot rely on many hours of transcribed or annotated speech, see Afrikaans, Icelandic, and Swahili in [4]. Sometimes, it is used for non-standard, widely spoken languages, lacking a shared orthography (no orthography or multiple proposed orthographies) as for Swiss German dialects [5] or Nasal and Besemah [6]. And sometimes to refer to non-standard, endangered languages lacking a shared orthography, like Bribri, Mi'kmaq and Veps [3].

These scenarios are mainly being addressed with two approaches: The first leverages self-supervised learning, and uses unlabeled data from the target language to learn linguistic structures [7]. Self-supervised learning is an optimal choice in low-resource settings because only requires to gather more audio data. However, it seems costly and prone to catastrophic forgetting [6] [4]. The second approach involves training a multilingual model on labeled data from highly-resourced languages and then applying the trained model to transcribe unseen target languages. This includes the benefits of a supervised learning setting and proved to be effective [8]. Pre-trained multilingual models can then be fine-tuned on just a smaller dataset of labeled data in the target language. Since fine-tuning is a straightforward, efficient approach, it is the preferred one to address the problem of low-resource languages [6]. However, the success of this approach still depends on the amount of available labeled data in the target language or whether or not it is possible to generate more, e.g., via data augmentation.

Several data augmentation approaches for low-resource languages are currently being explored, including self-learning [6], text-to-speech (TTS) [6] or optimized dataset creation approaches [9]. Bartelds and colleagues [6] propose data augmentation techniques to develop ASR for minority languages, regional languages or dialects. They employ a self-training method on Besemah and Nasal two Austronesian languages spoken in Indonesia. In self-training, a teacher XLS-R model is fine-tuned on manually transcribed data, the teacher model is used to transcribe unlabeled speech and then a student model is fine-tuned on the combined datasets of manually and automatically transcribed data. Since the collected 4 hours of manually transcribed speech for Besemah and Nasal followed different orthography conventions, the transcriptions were first normalized to working orthographies and then used for fine-tuning. In the same framework, they leveraged a pre-existing

TTS system available for Gronings, a Low-Saxon language variant spoken in the province of Groningen in the Netherlands, to generate more synthetic training data from textual sources and they achieved great results [6].

While fine-tuning paired with data augmentation techniques works for low-resource, widely-spoken languages, developing a speech recognition system for endangered spoken languages also involves ethical considerations towards the local community. More participatory research is required to understand the native speakers' relationship with the written form of their language, as well as with language technologies. In their position paper [3] Liu and colleagues emphasize the importance of creating language technologies in consultation with speakers, activists, and community language workers. They present a case study on Cayuga, an endangered indigenous language of Canada with approximately 50 native elder speakers and an increasing number of young L2 speakers. After gaining insights from the community, they began collaborating on a morphological parser. This tool aids teachers and young L2 students in language learning while gradually providing morphological annotations and segmentations useful for developing ASR systems for researchers. Blaschke and colleagues [10] surveyed over 327 native speakers of German dialects and regional varieties, finding that respondents prefer tools that process speech over text and favor language technology that handles dialect speech input rather than output. Understanding the needs of the speech community and differentiating them from those of linguistic researchers can guide research more effectively.

This paper outlines the first steps towards a speech recognition system for researchers to aid the systematic analysis of the phonetics and phonology of Campidanese, an endangered language spoken in southern Sardinia. To achieve this goal, we first describe the situation of the speech community of the target language, we then select five speech recognition multilingual and ready for inference models and evaluate them on Campidanese Sardinian. When multilingual models were not available for speech recognition task, we chose multilingual models fine-tuned on Italian, which we assume to be a relatively close language both genealogically and structurally. We assess the goodness of the models' inferences, first by computing the traditional evaluation metrics, i.e., average Word Error Rate (WER) and Character Error Rate (CER), and then carrying out a qualitative linguistic analysis to have better insights of which model best meets the needs for language documentation and research. This work is part of "New Perspectives on Diphthong Dynamics (DID)", a joint project between the University of Bozen and the Ludwig-Maximilians-Universität München, focusing on the study of diphthongs dynamics in two understudied languages, i.e., Campidanese Sardinian and Tyrolean and aims to build a corpus for the linguistic documentation of these two languages.

2. Campidanese Sardinian

Sardinian is a Romance language spoken on the Sardinia island in Italy [11]; it is considered an official minority language and is protected by National Law n.482/1999 and Regional Law n.26/1997 but does not have a written standard [12]. Sardinia has a high internal linguistic diversity but the two main macro varieties are Logudorese (ISO code 639-3 src), spoken in the northern sub-region and Campidanese (ISO code 639-3-sro), spoken in the southern sub-region of Sardinia [12]. To date, there are no quantitative studies on the real number of Sardinian speakers. The first sociolinguistic survey [13] carried out by Regione Sardegna in 2007 on 2437 speakers states that 68.4% of the respondents claim to know and speak a variety of the local languages. However, the survey was based on the speakers' self-assessment. As far as Campidanese Sardinian is concerned, Ethnologue lists it as an endangered indigenous language [14] and research [12] claims it is used as a first language just by some elder adults in the ethnic community, and not taught to children anymore. In 2017, Rattu [15] carried out a sociolinguistic survey on 310 Cagliari speakers, where a self-assessment questionnaire was followed by a language test (mostly translation tasks from Italian to Sardinian) and only a minority of respondents over the age of 45 achieved good or excellent results.

The Sardinian Regional Administration presented two proposals for an official standard language: the first in 2001, presented as a linguistic compromise but actually over representative of Logudorese (Limba Sarda Unificada LSU), and the second in 2006, mainly based on the central regional variety (Limba Sarda Comuna LSC) [12]. The latter remains the one used for communication by the Regional Administration, while in the Cagliari Province a proposal of orthographic rules for Campidanese called *Sa Norma Campidanesa* has been put forward in 2009 by the *Comitau Scientificu po sa normalisadura de sa bariedadi campidanesa de sa lingua sarda* [16]. Without discussing the issue of the orthographic norm, which is inherently political, we would like to point out that these proposals do not seem to have become part of everyday language use by the speech community [17]. This is primarily because they were not based on any official data regarding the linguistic and sociolinguistic situation or language use [18]. Therefore, these standards remained limited to administrative communications.

Some tendencies in the speakers' linguistic attitudes emerged from the DID project data collection fieldwork conducted in 2023 in the city of Sinnai. Native speakers of Campidanese are often unfamiliar with the written version of their language. Elder native speakers had no way or need to write the language, except in the last decade through social networks. Whereas, the few young people who use the language even in its written version to communicate with friends and family via message service apps, do not use *Sa Norma Campidanesa*, but rather use a transcription that intuitively approximates their pronunciation.

3. Experiments

3.1. Campidanese Sardinian dataset

We decided to evaluate the speech recognition models on a small sample of highly controlled Sardinian data, in order to carry out a qualitative linguistic analysis of the output transcription. The dataset includes short audios of read speech with an average length of 3.5 seconds (read_short), long audios of read speech with an average length of 23 seconds (read_long), and short audios of spontaneous speech with an average length of 5.3 seconds (spontaneous). Read speech is a subset of the corpus gathered during the DID project fieldwork in Sinnai. For the read_short, participants were asked to read aloud short sentences developed by the research group, using an orthography close to *Sa Norma Campidanesa*. In particular, twenty audio clips of four native speakers (2F and 2M) were selected. Two longer audio clips were selected from the same corpus: one of a female speaker reading an autograph poem, and another of a male speaker reading an excerpt of an autograph story. To have speech style variability, chunks of spontaneous speech from ethnographic interviews collected by Mereu [19] in Cagliari in 2016 were included. Twelve audio chunks were extracted from two of the interviews conducted with two male native speakers of Campidanese. The orthographic transcripts followed different Campidanese conventions either being written or validated by native speakers.

3.2. Methods

From HuggingFace's Open ASR Leader board [20], ready-to-test models with low Real-Time-Factor (RTF) values were selected. Out of the five tested models, two are multilingual models containing at least one Romance language in their training dataset i.e., `whisper-large-v2` and `multilingual-fastconformer-hybrid-large`; and three were multilingual models fine-tuned on Italian datasets and ready for inference, this is the case for `it-fastconformer-hybrid-large` from NVIDIA and `wav2vec2-large-xlsr-53-italian` and `wav2vec2-xlsr-53-espeak-cv-ft` from Facebook.

Open AI Whisper is a Transformer sequence-to-sequence multilingual and multitask model trained on performing multilingual speech recognition, speech translation, spoken language identification, and voice activity detection [21]. We tested it without passing a specific language.

The multilingual FastConformer Hybrid Transducer-CTC model is a model developed by NVIDIA, combining the FastConformer architecture with a hybrid Transducer-CTC approach [22]. NVIDIA FastConformers come across as very competitive for their efficiency and computational speed. We tested both the multilingual model version 1.20.0, trained on Belarusian, German, English, Spanish, French, Croatian, Italian, Polish, Russian, and Ukrainian [22], and the Italian model version 1.20.0 trained specifically on Italian (Mozilla Common Voice 12, Multilingual LibriSpeech and VoxPopuli) [23].

By Facebook we chose Wav2Vec 2.0 XLSR, a model that learns cross-lingual speech representations from the raw waveform of speech in multiple languages during pre-training [24]. We use `wav2vec2-large-xlsr-53-italian`, the Wav2Vec 2.0 model pre-trained on multilingual data from Multilingual LibriSpeech, Mozilla Common Voice and BABEL and fine-tuned on Italian [25]. To attempt an automatic phonetic transcription we used `wav2vec2-xlsr-53-espeak-cv-ft`, the same Wav2Vec 2.0 Large XLSR model, fine-tuned on multilingual Common Voice dataset to recognize phonetic labels [8].

In order to have a standard reference, traditional evaluation metrics for speech recognition systems like WER and CER were computed via the `evaluate` HuggingFace library [26]. Since the output text was normalized differently by the different models, a text normalization was done on both reference and hypothesis transcriptions, removing every special characters (non-alphanumeric characters) before computing WER and removing special characters and spaces (tabs, spaces and new lines) before computing CER. We made no additional changes to the inferences, and no default parameters of the models were modified. All tests were run locally to respect data privacy policies.

3.3. Models evaluation

Regarding the WER metric, we assume models to perform possible word recognition based on the inventory of multilingual or Italian tokens, since the model has not been trained or fine-tuned on any Sardinian data. This is why in our case average WER is poorly significant. We therefore evaluate performance mainly by looking at CER.

In Table 1 we can see there is little difference in the performance between Whisper medium and large-v2. Surprisingly, however, Whisper medium performs better on long read-speech data, reaching a CER of 0.22 versus Whisper large-v2 only achieving 0.36. This could be due to a better performance of the translation task in Whisper large-v2. However, the larger model performs better on spontaneous speech (CER 0.39) then the medium model

Table 1
Whisper Models

Model	Style	Length (s)	CER	WER
large-v2	read_short	3.5	0.69	1.02
large-v2	read_long	23.5	**0.36**	**0.76**
large-v2	spontaneous	5.3	0.39	0.90
medium	read_short	3.5	0.70	1.00
medium	read_long	23.5	**0.22**	**0.79**
medium	spontaneous	5.3	0.52	1.12

Table 2
FastConformer NVIDIA Models

Model	Style	Length (s)	CER	WER
FC-ML	read_short	3.5	0.69	1.00
FC-ML	read_long	23.5	**0.22**	**0.79**
FC-ML	spontaneous	5.3	0.34	0.88
FC-IT	read_short	3.5	0.69	1.00
FC-IT	read_long	23.5	**0.28**	**0.83**
FC-IT	spontaneous	5.3	0.41	0.97

Table 3
Wav2Vec XLSR Italian

Model	Style	Length (s)	CER	WER
W2V-IT	read_short	3.5	0.68	1.00
W2V-IT	read_long	23.5	**0.25**	**0.81**
W2V-IT	spontaneous	5.3	0.36	0.90

(CER 0.52). As shown in Table 2, both NVIDIA Fast Conformer models achieve low values on long audios of read speech. While multilingual FastConformer reaches the best values overall, Wav2Vec XLSR fine-tuned on Italian performs better than the multilingual FastConformer fine-tuned on Italian (see Table 3).

Overall, CER is relatively low on long read speech, which is intuitively understandable, considering the selected models have all been trained mainly on read speech (Mozilla Common Voice data and audio books). Poor performance on short audios was also expected, since all the tested models where pre-trained on longer audio chunks, ranging from 20 to 30 seconds [27] [21] [7]. Given the similar average length of the audio inputs, it is surprising that every model performs better on short spontaneous speech than on short read speech.

The relatively low CER values suggest promising potential, particularly for the multilingual models. Therefore, we decided to get more phonetically informative outputs to evaluate how well these models generalize beyond word boundaries and language-specific spelling conventions. We select `wav2vec2-xlsr-53-espeak-cv-ft`, a Wav2Vec 2.0 XLSR model fine-tuned on multilingual Common Voice dataset to recognize phonetic labels [28]. While using the exact same architecture as Wav2Vec2, Wav2Vec2Phoneme maps phonemes of the training languages to the target language using articulatory features [8]. Since the model outputs a string of tab-separated phonetic labels, we computed the CER metric only. As a reference, we used the story *Sa tramuntana e su soli* which was phonemically and phonetically transcription provided by Mereu [12]. The input file is a single 43-second audio of a young female native speaker of Campidanese Sardinian. When comparing the Wav2VecPhoneme predictions with the human phonemic transcription we get a Phoneme Error Rate (PER) of 0.28, while when comparing it with the phonetic human transcription, PER decreases to 0.23. This results suggest that an automatic transcription into phonemes rather than characters would be a path worth exploring, allowing a systematic description of the phonetics and phonology of endangered spoken languages, while bypassing the orthography issue. These results align with recent work on cross-lingual transfer [29] proposing a very similar solution to develop a multilingual phoneme recognizer.

4. Exploratory Linguistic Analysis

In this section, we present an exploratory linguistic analysis to evaluate to what extent the orthographic transcriptions from the tested ASR models capture the phonetic events present in the speech signal. The analysis is based on the inventory of phonological phenomena described for Campidanese Sardinian spoken in Cagliari [12].

In multilingual FastConformer's predictions some known phonological processes of Campidanese can be recognized. For instance, in Campidanese Sardininan the alveolar tap [ɾ] is an allophone of /r/ in word-medial intervocalic position and a sociophonetic variant of /t/ and /d/ in the Cagliari variety [12]. In examples 1 and 4, the intervocalic /t/ across word boundaries (*si lui* and *ma lui*) is transcribed as /l/, which can be considered a good orthographic approximation to an alveolar tap. Following a process of lenition of voiceless plosives and fricatives, the intervocalic labiodental fricatives /f/ across word boundaries are also consistently transcribed as their voiced counterpart /v/, see example 1 *asivato*, example 4 *con savorza* and *deno vusti*. Voiceless plosives /p/, /t/, and /k/ in word-medial intervocalic positions are expected to be realized with a long duration, in the predictions are recognized as geminate sounds, see example 5 in *deppidi* and *mascetti*, yet not always, see example 1 *depidi*. We also notice the insertion of paragogic vowels, which in Campidanese are inserted after a final consonant to avoid consonant in word-final coda position [12], as in example 1 *depidi* and *zinotenesi* or *a rosasa* in example 3. Except for *esaminat* in exemple 1 where it was expected and actually produced in the audio.

Although this model seems to propose an orthographic transcription close enough to the phonetic one, it sometimes makes systematic choices that are unfaithful to the acoustic signal. We provide an example where /u/ both in word medial and final position is generally transcribed as /o/, not only when there is an Italian equivalent or phonetically close lexical item e.g, antunietta>*antonietta*; coru>*coro*; su>*suo*; cun>*con*, but also when the item is unknown to the model ollastu>*ollasto*; dentradura>*dentradora*, giving reason to believe that the model might have information about the phonotactic constraints in Italian, e.g. no [u] in word final position.

1. esaminat si tui as fatu su percursu cumenti si depit [1]
   examina si lui asivato subercurso come zi depidi

2. e si non tenis atrus problemas in sa vida in foras [2]
   e zinotenesi a tus problema in savira in forez

3. sa vida no es stettia tuttu arrosas [3]
   savidano e stetti a dotto a rosasa

4. ma tui con sa forza de unu fusti di ollastu [4]
   ma lui con savorza deno vusti di ollasto

5. no si deppiti imperai ma sceti castiai [5]
   nosi deppidi imperai mascetti gastiai

Regarding Whisper large-v2, we notice in some cases a near-perfect Italian translation of the Sardinian input audios, see example 5 and 6 below; in others cases, a poorer Italian translation with the deletion of repetitions, as in 7. Surprisingly, in example 8 and 9 we see how the tentative translations (or identifications with the phonetically most similar lexical items in a known language) also happens to Portuguese. Similar behavior is observed in Whisper medium: tentative Italian and Portuguese translations, and hallucinations both in spontaneous and read short input audios.

5. esaminat si tui as fatu su percursu cumenti si depit
   esamina se lui ha fatto il suo percorso come si deve

6. e si non tenis atrus problemas in sa vida in foras

   em cima das evriagens o segundo mes ate faz sucesso

9. sanguidda si cuat in mesu e su ludu [8]
   sanguidas igual em mesa sulado açuludo

Similarly to multilingual FastConformer, Wav2Vec XLSR accounts for many of the phonological phenomena of Campidanese. The voiceless plosives /k/ and /p/, lenited to voiced fricatives [ɣ] and [β] when found in intervocalic environment across word boundaries [12], are transcribed as /g/ and /v/ in *gusta vingiara* and *sugauli* in example 13. While in Wav2Vec model the alveolar tap [ɾ] is rendered as /r/ instead of /l/ see *sirui* in example 10.

    sugauli coi melusu in gusta vingiara

14. ma tui con sa forza de unu fusti di ollastu
    madoi con savorza de unovusti diolastu

Unlike Whisper large-v2, Wav2Vec XLSR never performs translations and, unlike the FastConformer finetuned on Italian, does not seem to respect the Italian phonotactic constraints, see *diolastu* in example 14.

5. Conclusions and Future steps

The preliminary analysis carried out in this paper provided insight into how various speech recognition models transcribe data in a Romance language not encountered in the model training. All evaluated models improve their performance as the audio length increases. Best CER values are achieved on audio of read speech longer than 20 seconds. However, short audios of spontaneous speech with an average length of 5.3 seconds achieved a remarkably low CER, meaning better precision compared to the similarly short (3.5 seconds) read speech chunks. These results suggest that speech style might also play a role. To investigate whether the models are sensitive to speech style, other linguistic, speaker-specific, or technical variables, such as the topic, age, gender of the speaker, or the acoustic quality of the audio data, should be taken into account. For example, both datasets of spontaneous speech are produced by males over 45, and models might be biased toward an adult male speaker profile. For the time being, we attribute it to the poor representativeness of the dataset and will investigate it in future work.

[1] [He/she] makes sure you have done the proper training.
[2] And if you have no other problems in your life in general.
[3] Life has not been all roses.
[4] Yet you, with the strength of a wild olive trunk.
[5] It is not to be used but only looked at.
[6] That it is either one or two years long, and so on and so forth – that it has to – that it has to
[7] February sees the start of cheese making.
[8] The eel hides in the mud.
[9] The ox is a very important animal.
[10] The cabbage cooks best in this pan.

A controlled yet diverse dataset facilitated a qualitative linguistic analysis of the predictions. Interestingly, some models seem to follow the phonotactic constraints of the languages they have been trained on, but at the same time they generalize well to unfamiliar languages, providing quite accurate phonetically-like orthographic transcription of Campidanese Sardinian. These initial considerations should be validated with tests on a larger corpus to eliminate data bias and a more systematic linguistic analysis to avoid cherry-picking. We also plan to look in detail at the speech recognition models' architectures in order to make a informed choice at the fine-tuning phase.

In conclusion, it seems that state-of-the-art transcription models, especially multilingual ones, produce a phonetically accurate orthographic transcription of Campidanese Sardinian and thus provide a promising basis for fine-tuning. Specifically, `Wav2Vec2 large XLSR-53` and `STT Multilingual FastConformer Hybrid` proved to be the best models according to the evaluation metrics and preliminary linguistic analysis. `STT Multilingual FastConformer Hybrid` was the best and most efficient in terms of computational resources, which makes it our first choice for further testing and fine-tuning. However, it is worth noticing, speech recognition systems with orthographic output can be costly in terms of human and computational resources, poorly informative for speech researchers and uninteresting to native speakers; whereas recent work on multilingual automatic phonemic recognition seems a viable alternative worth exploring for documenting endangered spoken languages.

Controllable Text Generation To Evaluate Linguistic Abilities of Italian LLMs

Cristiano Ciaccio[1], Felice Dell'Orletta[1], Alessio Miaschi[1] and Giulia Venturi[1]

[1]*ItaliaNLP Lab, Istituto di Linguistica Computazionale "A. Zampolli" (CNR-ILC), Pisa, Italy*

Abstract

State-of-the-art Large Language Models (LLMs) demonstrate exceptional proficiency across diverse tasks, yet systematic evaluations of their linguistic abilities remain limited. This paper addresses this gap by proposing a new evaluation framework leveraging the potentialities of Controllable Text Generation. Our approach evaluates the models' capacity to generate sentences that adhere to specific linguistic constraints and their ability to recognize the linguistic properties of their own generated sentences, also in terms of consistency with the specified constraints. We tested our approach on six Italian LLMs using various linguistic constraints.

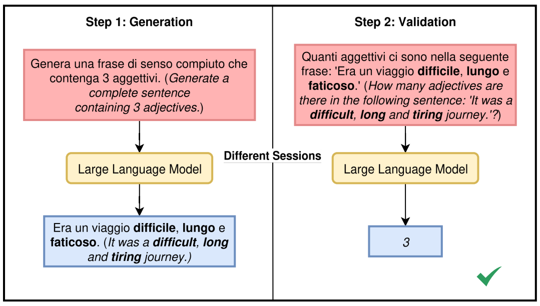
Keywords

Large Language Models, Sentence Generation, Controllable Text Generation, Linguistic constraints

1. Introduction and Background

Large-scale Language Models (LLMs) [1, 2, 3] have exhibited extraordinary proficiency in a wide range of tasks, from text generation to complex problem-solving, by producing coherent and fluent texts [4]. Their ability to understand context, generate human-like responses, and even engage in creative tasks underscores their potential in various applications. Such capabilities have been extensively evaluated against several benchmarks, as evidenced by the success of platforms such as the OpenLLM Leaderboard [5] or Italian LLM-Leaderboard [6], specifically developed to evaluate Italian models. However, despite their impressive capabilities, the evaluation of LLMs' linguistic abilities when generating sentences remains an understudied topic. In fact, while earlier works have demonstrated the implicit encoding of many linguistic phenomena within the representations of smaller models [7, 8, 9] or by prompting LLMs to assess their linguistic competence [10, 11, 12], there is no guarantee that generative LLMs can comply with such properties in generating texts.

Studies on Controllable Text Generation (CTG) indirectly assessed models' capabilities by examining their adherence to linguistic constraints [13]. For instance, [14] studied the abilities of LLMs in adhering to lexical and morpho-syntactic constraints when generating personalized texts. Nevertheless, these works are mainly focused on task-oriented scenarios (e.g. text simplification) and therefore they do not provide systematic evaluations of the linguistic abilities of these models.



Genera una frase di senso compiuto che contenga 3 aggettivi. (*Generate a complete sentence containing 3 adjectives.*)

Era un viaggio **difficile**, **lungo** e **faticoso**. (*It was a **difficult**, **long** and **tiring** journey.*)

Quanti aggettivi ci sono nella seguente frase: 'Era un viaggio **difficile**, **lungo** e **faticoso**.' (*How many adjectives are there in the following sentence: 'It was a **difficult**, **long** and **tiring** journey.'?*)

Figure 1: The diagram shows our evaluation framework composed of two main steps: the first involves the generation of a sentence that adhere to a specific linguistic constraint; while the second consists of asking the model, in a new session, to validate its own generated sentence. The reported example shows a correct case of constrained linguistic generation and validation, indicating a consistent behaviour across tasks.

From a complementary perspective, in recent years, several works have proposed diverse approaches to assess the consistency of LLMs as an essential component of the models' evaluation [15], where consistency can be defined as *"the requirement that no two statements given by the system are contradictor"* [16] or *"the invariance of its behaviour under meaning-preserving alternations in its input"* [17]. Despite their differences, all these approaches aim to understand the reasoning processes that the models employ in various reasoning tasks [18, 19] while also measuring the predictability and coherence of the models' generated responses under different conditioning inputs. Among these, [20] studied the consistency between generation (e.g. *"what is 7+8?"*) and validation (e.g. *"7+8=15, True or False?"*) of LLMs considering 6 different tasks (e.g. arithmetic reasoning, style

cristiano.ciaccio@ilc.cnr.it (C. Ciaccio); felice.dellorletta@ilc.cnr.it (F. Dell'Orletta); alessio.miaschi@ilc.cnr.it (A. Miaschi); giulia.venturi@ilc.cnr.it (G. Venturi)

transfer). [21], instead, employed several consistency checks to measure models' faithfulness and to understand whether self-explanations truly reflect the model's behaviour. Importantly, the training procedure of an LM does not explicitly target consistency [17], meaning this ability to produce non-contradictory statements eventually emerges as a byproduct of pre-training and fine-tuning. Therefore, studying models under such conditions serves as a valuable proxy for evaluating their capacity to handle different but complementary tasks, such as generation vs. validation.

In this paper, we bring together the two perspectives and propose an evaluation approach to thoroughly test the linguistic abilities of several Italian LLMs. Specifically, by instructing a model to generate sentences that adhere to a set of targeted linguistic constraints (e.g. *"Generate a sentence with 2 adjectives"*) and then asking to validate its own sentences (*"How many adjectives does this sentence have: <s>?"*), we seek to answer the following research questions: i) To what extent is an Italian LLM capable of generating sentences that adhere to specific linguistic constraints? ii) How consistent are LLM's responses to the validation questions w.r.t. the specified linguistic constraints? iii) How well can Italian LLMs recognize the linguistic features present in their own generated sentences?

Contributions. Our main contributions are:

- We propose a framework for evaluating the linguistic abilities of state-of-the-art Italian LLMs when generating text.
- We conduct extensive evaluations across different models and linguistic constraints.
- We assess models' consistency with the requested constraints and their ability to validate their own generated content.

2. Approach

For the purpose of this paper, we devised a two-step approach aimed at *i)* assessing LLMs' ability to follow a set of linguistic constraints, and *ii)* validating their ability to recognize the presence of linguistic constraints in generated sentences.

To achieve the first goal, we asked the models to generate sentences with targeted linguistic constraints corresponding to a set of morpho-syntactic and syntactic properties of a sentence, denoted as $P = \{p_1, p_2, ..., p_n\}$. In particular, for each property, we prompted each LLM to produce a fixed number of sentences having a precise value v_{p_i}, as drawn from a set of possible values $Vp = \{v_{p_1}, v_{p_2}, ..., v_{p_n}\}$. For instance, a prompt asking the model to generate a sentence with two verbs will have the following structure:

> *Genera una frase di senso compiuto che contenga 2 verbi.*
> (trad. *Generate a complete sentence containing 2 verbs.*)

Given the well-known difficulty of LLMs in producing texts with precise numerical constraints [13], we decided to constrain the models on increasing values of linguistic properties Vp_i, to evaluate their ability also to generate sentences following incremental constraints. Our premise lies in the fact that while an LLM may struggle to precisely generate a sentence with an exact value of a particular linguistic property, it is likely to be sensitive to incremental values, i.e. it can generate a sentence characterized by either the absence or the frequent occurrence of a linguistic property.

As a second step, we validate each model against their own samples:

> *Quanti verbi ci sono nella seguente frase: <s>?*
> (trad. *How many verbs does this sentence have: <s>?*)

where <s> corresponds to the sentence that the same LLM generated in the previous step. This validation process was conducted by evaluating the models' responses against the requested linguistic constraints' values and the actual property values generated by the models. Here the goal is twofold: first, to measure the linguistic consistency of a model, that is if the requested features in the generation step align with the ones found by the model in their own samples; secondly, to assess the models' ability to correctly recognize the actual properties of their generated sentences.

Due to some models struggling to produce reliable responses in a zero-shot scenario, we experimented with a few-shot scenario[1] to ensure more comparable results.

2.1. Linguistic Constraints

The linguistic properties P we employed as constraints in the generation process include raw, morpho-syntactic, and syntactic properties of a sentence. In particular, we tested the following ones: the length of the sentence in terms of tokens (*n_tokens*); a subset of Part-Of-Speech (POS) as defined by the Universal Dependency (UD) project [22], i.e. noun (*NOUN*), verb (*VERB*), adjective (*ADJ*) and adverb (*ADV*); the number of subjects and objects in a sentence (*subj* and *obj*), and the number of subordinative clauses in a sentence (*subord*) still as defined by the UD framework. These properties have been shown to play a highly predictive role when leveraged by traditional learning models on various classification problems and can also be effectively used to profile the knowledge encoded in the internal representations of

[1] See Appendix B.1 for details.

Details of the LLMs used in our experiments. The *Pre-train* column indicates if the model was pre-trained exclusively on Italian, the *SFT/IT* column shows whether the model underwent a supervised fine-tuning (SFT) or instruction-tuning (IT) phase for adaptation to the Italian language, and *CPT* (*Continual Pre-training*) indicates whether the model underwent a continual pre-training phase on the Italian language.

a pre-trained Transformer-based model and to enhance their linguistic abilities [23, 24].

Constraints Selection.

To ensure the selection of authentic property values, we relied on different sections of the Italian Universal Dependency Treebank (IUDT) version 2.5 [25], namely ParTUT [26], VIT [27], ISDT [28], PoSTWITA [29] and TWITTIRÒ [30]. To avoid dealing with excessively short or long sentences, possibly containing non-standard values, we filtered the treebanks to retain only sentences containing a minimum of 5 and a maximum of 40 tokens. The resulting dataset contains 26,744 sentences. Starting from this subset, we selected five increasing values for each linguistic property[2]. Specifically, we asked each model to generate 100 sentences for every value v_{p_i} within the set of five values V_p, thus obtaining a total of 500 sentences per property.

Moreover, since we performed our experiments in a few-shot scenario, we used 5 exemplar sentences for each linguistic property extracted from IUDT.

2.2. Models

We evaluated several Italian LLMs, with parameter counts ranging from 7 to 9 billion. We specifically leveraged the instruction-tuned variants of these models to assess their ability to adhere more closely to prompts containing detailed instructions. Importantly, we selected models that differ across several factors (architecture, the amount of pre-training and instruction tuning data, the language adaptation strategy, etc.) in order to investigate how these characteristics impact performance. The overall models used in our experiments are: ANITA [31], Camoscio [32], Cerbero [33], DanteLLM [6], Italia[3] and LLaMAntino [34][4].

2.3. Evaluation

Both steps of analysis were evaluated using two metrics. First, we computed the Success Rate (SR) for each model and linguistic property. Specifically, for the generation of sentences with linguistic constraints, we measured the SR as the fraction of times the model generated a sentence whose property value exactly matched the requested value. For the validation step, we computed the SR as the fraction of times the model's response accurately matched *i)* the requested linguistic constraint (consistency) and *ii)* the property value of the generated sentence.

As previously mentioned, given the difficulty LLMs have in following precise numerical constraints, we relied also on a metric that measures the models' abilities to comply with increasing values rather than precise ones. For the evaluation of the generation step, we calculated the Spearman correlation coefficients (ρ) between the increasing property values we requested and those extracted from the generated sentences. This metric provides an overall picture of the models' ability to follow constraints at a macro level, including increasing, decreasing, or removing a specific property when asked. For the validation step, the ρ correlation was computed between the responses produced by the model and *i)* the requested linguistic constraints, and *ii)* the property values of the generated sentences.

Models' generated sentences were linguistically annotated with Stanza [35] and further analyzed using Profiling-UD [36], a web-based application that captures multiple aspects of sentence structure. The tool extracts around 130 properties representative of the underlying linguistic structure of a sentence, derived from raw, morphosyntactic, and syntactic levels of sentence annotation, all based on the Universal Dependencies (UD) formalism [37]. Thus, it allows computing the distribution of the set of constrained linguistic properties P and their values within generated sentences.

3. Results

3.1. Sentence Generation

Table 2 reports the results in terms of Success Rate (SR) and Spearman correlation (ρ) obtained for each model and each linguistic property. When examining the average scores across all linguistic constraints (*Avg* column), we notice that the model rankings remain consistent across both evaluation metrics. Specifically, ANITA consistently outperforms the other models on average, while Italia (SR) and Camoscio (ρ) perform the worst. Interestingly, the scores do not correlate with the models' parameter sizes; for example, the largest model, Italia, ranks poorly in terms of SR. However, a distinction is

[2] The set of properties values are reported in Appendix B.2.

evident between architectures: models with more recent, higher-performing architectures like ANITA (based on LLaMA 3), DanteLLM, and Cerbero (both based on Mistral) tend to excel. Notably, ANITA stands out with its base model, LLaMA 3, being pre-trained on an impressive dataset of 15 trillion tokens and having already undergone an instruction tuning and alignment phase using both Proximal Policy Optimization (PPO) [38] and Direct Preference Optimization (DPO) [39] in the English language. This suggests that the aforementioned strategy may enhance instruction-following abilities since also DanteLLM was instruction-tuned on Italian starting from the English-instructed version of Mistral. On the contrary, Cerbero, which is based on the non-instruct version of Mistral, obtained lower performance compared to DanteLLM. Given the lack of insight into the models pretraining data and the importance of understanding this phenomenon, further study on the impact of instruction tuning before language adaptation is encouraged.

Linguistic Properties. When we analyze which linguistic constraints the models followed the most, we observe notable differences between the two evaluation metrics, highlighting their complementarity and their ability to capture diverse aspects of the models' constrained sentence generation capabilities. Specifically, the rankings of linguistic properties based on SR and Spearman correlation scores differ significantly. On average (*Avg* row), the top three linguistic characteristics with the highest SR are the use of subordination, subjects and objects (paired with adjectives). In contrast, the top three characteristics with the highest Spearman scores are the length of the generated sentences (*n_tokens*), the use of adjectives, and verbs. Interestingly, in terms of SR, on average the models struggle with generating sentences featuring a specific length in terms of the number of tokens. One possible explanation for this behaviour could be that, although sentence length can be considered a basic property, its wide range of variation makes it challenging for an LLM to generate sentences with an exact number of tokens compared to other properties. Conversely, *n_tokens* achieves the highest Spearman scores among all models indicating that the models are still capable of following an increasing trend in token constraints.

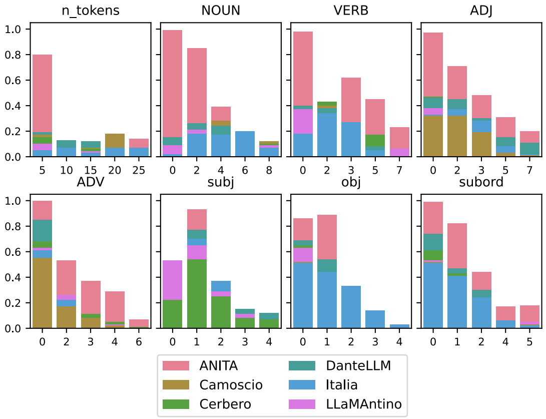

Figure 2: Success rate for each linguistic property and each model. Scores are reported for each group of feature values.

Figure 2 illustrates, for each model and each property, the SR scores obtained in the generation of sentences with a value v_{p_i}, reported on the x-axis. This analysis enables us to identify linguistic control elements that models can adhere to more accurately, thereby indicating their proficiency in mastering specific property values within the spectrum of Italian language possibilities. Generally, models achieve lower scores for high property values, while scores tend to be higher when the property value is 0, indicating the absence of the given property. These contrasting trends suggest that models can differentiate between generating sentences with or without a specific property and face greater difficulty with higher property values, which may be less common in Italian. An interesting exception is the *subj* property, where SR scores increase as the property value rises from 0 to 1. This indicates that models are less accurate at generating sentences without a subject.

Table 4
Success rate and Spearman correlation coefficients (*SR/ρ*) between the features extracted from the generated sentences and those predicted during the validation step. The best and worst scores for each property and each metric are highlighted in **bold** and *italic* respectively. Non-statistically significant correlation scores are reported with *##*.

3.2. Sentence Validation

As mentioned in Section 2, the validation step of our study is two-fold.

Consistency. Table 3 presents the results of the validation of the consistency of the LLMs, evaluated against the requested linguistic constraints' values. The results are reported for two sets of generated sentences: the entire set (*Cons.* in the table) and the subset including only the sentences generated by correctly following the constraints (*Cons.+*)[5]. A first observation concerns the fact that the scores, both in terms of SR and Spearman, are higher when we consider the *Cons.+* set. This suggests that when the models generate sentences that precisely adhere to the requested values, they tend to answer the validation question more accurately, thus showing greater coherence with the requested constraints. However, we can notice some differences across LLMs, linguistic characteristics and evaluation metrics.

By focusing on the ranking of the LLMs (*Avg* column), we find that ANITA is the most coherent model in terms of both SR and Spearman scores. This aligns with the results discussed in Section 3.1: the model that demonstrated the best controlled generation abilities is also the most capable of correctly answering the validation question and the most consistent with the requests. When we focus on the analysis of the linguistic constraints we observe some differences between the two evaluation metrics considered. In terms of SR, both for *Cons.* and *Cons.+*, we notice that the constraints the models are better able to follow (see Table 2) are also those the models can better recognize in the generated sentences. Specifically, these are the three syntactic properties of the sentence we considered (*subj*, *obj*, *subord*). Two main exceptions are ANITA and Camoscio. ANITA, while being the best model in generating sentences with the exact number of requested tokens (*n_tokens*), is the least able to recognize the length of the generated sentences. On the contrary, for the same constraint, Camoscio, with only a 0.1 SR in sentence generation, is the model most capable of correctly answering the validation question. Such a direct relationship with the generation abilities is less observable for the evaluation in terms of Spearman correlation scores. Namely, the ranking of the Spearman scores in the *Avg* row in Table 3 does not align with the ranking in Table 2. For example, consider the sub-

[5] Note that for this subset, the number of sentences for each model and linguistic property varies as detailed in Appendix C.

ject constraint: while it is the constraint that models are, on average, least able to incrementally follow, it is the one with which they are most consistent in terms of the requested values.

Recognizing linguistic properties. Table 4 reports the results of the second validation step. A general comparison between the *Avg* column here and the corresponding column in Table 2, reveals different trends, depending on the evaluation metric. This highlights that our approach effectively distinguishes the models' varying abilities. Specifically, in terms of SR, most models, except ANITA, show a stronger ability to recognize the linguistic properties of their own generated sentences than to correctly generate sentences with the requested constraint. Conversely, when considering Spearman evaluation, four out of the six models, i.e. ANITA, Camoscio, DanteLLM, and LLaMAntino, demonstrate greater proficiency in generating sentences following incremental constraints than in validating the linguistic properties of those sentences. A final remark concerns the ranking of the linguistic features (*Avg* row in the table). It generally aligns with the one discussed in Section 3.1 for both evaluation metrics. The main exception is the models' ability to recognize the exact number of subjects in their own generated sentences. This linguistic characteristic is the best recognized on average across the models in terms of SR (0.44), which is notably higher compared to the average SR of the generation abilities (0.27).

4. Conclusion and Future Works

In this paper, we presented the results of a new framework to extensively evaluate the linguistic abilities of Italian LLMs when generating sentences according to multiple linguistic constraints and, subsequently, when validating the linguistic properties of their own outputs. Results showed that models' architectures and dimensions of pre-training data have an impact on their ability to correctly follow the constraints, with ANITA being the best-performing model across all configurations. When validating each model against their own generated sentences, we noticed that i) LLMs tend to be more consistent with the requested constraints when they correctly followed them during the generation phase, and ii) the generation abilities do not always align with the ability of the models to recognize the linguistic properties of their generated sentences.

Our findings also highlighted that the evaluation metric chosen can significantly affect the results, underscoring the complexity of evaluating LLMs and the necessity for further research in this direction.

Considering that the evaluation of LLMs is an ongoing and multifaceted effort across all languages, we believe that this study opens the way for numerous further in-depth analyses focused on various aspects of evaluation. Among other aspects, we could evaluate the overall quality of the generated sentences, which we have not accounted for so far. Preliminary investigations revealed that the overall quality of the generations varies across Italian LLMs, with Italia appearing to be the most fluent[6]. Thus, future research should also involve a more comprehensive evaluation that compares the linguistic abilities of LLMs with their fluency and grammaticality.

A. Model details

The following section briefly discusses each model's peculiarities related to the training strategy, data and architecture to show the key differences between the tested models.

LLaMAntino 7B [34][7] is an instruction tuned language model based on Meta's LLaMA 2 7B [2]: a decoder-only transformer pre-trained on 2 trillion tokens of multilingual texts. The language adaptation phase was performed using QLoRA [40] on the filtered Oscar Dataset for the Italian language released by Sarti et al. [41] (20 billion tokens). The model was further instruction tuned on the Italian translated Dolly dataset [8].

ANITA 8B [31][9], is an instruction tuned model based on Meta's LLaMA 3 8B Instruct, a decoder-only transformer pre-trained on 15 trillion tokens of multilingual texts and further instruction tuned and preference aligned with DPO [39] and PPO [38] using QLoRA. Differently from LLaMAntino, ANITA delays the language adaptation phase by firstly undergoing an instruction tuning and DPO alignment in English on a set of ≈100k prompts[10]. Later, the model is adapted to the Italian language by performing SFT on a small sample of 100k examples from the Clean Italian mc4 Corpus [41].

Camoscio 7B [32][11] is an instruction tuned model based on Meta's LLaMA 7B [2], a decoder-only transformer pre-trained on 1 trillion tokens of English text. Camoscio was developed by performing SFT with LoRA [42] on the translated Alpaca [43] instruction dataset.

DanteLLM 7B [6][12] is an instruction tuned model based on the instruct version of Mistral 7B [3], a transformer decoder-only model pre-trained on internet-scale data (there are no public information on the data used for pre-training). DanteLLM is the result of a LoRA instruction tuning on the Italian SQuAD [44], Europarl dataset [45], Alpaca and Italian Quora [46, 47].

Cerbero 7B [33][13], is an instruction tuned model based on Mistral 7B. Differently from the other models, Cerbero avoids PEFT (such as LoRA/QLoRA) and directly finetunes Mistral 7B on the Fauno Dataset [47] and a synthetically generated chat dataset.

Italia 9B[14] is an instruction-tuned transformer model pre-trained from scratch on trillions of tokens of Italian texts. The company behind the model hasn't released detailed information on the data and architecture.

B. Further details on the experiments

B.1. Generation parameters and technical set-up

For the generation of linguistically constrained sentences we set the same parameters across all models: as decoding strategy we used nucleus sampling [48] (top-p = 0.92, top-k = 50, temperature = 0.8); in order to further ensure diversity during generation we randomly sample 1/3 tokens of the last generated sentence and set their probabilities to *-inf* for the next generation step exclusively. In the validation step the decoding is set to be greedy. Due to some models producing explanations and other uninformative textual data we relied on a 5-shot conditioning and on regular expressions to extract the sentences. Given a system prompt sys_p, a linguistic feature $feat$ and a value v, the linguistically constrained sentence generation task is formatted as follows:

> sys_p + Genera una frase di senso compiuto che contenga + v + $feat$. Non fornire spiegazioni.
> (trad. sys_p + Generate a complete sentence containing + v + $feat$. Do not give explanations.)

While in the validation step the model is prompted about recognising the linguistic properties of its own sentence $sent$:

> sys_p + Quante $feat$ ci sono nella seguente frase: '$sent$'? Non fornire spiegazioni.
> (trad. sys_p + How many $feat$ are there in the following sentence: '$sent$'? Do not give an explanation.)

For each model we used the author's recommended chat template and the specified system prompt when available, otherwise we exclude it. All models are loaded

Abstract

In this paper we address the problem of modal sense classification for the French modal verb *pouvoir* in a transcribed spoken corpus. To the best of our knowledge, no studies have focused on this task in French. We fine-tuned various BERT-based models for French in order to determine which one performed best. It was found that the Flaubert-base-cased model was the most effective (F1-score of 0.94) and that the most frequent categories in our corpus were material possibility and ability, which are both part of the more global alethic category.

Keywords

pouvoir, modal verbs, Modal Sense Classification, BERT, modality, French

1. Introduction

In this paper, we present our research into the automatic disambiguation of the French modal verb *pouvoir* (in English, this verb can be translated by can, could, may or might) in a corpus of semi-structured interviews[1]. This problem statement is part of a broader quantitative and qualitative analysis currently underway on modal markers in order to better understand which kinds of modal categories are prevalent in this kind of corpus. As an NLP task, the problem of the automatic disambiguation of modal markers relies on what is generally called “modal sense classification” (MSC). As far as we know, no studies have focused on disambiguating modal verbs using a machine learning approach in French. Our aim is to fill this gap by finding the best fine-tuned BERT model to classify the semantic values of the French modal verb *pouvoir* in a transcribed spoken corpus. The article is organized as follows. In section 2 we review related work on the task of modal sense classification. Section 3 describes our corpus and our linguistic model. Section 4 presents the annotation of the corpus with an annotation scheme. Section 5 presents our experiments in fine-tuning different BERT models in order to choose the most effective one. Finally, in section 6 we discuss our results and in section 7 we close our contribution with conclusions and suggestions for future research.

2. Related work

The first study to focus exclusively on modal sense classification was [1], who proposed logistic regression models for each modal verb in English, based on an ensemble of hand-crafted syntactic and lexical features. It was also the first study to present an annotation scheme and an annotated news domain corpus. Further studies pointed out the problem of the biased distribution and sparsity of data used in [1]. For example, two of these studies, [2] and [3], suggested creating a larger and balanced dataset using a paraphrase projection approach from German data (English-German parallel corpus of film subtitles and proceedings from the EU Parliament). More specifically, [2] updated the original feature set with semantic features. [3] also updated the original features of [1] with lexical and discourse features to improve the performances of the classifiers; in addition, they explored the influence of genre on the classification of modal verbs. Lastly, [4] proposed the most accurate and flexible alternative to classifiers based on manually engineered features. Their model is based on a CNN architecture and is able to automatically extract features that are relevant for classification (word embeddings). By adapting the model to German, they demonstrated the model’s ability to generalize across different languages. [5] introduced another model architecture in which a simple classifier is fed with a combination of three sets of hand-crafted features and a concatenation of pre-trained embeddings of context words. This representation of the modal context was obtained by testing various weighting schemes. More recent studies have attempted to solve the problem as a classical modal sense classification task by probing BERT architecture [6]. BERT-based models do not need a hand-crafted feature set and they are claimed to be better at capturing contextual information than previous models. [7] showed that BERT does not have a unique representation for each modal sense, but, given the same semantic

[1] The code and the annotated corpus is available on GitHub https://github.com/DiegoRossini/Modal-verbs-modality-detector. The model is available at https://huggingface.co/DiegoRossini/flaubert-pouvoir-modality-detector

value, BERT encodes it differently for each modal verb. For this reason, individual classifiers for each verb perform better than a classifier for each modal sense. Finally, [8] used BERT's last hidden layer representations of the English modal verbs and their context to feed a k-nn and logistic regression model. In addition, they tried to train a single common model for all the modal verbs but they showed that for some of them, including can and could, this does not improve the results. [8] used the [1] and [2] datasets and also introduced a new and richer dataset from COCA[2], characterized by 5 genres including the spoken genre.In general, BERT-based models outperform the frequency baseline and previous models for almost all modal verbs. Regarding French, as far as we know, no research has yet focused on the disambiguation of modal verbs using a machine learning approach. The only NLP approach is [9] which studied the notion of "possible" and adopted a symbolic approach with a set of rules to semantically annotate epistemic possibility. The present paper aims to fill this void by using a BERT architecture to solve the MSC task in a transcribed spoken French corpus. We present here the work carried out for the disambiguation of the modal verb *pouvoir*.

3. Corpus and linguistic model

This section presents our corpus (3.1) and the linguistic model (3.2) on which the annotation scheme is based.

3.1. The ES_CF corpus

Our corpus – named here corpus ES_CF – is composed of 221 semi-structured interviews extracted from two different corpora[3]. In the first corpus, named Eslo[4], we selected 207 interviews featuring questions to the citizens of Orléans about their habits and feelings regarding their city. In the second one, named CFPP[5], we selected 14 interviews containing similar questions but focusing on the city of Paris. An automatic tool, named ModalE, described in ([10]; [11]), was employed to count the different modal categories that are present in these two corpora. The tool is built on the typology proposed by [12]. Each French modal marker is associated with one or more modal categories depending on its more or less polysemous nature. The results indicate that the verb *pouvoir* is among the four most frequent modal markers[6] in the ES_CF corpus which contains globally 150.000 modal markers. The marker *pouvoir* is a "highly polysemous" marker as it can potentially be part of three categories: alethic, epistemic and deontic (see section 3.2 for their examination in detail). In order to determine the semantic value of each instance of polysemic modal markers, we propose a NLP approach for disambiguating the modal verb *pouvoir* in its context. Our approach is based on the linguistic model of [12].

3.2. Linguistic model for analysing semantic values of *pouvoir*

In French, several studies have focused on elucidating the various contextual meanings of the modal verb *pouvoir*, e.g. ([13]; [14]; [12]). In order to build our annotation scheme (see section 4.1), we rely on the analysis presented in [12]. This is the model that was used in the ModalE tool used for extracting modal markers [10]. As mentioned in section 3.1, this tool assigns 3 possible global modal categories to *pouvoir*: alethic, epistemic and deontic. A deeper analysis of pouvoir, based on [12], led us to consider that this modal verb can have 6 possible refined modal categories (see table 6): 4 belong to the alethic category (descriptive judgements on a reality independent of the subject), 1 is part of the epistemic category (descriptive judgements referring to a subjective evaluation of the reality by the subject) and 1 belongs to the deontic one (prescriptive judgements based on institutions or systems of conventions). In [12], the values of "possibilité matérielle" (material possibility) and "capacité" (ability) are first [12, p. 442] presented as two distinct values, and later [12, p. 448] as part of a single one. Since this ambiguity is not resolved in Gosselin's typology, we decided to treat them as two distinct values.

4. Corpus annotation

In order to follow a supervised learning procedure, it is necessary to have a manually annotated corpus. We describe here the process of manual annotation (4.1) and the constitution of 4 different versions of our annotated corpus (4.2) that we used for the experiments detailed in section 5.

4.1. Annotation procedure

Table 2 presents the elements of our annotation scheme based on [12]'s typology summarized in table 6 (for a fuller version with examples and definitions, see A). Table 2 shows the 7 possible modal categories of *pouvoir*

[2] https://www.english-corpora.org/coca/

[3] Among the different types of interviews and recordings which are present in these two corpora, we have extracted only the semi-structured interviews between an interviewer and an interviewee

[4] https://www.ortolang.fr/market/corpora/eslo (700 recordings in total).

[5] https://www.ortolang.fr/market/corpora/cfpp2000 (60 recordings in total).

[6] the others: "bien" (well) (7.3% of the total modal markers), "dire" (to say) (6.9%), "savoir" (to know) (5.6%), "pouvoir" (4.94%).

Table 1
Gosselin [12] categories for *pouvoir*

global modal categories	modal categories	examples
aléthique (*alethic*)	sporadicité (*sporadicity*)	Les alsaciens **peuvent** être obèses. (*Alsaciens may be obese.*) [12, p. 442]
	possibilité matérielle (*material possibility*)	D'ici on **peut** voir la mer. (*From here, one can see the sea.*) [12, p. 442]
	capacité (*ability*)	Maintenant qu'il est déplâtré, il **peut** marcher. (*Now that his cast has been removed, he can walk.*) [12, p. 442]
	possibilité logique (*logical possibility*)	Un triangle isocèle **peut** avoir un angle droit. (*An isosceles triangle can have a right angle.*) [12, p. 448]
épistémique (*epistemic*)	éventualité (*eventuality*)	Il **peut** faire beau cet après midi. (*The weather could be nice this afternoon.*) [12, p. 442]
déontique (*deontic*)	permission (*permission*)	Vous **pouvez** sortir. (*You can go out.*) [12, p. 442]

(the logical possibility category is included in the annotation scheme even though we did not find any examples in our corpus). We have also added an "undetermined" category, which includes the occurrences of *pouvoir* for which an annotator hesitates between two or more values and the ones that we were unable to annotate due to a lack of context. We annotated 24 interviews from the ES_CF (17 from the Eslo corpus and 7 from the CFPP corpus) with an average length of 15,000 tokens. The annotation was carried out by three annotators (first author and two linguistic masters students) using Glozz [15]. We then calculated two inter-annotator agreements using Fleiss' Kappa. The first one is called "strict" and includes the 6 values (excluding logical possibility). For the second one, denominated "broad", we decided to merge "ability" and "physical possibility" into a single category called "physical possibility and ability" because of the ambiguity that persists in Gosselin [12]'s typology (see section 3.2), confirmed also by the frequent disagreement between annotators on these two categories. We obtained a result of 0.6 for the strict inter-annotator agreement and 0.66 for the broad inter-annotator agreement. Since the result of the broad inter-annotator agreement was better, we decided to adopt this version of the annotated corpus for training. The model was trained on all the categories except for logical possibility and the "undetermined" category. The total number of occurrences of *pouvoir* manually annotated in the corpus is 879[7].[8]

4.2. Corpus preparation

Table 2
The 7 categories of *pouvoir* in the annotation scheme

global modal categories	modal categories
alethic	sporadicity
	material possibility
	ability
	logic possibility
epistemic	eventuality
deontic	permission
undetermined	undetermined

In order to effectively train and evaluate our classifier for detecting the semantic value of the French verb *pouvoir*, we prepared 4 distinct datasets, each crafted to address specific challenges and enhance performance (see examples in C).

- **Corpus Base**: this dataset contains 776 sentences with at least one occurrence of *pouvoir*. Serving as our foundational dataset, it suffers from an imbalance in the distribution of modality categories. This imbalance could bias the classifier toward more common categories, making it essential to address this issue in subsequent datasets.
- **Corpus Base Augmented**: to rectify the imbalance observed in the "corpus base", we created this augmented dataset containing 1716 sentences. We employed data augmentation using the cc.fr.300.bin model and the gensim library for lexical substitution. This process balanced the distribution of modality categories, resulting in a more evenly distributed training set for our classifier.
- **Corpus Context**: considering the significant influence of surrounding context on the meaning of the modal verb *pouvoir* we constructed a third dataset (776 sentences with context). This dataset includes sentences with *pouvoir* along

[7] sporadicity (71 occurrences), material possibility or ability (448), eventuality (131), permission (229)

[8] The annotated corpus is available on GitHub: https://github.com/DiegoRossini/Modal-verbs-modality-detector

with one speaker's phrase before and after, offering a broader contextual framework to help the classifier better understand the modal sense of *pouvoir* and make more accurate predictions (see .

- **Corpus Context Augmented**: this fourth and final dataset combines the benefits of both data augmentation and expanded contextual framing (1716 sentences with context).

5. Experiments and results

In our experiments, the primary objective was to identify the most effective configurations regarding training data and model selection for the token classification of the French modal verb *pouvoir*. We chose to perform token classification to isolate occurrences of *pouvoir*, enabling us to label them with the specific categories we developed. The primary evaluation metric used across these tests was the F1-score, which harmonically combines precision and recall. This metric is particularly crucial in scenarios such as ours where class imbalance is significant; over 97% of the dataset constituted the non-*pouvoir* class labeled "O". This label was used to mark all tokens that did not correspond to instances of *pouvoir*, allowing the model to focus specifically on identifying and classifying the modality of *pouvoir*'s occurrences.

5.1. Training Data selection

Initially, the corpus listed in 4.2 was experimented upon using the camembert-base model with a stratified train-validation-test split of 80-10-10 over seven epochs to determine the most effective training data. This split allowed us to monitor model performance on a small validation set during training, and the augmented context corpus (corpus_context_augmented) proved to be superior, achieving an F1-score of 0.90 in evaluation and 0.88 when the "O" class was excluded. These results indicated that data balancing coupled with contextual enhancements significantly benefits model performance. After identifying the corpus_context_augmented dataset as the optimal choice, we applied a 5-fold cross-validation strategy to evaluate the model's robustness. This cross-validation process was conducted on the 80% training portion of the dataset, while the 20% test set remained untouched. Cross-validation yielded further improvements in model performance, solidifying the combination of the corpus_context_augmented dataset and the camembert-base model as our most reliable setup.

5.2. Model performance comparison

After determining the optimal training data setup, we tested various pre-trained models to assess their effectiveness in the modal classification of the French verb *pouvoir*. Throughout this phase, we maintained the stratified 80-20 split for training and testing, ensuring that the 20% test set remained unseen for final evaluations. For all models tested, the training set was subjected to 5-fold cross-validation during training to leverage its demonstrated benefits. As shown in table 3, the best performing model was the flaubert-base-cased which achieved an F1-score of 0.94 and 0.92 when the "O" class was excluded[9]. One possible reason for its superior performance could be attributed to the extensive and diverse pretraining corpus it was trained on, which is specifically designed to capture various nuances of the French language. Given that our dataset is based on oral corpora, the flaubert-base-cased model may be particularly well-suited for this type of data, as the other models have been trained on less diversified data forms. In the final evaluations, the flaubert-base-cased model demonstrated strong performance in identifying non-modal occurrences and distinguishing specific modalities such as "eventuality" and "permission" (see confusion matrix and results per category in appendix B). However, it encountered some challenges with the "material possibility or ability" category, indicating slight semantic overlaps. The confusion matrix corroborates these findings, showing minimal misclassifications, particularly between categories such as "material possibility or ability”. This final analysis highlights that holistic advancements in both model selection and detailed category definition refinement are crucial. By leveraging models optimized for the French language such as FlauBERT, alongside meticulously curated and balanced training data, the task of modality classification for *pouvoir* is approached with an increasingly nuanced understanding and precision, promising further enhancements and consistency in future NLP applications of the same kind.

Table 3
Best model selection experiment result

model[10]	F1-score	F1-Score without "O" category
roberta-base	0,89	0,86

6. Discussion

The semantic substitution process was particularly challenging due to the resource-intensive nature of available models such as FastText[11] and the complexity of handling text derived from spoken language. Our approach involved using Spacy to capture verbs, determining the most semantically similar verbs with FastText, and then conjugating them to match the form of the original verbs. This sequence of operations proved extremely resource-demanding and difficult to implement. Additionally, Spacy and FastText both demonstrated significant difficulties with the French language, leading to several inconsistencies during lexical substitution. These findings underscore the need for more robust, language-specific tools to improve the accuracy and efficiency of semantic substitution in NLP tasks involving French, particularly with spoken text.

If we take a closer look at the model's results, we notice that "permission" is the second best classified category with an f-score of 0.95. However, a qualitative analysis of the classified sentences revealed some incongruences. Among the various uses of *pouvoir* with the value of permission, there are two that are very frequent (40% of permission annotations) and have a typical structure. These are the "*pouvoir* of politeness" (see Ex. 1.), a question that allows the subject to express a request politely, and the expression "je/nous/on" (*I/we/impersonal pronoun "on"*) + "pouvoir" + "dire" (*to say*) , called "pouvoir_dire" (see Ex. 2.).

> (1) Euh attends j'ai un train de retard tu **peux** répéter ? (*Uh, wait, I'm a bit behind, can you repeat that?*) (ESLO2_ENTJEUN_1235)

> (2) Enfin j'ai fait essentiellement des mesures on **peut** dire (*Well, I mostly took measurements, one could say [...]*) (ESLO2_ENT_1014)

Our model is biased by the fact that most of the permission *pouvoir* follow one of these two patterns that are characterized by a fixed structure: the model is not able to identify as *pouvoir* of permission any use that is different from 1. or 2.

> (3) Je suis nommé par le siège qui **peut** du jour au lendemain si je ne fais pas le travail me me basculer. (*I am appointed by headquarters, which can, from one day to the next, if I don't do the job, toss me out.*) (ESLO1_INTPERS_438)

For example, the model classifies Example 3. as "possibilité matérielle et capacité" even though the institution (i.e., "headquarters") granting permission to the subject is clearly mentioned. The solution will be to enrich the data of deontic *pouvoir* with some examples of different structures. To address this problem, it would be necessary to enrich and to vary, in terms of structures, the examples in the deontic category. Finally, we tested our model on all the 221 interviews in the ES_CF corpus. The results show that most instances of *pouvoir* belong to the category of physical possibility or ability (51% of pouvoir instances), followed by permission (35%), eventuality (9%) and sporadicity (5%). In general, the most representative modal category is the alethic one (value of material possibility and ability and sporadicity: 56%). These results are consistent with those we obtained in the manually annotated portion of the ES_CF corpus presented in section 4.1.

7. Conclusion

This study demonstrates significant first progress in the automatic classification of the French verb *pouvoir* by finding the best fine-tuned BERT model. Moderate to substantial inter-annotator agreement led to merging some subcategories for more streamlined annotations. The flaubert-base-cased model, with contextual data augmentation, achieved an impressive F1-score of 0.94 with cross-validation, highlighting the importance of context (see section 4.2 "Corpus Context"). However, challenges persist, such as limited training data and the need for better annotation tools and more powerful computational resources. The model struggles with certain deontic usages that humans easily identify. Intentional ambiguity by the speaker also poses a challenge for both annotators and the model. Future work should expand and enrich the dataset and consider training on full texts instead of isolated sentences to capture context better. [8] propose a similar approach, emphasizing the importance of taking a large context around the target token and advocating for the use of full texts as context. In the future, we will also experiment with an augmented context window of 10 lines before and after the target token. These enhancements will improve model robustness and set the stage for further advancements in natural language processing, particularly for classifying semantic values of French modal verbs. This is the first step in a larger project that will soon include the verb *devoir* (*must*). More globally, the ultimate goal of our approach is to be able to identify which modal categories are prevalent in any given corpus [16]. Indeed, given that the verb *pouvoir* is present in all types of texts, the ability to identify its modality becomes a necessary tool for refining the overall analysis of modality in different tasks such as sentiment analysis ([17] or hedge detection ([18]).

A. Annexe A: Extended version of annotation examples of the 7 semantic values of *pouvoir*

Table 4
Extended version of annotation examples of the 7 semantic values of *pouvoir*

Global modal categories	**Modal categories**	**Definitions**	**Examples**
aléthique (*alethic*)	**sporadicité** *sporadicity*)	Occurrences of pouvoir used to indicate the contingency of a state or process	Parfois dramatique comme les les romans qui **peuvent** rappeler des situations plus ou moins pénibles. (*Sometimes dramatic, like novels that can evoke more or less painful situations*) (ESLO1_ENT_003_C)
	possibilité matérielle (*material possibility*)	Occurrences of pouvoir where the source of the possibility they express is material conditions external to the subject.	C'est un un personnage donc il y a des choses que vous ne **pouvez** pas faire uniquement avec du verre et du plomb par exemple ces cheveux-là le nez la bouche oui. (*It is a character, so there are things you cannot do with just glass and lead, for example, the hair, the nose, the mouth, yes.*) (ESLO1_ENT_002_C)
	capacité (*ability*)	Occurrences of *pouvoir* where the source of the possibility they express is inherent characteristics of the subject.	À l'intérieur on a une galette on a un gâteau on le partage en X morceaux on peut pas le le faire grandir par le le un coup de baguette magique. (*Inside, we have a cake, we share it into X pieces, we cannot make it grow with a wave of a magic wand.*) (ESLO1_INTPERS_421_C)
	possibilité logique (*logical possibility*)	Occurrences of *pouvoir* used to indicate statements that are true by convention.	ø
épistémique (*epistemic*)	**éventualité** (*eventuality*)	Occurrences of *pouvoir* that indicate assumptions or personal judgments on the part of the speaker.	Les payer pour qu'ils euh fassent leur boulot et euh qu'on donne un un prix euh au meilleur grapheur money price et on prend cinq mille euros ça pourrait être pas mal. (*Pay them so they, uh, do their job and, uh, give a, uh, prize, uh, to the best graffiti artist, money prize, and we take five thousand euros, that could be nice*) (ESLO2_ENTJEUN_1228_C)
déontique (*deontic*)	**permission** (*permission*	Occurrences of *pouvoir* that indicate permission granted to the subject by an animate being, an institution, or by social or ethical laws.	Euh les gens sont libres de venir consulter quelque médecin que ce soit et ils **peuvent** en changer à tout moment et que donc euh après être venus me consulter euh si je ne leur plais pas. (*Uh, people are free to consult any doctor they choose and they can change at any time, and so, uh, after coming to see me, uh, if they don't like me.*) (ESLO1_ENT_003_C)
indeterminé (*undetermined*)	**indeterminé** (*undetermined*)	Occurrences of *pouvoir* for which the annotator hesitates between two or more values.	C'est ça ? justement je me dis comment est-ce que je vais **pouvoir** utiliser mes capacités informatiques ? (*That's it? Exactly, I'm wondering how I will be able to use my computer skills?*) (ESLO2_ENTJEUN_1235_C)
		Occurrences of *pouvoir* that are impossible to annotate due to lack of context (incomplete statements).	Parce que sinon on aurait **pu** ... (*Otherwise, we could have...*) (CFPP, Catherine_Lecuyer)

Topic Similarity of Heterogeneous Legal Sources Supporting the Legislative Process

Michele Corazza[1,*], Leonardo Zilli[1] and Monica Palmirani[1,*]

[1]University of Bologna, ALMA-AI, via Galliera 3, Bologna, Italy

Abstract

The legislative process starts with a deep analysis of the existing regulations at European and national levels to avoid conflicts and fostering the into force norms. Also the Constitutional Court decisions play a fundamental role in this analysis for checking the compliance with the constitutional framework and for including the inputs coming from this relevant court in the law-making process. Finally, it is also significant to compare the forthcoming proposal with the already presented bills regarding the same topic. This comparison is crucial to avoid overlapping and to coordinate the democratic dialogue with the different parties. In this light, this paper presents an unsupervised approach for calculating similarity between heterogeneous documents annotated in Akoma Ntoso XML, with the aim to support the information retrieval of similar documents using thematic taxonomy used in legal domain. The prototype has been developed for answering to a call for manifestation of interests launched by the Chamber of Deputy of Italy in order to adopt hybrid AI in the legislation process. It uses a completely unsupervised approach based on Sentence Transformers, meaning that neither annotated data or any fine-tuning process is required.

Keywords

Unsupervised learning, Sentence Transformers, Hybrid AI, Legal NLP

1. Introduction

The legislative process inside parliaments and official assemblies includes an initial phase of preliminary discovery of the existing regulations and rules in the same domain of the proposal, in order to synchronize the new bill with the legal system and to avoid conflicting norms. Secondly, a legal preliminary study must be conducted for applying legislative drafting techniques that have the aim of creating transparent and evidence-based legislation (e.g., Better Regulation https://commission.europa.eu/law/law-making-process/planning-and-proposing-law/better-regulation_en).
On the other hand, the fragmentation of the legal system imposes the task of an accurate preliminary legal analysis and research at different levels of legislation to the legislative department: at the European level in order to discover the norms in Regulations and Directives; at the national level to avoid overlapping with other existing acts; at the ministerial level to synchronize the technical and operative rules. Notably, it is crucial to check the decisions of the Constitutional Court to avoid to produce norms that are unconstitutional. On the other hand, the legal sources, considering their heterogeneous nature, follow some theory of law principles: i) *lex superior derogat inferiori*, following a specific hierarchy between the legal sources (e.g., an EU regulation is directly enforceable in the Member States); ii) *lex specialis derogat legi generali* (e.g., energy regulation overrides general green deal rules); iii) *lex posterior derogat legi priori* (e.g., the norms should be applied according to the principle of point-in-time with respect to the temporal model of the provisions and facts, the normative references in the preamble are static links fixed in time when the Parliament argues on the justification reasons). Another important check is done with the existing bills already proposed in the assembly to better manage the democratic dialogue between different parties' propositions. For this reason, having a dashboard that, in a unique portal, allows the retrieval, comparison, analysis of different heterogeneous legal sources is a fundamental instrument for this preliminary legal analysis. The documents are annotated in Akoma Ntoso XML [1] for creating a common framework for their representation that is capable of capturing the legal knowledge and metadata (e.g., jurisdiction, hierarchy, temporal model).

Additionally, we provide an unsupervised approach for classifying legal documents according to their topic, which is used to retrieve the relevant legal documents concerning some main legal topics (e.g., the subject of the Chamber of Deputies Committees defined by law [1], or EUROVOC top-level thematic classes) from a user input. This work was conducted on the use-case of the Chamber of Deputy of Italy's needs and documents, answering the

call for interests launched in February 2024 concerning the use of AI in Parliament [2].

The legislative language is a peculiar language that includes qualified part of the text like the preamble, normative part, definitions, normative references, exceptions, transitional norms, etc. For this reason, the task is not trivial and should take in consideration these peculiarities.

2. Related Work

The creation of models and methods for the legal domain is a challenging endeavour, as this field is characterized by some peculiar aspects that might lead general-purpose approaches to be inaccurate. Nevertheless, a multitude of different models and strategies have been proposed in this field, including models that have been trained specifically on this domain like LEGAL-BERT[2], which was fine-tuned from BERT[3] on legislative documents from the UK, US and EU, court documents from the European Court of Justice. Another model, called custom LEGAL-BERT[4] was instead trained on a corpus comprised entirely of Case Law from the Harvard Law Library. Another prominent example of ad-hoc models for the legal domain is called Pile-of-Law (PoL), from the name of the dataset that was used to fine-tune it, which comprises data from 35 different sources in English [5]. Interestingly, in terms of natural language processing applications for the legal domain, most approaches appear to be targeted at the judiciary rather than the legislative branch. Additionally, some approaches include common-law corpora (UK/US) that for our purpose (EU) could create relevant distortions in the dataset. In particular, a common task is the prediction of a judgment for a given case. This task has been attempted using multiple methods, including using a consistency graph and a transformer model to determine which articles have been violated in a given case [6]. The research is not limited to the English language, as there are contributions for Chinese court judgments [7] and rulings from the Indian Supreme Court [8].

Another crucial aspect of research in the wider field of legal informatics is the creation of formats, ontologies and tools that support the machine-readable representation of legal documents, from both the legislative and judiciary branches. Among these, one of the founding elements of our approach is the usage of the Akoma Ntoso XML standard [1, 9], which has been adopted by many international institutions [10, 11, 12, 13, 14] to represent legal documents. This standard allows the annotation of legal definitions, references, the hierarchical structure of legal documents, as well as the temporal aspects of legal documents.

3. Datasets and resources

The documents used for the project have been collected from different sources, resulting in four distinct datasets:

- *Corte Costituzionale*: Contains the orders and judgments of the Italian constitutional court, spanning from 1956 to 2018 (10725 documents), which have been downloaded and converted to Akoma Ntoso using an ad-hoc tool [3];
- *Progetti di Legge (PDL)*: A collection of Italian legislative bills from the legislatures XVIII and XIX (March 2018 to May 2024 - 3615 documents), extracted from the official website of the Chamber of Deputies of the Italian Parliament[4] in the HTML format and converted to Akoma Ntoso using a batch python parser[5].
- *EUR-Lex*: A collection of Regulations and Directives from the European Union, spanning from 2010 to 2021, extracted from the EUR-Lex website[6] and converted from Formex to the Akoma Ntoso format using our conversion tool [7].
- *Normattiva*: A collection of Italian legislative acts extracted from the Normattiva portal[8], which contains all legislative documents from the Italian parliament in Akoma Ntoso format. The documents from 2010 to May 2024 were selected, including Primary and Secondary Law.

When not already in the Akoma Ntoso XML format, as is the case for the PDL and Eur-Lex dataset, the documents have been converted to this format. Through this conversion, it is possible for us to extract portions of the document according to its hierarchical structure (articles, commas, lists, etc). This structural information is very important for the legal domain, as it allows to chunk documents while considering their structure (e.g., legal definitions, article, list of points). Furthermore, normative references are also annotated as such, and a unique URI is used to indicate them. The Akoma Ntoso standard also follows the FRBR conceptual model, which is used to distinguish between works (i.e a specific law), expressions (the various consolidated versions of each law that have been amended over time) and manifestations (the physical embodiment of an expression or work). Through the annotation of the hierarchical structure of documents, the references and the URI naming convention based on FRBR it is possible to resolve normative references, even when they refer to a part of a document, like a single article or paragraph. Furthermore, the FRBR

[2] https://comunicazione.camera.it/archivio-prima-pagina/19-37666

[3] https://gitlab.com/CIRSFID/cortecostituzionale-py

[4] https://www.camera.it/

[5] https://gitlab.com/CIRSFID/html2aknPDL

[6] https://eur-lex.europa.eu

[7] http://u2.cirsfid.unibo.it/formexplus2akn/frontend/

[8] https://www.normattiva.it/

model allows us to retrieve the consolidated version of a document which is temporally relevant for a given reference. Akoma Ntoso also includes legal metadata (e.g., jurisdiction, temporal information, modifications, definitions, law-making process, life-cycle of the document, classification) which improves the expressiveness of legal knowledge in the XML representation.

Each dataset follows semantically descriptive naming conventions for the documents, which facilitate subsequent data handling and processing steps in the pipeline of the project. Table 1 summarizes the number of documents contained in each dataset.

Dataset	N. of Documents
Corte Costituzionale	10725
PDL	3615
EUR-Lex	14305
Normattiva	3195

Table 1
Number of documents in each dataset

In order to deal with the highly heterogeneous nature of the datasets, labels describing a number of various topics have been used for categorizing the documents. The documents concerning Italy have been classified according to the labels of the Committees of the Chamber of Deputies. These Committees are represented as a string describing them, which contains their titles (shown in Table 2), as well as their description as presented in the Circolare del Presidente della Camera (16 ottobre 1996, n. 3), the official document that regulates the matters of competence for each of them. Only regarding the dataset of the Constitutional Court, the *"Giustizia"* (Justice) and *"Affari costituzionali, della Presidenza del consiglio e interni della Camera dei deputati"* (Constitutional Affairs, Presidency of the Council and Internal Affairs of the Chamber of Deputies) commissions were excluded as they apply to the vast majority of Constitutional Court documents.

Concerning the EUR-Lex dataset, the classification leveraged the European multilingual thesaurus, EuroVoc, using the top-level terms (shown in Table 3) and their immediate subcategories separated by semicolons. As for the Constitutional Court, the term *"Unione Europea"* (European Union) has been excluded as it is too general and relevant to all documents in the dataset.

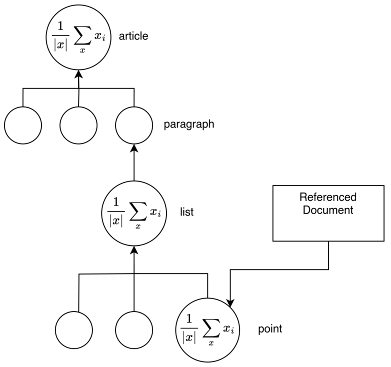
4. Document Classification

In order to classify documents according to their content, we used an approach based on the SentenceTransformers library [15], and selected the multilingual model "paraphrase-multilingual-mpnet-base-v2"[16]. This model is made multilingual from the monolingual Sentence Transformer model "paraphrase-mpnet-base-v2", in turn based on MPNet [17], which was trained using a contrastive loss and an approach similar to siamese networks to allow the direct application of a metric (cosine similarity) to its output vectors in order to measure the semantic proximity of sentences. The monolingual model is then used as a teacher in a teacher-student configuration to train the multilingual one so that both the original and translated versions of sentences have the same vector representation in the new model. The chosen model, in particular, was trained on parallel data and supports 50+ languages, including Italian and English. Crucially, the usage of a sentence transformer allows us to operate in a completely unsupervised way, without the need to use annotated data or to fine-tune the model for the classification task, since we can directly apply cosine similarity to measure semantic relatedness.

In order to produce a classification of the documents, we selected two components of the normative documents (Eur-Lex, Normattiva, PDL), namely their titles and articles. For the Corte Costituzionale dataset, we selected



$\frac{1}{|x|}\sum_x x_i$
article
paragraph
$\frac{1}{|x|}\sum_x x_i$
list
Referenced Document
$\frac{1}{|x|}\sum_x x_i$
point

Figure 1: A graphical visualization of the aggregation strategy used to obtain a vector representation for each article. In this example, the article is composed of multiple paragraphs, one of them contains a list and one point of the list contains a normative reference. The reference is resolved and aggregated with the relevant point, then the procedure leverages the structure of the document to produce element vectors from their children, until the root of the tree (article).

the introduction as a substitute for the title, while instead of the articles we used the decision portion of the documents, in addition to all textual content between parenthesis, which contains brief descriptions of referenced documents. The text between parenthesis is fed to the model and the results are averaged to produce a single vector. In the following sections, we use "titles" and "articles" for brevity, but these correspond to introduction and decision + parenthesis for the Corte Costituzionale dataset.

These components were extracted by applying the appropriate Xpath query to the Akoma Ntoso XML tree representing each document. The first step is to compute embeddings representing each title of the document. Then, we proceed to compute the article vectors. While in the case of titles we can just apply the sentence transformer directly to the text, the length of articles might prevent the model from producing accurate result, or even exceed the maximum allowed tokens for a given model. For this reason, our approach leverages the structure of articles, represented using Akoma Ntoso, to produce one embedding for each article. In particular, we proceed traversing the XML tree in a recursive manner, until we reach the XML elements that are leaves of the tree. We exclude the elements that appear inline in the text (eg dates, references, etc) in order to maintain the textual content of each leaf node (eg paragraph, item of a list, etc) intact. A visualization of the procedure is shown in Figure 1. In addition to its own textual content, each leaf node is associated with a list of the references in its text, which are resolved as follows:

- For punctual references (eg Article 3 of Regulation xx/yyyy/EU) we obtain the specific referenced portion of the document as an XML element;
- For generic references to an entire document (eg Regulation xx/yyyy/EU) we use the title and first article of the document to represent it.

Formally, then, an article a having children and references is represented by an embedding obtained from the model M using the following recursive procedure:

$$v(a) = \frac{1}{2 + |c(a)|}\left(M(t(a)) + \sum_i v(c_i(a)) + \frac{1}{r(a)}\sum_j R(r_j(a))\right) \tag{1}$$

Where:

- $t(a)$ is the textual content of the article which is not included in any of its non inline children;
- $c(a), c_i(a)$ represent the set of all non inline children of a and the i-th child element of a, respectively;
- $r(a), r_j(a)$ represent all the references in the text of the article, and the j-th reference in the text, respectively.

In order to represent references, then, we can define a function R that works as follows:

$$R(i) = \begin{cases} v(i) & \text{if } i \text{ is a punctual reference} \\ \frac{1}{2}M(T(i)) + v(A_1(i)) & \text{otherwise} \end{cases} \tag{2}$$

Where $T(i)$ represent the title of the referenced document, while $A_1(i)$ is the first article of the document. Overall, the function $v(a)$ as defined previously computes an average vector representation for each article, which aggregates the embeddings of all its children but also considers the normative references contained in the text.

Once we obtained the vector representation of each article of each document and its titles embeddings, we can compare them with the vector representations of our topics, the EuroVoc terms for the European legislation and the Chamber commissions for the Italian documents. Then, the similarity between each document and the subjects is derived from the sum of the cosine similarity between its title and the average similarity between the topics and each article. Finally, the maximum similarity value obtained by this procedure is used to classify each document using one of the topics.

5. Searching by topic

In order to provide a topic-based search that can be used in the Italian legislative process, the final step is to provide an interface to query each of the four datasets, by providing information about the more relative topic for a given query. Our approach is based on the possibility to input an arbitrary textual input, as well as a set of keywords that are relevant to what the user is interested in. Before any further processing, the keywords are separated by a semicolon ";" and encoded as a single string. In order to obtain a vector representation of the user inputs, we can then use the model to obtain a vector representation from the arbitrary input, as well as the semicolon-separated keywords. Then, the two vectors are averaged and used in all further processing, obtaining the query vector.

The first step of the topic-based search is the comparison between the topic list (the EuroVoc terms or the Camera commissions, according to the selected dataset) which returns the two most similar subject in terms of cosine similarity with the query vector. For these two topics, the system then computes the similarity of the query vector with each of the documents that have been classified with the specified subject.

The system described in this article is available on a website[9] which includes multiple tools for legal drafting in the context of a call from the Italian Camera dei Deputati expression of interest. The system is available under "Cerca", followed by "Ricerca Avanzata" on the panel that appears on the right, and finally by inserting the query and keyrords, followed by the "Cerca Argomento" button. An example of the layout and results of this system is shown in Figure 2. Additionally, we allow users to select a date when querying the system, meaning that only documents and consolidated versions that were in vigour at a specific time. This is a crucial feature for the legal domain, where a judge might need to know which laws were in vigour when an alleged crime was committed.

6. Evaluation and Results

In order to evaluate the performance of our subject-based classification, we asked three experts of the legal domain to annotate 100 random documents for each dataset between them, and proceeded to measure the accuracy of our classification when compared to the annotated ground truth (Table 4). The fact that experts were involved in the annotation of the results is crucial for the legal domain, since this allows the legal interpretation of the results, which can only be accomplished through an evaluation by legal experts [18].

While this is just a preliminary assessment of the classification performance of our unsupervised model, it is possible to derive that the label applied to the documents is correct in at least 39% of the cases, meaning that the approach is indeed able to link a document with its more relevant anchor with a good level of approximation.

Titolo: Regolamento recante la disciplina dell'utilizzazione delle terre e rocce da scavo.

Figure 2: The first results of our search by topic system. Using the query "land consumption" in Italian on the Normattiva dataset, the system returns the appropriate Camera commission (environment, territory and public works) and the first two results are relevant (one is about waste management, the other about rocks and earth from excavation projects).

Dataset	Accuracy
Corte Costituzionale	0.45
PDL	0.39
Normattiva	0.47
EUR-Lex	0.58

Table 4
Accuracy values for all four datasets, when compared with the manually annotated documents.

When comparing the result, it is interesting to note that among the Italian datasets, which use the same categories, the Normattiva and Corte Costituzionale accuracy seems higher, while the PDL dataset shows a lower performance. This suggests that the finalized version of documents issued by the parliament and the Constitutional court might be simpler to classify in an unsupervised way, while the more draft-like qualities of the PDL dataset hinder the classification efforts.

7. Conclusions and Future Work

In this article, we present an unsupervised approach that aims to support the Italian legislative process, by providing useful insights into documents from the relevant European and Italian institutions (European Union, Constitutional Court, Italian Parliament). The system doesn't

[9] http://u2.cirsfid.unibo.it/portale-camera

only provide with a ranking of relevant documents, but it also returns the two most relevant EuroVoc terms (for EU documents) and Chamber commissions (for Italian documents). This allows the user a more thorough exploration of the relevant subjects, while also supplying suggestions in terms of specific documents.

Our approach is completely unsupervised and it does not rely on any form of annotation, meaning that scaling up the approach to more documents, or even using more performant models do not require any fine-tuning, with the procedure consisting in obtaining the article and title vectors for all documents. Furthermore, the adopted approach leverages the hierarchical nature of legislative documents, as represented in Akoma Ntoso XML in order to produce embeddings that are based on the structure of the document. Moreover, using a structured format as our input allows us to resolve normative references, without which some of the of a document will be impossible to understand for an automatic system.

The evaluation performed on the classification system showed a promising level of performance for an unsupervised model, which doesn't rely on any information about the specific task. Additionally, the multilingual model used in our method allows users to work both on English and Italian, both in terms of queries and in terms of results, with satisfying results. Nevertheless, it would be possible to improve the quality of the results by testing other models, which might yield better performance.

The validation of the search by topic task has been assessed by two senior legal researcher in the team, however it is recommendable to organize a session with relevant end-users with some concrete scenarios for returning relevant documents and categories given a user query. For this task, it would be necessary to involve the relevant stakeholders, meaning experts involved in the drafting of legislative documents in Italy. Nevertheless, the project has been evaluated by scientific experts [10] appointed by the Italian Chamber of Deputies in the context of its manifestation of interest and it was included as part of the work by of one of the two winning consortiums.

The experimental results obtained in this paper constitute a study of the application of pre-existing Sentence Transformer models in an unsupervised way to the classification and search of Italian legal documents. While we achieved satisfactory results, our approach could still be improved by improving upon the base methodology and conducting a more thorough exploration of other multilingual models. Furthermore, a formal evaluation by the stakeholders would also improve our understanding further specific parameters that arise during the legislative process.

Join Together? Combining Data to Parse Italian Texts

Claudia Corbetta[1,2,*,†], Giovanni Moretti[3,†] and Marco Passarotti[3,†]

Abstract

In this paper, we create and evaluate non-combined and combined models using Old and Contemporary Italian data to determine whether increasing the size of the training data with a combined model could improve parsing accuracy to facilitate manual annotation. We find that, despite the increased size of the training data, in-domain parsing performs better. Additionally, we discover that models trained on Old Italian data perform better on Contemporary Italian data than the reverse. We attempt to explain this result in terms of syntactic complexity, finding that Old Italian text exhibits higher sentence length and non-projectivity rate.

Keywords

Parsing, Universal Dependencies, Combined Model, Old Italian, Contemporary Italian, Non-Projectivity

1. Introduction

High-quality textual data (semi-)manually enhanced with different layers of metalinguistic annotation are extremely valuable resources for conducting linguistic analysis. As for the syntactic layer of annotation, the de facto standard for dependency-based annotation is Universal Dependencies (UD),[1] an initiative that provides machine-readable annotations for a wide variety of languages, including historical languages [1]. At the current state of art,[2] Contemporary Italian is well-represented in UD, whereas Old Italian is only represented by one annotated text (a portion of the *Divine Comedy* of Dante Alighieri). The creation of additional Old Italian annotated data is therefore advisable.

Since a fully manual annotation process is time-consuming and requires significant effort, we aim to expedite it by using a parser that pre-parses the data, leaving the human annotator with only a manual revision task.

To address this, given the scarcity of Old Italian data, we create a combined parser using both Contemporary and Old Italian data. The objective is to determine whether a combined model with an expanded training dataset performs better compared to non-combined models (see [2] for Spanish language and [3] for Stanza combined models).

The paper is organised as follows: Section 2 provides a brief description of the Italian language, the syntactic resources and the Italian data available; Section 3 details the data used for the experiments, presents the performances of non-combined and combined models, and evaluates their performances; Section 4 analyzes the syntactic complexity of each test set (Old and Contemporary Italian) to address accuracy differences; and finally, Section 5 provides the conclusion.

2. Talking about Italian

Italian is a Romance language derived from Latin, and its development is closely connected with the political, cultural and economic system of Italy during the Late Middle Ages [4, 5, 6, 7]. Even though the evolution and history of the Italian language "can be properly understood only within the wider context of the evolution of the Italian dialects" [5, p. 3], the dialect spoken in Florence (Tuscany) in the thirteenth century, known as Florentine, played a pivotal role in establishing the foundation of the Italian language. The pre-eminence of Florentine over other Italian dialects was established due to the importance and prestige of Florentine literature. Its widespread success contributed to the codification of Florentine as the *lingua volgare* in the sixteenth century, distinguishing it as the spoken Italian language in contrast to Latin, which was still used for written cultural discourse [8].

Even though Florentine (and, more generally, Tuscan dialects) is considered conservative in its linguistic evolu-

[2] We refer to version 2.14 of UD.

tion [5, p. 5], it is now widely recognized by most scholars as distinct from Contemporary Italian [9, p. 8]. Among the differences between Contemporary Italian and Florentine (henceforth referred to as Old Italian),[3] several syntactic distinctions have been noted [10, 11]. These include, among others, the position and order of clitics, the use of the marker *sì* 'that' as a thematic marker, and differences in the use of compound tenses [11, p. 425-444].

2.1. Syntactic resources

High-quality (semi-)manually annotated treebanks, i. e. corpora with annotations on various linguistic levels,[4] are indispensable tools for in-depth analysis of the syntax (and morphology) of languages. Treebanks not only facilitate faster, easier, and more precise querying of syntactic structures, but also aid in tracking the evolution of syntactic patterns in languages through time [13].

Among the dependency treebanks, UD is a pivotal initiative displaying cross-linguistically consistent treebanks for many languages [14]. As of the current version 2.14, UD includes 283 treebanks and 161 languages, encompassing historical languages such as Latin (e.g. *Index Thomisticus* Treebank, ITTB [15]), Old French (PROFITEROLE [16]) and Ancient Greek (e.g. PROIEL [17]), among others.

In Subsection 2.2, we describe UD treebanks of Italian language.

2.2. Italian data

Regarding Italian, UD includes 9 Contemporary Italian treebanks, spanning various genres, as reported in Table 1.

Table 1
Contemporary Italian UD treebanks (in UD 2.14).

Treebank	Syntactic words	Genre
ISDT	298K	legal,news, wiki
VIT	280K	news, non fiction
ParTUT	55K	legal, news, wiki
ParlaMint	20K	government legal
TWITTIRO	29K	social
Valico	6K	learner-essays
PoSTWITA	124K	social
MarkIT	40K	grammar-examples
PUD	23K	news, wiki

Concerning Old Italian, the only treebank present in UD is Italian-Old [18], encompassing the *Divine Comedy*, a poetic text written by Dante Alighieri (1 265-1 321). Currently, Italian-Old contains the first two *Cantiche* of the poem, namely *Inferno* and *Purgatorio*, amounting 80 694 tokens, 82 644 syntactic words[5] and 2 402 sentences.[6]

The divergence in annotated data available for Contemporary Italian (around 875K syntactic words) versus Old Italian (82K syntactic words) is considerable.

Considering that i) treebanks are essential for expanding the sample of comparable data and that ii) the manual annotation of data is an extremely time-consuming effort, the development of automatic parsers is crucial to expedite and assist the annotation process.

The shortage of gold-annotated data for Old Italian, compared to the large amount of data available for Contemporary Italian, led us to recognize the potential of testing combined models, i.e., models with a training set composed of both Old and Contemporary Italian data.

3. Combining Old Italian with Contemporary Italian data

Considering the aforementioned divergence in data, we create and evaluate the performance of a combined Contemporary-Old Italian model to understand whether joining datasets from different periods could improve parsing accuracy.

We train models using Stanza [19], a neural pipeline for natural language processing, with different training sets. Specifically, we train models based on Contemporary Italian data (henceforth CI), Old Italian data (henceforth OI), and a combination of Contemporary and Old Italian data (henceforth Combi).

In Subsection 3.1 we detail the selection and partitioning of the data. Subsection 3.2 outlines the creation of models and presents the resulting scores. Finally, Subsection 3.3 discusses the combined Contemporary-Old Italian model.

3.1. Selection and partitions of data

To build the model based on OI data, we use the only Old Italian treebank available, Italian-Old.

Among all the Contemporary Italian UD treebanks, we select two treebanks, ISDT (Italian Stanford Dependency Treebank) and VIT (Venice Italian Treebank). We select ISDT [20], as it is the Italian treebank with the highest

[3] We adhere to the definition of Salvi and Renzi [9], who use the term Old Italian to refer to the language spoken in Florence during the 13th and 14th centuries.

[4] Treebanks usually provide information on sentence tokenization, word lemmatization, and both morphological and syntactic details. Syntactic analysis is mandatory in a treebank, and can be encoded in either dependency syntax or constituency syntax [12].

[5] We use the term "syntactic words" and "tokens" following the UD definition (see https://universaldependencies.org/u/overview/tokenization.html).

[6] The numbers refer to UD version 2.14, see https://universaldependencies.org/treebanks/it_old/index.html.

Table 2
Number of sentences (sent) and tokens (tok) for the train/dev/test partitions of each dataset.

	VIT1	VIT2	VIT3	ISDT
train	1 697 sent - 53 662 tok	2 195 sent - 52 076 tok	2 189 sent - 52 016 tok	2 766 sent - 58 091 tok
dev	356 sent - 11 515 tok	317 sent - 11 168 tok	413 sent - 11 144 tok	591 sent - 12 465 tok
test	354 sent - 11 473 tok	318 sent - 11 136 tok	438 sent - 11 096 tok	606 sent - 12 402 tok

UD star ranking. This ranking, designed by the UD organizers, quantifies various qualities of the corpora, such as their usability and the variety of genres they encompass. Moreover, since Italian-Old is based on the poetry genre, to minimize a potential genre gap (the influence of genre on parsing has been addressed in [21]), we also select VIT [22], that includes, albeit with a limited number of words, literary texts.[7] We point out that, up to now, no CI treebanks contain poetry (see Table 1).

To avoid the CI data overwhelming the OI data due to their size disparity, we partition the CI data. The VIT treebank, consisting of 259.625 tokens, 280.153 syntactic words, and 10.087 sentences, allows us to partition the data into three parts, with each part closely matching the size of the Italian-Old dataset. Specifically, we divide the VIT dataset into three partitions of 34%, 33% and 33%, respectively named VIT1, VIT2 and VIT3. Additionally, we further divide each partition (VIT1, VIT2 and VIT3) into train, test, and dev sets with a split of 70%, 15%, and 15%, the same used in Italian-Old dataset. Unlike the VIT treebank, the ISDT is not directly partitionable, as it counts 278 461 tokens, 298 375 syntactic words, and 14 167 sentences. Therefore, we shuffled the data and extracted a total of 82 500 tokens (the same size of OI data), which were then partitioned into train, dev, and test sets with a ratio of 70%, 15%, and 15%, respectively.

We report in Table 2 the partition of each datasets in train/dev/test.

3.2. Creation of models and scores

With each partition (OI, VIT1, VIT2, VIT3 and ISDT), we train 5 models using Stanza, with the training and dev sets, and we evaluate them on the respective test sets. Within the CI-VIT datasets, we retain only the model that performs best, namely VIT1.

We then use the model built on OI data to parse the CI test sets, and vice versa.

In Table 3 and Table 4, we report the scores of both Label Attachment Score (LAS) and Unlabel Attachment Score (UAS)[8] of the OI model and the VIT1, and of the OI and the ISDT respectively.

For both VIT1 and ISDT scenarios, results show that using a model trained on in-domain data, namely data that pertain to the same textual domain as the test set (VIT1 on VIT1, OI on OI, and ISDT on ISDT), yields higher performance than using out-of-domain data (ISDT on OI, VIT1 on OI, and OI on VIT1 and ISDT). These results align with literature on in-domain testing [25].

Table 3
Evalutation metrics with VIT1 and OI models (where "->" stands for "on").

	VIT1 -> VIT1	OI -> OI	VIT1 -> OI	OI -> VIT1
LAS	71.60	75.86	42.83	68.53
UAS	77.70	82.24	56.13	75.53

Table 4
Evalutation metrics with ISDT and OI models.

	ISDT -> ISDT	OI -> OI	ISDT -> OI	OI -> ISDT
LAS	88.55	75.86	51.62	74.83
UAS	91.41	82.24	63.03	80.93

While analyzing the scores of out-of-domain parsing (ISDT on OI, VIT on OI, and OI on ISDT and VIT), we notice that the model trained on OI data performs better on CI data in both scenarios, whereas CI models yield lower scores when applied to OI text. The differences in scores are approximately 20 points in favour of the OI model, specifically 25.7 (LAS) and 19.4 (UAS) compared to VIT1, and 23.21 (LAS) and 17.9 (UAS) compared to ISDT.

We attempt to explain the outperformance of the OI model in Section 4.

3.3. Joining model

To challenge the results obtained in 3.2, we build combined models with Stanza by merging OI data with CI data. Specifically, we create two models: CombiVIT, and CombiISDT. For each combined model, the test, dev, and train sets are created by merging the corresponding test, dev, and train sets of the VIT1 data and ISDT data with those of the OI data.

In Table 5, we report the UAS and LAS scores obtained.

We notice that in both scenarios the combined models perform better on CI data than on OI data, with the combined models outperforming by 13.74 (LAS) and 10.1 (UAS) for CI-VIT data and 12.58 (LAS) and 8.87 (UAS) for CI-ISDT data.

[7] The VIT treebank contains 10 000 words of literally genre [22, 23]. Refer also to the read.me to further details (see A).
[8] Refer to [24] for an insight into the aforementioned metrics.

Table 5
Evaluation metrics with combined models.

	CombiVIT -> VIT	CombiVIT -> OI	CombiISDT -> ISDT	CombiISDT -> OI
LAS	69.11	55.37	87.76	75.18
UAS	74.96	64.86	90.85	81.98

According to the results in Table 5, CI texts appear to be easier to parse, suggesting a simpler syntactic structure compared to OI text. To verify this claim and shed light on these results, in Section 4, we measure several syntactic parameters to gather information about the tree structures of both OI and CI tests.

4. An insight to OI and CI data

To analyze the complexity of tree structures in each test set (CI-ISDT, CI-VIT, and OI), we calculate:

- *type-token ratio* (TTR): the number of types divided by the number of tokens (excluding punctuation);
- *tree depth* (Depth): the longest path from the root of an oriented a-cyclic graph (i.e, the syntactic tree) to a leaf;
- *lexical density* (Lex. Den.): the number of content words, i.e. words that possess semantic content and contribute to the meaning of the sentence,[9] divided by the total number of syntactic words (excluding punctuation marks);
- *sentence length* (Length): the number of syntactic words (excluding punctuation marks) in each sentence.

Table 6 presents the average of the aforementioned measures. Additionally, we report for each test the minimum and maximum values of sentence length and tree depth.

Table 6
Average of type-token ratio, tree depth, lexical density, and sentence length of the OI, CI-ISDT and CI-VIT test sets.

	OI	CI-ISDT	CI-VIT
Avg. TTR	0.92	0.956	0.931
Avg. Depth	5.201	4.153	5.542
Avg. Lex. Den.	0.488	0.516	0.496
Avg. Length	30.095	16.873	26.636
Min - Max Length	7 - 112	1 - 92	2 - 100
Min - Max Depth	2 - 11	0 - 13	1 - 16

Among the measures described, the OI test does not differ significantly from the CI values. The only measure in which the OI test differs from the CI tests is sentence length (Avg. Length): OI presents a higher average sentence length, surpassing the CI-ISDT average by 13 points and the CI-VIT average by 3.5.

Therefore, considering the parameters evaluated, only the sentence length could be considered to explain the possible overperformance of OI on CI data.

In Subsection 4.1, we evaluate another parameter that is related to the complexity of tree structure, namely non-projectivity (i.e., the number of structures where a head and its dependents form a discontinuous constituent). It has been demonstrated [27] that sentence length is interconnected with non-projectivity. Specifically, non-projective sentences exhibit greater sentence length compared to projective ones. By calculating non-projectivity, we aim to determine whether sentence length (which has been proven to be higher in OI test) and non-projectivity might indicate more complex structures in OI texts, thereby contributing to the overperformance of the OI model on CI data.

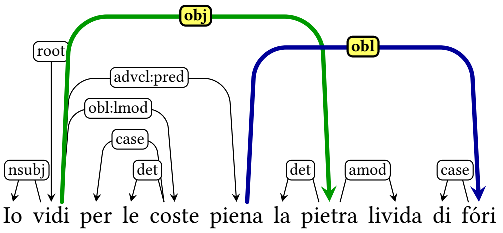
4.1. Non-projectivity

Non-projectivity arises when sentences exhibit non-local dependencies. While constituency approaches may handle similar structures using empty categories and coindexation [28], dependency-based approaches result in discontinuous dependencies that lead to non-projectivity.

We illustrate an example of non-projectivity, showing the non-local dependency relation of the oblique (`obl`) dependency relation of the node *fóri* 'holes', which is a dependent of the node *piena* 'full'. This relation causes non-projectivity with the node *pietra* 'rock', which is dependent on the root (`root`) of the sentence *vidi* 'saw' with an object (`obj`) dependency relation.

> *Inferno*, XIX, vv. 13–14:
>
> Io vidi per le coste (...) / piena la pietra
> livida di fóri
>
> 'Along the sides (...), / I saw that livid rock
> was perforated'

[9] We select as content words all words belonging to the following Universal parts of speech [26]: NOUN 'noun', VERB 'verb', ADJ ' adjective', ADV 'adverbs', and PROPN 'proper noun'.



The non-projectivity of syntactic dependency trees presents a challenging task for parsing in natural language processing [29], with non-projective structures proving more difficult to parse. Concerning our task, we investigate the number of non-projective structures in each test set to determine whether the overperformance of OI on CIdata may be associated with a higher prevalence of non-projective structures, thereby confirming that having more non-projective structures in the training set is beneficial.

We calculate non-projectivity of the OI, CI-VIT, and CI-ISDT test sets. In Table 7 we report the total number of edges, the number of non-projective edges, and the ratio of non-projectivity expressed in percentage of each test set.

Table 7
Non-projectivity of OI, CI-VIT, and CI-ISDT test sets.

	OI	CI-VIT	CI-ISDT
Total edges	12 307	11 473	12 402
Non-projective edges	176	24	7
Non-projectivity ratio in %	1.43%	0.21%	0.06%

As shown in Table 7, OI shows a higher rate of non-projectivity compared to CI texts. In particular, the non-projectivity in OI is 7 times higher than in CI-VIT and 24 times higher than in CI-ISDT. The high rate of non-projective structures in OI could be related to the genre of the text, i.e., poetry, which reflects a more creative use of language and frequently employs inversions.

5. Conclusion

In this paper, we create and evaluate non-combined and combined models of Old Italian and Contemporary Italian data.[10] In light of the scarcity of manually annotated Old Italian data compared to the richness of Contemporary Italian data, the aim of this work is to determine whether combining data to train a combined model could lead to better accuracy in parsing, thereby facilitating the process for human annotators.

We observe that combining Contemporary Italian and Old Italian data, even though it increases the data size of the model, does not lead to better LAS and UAS accuracy scores. This confirms, in line with other studies [30, 31, 21, 32, 3], that having an in-domain training set is preferable.

Additionally, we notice that the model trained on OI data performs better on Contemporary Italian texts than the reverse (i.e. models trained on Contemporary data on OI texts). To explain these results, we investigate the syntactic complexity of each test set (OI, CI-ISDT, and CI-VIT). Specifically we evaluate sentence length, tree depth, lexical density and the type-token ratio. We notice that the tests differ only in the sentence length. We then proceed to calculate another parameter of syntactic complexity, namely non-projectivity.

We discover that OI texts present a higher number of non-projective sentences. We hypothesize that the high level of non-projectivity could be connected to the genre of OI text, namely poetry. Thus far, the lack of UD treebanks for OI prose texts and for CI poetry texts have prevented us from investigating whether the high degree of non-projectivity observed in OI test (based on the Italian-Old treebank) is characteristic of the poetry genre or specific to OI. Such question will be left for further studies.

Finally, we are currently working to increase the amount of manually annotated OI data, expanding both the range of authors and the genres of the texts considered. This will allow us to evaluate the model's performance both within and outside its domain (in terms of authorship and text typology), as well as to assess its potential applicability to other OI texts.[11]

Abstract

Large Speech Models (LSMs), pre-trained on extensive unlabeled data using Self-Supervised Learning (SSL) or Weakly-Supervised Learning (WSL), are increasingly employed for tasks like Speech Emotion Recognition (SER). Their capability to extract general-purpose features makes them a strong alternative to low-level descriptors. Most studies focus on English, with limited research on other languages. We evaluate English-Only and Multilingual LSMs from the Wav2Vec 2.0 and Whisper families as feature extractors for SER in eight languages. We have stacked three alternative downstream classifiers of increasing complexity, named *Linear, Non-Linear, and Multi-Layer*, on top of the LSMs. Results indicate that Whisper models perform best with a simple linear classifier using features from the last transformer layer, while Wav2Vec 2.0 models benefit from features from the middle and early transformer layers. When comparing English-Only and Multilingual LSMs, we find that Whisper models benefit from multilingual pre-training, excelling in Italian, Canadian French, French, Spanish, German and competitively on Greek, Egyptian Arabic, Persian. In contrast, English-Only Wav2Vec 2.0 models outperform their multilingual counterpart, XLS-R, in most languages, achieving the highest performance in Greek, Egyptian Arabic.

Keywords

Cross-lingual Speech Emotion Recognition, Large Speech models, Transfer Learning

1. Introduction

Speech Emotion Recognition (SER) aims to identify emotions from speech audio, enhancing Human-AI interaction in fields such as healthcare, education, and security [1]. Traditional methods rely on Low-Level Descriptors (LLD) like spectral, prosodic, and voice quality features [2], using classifiers such as KNN, SVM, or Naïve Bayes [3]. Deep learning has introduced advanced techniques, including Convolutional Neural Networks (CNNs) [4, 5, 6], eventually followed by Recurrent Neural Networks (RNNs) [7, 8], and Transformers [9, 10, 11]. Transformers' ability to learn from extensive datasets has led to Large Speech Models (LSMs), which generalize across various speech tasks. Common training approaches for these models include Self-Supervised Learning (SSL), which uses data itself to learn general-purpose features [12], and Weakly-Supervised Learning (WSL), which pairs audio with text for tasks like transcription and translation [13]. The general-purpose knowledge of LSMs makes them effective feature extractors for SER. Research has adapted LSMs for SER in English [14, 15, 16, 17], but efforts for other languages are limited, focusing on Wav2Vec 2.0 [18] for cross-lingual SER [19, 20, 21].

This study examines how effective LSMs are as feature extractors for cross-lingual SER, using nine datasets across eight languages: *Italian, German, French, Canadian French, Spanish, Greek, Persian, and Egyptian Arabic.* Specifically, we utilize LSMs from the Wav2Vec 2.0 and Whisper [13] model families, pre-trained with SSL and WSL approaches, respectively. We introduce Whisper due to its underexplored use in cross-lingual SER. To assess the effectiveness of LSMs as feature extractors, we test three classifiers of increasing complexity—*Linear, Non-Linear, and Multi-Layer*—across nine datasets. This evaluation determines which classifier best suits each LSM across different languages. Moreover, our study includes both English-Only and Multilingual models from the Wav2Vec 2.0 and Whisper families, aiming to evaluate the effectiveness of multilingual pre-training for cross-lingual SER.

The main contributions of this work are:

- We evaluate LSMs from the Wav2Vec 2.0 and Whisper models as feature extractors for cross-lingual SER across eight languages.
- We test three types of downstream classifiers—Linear, Non-Linear, and Multi-Layer—and find that Whisper models' last Transformer layer features are well-suited for a Linear classifier, whereas Wav2Vec 2.0 models perform better with

features from the middle and early Transformer layers.
- We compare English-Only and Multilingual LSMs, revealing that Whisper models benefit from multilingual pre-training performing best on Italian, Spanish, Canadian French, French, and German and competitively on Greek, Egyptian Arabic, Persian. Conversely, English-Only Wav2Vec 2.0 models surpass multilingual XLS-R in most languages, achieving the highest performance in Greek, Egyptian Arabic.

2. Background

2.1. Large Speech Models

Recent developments in natural language processing and computer vision have harnessed large volumes of unlabeled data through Self-Supervised Learning [22, 23, 24]. Building on techniques such as masked language and image modeling, Wav2Vec 2.0 [18] introduced a LSM trained on extensive audio datasets using masked speech modeling. Wav2Vec 2.0 features seven 1D convolutional blocks for initial feature extraction, followed by 12 or 24 transformer blocks (depending on the model variant) for contextual processing. The model masks part of the latent features and reconstructs them using the surrounding context. To further refine LSMs for tasks like emotion recognition, methods such as WavLM [25] have been developed. WavLM incorporates speech denoising alongside masked modeling, demonstrating broad effectiveness across various tasks in the SUPERB benchmark [26]. Moreover, XLSR-53 [27] extends the Wav2Vec 2.0 framework to cover 53 languages, sharing the latent space across these languages. This approach has shown superior performance over monolingual pretraining for automatic speech recognition. XLS-R [28] further advances this by scaling to 128 languages, excelling in speech translation and language identification. In comparison, Whisper [13] leverages large-scale weak supervision from audio-transcription pairs to train an encoder-decoder transformer. Using log-mel spectrograms, Whisper is trained in a multitask framework that includes multilingual transcription and translation, establishing itself as an effective zero-shot model for multilingual tasks.

2.2. Cross-Language Speech Emotion Recognition

Emotion recognition in languages beyond English, like Italian [29], French [30], Persian [31, 32], and Spanish [33], is crucial but often limited by data availability. Recent efforts have focused on improving cross-lingual and cross-modal knowledge transfer. Techniques like dual attention [21] and tensor fusion [34] enhance audio and text interaction in languages such as Italian, German, and Urdu. Self-supervised pre-training methods, including variational autoencoders, have also been effective in transferring knowledge across languages like German [35, 36]. The advent of LSMs pre-trained with self-supervision has further increased the potential for transfer learning due to their high generalization capabilities [15]. However, most research primarily focuses on adapting multilingual Wav2Vec 2.0 models (XLSR-53) [19, 37, 20, 21]. This work expands the scope of analyzed LSMs including WSL models as Whisper. Additionally, we evaluate the ability of English-only models to transfer knowledge to other languages, beyond just multilingual models.

3. Method

In this section, we describe the methodology for evaluating the effectiveness of LSMs as feature extractors for downstream SER in various languages. We stack a classification model on top of the LSM backbone, with its parameters frozen. All LSMs used in this work share the same overall architecture, which we describe below along with the stacked classification model.

Formally, the input audio A (raw waveform or log-mel spectrogram) passes through a convolutional encoder $\mathscr{z} : A \rightarrow Z$, mapping the audio to latent features $Z = \{z_1, \dots, z_T\}$, where T is the sequence length and each frame z_i typically corresponds to 25 ms with $z_i \in \mathbb{R}^d$. Then, Z passes through a Transformer encoder consisting of l layers $\mathscr{h}^l : Z \rightarrow H$, enriching the latent features with contextual information, resulting in $\{h_1^l, \dots, h_T^l\}$ for each of the $l = 1, \dots, L$ Transformer layers. Here, $l = L$ corresponds to the output features of the last layer, with $h_i^l \in \mathbb{R}^d$. The features $\{h_1^l, \dots, h_T^l\}_{l=1,..,L}$ are considered the extracted features from the LSM and are fed into a downstream classifier $\mathscr{y} : H \rightarrow Y$, which maps these features to the output class logits $\{y_1, \dots, y_k\}$. The output class label y^* for audio A is given by:

$$y^* = \arg\max_k \operatorname{softmax}\left(\mathscr{y}\left(\mathscr{h}\left(\mathscr{z}(A)\right)\right)\right) \tag{1}$$

Inspired by previous work that uses probing to evaluate the quality of features extracted from backbone models [38, 39], we evaluate three different downstream classifiers of increasing complexity: *Linear Classifier* ($\mathscr{g}_l$), *Non-Linear Classifier* ($\mathscr{g}_{nl}$), and *Multi-layer Classifier* ($\mathscr{g}_{ml}$). Figure 1 illustrates their architecture, which is detailed below.

3.1. Linear Classifier

For the linear classifier, we use a simple feed-forward neural network that consists solely of linear projections.

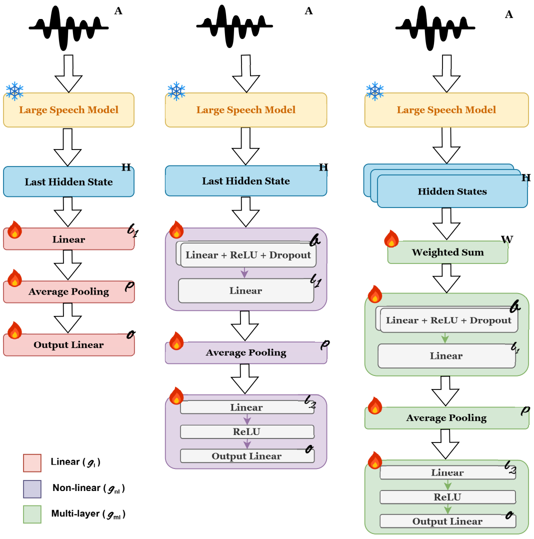

Figure 1: The three downstream classifiers used in this work are: Linear (red), Non-Linear (purple), and Multi-Layer (green). The snowflake icon represents frozen weights, while the fire icon denotes trainable weights.

Specifically, given the features from the last Transformer layer $\{h_1^L, \ldots, h_T^L\}$, they are first projected by a linear layer $\ell_1 : \mathbb{R}^d \to \mathbb{R}^m$ that is shared across all frames, then aggregated by average pooling $\mathscr{p}$, and finally pass through the classification layer $\mathscr{o} : \mathbb{R}^m \to \mathbb{R}^k$ to obtain the output class logits. The function $\mathscr{g}_l$ is compactly defined as:

$$\mathscr{g}_l\left(h_1^L, \ldots, h_T^L\right) = \mathscr{o}\left(\mathscr{p}\left(\ell_1\left(h_1^L, \ldots, h_T^L\right)\right)\right) \tag{2}$$

The absence of non-linear activations allows us to evaluate the quality of the features extracted from the LSM based on the linear classifier model's ability to handle the SER task.

3.2. Non-Linear Classifier

To increase the complexity of the classification model, we utilize a series of linear layers interleaved with ReLU activations both before and after feature pooling. We follow the same architecture as in [14, 15], but unlike them, we only feed the features from the last Transformer layer L to the model. Each $\{h_1^L, \ldots, h_T^L\}$ passes through two shared linear layers, ReLU, and dropout blocks ($\mathscr{b}$), followed by a linear layer (ℓ_1). Linear layers are functions $\ell : \mathbb{R}^d \to \mathbb{R}^m$. Projected features are averaged, pass through ℓ_2 and ReLU, and are classified by $\mathscr{o}$. Thus, $\mathscr{g}_{nl}$ is:

$$\mathscr{g}_{nl}\left(x = h_1^L, \ldots, h_T^L\right) = \mathscr{o}\left(\mathrm{ReLU}\left(\ell_2\left(\mathscr{p}\left(\ell_1\left(\mathscr{b}\left(x\right)\right)\right)\right)\right)\right) \tag{3}$$

3.3. Multi-Layer Classifier

As a third option, we adopt the approach from [14, 15], which utilizes all hidden states of the Transformer encoder. The features $\{h_1^l, \ldots, h_T^l\}_{l=1,..,L}$ are combined into a new sequence $\{h_1^*, \ldots, h_T^*\}$ using a learnable weighted sum. The function $\mathscr{s} : \mathbb{R}^{L \times T \times d} \to \mathbb{R}^{T \times d}$ maps $\{h_1^l, \ldots, h_T^l\}_{l=1,..,L}$ to $\{h_1^*, \ldots, h_T^*\}$ as follows:

$$h_t^* = \sum_{l=1}^{L} w_l \cdot h_t^l \quad \text{for } t = 1, \ldots, T \tag{4}$$

where $w_1, \ldots, w_L$ are the weights assigned to each Transformer layer, ensuring $w_l \in [0, 1]$ and $\sum_{l=1}^{L} w_l = 1$. The resulting sequence $\{h_1^*, \ldots, h_T^*\}$ is then processed by the same pipeline as the *Non-Linear Classifier*, resulting in:

$$\mathscr{g}_{ml}\left(x = \{h_1^l, \ldots, h_T^l\}_{l=1,..,L}\right) = \mathscr{g}_{nl}\left(\mathscr{s}(x)\right) \tag{5}$$

This classifier leverages internal layer information, which has proven beneficial for paralinguistic and linguistic downstream tasks [39, 40, 41, 42]. By investigating the contribution of internal LSM layers for SER across various languages, we corroborates previous findings for Wav2Vec 2.0 models and provide new insights for Whisper models.

4. Experiments

4.1. Datasets and Metrics

In this study, we conduct experiments using 9 distinct datasets spanning 8 different languages: *Greek, French, Italian, German, Spanish, Egyptian Arabic, and Persian.* The datasets vary in their collection methodologies, such as acted emotions and elicitation methods. The participant demographics may be balanced by gender (e.g., CaFE, EYASE), by emotion (e.g., EMOVO), or may not be balanced at all. For all datasets, we conduct our experiments in a speaker-independent setting to prevent evaluation on speaker-dependent features. Table 1 provides an overview of the dataset statistics, with a more detailed description given below.

AESDD [43]: The Acted Emotional Speech Dynamic Database comprises 500 recorded samples from 5 actors (3 females, 2 males) expressing 5 distinct emotions in Greek. Each actor performed 20 utterances per emotion, with some utterances recorded multiple times. In later versions, additional actors were included, bringing the total to 604 recordings from 6 actors.

CaFE [44]: This dataset includes recordings of 6 different sentences delivered by 12 actors (6 female, 6 male) portraying the Big Six emotions and a neutral state in Canadian French. It offers a high-quality version with a sampling rate of 192 kHz at 24 bits per sample, as well as

Dataset	Language	# Samples	Emotions
AESDD	Greek	500	anger, disgust, fear, happiness, and sadness
CaFE	Canadian French	936	anger, disgust, fear, happiness, surprise, sadness, and neutrality
DEMoS	Italian	9697	anger, disgust, fear, happiness, surprise, sadness, and neutrality
EmoDB	German	535	anger, disgust, fear, happiness, boredom, sadness, and neutrality
EmoMatch	Spanish	2005	anger, disgust, fear, happiness, surprise, sadness, and neutrality
EMOVO	Italian	588	anger, disgust, fear, happiness, surprise, sadness, and neutrality
EYASE	Egyptian Arabic	579	anger, happiness, sadness, and neutrality
Oréau	French	502	anger, disgust, fear, happiness, surprise, sadness, and neutrality
ShEMO	Persian	400	anger, happiness, sadness, and neutrality

Table 1
Summary statistics of the 9 datasets used in this work.

a down-sampled version at 48 kHz and 16 bits per sample. The total number of samples amounts to 936.

DEMoS [45]: DEMoS contains 9697 audio samples from 68 volunteer students (299 females, 131 males) expressing the Big Six emotions plus the neutral state in Italian. Instead of acted emotions, samples were generated using an elicitation approach. The recordings, with a mean duration of 2.9 seconds (std: 1.1s), are provided in 48 kHz, 16-bit, mono format.

EmoDB [46]: This collection includes 535 utterances across 7 emotional states, spoken in German by 5 female and 5 male actors. Each actor performed a set of 10 sentences, which were down-sampled from the original 48 kHz to 16 kHz.

EmoMatch [33]: Consisting of 2005 recordings, EmoMatch features samples from 50 non-actor Spanish speakers (20 females, 30 males) expressing the Big Six emotions and a neutral state. The dataset is a subset of the larger EmoSpanishDB and contains recordings sampled at 48 kHz with a 16-bit mono format.

EMOVO [47]: EMOVO presents 588 Italian audio recordings from 3 male and 3 female actors simulating the Big Six emotions plus a neutral state. Each actor voiced 14 utterances, and the recordings are provided in 48 kHz, 16-bit stereo WAV format.

EYASE [48]: EYASE contains 579 utterances in Egyptian Arabic, recorded by 3 male and 3 female professional actors. The recordings, ranging from 1 to 6 seconds in duration, were labeled as angry, happy, neutral, or sad and sampled at 44.1 kHz.

Oréau [49]: The Oréau dataset features 502 audio samples from 32 non-professional actors (25 male, 7 female) who voiced 10 to 13 utterances in French for the Big Six emotions plus a neutral state.

ShEMO [50]: ShEMO comprises 3000 semi-natural recordings from 87 native Persian speakers (31 female, 56 male). The dataset captures 5 of the Big Six emotions—sadness, anger, happiness, surprise, and fear—plus a neutral state. The samples were up-sampled to a frequency of 44.1 kHz in mono-channel format, with an average length of 4.11 seconds (std: 3.41s).

The audio is resampled to 16 kHz, and a stratified train/validation/test split is performed with ratios of 80/10/10. All results are reported using the macro F1 score, expressed as a percentage. We conducted 3 runs, presenting the mean ± standard deviation.

4.2. Experimental Details

Baseline As a baseline to evaluate LSM transfer learning capabilities, we adopt the Audio Spectrogram Transformer (AST) [51], a fully transformer-based architecture recently proposed as a substitute for CNNs [9, 10, 11]. We train AST from scratch on each of the 9 datasets using the same hyperparameters as [51].

LSM Models We use pre-trained checkpoints for both English-Only and Multilingual models: Wav2Vec 2.0 Base, Wav2Vec 2.0 Large, XLS-R from the Wav2Vec 2.0 family, and Whisper Small (EN) (Whisper Small pre-trained only on English data), Whisper Small, Whisper Medium from the Whisper family. The LSM backbones are kept frozen and used exclusively as feature extractors.

Training We follow the same hyperparameters settings as [15] to train the downstream classifiers. Specifically, we train for 30 epochs using the Adam optimizer with a learning rate of 5.0e-04, weight decay of 1.0e-04, betas set to (0.9, 0.98), and epsilon of 1.0e-08. The dimension of the classifier projection m is 256.

4.3. Results

To present our results, we first compare the performance of the various classifiers (see Section 3) for each LSM utilized. This analysis provides insights into the characteristics of features extracted from Wav2Vec 2.0 and Whisper models for downstream SER tasks. After identifying the best classifier for each LSM, we then compare the performance of English-Only and Multilingual LSMs across the 8 languages covered in this study.

4.3.1. Comparison between downstream classifiers

We examine the results in Table 2, comparing three classifier methods for Wav2Vec 2.0 and Whisper models. The

Backbone	Linear	Non-Linear	Multi-Layer
Wav2Vec 2.0 Base	47.87 (± 0.93)	42.07 (± 5.27)	**53.42** (± 1.27)
Wav2Vec 2.0 Large	12.09 (± 1.50)	12.93 (± 3.31)	**57.50** (± 0.03)
XLS-R	5.43 (± 0.40)	5.86 (± 0.07)	**40.89** (± 2.00)
Whisper Small (EN)	**58.16** (± 0.15)	53.50 (± 0.98)	49.73 (± 2.02)
Whisper Small	**60.87** (± 0.26)	54.86 (± 0.93)	45.14 (± 1.54)
Whisper Medium	**60.72** (± 0.16)	55.56 (± 1.09)	37.95 (± 2.27)

Table 2
Performance of various LSM backbones using *Linear*, *Non-Linear*, and *Multi-Layer* classification methods. F1 scores are averaged across all 9 datasets. For each LSM, the best classifier is highlighted in bold.

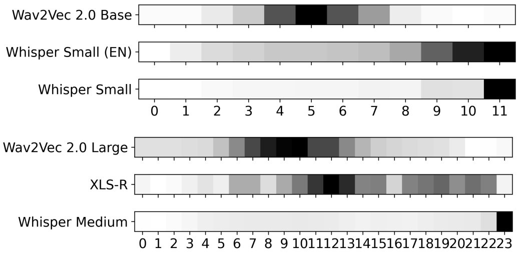

Figure 2: Greyscale map of layer weight distribution from the *Multi-Layer* classification method. Weights are averaged over all 9 datasets for each model. Darker shades indicate higher weights.

table shows average F1 scores across 9 datasets, highlighting the most effective classifier for each LSM in cross-lingual SER tasks.

For Wav2Vec 2.0 models, the Multi-Layer Classifier performs best, with F1 scores of 53.42, 57.50, and 40.89 for Wav2Vec 2.0 Base, Wav2Vec 2.0 Large, and XLS-R. The Linear and Non-Linear classifiers perform similarly, especially for Wav2Vec 2.0 Large and XLS-R, suggesting improvements are due to using features from internal Transformer layers rather than non-linear activations. For Whisper models, the Linear Classifier performs best, with F1 scores of 58.16, 60.87, and 60.72 for Whisper Small (EN), Whisper Small, and Whisper Medium. Increasing classifier complexity with non-linear activations decreases performance, likely due to general information loss caused by complex transformations. The Multi-Layer Classifier performs worse, indicating that using also features from internal layers is less effective than using features from the last layer alone.

This comparison reveals that Wav2Vec 2.0 models benefit from features extracted from internal Transformer layers and exhibit less sensitivity to classifier complexity, consistent with prior research [41, 39]. Conversely, Whisper models achieve better performance with features from the last Transformer layer when using a simple linear classifier, offering new insights into their effectiveness for SER across multiple languages. We hypothesize that this differing behavior may be related to their respective Self-Supervised and Weakly-Supervised pre-training approaches, which warrant further investigation. To gain further insights into the importance of Transformer layers in Wav2Vec 2.0 and Whisper for SER, we leverage the weights learned in the Multi-Layer classifier as follows.

Transformer Layer Weights. We analyze the weights $w_1, \dots, w_L$ from the Multi-Layer Classifier to assess Transformer layer importance. Figure 2 illustrates that Wav2Vec 2.0 models assign greater weight to the early and middle layers, whereas Whisper models emphasize the later layers. This observation confirms the earlier findings, suggesting that paralinguistic information in Whisper models is embedded in the features of the later Transformer layers.

4.3.2. Comparing English-Only and Multilingual LSMs Across Different Languages

In this section, we compare English-Only and Multilingual LSMs with the AST baseline across 9 datasets. Table 3 displays F1 scores for the optimal classifiers found in the previous section: *Multi-Layer* for Wav2Vec 2.0 and *Linear* for Whisper models.

Transferring knowledge from LSMs proves to be effective across all datasets compared to the baseline. For instance, Wav2Vec 2.0 Large scores 53.40 in Egyptian Arabic, while Whisper Small scores 51.98 and AST scores 33.23. This indicates that LSMs are effective feature extractors for cross-lingual SER on multiple languages.

When comparing English-only and Multilingual models, we differentiate between the Wav2Vec 2.0 and Whisper families. For Wav2Vec 2.0, we observe that Wav2Vec 2.0 Base and Large generally outperform XLS-R (e.g., 87.85 and 88.31 vs. 67.71 for DEMos), except in Persian, where their performance is comparable. This indicates that multilingual pre-training may not be as effective for Wav2Vec 2.0 models across various languages. We speculate that this may be due to the limitations of SSL pre-training, which might struggle with the diverse range of languages and lose important paralinguistic features that are retained in English-only models. Further investigation with a wider range of SSL-pretrained LSMs could provide more insights. As regards to Whisper, Multilingual Whisper Small outperforms its English-only version, with the exception of Greek and Persian, likely due to limited pretraining data for these languages, which resulted in higher word error rates compared to other languages in this study [13]. Multilingual Whisper models achieve best performance in Canadian French, Spanish (66.71, 73.13 with Whisper Small), Italian, German, and French (91.17, 90.64, 95.22 with Whisper Medium). This improvement is likely due to the larger pretraining datasets for these languages and the similarities between

Dataset/Model	AST	English-Only			Multilingual		
		Wav2Vec 2.0 Base‡	Wav2Vec 2.0 Large‡	Whisper Small†	XLS-R‡	Whisper Small†	Whisper Medium†
AESDD (el)	19.84 (± 0.16)	25.45 (± 0.98)	**28.89** (± 2.64)	28.04 (± 0.99)	9.16 (± 1.25)	26.34 (± 1.65)	27.62 (± 0.62)
CaFE (fr-ca)	10.96 (± 6.26)	50.52 (± 3.54)	47.74 (± 0.33)	60.66 (± 0.76)	18.66 (± 0.01)	**66.71** (± 0.72)	55.03 (± 0.38)
DEMoS (it)	13.75 (± 4.26)	87.85 (± 0.01)	88.31 (± 0.74)	88.24 (± 0.21)	67.71 (± 1.47)	90.61 (± 0.14)	**91.17** (± 0.20)
EmoDB (de)	46.11 (± 6.55)	81.75 (± 7.30)	88.84 (± 7.48)	83.31 (± 0.18)	67.39 (± 4.33)	87.21 (± 1.11)	**90.64** (± 1.47)
EmoMatch (es)	36.10 (± 2.63)	69.84 (± 0.69)	71.85 (± 1.55)	67.59 (± 0.35)	44.14 (± 0.25)	**73.13** (± 2.54)	68.23 (± 0.78)
EMOVO (it)	15.74 (± 1.24)	16.47 (± 0.61)	20.33 (± 1.31)	27.30 (± 0.16)	14.86 (± 2.11)	41.05 (± 1.21)	**50.19** (± 0.29)
EYASE (ar-eg)	33.23 (± 4.58)	46.31 (± 3.62)	**53.40** (± 1.56)	42.65 (± 0.70)	47.27 (± 1.36)	51.98 (± 0.88)	37.32 (± 3.62)
Oréau (fr)	19.01 (± 2.35)	52.86 (± 0.07)	58.42 (± 4.14)	82.27 (± 0.23)	32.51 (± 4.89)	92.70 (± 1.67)	**95.22** (± 0.84)
ShEMO (fa)	36.15 (± 0.85)	60.55 (± 3.90)	57.52 (± 9.09)	**67.93** (± 0.37)	61.24 (± 8.93)	63.88 (± 1.21)	63.85 (± 1.58)

Table 3
Performance of Wav2Vec and Whisper models across 9 datasets, divided into English-Only and Multilingual LSMs. AST is the baseline. † indicates a Linear Classifier, ‡ a Multi-Layer Classifier. Bold values are the highest scores, and underlined values highlight the best between English-Only and Multilingual models.

Canadian French and French. We believe that multilingual pretraining benefits Whisper models by capturing language-specific features more effectively through WSL and multitask learning. However, further research is needed to evaluate the effectiveness of multilingual pretraining with WSL compared to SSL across a broader range of LSMs.

5. Conclusion

This paper examines the capabilities of Wav2Vec 2.0 and Whisper models as feature extractors for cross-lingual SER across eight languages, considering both English-Only and Multilingual variants. Our findings reveal that LSMs are effective feature extractors compared to a full Transformer baseline trained from scratch. We observe that Whisper models encode acoustic information primarily in the features of the last Transformer layer, whereas Wav2Vec 2.0 models rely on features from middle and early layers. Furthermore, we show that multilingual pre-training benefits Whisper models, leading to strong performance in Italian, Canadian French, French, Spanish, German, and competitive results in Greek, Egyptian Arabic, and Persian. In contrast, English-Only Wav2Vec 2.0 models outperform their multilingual counterpart, XLS-R, in most languages, achieving top performance in Greek and Egyptian Arabic. We attribute the disparity in multilingual pre-training effectiveness to the differences between SSL and WSL strategies, which should be explored further.

Building a Pragmatically Annotated Diachronic Corpus: the DIADIta Project

Irene De Felice[1,*] and Francesca Strik-Lievers[2]

Abstract

We present here the first stages of the construction of the DIADIta corpus, a diachronic corpus of Italian annotated for interactional pragmatic phenomena. This corpus aims to fill a gap in the resources available for the historical pragmatics of Italian. First, we describe the annotation scheme, which is structured into four levels covering a wide range of pragmatic (or pragmatically relevant) categories: speech acts (e.g., apology; threat), forms (e.g., discourse marker; expressive), pragmatic functions (which are speaker-oriented, e.g., mitigation; turn-taking), and pragmatic aims (which are interlocutor-oriented, e.g., attention-getting; request for agreement). We then discuss how the results of an initial annotation exercise provide insights for refining the annotation procedure.

Keywords

diachronic corpus pragmatics, historical pragmatics, interaction, Italian, pragmatic annotation

1. Introduction

The DIADIta project[1], situated within the framework of historical pragmatics [1], aims to investigate the specific pragmatic features and strategies of dialogic interaction in different phases of the Italian language, and to understand how these features and strategies interrelate with one another and change over time. Although the last fifteen years have witnessed a growing interest in the historical pragmatics of Italian [2], there is still a lack of an in-depth study on this topic, one that is able to fully account for how different communicative strategies and different linguistic categories (primarily, but not exclusively, pragmatic) interact with each other, both in synchronic and diachronic perspective. The DIADIta project aims to address this gap.

A key goal of the project is to build a diachronic corpus annotated for a wide range of pragmatically relevant linguistic phenomena. The DIADIta corpus, which will contribute to the recently established field of diachronic corpus pragmatics [3], will consist of at least 24 Italian literary texts of different genres dating from the 13th to the 20th century: in most cases, plays, novels and short stories where dialogic interactions between characters are particularly frequent. Once completed, the corpus will be freely accessible and searchable from the project website (www.diadita.it) and will be possibly further expanded and enriched with other texts of different literary genres.

In this paper, we present the first steps we have taken to lay the foundation for the DIADIta corpus. After a brief review of related literature and resources (Section 2), we describe the structure of the annotation scheme, outlining the theoretical and methodological assumptions that underlie it and highlighting its most innovative aspects (Section 3). Then, we present the results of an annotation exercise on a play by Luigi Pirandello, with which we tested the reliability of the scheme. In the light of these results, we also briefly discuss some improvements that we plan to apply in the next stages of the corpus annotation process (Section 4). The last section draws the conclusions of the study (Section 5).

2. Pragmatically annotated (diachronic) corpora: challenges and resources

Most existing corpora are not well suited for research focused on pragmatics, unless one adopts a form-to-function approach, which implies searching for specific keywords or linguistic structures that are known or supposed to express pragmatic functions (e.g. discourse markers, specific verb forms and syntactic structures, etc.; see [4, 5]). Such an approach is not viable in the field of diachronic pragmatics: in this case, a function-to-form approach must usually be adopted, since certain pragmatic functions remain stable over time, while the linguistic means by which speakers express them may vary [6, 7]. The problem is, of course, that "functions cannot be searched for automatically" [8, p. 5].

Corpora annotated with pragmatic information that allow for searches based on a function-to-form approach are rare, partly due to the difficulties arising in their construction [9]. First of all, the annotation of pragmatic categories requires a great deal of interpretation on the part of the annotator. Moreover, this type of annotation, "unlike, for example, POS (part-of-speech) or semantic tagging/annotation, almost always needs to take into account levels above the individual word and may even need to refer to contextual information beyond those textual units that are commonly referred to as a 'sentence' or 'utterance'" [10, p. 84]. Therefore, due to its inherent difficulties, the annotation of pragmatic categories is still mostly a manual, time-consuming task and "it is doubtful whether the process of manual classification will ever be fully replaced" [8, p. 15]. Nevertheless, some attempts have been made to design annotation schemes that allow for (semi-)automatic annotation of specific pragmatic categories. In particular, most efforts have focused on speech acts. Consider, for instance, the *Speech Act Annotated Corpus* project (SPAAC; [11]) and the *Dialogue Annotation and Research Tool* (DART; [12, 13]; for a discussion of widely known models and tools for speech act or dialogue act annotation, including the DAMSL and the SWBD-DAMSL models, see [10, 14], and more recently [15]). The international standard DiAML (*Dialogue Act Markup Language*, ISO 24617-2; see [16]) also concerns speech acts found in dialogue. In this annotation scheme, a given dialogue segment may express multiple acts, and a given act may be assigned multiple communicative functions: a feature that is also crucial in our annotation scheme (see Section 3.1).

Corpora annotated with pragmatic categories for English include, among others, the *SPICE-Ireland Corpus*, which is derived from the spoken data of the *International Corpus of English: Ireland Component* (*ICE-Ireland*) and provides information on the speech act function of utterances, discourse markers, and quotatives. The *Sociopragmatic Corpus* (SPC) is a subsection of the *Corpus of English Dialogues* (CED) and comprises drama and trial proceedings dating from 1640 to 1760. This historical corpus can be used to investigate the extent to which the role of the participants affects the realization of pragmatic functions [8], since gender, status/social rank, role, and age are annotated for each participant.

For the Italian language, there are numerous corpora that collect texts from historical varieties of Italian (e.g. DiaCORIS – *Corpus of Diachronic Written Italian*; CEOD – *Digital Nineteenth-Century Epistolary Corpus*), some of which also provide morphological information (e.g. MIDIA – *Morphology of Italian in Diachrony*). There are also corpora designed to enable or facilitate pragmatic analysis. For example, the LABLITA corpus [17], developed within the pragmatic framework of the *Language into Act Theory* (L-AcT), brings together in a single resource a collection of three spoken Italian corpora recorded in Tuscany since 1965. One of the most innovative aspects of the corpus is that the transcripts are aligned with the acoustic source via utterance, i.e., "the linguistic counterpart of a speech act" [17, p. 93]. Linguistic implicatures (presuppositions, implicatures, topicalizations, and vagueness) are annotated in the IMPAQTS corpus, which collects Italian political discourses since 1946 [18].

Although this is a brief and non-exhaustive overview of the resources in this field, the few examples provided are sufficient to demonstrate that, overall, it is still true what Archer and colleagues wrote in 2008, that is, that "[w]ork in the area of pragmatics and corpus annotation is much less advanced than other annotation work (grammatical annotation schemes, for example)" [19, p. 613]. Furthermore, to the best of our knowledge, a diachronic corpus annotated with a rich set of pragmatic features is currently lacking among the corpora developed for Italian, and we find no equivalents among the corpora developed for other languages either. Most notably, there is no resource capable of accounting for both the linguistic means that express different pragmatic functions in various historical varieties of a language, and the ways in which these linguistic categories interact with one another in both a synchronic and diachronic dimension. This led to the design and construction of the DIADIta corpus.

3. Annotation scheme

The annotation scheme created within the DIADIta project is designed to cover a wide range of pragmatically relevant phenomena, especially those with a clear interactional value. Given that no existing tagset fully met the project's needs to encompass a broad spectrum of linguistic—and particularly pragmatic—

phenomena, the annotation scheme has been developed by drawing from a number of categories whose relevance is well established in pragmatic studies, such as POLITENESS, DISCOURSE MARKERS, further enriched with other linguistic categories that proved to have significant implications on the pragmatic front, such as EPISTEMICITY and EVIDENTIALITY.

So far, the scheme is organized into four levels of annotation (for a detailed description of the individual tags, please refer to the DIADIta annotation guidelines available on the project's website):

- **Forms**: This level includes linguistic expressions (belonging to different parts of speech, and with variable extension) that have an interactional pragmatic value, and in particular: DISCOURSE MARKERS (e.g., *Senti, io me ne vado*, 'Listen, I'm leaving'), EXPRESSIVES (e.g., *Smettila, idiota!*, 'Stop it, you idiot!') and REPETITION, when it has a pragmatic value (e.g., *Lo giuro, lo giuro!*, 'I swear it, I swear it!', where the repetition intensifies the oath).
- **Pragmatic functions**: This level includes a set of categories that have (also, or exclusively) a pragmatic value, such as: POLITENESS, VAGUENESS, DISAGREEMENT, IMPOLITENESS, INTENSIFICATION, EPISTEMICITY, TURN-TAKING.
- **Pragmatic aims**: This level focuses on the reaction that the speaker intends to provoke in the interlocutors, for example attracting their attention (ATTENTION GETTING) or requesting their confirmation or manifestation of agreement (REQUEST FOR CONFIRMATION/AGREEMENT)[2].
- **Speech acts**: This level includes the main types of expressive (e.g., DERISION, PROTEST), directive (e.g., ORDER, REQUEST), commissive (e.g., COMMITMENT/PROMISE, THREAT), and assertive (e.g., ASSERTION, CORRECTION) speech acts.

Each of the four levels includes several tags (N=57), as summarized in Appendix A.

3.1. Interaction between categories

As illustrated by examples from Luigi Pirandello's play *Enrico IV* (1921), the same string of text can be annotated with multiple tags, either from the same level (ex. 1) or from a different level (ex. 2). Furthermore, a string of text tagged with a certain tag can contain a smaller string tagged with a different tag, either from the same level (ex. 3) or from a different level (ex. 4):

1. Di Nolli: *Lasciamo andare, lasciamo andare, **vi prego**.*
   Di Nolli: 'Let it go, let it go, I beg you.'
2. D. Matilde: [...] *Non ti vedi in me, tu, là?*
   Frida: ***Mah!*** *Io, veramente...*
   D. Matilde: '[...] Don't you see yourself in me, there? '
   Frida: 'Well! I, actually...'
3. Bertoldo: [...] *Ho detto bene: non era vestiario, questo, del mille e cinquecento*!
   Arialdo: ***Ma che mille e cinquecento!***
   Bertoldo: '[...] I said it right: this wasn't clothing from the fifteen hundreds!'
   Arialdo: 'What fifteen hundreds!'
4. Bertoldo (arrabbiandosi): ***Ma*** *me lo potevano dire,* ***per Dio santo****, che si trattava di quello di Germania e non d'Enrico IV di Francia!*
   Bertoldo (getting angry): 'But they could have told me, for God's sake, that it was about the one from Germany and not Henry IV of France!'

In ex. 1, *vi prego* 'I beg you' is labeled with two tags from the pragmatic functions level: it has both a POLITENESS function and an INTENSIFICATION function (it intensifies the force of the directive act expressed by the whole utterance).

In ex. 2, *Mah!* 'Well!' is tagged as a DISCOURSE MARKER (forms level) but is also considered an expression of EPISTEMICITY and DISAGREEMENT (functions level). By using this interjection, the character Frida expresses a low degree of certainty regarding the truth of Donna Matilde's statement, thus also demonstrating that she does not fully agree with her.

In ex. 3, the entire utterance by Arialdo, who mocks Bertoldo in front of his friends (speech act of DERISION), is labeled at the level of pragmatic functions as a manifestation of DISAGREEMENT and IMPOLITENESS. However, it also contains the DISCOURSE MARKER *ma che* 'what,' which is also labeled – again at the pragmatic functions level - as a TURN-TAKING marker.

In ex. 4, the whole utterance by Bertoldo is labeled as a PROTEST (speech acts level). Within this utterance, *ma* 'but' is labeled as a DISCOURSE MARKER (forms level) and as a TURN-TAKING marker (pragmatic functions level), and *per Dio Santo* 'for God's sake' is labeled with the tags EXPRESSIVE (forms level) and INTENSIFICATION

[2] To avoid overburdening the tagset, we have chosen to merge certain categories that, despite being well-defined on a theoretical level, are often difficult to distinguish in practice from other closely related functional categories, such as REQUEST FOR CONFIRMATION and REQUEST FOR AGREEMENT.

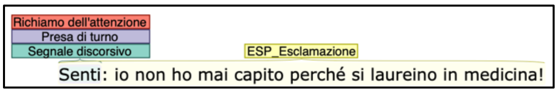
(pragmatic functions level), since it is used to strengthen the illocutionary force of the act itself.

3.2. Annotation tool

As shown in Section 3.1, allowing overlapping annotations from the same and different levels is essential to capture the multifunctionality of pragmatically relevant expressions and the interaction between linguistic and pragmatic categories. For instance, *Mah!* 'Well!' serves as a DISCOURSE MARKER that expresses DISAGREEMENT while also conveying EPISTEMICITY, in ex. 2 discussed above. Moreover, having multiple annotators work on the same text is necessary for identifying and discussing cases of disagreement, especially in the early stages of the project.

For collaborative projects of this type, a web-based tool is the most suitable instrument [20]. For this first annotation exercise, we chose INCEpTION [21], which allows the creation and easy modification of a tagset (in our case multiple tagsets, one for each annotation level) and the overlapping and nesting of different tags. The annotation performed on INCEpTION is of the standoff type: the texts are therefore not modified, and the annotations are stored in a separate document (see Finlayson & Erjavec [22, p. 178], who consider standoff annotation a best practice, compared to inline annotation).

As an example, Figure 1 presents a screenshot of an annotation, again on the play *Enrico IV*. A stratification of annotations can be observed, with the entire utterance *Senti: io non ho mai capito perché si laureino in medicina!* ('Listen: I have never understood why they graduate in medicine!') labeled as an EXCLAMATION speech act, *senti* 'listen' as a DISCOURSE MARKER with the pragmatic function of TURN-TAKING and the pragmatic aim of ATTENTION-GETTING.



Senti: io non ho mai capito perché si laureino in medicina!

Figure 1: Screenshot of the annotation in INCEpTION. The four different colors represent different annotation layers: forms, pragmatic functions, pragmatic aims, speech acts.

3.3. Annotation guidelines

As the annotation scheme and the few examples provided in Section 3.1 clearly demonstrate, the annotation of the DIADIta corpus is extremely complex. Indeed, Weisser [10, p. 84] observes, "[a]ny type of linguistic annotation is a highly complex and interpretive process, but none more so than pragmatic annotation". Therefore, it is essential to have a meticulously detailed annotation manual to guide annotators.

The first text tested for the pragmatic annotation of the categories initially selected for our project is the first act of Pirandello's *Enrico IV* (9,216 words). We began by independently annotating the text and subsequently discussed our work until a consensus was reached on each annotation.

The total number of annotations for the first act is 958. This very first phase of the annotation process has been crucial for refining the tagset, which is now in the form shown in Appendix A, and for developing guidelines with practical instructions for annotation. The current version of the DIADIta annotation guidelines is available on the project's website. The guidelines provide a brief definition for each annotation level and tag, along with basic references and examples from the annotated texts in the corpus. They also specify constraints for applying certain tags. For example, the tag EXPRESSIVE (forms level) is used to annotate lexical elements such as exclamations, vulgarisms, insults, or curses that express "subjective sensations, emotions, affections, evaluations or attitudes" [23, p. 33]. However, it is also specified that this tag should only be applied when it co-occurs with one or more tags from the pragmatic functions or pragmatic aims levels; i.e, only in contexts where expressive forms are relevant at a pragmatic, interactional level. Consider examples 5 and 6:

5. Secondo valletto: *Eh, **santo Dio**, potevate dircelo!*
   Second valet: 'Oh, holy God, you could have told us!'
6. Frida: *Fa di professione lo **scemo**, non lo sa?*
   Frida: 'He acts the fool professionally, don't you know?'

In ex. 5, *santo Dio* 'holy God' is tagged as EXPRESSIVE because it also has an INTENSIFICATION function, as it intensifies the expressive force of a PROTEST speech act. In contrast, in ex. 6, *scemo* 'fool', despite being an expressive used in a DERISION speech act, is not tagged because it does not seem to serve primarily a specific pragmatic function or aim in the interaction.

4. Results and discussion

To test the reliability of the adopted scheme, we annotated the second act of Pirandello's *Enrico IV* (6,968 tokens) in INCEpTION. This annotation process benefited from our previous joint annotation experience on the first act of the same play and, most importantly, relied on the established annotation guidelines. The annotation performed separately by the two authors resulted in 818 and 906 annotations, respectively, for a total of 1,724 annotations.

To test the inter-annotator agreement we adopted Krippendorff's α metric [24, 25, 26, 27], a unitizing measure that is particularly suitable for assessing the level of agreement in our case, because it can produce partial agreement scores from all annotations by also taking into account their partial overlaps. For instance, for *eh sì* ('oh, yes'), one annotator assigned the tag AGREEMENT (pragmatic functions) to the entire expression, while the other annotator assigned the same tag only to *sì*. This kind of annotation is considered incomplete, but is still used to compute the agreement. The agreement score is, of course, lower in such cases compared to complete annotations, where the same tag is assigned to the same length of spans by both annotators. Table 1 presents the agreement scores and the number of annotations for each of the four layers of our annotation scheme[3].

Table 1
Number of annotations and IAA scores (Krippendorff's α; α value may range from -1 to 1). FSL=Francesca Strik-Lievers, IDF=Irene De Felice.

	FSL	IDF	Krippendorff's α
Forms	171	168	0.71
Functions	327	390	0.34
Aims	29	38	0.05
Speech acts	291	310	0.56

According to Landis and Koch's [28] scale, our levels of agreement should be considered as *slight* for the pragmatic aims level, *fair* for the functions level, *moderate* for the speech acts level, and *substantial* for the forms level.

These results clearly demonstrate that, even though the annotation was performed by expert annotators following detailed guidelines, pragmatic annotation remains a highly complex and fine-grained task, especially when annotators have to assign many labels, and often multiple labels to the same token(s). In many cases, to understand the pragmatic function of a linguistic unit, the annotator must go well beyond the level of the single word, phrase or sentence, and necessarily consider the linguistic co-text, or even the extralinguistic context, as far as it can be reconstructed from a written text. Therefore, in this specific field of annotation, reaching an α value higher than 0.67, which is sometimes considered essential to draw at least "tentative conclusions" [24, p. 241] in other computational linguistic tasks, may be exceptionally challenging, even for expert annotators. Other complex pragmatic annotation models created for discourse annotation tasks have also failed to achieve high levels of agreement. For instance, *slight* to *moderate* values of agreement produced by the α metric are also reported by Duran et al. [27] for the *Conversation Analysis Modeling Schema - CAMS* (cf. also Castagneto [14], who reports moderate agreement values for the Chiba and DAMSL annotation models).

Therefore, a low level of agreement was to be expected and, from our point of view, this should not necessarily be understood as an indication of low annotation quality, inadequate training, or poorly defined guidelines [29], since when there are two partially or completely disagreeing annotations, it is not always the case that one is correct and the other wrong. In many cases both can be acceptable, as in example 7, in which Matilde's reaction to the doctor's question was considered by one annotator as an EXCLAMATION, and by the other as a RESPONSE to his request for information:

7. Dottore (stordito): *Come dice?*
   D. Matilde: ***Quest'automobile, dottore!*** *Sono più di tre ore e mezzo!*
   Doctor (stunned): 'What did you say?'
   D. Matilde: 'This car, doctor! It's been over three and a half hours!'

Discrepancies may also stem from differences in annotated span lengths, even when the same tag is chosen. For instance, in example 8, one annotator marked AGREEMENT for the entire statement by Belcredi (*Sì, forse, quando disse...*), while the other one marked AGREEMENT only for *sì* 'yes'.

8. D. Matilde: *Non è vero! – Di me! Parlava di me!*
   Belcredi: ***Sì, forse, quando disse***...
   D. Matilde: *Dei miei capelli tinti!*
   D. Matile: 'That's not true! Me! He was talking about me!'
   Belcredi: 'Yes, maybe, when he said...'
   D. Matilde: 'About my dyed hair!'

The analysis of cases of disagreement has been also useful in order to revise certain aspects of the tagset. For instance, after this exercise we have decided to merge the COMMITMENT/PROMISE speech act with OATH in future annotations, given that in many cases it is very difficult to distinguish between them. It has also been useful to identify unclear points in the guidelines, and to better plan the next phases of the project. In particular, we intend to: (i) release an updated version of the guidelines with clearer descriptions of some aspects of the

[3] The inter-annotator agreement is calculated with INCEpTION 33.3-SNAPSHOT (b5644aca).

annotation process; (ii) ensure that each text in the corpus is annotated or revised by at least two expert annotators; and (iii) include validation tasks at a regular rate in the project workflow to revise annotations for small groups of texts in order to reach better intra- and inter-text consistency.

5. Conclusions

This paper has outlined the initial steps in creating the DIADIta corpus, a pragmatically annotated diachronic corpus for Italian. This corpus is characterized by its rich, multi-layered annotation scheme organized into four dimensions: forms, pragmatic functions, pragmatic aims, speech acts. This structure allows for nuanced analysis of pragmatic strategies in literary texts from the 13th to the 20th century. The innovative approach of annotating complex interactional features highlights the value of this corpus as an unparalleled tool for examining the evolution of pragmatic functions and forms over time, enabling detailed and multi-dimensional analysis of text data.

We have also detailed an annotation exercise on a play by Pirandello that illustrates the task's complexity (reflected in the low level of agreement in some layers), but also the richness of the annotations. This first exercise is crucial for refining the annotation process and improving clarity and reliability in applying a pragmatic annotation model to historical texts.

Acknowledgements

Building CorefLat
A linguistic resource for coreference and anaphora resolution in Latin

Abstract

This paper presents the initial stages of a project focused on coreference and anaphora resolution in Latin texts. By building a corpus enhanced with coreference/anaphora annotation, the project wants to explore empirically a layer of metalinguistic analysis that has not been yet extensively investigated in linguistic resources and natural language processing for Latin. After reviewing the related work on this NLP task, the paper discusses annotation criteria and data analysis, providing examples about a few issues that emerged during the annotation process.

Keywords

Latin, Coreference, Anaphora, Annotation, Corpora

1. Introduction

Over the past decade, research on linguistic resources and natural language processing (NLP) for Latin has seen remarkable growth[1]. However an important layer of metalinguistic annotation such as coreference and anaphora resolution still remains quite neglected. Indeed, except for the (meta)data produced by the FIR-2013 project *Development and Integration of Advanced Linguistic Resources for Latin* [2], there are neither corpora enhanced with coreferential/anaphoric annotations nor NLP tools for automatic coreference/anaphora resolution for Latin. This absence limits the degree of granularity of information extraction from Latin corpora. Such a limitation is particularly compelling, as Latin texts are mainly used for purposes of research in the Humanities, like literary, stylistic and philosophical analysis. To give an example, investigating in Latin texts a philosophical concept conveyed by a word, like *voluntas* 'will', or studying the turns of a certain character in a drama would highly benefit from a textual resource where, for instance, the ana-/cataphoric references of pronouns are resolved.

The PRIN 2022 project *Textual Data and Tools for Coreference Resolution of Latin* was granted funding to overcome such situation. Run jointly by the Università Cattolica of Milan and the University of Udine, the project stems from the FIR-2013 pilot experience, having the short-term objective of developing a large-scale and balanced dataset of Latin texts enhanced with coreference/anaphora resolution (called CorefLat). Based upon this annotated dataset, the project has two long-term objectives.

The first aims to develop and evaluate a set of trained models for automatic coreference/anaphora resolution of Latin.

The second long-term objective wants to publish the metadata pertaining to coreference/anaphora resolution as Linked Data, to make them interoperable with other (meta)data in the Web. To this aim, the texts of the annotated dataset are selected among those published in the LiLa Knowledge Base, a collection of multiple linguistic resources for Latin modelled using the same vocabularies for knowledge description and interconnected according to the principles of the Linked Data paradigm [3][2].

This paper details the initial stages of the creation of the CorefLat annotated dataset.

2. Related Work

Coreference (henceforth CR) and anaphora (henceforth AR) resolution are often treated as a single, yet diverse, task in NLP. To understand the difference between CR and AR, it is necessary to distinguish between the concept of "mention" and that of "entity". A mention is defined as an instance of reference to an object, while an entity is the object to which a mention refers in a text. CR consists in finding in a text all mentions of (strictly speaking, real-world) entities such as persons or organisations, regardless of their textual representation. Instead, in AR the interpretation of a mention (known as "anaphora" or "cataphora", e.g., a pronoun) depends on another mention present in the text, whether antecedent or following in the word order. If both mentions refer to the same entity, they are considered to be coreferential, which makes AR and CR closely bound to each other. Since ana-/cataforic relations are present in the text, the need of world knowledge in AR is minimal. In contrast, CR has a much broader scope: co-referential terms can have completely different grammatical properties and/or functions (e.g., different gender and part of speech) and yet, by definition, they can refer to the same entity.

In NLP, the CR task is usually not meant in a strict sense, as it consists in finding all mentions of each entity in a text regardless of their relation to the real world. Accordingly, our project adopts this same interpretation of the CR task [4].

Since the 1960s, coreference and anaphora resolution has been a central topic in NLP studies, but it was considered a difficult task, typically requiring the use of sophisticated knowledge sources and inference procedures. In 1983, Roberto Busa pointed out the absence of resources and tools for pronoun coreference resolution: "[...] avete mai incontrato tavole e concordanze computerizzate nelle quali il programma automaticamente abbia [...] collegato i pronomi alle forme di cui sono vicari?" [5, 7.2][3].

Like for other NLP tasks, during the 1990s research on CR/AR gradually shifted from heuristic approaches to machine learning approaches, thanks to the public availability of annotated corpora produced for the aims of shared tasks dedicated to coreference resolution, such as Message Understanding Conference (MUC) conferences [7], and Automatic Content Evaluation (ACE) Program conferences [8]. These corpora mainly include news article and newswire texts in English. The ACE corpus also features Arabic and Chinese texts from web-blogs and telephone conversations. The tendency to focus coreference and anaphora annotation on newspaper texts is also confirmed by those selected for the CoNLL shared task on modeling unrestricted coreference in OntoNotes [9, 10], as well as by the NXT-format Switchboard Corpus [11]. In addition, some treebanks feature CR/AR, encompassing a wide range of languages, including English and Czech [12], German [13], Japanese [14], Italian [15], Spanish and Catalan [16]. To the best of our knowledge, there is no specific Latin corpus enriched with CR/AR. The only currently available texts that include this layer of annotation come from Latin treebanks. The FIR-2013 project mentioned above built a CR-annotated dataset including works by Sallust, Caesar and Cicero (taken from the Latin Dependency Treebank [17]), and by Thomas Aquinas (from the *Index Thomisticus* Treebank [18]). However, the selection of texts in this dataset is quite unbalanced as for both literary genres and authors. Out of the more than 45,000 total annotated tokens, about 27,000 are taken from Thomas Aquinas' *Summa contra Gentiles*, and more than 10,000 are from Sallust's *In Catilinam*. This given, our project wants to create a more balanced dataset by increasing and differentiating the quantity of annotated texts for both Classical and Late Latin.

3. Building CorefLat

3.1. Annotation Criteria and Data Selection

To create a resource that adheres to the most unified and widely shared annotation criteria for CR/AR, the annotation style of CorefLat resembles the one developed for the GUM corpus and follows the recommendations proposed by the (ongoing) Universal Anaphora (UA) project[4], which aims to create, gather, and distribute harmonized resources for CR/AR.

While building CorefLat, we decided to focus on a subset of the different types of coreference and ana-/cataphora prescribed by the GUM and UA recommendations. The types that we selected are listed below:

- anaphoric pronouns referring back to something: ***domine qui*** *et semper vivis* (Aug. *Conf.* 1.6.8) '**Lord** (you) **who** live for ever';
- cataphoric pronouns referring forward to something: *invocat* ***te***, ***domine*** (Aug. *Conf.* 1.1.1) 'invokes **you**, **Lord**';
- content-rich lexical item - coreferring the same lexical mention: ***laudes*** *tuae, domine,* ***laudes*** *tuae per scripturas tuas suspenderent palmitem cordis mei* (Aug. *Conf.* 1.17.27) 'Your **praises**, Lord, your **praises** throughout your Scriptures would have supported the vine shoot of my heart';

[3] "[...] have you ever come across computerized tables and concordances in which the programme automatically [...] connects pronouns with the nouns that they represent?". Translation taken from [6, 137-138].

[4] https://universalanaphora.github.io/UniversalAnaphora/

- split antecedents - the referred items are more than one: *an vero* ***caelum*** *et* ***terra, quae*** *fecisti et in* ***quibus*** *me fecisti, capiunt te?* (Aug. *Conf.* 1.2.2) '**heaven** and **earth**, **which** you made, and in **which** you made me, encompass you?'.

Such a limited set of types of coreference was selected to address the fundamental aim of the two-year long funded project, namely building and distributing a Latin corpus enhanced with coreferential annotation, which is not yet available for this language.
Texts are annotated manually by two independent annotators, using the Content Annotation Tool (CAT)[19], formerly known as the CELCT Annotation Tool, which was created specifically for textual coreference annotation. The tool is highly customizable, making it possible, for instance, to distinguish between annotations of mentions and those of entities. (Meta)data are saved in XML and are then converted in CoNLL-U Plus following the recommendations of the UA initiative[5].
In CorefLat, coreferences are not annotated as chains, but rather as relations. In a coreference relation two elements are involved: the one referring (mention) and the one referred (entity). In our annotation, each mention points directly to the one entity it refers to, rather than to any previous mention of the same entity. Consider the example in (1).

(1) *Magnus es,* ***Domine****, et laudabilis valde. Magna virtus* ***tua*** *et sapientiae* ***tuae*** *non est numerus.* (Aug. *Conf.* 1.1.1) 'Great are you, O **Lord**, and surpassingly worthy of praise. Great is **your** goodness, and **your** wisdom is incalculable'[6].

In sentence (1), we identify two coreference relations: the first one involves the mention *tua* and the entity *Domine*, and the second one involves the mention *tuae* and the same entity *Domine*. Typically, the referred element is a noun, nevertheless it happens to get through cases where the referred entity is represented by a function word, such a pronoun, like in example (2):

(2) *nec valerem* ***quae*** *volebam* ***omnia*** *nec* ***quibus*** *volebam* ***omnibus***. (Aug. *Conf.* 1.8.13)
'I was incapable of achieving **all that** I wanted, and by **all that** I wanted.'

In (2), the relative pronoun *quae* refers to the quantifying pronoun *omnia*, like *quibus* refers to *omnibus* in the reminder of the sentence. Since *omnis* 'all' (lemma of both *omnia* and *omnibus*) is a function word, no content-rich entity is concerned in this coreference relation. Moreover, it should be noted that sometimes the entity is not explicitly expressed in the text. To address this issue, we create external entities to which the respective mentions are linked by tagging. For instance, in example (3), the pronoun *nos* 'we' refers to the two lovers in Plautus' comedy *Curculio*, namely the girl *Planesium* and the boy *Phaedromus*, whose names are not explicitly mentioned in the sentence for economy's sake, as the two characters are present on stage and pronounce these lines themselves.

(3) *quo usque, quaeso, ad hunc modum / inter* ***nos*** *amore utemur semper surrupticio?* (Pl. *Curc.* 1, 204-205)
'How much longer, please, will we always conduct **our** love affair in secret?'

In such a case, we tag the mention *nos* as linked to the entities "Planesium" and "Phaedromus" that are created external to the text.

The annotation task is performed on a collection of Latin texts already enriched with lemmatization and Part-of-Speech (PoS) tagging and linked to the LiLa Knowledge Base. The following texts were chosen according to selection criteria aimed to ensure a sufficiently representative and balanced corpus as for both literary genre and era.

- Classical Latin: data are excerpted from the *Opera Latina* corpus by LASLA[7], an extensive collection of approximately 1.7 million words from over 130 lemmatized and morphologically tagged Classical and Late Latin texts[8].
- Late Latin: data are taken from the text of Augustine's *Confessiones* provided by The Latin Library[9].

At present, no annotation of Medieval Latin texts was performed, as data from this era are largely provided, albeit in unbalanced fashion, by the results of the FIR project.

3.2. Results

So far, we annotated the following excerpts: the first book from Augustine's *Confessiones*, a philosophical prose text, and a comedy of Plautus: *Curculio*. The workload was split equally between the two annotators; however, the last 50 sentences of the first book of Augustine's *Confessiones* were annotated by both annotators to measure

[6] English translations of Latin examples are taken, with minor changes, from [20] (Augustine) and [21] (Plautus).

[7] https://lasladb.uliege.be/OperaLatina/

[8] The *Opera Latina* corpus in the LiLa Knowledge Base is available at https://lila-erc.eu/data/corpora/Lasla/id/corpus.

[9] http://www.thelatinlibrary.com. The text is available in LiLa at https://lila-erc.eu/lodview/data/corpora/CIRCSELatinLibrary/id/corpus/Confessiones

their agreement. Inter-annotator agreement was calculated through the Dice coefficient similarity metric, which is widely adopted in NLP [22, 23]. Its value ranges from 0 to 1, with 1 indicating that two sets are identical and 0 meaning that they have no overlap. Once evaluated that the annotated markables span the same tokens for the two annotators in all cases, we calculated the similarity values as for entities (0.817) and mentions (0.824), which are comparatively highly acceptable for this task [24, 25, 26]. Additionally, the Cohen's Kappa coefficient was measured, yielding the following agreement values for each markable class: for the markable class 'mention' the resulting value is 0.8139902, whereas for the markable class 'entity', the value obtained is 0.8118851.
Table 1 presents the data derived from the analysis of the two texts. To highlight the quantitative significance of the coreference phenomenon, it shows the total number of tokens in the texts analyzed, along with the number of tokens involved in coreference relations. Additionally, the table shows the total number of coreference relations, and their respective entities and mentions. The tokens involved in a coreference relation account for the 12.16 percent of the total in *Confessiones*, while in *Curculio* they represent the 16.7 percent of the total. In both cases the percentages exceed the data produced by the FIR project, where the phenomenon concerns approximately the 8 percent of the tokens of the Latin texts annotated therein. The table clearly indicates that *Curculio* exhibits a greater number of coreferences despite having a lower total number of tokens. This difference is statistically significant: the chi-squared test performed on these data yielded a chi-squared statistic of 49.18 and a p-value lower than 0.00001. Given that the p-value is lower than the conventional alpha level of 0.05, coreference relations vary significantly from a statistic point of view in *Confessiones* and in *Curculio.* The coreference phenomenon is indeed widespread in the language of Plautus's theatre. This may be due to the fact that Plautus's language mimics, to some extent, everyday spoken language. Furthermore, the presence of numerous dialogues, where speakers often interrupt each other's turns, implies frequent references to the recipients with whom the characters interact. The text structure, characterized by numerous allocutions, also contributes to the high number of coreferences.

Table 1
Data obtained from the analysis of the corpus

Category	*Confessiones*	*Curculio*
Tot. token	6,133	5,853
Token in coref.	746	976
Coref. relation	521	796
Entity	202	577
Mention	542	569

3.3. Annotation Issues

In this section, we present and discuss three examples of annotation issues. On one hand, we address a problematic case regarding the application of our annotation scheme on the data, which was the primary reason for disagreement between the two annotators (example 4). On the other hand, we present two cases that highlight the fundamental role of context (example 5) and of the literary genre (example 6) for the coreference resolution task. The limited number of cases presented below is consistent with our prior decision to restrict the scope of annotation to only a subset of coreferential phenomena. We hypothesize that expanding the range of annotated coreference types or enlarging the corpus of annotated texts (in terms of quantity and literary genre) would lead to greater annotation challenges.
Starting from the first annotation issue, the most relevant disagreement between the two annotators concerns how to link mentions that are distant in the text from the entity they refer to. Example (4) shows a representative case of this type of disagreement.

(4) *Bonus ergo est* ***qui*** *fecit me, et* ***ipse*** *est bonum meum, et* ***illi*** *exulto bonis omnibus quibus etiam puer eram. Hoc enim peccabam, quod non in* ***ipso*** *sed in creaturis* ***eius*** *me atque ceteris voluptates, sublimitates, veritates quaerebam, atque ita inruebam in dolores, confusiones, errores.* (Aug. *Conf.* 1.20.31)
'Therefore the one who made me is good, and he himself is my good, and I rejoice in him for all the good things of which I consisted even in childhood. This was my sin: I sought pleasures, exaltations, truths not in he himself but in his creations, which is to say, in myself and other things'.

The pronouns in (4) are references to the entity God, which is explicitly expressed six sentences above in the text. The reader has no difficulty decoding these pronouns because the first-person narrator is discussing his relationship with God, to whom he is constantly referring. Therefore, it is not necessary to explicitly state the entity in every sentence.

The sentence in (4) can be annotated in two distinct ways: each pronoun can either be directly linked to the entity 'God' within the text, or be linked to the first pronoun concerned in (4) (*qui*), which gets then linked to the external entity 'God'. During the annotation process, the two annotators diverged: one selected the former method, while the other opted for the latter. There is no upper limit to the number of sentences after which a mention cannot be associated with the entity to which it refers [27]. When CR and AR first emerged as NLP tasks, there were concerns that machines could not yield acceptable results if the mention and the entity were too distant from each other [28]. However, contemporary methods achieve satisfactory results even with long-distance coreference, exceeding 200 sentences [29]. Additionally, given that we focus on literary texts, which feature long-distance coreferences more frequently than other textual types [30], it is imperative that we devote particular attention to this specific type of coreference. The two options chosen by the annotators are both equally valid. To harmonize the annotation process, we decided to link the mention to the external entity beyond a certain threshold, which was set at five sentences[10].

Sentence (5) from Plautus' *Curculio* exemplifies another challenging case of ambiguity, which further complicates the annotation process:

(5) Pal.: *Quid? tu te pones Veneri ieientaculo?* Phaed.: *Me, te atque* ***hosce omnis****.* (Pl. Curc. 1, 73-74)
Pal.: 'What? You'll offer yourself a breakfast to Venus?' Phaed.: 'Yes, myself, yourself, and all these here.'

As is typical in theatrical texts, much is left to the audience' inference. In this instance, the actor's gestures serve to disambiguate the phrase *hosce omnis*, which could refer either to the group of slaves accompanying the character Phaedromus or to the audience itself [31, 32, 33]. The annotators decided to follow the interpretation provided by Paratore [34], according to whom, *hosce omnis* refers to the audience. In this example, an agreement in gender and number between the mentions and the potential antecedents inferred from the context can be observed. Disambiguating the antecedent not only requires understanding the text but also knowing the specific characteristics of the literary genre concerned.

Another case in which the importance of literary genre and knowledge of context becomes evident is as follows.

(6) Cvrc.: [...] *Lyconem quaero tarpezitam.* Lyc.: *Dic mihi, quid eum nunc quaeris?* (Pl. Curc. 3, 406- 407): Cvurc.: 'I'm looking for the banker Lyco.' Lyc.: 'Tell me, why are you looking for him now?'

The dialogue cited here between the two characters, Curculio and Lyco, plays on a comedic ambiguity: Curculio knows he is speaking to Lyco, while Lyco believes that Curculio is unaware of his identity. When Curculio asks to speak with Lyco, Lyco responds by speaking about himself in the third person, thereby concealing his identity. For this reason, both the first-person pronoun 'mihi' and the third-person pronoun 'eum' refer to the same entity. This case clearly demonstrates the importance of understanding both the context and the specific narrative techniques of the textual genre in order to effectively resolve coreferences.

4. Conclusion and Future Work

In this paper, we provide an overview of the current state of a project aimed to build a Latin corpus enhanced with coreference and anaphora resolution. We detailed the annotation criteria and discussed a few annotation challenges, highlighting how this annotation layer necessitates a profound interaction among various fields of expertise, including linguistics, textual criticism, and literature.

In the near future, our aim is to expand the annotated corpus and to further extend the evaluation of inter-annotator agreement by incorporating the metrics as those proposed by Kopeć and Ogrodniczuk [35], such as the MUC score [36]. Once a sufficiently large dataset will be available, NLP will be concerned too, as we plan to exploit the annotated dataset to train and evaluate a stochastic model in supervised fashion to perform automatic CR/AR of Latin, usable also in NLP pipelines like, for instance, UDPipe [37] and Stanza [38]. We expect such a model to prove helpful to provide the Latin treebanks currently available in the Universal Dependencies (UD) initiative [39] with a layer of so-called enhanced dependencies, which also includes coreference and anaphora resolution. This would position Latin on an equal footing with other contemporary languages for which CR/AR annotations are also publicly accessible in treebanks [40] [11]. Given that one of the UD Latin treebanks, the *Index Thomisticus* Treebank, is already published as Linked Data in the LiLa Knowledge Base [41], having the treebank enriched with enhanced dependencies will require to model and publish therein the metadata about CR/AR.

The contribution of our project can also be considered within the broader context of NLP task on Latin. For instance, the corpus enriched with coreference annotations could enhance a task such as Emotion Polarity Detection, which was one of the shared tasks at the last edition of the evaluation campaign EvaLatin 2024. In the long term, a follow-up of the project will consist in building further textual datasets that feature other layers of coreferential annotation recognized by the GUM framework, such as appositive, attributive, and predicative coreferences, along with discourse deixis, and non-proper coreferences. Finally, given the current spread of Large Language Models and their highly promising accuracy rates on a wide range of NLP tasks, our data could be used to fine-tune

[10] The threshold is sentence-based rather than token-based as sentence is the usual relevant unit adopted in CR/AR, where indeed it is regular distinguishing between, for instance, intra- and inter-sentential anaphora.

[11] https://universaldependencies.org/u/overview/enhanced-syntax.html

already models for Latin, such as the Latin BERT [42].

5. Acknowledgements

This contribution is funded by the PRIN 2022 project "Textual Data and Tools for Coreference Resolution in Latin" (CUP J53D23013680008), a project carried out jointly by the Università Cattolica del Sacro Cuore in Milan and by the University of Udine.

Abstract

Explainable abusive language detection has proven to help both users and content moderators, and recent research has focused on prompting LLMs to generate explanations for why a specific text is hateful. Yet, understanding the alignment of these generated explanations with human expectations and judgements is far from being solved. In this paper, we design a before-and-after study recruiting AI experts to evaluate the usefulness and trustworthiness of LLM-generated explanations for abusive language detection tasks, investigating multiple LLMs and learning strategies. Our experiments show that expectations in terms of usefulness and trustworthiness of LLM-generated explanations are not met, as their ratings decrease by 47.78% and 64.32%, respectively, after treatment. Further, our results suggest caution in using LLMs for explanation generation of abusive language detection due to (i) their cultural bias, and (ii) difficulty in reliably evaluating them with empirical metrics. In light of our results, we provide three recommendations to use LLMs responsibly for explainable abusive language detection.

Keywords

Large Language Models, Hate Speech Detection, Explanation Generation, Human Evaluation

1. Introduction

Explainability is a crucial open challenge in Natural Language Processing (NLP) research on abusive language [1] as increasing models' complexity [2], models' intrinsic bias [3], and international regulations [4] call for a shift in perspective from performance-based models to more transparent models. Moreover, recent studies have shown the benefits of explanations for users [5, 6] and content moderators [7] on social media platforms. The former can benefit from receiving an explanation for why a certain post has been flagged or removed whereas the latter are shown to annotate toxic posts faster and solve doubtful annotations thanks to explanations.

Several efforts have moved towards explainable abusive language detection in the past years, like the development of datasets containing rationales (i.e., the tokens in the text that suggest why the text is hateful) [8] or implied statements (i.e., description of the implied meaning of the text) [9, 10], and shared tasks on explainable hate speech detection [11, 12], *inter alia.* With Large Language Models (LLMs) like FLAN-T5 [13] showing remarkable performance across tasks and human-like text generation [14, 15, 16], recent studies have explored LLMs for explainable hate speech detection, wherein classification predictions are described through natural language explanations [17, 18]. For instance, [19] used chain-of-thought prompting [20] of LLMs to generate explanations for implicit hate speech detection.

However, most of these studies rely on empirical metrics like BLEU [21] to evaluate the generated explanations automatically. Consequently, the human perception and implications of these explanations remain understudied, as well as the extent to which empirical metrics approximate human judgements. [22] recruited crowdworkers to evaluate the level of hatefulness in tweets and the quality of explanations generated by GPT-3. Instead, we conduct an expert survey investigating four LLMs and five learning strategies across multi-class abusive language detection tasks to answer the following questions: **RQ1:** How well do LLM-generated explanations for abusive language detection match human expectations? **RQ2:** How well do empirical metrics align with human judgements? **RQ3:** What makes LLM-generated explanations good, according to experts?

2. Experimental Setup

To answer these research questions, we design a before-and-after study, surveying participants about their prior expectations about LLM-generated explanations and then showing them examples generated by several LLMs with diverse learning strategies[1], followed by further interviews. To ensure robustness of our results, we recruited experts in the field, i.e., AI researchers, as described below.

2.1. Data

For our experiments, we use the HateXplain [8] and the Implicit Hate Corpus [9] as they encompass different levels of offensiveness (i.e., hate speech, offensive, neutral), expressiveness (i.e., explicit hate, implicit hate, neutral), multiple targeted groups, and explanations for the hateful label (Table 1). These datasets contain unstructured explanations of the words that constitute abuse (in HateXplain) and the user's intent (in Implicit Hate). In view of previous research arguing the need for structured explanations in hateful content moderation [1], we use the following template to create structured explanations, that we will use as ground-truth: "*Explanation: it contains the following hateful words (implied statement):*" for abusive content in HateXplain (Implicit Hate Corpus), and "*The text does not contain abusive content.*" for neutral content.

Dataset	Labels	Target	Explanation
HateXplain	hate speech, offensive, neutral	women, black, ...	Token-level
Implicit Hate	implicit hate, explicit hate, neutral	Jews, whites, ...	Implied statement

Table 1
Summary of datasets used.

2.2. Methodology

We extensively investigate four popular LLMs across five learning strategies on their ability to detect multi-class offensiveness and expressiveness of abusive language and to generate explanations for the classification.

Models. We use different open-source LLMs (Table 2): the base versions of **FLAN-Alpaca** [23, 24], **FLAN-T5** [13], **mT0** [25], and the 7B foundational model **Llama 2** [26], which is an updated version of LlaMA [27].

Model	Instruction Fine-tuned	Toxicity Fine-tuned
FLAN-Alpaca	☒	☒
FLAN-T5	☒	☒
mT0	☒	-
Llama-2	-	-

Table 2
Summary of models used.

Learning strategies. As different prompting strategies might yield different results, we test five distinct learning strategies using the established Stanford Alpaca template[2] (cf. Appendix A for prompt details):

(1) zero-shot learning (zsl): we pass *"Classify the input text as* `list_of_labels`*, and provide an explanation"* in the instruction field of the template. The `list_of_labels` changes according to the dataset used;

(2) few-shot learning (fsl): we pass three additional examples to the aforementioned template, which are randomly sampled with equal probability among the labels to account for class imbalance in the datasets. We experimented with different numbers of examples (i.e., passing one, three or five examples), and chose three as it was the best strategy;

(3) knowledge-guided zero-shot learning (kg): instead of passing additional examples in the prompts, we add external knowledge retrieved by means of an entity linker[3], which first detects entities mentioned in the input text, and then retrieves the relevant information from the external knowledge base. We use Wikidata [28] for encyclopedic knowledge, KnowledJe [29] for hate speech temporal linguistic knowledge and ConceptNet [30] for commonsense knowledge. We modify the prompt template with an additional field called 'context' to account for this external knowledge;

(4) instruction fine-tuning (ft): we use the same prompts used in (1) to instruction fine-tune Llama-2;

(5) knowledge-guided instruction fine-tuning (kg_ft): we use the knowledge-guided prompts developed in (3) to instruction fine-tune Llama-2.

Empirical eval metrics. We evaluate how closely the LLM-generated explanations match the ground-truth across eight empirical similarity metrics due to the challenge of simultaneously assessing a wide set of criteria [31, 32, 33]. Following established NLG research [34, 35], we choose BERTScore [36] and METEOR [37] for semantic similarity. For syntactic similarity, we select BLEU [21], GBLEU [38], ROUGE [39], ChrF [40] with

[1] The data containing the LLM-generated explanations are publicly available at https://github.com/ChiaraDiBonaventura/is-explanation-all-you-need

[3] If available, we use the API provided by the knowledge source, spaCy otherwise. https://spacy.io/

its derivates ChrF+ and ChrF++ [41, 42]. Additionally, we present an expert evaluation following our survey.

2.3. Survey Design

To evaluate how well LLMs align with human expectations and judgements in explanation generation, we design a before-and-after study as follows.

Before treatment. We ask for participant's background information, e.g., gender identity, native language and how they would rate the usefulness and trustworthiness of a language model for explanation generation. Specifically, we ask "How useful would you rate a system that provides you a textual explanation for its classification with respect to receiving only its classification?" and "How trustworthy would you rate a system that provides you a textual explanation for its classification with respect to receiving only its classification?" on a 1-5 Likert scale.

Treatment. As for the treatment, we show participants a sample of 70 texts from the datasets, paired with up to four different explanations. Specifically, given a text and ground-truth explanation, participants are asked if the text is correctly explained. If yes, they are asked to rate three different LLM-generated explanations with respect to the ground-truth on a 1-3 scale. These explanations are randomly sampled among the four LLMs and five learning strategies discussed in Section 2.2.

After treatment. Finally, we ask participants' opinion on the usefulness and trustworthiness of explanation generation, having seen the LLM-generated explanations. In addition, we ask general opinions related to what type of errors they observed most frequently, and what a good explanation would look like.

The full list of questions is in the Appendix B. The institutional ethical board of the first author's university approved our study design. We distributed the survey through channels that allow us to target individuals working in AI who are familiar with the field of language models and/or AI Ethics, including NLP reading groups and AI Ethics interest groups. To ensure the reliability of our before-and-after study, participants were given 1 hour to complete as many answers as they could. We collected answers from 15 participants, of which 33% (67%) identify as female (male), and 33% (67%) are (non) English native-speakers. The average level of participants' expertise in abusive language research is 2.47 out of 5 (self-described)[4], and their continents of origin include Europe (60%), Asia (26.67%), Africa (6.67%), and Latin America (6.67%).

3. Results and Discussion

Our 15 participants reach a fair agreement, with Krippendorff's alpha [43] equal to 38.43%.

Fig. 1 shows changes in the relative frequencies of participant scores in the usefulness and trustworthiness of explanations before and after treatment. Participants' responses before treatment have expectations of textual explanations for classifications of being "highly useful" (above 50%; highest possible score) in terms of usefulness, and "moderately trustworthy" or "neutral" (above 40%; second and third best possible score) in terms of trustworthiness. However, scores for after treatment show participants changing their usefulness scores towards "moderately unuseful" (40-50%; second worst possible score) and their trustworthiness scores to "highly untrustworthy" (above 30%; worst possible score). Agreement differs in each category: usefulness is much more consensual, whereas trustworthiness is judged with higher variance. In general, LLM-generated explanations do not meet human expectations in terms of usefulness and trustworthiness. Specifically, exposing participants to these explanations leads to an average percentage decrease of 47.78% and 64.32% in the perception of the usefulness and trustworthiness of explanations, respectively.

Fig. 2 shows the scores of all empirical metrics and expert evaluation for all models on explanation generation. Overall, similarity metrics tend to be highly volatile with respect to each other. For instance, FLAN-Alpaca prompted with zero-shot learning (i.e., 'alpaca_zsl' in the figure) generates explanations that are more than 70% semantically similar to the ground-truth explanations according to BERTScore while being less than 20% semantically similar according to METEOR. Similarly for syntax: BLEU and GBLEU similarity scores are less than 3% whereas ROUGE and chrF/+/++ are in the range 9%-21%. Moreover, we observe that BERTScore has a tendency to over-score explanations compared to human evaluation scores. Contrarily, METEOR, BLEU, GBLEU, ROUGE and chrF/+/++ have a tendency to under-score explanations. Instruction fine-tuning helped all metrics to approximate expert evaluations better, especially when tuned on knowledge-guided prompts. We use the Spearman's rank correlation coefficient to compare the correlation between human scores and those provided by all the other metrics. In detail, we rank the models for each type of metric, and then we compute the Spearman correlation between the rank obtained by human scores and those obtained by other metrics. Table 3 reports all the correlation scores. We observe that BERTScore is the most correlated with humans in both tasks. Also,

[4] The list of levels to choose from was: 1=Novice, 2=Advanced beginner, 3=Competent, 4=Proficient, 5=Expert.

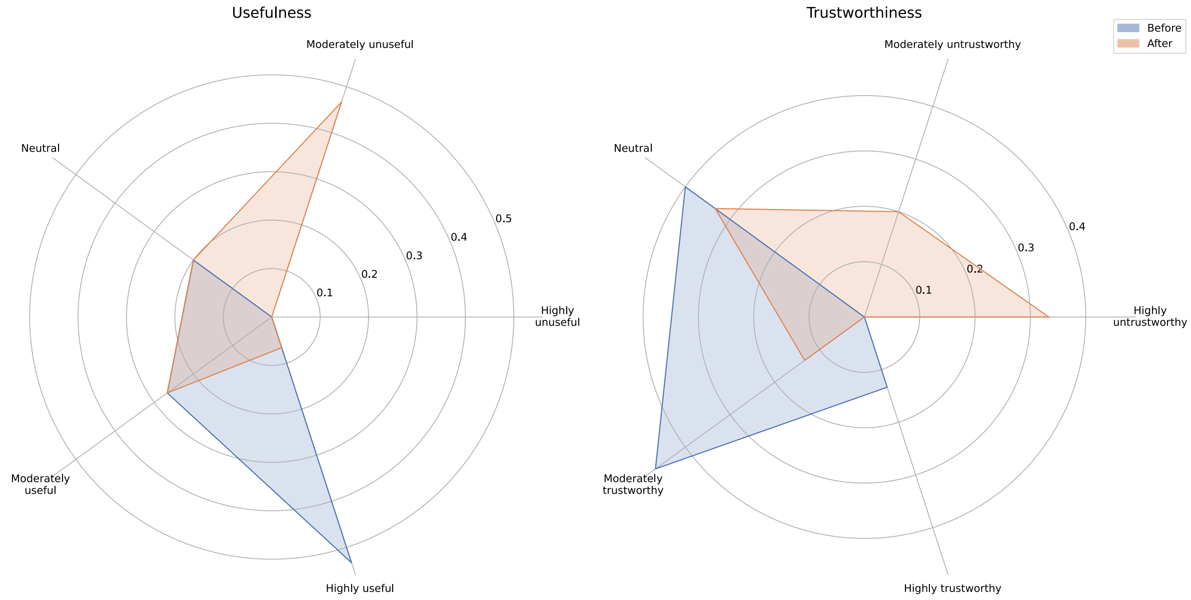

Figure 1: Relative frequencies of Likert scores before and after treatment on usefulness and trustworthiness of LLMs for explanation generation in abusive language detection.

chrF/+/++ metrics are highly correlated with humans while all the other metrics based on syntactic matches are slightly correlated with humans. Results show that semantic metrics are more similar to how humans evaluate the quality of the explanation generated by LLMs. Only one metric (ROUGE) shows a different behaviour between the two tasks.

Since 38.55% of the ground-truth explanations were not rated as good explanations by participants, we further investigated what are the most common errors and what makes an explanation good. Table 4 returns the most common error categories reported by participants. Most of them are related to logical fallacies (e.g., contradictory statements, hallucination), especially in the context of sarcasm and self-deprecating humour, rather than linguistic errors (e.g., grammar, misspellings). It is worth noticing that 13.33% of the participants reported that LLM-generated explanations contain cultural bias (e.g., stereotypes), with the implication of potentially perpetuating harms against the targeted victims of abusive language. As for desiderata, 73.33% of participants would like to receive textual explanations that are coherent with human reasoning and understanding, i.e., that are relevant and exhaustive to the text they refer to while being logically and linguistically correct. A remaining 20% thinks that a good explanation must be coherent with model reasoning instead. In other words, participants are much more concerned about how the explanation looks like rather than its reflection of the inner mechanism of the model reasoning. To quote a participant's perspective, "*I would want the explanation to be helpful to me and guide my own reasoning*".

Metric	**Spearman Coeff.**	
	Implicit Hate	**HateXplain**
bertscore	0,80	0,91
meteor	0,64	0,89
chrf1	0,60	0,83
chrf2	0,60	0,81
chrf	0,57	0,83
gbleu	0,53	0,25
rouge	0,50	0,86
bleu	0,27	0,11

Table 3
The Spearman coefficient between each metric and experts' scores.

Error Category	**Relative Frequency**
Logical Errors	26.67%
Vagueness	20.00%
Cultural Bias	13.33%
Hallucination	13.33%
Irrelevant Info	13.33%
Other	6.67%

Table 4
Percentage of error categories reported by participants.

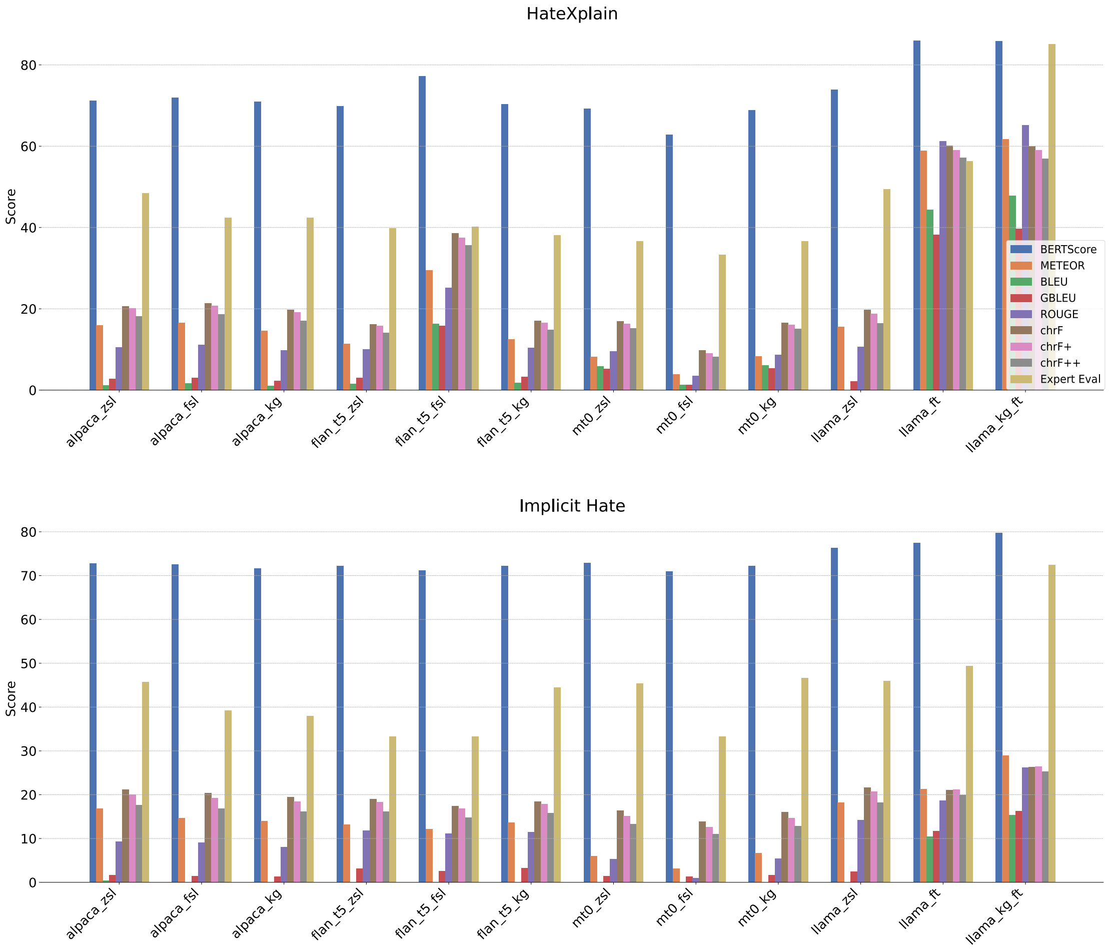

Figure 2: Evaluation of explanation generation by LLMs across empirical metrics and human eval.

4. Conclusion

In this paper, we conducted a before-and-after study to understand human expectations and judgements of LLM-generated explanations for multi-class abusive language detection tasks. Contrarily to previous research [22], we investigated multiple LLMs and learning techniques, and we surveyed AI experts who are familiar with abusive language research instead of crowdworkers. We found that human expectations in terms of usefulness and trustworthiness of LLM-generated explanations are not met: after seeing these explanations, the usefulness and trustworthiness ratings decrease by 47.78% and 64.32%, respectively. Secondly, our results show that empirical metrics commonly used to evaluate textual explanations are highly volatile with respect to each other, even when they measure the same type of similarity (i.e., semantic vs. syntactic), and therefore pointing at the need of more reliable metrics for the empirical evaluation of textual explanations. In general, BERTScore and METEOR metrics exhibit the strongest correlation with human judgements. Lastly, our study provides evidence of the desiderata for LLM-generated explanations, suggesting that explanations should be coherent with human reasoning rather than model reasoning. Participants value the most textual explanations that are relevant and exhaustive to the text they refer to, while being logically and linguistically correct. Justifications for this preference lie on the fact that abusive language detection heavily relies on additional context and knowledge about slang and slurs, for which receiving an explanation is helpful to participants' understanding of the text. Future work should investigate whether this preference holds for other domains as well. In light of our findings, we conclude with three recommendations to use LLMs responsibly for explainable abusive language detection: **(1)** be aware of the cultural bias these models might exhibit when generating free-text explanations, which can further harm targeted groups; **(2)** if possible, instruction fine-tune LLMs for explanation generation of abusive language detection. This not only could ensure the generation of structured explanations as advised by previous research [1] but it also returns the highest evaluation scores, both empirically and expert-wise, when using knowledge-guided prompts; **(3)** opt for a combination of empirical metrics to evaluate textual explanations when no human evaluation is possible, since no particular empirical metric seems to generalise across different learning techniques, models and datasets, making the ground-truth lie somewhere in between BERTScore (upper bound) and BLEU (lower bound).

A. Prompt Details

Table 5 shows the two types of prompts we used in our experiments, following the template of the Stanford Alpaca project. The two categories differ for the 'context' that is passed in the knowledge-guided version, which contains the information extracted from the knowledge sources linked to the text. As described in the Section 2.2 of the paper, we used the vanilla prompts for zero-shot learning, few-shot learning, and instruction fine-tuning whereas we used the knowledge-guided prompts for knowledge-guided zero-shot learning and knowledge-guided instruction fine-tuning.

B. Survey Questions

Participants were presented with the questions shown in Table 6.

Category	Prompt Template
Vanilla	Below is an instruction that describes a task, paired with input text. Write a response that appropriately completes the instruction. Instruction: Classify the input text as `list_of_labels`, and provide an explanation. Input text: `text_to_classify`. Response:
Knowledge-guided	Below is an instruction that describes a task, paired with context and input text. Write a response that appropriately completes the instruction based on the context. Instruction: Classify the input text as `list_of_labels`, and provide an explanation. Context: `knowledge_source_linked`. Input text: `text_to_classify`. Response:

Table 5
Details of vanilla prompts and knowledge-guided prompts passed to the LLMs in our experiments.

Part	Questions
Before Treatment	“Which gender do you identify as?” “Are you an English native-speaker?” “What is your country of origin?” “What is your level of expertise on language models or abusive language?” “How useful would you rate a system that provides you a textual explanation for its classification with respect to receiving only its classification?” “How trustworthy would you rate a system that provides you a textual explanation for its classification with respect to receiving only its classification?”
Treatment	“Do you think explanation 1 provides a good explanation given the text?” “If your answer was yes, does explanation 2 mean the same thing as explanation 1?” “If your answer was yes, does explanation 3 mean the same thing as explanation 1?” “If your answer was yes, does explanation 4 mean the same thing as explanation 1?”
After Treatment	“Having seen these explanations, how useful would you rate a system that provides you a textual explanation for its classification?” “Having seen these explanations, how trustworthy would you rate a system that provides you a textual explanation for its classification?” “What was the main error you noticed in these explanations?” “What do you think makes a textual explanation good?” “Do you have any comment you would like to share?”

Scalable Query Understanding for E-commerce: An Ensemble Architecture with Graph-based Optimization

Giuseppe Di Fabbrizio[†], Evgeny Stepanov[†], Ludovico Frizziero[†] and Filippo Tessaro[†]

Abstract

Query understanding is a critical component in e-commerce platforms, facilitating accurate interpretation of user intent and efficient retrieval of relevant products. This study investigates scalable query understanding techniques applied to a real-world use case in the e-commerce grocery domain. We propose a novel architecture that integrates deep learning models with traditional machine learning approaches to capture query nuances and deliver robust performance across diverse query types and categories. Experimental evaluations conducted on real-life datasets demonstrate the efficacy of our proposed solution in terms of both accuracy and scalability. The implementation of an optimized graph-based architecture utilizing the Ray framework enables efficient processing of high-volume traffic. Our ensemble approach achieves an absolute 2% improvement in accuracy over the best individual model. The findings underscore the advantages of combining diverse models in addressing the complexities of e-commerce query understanding.

Keywords

Query classification, Query understanding, Distributed and scalable machine learning.

1. Introduction

Accurately understanding and classifying user queries is crucial for providing a seamless shopping experience by boosting the product search results relevance in e-commerce [1]. Query understanding enables e-commerce platforms to interpret users' intents, retrieve relevant products, and personalize the user's journey through the shopping experience. However, the task of query understanding in e-commerce presents several challenges due to the diverse nature of queries, the large-scale product catalogs, and the need for efficient processing of high-volume traffic with noisy behavioral signals [2, 3].

Query understanding in e-commerce involves multiple sub-tasks, such as query classification, entity recognition, and intent detection. Query classification aims to categorize user queries into predefined product categories, facilitating improved product retrieval and ranking [4, 5]. Entity recognition identifies key information within the query, such as brand names, product attributes, and numerical values, which can be used to refine the search results [6]. Intent detection focuses on understanding the user's underlying goal, such as product discovery, comparison, or purchase [7].

One of the primary challenges in query understanding is the inherent ambiguity and diversity of user queries. E-commerce queries are often short, lacking context, and can have multiple interpretations [8]. Moreover, the large-scale product catalogs in e-commerce platforms, spanning thousands of categories and millions of products, pose a significant challenge in accurately mapping queries to relevant categories and products.

Various approaches have been proposed to address these challenges, leveraging traditional machine learning techniques and deep learning models. Rule-based systems and keyword matching have been widely used for query classification and entity recognition [9]. However, these approaches often struggle with the variability and complexity of natural language queries. Different query intents require different algorithms to yield optimum results [10]. Queries can be classified into *navigational* (e.g., product category, brand, title) and *informational* (e.g., product-related questions). While navigational queries require exact matching to catalog products, informational queries necessitate applying more complex understanding techniques.

Another critical aspect of query understanding in e-commerce is efficiently processing high-volume traffic. E-commerce platforms receive millions of queries daily, requiring scalable and real-time query understanding systems. Distributed computing frameworks, such as Apache Spark and Ray, have been employed to parallelize query processing and handle the massive scale of e-commerce data [11, 12].

In this paper, we propose an ensemble approach for query understanding in e-commerce, combining deep learning models and traditional techniques. Our approach leverages the strengths of both deep learning, such as DistilBERT [13], and traditional models, including logistic regression and rule-based systems. By integrating these diverse models, we aim to capture the

nuances of user queries and provide robust performance across various query types and categories.

We introduce an optimized graph-based architecture based on the Ray framework [12], enabling efficient processing of high-volume traffic and ensuring scalability.

2. Query understanding ensemble architecture

In this paper, we focus on navigational queries and classify them into product taxonomy categories while applying named entity recognition (NER) to capture relevant product attributes, such as *Brand*, *Nutrition*, *Flavor*, and numeric attributes like *quantities* and *measurements*. Figure 1 shows a typical example of a navigational search query in an e-commerce grocery domain where the query *"Pacific chicken broth organic gluten free"* is parsed into its attributes and categorized into its taxonomy label.

Classifying user queries into product taxonomy categories is a typical document classification problem that is complex and actively researched. The problem is complicated by the nature of available data, which can be either product descriptions with user-provided categories or user queries associated with catalog categories from user click-stream data. Products in the catalog are described in terms of attributes with associated values, and a subset of this mapping constitutes a set of entities that should be identified to build a search query and provide better search results.

Due to the rate of change in e-commerce, the classical approach of query annotation and model training is prohibitive. Consequently, the query understanding problem is cast as a document classification problem for matching user queries to the product taxonomy tree (categories) and a sequence labeling problem for entities of interest. For each problem, we propose using an ensemble approach with multiple models having different label sets and relations. Specifically, we predict two levels of the product taxonomy tree (L1 and L2) and extract the corresponding entities mentioned in the queries. Each level is predicted by an ensemble of models composed of business rules and machine learning models. Similarly, different machine learning and rule-based models are used to extract entities of interest.

2.1. Query understanding pipeline and ensemble components

The query understanding pipeline's classification and entity extraction components are trained and tested on pre-processed user queries. Common text pre-processing steps are applied, including spaCy's tokenization, lowercasing, and number normalization [14].

The classification ensemble consists of business rules, implemented as a lookup table, and two machine learning models: logistic regression and DistilBERT. DistilBERT is a compressed version of BERT [15] that retains 97% of the original model's performance while being 40% smaller and 60% faster at inference time. The key idea is to leverage knowledge distillation during the pre-training phase to learn a compact model that can be fine-tuned for downstream tasks. Integrating DistilBERT into a query understanding pipeline, alongside business rules and logistic regression, enhances the system's accuracy and robustness.

The entity extraction ensemble comprises: (1) a conditional random fields model; (2) a catalog-based lookup table to extract *Brand*, *Flavor*, and *Nutrition*; and (3) a rule-based Duckling library[1] to extract numerical entities such as *Price* and *Quantity*.

2.2. Classification decision fusion

In our ensemble learning scenario, the models are trained on different data and have different, potentially overlapping label spaces, unlike typical ensemble learning, where the same data is used to train all models. Due to the label space differences, decision fusion is performed on the predictor-by-label prediction matrix of confidence scores rather than using a simple majority voting strategy. Rule-triggered hypotheses are assigned to a confidence score of 1.0 taking priority on model-based predictions.

The decision fusion process takes a matrix of confidence scores as input and outputs a vector of aggregated confidence scores. The label space difference is addressed by applying a max operation on the column of prediction scores per label, ignoring the values with respect to the label space membership. Taking the maximum score per prediction approximates the product rule [16]. The final label is decided as the $argmax$ of this confidence score vector. Unlike voting-based decision fusion, such an approach allows aggregation of decisions from rules and any number of predictors.

2.3. Entity span consolidation

Span consolidation aggregates entity extraction hypotheses from one or several entity extractors into a shallow parse containing only non-overlapping spans. By default, this process is performed for spans from the same model, but it can also be enabled for an ensemble of extractors.

Inspired by [17], the span consolidation is performed in three steps: (1) *Identity consolidation*: Resolves identical spans by keeping the span with higher confidence, or randomly if confidences are equal; (2) *Containment consolidation*: Resolves spans contained within each other by keeping the longer span, i.e., the one that contains the other; (3) *Overlap consolidation*: Resolves overlapping spans by keeping the longer span, or alternatively merging them and assigning the label of the longest span. *Priority consolidation* can be used to give higher weights to predictions from extractors with higher confidence.

The decision fusion and span consolidation are generally applied as the final step of the query understanding pipeline to yield hypotheses containing only a non-overlapping set of entities and a single classification prediction per level, as described in Section 4.

3. Models and ensemble evaluation

The engine's configuration represents the ensemble as a sequence of operations, called nodes, organized into a graph. The edges of this graph represent the interdependencies between nodes. The engine organizes and dispatches computations to maximize parallelism. Machine learning models for query classification are trained on product catalog data and tested on user queries, ensuring equal representation of head, torso, and tail queries in terms of frequency. Table 1 shows the sizes of the training and testing data, and the output categories. We predict two levels of product taxonomy: L1 with 17 categories and L2 with 169 categories. However, not all L1 categories have L2 labels, making the L2 sets subsets of the L1 data. The NER test set is a subset of the manually annotated test data for non-numerical entities.

The performance evaluation of the component models and the ensemble utilizes precision, recall, and F1-score metrics. For multi-class classification tasks, we report accuracy along with macro-averaged precision, recall, and F1-score to account for dataset imbalance. Entity extraction performance is assessed using micro-averaged metrics and token-level accuracy, adhering to CoNLL-style evaluation protocols.

To quantify the efficacy of the model ensemble, we conducted a comparative analysis against logistic regression and DistilBERT for level one predictions, with results presented in Table 2. DistilBERT demonstrates superior performance compared to logistic regression across all metrics. The ensemble model, however, consistently outperforms both individual models.

Consequently, the query understanding system adopts the ensemble approach in lieu of individual models. Rule-based components are excluded from this evaluation due to their limited data coverage and restricted label subsets.

Level two models show similar performance patterns to level one, though with lower performance due to the larger label space and fewer training documents per label. Entity ensemble performance aligns with other ensembles, favoring precision.

While the ensemble approach demonstrates improved performance, it faces challenges with certain query types. Extremely short queries (e.g., "chips" can refer to potato, tortilla, or chocolate) can be ambiguous without context. Highly ambiguous queries (e.g., "greens") may span multiple categories within the grocery domain. Novel products or brands not present in the training data pose difficulties. Complex, multi-intent queries (e.g., "organic gluten-free pasta sauce and whole grain spaghetti") can lead to misclassifications or incomplete entity extraction.

Future work could explore incorporating user session data or personalization techniques to provide additional

context for ambiguous queries and improve handling of out-of-vocabulary terms and multi-intent queries.

4. Graph-based architecture for scalable processing

Query understanding systems in e-commerce search engines must generate real-time responses within strict service level agreements (SLA). They execute complex logic involving different models interacting both in series and parallel.

Our engine is constructed as a sequence of operations (nodes) arranged in a graph showing their interdependencies (edges). Like neural networks, the graph-based engine organizes and dispatches each computation to maximize parallelism.

Parallelization occurs at multiple levels, including inter-operation parallelism and entire graph replicas, depending on deployment requirements. Each operation within the graph is a complex model component, requiring specific optimization strategies, such as data vectorization and memory sharing, to optimize the overall graph structure.

We represent the graph using the notation `node: [arg1, arg2, ..., argN]`, where `node` requires incoming edges from `arg1` through `argN`. The full configuration of the graph can be seen in Appendix A

The engine processes the notation by following these steps: First, it optimizes the graph by joining (inlining) nodes based on certain criteria, which increases parallel operations as much as possible. Next, it decides how many replicas of the graph to run on a single physical server. Each node is then mapped to a separate system process using the *Actor* model [18] for inter-process communication, with message passing between processes handled using Ray [12].

Each node is initialized by loading the models into memory, leveraging shared memory and copy-on-write primitives provided by the server's operating system. Each node is loaded only once, and subsequent processes assigned the same node reference the original memory. Since the models are used for inference, not training, there are no write operations, reducing memory footprint and improving loading times. Finally, the batching service handles the backpressure control system and the REST API for listening to incoming requests.

At startup, the engine performs several optimizations on the graph topology. The simplest is graph *culling*, removing nodes that do not interact with others. Each node's expected computational burden can be specified. Simple nodes (e.g., string regex preprocessors) are less resource-intensive than full neural network nodes. The engine modifies the graph by combining nodes or *inlining* to facilitate parallel operations and minimize costly interprocess communications. This results in lighter nodes being replicated multiple times and fused into heavier nodes, each mapped to a single system process.

After inlining, the engine performs graph linearization, converting the graph into a linear sequence, where each node depends only on preceding nodes, not subsequent ones. The engine dispatches nodes in order, synchronizing results only when necessary. This strategy minimizes pauses and maximizes parallelism. Nodes with a higher computational burden are prioritized, reducing the need for the backpressure control system, leveraging the fact

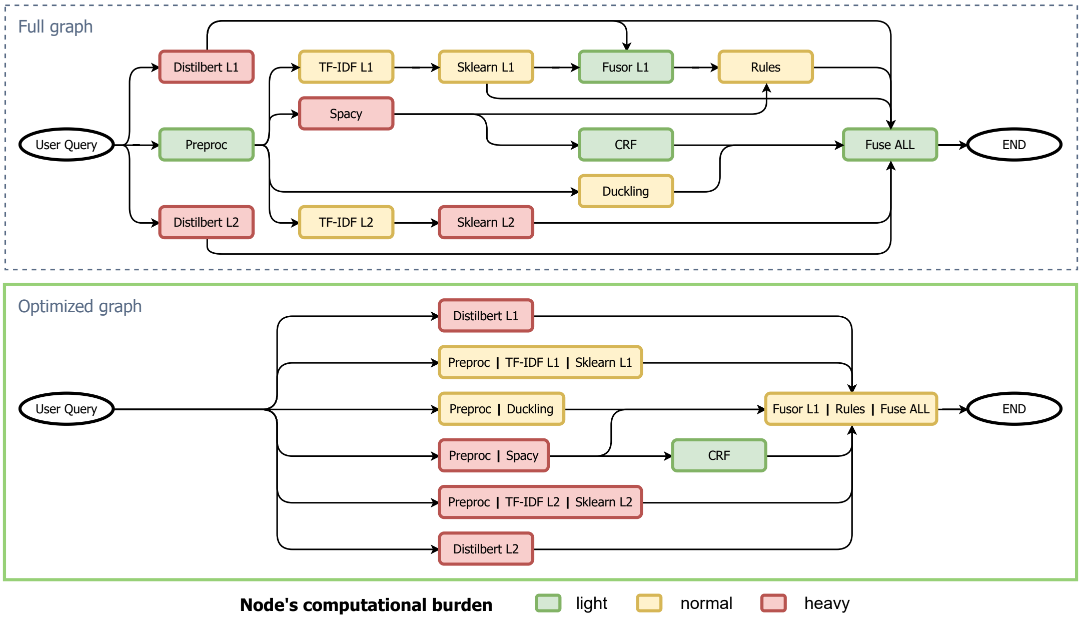

Figure 2: Visualization of the ensemble as a computational graph. (Top) The graph as defined in Appendix A. (Bottom) The graph after optimization by the engine.

that CPU and data transmission tasks are handled by separate CPU circuitry.

Query understanding systems receive hundreds of individual requests per second. Processing a single request is expensive due to inter-node communications. Batching multiple requests reduces overhead and enables vectorization, leveraging hardware primitives for efficient processing. The batching algorithm uses two thresholds: *batch size* and *waiting time* for further samples. This balances server resource utilization and processing time.

Lastly, the engine addresses CPU oversubscription [19], which occurs when parallel execution threads exceed available CPU cores, leading to overhead from context switching. The backpressure control system ensures no more than N nodes run in parallel, enhancing performance by reducing oversubscription. The number N depends on available CPU resources and the code executed within each node. A simple formula for determining N is:

$$N = \left\lfloor \frac{M_{cpu}}{\max_{i\in nodes}(threads_i)} \right\rfloor + 1 \tag{1}$$

where $threads_i$ is the number of threads or processes that an individual node can utilize independently, and M_{cpu} denotes the available CPU cores on the server.

5. Performance analysis at scale

Multiple tests were conducted using different AWS[2] EC2 instances on the engine described in Section 4 and the ensemble configuration as in Appendix A. The optimal balance between cost, latency, and throughput was achieved with the `m6i.2xlarge` instance, which features 8-Cores Intel Xeon vCPU @ 3.5GHz, for which we report the results.

The test's target SLA stipulated that response times for 99% of requests should remain below 100ms.

All tests initiate a single instance of the engine with a graph replication factor of one[3]. Another server, which hosts the client simulator implemented using a Python package called Locust, is instantiated. Both servers share the same AWS network. The simulator issues multiple queries to the engine's server, each randomly sampled from a dataset of actual queries over a sustained duration of 30 seconds. The rate of each request follows an exponential distribution with a rate of T requests per second, mimicking a Poisson process, a common model for traffic patterns.

Table 3 reports the execution times of each node, along

[2] https://aws.amazon.com/

[3] Replication factors greater than one were also tested, but they caused immediate CPU oversubscription problems, as anticipated. The SLA targets were unattainable without resorting to costly GPUs.

rest api	55.85	84.35	**92.82**

Batching enabled

with the main engine loop responsible for scheduling them and the outer REST API handling incoming requests and facilitating the connection between the engine and the outside world. The runtime of each individual node must be strictly shorter than the main engine loop, representing the actual time taken for parallel graph execution. Node runtimes do not consider inter-process communication, which is accounted for in the main loop. On the other hand, the Rest API contributes to the main loop by including the time required to handle the HTTP connection with the requesting client. The outer Rest API time must stay below 100ms @ 99% percentile to comply with the target SLA.

When batching is disabled, at the given rate T, new requests arrive while the server is still processing previous ones. These requests are immediately dispatched, leading to CPU oversubscription, which slows down all requests. This effect tends to cascade, as the increased processing time makes it more likely that other requests will arrive, further slowing the system.

When batching is enabled, the engine pauses to accumulate requests into a batch until thresholds of 5 samples or $50ms$ are met. Given each request arrives every $1/T \approx 30ms$, the average batch size is around 1.5 samples. Therefore, vectorization alone cannot explain the server's ability to meet the target SLA. The process unfolds as follows: (1) the first batch is dispatched for processing, (2) for the next $50ms$, new requests are queued into a new batch while (3) the engine likely completes the first batch within $51.7ms$ (with 99% probability), (4) the second batch is then dispatched, utilizing just released resources. Thus, batching acts as backpressure control on cheaper hardware without a GPU and at low rates of T. In production, multiple instances would handle fluctuating traffic, making batching efficient for scaling while meeting the SLA. The optimal batching period should match the main loop time @ 99%, which is around $50ms$ in this case.

From a single request's perspective, with $T = 30tps$, batches are dispatched precisely every $50ms$, meaning requests encounter a uniform distribution over this interval with an average wait of $25ms$ in the batch queue. The entire batch is then processed, typically taking X time to complete before the response is extracted and forwarded through the HTTP channel, taking an additional Y. Empirically, X represents the main loop runtime, averaging around $30ms$ @ 50%. The Rest API, implemented using FastAPI[4], has been benchmarked to yield a duration of $Y \approx 2 - 5ms$, giving us

$$\text{REST API @50\%} = 25\text{ms} + 30\text{ms} + 2\text{ms} \approx 56.25\text{ms}$$

For REST API @ 99%, the wait time is always $25ms$ on average, but X and Y change accordingly, giving approx $90 - 95ms$.

6. Conclusion and future work

This paper proposed a novel ensemble approach for query understanding in e-commerce, combining deep learning models like DistilBERT with traditional techniques like

[4] https://fastapi.tiangolo.com/

logistic regression and rule-based systems. The ensemble architecture aimed to capture the nuances of user queries and provide robust performance across query types and categories. Data augmentation techniques were employed to improve the DistilBERT model's handling of brands, misspellings, and short queries. An optimized graph-based architecture using the Ray framework enabled efficient, scalable processing of high-volume traffic.

While the ensemble performed well, there are limitations to address in future work. The system focused only on navigational queries for product categorization and entity extraction. Extending it to handle informational and other query types could further improve relevance. Exploring more advanced data augmentation, model compression, and hardware acceleration techniques could enhance accuracy and efficiency.

The query understanding ensemble demonstrated the value of combining diverse models and leveraging distributed computing frameworks for scalability in e-commerce search engines. E-commerce platforms can benefit from adopting similar, ensemble-based approaches customized to their query traffic and product data. The architecture enables efficient real-time query processing while meeting strict latency requirements, critical for delivering a seamless shopping experience.

7. Appendix

A. Graph configuration

In our query understanding system, the relationships between various models and preprocessing components are organized within a graph-based architecture. This architecture plays a crucial role in managing the interdependencies between different models, ensuring efficient computation and scalability.

The graph representation is designed to handle the integration of multiple machine learning and rule-based models while facilitating optimized parallel processing. Each key in the graph corresponds to a node, which indicates a component or model, and the associated value is a list of other nodes that provide input to it. This differs from traditional adjacency lists, where the focus is on child nodes. Instead, in our graph, the value lists contain ancestor nodes, indicating which components feed information into the current node.

A key aspect of this architecture is that certain elements, such as `user_query`, are considered implicit nodes representing external inputs to the system. These external inputs play a foundational role in initiating the data flow throughout the graph. The architecture is designed to handle multiple outputs, listed within the `outputs` key. This is not a graph node but serves as an indicator to the engine of what to select as the final result. The output key is also vital for the process of graph topology optimization and linearization described in Section 4. This representation not only makes it easier to track data flow but also helps optimize the query understanding ensemble for real-time processing in e-commerce environments.

Figure 3: Graph Representation of Query Understanding Ensemble

```

    rules, crf, distilbert_l1, sklearn_l1,
    distilbert_l2, sklearn_l2, vui_duckling
  ]
outputs: [ user_query, preprocessor, parse ]
```

Figure 3 illustrates the graph structure that defines the Query Understanding Ensemble. The nodes represent components that work together to process user queries and extract meaningful insights. The graph starts with preprocessing steps that normalize and clean the user input. Subsequently, components such as `DistilBERT` and `TF-IDF` are leveraged to extract semantic features and contextual information. Additional models like the `CRF` (Conditional Random Fields) and `vui_duckling` focus on identifying specific entities such as brands, quantities, and attributes.

The outputs from these models are fused together through specific nodes such as `fusor_l1` and `fuse_all`, which combine signals from the intermediate models based on confidence scores and rule-based decisions. The final outputs represent the processed user query, refined and enriched through multiple layers of analysis, ready for downstream tasks such as categorization and search relevance adjustments.

This architecture's flexibility and efficiency enable it to handle the complexities of e-commerce queries in real time while supporting high-volume traffic and diverse query types. It also lays the groundwork for the performance optimizations and parallel processing strategies outlined in Section 4.

ELIta: A New Italian Language Resource for Emotion Analysis

Eliana Di Palma[1,2]

[1]*Sapienza, University of Rome*
[2]*Roma Tre University*

Abstract
Emotions and language are strongly associated. In recent years, many resources have been created to investigate this association and automatically detect emotions from texts. Presenting ELIta (Emotion Lexicon for Italian), this study provides a new language resource for the analysis and detection of emotions in Italian texts. It describes the process of lexicon creation, including lexicon selection and annotation methodologies, and compares the collected data with existing resources. By offering a non-aggregated lexicon, ELIta fills a crucial gap and is applicable to various research and practical applications. Furthermore, the work utilises the lexicon by analysing the relationships between emotions and gender.

Keywords
emotions, language resource, italian, emotion lexicon, word-emotion association

1. Introduction and Related Works

Emotions and language are deeply interrelated human characteristics. Language serves as a tool to communicate our feelings, while affective studies have shown that emotion permeates all aspects of language [1, 2], such as morphology [3, 4, 5], phonology [6, 7], and semantics [8, 9]. This intricate relationship has recently attracted significant attention in fields such as computational linguistics, natural language processing (NLP), and affective computing. Research focusing on the identification of emotions from texts has produced various language resources, particularly emotion lexicons developed using diverse annotation methodologies, ranging from manual [10, 11] to automatic [12, 13], and from expert judgment [14, 15] to crowdsourcing [16, 17].

Most studies follow the dimensional approach to emotions [18, 19]. According to this perspective, the PAD (Pleasure, Arousal, Dominance) [20] or VAD (Valence, Arousal, Dominance) [19] model posits that the fundamental dimensions of VALENCE (the intrinsic attractiveness (positive VALENCE) or aversion (negative VALENCE) of an event, object or situation), AROUSAL (the level of physiological activation, ranging from sleep to excitement) and DOMINANCE (the degree of control a person feels over a situation) explain the majority of the emotional meaning of words. This approach has been highly productive for research on emotional language and the creation of language resources, exemplified by the ANEW (Affective Norms for English Words) [21, 22], NRC VAD [23], and the EmoBank corpus [11].

Alternatively, some researchers argue for the existence of a limited number of discrete primary emotion categories that have evolved to serve various adaptive functions through specific neural signatures, facial expressions, cognitive evaluations, and behavioral action tendencies [24, 25]. These basic emotions typically include JOY, SADNESS, DISGUST, ANGER, FEAR, SURPRISE, whereas Plutchik also considers TRUST and ANTICIPATION. Despite objections to the basic emotions model [27], it has inspired the creation of resources such as the NRC Lexicon (EmoLex) [17] (translated into over 100 languages, it's the most widely used lexicon in emotion detection), and the datasets Feel It [28] and Multiemotion It [29].

More recently, the field of computational linguistics and NLP has recognized the need for resources specifically created for languages other than English. Critics argue against relying solely on translations, advocating for lexicons created from texts in the target language and manually annotated [30, 31, 32]. This approach has led to the development of lexicons like the Portuguese emotional lexicon [30], which embodies the principle of ”each language for itself.”

For the Italian language several language resources with emotional annotations have been produced over the years. The initial ItEM lexicon [33] began by collecting seed words through an association task linking words to labels (Plutchik's basic emotions), then employed cosine similarity to expand the lexicon, assuming that neighboring words in semantic space share similar emotional connotations. The results, validated through crowdsourcing, showed low reliability for the emotions TRUST, ANTICIPATION (translated as 'attese') and SURPRISE. The more recent Depeche Mood ++ [34] was automatically created from judgements given by readers of articles on the 'Corriere della Sera' newspaper website and uses a

CLiC-it 2024: Tenth Italian Conference on Computational Linguistics, Dec 04 — 06, 2024, Pisa, Italy
eliana.dipalma@uniroma1.it (E. D. Palma)
0000-0003-2154-2696 (E. D. Palma)

unique scale of emotions not directly comparable to others, such as ANNOYED, AFRAID, SAD, AMUSED, and HAPPY. [34].

In the case of Affective Norms [21], the tendency to create resources by adapting the English model with annotations in L1 languages other than English has resulted in Affective Norms for several languages, including Spanish [35] and Dutch [36]. For Italian, there has been a specific adaptation of the ANEW collected by [37].

Despite the existing resources in the literature, a notable gap persists. There is a lack of manually annotated Italian language resources that combine both discrete emotion annotations and dimensional evaluations. Furthermore, no available resource provides a non-aggregated version of the data.

This paper presents **ELIta** (**E**motion **L**exicon for **I**talian), an innovative resource designed for the analysis of emotions in the Italian language and emotion detection from text. **ELIta** aims to bridge this gap by providing a lexicon annotated using both categorical and dimensional approaches, and by offering a non-aggregated version of the data. This aligns with the perspectivist viewpoint, which values disagreement as valuable information [38, 39, 40, 41]. The development process of **ELIta**, including lexicon selection, annotation methodologies, and a comparative analysis with existing Italian sentiment lexicons, is thoroughly described. Finally, analyses of the relationships between emotions and between dimensions and gender are presented.

2. Emotion Lexicon Creation

Lexicon Selection The lexicon for this study is constructed from existing resources in the literature. The major pool from which it draws is De Mauro's 'Nuovo Vocabolario di Base' (NVdB) [42]. This selection is made by reason of its representativeness of contemporary Italian language usage in different types of text. In line with EmoItaly [43], 186 emoji have been added to the lexicon so that it can also be used for texts from Social Networks.

Furthermore, as a foundational layer, the seed-words of ItEM [33] were incorporated. To ensure broad coverage, high-frequency words (recurring more than 200 times) from the Depeche Mood ++ [34] lexicon by Araque et al. were included.

The selection process favoured content words (verbs, nouns, adjectives and adverbs) over function words (determiners, conjunctions).

The final lexicon comprises 6905 items, including both words and emojis. The data set contains 21 % adjectives, 50 % of nouns, 21 % verbs and 8 % of words that can be considered both as adjective and noun. In addition, a smaller number of adverbs, expressions (e.g. 'restare a bocca aperta' *be looking open-mouthed*) and interjections (e.g. 'beh', 'boh') have been included.

Consistent with the research of Montefinese et al. and previous studies [44], participants were not explicitly instructed to disambiguate words with multiple grammatical meanings.

Annotation Schema In order to collect a versatile dataset adaptable to different research approaches, the data collection involved an annotation process that included both the association of words with basic emotions [26] and the evaluation of the items according to VAD dimensions [20]. In the case of basic emotions, it was decided to use the translation 'aspettativa' for ANTICIPATION instead of 'attese' as in ItEM in order to avoid misunderstandings and associations of the "attese-treno" type. Furthermore, to provide additional context for the analysis, participants were asked to share their demographic information.

Data collection Data were collected from two primary sources from April 2023 to May 2024. An online questionnaire in the form of a website [1] created from scratch was used to rate the words. The website was shared for annotation via mailing lists (such as LinguistList and AILC) and social networks. The participation was on a voluntary basis and without payment. In this system, the words to be rated in each questionnaire were randomly chosen. That is, each time the questionnaire was accessed, the system randomly chose the words from the entire list of 6, 905 words. Thus, each participant rated a different set of words.

When accessing the website, participants first agreed to an informed consent. Then, they were given the guidelines for both categorical and dimensional annotation. On the third screen, they had to provide the demographic information concerning age and gender, and select the time slot to spend on the annotation process (from 3 to 10 words, with the possibility of extending the annotation process at the annotator's discretion).

Participants were asked to rate the extent to which each word is associated to a list of emotions, using a scale from "non associated" (0), "weakly associated" (0.25), "moderately associated" (0.75) to "strongly associated" (1) [17]. Next, participants were shown the dimensions using the Self-Assessment-Manikin from the ANEW [21] (see Fig. 1) to assess the extent to which each word convey VALENCE, AROUSAL, and DOMINANCE using a 1 to 9 scale. The guidelines in the latter case were mutuated from Montefinese et al.(2014).

Additionally, the Prolific platform was used to recruit native Italian speakers as participants from March 2024 [2].

[1] https://emotionlexicon.com/

[2] In this case, the annotators were paid according to the rules established by the platform.

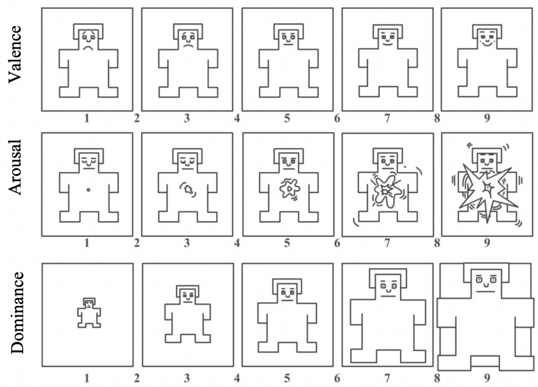

Figure 1: *Self-Assessment Manikin* da Bradley and Lang (1994)

A total of 100 different questionnaires were created and completed on the platform, each containing 65 words/emojis. Words and emojis were selected based on existing annotations to ensure a minimum annotation threshold of five per word (such as in the NRC lexicon [17]).

Description of ELIta The collected data underwent a rigorous filtering process to ensure quality and accuracy. Participants with exceptionally fast completion times were excluded. Additionally, despite the subjective nature of the task, annotations with clear anomalies were removed, such as associations deemed illogical (e.g., 'worsening' *peggioramento* strongly associated with JOY).

The total number of annotations gathered is 35, 412. For each of the 6905 words/emojis in the lexicon, from a minimum of 5 annotations to a maximum of 10 annotations were collected (on average 5.13 annotations per word).

From the demographic metadata, it can be observed that the majority of annotations come from women and the most frequent age group is 25-34 years old (see table 1).

Table 1: Number of annotations by gender and age. The highest number of annotations for each age and gender are highlighted.

	Women	Men	Non binary	Not specified
18-24	4201	2318	108	73
25-34	9052	6797	654	18
35-60	6568	4766	8	11
60	267	550	13	8

Versions

The lexicon is provided in several versions [3]:

RAW Version including all annotations and demographic information with an inter-annotator agreement (calculated with Krippendorff [45]) of 0.67, which can be explained by the subjective nature of the task (associating words with emotions in isolation). Various factors such as gender, age and socio-cultural background can influence the IAA in such subjective tasks.

GOLDEN A second, non-aggregated version was also released, in which the five most similar annotations were selected for words with more than five annotations, thereby excluding the outliers. Additionally, an automatically generated 'golden standard' annotation was added for each word, calculated based on the majority vote from the five annotations for each emotion. This approach emphasizes the majority vote while retaining all individual entries. This '**ELIta**-golden' version achieves an Inter-Annotator Agreement (IAA) of 0.874. The annotations are categorized by origin into '**ELIta**,' '**ELIta**-selected' for selections made from more than five annotations, and 'golden.' In this case, demographic information is absent, but association intensity is preserved.

INTENSITY One of the aggregate versions created from the golden version retains the intensity values of the original annotations, with the single value calculated as the average of the six annotations (five original + one golden). The decision to use the golden version is to balance the few annotations with one representative of the majority. In this case, the labels of LOVE automatically calculated from the values of JOY and TRUST and 'neutral' were also added.

BINARY The second aggregated version, converts the aggregated float values to integers, providing a binary representation of the basic emotions: 0 for values below 0.50 and 1 for values above 0.50.

3. Analyses and Discussion

3.1. Comparative Analyses

To evaluate the similarities and differences of the newly developed **ELIta** lexicon, it was conducted a comparative analyses with other language resources for Italian: EmoLex (NRC-AIL) [46], ItEM [33], and ANEW [37]. The **Intensity** version of **ELIta** was used for all analyses.

Correlations were calculated for each basic emotion and VAD dimension against the italian translation of EmoLex (NRC - AIL Affective Intensity Lexicon [46]), the cosine values of ItEM [33], and the dimensions of the Italian Affective Norms [37].

[3] https://github.com/elianadipalma/ELIta

ELIta vs. EmoLex Comparing the 2, 388 shared items, the results showed a moderate correlation of 0.51. JOY exhibited the highest correlation (r = 0.65), while ANTICIPATION (r = 0.38) and SURPRISE (r = 0.35) showed the lowest. The results show even more the need to use lexicons specifically created for the target language.

ELIta vs. ItEM With 3, 299 shared items, Pearson correlations were calculated between the degree of association of ELIta for each basic emotion and the cosine similarities between the words and emotion-labels of the basic emotions. Correlations were generally low, with the highest for ANGER (r = 0.29). The lower correlations are in line with previous observations on the difficulty of annotating emotions such as TRUST (r = 0.18), ANTICIPATION (r = 0.14) and SURPRISE (r = 0.13).

ELIta vs. ANEW The two resources share 762 items. The analysis revealed a strong correlation (r = 0.88) for VALENCE, while AROUSAL (r = 0.48) and DOMINANCE (r = 0.61) showed lower correlations. The observed outcomes are consistent with research showing AROUSAL and DOMINANCE as the dimensions most variable [35, 37].

To identify the words for which the two annotator groups provided significantly different ratings, a linear regression was used. This statistical model allows to estimate the extent to which ELIta ratings can be predicted by Affective Norms ratings and to identify the words for which this relationship is weaker. [4].

The results show a more negative connotation of words linked to the religious sphere, for example, 'church' *chiesa* and 'god' *dio* have shifted from positive to negative. Similarly, 'fur' *pelliccia* 'circus' *circo* and 'justice'*giustizia* have also transitioned from positive to negative. Conversely, the terms 'lesbian' *lesbica* and 'mad' *folle* have shifted from negative to positive.

Examining the associations of these words with basic emotions, it can be noted, for example, that the predominant emotion associated with the word 'church' is ANGER with a mean intensity of 0.54, followed by SADNESS and DISGUST. Analogously, 'fur' is associated most strongly with 0.75 to SADNESS and with 0.70 to ANGER, and 'circus' is more associated with DISGUST and SADNESS. The word 'god' presents an interesting contrast. Although it has a negative VALENCE (M = 4.6) compared to the ANEW result (M = 8.3), the primary emotions associated with it are TRUST (0.67) and ANTICIPATION(0.46). The word 'lesbian' does not appear to be associated with any emotion, except very weakly with JOY (M = 0.20), while 'mad' results associated more with JOY and SURPRISE (M = 0.42).

Regarding AROUSAL, terms such as 'optimism' *ottimismo*, 'erotic' *erotico*, 'success' *successo*, 'food' *cibo*, and 'in love' *innamorato* have shown increased activation. In contrast, terms like 'unpleasant' *spiacevole*, 'discouraged' *scoraggiato*, 'boredom' *noia*, 'cold' *freddo*, and 'rain' *pioggia* are associated with less activation in the ELIta lexicon.

For DOMINANCE, there is an increased sense of dominance associated with terms such as 'hatred' *odio*, 'optimism' *ottimismo*, 'triumph' *trionfo*, 'triumphant' *trionfante*, 'to sleep' *dormire* and 'to travel' *viaggiare*. Conversely, the sense of submission is associated with terms like 'earth' *terra*, 'nature' *natura*, 'circus' *circo*, and states of illness such as 'fever' *febbre*.

These differences may reflect the different sensibilities of the annotators. The affective norms of [37] were published in 2014, while the majority of the annotators of the proposed ELIta lexicon belong to the age range of 25-34 years. ELIta can thus be seen as a limited update to the norms proposed by Montefinese et al. (2014).

Although generational characteristics may influence the results, it is important to consider that the comparison was based on the means of responses from approximately 20 persons for the Norms and 5 persons per word for ELIta. The lower number of annotators for ELIta could imply that the individuality and socio-cultural background of each participant have a greater impact on the results. Therefore, further analyses should be conducted.

3.2. Correlations and Gender Variation

Once the data as a whole had been analysed in comparison with other lexicons, the annotations were analysed to examine the relationship between the different emotions and dimensions, and whether there were differences between genders in the association between words and emotions.

Correlations Firstly, Pearson correlations between categories and dimensions were calculated. (see Fig. 2).

The results show a moderate correlation between AROUSAL and negative emotions, particularly FEAR (r = 0.45) and ANGER (r = 0.40). Consequently, the correlation between AROUSAL and VALENCE turns out to be weakly negative ($r = -0, 17$).

Furthermore, it can be noticed that negative emotions tend to co-occur, suggesting that words associated with SADNESS may also be linked to ANGER, DISGUST, or FEAR [47]. Conversely, JOY shows a moderate to strong correlation with TRUST (r = 0.66), ANTICIPATION (r = 0.62) and SURPRISE (r = 0.49).

Interestingly, there is a moderate correlation between DOMINANCE and JOY (r = 0.53), indicating that words with positive VALENCE are also associated with a greater sense of control (r = 0.7), while negative ones are associated to a sense of submission ($r = -0.40$ to $r = -0.53$) [48]. An exception is given by words such as 'nature' which, as

[4] Plots are available in the appendix, see Fig. .6.

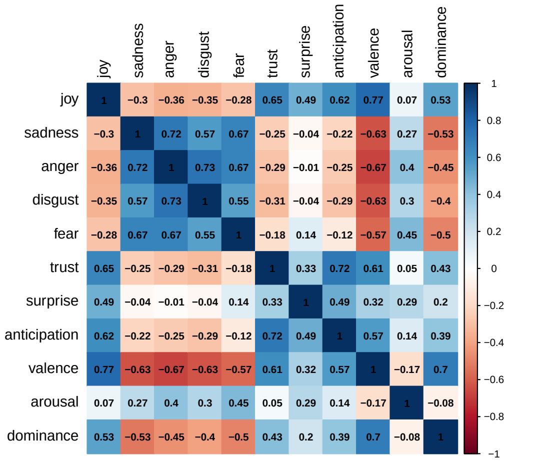

Figure 2: Correlations between basic emotions and VAD dimensions.

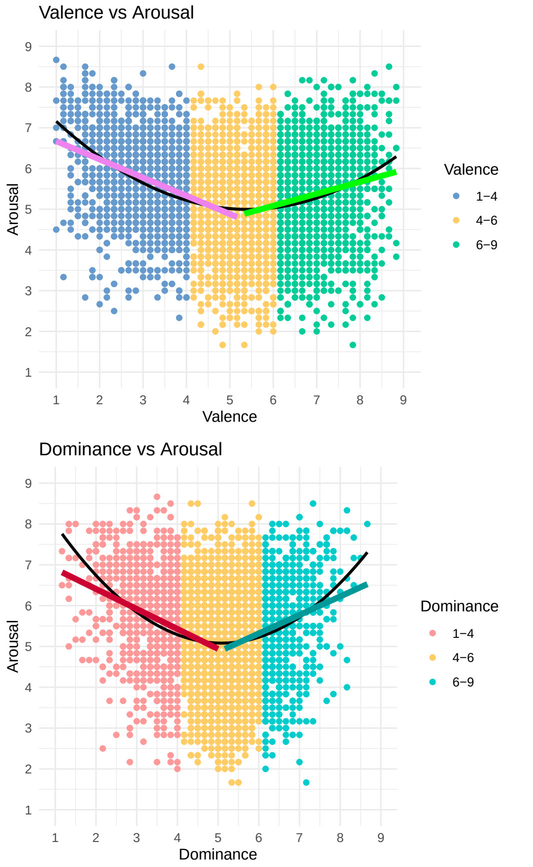

Figure 3: Scatterplots of the distributions of ELIta according to dominance and arousal dimensions, and valence and arousal dimensions. The lines represent the linear regression according to the values before the valence median (in purple) or the dominance median (in red), and after the valence median (in green) or the dominance median (in teal).

we have seen, has a low rating (M = 3.5) for dominance but is strongly associated with joy (M = 1).

Surprise shows positive correlations both modestly with joy and anticipation, and weakly with fear, and trust, although it is a more neutral emotion than the others, it is generally more prone to have a positive valence (r = 0.32).

ELIta's findings for Italian corroborate patterns previously identified by Ferré et al. (2016) for Spanish and Sarli and Justel (2021) for Argentinian Spanish.

The correlations and regression analyses revealed patterns consistent with the other resources: a U-shaped relationship between valence and arousal, dominance and arousal (see Fig. 4, and a linear relationship between dominance and valence (see Fig. 3). These results suggest that highly negative or positive items, as well as words associated with low or high control, tend to elicit greater emotional and physiological activation. Meanwhile, greater positivity corresponds to a greater sense of control.

These analyses have positioned **ELIta** as a valuable resource for emotional language research. Despite variations in sample size, the data mirror the trends and distributions observed in existing emotion analysis literature [35, 21, 48, 22, 49]. Consequently, **ELIta** can be considered a psychologically valid resource for emotion research.

Gender variation Gender is a significant factor influencing the annotation of subjective constructs such as emotions. Previous research has shown that men and women often respond differently to the same stimuli [37, 21, 22].

To investigate the impact of gender on emotion annotation, a subgroup of words/emojis annotated by both men and women (n=6, 219) was considered. For each word, the mean emotional ratings provided by the different gender groups were calculated. Subsequently, the correlation between the mean ratings was assessed, and statistical tests were conducted to identify any significant differences between the groups.

The most significant differences were found in annotations of arousal, with a correlation of 0.20 and a statistically significant difference calculated using a t-test with a $p - value < 0.005$ (M = 5.39 for women and M = 5.13 for men). As also reported in the literature, women tend to annotate words not only as more arousing, but also with more extreme values on the valence scale, i.e. rating unpleasant words as more negative and pleasant words as more positive.

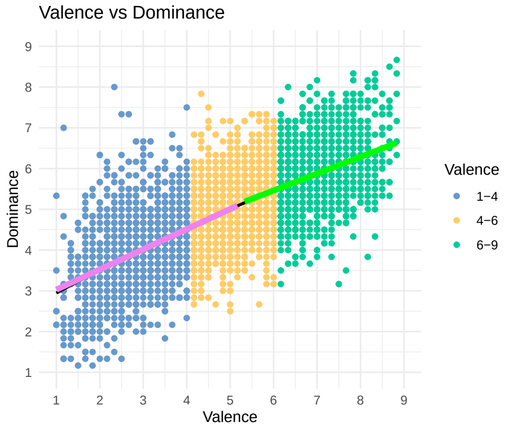

Figure 4: Scatterplot showing the relationship between DOMINANCE and VALENCE in **ELIta**. The lines represent the linear regression according to the values before the VALENCE median (in purple), and after the VALENCE median (in green).

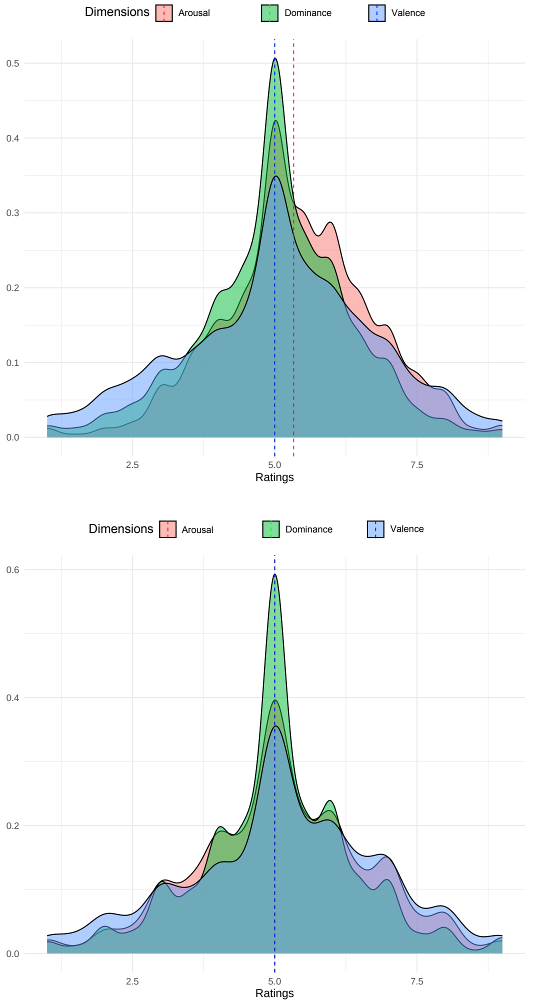

Figure 5: Dimensions distribution in the annotations of men (bottom) and women (top)

VALENCE also showed a significant difference ($p - value$ = 0.017), with women assigning higher AROUSAL and lower VALENCE ratings compared to men (M = 5.08 for women and M = 5.15 for men), although it showed a stronger correlation (r = 0.64) than the other dimensions. These results confirm previous findings [37].

Unlike previous studies [37], the results did not show significant differences in DOMINANCE ($p - value > 0.05$, $r = 0.30$).

Regarding basic emotions, women reported significantly higher levels of FEAR ($p < 0.001$) and lower levels of TRUST and SURPRISE (both $p < 0.01$) compared to men, according to the t-test. For example, female participants expressed significantly lower levels of TRUST towards relationship-related words than male participants, with mean scores for 'partner' *partner*, 'spouse' *sposo*, and 'wedding' *nozze* ranging from 0.5 to 0.87 compared to mean male rating of 1.

These findings indicate that gender significantly influences emotion annotation, particularly for AROUSAL and VALENCE (see Fig. 5). The outcomes again corroborate trends observed in the literature for other languages [49], underlining the importance of offering non-aggregated resources to better represent the differences between speakers.

4. Conclusions

This research introduces a new lexicon for Italian that collects word-emotion associations. Notably, it is the first lexicon, to the authors' knowledge, to be annotated using both categorical and dimensional approaches. Furthermore, it offers an innovative non-aggregated version of the data, reflecting a 'perspectivist' approach that values disagreement as valuable information, such as women showing a greater tendency towards negative VALENCE and higher AROUSAL ratings than man. Analyses using correlations between basic emotions and dimensions, along with comparisons to existing resources such as ANEW, underscore the lexicon's potential to deepen our understanding of the interplay between emotions and language. While **ELIta** represents a significant step forward in capturing the complexity of emotion-language interactions in Italian, continued development will be essential to addressing its current limitations and maximizing its utility as a comprehensive tool for emotional analysis.

Comparing Large Language Models verbal creativity to human verbal creativity

Anca Dinu[1],*,†, Andra Maria Florescu[1],*,†

[1]University of Bucharest, Șoseaua Panduri 90, Sector 5, Bucharest, 050663, Romania

Abstract

This study investigates the verbal creativity differences and similarities between Large Language Models and humans, based on their answers given to the integrated verbal creativity test in [1]. Since this article reported a very small difference of scores in favour of the machines, the aim of the present work is to thoroughly analyse the data through four methods: scoring the uniqueness of the answers of one human or one machine compared to all the others, semantic similarity clustering, binary classification and manual inspection of the data. The results showed that humans and machines are on a par in terms of uniqueness scores, that humans and machines group in two well defined clusters based on semantics similarities between documents comprising all the answers of an individual (human or machine), per tasks and overall, and that the separate answers can be automatically classified in human answers and LLM answers with traditional machine learning methods, with F1 scores ranging from 68 to 74. The manual analysis supported the insight gained from the automated methods in that LLMs behave human-like while performing creativity tasks, but there are still some important distinctive features to tell them apart.

Keywords

creativity assessment, LLM creativity, verbal creativity, semantic similarity clustering

1. Introduction

Creativity has made it possible for humanity to survive and develop since prehistoric times. Despite the perception that some people are more creative than others, many psychologists argue that everyone has the capacity for creativity or that creativity is innate and encoded in human nature [2].

Creativity is inherently interdisciplinary, involving domains like psychology, cognitive sciences, philosophy, arts, engineering, mathematics, or computer science. Recently, it has become a field of interest in GenerativeAI (GenAI) [3] in general, and in particular, in Large Language Models (LLMs) [4].

However, much of the current research in generative models [5] is concerned with constraining them so they do not harm people, so they are well-behaved, factual, non-hallucinating, non-biased, non-negative, non-misleading, non-toxic, etc., and for a good reason. In contrast, fewer studies (see section 2) focus on encouraging them to be original, unconstrained, or creative, although computational creativity, as a research field, dates back to the late '90s [6], [7] with various disciplines including creative writing, music, or graphics, utilizing artificial intelligence, particularly neural networks, heuristics, and so on. A good survey on LLMs' verbal creativity is [8]. Since work on LLMs creativity is just at the beginning, there is a need for methods, resources, and evaluation to better understand LLMs' creative abilities and their differences and similarities with human creative traits.

In a recent article, [1] designed a verbal creativity test, integrating a wide range of tasks and criteria inspired from psychological creativity testing, and administrating it to both humans and LLMs. The scope of this paper is to analyze the answers given by LLMs and human respondents to this previous study, for a direct comparison of human and machine verbal creativity. To this end, we will compute uniqueness scores, cluster the individual answers per task and overall, perform supervised binary classification with classic machine learning methods on all answers and manually analyze some of the data particularities.

2. Theoretical background and previous work

The formal study of creativity and of its mechanisms and processes started with J.P. Guilford's plead for creativity in the 1950s [9]. Since then, thousands of articles and books have been published on different aspects of creativity [10].

Creativity is a notoriously hard-to-define notion, because it is trans-disciplinary, branched in a variety of domains. It can also be of many kinds like verbal, graphical, musical, or kinetic creativity. While the last three kinds of creativity are related to arts, verbal creativity is the most general kind, expressing the overall creativity

of ideas.

Regardless of the domain perspective and of the kind of creativity, a basic idea in defining it, common to most of the definitions, is that creativity represents the ability of an individual to come up with something original or innovative, of good quality, and appropriate, based on prior knowledge [11]. One can be creative, but lack appropriateness of the idea or artifact produced, hence diminishing its quality in terms of creativity.

Another related aspect of creativity, as stated by [12], is represented by two types of thinking during the creative process:

- *divergent thinking*, which concentrates on the numerous ideas appearing during a creative task, and
- *convergent thinking*, which restricts them to the only best-fitted or appropriate ones. So, even if an idea or artifact might seem creative from a divergent perspective if it is unreasonable to the point of being completely unrelated to the initial creativity task to begin with, the overall creativity level drastically diminishes.

With the recent rise of generative models like LLMs such as Chat GPT[1] or Copilot, the interest in computational creativity peaked, in an attempt to harvest the creative potential of the machines, in spite of many challenges such as safety, ethical problems, methodological norms, evaluating standards, etc.

Previous studies on machine creativity are fragmented: some are task-specific, like, for instance, using just role-plays[13], or just storytelling [14], while others focus on just one LLM [4], or just on one type of creativity assessment [15].

In this study, we mind this research gap by analyzing the creative responses to a wide range of tasks, of a considerable number of LLMs, from [1], who proposed a comprehensive assessment benchmark for testing the verbal creativity of both LLMs and humans, alike. It consists of six tasks, inspired from human psychology:

1. *Alternative Uses* (AUT), where the test taker is asked to come up with uncommon uses for an ordinary object,
2. *Instances*, for which the aim is to name as many things as one can think of that have a common feature,
3. the *Similarities*, which consists of stating as many as possible commonalities of two specified objects,
4. the *Causes*, where the aim is to guess the cause of a given situation,
5. the *Consequences*, for which one should guess the effects of a specified situation , and
6. *Divergent Association* (DAT), where the respondent has to produce seven nouns that are maximally semantically different, in all their senses and uses.

In [1], ten LLMs and ten humans were tested on this verbal creativity test, including the six tasks above. The authors stated that their goal was to test the creativity of the selected LLMs in their default architecture, and, thus, they did not change any settings that could have modified the creativity level, such as temperature or top-K. The collected answers given to this test are the input data for the present article.

3. Analysis

Creativity assessment is usually performed with human evaluators who take into account the four creativity criteria formulated by [9, 12]:

1. originality: uniqueness of the creative answers,
2. flexibility: how semantically distant the answers are,
3. elaboration: how detailed are the answers, and
4. fluency: how many answers are given.

[1] automatically evaluated the verbal creativity by using the Open Creativity Scoring with AI (OCSAI) tool [16], an open-source software that uses traditional semantic distance and fine-tuned GPT for scoring the creativity between the prompt and the answer. The results showed a slightly better score of the overall verbal creativity, computed as the mean of the scores for all the 6 tasks, for the machines, with a value of 0.58, compared to humans, with 0.51. Given that the difference is of just 7 decimals, one of our goals for this study is to analyze more in-depth the differences and similarities of the answers of humans and machines to the verbal creativity test, looking specifically for distinctive features, rather than raw scores. The ten selected LLMs from the previous study were accessed via: HuggingChat[2] (LLAma-3-70B, Mixtral-8x7B[3]), via Hugging Space [4](Cohere- c4ai-command-r-plus, Yichat-34B), locally (Falcon through GPT4All[5]), or directly from their web pages (Copilot(Balanced Mode) [6]), Gemini-free version[7], Jais-30B[8], Youchat from You.com-Smart mode[9], Character AI (Character Assistant[10]).

The humans were non-native fluent English speakers who responded to the verbal creativity test as volunteers, either in a lab or at their homes by completing a Google Form. Their background was all academic, from students, undergraduates, graduates and professors, the average age being 26.

We implemented all the experiments in Google Colab[11] and we have used three LLMs to assist us with the codes: Claude[12], Copilot[13] and Gemini[14], in a setting of mostly zero-shot prompt engineering, with the standard settings and parameters.

For data analysis, we used Python and the following libraries: Spacy[15], Scikit-learn[16], Matplotlib[17], Numpy[18], and Pandas[19].

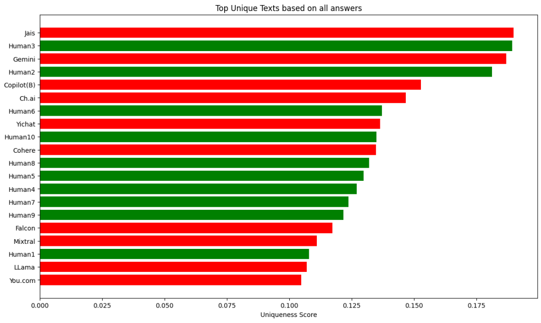

Figure 1: Ranking of uniqueness scores for humans and machines

3.1. Data

The databases of verbal creativity answers contains 4530 answers, totalling 13714 words. The test was organized in 6 tasks. Five out of the six tasks have five items each and a maximum of 10 answers per item. An answer can have a maximum of 5 words. The sixth task, DAT, consists only of one item of 10 single-words answers, but only the most semantically different 7 out of the ten given by the respondents were taken into account by the DAT web page [20]. That amounts to 2570 answers for the machines, which responded always with the maximum number of answers, 10, even if the instruction was the same for both humans and machines to give between 1 and 10 answers per task. The human respondents gave any number of answers in the range 1 to 10, obtaining thus 1960 human answers. As such, the database is unbalanced, with with more than a third more machine answers compared to human answers.

3.2. Uniqueness scores for the answers of humans and machines to the verbal creativity test

One of the criteria for assessing creativity in psychology is the degree of originality of the answers of one individual, compared to the answers of all the other individuals. The evaluation of this criterion is done manually and is time-consuming, since it includes assessing not only word similarities, but also similarities between ideas of the different individuals. [1] did not use this criterion, since one of their goals was to evaluate the answers fully automatically. Nevertheless, the uniqueness of the answers of an individual constitutes an important clue to their creativity. Hence, to better understand the uniqueness trait of both humans and machines, we computed uniqueness scores as if follows.

We grouped the creativity test answers of both humans and machines in separate files, each containing all the answers of a particular individual. We thus obtained 20 answer files, 10 for humans and 10 for LLMs. After removing the stop words, we generated embeddings for each file, and then we computed their pairwise semantic similarity, using spaCY library. The uniqueness scores were obtained as the inverse of the average semantic similarity scores between an individual and all the others. The ranking obtained in the decreasing order of uniqueness is depicted in figure 1, where one can see that the humans (in green) and the machines (in red) are mostly intermingling.

This uniform distribution of humans and machines in terms of uniqueness scores shows that humans and machines are on a par in this respect.

3.3. Semantic similarity clustering of the answers of humans and machines

The aim of this experiment was to investigate if individual humans and individual machines cluster together, based on semantic similarity of their answers to the creativity test. We used the word embedding of the 20 individual files described in subsection 3.2. To reduce the dimensionality of the vector space for the 2D plot, we used Principal Component Analysis (PCA), from spaCY library.

In figure 2 we can see how the LLMs (dots in red) perfectly cluster together, just as the humans (dots in green) do, considering all responses to the six tasks. This result indicates that from a semantic perspective, humans and LLMs generate creative answers differently, or at least that there are discriminating features to distinguish

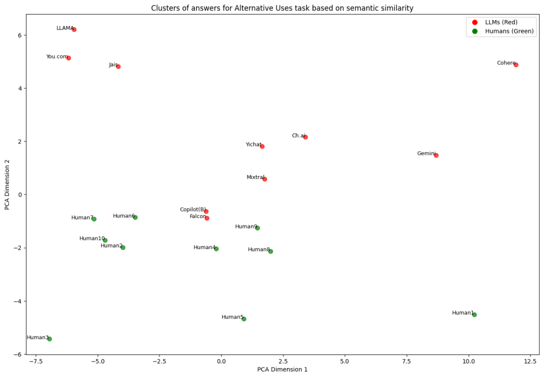

Figure 3: Semantic similarity clusters of answers for Alternative Uses

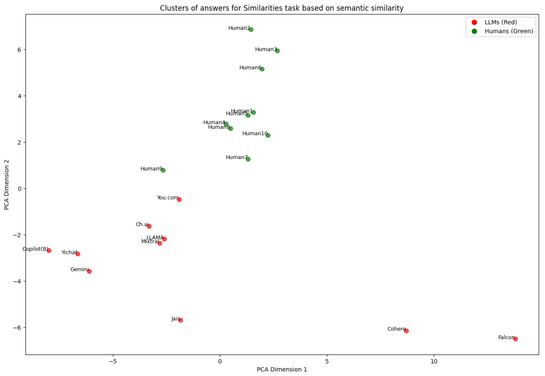

Figure 5: Semantic similarity clusters of answers for Similarities

between the two.

We also plotted the clusters per answers to a specific task, for all the 6 tasks, in figures 3, 4, 5, 6, 7, and 8. Generally, the answers of the humans and of the machines clearly clustered by their kind, with the exception of the task *Instances*, where the humans and the LLMs were interposed, meaning that the semantic content of their answers was not specific to any of the two classes. A bit of mixing appeared also in *Divergent Association Task* (DAT). The not so clear separation of humans and machines for Instances and DAT tasks might result from the fact that the responses to these particular tasks are inherently very short, of just one or two words for *Instances* task and of just one word for the DAT.

3.4. Binary classification of human and machine creativity answers

As the clusterization experiment suggested, the answers to the verbal creativity test are almost linearly separable in two classes (humans and machines) at individual level. In this binary classification experiment, we investigated if they also have distinctive features at the answer level. For this, we trained several traditional machine learning (ML) classifiers to discriminate between the answers of humans and of LLMs to the verbal creativity test. The two classes were represented by all the answers of the humans and, separately, by all the answers of the LLMs, with one answer per line, excluding the *DAT* task, since it only required enumerating words. As the LLMs always gave the maximum number of answers required in the test, the dataset was unbalanced (2500 answers for LLMs and 1890 for humans). To address this problem of unbalanced dataset, we implemented a simple random under-sampling technique, thus obtaining 1890 answers for each class, humans and LLMs. We then employed the Term Frequency-Inverse Document Frequency (TF-IDF) vectorization technique to convert the text data into numerical features. The vectorizer used a maximum of 1000 features, for capturing all important aspects and dealing with computational complexity. Stratified sampling was used to ensure a dataset split for an 80/20 training and

Table 1
Binary classification scores

	SVM				NaïveBayes				RandomForest			
	Prec.	Rec.	F1	accu	Prec.	Rec.	F1	accu	Prec.	Rec.	F1	accu
Humans	0.78	0.60	0.68	0.71	0.70	0.83	0.76	0.74	0.67	0.80	0.73	0.71
LLMs	0.67	0.83	0.74		0.79	0.65	0.71		0.76	0.61	0.68	

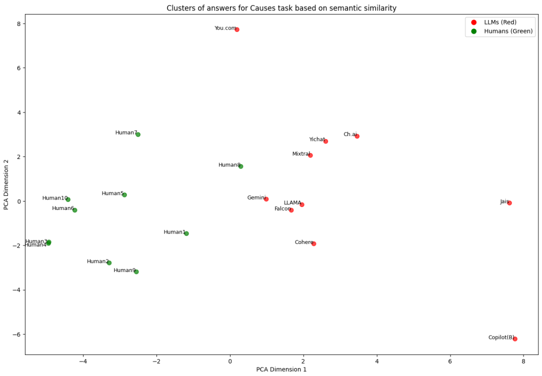

Figure 6: Semantic similarity clusters of answers for Causes

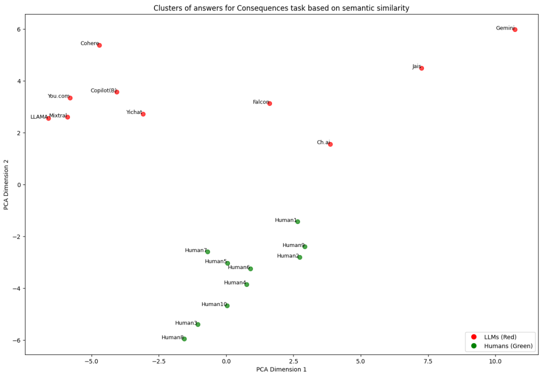

Figure 7: Semantic similarity clusters of answers for Consequences

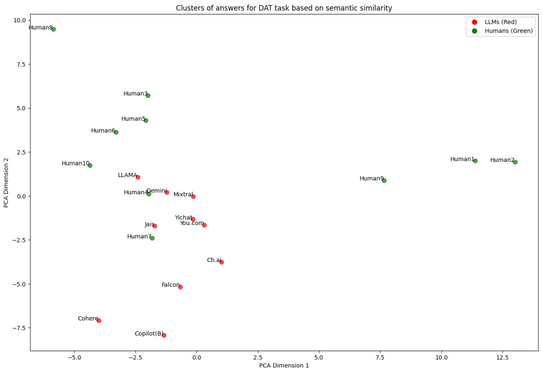

Figure 8: Semantic similarity clusters of answers for DAT

testing ratio. Thus, training and testing sets contained the same number of samples for each category, e.g. 1512 answers for training, and 378 answers for testing.

In table 1, we give the best three classifier methods, with precision, recall, accuracies, and F1 scores. The NaïveBayes classifier obtained the highest accuracy, of 0.74, followed at just three decimals by both the Support Vector Machine (SVM) classifier and the Random Forest classifier, with an accuracy of 0.71.

This moderate performance of the ML models suggests that either the dataset is too small for the models to perform better, or that there is a fair amount of similarity between the answers of humans and machines that prevents the model to better learn to discriminate between human and machine answers. Further experiments are needed to see if by enlarging the dataset or by experimenting with SOTA transformers to see wheter the performance rises considerably or not.

3.5. General considerations

We manually inspected the first two most unique LLMs and humans to see what makes their answers so different from the others but also investigated the uniqueness scores correlation with the quality and creativity.

The first positioned on the uniqueness ranking, the LLM Jais, had the tendency to respond to the *Similarity* task with word obtained by nominalization (deriving nouns from verbs), like, for instance, "dependency", "curiosity", "belonging", and "growth", as opposed to all the other LLMs, which responded with regular nouns. It also tended to use answers that started with the same prefix: “Unfiltered”, "Unmatched", "Unrestricted", and "Unyielding", and to use the same word followed by other words, like in, for instance, "Thought policing", "Thoughtful shopping", and "Thought clones". In this respect, Jais gave the most unique answers, which, obviously, were not also the most creative.

The second positioned on the uniqueness ranking, Human 3, started the majority of their answers with "use" or "use it as". This respondent also repeated the starting point of most of their answers, like in "what...", "getting a ...", "where ...", "in a...". These features seem enough to score highly w.r.t. uniqueness, but fail to correlate with the quality of the creativity.

This inspection shows that the most unique answers are not necessarily the most creative. If the bulk of the respondents give good-quality answers, that might result in a high uniqueness score for lower-quality or less creative responses.

We also checked the appropriateness of the answers given by both humans and machines, which is an important requirement of genuine creativity, as mentioned in section 1. Creativity requires divergent thinking, but true creativity emerges when convergent thinking also restricts the divergence to only those responses that are appropriate for the creative assignment [12].

In general, humans gave fairly suitable answers. Instead, not all the LLMs managed to generate all the answers in an appropriate manner. For instance, for the *Consequences* task, for the item "There is a virus and only children survive", Gemini, although responded creatively, failed to also respond suitably. This model gave four out of the ten answers that are either paradoxical, or non-sensical, in a situation that clearly implies that only children are alive, so there are no adults around: "Toy Factories booming", "Geriatric Theme Parks", "Grandparents raise parents", "Parents taught by Tablets".

Another manual scrutiny focused on analyzing the similar or the different patterns of LLMs and humans when responding to a particular task. We found that several LLMs answered to the *Divergent Association Task* with the same word among the seven required ones. For instance, "Serendipity" was used by three models. This phenomenon is not specific only to the machines. For the Guessing Causes Task, Human 3 and Human 4 produced similar answers, like, for instance, both gave the answer "earthquake", or produced the same idea, like "green lights"/"because of green lights", "eating something bad"/"they ate something bad", "St Patrick's Day"/"St. Patrick's day party", "poor construction"/"faulty structural integrity", "looking at screens too much"/"too much screen time".

Also, we noticed some peculiarities of individual LLMs, such as Falcon's generation of only words starting with the letter "a" for DAT, or Cohere's generation of only opposite words for this task: "love", "hate", "peace", "chaos".

Moreover, humans seem more personally involved in answering than LLMs, which tend to give only general answers to the tasks, with some exceptions. Some LLMs seem to respond "humanly", even producing humor and figurative speech, while others only respond quite standard or "robotic".

Overall, the LLMs's distribution is similar with the humans' distribution, varying from one individual to another.

4. Ethical considerations

We did not use or disclose any personal data from the human participants, who remained completely anonymous and took part in this research as volunteers. There are no ethical concerns with regard to publishing this research.

5. Limitations

The dataset for this research was small and slightly unbalanced since the humans answered based on their mood or capabilities, while the LLMs answered strictly with a maximum of ten answers per task.

Also, the sample pool is quite small, as there were only ten humans and ten LLMs involved, so the results might be unstable when enlarging the dataset.

Due to lack of space, this study focuses more on automated methods of analysis, than on manual analysis, thus lacking a more in-depth insight into the patterns of the collected answers to the verbal creativity test from both humans and machines.

Finally, this study compares the creativity answers of humans and LLMs in English, but the human participants to the test were non-native (fluent) English speakers, which can potentially decrease their creativity score, compared to scores they could obtain in their own native language.

6. Conclusion and future works

This study showed that there are some differences between human and machine answers given to a verbal creativity test, but also plenty of similarities.

The LLMs' answers vary much like the humans answers. Individual, unique answers, w.r.t. to the set of all answers are produced by both humans and machines alike, with no noticeable difference.

Still, at a semantic level, humans and machines generally group together as individuals.

The performance of automatic classification between human and machine answers is moderate and leaves room for improvement.

The general findings of this study indicate that LLMs' creative capabilities are comparable with human abilities and, as such, they could be put to good use in the creative domain. Humans "just" need to adapt to their usage, mind the ethics and safety issues, and discern the information at every step, instead of blindly using them.

In future work, we will focus on expanding the dataset, by adding more LLMs' and humans' answers to the test, for a better statistical coverage.

Also, we aim to manually investigate more in-depth the database, to look for more systematic patterns for both humans and machines.

As creativity remains a domain with endless possibilities, we also plan to investigate other aspects of LLMs' creativity, such as language or image.

Another future approach worthy of pursuing is using Deep Learning approaches instead of traditional Machine Learning approaches for the binary classification task, or using metrics specific to LLM-generated tasks.

7. Appendix Verbal Creativity Test

There are 6 types of creativity assessments in this test. **Note**: Be as creative, original, and innovative as possible. Pay attention to the word and answer limit! Try to think of as many answers as possible within the limit!

1. Alternative uses Test Name up to ten unusual uses for the following five items. Use a maximum of five words. Give one answer per line.

1. Lipstick
2. Avocado
3. Whistle
4. Chalk
5. Pantyhose

2. Instances Use a maximum of five words per answer. Give one answer per line. Name up to 10 things that:

1. Things that can harm one's self-esteem
2. Things that you have control of in your life
3. Situations where it is good to be loud
4. Things that can flow
5. Things that you can mark on a map

3. Similarities How are the following 2 terms alike? Use a maximum of three words to describe a common feature of the following pair of words. Give one answer per line. Give up to ten answers:

1. Prison & School
2. Eyes & Ears
3. House & Den
4. Earthquake & Tornado
5. Baby & Cub

4. Causes

1. Crash of a building
2. Everybody turns green at a party
3. Social media disappears
4. Humanity becomes shortsighted
5. Your hat does not fit you anymore

5. Consequences

1. There is a mutation and men are the ones giving birth
2. There is a virus and only children survive
3. People can read each other's thoughts
4. You wake up as your child self
5. AI replaces teachers and professors

6. Divergent Association Task (DAT)

Write ten words that are as different from each other as possible, in all meanings and uses of the words.

Rules:

Only single words in English. Only nouns (e.g., things, objects, concepts). No proper nouns (e.g., no specific people or places). No specialized vocabulary (e.g., no technical terms). Think of the words on your own (e.g., do not just look at objects in your surroundings).

Abstract

In this paper we build a dataset of Italian graphical syllables (called ItGraSyll). We perform quantitative and qualitative analyses on the syllabification and stress assignment in Italian. We propose a machine learning model, based on deep-learning techniques, for automatically inferring syllabification and stress assignment. For stress prediction we report 94.45% word-level accuracy, and for syllabification we report 98.41% word-level accuracy and 99.82% hyphen-level accuracy.

Keywords

syllabification, stress assignment, Italian,

1. Introduction

Word syllabification and syllable analysis are two related issues of great importance in the study of language (written or spoken). These topics have attracted a large category of researchers, from pure linguists, in phonetics, to psycholinguists, computer scientists, speech therapists, etc. Thus, the syllable plays an important role in language learning and acquisition, speech recognition, speech production [1, 2], language similarity [3], in text comprehensibility (Kincaid-Flesch formula [4]), in speech therapy, in poetry analysis [5, 6], etc. Each language has its own way of grouping sounds into syllables and its own rules for dividing words into syllables. Linguistically, the syllable represents "the smallest phonetic trance likely to receive an accent and only one" [7], and the syllabic cut is seen by De Saussure [8] on the border between the implosion and the explosion of the spoken sound: "If in a chain of sounds one goes from implosion to explosion, one obtains a particular effect which is the indication of the boundary of the syllable".

The analysis of the words' syllabic structure also plays an important part in historical linguistics [9], not only in diachronic phonetics and phonology, but also in lexicology. Romance comparative linguistics, in particular, still needs a detailed overview of this aspect, as syllable, segmentation and prosody can give strong account on phonetic changes that haven't been explained yet. The "prosodic revolution" [10] from Latin to the Romance languages – including syncope (the loss of an intermediate syllable) and apocope (the loss of the final syllable) at a large scale – has led to major changes, but their weight is different from one idiom to another: while the Western Romance languages manifest highly evident differences from the Latin phonological and prosodic system, and the Eastern languages are considered to be most conservative from this point of view, Italian seems to be in between [10]. On the other hand, in Latin, the relation between stress and quantity grew stronger, thus short stressed vowels progressively gained length. It is noteworthy that this situation is best preserved in Italian, and not in the Eastern Romance idioms: thus, in Italian stress cannot skip a heavy penultimate syllable, and stress cannot fall further back than the antepenultimate syllable, a twofold characteristic feature of the Latin prosodic system. This is why we are taking Italian as a starting point for a larger-scale study, oriented towards all Romance languages. The main difference between Latin and its modern descendants is that Latin stress was quantity- sensitive, leading thus to the following rule: in polysyllabic words, stress fell on a heavy penultimate (meaning, containing a long vowel), otherwise on the antepenultimate. Due to the collapse of vowel quantity as a distinctive feature in the vocalic system, no Romance language has retained the Latin stress rule as such [10]. As, from a statistic point of view, the greatest part of the Romance lexicon is represented by penultimate stressed words, a basic automatic mechanism would assign penultimate stress by default, whereas for both final and antepenultimate stress, the machine (as well as, not in a few cases, non-native speakers) would need further specification. As a consequence of the loss of Latin vowel quantity, Romance stress has ceased to be completely predictable. That is, partially, why in the majority of the traditional Romance compara-

tive or historical grammars, there is no specific section devoted to syllabification [11], or, if there is, it focuses either on general prosodic features [12], or on the vowel evolution depending on its presence in an open or closed syllable [13]. The lack of a section dedicated to syllabification is also common in the historical grammars of Italian [14, 11, 15]. We will focus in this research only on written form of words, so we will investigate only the graphical syllabification and stress. By focusing on the graphical syllabification and stress in Italian, we aim to take a step forward towards the complete evaluation of the prosodic changes that took place in the transition from Latin to the Romance languages, and their influence on the Romance phonetics and phonology. A machine-learning model, capable of automatically inferring graphical syllabification and stress assignment, along with the purpose of creating a data-base containing the quantitative and qualitative description of syllabification and stress in the Romance languages, could be the first important task in the greater challenge of tracing the similarities and differences between the Romance languages and, more important, between Romance and Latin. From a typological point of view, the study of syllabification and stress can shed a new light on the universal features that, by defining our phonoarticulatory and phonoacoustic apparatus, have guided the languages' development and change. Given the promising results of this analysis, the present study can establish the basis of a research of the syllable in other languages, either linguistically or typologically related to Italian.

One of the studies that address automatic syllabification in Italian belongs to Bigi and Petrone [16], who proposed a tool that performs rule-based automatic segmentation. Adsett and Marchand [17] and Adsett et al. [18] investigated whether data-driven approaches outperform rule-based approaches for a language with a low syllabic complexity, such as Italian. The authors reached the conclusion that even in this case data-driven systems are the more appropriate approach. In terms of machine learning, the tasks of automatically inferring syllable boundaries and predicting stress assignment can be naturally framed as sequence labeling problems. While automatic syllabification has received more attention recently [19, 20, 21, 22, 23, 24], stress placement has not been investigated as much [25].

Given the complexity of syllable applications and word syllabification, the presence of electronic resources dedicated to them becomes a necessity. While native speakers of a language generally do not have great difficulty in spelling words, the same cannot be said of those who learn a foreign language who often tend to apply their own rules to foreign words, and problems arise in automatic syllabification. This is because the rules of syllabification are linguistic rules, and they cannot always be easily modeled by the computer when there are no other linguistic factors that those rules take into account. For example, a rule that is present in many languages distinguishes between a vowel and a semivowel, but the computer is not able to easily recognize when the same sign has the value of a vowel and when it is a semivowel. Because of this, rule-based adaptations of syllabification systems [26] generally have higher errors, and many languages do not have an automatic syllabification system yet (for example, in the Python library, only a few languages have syllabification). The last few decades have brought the first data-driven syllabification systems.

However, in order to build such a system, training data is needed, and there are many cases in which the available data do not cover the whole language, and thus the systems have different results when the test corpus is changed.

Starting with these remarks, our main contributions are:

- We propose ItGraSyll (Italian graphical syllables), a dataset of $114,503$ Italian words, in orthographic form, containing annotations for their orthographic syllabification and stress placement[1]
- We perform quantitative and qualitative analyses of the previously built dataset.
- We analyze stress placement in the context of the Italian syllables.
- We propose an automatic system of syllabification for Italian words.

2. Quantitative Analysis

In this section we perform various measurements regarding the syllables and stress placement of Italian written words and analyze the results. We perform, on Italian, an investigation similar to a previous investigations conducted on Romanian by Dinu and Dinu [27], Dinu and Dinu [28].

2.1. Data

We build a dataset of Italian words starting from the online version of *Dizionario italiano De Mauro*,[2] which provides information regarding graphical syllabification and stress placement for the Italian vocabulary. Stressed syllables are also shown by having accents on the dominant vowel. Going further, this dataset will be referred to as ItGraSyll.

We performed several pre-processing steps. We cleaned the resulted dataset by removing duplicates, prefixes and suffixes in order to remain with the base word;

[1] The dataset is available for research purposes upon request at: https://nlp.unibuc.ro/resources.html#itgrasyll

[2] https://dizionario.internazionale.it/

abbreviations and unwanted punctuation marks such as dots, commas, apostrophes and dashes were also excluded so we can correctly process each word and its syllable division. Finally, the dataset consists of $114,503$ words in orthographic form having between one and eleven syllables. The distribution of words per number of syllables is represented in Table 1.

#syll.	#words	Examples

Table 2
Top 20 most frequent syllables.

2.2. Syllables

We identified $\#Type_{syl} = 3730$ (type syllables) in Italian. The total number of syllables (token syllables) is $\#Token_{syl} = 483,931$. So, the average length of a word measured in syllables is $Words_{av-syl}$ = 483,931/114,503 = 4.226. The 114,503 words are formed of $\#Letters$ = 1,133,515 letters (graphemes). So, the average length of a word measured in letters is $Word_{av-let}$ = 1,133,515/114,503 = 9.899.

In order to characterize the average length of a syllable measured in letters, we investigated two cases: a) the average length of the token syllables measured in letters is: $LSyl_{token}$ = 1,133,515/483,931 = 2.342 b) the type syllables are formed of $\#TypeSyl_{let}$ = 13,576 letters. Thus, the average length of a type syllable measured in letters is $LSyl_{type}$ = 13,576/3,730 = 3.639.

These statistics are computed for the words extracted from the dictionary, which were considered to be equally weighted. This excludes any information relating to the frequency of the words with respect to writing or speech. For future research, large corpora of Italian texts can be leveraged in order to recompute these values and include frequency-based weights.

A list of the most frequent 20 syllables is included in Table 2.

2.3. Syllable Structure

We identified a total of 67 different consonant-vowel structures. The most frequent 7 structures cover almost 97% of the total. Depending on the type-token ratio, the most frequent consonant-vowel structures are the following: a) for the type syllables: cvc (25%), ccvc (20.9%), cvvc (7.79%). b) for the token syllables: cv (58%), cvc (15%), ccv (7%), cvv (4.74%) and v (4.32%). Moreover, we observe that the cv structure corresponds to 40 out of the most frequent 50 syllables from the dataset.

2.4. Stress Placement

We identified a total of 2,883 stressed syllables (type syllables). So, 847 syllables are never stressed. The most frequent 20 stressed syllables are represented in Table 3. We observe that the most frequent stressed syllable (*men*) has a very high stress ratio (90%) when we compare the stressed occurrences with all its occurrences (stressed and unstressed) in our database. While in the top 20 of all syllables, *men* is the only syllable of length 3 (on the 14th position), for stressed syllables there are a couple of other syllables with a length greater than 2 (*zio* on position 6 with 34% stress ratio, *gia* on position 19 with 65% stress ratio).

We investigate stress placement with regard to syllable structure and we provide in Table 4 the percentages of words having the stress placed on different positions (for top 5), counting syllables from the beginning and from the end of the words as well. We observe that in most cases the stress is placed on the second to last syllable.

Index	Syllable	Frequency	Stress ratio (%)
1	men	7120	90
2	ta	5809	45
3	na	3348	40
4	to	3254	15

Syllable	%words
1st	3,330
2nd	94,225
3rd	16,113
4th	14
5th	1

(b) counting syllables from the end of the word

Table 4
Stress placement for Italian.

2.5. Syllables' Usage

The syllables have a less intuitive behaviour, usually a small number of syllables cover a large part from a language. This is valuable for a large category of natural languages, including English, Dutch, Romanian [28], Korean, Chinese, etc. We investigate here if this empirical law is also applicable to Italian. We made this investigation both on stressed and general syllables.

2.5.1. General Syllables

The most frequent 30 Italian syllables (when stress placement is disregarded) cover almost 50% of $\#Token_{syl}$, the most frequent 50 syllables cover 61%, the most frequent 100 cover 74% and the most frequent 150 syllables (i.e. 4% of $\#Type_{syl}$) cover 80% of $\#Token_{syl}$. Over this number, the percentage of coverage rises slowly. 2,281 (61%) syllables of type syllables occur less then 10 times, and 1,174 syllables occur only once (*hapax legomena*).

2.5.2. Stressed Syllables

A similar trend can be observed also for the stressed syllables. Further, we notice that the most frequent syllables cover a wide ratio of the total syllable frequency. For example, the 10 most frequent stressed syllable represent 31% of the total of stressed syllables, the top 50 syllables, 60% and the top 200 syllables, 81% of the token syllables. The values are plotted in Figure 1, for all syllables and for stressed syllables.

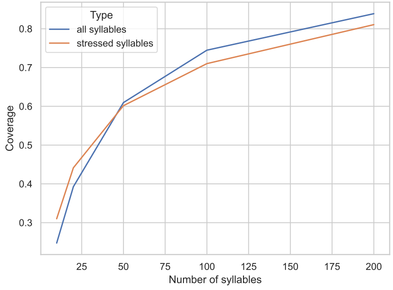

Figure 1: The coverage of most frequent syllables.

This results proves that the law is true for Italian too, a very small number of syllables cover a large part from Italian language (there are necessary only 150 syllables to cover 80% from language).

3. Minimum Effort Laws

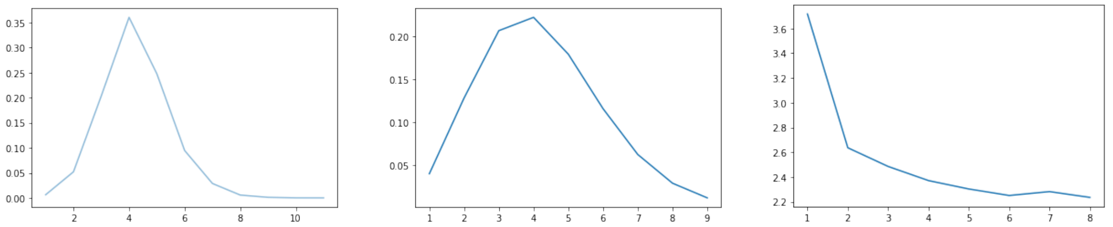
In this section we discuss two minimum effort laws that have been previously investigated for other languages and verify whether they apply for Italian as well.

3.1. Chebanow

Denoting by $F(n)$ the frequency of a word having n syllables and by $i = \sum nF(n)/\sum F(n)$ the average length (measured in syllables) of the words, Chebanow [29] proposed the following law between the average i and the probability of occurrences $P(n)$ of the words having n syllables:

$$P(n) = \frac{(i-1)^{n-1}}{(n-1)!} * e^{1-i} \qquad (1)$$

For Italian, $i = 4.226$.



(a) The probability distribution of the length of words.

(b) Theoretical representation of the probability distribution of the length of words.

(c) Menzerath's Law: The more syllables in a word, the smaller its syllables.

Figure 2: Minimum effort laws.

Model	Hyphen Acc.	Hyphen F1	Word Acc.
GRU for syllabification w/o stress markers	99.74%	99.69%	97.61%
GRU for syllabification w/ stress markers	99.82%	99.79%	98.41%
GRU for stress prediction	—	—	94.45%

Table 5
Performance metrics computed for the automatic syllabification and stress prediction on the test set. We computed accuracy and F1 scores on the sequence labelling predictions for syllabification, in order to assess how well the model predicts the positions where the syllables split. Word level metrics were computed for both syllabification and stress prediction; this kind of metrics are more strict since any misplaced hyphen in the syllabification makes the entire prediction wrong.

In Figures 2a and 2b we plot the probability distribution of the length of words (in syllables) – the practical and theoretical representations.

We observe that the two curves have comparable shapes, with a more prominent peak for the probability distribution in Figure 2a; this peak can be influenced by the fact that it is determined based on all the words in the dictionary, where many 4-syllable words are present.

3.2. Menzerath

Menzerath's law – later generalized by the Menzerath-Altmann law [30] – states that the bigger the number of syllables in a word, the lesser the number of phonemes composing these syllables. In other words, Menzerath's law expresses a negative correlation between the length of a word in syllables and the lengths in phonemes of its constitutive syllables. In cognitive economy terms, this means that the more complex a linguistic construct, the smaller its constituents. The law is expressed as follows:

$$y = \alpha x^{\beta} e^{-\gamma x} \tag{2}$$

where y is the syllable length (the size of the constituent), x is the number of syllables per word (the size of the linguistic construct), and α, β, γ are empirical parameters. Figure 2c shows that the law is satisfied for Italian.

4. Automatic Syllabification and Stress Assignment

We further investigate how a deep-learning model can automatically infer the syllabification and stress assignment of Italian words, given their orthographic representation.

4.1. Methodology

Both tasks can be defined in terms of a sequence labelling problem, strategy which was previously successful used for Romanian[31, 32]. Let us consider, for example, the word *medaglione* (the Italian translation of the word "locket"). For syllabification we can label each letter from the word either with the label 1, denoting that a syllable starts from that letter, or with the label 0, meaning the respective letter is not the first letter in its syllable. Similarly, for identifying the stressed vowel, we can label its position with a 1 and all other letters are assigned the label 0. We thus obtain for our example the sequence 1010100010 for syllabification and the sequence 0000000100 for stress prediction (i.e. *me-da-gliò-ne*, the *o* vowel is stressed).

With these definitions, we can now construct machine learning models for labelling the character sequences. The model we propose is a recurrent neural network based on Gated Recurrent Units (GRU) [33]. The model architecture is comprised from the following components:

- a character embedding layer, producing 64-dimensional vectors for each unique character
- a stacked bidirectional GRU, with 3 layers and a 128-dimensional hidden state; a 0.2-rate dropout applied after each of the first two layers
- 0.5-rate dropout, after the last GRU layer, along with one-dimensional batch normalization
- a time-distributed fully-connected layer with 256 output nodes and ReLU activation
- a linear layer that projects the 256-dimensional vector into a single number, on which sigmoid activation is applied to infer the binary labels.

For training the models for both tasks, the dataset of words is split into 50% training examples and 50% test examples, unseen during training.

The loss function computed for the prediction made for a word, regardless of the task on which the model is trained, is the average of two terms: the first one is the average character-wise binary cross-entropy, while the second one is the root mean squared error computed between the vector of predicted labels and the ground-truth vector. The model is optimized using the Adam optimizer [34], with a learning rate of 0.0003, no weight decay, bath size of 32, and a LR scheduler that halves it every 5 epochs. The models are trained for 10-15 epochs.

For the task of automatic syllabification, we wanted to check if the presence of the stress markers affects the performance of the model. Because of that, we trained two models: the first one was trained using the spelling of the words with the stress markers removed, while the second one was trained with them included.

Stress Assignment Errors	
True	**Predicted**
bàlano	balanò
fèmore	femòre
dòlmen	dolmèn
tùtolo	tutòlo
pudìco	pùdico
corsìa	còrsia
Syllabification Errors	
True	**Predicted**
mu-o-ne	muo-ne
bion-da	bi-on-da
cli-en-te	clien-te
co-di-a-to	co-dia-to
ma-nu-brio	ma-nu-bri-o
spa-tria-to	spa-tri-a-to

Table 6
Examples of erroneous test predictions provided by the deep-learning models.

4.2. Results Anaysis

Table 5 contains the metrics computed on the test set, using the models trained for syllabification (both with and without stress markers) and the model trained for predicting the stressed vowel. We obtained a remarkable hyphen accuracy of 99.74% for syllabification without the stress markers, and, when we add the stress markers, we obtained an increasing accuracy, obtaining 99.82%. Including the stress markers into the data used for syllabification improved the metrics across the board, most notably with a $\sim$ 1% increase in word-level accuracy, which considering the large amount of data, and the high accuracy scores is a significant improvement (460 fewer syllabification mistakes as opposed to the approach that excludes stress markers). Regarding the stress prediction, we obtained an accuracy of 94.45%. Table 6 showcases a series of wrong predictions generated by the models on the tests sets for stress assignment and syllabification.

We also look into the accuracy scores computed for the test set, when it is bucketed based on the real number of syllables of the test words. These results are shown in Figure 3 and Table 7. For stress assignment, accuracy decreases to a global minimum for disyllabic words, then starts to increase again with the number of syllables. For the syllabification task, including the stress markers seems to outperform excluding them in most scenarios, while both accuracies achieve a peak around the 5 syllables mark. This result seems to align with the distribution of syllables in the dataset, i.e. obtaining higher scores for the number of syllables with more examples. For stress assignment errors, we also investigate the placement of the predicted stressed syllable in relation with the true one (see Table 8). 95.6% of the errors misplaced the stressed syllable at most one position to the left, or to the right, while almost two thirds of the erroneous predictions placed the stress on the first syllable to the right of the correct one.

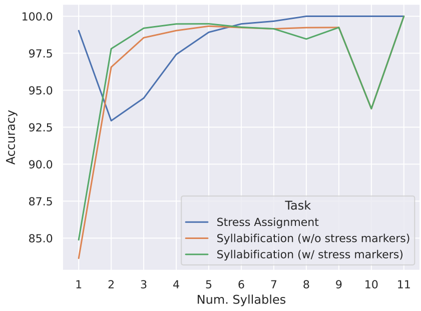


Figure 3: The test accuracies for each of the three tasks, computed independently on the test words, bucketed by their true number of syllables.

Num. Syllables	Num. Words	Stress Assignment	Syllabification (w/o SM)	Syllabification (w/ SM)
1	721	99.03%	83.63%	84.88%
2	5,960	92.94%	96.56%	97.80%
3	23,286	94.46%	98.55%	99.19%
4	41,253	97.42%	99.03%	99.48%
5	28,357	98.92%	99.33%	99.49%
6	10,829	99.48%	99.23%	99.26%
7	3,294	99.67%	99.15%	99.15%
8	650	100.0%	99.23%	98.46%
9	132	100.0%	99.24%	99.24%
10	16	100.0%	93.75%	93.75%
11	5	100.0%	100.0%	100.0%

Table 7
Similar to Figure 3 this table contains the actual values of the test accuracies for the three tasks: stress assignment, and syllabification with/without stress markers (SM) included. These scores are computed separately for words with the same number of syllables.

Stressed Syllable Delta	Num. Errors	Pct. Errors
-2	21	0.74%
-1	804	28.38%
0	95	3.35%
1	**1,809**	**63.85%**
2	102	3.60%
3	2	0.07%

Table 8
Starting from the incorrect predictions for stress assignment, we compute how far the assigned stress is from the actual one, in numbers of syllables (delta). A delta of -2 means that the predicted stressed syllable is the second one to the left of the correct stressed syllable. A delta of 0 in this situation means that the algorithm predicted the stressed vowel incorrectly, but the prediction sits inside the correct stressed syllable.

5. Conclusions

In this paper we have investigated graphical syllabification and graphical stress assignment for Italian words. We have started by building ItGraSyll, a dataset of Italian graphical syllabified words, with stress annotations as well, on which we have performed several quantitative and qualitative analyses, including the verification of two minimum effort laws for the case of Italian. Finally, we have proposed a recurrent neural network machine learning model for automatic syllabification and stress assignment for Italian written words. For stress prediction we have obtained 94.45% word-level accuracy, and for syllabification we have obtained 98.41% word-level accuracy and 99.82% hyphen-level accuracy. In future work we intend to extend the analysis from dictionary level to corpus level and to investigate other languages as well.

Abstract

English grammar Multiple-Choice Cloze (MCC) exercises are crucial for improving learners' grammatical proficiency and comprehension skills. However, creating these exercises is labour-intensive and requires expert knowledge. Effective MCC exercises must be contextually relevant and engaging, incorporating distractors—plausible but incorrect alternatives—to balance difficulty and maintain learner motivation. Despite the increasing interest in utilizing large language models (LLMs) in education, their application in generating English grammar MCC exercises is still limited. Previous methods typically impose constraints on LLMs, producing grammatically correct yet uncreative results. This paper explores the potential of LLMs to independently generate diverse and contextually relevant MCC exercises without predefined limitations. We hypothesize that LLMs can craft self-contained sentences that foster learner's communicative competence. Our analysis of existing MCC exercise datasets revealed issues of diversity, completeness, and correctness. Furthermore, we address the lack of a standardized automatic metric for evaluating the quality of generated exercises. Our contributions include developing an LLM-based solution for generating MCC exercises, curating a comprehensive dataset spanning 19 grammar topics, and proposing an automatic metric validated against human expert evaluations. This work aims to advance the automatic generation of English grammar MCC exercises, enhancing both their quality and creativity.

Keywords

Large Language Models, Distractor Generation, Multiple-Choice Cloze, Evaluation Metric

1. Introduction

English grammar Multiple-Choice Cloze (MCC) exercises are widely used tools for enhancing a learner's grammatical proficiency and comprehension skills. They consist of fill-the-gap questions where the gap must be filled by choosing one correct solution (*key*) among several options. The incorrect alternatives are called *distractors*. Devising these exercises is a labour-intensive process requiring expert knowledge in language teaching and content creation. The exercises must be contextually relevant to help learners understand how rules apply in real-life situations. This requires crafting sentences and scenarios that are both engaging and educational. Learners have different levels of proficiency, from beginners to advanced. Striking the right balance ensures that learners are neither bored nor frustrated, which is crucial for maintaining their motivation and progress. In MCC exercises this is done by choosing distractors that are incorrect but plausible, thus keeping the exercise challenging for the learner. Studies in Communicative Language Teaching demonstrate that the learner must possess the knowledge of grammatical structures and the ability to compose syntactically well-formed propositions, and they must also acquire the ability to employ grammatical forms in discourse [1][2].

Recently, there has been a growing interest in applying LLMs in education [3]. However, the adoption of LLMs for English grammar MCC exercise generation is still limited. Some proposals focus on testing vocabulary [4] or use LLMs by constraining their generation capability, for example using fixed part-of-speech sequences [5]. Although the outputs of these models are grammatically correct typically they lack creativity [6].

In this work, we investigate the potential of LLMs in automatic exercise generation without hampering their creativity. Our working hypothesis is that LLMs can generate self-contained sentences, recreating situational contexts that elicit the *communicative competence* of the learner [7]. Our main objective is to understand to what extent can LLMs generate accurate grammar exercises without providing predefined constraints or POS sequences. To pursue this objective, we analyzed the available English grammar MCC exercises dataset [8]. We observed that it has limited diversity, some topics are underrepresented, and there are often mistakes. Existing literature does not offer a single agreed-upon automatic metric for evaluating the quality of the generated gram-

mar exercises. Therefore, we set out to identify such a metric and validate its alignment with human judgment. In this paper, we present a novel solution utilizing an LLM to generate English grammar MCC exercises. Our contribution also focuses on curating an MCC dataset that spans 19 topics. Lastly, we propose an automatic metric to evaluate the exercise's correctness and verify the validity of our contribution thanks to human expert evaluation.

2. Task description

Grammar exercises should define the range of abilities to be assessed and avoid the influence of irrelevant factors like past knowledge or cultural background [9]. We followed the Best-practice guidelines for creating grammar MCC items defined in [10] [11]. According to them, each item consists of three components.

- **Body**: the sentence with a gap in place of the key.
- **Key**: the correct answer.
- **Distractor**: the incorrect answer.

The body plays a central role in designing effective exercises. Learners should be able to infer the key based on the helpful elements present in the body. However, the effectiveness of an exercise depends mainly on the quality of its distractors. Ideally, challenging distractors should be homogeneous, plausible, and unambiguous. Homogeneous distractors share the same syntactic category as the key [12]. Plausible distractors provide a credible alternative to the key. Lastly, unambiguous distractors ensure that none of them could be considered correct if used in place of the key [10].

3. Related Works

The generation of MCC exercises has been explored from various perspectives. In this section, we will briefly discuss the main related approaches.

3.1. MCC Dataset

Prior works in creating MCC datasets are very limited. To the best of our knowledge, the only one in English was presented by Liu et al. in their work SC-Ques [8]. It comprises real English test items for students developed by teaching professionals. The dataset contains roughly 300k MCC sentence completion exercises, composed of the question body, a varying number of alternative answers, and the key (i.e. the correct alternative). It comprises both exercises with only single or multiple blanks. It has various limitations, discussed in Section 5.

3.2. Grammar MCC Exercise Generation

A large share of prior works uses rules to create Grammar MCC Exercises (Sumita et al. [13], Brown et al. [14], Smith et al. [15], Majumder and Saha [16], Lin et al. [17]). They all follow a three-fold process: (1) select sentences from arbitrary sources, (2) insert the blank into the sentence, and (3) generate distractors for the blank. Sentences usually come from corpora or user-submitted passages. Many solutions restrict gap detection into fixed schemes: Sumita et al. [13] picked out the leftmost single verb, Lin et al. [17] only selected adjectives as a blank. One of the few exceptions is Goto et al. [18], who proposed a method based on Conditional Random Fields (CRFs) [19]. Methods that extract sentences from arbitrary text suffer from several limitations. First of all, they lack customization options, such as adjusting for the subject or difficulty level of the exercise. Additionally, they are limited by the length and quality of the extracted texts, which can negatively impact the system's results.

Recently, parts of MCC generation have been executed by Neural Networks instead of rule-based algorithms. Bitew et al. [20] use a variation of the RoBERTa [21] model to predict the gap positions within the sentence. To decrease the ambiguity Matsumori et al. [22] trained a Masked Language Model for gap score prediction of each candidate sentence. Chomphooyod et al. [23] proposed a system that uses Transformers [24] to generate candidate sentences given a POS sequence, a keyword and a desired grammar topic.

3.3. Metrics

In the literature, the evaluation of MCC exercises is mainly based on judgments expressed by human annotators. Slavuj et al.[25] asked annotators to perform the language tasks, assuming that the presence of incorrect answers would be a sign of ill-formed exercises. Teachers were then asked to provide feedback on any pitfalls they encountered. Malafeev [26] simply attended to suitability for classroom use. Chomphooyod et al. [23] evaluates for each exercise different aspects such as the grammatical and semantic correctness, the relevance with respect to the topic, and its acceptability.

Very few automatic metrics have been proposed to evaluate exercise generation. Bitew et al. [20] rely on span overlap with respect to ground truth to assess the consistency of gap detection. March et al. [27] test the effectiveness of distractors by their selection rate.

Since an important criterion for exercise collection is diversity, often similarity measures have been applied to MCC exercise. Metrics like BLUE [28], ROUGE [29], and METEOR [30] have been used even though originally designed for different applications.

4. Approach

To overcome the limitations of existing solutions, we utilized an LLM to generate exercises in a single, constraint-free step. We chose Llama3 [31] due to its acceptable balance between computational cost and performance. To evaluate its effectiveness, we engineered a well-structured prompt (Appendix B.2). However, the results were unsatisfactory. The model exhibited significant difficulties with certain grammar topics and consistently failed to generate effective distractors. Therefore we decided to fine-tune the model using a well-formatted dataset containing exercises with distractors that meet our criteria. Each dataset example includes four features: the grammar topic, the exercise text, the key, and the distractors. The model is trained to produce the exercise text, key, and distractors when given a specific grammar topic as input. The prompt used during the fine-tuning and an example of input-output text can be found in the appendix section B.1.

To assess the correctness of the generated items, we devised metrics that evaluate the minimal structural requirements of an exercise thanks to rule-based analysis. These are defined in section 7. To monitor the results we used SELF-BLEU [6], a metric that inspects repetitions checking continuous lexical overlap.

5. Dataset Curation

We developed the fine-tuning dataset based on the data released by [8]. The data underwent three pre-processing steps: cleaning, grammar topic identification, and removal of similar examples.

Data cleaning First, we got rid of improperly formatted examples and cleaned the text to comply with the tokenizer specifications and limit potential noise. Items with multiple blank spaces or fewer than two distractors were discarded. Next, we filtered out exercise texts containing instructions, non-Latin symbols or letters, emails, phone numbers, and links.

Extraction of the grammar topic The second step involves the assignment of the grammar topic to each exercise thanks to the Pattern Matcher. First, grammar topics are defined in a tailor-made grammar taxonomy with the aid of spaCy Dependency Matcher. Given a set of sentences, this tool allows one to identify whether each sentence features the described grammar topics, and if so, at what position. The relevant topic is chosen by comparing the overlap between the position of the topic detected by Pattern Matcher and the key span[1]. To ensure the exclusively grammatical nature of the exercises, distractors are checked using the metrics proposed in Section 3.3. All exercises lacking valid distractors are then discarded.

Deduplication We deduplicated and removed all the similar exercises, to increase the quality of our dataset [32]. Exercises are clustered by topic and compared in terms of embeddings through cosine similarity. Using a threshold T_p, where p denotes the topic, all elements exceeding the limit are discarded. Lastly, we noticed that SC-Ques [8] had an unbalanced representation of grammar topics. For example, in half of the WH-questions have "How" as the key. For each topic, a maximum ratio of key presence is established, and superfluous data are discarded.

After pre-processing, the least represented class contained a quarter of the examples present in the most represented one. The only exception was the "WH-questions" class, which was underrepresented. Therefore, we upsampled the class with synthetic exercises using GPT-4 [33]. The dataset is composed by several fields: the filled_text (complete exercise sentence), the gapped_text (sentence with a blank gap), the key (the text removed to create the gap), and the list of distractors.

6. Fine-Tuning

We designed the fine-tuning process to generate exercises on specific grammar topics with a fixed number of distractors. The model's expected response is a JSON-encoded exercise coherent to the dataset structure described in Section 5. We observed that including the filled_text in the output improves overall accuracy and reduces similarity among exercises. An example from the fine-tuning dataset can be found in the appendix section B.1. To reduce the computational resources required for fine-tuning, we employed the Quantized Low-Rank Adapters (QLoRA) [34] approach. Our tests on small models revealed that this strategy prevents significant shrinkage of the model's dictionary during fine-tuning. Consequently, the generated exercises exhibit greater variability, enhancing the model's creativity.

7. Evaluation Metrics

Two metrics are used to track the model's performance on diverse aspects. First, we introduce a metric that evaluates the minimal structural requirements of an exercise. Secondly, we control for language diversity to have more interpretability on the results.

[1] The key span is the range of positions the key belongs to.

7.1. Structural Compliance

This metric evaluates the structure and well-formedness of the exercise. Decomposing the validation stage into two steps, we design two rule-based components, namely *pertinence* and *homogeneity*.

The former oversees that the gap placeholder is located in the intended position and that the key includes the correct grammar form. The second component checks that the distractor fulfils the criterion of homogeneity as described in the section 2. To achieve this, grammar topics have been grouped into two classes.

Inflectional They must have the same lemma as the key so as to rule out the influence of lexis and semantics. We also make adjustments to account for circumstances when the key and the distractor are identical, as well as for handling variation of the auxiliary verb.

Free morphemes Exercises of this group limit acceptable keys and distractors to a narrow range of options. So, we manually compile a list of admitted words for each grammar topic. If the distractor belongs to that list and is not identical to the key, it is deemed homogeneous.

Some grammar topics may be built with distractors of any of the two classes. If either of the checks is successful, the distractor passes the test of fitness.

7.2. Language Diversity

LLMs often experience the so-called repetition problem, where their output includes excessively repeated segments of text, creating an undesirable effect [35]. In the context of the generation of thousands of exercises, duplicates or overly similar sentences are highly likely to occur. In order to assess this phenomenon we decided to rely on continuous lexical overlap by using Self-BLEU [6] onto 2-to-5-grams to capture multi-word repetitions.

8. Experiments

We fine-tuned the Huggingface implementation of Meta-Llama-3-8B-Instruct[2]. The model was first quantized to 4-bit precision and then fine-tuned using LoRA adapters, with the following configuration: rank equal to 64, alpha 16, and a dropout percentage of 0.1. The adapters have been added on top of all the attention linear layers to not significantly degrade performance. The training hyperparameters are: a constant learning rate of 2e−4, max gradient norm of 0.3, and a weight decay equal to 1e−2. The number of epochs was set to 3, using a batch size of 1 and gradient accumulation equal to 16. The train lasted two hours on a NVIDIA RTX A6000.

9. Results

To evaluate performances, for each grammar topic we generated 50 exercises, setting the number of distractors to 1. We use the sampling decoding strategy with a temperature equal to 0.7 to balance the creativity and the coherence of the output.

The exercises are categorized according to their grammar topic. For each exercise, we assessed its structural compliance and its similarity to the exercises within the same grammar topic that has been labelled structurally correct, using the metrics described in section 3.3. The results are then averaged to obtain the accuracy for each grammar topic. In the end, the model performances are computed by averaging the topic scores. The results are reported in Table 1.

Overall, the outcomes are satisfactory. The model on average scores a Structural Compliance (SC_H) equal to 85%, indicating its ability to generate well formed exercises. It achieves a self-BLEU similarity of 7%, demonstrating that text repetitions are limited. Looking at the individual SC scores, we observe that the model tends to perform better on free morphemes grammar topics. We suppose this is due to the limited number of possible key/distractor options. Furthermore, we observed that due to spaCy limitations in properly labelling certain verbs, grammar topics related to verbal tenses are more prone to be misidentified. This limitation causes occasional misjudgment of the exercise's structural compliance, leading to a negative effect on the topic performance.

9.1. Human Evaluation

To assess classroom suitability a human evaluation was performed on all 950 exercises by a computational linguist with a background in pedagogy in language teaching. Each generated exercise (**EC**) was evaluated on four criteria:*Plausibility*, *Ambiguity* (defined in section 2), *Common Sense*, *Acceptability*. Common Sense means that the exercise sentence should be coherent with common sense. Acceptability indicates that a sentence does not perpetuate stereotypes or display inappropriate content, such as violence. If any of these criteria is not met, the item is flagged as incorrect.

The results presented in table 1 have established that 79% of the items satisfy all the requirements to be administered to learners. We conducted an error analysis. The results are summarized in Table 2. *Common sense* was the most frequently observed inaccuracy, although the magnitude of the issue is modest. As expected, ambiguous

Results of the evaluation on the generated exercises. $\mathbf{SC}_A$ is the Structural Compliance evaluate by our metric, $\mathbf{SC}_H$ evaluated by the human annotator and **EC** is the exercise correctness. The double lines divide the results from the automatic metric (left) to those obtained by the human-eval (right). More results on error analysis can be found in table 2.

distractors remain an open matter in the field, especially for tense-based topics. Instead, we can notice that the generation of sentences with bias or trivial exercises is almost absent.

Furthermore, we asked the annotator to evaluate the structural compliance of the exercises ($\mathbf{SC}_H$). Then we computed the Precision, Recall and F1 scores using annotator judgements as golden labels. The results show that our automatic structural compliance metric ($\mathbf{SC}_A$) has an F1 score of 95% w.r.t the human evaluation, with a Precision of 98% and a Recall of 91%. This highlights its effectiveness in predicting the overall structural quality of the exercises.

10. Conclusion

We investigated the use of an LLM to generate English MCC grammar exercises. To that end, we curated a new English grammar MCC exercises dataset. We devised metrics for the automatic evaluation of such exercises. We evaluated our work using said metrics, and a human study involving domain experts. Our findings demonstrate the model's ability to generate exercises suitable for educational use. The generated exercises exhibit a low similarity score, indicating that our method can effectively produce original exercises: a significant advantage from prior art, mostly relying on rule-based methods. We observe that human evaluation correlates positively with the proposed structural compliance metric, corroborating our metric as an indicator of exercise structure correctness and alignment with human expert preferences. We found that a key factor of our method was the availability of high-quality fine-tuning data.

One limitation was the presence of many similar exercises in the SC-Dataset [8] we used to build our resource from. After removing similar exercises, only 30% of the original data was left. Another limitation is the sensitivity of the evaluation metric to the Pattern Matcher, concerning the evaluation of the key and the distractors, which caused some false negatives.

The curated dataset and model will be available to the community.[3].

Acknowledgments

We wish to thank *Zanichelli editore* for their support which enabled data up-sampling, human evaluation, and experimentation with their infrastructure. We also thank Eleonora Cupin for her valuable contribution to the human evaluation of the dataset.

A. Error analysis

Thanks to the human evaluation we conducted a small error analysis on the errors made by the model. By analyzing the exercises that the annotator marked as incorrect we found out that the major issue is the coherence of the exercise sentence. More precisely, 75% of the wrong exercises has a meaningless or absurd exercise sentence. This behaviour is directly related to the hallucinations suffered by LLMs[36]. The second prevailing error is the ambiguity between the key and the distractors. The model does not possess a deep understanding of what a distractor is. In fact some generated distractors are interchangeable with the key.

Despite these limitations, the model is very effective in producing exercises that are not trivial (plausibility error rate at 1%) and negligibly affected by bias and stereotypes.

grammar topic	**CS**	**Acc**	**Amb**	**P**
articles	1.00	-	-	-
comparison adjectives	0.64	0.36	-	-

B. Prompts

In this section, the prompts used in our work are presented. utilize the Llama3 chat template format, but to make the text more readable we use three placeholders: #SYSTEM, #USER and #ASSISTANT.

B.1. Fine-Tuning prompt

The prompt used to fine-tune the model has the same structure for all the grammar topics. The only varying parts are the name of the grammar topic and the number of distractors required. These parts are highlighted by the brackets and change depending on the dataset items. The prompt used is the following.

```
Write a multiple-choice gap exercise on {grammar_topic} with {n_distractors}
    distractors.
```

Listing 1: Fine-tuning prompt.

A training example is created by concatenating to the prompt the desired JSON representation of the exercise. We decided to use this format because it is easier to use at inference time. An example of training data is the following.

```
# USER
Write a multiple-choice gap exercise on comparisons with 3 distractors.
# ASSISTANT
{
 "filled_text": "Thanks to high technology, doctors can better assess
     patients' conditions.",
 "gapped_text": "Thanks to high technology, doctors can ___ assess patients'
     conditions.",
 "solution": "better",
 "distractors": ["best", "good", "well"]
```

Listing 2: Example from the Fine-Tuning dataset.

B.2. Baseline prompt

To test the performances of the baseline Llama3 we utilize its instruction-tuned version, Llama3-Instruct that can follow direction given by the user. This model is not able to answer correctly using the prompt described above. Therefore, we construct an alternative one in which all the useful information is given to the model. We include the structure of the exercise, the roles of each component with their constraints and the desired format of the output. The results are the following.

```
# SYSTEM
You are an english teacher creating multiple-choice-gap exercises.
# USER
Write one exercise on {grammar_topic}.
It must contains the:
 - sentence: the body exercise text that must contain the tag <GAP> instead
     of the solution
 - solution: the that correctly fill the gap
 - distractor: a word related to the solution, but different
The distractor must be such that if substituted to the solution, the sentence
     is wrong.
Do not generate any exaplanation.
The output must be a JSON object with the following structure:
{"sentence": str, "solution": str, "distractor": list[str]}
```

Listing 3: Prompt used to the generation of exercises with the base Llama3 model.

C. Ethical Considerations

This section outlines the ethical considerations of the system we developed.

Bias and Fairness The dataset used in this study is obtained from a publicly available source, ensuring that all data was collected with appropriate consent. To protect personal information, we removed all sensitive data such as phone numbers, email addresses and URLs. Since humans created this data, we assume that proper names or any reference to existing entities are invented. Moreover, those that contain preferences such as films, books, etc., we assume do not reflect real preferences of the users. We suppose that events or situations described in the exercises are not related to existing facts. Finally, since the data have been created by professional creators we assume that any possible bias or stereotype in the dataset is not intended and it is a coincidence.

Accuracy and Reliability The accuracy of the generated exercises is paramount. We employ both automated validation tools and human expert reviews to ensure the correctness and reliability of the content. Any inaccuracies identified are promptly rectified. We acknowledge the potential for bias in LLM-generated content. However, the human evaluation highlights a negligible presence in the generated outputs.

Transparency We strive for transparency by documenting the sources of our training data and explaining the model architecture. All the techniques used to manipulate the data and the steps done are described step by step highlighting all the important aspects.

Educational Impact We assess the impact of LLM-generated exercises on learning outcomes. We aim to enhance personalized learning while preventing over-reliance on automated systems. The content is designed to be inclusive and accessible to all students.

ReCLAIM Project: Exploring Italian Slurs Reappropriation with Large Language Models

Abstract

Recently, social networks have become the primary means of communication for many people, leading computational linguistics researchers to focus on the language used on these platforms. As online interactions grow, recognizing and preventing offensive messages targeting various groups has become urgent. However, finding a balance between detecting hate speech and preserving free expression while promoting inclusive language is challenging. Previous studies have highlighted the risks of automated analysis misinterpreting context, which can lead to the censorship of marginalized groups. Our study is the first to explore the reappropriative use of slurs in Italian by leveraging Large Language Models (LLMs) with a zero-shot approach. We revised annotations of an existing Italian homotransphobic dataset, developed new guidelines, and designed various prompts to address the LLMs task. Our findings illustrate the difficulty of this challenge and provide preliminary results on using LLMs for such a language specific task.

Warning: This paper contains examples of explicitly offensive content.
Our positionality: This paper is situated in Italy in 2024 and is authored by researchers specializing in Natural Language Processing (NLP). Beyond our academic work, we are sensitive to *anti-hate speech* issues. Our backgrounds fields are theoretical linguistics, computer science and NLP.

Keywords

Semantic requalification process, Homostransphobia detection, Slurs, Natural Language Processing, Large Language Models

1. Introduction

In recent years, social networks have become the primary means of communication for most people. With the daily growth of online interactions, it has become urgent to recognize and prevent the spread of offensive messages against different target groups based on gender, sex, sexual orientation, race, religion, language, or political orientation. Moreover, categorizing hate speech with clear-cut boundaries is overly simplistic, as it includes various forms of abusive language that imply disrespect and hostility. A recent challenge is finding a balance between detecting hate speech and preserving the free spread of ideas and opinions on the web, while promoting inclusive and fair language. Thiago et al. (2021) [1] highlighted how automated analysis can misinterpret context, risking the censorship of marginalized groups languages, such as those of the LGBT+ community. Another study by Pamungkas and colleagues (2020) [2, 3] emphasized the importance of considering context in Natural Language Processing (NLP) tasks to avoid misinterpretations of word meanings, noting that the same swear word can be used both abusively and non-abusively. An example of this phenomenon is the semantic reappropriation, a practice in which terms historically used as slurs against a specific target group lose their offensive intent in certain contexts, by expressing a sense of belonging and solidarity within the group members [4]. Although community visibility and the use of specific slang have been approached for years, to our knowledge only some hate speech studies specifically addressed slurs, and few focused on slurs semantic reappropriation [5]. Nowadays, recognizing this kind of semantic shift through NLP tools is crucial to avoid the risk of removing not abusive speech in online contents, which could paradoxically harm marginalized users [6, 7].

Our study is the first with the aim of investigating reappropriative use of slurs in Italian, highlighting the need to take a step ahead from the existing abusive language detection models. Having in mind the capability of LLMs in classification task, we leveraged a LLM with a zero-shot approach in order to recognize the presence of reappropriative uses in our dataset.

This study makes the following contributions:

- We partially revised the original annotation previously conducted on the HODI dataset (Homo-

CLiC-it 2024: Tenth Italian Conference on Computational Linguistics, Dec 04 — 06, 2024, Pisa, Italy

transphobic Dataset in Italian)[1] [8], by developing new annotation guidelines.
- We used a LLM specifically fine-tuned on Italian language by leveraging prompt engineering.
- From a linguistic point of view, we showed why certain features of the Italian language make this task particularly challenging.

This paper is structured as follows: in the Section 2 we review the most significant related work on hate speech detection and zero-shot approaches leveraging LLMs. In the Section 3 we describe our methodology for the dataset creation and the implementation of zero-shot tasks. In Sections 3 and 5 we respectively report results, analysis and main limitations of this work. Finally, in the last Section 6 we draw conclusions of the current research.

2. Related work

As presented above, hate speech is a challenging task, due to magnitude of the phenomenon and the difficulties of defining clear boundaries. Some recent developments in AI underlined the challenge of building corpora and models to automatically detect the abusive (or not abusive) nature of slurs in social media texts. Pamungkas' et al. (2020) [2] research focused on the use of swear words in English and aimed at differentiate between offensive and non-offensive occurrences of slurs. A Twitter English corpus, SWAD (Swear Words Abusiveness Dataset), was developed by manually annotating the abusive charge at the word level and models were trained to automatically predict abusiveness.

Over the last decade, most studies approached the hate speech detection in terms of binary classification [9]. For instance, Plaza et al. (2023) [10] examines this task by comparing the performances of an encoder-decoder model with several BERT-based models in both zero-shot learning and fine-tuning scenarios. The findings show that BERT-based models perform poorly in zero-shot learning, while the others, even without additional training, achieves results comparable to fine-tuned models.

Nowadays, research indicates that hate speech changes depending on the target groups [9]. Detecting homotransphobic hate speech (i.e. a specific abusive language addressed to LGBT+ community) has emerged as a critical research area, with various scholars proposing solutions in different languages such as English [11] and Italian [8, 12].

However, only few studies focused on the detection of slurs that have undergone a semantic reappropriation process. Zsisku and colleagues (2024) [5] approached the task by collecting the Reclaimed Hate Speech Dataset (RHSD), the first hate speech dataset dedicated at investigating the use of reclaimed slur terms, and by fine-tuning a baseline model which resulted in the Reclaimed Hate Speech (RHS) model.

As far as the Italian language is concerned, slurs recently became a significant topic from a linguistic and philosophical point of view, but there are not studies focusing on slurs reappropriation detection task. Philosophy of language studies highlighted that a key area of interest is slurs echoic uses, where target communities reappropriated derogatory terms to express pride, solidarity, or use them as tools for political and social activism [13, 4]. Nossem (2019) [14] observed a productive role in creating localized versions of *queer* by reappropriating and redefining existing local alternative terms, specifically *frocio* and *frocia*, *femminiellə*, and *ricchione*. At this point, it should be noted that Italian, differently from English language, lacks terms like *queer*, which bring with them such a long socio-cultural and historical background. The semantic requalification process of homotransphobic slurs is at its first steps and consists of a challenging task that has not yet been investigated in computational domains with LLMs.

3. Methodology

3.1. Dataset creation

To our knowledge, there are no available annotated datasets in the Italian language focusing on the phenomenon of slurs semantic reappropriation. To address the issue of limited data, in this preliminary research we utilized the HODI dataset [8], which contains 6000 Italian Twitter messages collected by using a set of 21 keywords (i.e., *gay, pride, lesbica, frocio*). The dataset is a collection of sentences directed against LGBT+ community who are target of homotransphobia. Our argument is that in such a corpus it is possible to find slurs used in both abusive and reappropriative contexts. With the aim of collecting messages suitable for our study, we filtered the HODI dataset by selecting tweets that contain at least one denigratory term, by adopting a two-fold strategy. To select the homotransphobic swear words, we used the HurtLex lexicon[2] [15], a multilingual lexicon containing an organized list of denigratory terms divided into 17 categories (i.e. negative stereotypes, ethnic slurs, moral and behavioral defects, words related to homosexuality). From HurtLex, we selected only the words categorized as homotransphobic, then we further narrowed the list to those that satisfy the slur definition[3] provided by Bianchi

[1] The HODI dataset was created for a shared task focused on identifying homotransphobia in Italian tweets.

[2] https://github.com/valeriobasile/hurtlex

[3] Bianchi (2014) [4] defines slurs "derogatory terms -such as 'nigger' and 'faggot'-targeting individuals and groups of individuals on the basis of race, nationality, religion, gender or sexual orientation. According to most scholars, slurs generally have a neutral counterpart,

Table 1
Examples of the target words in abusive context (Context 1) and semantic reappropriation context (Context 2)

Intention	Tweet	Translation
Abusive	Questo **frocio** con il tatuaggio del nome del moroso odio i gay.	This **fag** with the tattoo of his boyfriend's name I hate gays.
Not abusive	Io ero 6/7enne ed ero il **ricchione** alle elementari, all'oratorio, alle medie, al liceo e tutta la vita. E mi va bene così, c'è più colore in questo mondo 🌈 .	When I was 6/7 years old, I was the **gay** one in elementary school, at the youth center, in middle school, in high school, and all my life. And I'm okay with that, it adds more color to this world.

(2014,2015) [4, 16]. We chose to exclude words such as *gay, omosessuale, omofilo, pederasta*, and *diverso* because they are not strictly derogatory terms, hypothesizing that if words are not perceived as abusive, they cannot undergo a process of semantic reappropriation. After obtaining a list of 17 words, we filtered the HODI dataset by selecting only the tweets that contained at least one of the following target words: *anomalo, chiappa, frocio, invertito, travestiti, checca, deviato, culattone, finocchio, finocchi, finocchietto, sesso anale, frocia, ricchione, trans, troia, stesso sesso.* The resulting subset is a collection of 1742 tweets (see two examples in table 1).

3.2. Annotation guidelines

Establishing guidelines for such a subjective and previously unexplored topic has been challenging. Since the phenomenon lacks clear boundaries, we aimed to describe the task as clearly as possible. With this in mind, we based our guidelines on previous works in the field of the philosophy of language [4, 16, 13]. We asked three expert annotators to decide whether the target words in each tweet are used in a reappropriative context or not. Building on previously cited works, we defined reappropriation as the use of derogatory epithets by members of the target groups in a manner that is generally considered non-offensive. To better define the phenomenon we highlighted different contexts in which this linguistic behaviour could occur:

Friendly contexts – members of the target group use the derogatory terms in a non-offensive way in informal contexts.

- *Mamma mia raga come mi ha messa di buon umore il #LiguriaPride non mi sentivo così da un sacco grazie energia frocia* 😭 😭 ❤️ 🌈 🌈 🌈
[**English translation:** Mamma mia guys how the #LiguaPride has put me in such a good mood I haven't felt this way in a long time thanks FROCIA energy]

Political reappropriation contexts – target groups reclaim the use of derogatory epithets as a tool to emphasize a conscious and common political struggle.

- *Happy #PrideMonth e ricordatevi che l'orgoglio si celebra non solo quando andate a ballare nelle discoteche gay, ma anche quando si tratta di metterci la faccia e combattere per la causa perché altrimenti il ricchione lo state facendo solo col culo degli altri e non è carino* ❤️ 🌈
[**English translation:** Happy #PrideMonth and remember that pride is celebrated non only when you go dancing in gay discos, but also when it comes to put your face out there and to fight for the cause because otherwise you are just being RICCHIONE on other people's ass and it is not nice]

Artistic contexts – artists reclaim derogatory epithets to subvert the dominant socio-cultural norms.

- *Poca gente che li guarda, c'è una checca che fa il tifo Se #LucioDalla avesse scritto #AnnaEMarco nel 2022 sarebbe stato accusato di omofobia, lui. Invece ha scritto una canzone immensa*
[**English translation:** Few people look at them, there is a CHECCA cheering if #LucioDalla had written #AnnaEMarco in 2022 he would have been accused of homophobia. Instead he wrote a great song]

3.3. Zero-shot learning approach

After obtaining the described subset, we utilized zero-shot Learning (ZSL) with prompting to assess the model's ability to determine whether the target words are used in abusive or non-abusive context. Specifically, we employed the Qwen model [17], a multilingual decoded-only LLM pre-trained on Italian.

We define the temperature of the model to be 1, a fair trade-off between randomness and determinism in the results, and a maximum sequence length of 2024. For inference, an A100 GPU provided by Google Colab was

i.e. a non-derogatory correlate: 'Boche' and 'German', 'nigger' and 'African-American' or 'black', 'faggot' and 'homosexual'".

Table 2
Inter-annotator agreement metrics

Fleiss' Kappa	0.57
Annotators	**Cohen's kappa**
Annotator 1 vs Annotator 2	0.559
Annotator 1 vs Annotator 3	0.528
Annotator 2 vs Annotator 3	0.617

used. The code is available on the following GitHub page[4].

As previously discussed, collecting a large-scale corpus for reappropriated language detection is challenging. To address the lack of data, we used a ZSL approach, prompting the model to recognize the presence of semantic requalification without providing additional information. This method evaluates the model's ability to generalize effectively with no training data, taking into account only information acquired during the LLM training phase.

Different studies [18, 19] showed that ZSL results are significantly influenced by the appropriateness and precision of the prompts used. Additionally, multiple researchers [19] proposed different methods to improve performances. Plaza-del-Arco et al. (2022) [18] demonstrated that one of the most critical factors is ensuring that the prompt fits well with the utilized corpus. Taking this into account, we designed four different prompts using the HODI sub-corpus with the reappropriation annotation as the gold standard, each including specific details about the task and the corpora. The first one is the most general - explaining only the task in few words - while the fourth is as precise as possible providing full list of target words (full prompts are provided in Appendix A).

4. Results

4.1. Annotation statistics

We calculated the annotator agreement firstly by using Fleiss' Kappa, obtaining 0.57, secondly through Cohen's Kappa between pairs of annotators (all metrics are displayed in table 2). The moderate agreement and metrics variability highlighted the task's difficulty and subjectivity. Despite the three annotators being experts on the topic, they encountered challenges in distinguishing the use of slurs.

The majority annotation indicates that out of a total of 1742 examples, only 168 were annotated as reappropriated.

To better understand annotators disagreements and collect challenging examples, we conducted an analysis on tweets labeled differently (some examples in Appendix B). We observed that out of a total of 217 tweets with annotation disagreement, 67 (30.88%) contained the word ”frocia”. This word likely caused confusion due to its unique history: unlike the other target words ”frocia”, feminine form of ”frocio”, originated in an already reappropriative context [5] [14]. In some cases, due to a lack of context, it was very difficult to understand the real communicative intent of tweets (i.e., *Sono ricchione. (senso andiamo)* - ”I'm gay. (like, let's go)”). In other instances, it was challenging to determine whether the person who wrote the message is part of the LGBT+ community or not (*Oggi il mondo mi sta urlando contro che sono un ricchione colossale senza speranza ed io gli sto dando ragione* - ”Today the world is shouting at me that I'm a colossal hopeless queer, and I'm agreeing with it”), assuming that only members of target community can use slurs in reappropriative sense. Finally, we also identified some noisy data in which target words have different meanings. For example, in the sentence *Il 4 è l'onomastico di checca frenzis ci ubriachiamo* (”On the 4th, it's Checca Frenzis' name day, so we're getting drunk”) the term ”checca”[6] is likely used as a diminutive of the Italian name ”Francesca”.

We also noticed that in some cases tweets labelled as reappropriative were also labelled as homotransphobic in the original annotation of HODI dataset. Due to this apparent contradiction, we conducted a qualitative linguistic analysis on this data. We realized that in four examples (*Oggi avrò di che parlare coi colleghi..un etero analfabeta che conquista l'attenzione di una checca alfabetizzata 😎, mi raccomando vai a fare la quarta dose che forse ti aiuta a dimenticarmi. Ciao* - ”Today I'll have something to talk about with my colleagues... an illiterate straight guy who captures the attention of a literate queer. Make sure to get your fourth dose, maybe it'll help you forget about me. Bye”), it is unclear whether the writer is part of the LGBT+ community or not. In other words, it is uncertain if the users were using slurs to refer to themselves with reappropriative intent or to other persons in abusive term. In addition, in some of these examples, target words were used as part of figures of speech, mostly similes (*Fare come una checca* - ”Behave as a faggot”). These expressions, highly lexicalized in Italian and often used as abusive idiomatic phrases, likely increased the difficulty in recognizing the correct usages.

[4] https://github.com/marcocuccarini/ReCLAIMProject

[5] Nossem (2019) considers ”frocia” as a calque of the English “queer” or ”Alternatively, we could see it as a new concept which is specific to the Italian linguistic and cultural context, rather than an adaption or appropriation of the English “queer”, i.e. some sort of a territorialised post-queer” [14].

[6] ”Checca” as well as being a diminutive form of the Italian name ”Francesca” is a colloquial and somewhat derogatory term in Italian used to refer to a gay man

Table 3
Zero-shot classification task results

Index	Weighted F1	Macro F1	Accuracy
1	0.64	0.43	0.55
2	0.73	0.49	0.66
3	0.66	0.45	0.57
4	**0.79**	**0.58**	**0.82**

4.2. LLM classification results

The results of the ZSL approach are detailed in Table 3. Notably, performances change among the prompts. The fourth prompt, which is the most specific, achieves the highest performance as it specifies all the target words considered during dataset construction. In contrast, the third one, focusing specifically on detecting homotransphobia by asking if the text intends to offend on the basis of sexual orientation or gender identity, has low performances. Among the four prompts, the first one (”Determine if the sentence contains semantic reappropriation; respond ’True’ if it does and ’False’ otherwise.”) has the worst performances, likely due to the ambiguity of the expression ”semantic reappropriation” for the model. Additionally, the model struggled to recognize the minority class (semantic requalification) because it is very complex for the model to recognize the context of the use of a slur, whether it is used to offend or not. This requires a deep understanding of the context and social dynamics, and it can also be a challenging task for humans.

To address this issue, balancing the information in the prompt by providing more details about semantic requalification could improve the model's overall performances. Therefore, we did not achieve very good performances, highlighting the importance of collecting new data and reviewing the computational approach.

5. Limitations and future works

The semantic requalification of slurs turned out to be a complex and time-consuming process in several aspects. Although the study has taken its first steps, some limitations must be acknowledged. Firstly, we realized that the HODI dataset [8] was not completely suitable for our purposes. Tweets had been collected for the homotransphobia detection aim and the difference of research goals did not provide us the right data to investigate the semantic requalification process of slurs. Secondly, a binary annotation proved to be limiting due to the difficulty of the task. The subjective evaluation of the annotators does not allow the problem to be simplified in terms of the presence or absence of semantic requalification process; therefore, a new scalar annotation scheme is probably required. Furthermore, the fact that only experienced young researches sensitive to LGBT+ issues were involved in the annotation task may have led to bias in the results.

As future work we plan to:

- create a new dataset and annotating it by following a perspectivist approach [7][20], i.e. by collecting different points of view from various social media, involving annotators with different backgrounds, in terms of age, origin, education, in/out target groups, and providing more context information during the annotation phase in order to better understand slurs' meanings and intents.
- through different LLMs, investigate which approach has better performances in recognising different uses of slurs, for instance by using ZSL approach between pairs of examples or defining few-shot with new suitable data.
- regarding ethical considerations, it is crucial to directly and actively involve the LGBT+ community. Gathering viewpoints and suggestions from those who experience daily oppression and denigration is essential not only to strengthen the research methodology but also to ensure its relevance and sensitivity to their lived experiences.

6. Conclusion

This paper presents the first attempt to specifically address the detection of slur reappropriation in the Italian language. One of the reasons that motivated us to undertake this task is the need to ensure a safe linguistic environment on social networks without risking the censorship of individual freedom of expression. Since there was no existing dataset to explore homophobic slurs in the Italian language, we filtered a pre-existing homotransphobic dataset to build a subset containing only tweets with slurs occurrences, used both abusively and non-abusively. We then designed precise new guidelines and annotated the filtered subset, focusing on the presence of slur semantic reappropriation. With the newly annotated dataset, we approached a classification task using LLMs with zero-shot techniques. Leveraging the Qwen model [17], we proposed four different prompts. As suggested by previous literature, more specific prompts and those better suited to the dataset yielded better performance. In this work, we proposed an important and under-explored task through a two-fold contribution. On one hand, we highlighted the lack of data in the Italian language dealing with this phenomenon and the necessity of building

[7] https://pdai.info/

an up-to-date corpus that comprehensively includes multiple sources and semantic contexts. On the other hand, we demonstrated a possible approach by leveraging new state-of-the-art LLMs. Finally, it is important to have in mind that compared to English, Italian has a different history and cultural background, resulting in a much slower linguistic evolution. This makes establishing precise characteristics of this topic a challenging task due to the lack of solid foundational knowledge. In conclusion, we believe that bringing attention to the issue will lead to anti-discrimination activities, the creation of safer spaces in online communication, and the inclusion and acceptance of LGBT+ communities.

Abstract

We investigate how Raymond Queneau's *Exercises in Style* are evaluated by automatic methods for detection of artificially-generated text. We work with the Queneau's original French version, and the Italian translation by Umberto Eco.

We start by comparing how various methods for the detection of automatically generated text, also using different large language models, evaluate the different styles in the opera. We then link this automatic evaluation to distinct characteristic related to content and structure of the various styles.

This work is an initial attempt at exploring how methods for the detection of artificially-generated text can find application as tools to evaluate the qualities and characteristics of human writing, to support better writing in terms of originality, informativeness, clarity.

Keywords

GPT, style, generated text, human writing

1. Introduction

The extraordinary writing ability of the latest chatbots and virtual assistants based on Large Language Models (LLMs) poses a significant question for anyone who attempts to write today —- be they a scientist, a writer, or a lover: is it worth the effort to engage in the act of writing?

For those not hindered by excessive laziness and who, with courage, still tackle writing with determination and passion, this question implies a more specific one: am I writing a text that an artificial intelligence could not have produced?

We believe that the answer to this question may, in the future, come from the LLMs themselves given that they are designed to assess the probability of the occurrence of the next word in a text. We envision a future where LLMs, although widely used to produce essentially obvious texts, will assist those who still engage in writing to create texts worth reading, if only because the artificial intelligence, having read and statistically evaluated almost everything ever written, considers them non-obvious and distinct from what it would have produced itself.

The ability of LLMs to evaluate the probability of the next word in a text stems from the extensive corpus of writing they are trained on. Consequently, their evaluation of a piece of writing is ultimately based on an indirect comparison between the given text and the entire body of literature they have been exposed to. Using LLMs to assess how much a text differs from the production capabilities of LLMs inherently implies an evaluation of the novelty it represents compared to known literature.

Starting to move in this direction, this article explores whether an LLM can be used to help humans answer this question. In this first attempt we do this not based on the content intended for communication but on the style. We have conducted a preliminary study on the possibility of using LLMs to evaluate how and to what extent a certain writing style and/or a specific text differs from what a machine can achieve.

We took as a reference Raymond Queneau's "Exercises in Style" [1], which draws from Erasmus of Rotterdam's "De Utraque Verborum ac Rerum Copia" [2] a bestseller widely used for teaching how to rewrite pre-existing texts and how to incorporate them into a new composition. In Queneau's work, the same simple story is revisited each time in a different literary style. We asked ourselves and conducted experiments on how much the texts in various styles used by Queneau differ from the writing abilities of LLMs, which have acquired their skills by learning statistical relationships from vast amounts of text.

Calvino had already attempted to answer this question: "What would be the style of a literary automaton?" He replied, "The test for a poetic-electronic machine will be the production of traditional works, of poems with closed metric forms, of novels with all the rules". We believe it has indeed happened this way, as today's chatbots and virtual assistants are built from a language model.

In this work, we provide initial evidence that language models recognize those texts that are more traditional, particularly used in spoken language or by classical characters as more probable while they deem more unlikely experimental and innovative texts. However, we find

evidence that even for powerful LLMs it remains difficult to cut a clear line between experimental texts and those that instead incur the risk of becoming unreadable.

2. Related Work

The evaluation of text readability may dated back at least to the work of Flesch in 1948 [3]. Flesch's method was based on simple surface properties of text (i.e., words per sentence and syllables per word). Since then a steady evolution of methods involved more complex NLP and ML as new tools were developed (see the surveys [4, 5]).

An example of the use of LLMs on this topic is the work Miaschi et al. [6], which investigated the correlation between a readability score measured by an automatic readability tool (READ-IT [7]) and the perplexity measured by an LLM, yet they found no significant correlation between the two dimensions.

Hayati et al. [8] compared human and BERT-based relevance scoring of words in a sentence to determine its style, polite or offensive, as well as the expression of sentiment and emotions. They found a loose correlation in the way words are identified as relevant by humans and BERT, with BERT giving more relevance to context word (e.g. "baseball" for the emotion of joy), while human are more focused on words perceived as "typical" of the style. (e.g., "smile" for joy).

The style transfer process is the task of rewriting a passage of text changing the set of lexical choices and syntactic structures, yet not substantially changing the actual content of the text. Krishna et al. [9] surveys the style transfer literature and proposed a style transfer method trained on reconstructing a style-specific text (inverse paraphrase) on pseudo-parallel data generated using a diverse paraphrase model.

Qi et al. [10] proved that a change of the writing style, made using a trained model, can be an effective means of attack to BERT-based classifiers, e.g., letting an offensive text be classified as non-offensive just by rewriting it using a Bible-like style. Similarly Krishna et al. [11] have shown that automatic paraphrasing can be extremely effective at breaking the ability of detection method to recognize artificially generated text.

3. Writing with style

Queneau's original work in French of 1947 [1] tackles on telling the same short story using 99 different styles. The first style, Notations, is a clear report of a sequence of events, each with details that together define the actual content of the story that is reported in all of the other 98 versions. Each version has a defining title that denotes its style. Styles can be grouped by similarity; Barbara

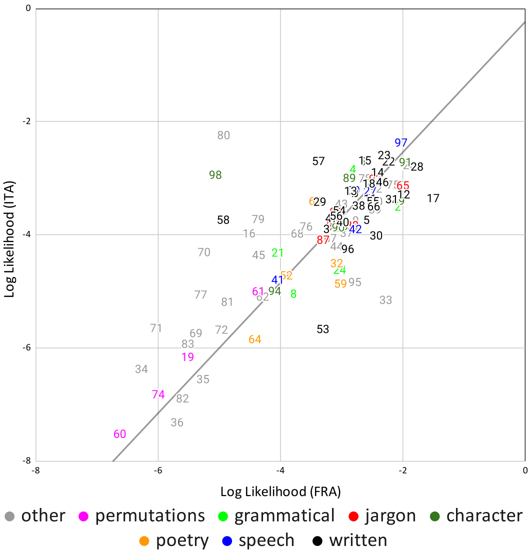

Figure 1: Log Likelihood for both the Italian and French versions of "Exercises in Style". The numbers provided correspond to the IDs in Table 1. The colors indicate the exercise group. The line show the correlation ($R^2 = 0.805$).

Wright, who made the English translation in 1958 [12], reports to have roughly identified seven groups[1]:

- different types of speech;
- different types of written prose, e.g., Official Letter, Philosophic;
- five poetry styles, e.g., Haiku, Ode;
- eight language-based character sketches, e.g., Reactionary, Biased, Abusive;
- grammatical and rhetorical forms, e.g., Litotes, Synchesis, Parts of speech;
- jargon, e.g., mathematical, botanical;
- and the very specific group of Permutations, by groups of letters or words.

Along time, new editions presented variations in the list of styles. For example, five styles in the original edition[2], were replaced by other five in the edition of 1969[3], the one we used in our experiments.

Queneau's opera has been translated in more than 30 languages. The Italian translation was made by Umberto Eco [13], in 1983. Similar to other translations, the Italian translation reports almost all the original styles, but some are considered untranslatable and replaced with variants

[1] In the preface of the book where the groups are listed, Wright did not report a complete assignment of all styles to these groups, only hinting a few cases for some of them.

[2] Réactionnaire, Feminine, Hai-Kai, Permutations de 2 á 5 lettres, Permutations de 9 á 12 lettres.

Scores and ranks of the various styles with respect to various detection methods. Styles are ranked by the DetectGPT score on Italian. Groups are indicated by their initials (Π is used for *permutations*) and are color-coded consistently with the previous figures.

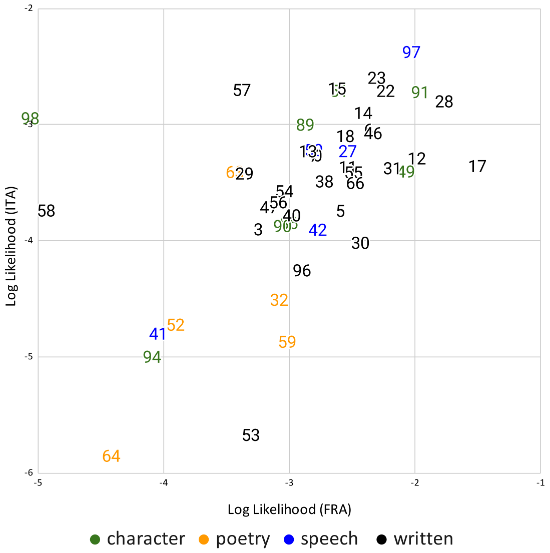

Figure 2: Log Likelihood for the main groups, presented in a zoomed-in view.

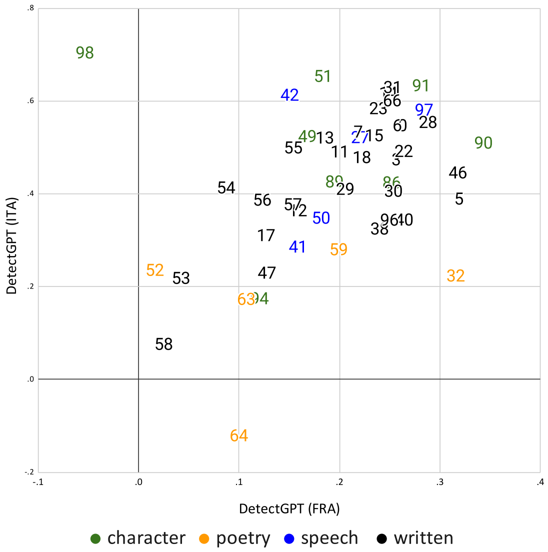

Figure 3: DetectGPT scores for the main groups.

semantically similar to the original ones, or relevant for other reasons. For example the style Homophonique was replaced by Eco with a style named Vero? (True?), because French has many homophones while Italian has not. The Vero? style links to the repeated use of intercalation and links to the Alors style of the French edition. Eco also decided to not translate the Loucherbem style, based on the slang spoke by Parisian and Lyonnaise butchers, considering not interesting to link it to an Italian slang or dialect, whereas dialect-based styles already were included in the opera. Eco replaced it with its own version of the Réactionnaire style from the first edition, which he liked more, as he detailed in the preface of his translation.

4. Style and detection, is there a relation?

The Research Question (RQ) we wish to answer is the following: **Can we use Machine Generated Text (MGT) detection methodologies to measure some qualities and characteristics of the style used in writing a piece of text?**

Our assumption supporting the relevance of this RQ is that LLMs, trained on trillions of tokens, naturally approximate an *average writing style* that is necessarily "average" and thus not original or unique. On the other hand, original and surprising writing styles, which by definition will come in many very different forms, will be less frequent, and sparse across the long tail in the distribution of training data, and thus modeled as less likely according to the LLMs.

We use two metrics to measure the style of texts according to language models, *Log Likelihood* (LL) and *DetectGPT* [14], these metrics are used to detect text generated by a given language model since on average they will be higher for text that a language model has generated, when compared to text written by a human.

We focus on Eco's Italian and Queneau's original French versions of the style exercises. To measure the scores, we use LLMs tuned for these languages. For Italian we use Anita [15] while for French Mistral [16].

As a first validation of our assumption, Figure 1 shows the correlation between the *Log Likelihood* each writing style passage is assigned in Italian (y-axis) and in French (x-axis). The Figure shows significant correlation and zooming in on the higher *Log Likelihood* texts, Figure 2, we see that the correlation persists.

Similar results hold for *DetectGPT*, Figure 3, shows the correlation between this score for the Italian texts and for the French ones, and the correlation is close to the one for *Log Likelihood* shown in Figure 2.

Both Figures 2 and 3 show style number 98 as a kind of outlier. This is a correct measurement as style 98 is actual two different styles between the two versions, Loucherbem in French, and Reazionario in Italian, as reported in Section 3.

Both *Log Likelihood* and *DetectGPT* appear to behave consistently across languages and styles, supporting our hypothesis that some characteristics of the writing styles are captured by these scores.

4.1. Analysis of Detection Scores of Styles

Table 1 shows the actual value of *Log Likelihood* and *DetectGPT* for each passage in both Italian and French as well as their ranking among all style exercises, ranked based on the *DetectGPT* score in Italian. We adopted Wright's grouping of styles, assigning each style to one of the seven groups listed in Section 3, and also adding an "other" group for styles for which we could not find a clear positioning in Wright's groups (typically the styles based on almost obsessive repeated use of some kind of expression). The (colored) *gr.* column reports the style group that is assigned to each style exercise and we can observe that ranking the styles based on the *DetectGPT* scores in Italian (as they are reported in the table) highlights a few prominent patterns which we now describe.

The ***permutation*** class is present only in the lower ranks, and indeed the texts belonging to this group are hard to read and don't show any recognizable stylistic pattern, they are more akin to games that makes sense only within the context of Queneau's book.

The texts belonging to the ***jargon*** class are also grouped together, with the exception of the "Zoologico" (Zoological), "Botanico" (Botanical) and "Medico" (Medical) ones, and are still in the lower end of the tail. Anecdotally, the three ***jargon*** styles that are in higher ranks are likely to be present in higher quantity in LLMs training data justifying the ranking shift.

The ***poetic*** class is the next one in average rank, just higher than the *permutation* one, with the exception of the "Tanka" style, which is indeed a very short text, with almost no syntax connecting minimal sentences.

Interestingly, right above the *poetic* group stands the ***grammatical and rhetorical*** group; indeed rhetorical figures are a key component of poem writing. This group is evenly spread among the middle ranks, with the exception of "Parti del discorso" (Part of speech), which is in a lower position, and which also the one with more loose relation with *grammatical and rhetorical* group.

The ***writing*** group, contains a large number of styles and is spread across several ranks, however it is heavily skewed towards the higher ranks.

The ***speech*** group is entirely in the higher ranks and as its spoken source suggests it has a strong character-rooted component.

Accordingly, the only group that ranks higher than *speech* is ***character***[4] which, with only two exceptions, "Ingiurioso" (Offensive) and "Impotente" (Powerless), always ranks in the top quarter, takes all 3 top ranks and is the highest ranking one. The last line of Table 1 reports the ranks and scores for the Loucherbem style, which exists only in the French version. The ranks are very low as this style uses almost made up words to replicate the phonetics of the jargon.

The ***other*** group which contains all those styles which are harder to assign to a specific group is evenly spread across the lower ranks with few exceptions indicating that the texts that compose it are indeed quite varying and hard to group together.

An overall look at the ranking without considering the groups suggests a relation between the scores of detection methods and some characteristics of the styles. Styles that make use of unusual, or just made up words, or do not use a correct syntax, get low detection scores. Styles that are based on a clean, modern prose, with a simple syntax, get high detection scores. The middle ranks show a smooth transition among the two extremes, in which the use of unusual terms or syntax is more frequent as the detection scores get lower.

5. Conclusions

This work is a first exploration of the idea of designing tools that evaluate how and to what extent a writing style and/or a specific text differs from what a machine can achieve. We tested for this task the use machine generated text detection tools, under the hypothesis of a correlation between their detection scores and our goal of discovering the many facets that build an original human written text. We applied them to Queneau's exercises in style, in which the same story is written using a rich and varied set of writing styles. We have found a consistent correlation between the scores assigned by detection methods, across detection methods and across languages.

The comparison of the styles with their detection scores indicates that lower scores from detection methods are correlated with the use of unusual terms or syntax, while higher scores are more related to styles that are based on a clean and more prose, with a smooth transition among this two extremes. The ranks thus do not indicate a "better" or a more "interesting" style, yet they confirm Calvino's statement we reported in the introduction: content that is akin to a machine-generated one is the one that produce "traditional" content, following the main rules of writing.

Writers willing to depart from sounding "ordinary" could indeed use detection methods to estimate these aspects on their content, with the caveat that while a mid-level detection score may suggest some original traits in text, low scores may not indicate a more original or interesting text, but they may likely derive from an obscure or plainly unreadable text.

Given the positive results of this first investigation, future developments will be based on the use of texts specifically written for this activity. This will have the advantage of having full control over the contents and to have the guarantee that they have never been part of the LLMs training data.

Abstract

This paper presents a novel pipeline for constructing multimodal and multilingual parallel corpora, with a focus on evaluating state-of-the-art automatic speech recognition tools for verbatim transcription. The pipeline was developed during the process of updating the European Parliament Translation and Interpreting Corpus (EPTIC), leveraging recent NLP advancements to automate challenging tasks like multilingual alignment and speech recognition. Our findings indicate that current technologies can streamline corpus construction, with fine-tuning showing promising results in terms of transcription quality compared to out-of-the-box Whisper models. The lowest overall WER achieved for English was 0.180, using a fine-tuned Whisper-small model. As for Italian, the lowest WER (0.152) was obtained by the Whisper Large-v2 model, with the fine-tuned Whisper-small model still outperforming the baseline (0.201 vs. 0.219).

Keywords

multimodal corpora construction, translation and interpreting corpora, verbatim automatic speech recognition

1. Introduction

The present paper introduces a pipeline for the construction of multimodal and multilingual parallel corpora that could be used for translation and interpreting studies (TIS), among others. The construction of such resources has been acknowledged as a "formidable task" [1], which if automated —as we propose— involves a number of subtasks such as automatic speech recognition (ASR), multilingual sentence alignment, and forced alignment, each of which poses its own challenges. Yet tackling these subtasks also offers a unique way to evaluate state-of-the-art natural language processing (NLP) tools against a unique, multilingual benchmark. In this paper we discuss the development of a modular pipeline adaptable for each of these subtasks and address the issue of whether performing ASR with OpenAI's Whisper [2] could be suitable for verbatim transcription.

We showcase the utility of this pipeline by expanding the European Parliament Translation and Interpreting Corpus (EPTIC), a multimodal parallel corpus comprising speeches delivered at the European Parliament along with their official interpretations and translations [1, 3]. The transcription conventions adopted for the compilation of EPTIC were developed *ad hoc* and aim at reproducing minimal prosodic features, but can still be considered an instance of verbatim transcription [3, 1]; the issue of what truly constitutes *verbatimness* is still an object of debate and will be further discussed. There is fairly widespread agreement on the statement that every transcription system reflects a certain methodological approach [4, 5], and that by "choosing not to transcribe a particular dimension, the researcher has implicitly decided that the dimension plays no role in the phenomenon in question" [4]. To investigate the characteristics of Whisper's [2] transcriptions in English and Italian, we formulate the following two research questions: **RQ1** Is it possible to use fine-tuning to adapt the transcription style to the one of an expert annotator? **RQ2** What is the impact of speech type (native, non-native, interpreted) on transcription quality?

We find that satisfactory results can be achieved with automatic speech recognition, although challenges remain, especially with regards to the verbatimness of the transcription —a crucial factor in corpora intended for TIS. Fine-tuning Whisper-small on English data obtains a lower word error rate (WER) of 0.180 compared to Whisper-large v2 (0.194), potentially indicating that fine-tuning Whisper models holds promise for improving their performance in terms of adhering to a certain transcription style. However, this was not the case when considering the experiments based on Italian. In the Italian scenario, Whisper-large-v2 obtained a WER of 0.152 compared to a WER of 0.201 obtained by the fine-tuned Whisper-small model. It should be noted, however, that this constituted an improvement over the baseline Whisper-small model, which obtained a higher WER of

0.219. A significant limitation in the case of fine-tuning in Italian was constituted by the smaller amount of data available for tuning compared to English. Lastly, we find that sentence alignment can be facilitated through state-of-the-art embedding-based tools, whereas forced alignment can be considered a largely solved problem. This makes the construction of corpora such as EPTIC more streamlined and requiring less human intervention, with wider implications for multilingual corpus construction in the field of TIS and beyond.

2. Related Work

Recent advancements in the field of corpus linguistics have led to a multitude of complex multilingual and multimodal corpora, as well as novel approaches to corpus construction. Transcribing spoken data, identifying prosodic features, and aligning parallel texts are some of the tasks that are commonly involved. In this sense, a particularly representative case in point is constituted by interpreting corpora, such as EPIC [6], DIRSI [7], and EPTIC [3, 1], the latter also including translated texts. Based on data obtained from the European Parliament, these complex corpora require multi-step approaches for gathering and processing parallel, multilingual texts and multimodal data. Though the construction of translation and interpreting corpora has been largely carried out manually, it can also constitute a unique opportunity for developing new tools and benchmarking recent advancements in the fields of NLP and ASR. ASR, in particular, has garnered increasing attention due to the time-consuming nature of spoken data transcription.

A related research strand in the field of ASR concerns the level of detail of the transcriptions produced by ASR systems, as the task is usually not only to transcribe the speech but to make sure that prosodic features, such as disfluencies, are maintained. [8] conducted a comprehensive comparison of different ASR systems and acoustic models for disfluency detection and categorization, examining Wav2Vec [9], HuBERT [10], WavLM [11], Whisper [2], and Azure [12]. Their findings indicate that fine-tuned models generally outperform their off-the-shelf counterparts. [13] evaluated pre-trained models, revealing that Whisper-Large achieved the best overall WER and chrF (character n-gram F-measure [14]) scores. [15] demonstrated the potential of Whisper for adaptation in spoken language assessment with limited training data. In the realm of commercial ASR services, [16] explored IBM's offering for transcribing English source speeches and their interpretation, reporting an impressively low error rate of 4.7%. [17] conducted a systematic comparison of automatic transcription tools, evaluating factors such as data protection, accuracy, time efficiency, and costs for English and German interviews, and found that Whisper performs best overall among the tools considered.

Despite these advancements, several limitations persist in the current research. First, most studies focus primarily on English, with only some including other languages such as Chinese [16]. Furthermore, the field of speech disfluency research faces challenges due to the scarcity of publicly available benchmarking datasets, attributed to high annotation costs, the clinical nature of some tasks, and the use of proprietary datasets [18]. The choice between Wav2Vec and Whisper remains a point of debate, with [8] finding similar results for both after fine-tuning, while Azure off-the-shelf performed best, followed by Whisper off-the-shelf. Still, [17] did not explore fine-tuning, and [8] suggests that fine-tuned models generally perform better. The requirement for punctuation marks in some corpora, such as EPTIC, introduces another consideration in model selection. Wav2Vec does not output punctuation, while Whisper does, potentially influencing its suitability for certain applications. Additionally, while [13] used a large corpus, [15] indicated that Whisper can perform well with less data, highlighting the need for further investigation into optimal data requirements.

3. Corpus Construction

The present work is based on the European Parliament Translation and Interpreting Corpus (EPTIC), a multimodal parallel corpus comprising speeches delivered at the European Parliament (EP) along with their official interpretations and translations.[1] Within EPTIC, the corpus construction process revolves around individual speech events, where edited *verbatim* reports published by the EP and transcriptions of the speeches are accompanied by transcriptions of interpretations and official translations into other languages. These components form a multi-parallel corpus, i.e. a corpus containing verbatim transcriptions of source speeches, official verbatim reports and corresponding target translations and interpretations (quasi parallel at the intermodal level [3]). The English partition consists of source English texts and their translations into various languages. Corpora containing translations in both possible directions (e.g., from English to French and vice versa) are referred to as bidirectional, while those with translations in only one direction are referred to as unidirectional. Table 1 shows the languages included and the size of the latest version, EPTIC v2, planned for release by the end of 2024.

Our approach to corpus expansion began with a review of previous guidelines for developing EPTIC [1, 19]. The former procedure first involved obtaining data by either scraping texts from the EP website[2] or by man-

Finnish	–	–	11,624	12,045

ually downloading videos and then transcribing them. Transcripts of the original speeches and interpretations were manually adapted following editing conventions to annotate features of orality such as disfluencies and timestamped using Aegisub.[3] Then, the texts were automatically segmented into sentences and aligned across languages and modalities, for instance between transcriptions and verbatim reports, with the help of the Intertext Editor alignment tool.[4]

The creation of the new workflow started with the previous procedure as a basis. It was first subdivided into separate tasks, the main ones being automatic speech recognition, multilingual sentence alignment, and forced alignment. Software selection was based on criteria such as ease of use and setup, compatibility with the Python programming language, linguistic coverage, and compatibility with Sketch Engine, an established corpus query tool for teaching and research [20, 21]. Python v. 3.11.5 was used along with the Poetry[5] package manager for portability.[6] Next, we discuss the tasks and the considerations made when designing the pipeline.

Automatic Speech Recognition has seen recent advancements, with the introduction of Whisper [2] and Wav2Vec 2.0 [9]. However, achieving a reasonable level of transcription quality is complex and context-dependent, as it can be interpreted and evaluated differently depending on the domain, task, and application [22]. We decided to employ the WhisperX[7] variant of Whisper, given its documented reliable performance for long-form transcription, which is oftentimes needed when dealing with parliamentary speech [23].

Sentence Alignment involves identifying and aligning parallel sentences, both mono- and multilingually. For this task, we use Bertalign [24]. Unlike predecessors such as Hunalign[8] that rely on lexical translation probabilities, Bertalign employs sentence embeddings to identify parallel sentences, providing a more robust approach for handling semantic similarities. We used a version of the tool that has been extended to produce outputs in the Sketch Engine format for corpus indexing [20, 21].

Forced Alignment, the task of automatically aligning audio with transcriptions, is the most mature task for spoken corpora. Although WhisperX performs timestamping during transcription, we experimented with forced alignment on an existing portion of spoken EPTIC data, using the aeneas library, which supports more than thirty languages.[9]

The pipeline is structured in a modular fashion so as to maximize reusability. The process begins with the extraction of text and video data from the EP website, using ad-hoc scripts which partially automate scraping of the EP website. Transcription is then performed using WhisperX. To remove mistranscriptions and to ensure adherence to the transcription guidelines, the transcripts undergo manual review to incorporate disfluencies and rectify potential mistranscriptions. Once the texts have been transcribed, they undergo sentence splitting and sentence alignment using Bertalign. Relevant metadata, encompassing session topics, are automatically retrieved from the EP website. The only item requiring manual input is the speech type, which can be defined as impromptu, read out, or mixed. After exporting the alignments in the Intertext format and performing part-of-speech tagging with Sketch Engine, the texts and metadata are converted to the vertical format required for indexing in Sketch Engine [20, 21].

4. ASR for Verbatim Transcription: Evaluating Whisper

We require an ASR system to produce a verbatim transcription where all words are transcribed, along with disfluencies and extra-linguistic information. However, *verbatimness* is a broad concept, given the variety of transcription conventions existing in linguistics [17]. Whisper has been observed to produce transcripts "often almost comparable to the final read through of a manual (verbatim to gisted) transcript" [17], where gisted refers to a transcription that "omits non-essential information (e.g., filler words, word fragments, repetition of words), and summarizes or grammatically correctly rephrases the audio content" [17]. Hereby, we define a verbatim

Table 2
Performance of Whisper by language, expressed in WER.

Model	English	Italian	French	Slovenian
Small	0.212	0.219	0.162	0.463
Small-FT	**0.180**	0.201	–	–
Medium	0.196	0.173	0.213	0.327
Large-v2	0.194	**0.152**	**0.118**	**0.262**

Table 3
Speech performance across types, expressed in WER.

Speech Type	English	Italian
Native	0.104	0.131
Non-native	0.110	–
Interpreted	0.222	0.188

transcription as a transcription where "all words are transcribed without additional grammatical corrections [and] word repetitions, utterances, word interruptions, and elisions are kept" along with some rudimentary extra-linguistic contextual information, such as applauses [17].

As part of our experiments, we tested the HuggingFace release[10] of the Whisper models. The test set included English, Italian, French, and Slovenian, though further experiments were conducted exclusively with English and Italian due to dataset limitations. We used 7 hours of audio for English, 5 for Italian, 1.5 hours for French and 1.5 hours for Slovenian. Besides evaluating the models on the whole set of held-out data, we computed word error rates (WERs) for different speech types: native speech, non-native speech, and interpreted speech.[11] In addition to experimenting with the out-of-the-box versions of Whisper, we explored fine-tuning Whisper-small for English and Italian. To train and test the models, we used 80% of the data for training, 10% for validation, and 10% for testing. The training parameters for the Whisper-small model were set to a batch size of 16, a learning rate of 1e-5, mixed-precision training enabled, and a maximum of 5,000 training steps. Evaluation and saving checkpoints were enabled every 1,000 steps, optimizing for WER.

The experimented Whisper models showed a robust performance across languages and speech types. Our findings suggest that satisfactory results can be achieved for Italian, which exhibits a low WER of 0.152, and English, with a WER as low as 0.194. The full set of results is presented in Table 2, where the fine-tuned model is referenced as Small-FT. This fine-tuned model obtained the lowest WER for English, performing better than Whisper-large-v2, which could indicate that the model is learning to produce a more verbatim transcription. In the case of Italian, the fine-tuned model obtains a lower WER compared to the baseline Whisper-small model (0.201 for the fine-tuned model compared to the WER of 0.219 obtained by the baseline Whisper-small). However, the lowest WER of 0.152 is obtained by Whisper-large-v2, which could be attributed to the lower amount of data available for fine-tuning compared to English.

Lastly, to address **RQ2**, we evaluated whether factors such as *nativeness* influenced the WER. Findings for these experiments are presented in Table 3, and indicate a WER of 0.104 for native English speakers, 0.110 for non-native speakers, and a notably higher WER of 0.222 for interpreted speech. Similar results were also obtained for Italian, with a WER of 0.131 for native speakers and 0.188 for interpreted speech, which provides further evidence for the finding of interpreted speech being more challenging to transcribe [16].

To further explore the claim that fine-tuning improves the performance of the model by steering its output towards a more verbatim transcription, we now present the results of a qualitative error analysis. We consider a set of "markers of verbatimness" based on the definition in [17]: contractions, truncated words, discourse markers, repetitions, filled pauses and empty pauses. The following paragraphs present results that emerge from the analysis, with examples provided in Table 4. Following [15], we furthermore report the recall metric for each category.

As for contractions, they are sometimes incorrectly resolved by the standard Whisper-large-v2 model; fine-tuning results in improvements. For instance, in the example shown in Table 4, the fine-tuned version of Whisper-small maintains the contraction while the large model does not. Generally, however, Whisper-large-v2 shows acceptable performance even when fine-tuning is not performed, as Whisper was trained with unnormalized transcripts including contractions, punctuation and capitalization [2].

Truncations are not transcribed by the Whisper models out-of-the-box. Fine-tuning shows some promising results, though truncations are not always transcribed reliably and transcription errors are sometimes introduced, as illustrated in Table 4. This is possibly due to the observation in [15] that, being largely trained on speech data with a high level of inverse text normalization (ITN), a process including disfluency removal, Whisper tends to omit features of orality in favor of readability, which is unfavorable for the purpose of verbatim transcription.

Discourse markers are mostly transcribed in English, even by the baseline Whisper-large-v2. In Italian, discourse markers are omitted considerably more often. An example of this is provided in Table 4. This could be attributed to the fact that, even though Whisper models have been trained to produce transcriptions without any significant standardization [2], the amount and qual-

(c) …azioni che rivelano il volto frimente …	0.00	0.00
Filled pauses		
(a) …azioni che **…** rivelano il volto opprimente …	100.00	100.00
(b) …azioni che **…** rivellano il volto frimente …	56.50	88.20
(c) …azioni che rivelano il volto frimente …	0.00	0.00

ity of training data for English are likely more extensive and varied compared to Italian, especially when it comes to examples of spontaneous speech. As for repetitions, the example in Table 4 shows both a repetition and a truncation, a common occurrence due to disfluent speech often comprising a combination of both. In the example, the fine-tuned Whisper-small model accurately transcribes both disfluencies, while Whisper-large-v2 rephrases them into a corrected transcription. Overall, the baseline Whisper-large-v2 model always omitted repetitions both in English and Italian. This could be due to the powerful language model used by Whisper, which has been observed to correct such errors [13].

The last examples in Table 4 illustrate transcriptions of empty and filled pauses. Whereas Whisper-small-FT often captures them, the baseline model does not. However, the fine-tuned model's performance is not consistent, and occasionally non-existent empty pauses are transcribed by the model. As in the case of truncations, pauses are never transcribed by Whisper-large-v2, likely due to the models having been trained on data processed with ITN.

5. Conclusions and Future Work

This paper presented a novel pipeline for constructing multimodal and multilingual parallel corpora, with a focus on evaluating state-of-the-art automatic speech recognition tools for verbatim transcription. Experiments with Whisper models on EPTIC revealed robust performance across languages and speech types, particularly for English and Italian. However, some limitations remain regarding ASR performance and achieving verbatim transcriptions. Fine-tuning Whisper showed promising reductions in WER, particularly for English, indicating the potential of adapting the model to use a more verbatim style. Yet qualitative analysis revealed inconsistencies in handling disfluencies, truncations, and discourse markers. Furthermore, higher WERs for non-native and interpreted speech underscore remaining challenges.

Future research efforts could explore incorporating additional metrics beyond WER to better capture the degree of *verbatimness* in the transcriptions, and expanding the Italian dataset to potentially improve the performance of the fine-tuned model. Another avenue for research could include augmenting the dataset with external data containing pairs of audio and verbatim transcripts, most notably the Switchboard corpus introduced in [25]. Other methods besides fine-tuning could be explored to enhance the quality of transcriptions, for instance by leveraging the official verbatim reports on the European Parliament's website. Lastly, a model could be developed for detecting the metadata item relative to the speech type, i.e. impromptu, read out, or mixed, based on textual or multimodal features.

Abstract

In recent years, the Gender Based Violence (GBV) has become an important issue in modern society and a central topic in different research areas due to its alarming spread. Several Natural Language Processing (NLP) studies, concerning Hate Speech directed against women, have focused on misogynistic behaviours, slurs or incel communities. The main contribution of our work is the creation of the first dataset on social media comments to GBV, in particular to a femicide event. Our dataset, named GBV-Maltesi, contains 2,934 YouTube comments annotated following a new schema that we developed in order to study GBV and misogyny with an intersectional approach. During the experimental phase, we trained models on different corpora for binary misogyny detection and found that datasets that mostly include explicit expressions of misogyny are an easier challenge, compared to more implicit forms of misogyny contained in GBV-Maltesi.

Warning: This paper contains examples of offensive content.

Keywords

Hate Speech, Misoginy Detection, Femicide, Social media, News, Responsibility framing

1. Introduction

Nowadays, the term **Gender Based Violence (GBV)** is used to identify all forms of abuse based on gender hatred and sexist discrimination [1]. Scholars in social science have defined as "rape culture" the society that normalizes sexist behaviours: from more common occurrences like victim blaming, slut shaming and gender pay gap to the apex of violence with femicide [2]. While general violent crimes decreased over time, GBV did not, alarming various bodies in modern society[1]. A report from the EU commission[2] states that 31%, 5% and 43% of European women suffered respectively from physical, sexual and psychological violence. Regarding the Internet sphere, a survey found that 73% of women journalists experienced online violence (threats, belittling, shaming,...) [3]. These statistics become even more alarming when we consider studies that show the correlation between misogynistic online posts and GBV [4].
Like other countries, Italy is affected by GBV, with the national observatory managed by the "Non Una di Meno" association reporting 117 femicides in 2022, 120 in 2023 and more than 40 until June 2024[3].

Several studies about Hate Speech (HS) directed towards women often focus on developing taxonomies [5] rather than investigating low resource subjects in computational linguistics like GBV. These works often gather corpora by keyword search of gender slurs [6], retrieving comments left on misogynistic spaces like incel blogs [5, 7] or considering messages directed towards popular women figures highly debated on social media [8].

As GBV is a broad topic, we want to clarify that we focus on GBV in Western societies, particularly in Italy. The main goal of this project is to show what is the current perception of femicides expressed through comments on social media, focusing on the specific case of Carol Maltesi. We chose this femicide because the victim was a sex worker, meaning that she presented an intersectional trait, and it was a popular case in the media, enabling us to select enough material for the study. Further, we want to highlight how the socio-demographic characteristics of the victims determine the way they are described and how this influences the perception of the news. For instance, victim's features such as age, job, origin, skin

color, nationality, religion have different weight and determine the lesser or greater spread of the news [9]. To overcome the cited issues in current literature, in this research we considered the phenomenon by focusing on users' reactions in social media to news about femicides. We collected YouTube comments in response to videos talking about a specific case. In order to overcome the constraints of traditional sentiment analysis schemas, we annotated the data following a new semantic grid that can be used as a standard for comments regarding GBV.

In the experimental phase of this work, we created models based on different Italian misogyny datasets (including ours). The goal of such experiments is to analyze the different features of these corpora and what forms of misogyny are harder to detect. We performed both a quantitative and qualitative analysis of the results.

In the next sections, we describe: related work on hate speech and misogyny detection(Section 2), the annotation scheme and both a quantitative and qualitative analysis of the dataset (Section 3), and the results obtained in our experiments (Section 4). Lastly, we present some conclusions and delineate possible future developments (Section 5).

2. Related Work

In recent times, the creation and dissemination of hate speech are increasingly pervasive on online platforms, making social media a fertile ground for hateful discussions [10]. The escalation of offensive and abusive language, understood as content that discriminates a person or group on the basis of specific characteristics such as ethnicity, gender, sexual orientation, and more has aroused considerable interest in various fields. In fact, over the last decade, a large number of computational methods involving NLP and Machine Learning have been proposed for automatic online hate speech detection [11, 12]. Most of prior works have mainly considered hate speech as a classification task, by distinguishing between hate and non-hate speech. Hate speech takes on different nuances depending on the target groups at which it is directed, i.e. depending on the specific features that the target group have in common. Moreover, in some cases, these traits may intersect with each other, leading to different degrees of discrimination. This concept takes the name of intersectionality [13].

Among abusive languages, misogyny, considered as a specific offensive language against women, has become a contemporary research topic [14]. In automatic hate speech detection field, the Automatic Misogyny Identification (AMI) [15] series of shared tasks launched in EVALITA [6] and the SemEval-2019 HatEval challenge [16] have produced evaluation frameworks to identify misogynous tweets in English, Italian and Spanish [17].

Misogyny has become a pervasive phenomenon, widespread in very different spheres and expressed in both explicit and implicit forms [5, 18]. For this reason, even in online conversation about a dramatic act such as femicide, it is possible to find examples of veiled or explicit hostility towards the victims. The femicide phenomenon has been studied from different points of view. Several studies focused on GBV representation in Italian media [19, 20]. In 2020, Mandolini focused on the journalistic narratives of femicide in newspapers by means of a qualitative discourse analysis on two specific case studies [21]. The researcher attempted to describe changes in attitudes in the portrayal of femicide, focusing on discursive strategies that (directly or indirectly) blame the victim and implicitly excuse the perpetrator, referring to gender stereotypes and romantic love rhetoric.

Other studies focused on the responsibility framing in femicides news, by conducting an experiment where annotators rated excerpts from local newspapers on how much responsibility was given to the perpetrator [22]. As far as we know, there is only one line of work in NLP on GBV [23, 24, 25], which focuses on reader's perception of femicide news headlines and analyses the perception of responsibility attributed to victim and perpetrator; whereas, to our knowledge, there is no other study analysing social media reactions to GBV cases.

3. Dataset

3.1. Corpus Background

In a preliminary phase of our work, we conducted a research on the femicide case of Sara Di Pietrantonio[4], 22 years old, a white Italian student, from a wealthy family, murdered by her ex boyfriend on May 2016 [21]. In this preliminary research we set out to develop a corpus by collecting Twitter users' comments to femicide news on newspapers published online [5]. We created an annotation scheme for the data corpus consisting of two layers: the first focused on the dimensions of sentiment analysis and composed of three subtasks (subjectivity, polarity and irony), relevant for the detection of sentiment in social media [26]; the second focused on hate speech detection, including labels for misogyny, aggressiveness and its target. For more details on the annotation scheme and corpus description, please read below Appendix A.

Observing the results of the preliminary study, we discovered how the victim's characteristics influence the way newspapers present her femicide and users talk about it on social media. In fact, analyzing Di Pietrantonio's case, as she was a young, white, wealthy and Italian

[4] https://www.agi.it/cronaca/news/2019-09-11/sara_di_pietrantonio_processo_tappe-6170806/

[5] the dataset is available at https://github.com/madeddumarco/GBV-Maltesi

student, we found very few examples of misogyny and, in most cases, the aggressiveness was directed against the perpetrator. Furthermore, the scheme was not considered sufficiently suitable for bringing out important elements of femicide cases. In fact, the annotators expressed their difficulties caused by the scheme developed as it was deficient and too simplistic to recognise complex features of femicide events. In order to solve these issues, we decided to direct our efforts on another case study in which the victim exhibits intersectionality traits, which we assume may lead to more misogynistic content. In addition, we developed new schema and guidelines to have more accurate annotations specifically related to the femicide domain.

3.2. Data Collection

In this section we provide a description of the new dataset built and the methodology used.

As mentioned above, we focused our research on the femicide of Carol Maltesi[6], a 26 years old, white Italian woman, mother and online sex worker, who was brutally murdered in January 2022 by her ex partner, Davide Fontana, a 44 years old white Italian bank employee.

With the aim of collecting users' responses to femicide, we chose to collect comments using YouTube Data API, as it is freely available and allows us to easily access comments focused on specific news. The process of obtaining data followed several steps: first, we selected the 31 most popular YouTube videos based on number of views and comments. We chose videos about Maltesi femicide from different types of sources: national (mainly the Italian broadcaster RAI) and local news. The selection of videos is diachronic spanning from March 2022 to June 2023; this was done because the various media channels covered the story as it evolved starting from the discovery of the nameless body and ending with the sentence given to the perpetrator. Afterwards, we collected comments from all the videos selected. Due to the API policy, we were restricted to collect only first-level comments and at most 5 oldest responses to them. In total, we retrieved 3,821 comments.

3.3. Annotation Scheme

From the previous experience of the Di Pietrantonio corpus, we decided that a generic sentiment analysis schema proved to be too rigid to understand such a complex phenomenon. We created an annotation scheme and a new online platform to facilitate the raters work. We involved 5 annotators, 4 of them self-identified as women and 1 as a man, all interested in the topic and mostly coming from humanistic background. They were all students and voluntarily participated to the project. The annotation guidelines were decided with the annotators after a pilot study and a subsequent group discussion where the raters pointed out the main faults of the schema. Each annotator analyzed all the comments according to the following guidelines:

- *Non classifiable:* if the comment cannot be analysed because it is not written in Italian, because it consists only of emojis, because it is not comprehensible or not relevant to the topic (any comment that was marked as NC from at least 1 annotator was removed from the corpus);
- *Empathy:* whether, in the comment, there are expressions of empathy in support of the victim, her family or the event in general (i.e., condolences);
- *Misogyny:* whether, in the comment, there is a presence of discriminatory expression against women, including blaming, objectifying, discriminatory and sexist practices used towards them and their life choices. If misogyny is present, we asked annotators to indicate its target (group or individual) based on [16]. Moreover, we asked to specify if the expressed misogyny contained intersectionality traits and to select from a list what other dimensions were involved: age, religion, job, nationality, skin color, class, sexual orientation, gender, physical condition, educational background, language and culture;
- *Aggressiveness:* whether there is aggressiveness in the comment and to whom it is directed (allowing multiple choices): victim, perpetrator, social network (family, friends, colleagues), media, rape culture;
- *Responsibility:* if there is explicit attribution of responsibility for the murder in the text, state who is blamed (allowing multiple choices): victim, perpetrator, social network (family, friends, colleagues), media, rape culture;
- *Humor:* specify whether the text conveys humorous content through irony, sarcasm, word games or hyperbole;
- *Macabre:* specify whether there are macabre aspects detailing how the victim was killed;
- *Context:* indicate whether the context was helpful to better understand the meaning of the comments;
- *Notes:* free space for suggestions, observations or doubts.

3.4. Dataset Analysis

The dataset, GBV-Maltesi [7], is composed of 2,934 comments annotated on all categories by all annotators. We

[6] https://www.agi.it/cronaca/news/2024-02-21/omicidio-maltesi-condannato-ergastolo-ex-davide-fontana-25397937/

(a) Distribution of the misogyny label and its subcategories

(b) Distribution of the aggressiveness label

(c) Distribution of the responsibility label

Figure 1: Histograms for distributions of relevant labels

aggregated dimensions through majority voting. As our schema is composed by many different labels, we will focus only on the dimensions that we consider the most relevant, but all statistics can be found in Appendix C.

Starting from misogyny, in Appendix C and in Figure 1a, we can see that 9.03% of cases are positive. This unbalance is typical of hate speech datasets [27] and we consider it surprisingly high if we take into account the tragic theme of GBV. It is very interesting that intersectionality represents over 50% of misogynous examples indicating how the personal traits of the victim affect the perception of the users commenting. Unsurprisingly, as the victim was a sex worker, 'work' is almost always the category chosen by the annotators. The target of misogyny was mostly individual, confirming the findings of SemEval-2019 Task 5 [16]. The annotators explained to us how the misogyny target was a difficult category to annotate as often comments used the victim as an example to offend the broader group of women and sex workers.

Aggressiveness is more present than misogyny in our dataset, with 24% positive examples mostly directed towards the perpetrator. Responsibility follows a similar trend with 32.89% positive examples most directed towards the perpetrator. Unlike aggressiveness, we can see a significant amount of comments holding the victim responsible (6.55%).

In Appendix B, we reported the inter-annotator agreement (IAA) scores for all dimensions. As our dataset is fully annotated by multiple people, the metric we chose is Fleiss' Kappa [28]. The metric has a possible range of [-1,1], with 1 indicating perfect agreement, and any value of $\kappa \leq 0$ indicates more disagreement between the annotators than expected by chance. We can see that most dimensions have a κ in the [0.2, 0.7] range, indicating variable levels of agreement depending on the label. The dimensions with the highest agreement at 0.69 are empathy towards the event and aggressiveness towards the perpetrator. In fact, annotators explained to us that these two categories were the easiest phenomena to annotate as they lacked ambiguity. On the other hand, we can see that aggressiveness towards the victim is much lower (0.28). In our discussions with the raters, it emerged how attacks towards the victim were harder to identify as they were more subtle leading to disagreement among annotators.

4. Experiments

We conducted experiments to validate our resource and to gain more insight into the difficulty of the misogyny detection task. The goal of this analysis is to understand how the presence of different forms of misogyny (implicit and explicit) affect the evaluation of modern classification models. We consider as explicit misogyny discourses that intentionally spread hate towards women mostly through slurs and other aggressive behaviors. Meanwhile, we intend implicit misogyny as more subtle and less conscious practices like victim blaming, slut shaming, de-responsibilization of the perpetrator and more. In addition to our corpus, we used 3 other datasets regarding the topic in Italian: AMI [6], PejorativITy [29] and Inters8 [8]. The former two have been mainly gathered by keyword search of sexist terms[8], meanwhile, Inters8 and our corpus are focused on more implicit forms of sexist hate directed towards a specific woman (i.e., Silvia Romano and Carol Maltesi). Details about all the datasets can be found in Appendix D.

To explore the potential bias of models towards explicit forms of misogyny, we created 4 different models for binary misogyny detection: BERT-Maltesi, BERT-AMI, BERT-PejorativITy and, BERT-Inters8 that were respectively trained on the GBV-Maltesi, AMI, PejorativITy and

[8] AMI is created following an hybrid approach selecting also comments from known misogynistic accounts and responses directed to feminist public figures. We conducted a qualitative analysis and we found that the misogyny contained is almost always explicit and depending on slurs. This lead us to place it in the keyword category.

Model	Maltesi Test		Intes8 Test		PejorativITy Test		AMI Test	
	F1 Macro	F1 1-Label	F1 Macro	F1 1-Label	F1 Macro	F1 1-Label	F1 Macro	F1 1-Label
BERT-Maltesi	**0.611**	**0.351**	0.512	0.174	0.571	0.436	0.633	0.611
BERT-Inters8	0.377	0.169	**0.621**	**0.49**	0.55	0.538	0.659	0.725
BERT-PejorativITy	0.528	0.226	0.483	0.128	**0.67**	**0.604**	0.675	0.732
BERT-AMI	0.494	0.155	0.59	0.299	0.654	0.601	**0.877**	**0.886**
Average	0.502	0.225	0.551	0.273	0.611	0.545	0.711	0.738

Table 1
Results for binary misogyny detection on all datasets

Inters8 datasets. The models were just trained on the comments and were not given any other extra-information such as video transcriptions. The only label we analyzed was **misogyny** and all datasets were divided in training, validation and, test sets following a 60%, 20% and, 20% split. We used the existing splits when provided in the papers[9], else, we randomly created them. All models are binary classifiers created by fine-tuning BERT [30], in particular we used the Italian version AlBERTo [31]. Due to the imbalanced nature of most corpora, the models were trained with a focal loss [32] setting the hyperparameter $\gamma = 2$. Models were trained for 5 epochs but, to avoid overfitting, we implemented an early stopping function which ends training after 2 epochs that report an increase in validation loss. We tested all models on their own test set and the other 3 corpora.

We want to underline that our goal is not to compare performance of the different models between each other as they have different number of training sets and positive examples. Rather, we intend to focus on how different test sets are more difficult compared to others which helps us understand what the current challenges in misogyny detection are.

In Table 1, we reported the positive label and the macro average f1-scores of all experiments. In addition, we also calculated the average scores for each test set. The best scores achieved on a certain test set are in bold, meanwhile, we underlined the best scores for cross-dataset testing. As expected, we can observe that all models had the highest score for their own set. Meanwhile, for cross-dataset testing, we can see that the models that tend to perform the best are BERT-PejorativITy and BERT-AMI. We suspect that this is caused by the dataset composition as their training sets present more positive examples compared to the others.

Interestingly, we can observe that certain models recorded higher scores on other test sets that were not their own. This mostly happens when focusing on BERT-Maltesi and BERT-Inters8, which record higher scores on AMI and PejorativITy. Even PejorativITy increseases its scores when tested on AMI. Observing the average scores for each test, we can see that Maltesi and Inters8 are the most challenging datasets. This is especially true when observing the average f1-score on the positive label with the score being in the [0.2, 0.3] range, compared to much higher scores for PejorativITy and especially AMI. These trends indicate how misogyny detection is a much harder task when considering datasets that contain less explicit forms of hate (e.g., not gathered by keyword search of sexist slurs).

In addition, we conducted a qualitative analysis on the errors of the various classifiers. We found that for each test set most classifiers misclassified the same type of examples. Models almost never recognized texts which contained victim blaming and slut shaming in the GBV-Maltesi Dataset. The errors made on Inters8 mostly coincide with examples that are also racist and Islamophobic. The cases which proved to be more difficult in PejorativITy and AMI contain less explicit animal epithets like "cavalla" and nouns that refers to sex worker in a less explicit way like "cortigiana".

5. Conclusion and Future Works

In this paper, we presented GBV-Maltesi which is the first dataset regarding social reactions to GBV, in particular to a femicide case. The topic was chosen to shed light on the importance of having misogyny corpora that include forms of sexism that are more implicit and complicated to detect compared to the existing ones that focus on slurs and offensive terms. We also focused on the intersectionality aspects to better explore online hate. GBV-Maltesi is composed of 2,934 comments all annotated by 5 annotators and it is available at https://github.com/madeddumarco/GBV-Maltesi. In order to overcome limitations of generic semantic schema, the corpus has been annotated following a new schema specifically created for cases of GBV. In the experimental phase of our work, we created different misogyny binary classifiers and tested them in a cross-dataset way. We found that datasets gathered on keyword collection are easier benchmarks as the model showed bias towards slurs and not identifying more implicit cases of misogyny. This research on online discourse about GBV is not meant to be exhaustive, as several questions are still open.

[9] PejorativITy provides a training and test split, but analyzing the code we found that the test set was used as a validation set so we decided to create a new one.

As future works, we intend to focus on how different framing of news can cause different online reactions, analyzing the differences between video transcripts of femicide news and the comments collected, in terms of words used, implicit references, attributions of guilt and descriptions of the people involved in the story. We also intend to gather more annotated corpora regarding femicides to explore how other characteristics of the victim (e.g., origin or skin color) and time of the murder differently influence the online reactions. In this regard, we intend to explore the question by investigating whether and how the discourse on misogyny changes depending on whether it is addressed to living or dead women (i.e., Giulia Cecchettin femicide and abusive discourse against her sister, Elena Cecchettin). Lastly, we would like to extend our research by following an intersectional approach, considering all the dimensions and characteristics that make up the identity of both victim and perpetrator. To conclude, we strongly advocate the importance of write the news correctly, as this has deep consequences on the readers' perception and the way they talk about it.

Ethics Statement

The dataset was created in accordance with YouTube's Terms of Service. Considering the large number of users writing comments collected in the dataset, it was not possible to explicitly ask for their consent. No sensitive data are provided in the dataset and users' mentions have been anonymized to protect their privacy.

All the annotators involved in this research were free to participate without pressure or obligation. From the initial stages, they were aware of being free to leave at any time without negative consequences. During the annotation phase, we met several times to make sure that the topic did not disturb them psychologically or emotionally. We informed them to take their time, doing the annotation only when they felt like it and to contact us for support. This approach continued for all the research stages.

Acknowledgements

We would like to thank Chiara Zanchi for discussing with us the direction of this work in its early stages. In addition, we would like to thank Sara Gemelli and Andrea Marra for their contribution to the creation of the annotation scheme and guidelines. Also, we reiterate our gratitude to the annotators who professionally worked on a difficult topic like GBV. This work was also partially supported by "HARMONIA" project - M4-C2, I1.3 Partenariati Estesi - Cascade Call - FAIR - CUP C63C22000770006 - PE PE0000013 under the NextGenerationEU programme.

A. Details about the Di Pietrantonio Dataset

The dataset GBV-DiPietrantonio is composed of 691 tweets fully annotated by 3 annotators, 2 of which self-identified as women and 1 as a man. The tweets were collected by gathering responses to news which covered the news of Di Pietrantonio femicide. The annotation scheme is composed of the slightly modified SENTIPOLC scheme[33] which consists of Subjectivity, Polarity (Positive, Negative) and Irony. In addition the semantic grid contained Misogyny, Aggressiveness and Target of Aggressiveness (towards Perpetrator, Victim, Other), Context, and Notes.

The statistics of the gold standard for the Di Pietrantonio dataset are in Table 2.

B. Agreement of the Maltesi Dataset

Table 3 contains the agreement values calcolated with Fleiss' Kappa for all dimensions in the Maltesi dataset.

Dimension	Fleiss' kappa
Misoginy	0.56
Target	0.48
Intersectionality	0.32
Aggressiveness	0.53
Agg. Perpetrator	0.69
Agg. Victim	0.28
Agg. Social Network	0.23
Agg. Media	0.40
Agg. Rape Culture	0.10
Responsibility	0.21
Resp. Perpatrator	0.25
Resp. Victim	0.55
Resp. Social Network	0.13
Resp. Media	0.23
Resp. Rape Culture	0.19
Empathy towards the event	0.69
Humor	0.45
Macabre	0.49
Context	-0.11

Automatic Error Detection: Comparing AI vs. Human Performance on L2 Italian Texts

Irene Fioravanti[1], Luciana Forti[1] and Stefania Spina [1]

[1] *University for Foreigners of Perugia, Piazza Fortebraccio 4, 06123 Perugia, Italy.*

Abstract

This paper reports on a study aimed at comparing AI vs. human performance in detecting and categorising errors in L2 Italian texts. Four LLMs were considered: ChatGPT, Copilot, Gemini and Llama3. Two groups of human annotators were involved: L1 and L2 speakers of Italian. A gold standard set of annotations was developed. A fine-grained annotation scheme was adopted, to reflect the specific traits of Italian morphosyntax, with related potential learner errors. Overall, we found that human annotation outperforms AI, with some degree of variation with respect to specific error types. We interpret this as a possible effect of the over-reliance on English as main language used in NLP tasks. We, thus, support a more widespread consideration of different languages.

Keywords

Error detection, error correction, artificial intelligence, large language models, L2 Italian.

1. Introduction

Identifying errors in texts written by second language (L2) learners is a relevant task in several research areas, which can also have practical applications in a variety of fields. Error analysis is a traditional approach adopted in second language acquisition research for decades (Corder 1967), which learner corpus research has more recently revisited in light of the availability of learner corpora and corpus-based methods of analysis (Dagneaux et al. 1998). In addition, acquisitional research on learners' errors has relevant pedagogical implications involving error-related feedback: appropriate corrective feedback can lead to improved writing skills in both L1 and L2 writing (Biber et al. 2011). Furthermore, automatic error detection and categorisation is key in language testing and assessment research and practice, with reference to automated essay scoring (e.g., Song 2024), which has important implications for rubric descriptors.

The interest of Natural Language Processing (NLP) in grammatical error correction (GEC) and grammatical error detection (GED) relies on the creation of systems used in Intelligent Computer-Assisted Language Learning (ICALL), Automated Essay Scoring (AES) or Automatic Writing Evaluation (AWE) contexts. ICALL systems integrate NLP techniques into CALL platforms, providing learners with flexible and dynamic interactions in their learning process. AES systems automatically grade written texts with machine learning techniques, as well as AWE systems, which also provide learners with feedback.

Identifying and annotating errors in the performance of L2 learners, while beneficial for both pedagogical and research purposes, presents considerable challenges. This process is typically conducted manually in the case of learner corpora due to the inherent nature of errors as latent phenomena. The manual identification of learners' errors requires a substantial degree of subjective judgment by human annotators (Dobrić 2023), as well as a considerable investment in terms of time.

The present study aims to contribute to the evaluation of the performance of Large Language

Models (LLMs) in the task of automatic grammatical error detection (GED) in written texts produced by L2 learners. In particular:

1. it evaluates the behaviour of different LLMs in relation to an error detection task in written texts produced by L2 learners of Italian, a language other than English, in line with recent studies criticising the over-reliance on English in NLP research (Søgaard 2022) and seeking to contribute to the very few studies that do consider languages other English (e.g., MultiGED-2023; Volodina et a. 2023);
2. it targets specific error types and grammatical categories in order to mitigate the problems arising from the broadness of the notion of error, focusing on clear-cut and possibly unambiguous error categories;
3. it relies on a high degree of accuracy in error annotation, which was manually performed by three researchers on a small learner dataset serving as the test set on which the systems are evaluated;
4. it assesses the performance of LLMs in error detection and categorisation, through a comparison with the performance of native Italian students and advanced learners of L2 Italian on the same task.

2. Related works

Research on automatic error detection in L2 written texts, mainly adopting machine learning approaches, has significantly developed in recent years (Bryant et al. 2023), especially within the framework of shared tasks focused on GED and GEC. For instance, Di Nuovo et al. (2019; 2022) implemented a novel Italian treebank which includes texts written by learners of Italian. An annotation scheme suitable for L2 production was proposed encompassing UD and error annotation.

The CoNLL-2014 Shared Task on Grammatical Error Correction (Ng et al. 2014) was based on the identification of 28 error types involving major grammatical categories as well as spelling and punctuation errors. The test set consisted of 50 essays on two different topics, written by 25 learners of L2 English, that were error-annotated by two native speakers. The BEA Grammatical Error Correction shared task (Bryant et al. 2019) used a larger dataset (350 essays written by 334 learners and native speakers of English) and a similar taxonomy consisting of 25 error types. More recently, the NLP4CALL shared task on Multilingual Grammatical Error Detection (MultiGED-2023; Volodina et al. 2023) was the first multilingual shared task including four languages in addition to English: Czech, German, Italian and Swedish. The datasets used for the task varied across languages: the Italian dataset consisted of 813 written learner texts. Participants mainly used systems based on pre-trained LLMs.

A recent study by Kruijsbergen et al. (2024) focused on L1 and L2 Dutch and explored the capabilities of LLMs in written error detection, with both a fine-tuning and a zero-shot approach through prompting a generative language model (GPT-3.5). Results highlight that the fine-tuning approach largely outperforms zero-shotting, both for L1 and L2.

3. Method

To evaluate AI performance in automatic GED on L2 written texts, we designed our study based on the following stages: selection of the text sample; error type identification; definition of the gold standard (henceforth, GS); evaluation of LLMs' annotations; comparison between LLMs and human performance.

3.1. Sample texts

We used authentic L2 data derived from a learner corpus of Italian, the CELI corpus (Spina et al., 2022; Spina et al., 2024). It is a pseudo-longitudinal corpus of L2 Italian, representative of written Italian produced by intermediate and advanced learners. The CELI corpus is made of four subcorpora, one for each proficiency level (B1; B2; C1; C2) equally designed in terms of tokens. Eleven texts were randomly selected from the B1 subcorpus, of the total size of 1,335 tokens. We focused on morphosyntactic errors only. We chose to extract our texts from the B1 level, assuming they would be characterised by a higher number of morphosyntactic errors compared to higher proficiency levels. To make the annotation task easier, we divided each text into sentences. Details about the sentences' sample can be found in Table 1.

Total number of sentences	67
Average and range of sentences' length (in tokens)	79; 29-143
Range of number of sentences in each text	5-7

Table 1. Description of the sentences' sample.

3.2. Error type identification

Contrary to previous study (Ng et al. 2014; Bryant et al. 2019) that employed a broad notion of error, we focused only on specific morphosyntactic errors (selection (S), addiction (A), omission (O), ending (E)) within four Parts of Speech (PoS; articles (A), prepositions (P), nouns (N), verbs (V)), for a total of eight error types (Table 1). This choice was due to the fact that Italian is a morphologically rich language, and that the four selected grammatical categories are a frequent source of errors for learners.

Type	PoS	Description	Example
AS	article	selection of the wrong article	_In montagna ci sono *_**_i_** _alberi._
AA	article	unnecessary use of the article	_Ho fatto *_**_la_** _fatica a salire le scale._
AO	article	absence of the article although necessary	_Maria ha fatto * compiti ieri._
NE	noun	incorrect ending of the noun	_Ho comprato tre *_**_mela_**_._
VE	verb	incorrect ending of the verb	_Ieri Luca *_**_andavo_** _in spiaggia._
PS	preposition	selection of the wrong preposition	_Domani parto *_**_a_** _Roma._
PA	preposition	unnecessary use of the preposition	_Ho comprato *_**_a_** _un libro._
PO	preposition	absence of the preposition although necessary	_Anna è andata * casa._

Table 1. Description of the eight error types.

3.3. Annotation

The outputs of the four LLMs were compared to a benchmark (GS) obtained from the annotation of three researchers. Three Italian trained linguists (i.e., the three authors of this paper) manually annotated the sample texts. The three researchers annotated only the error types described above. Initially there was a substantial agreement between the three linguists (k = 0.61). The three annotators disagreed mostly on the PA error (k = 0.39). Any inter-annotator disagreements were resolved through negotiation until a partial agreement (i.e., two annotators out of three) was reached. The agreement turned out to be improved (k = 0.81). Then, all the remaining disagreements (i.e., the cases that reach a partial agreement) were resolved reaching a perfect annotator agreement prioritising the two annotators' decision over the third one (k = 1). In the GS, 47 grammatical errors were identified with an average of 4 errors per text, while no errors were found in 32 sentences. On average, each sentence contained 2 errors.

3.3.1. LLMs

ChatGPT-4o (July 2024 version), Copilot, Gemini and Llama3 were evaluated. Several steps were followed to arrive at the final prompt, which can be found in Appendix A. We started giving the prompt in Italian and presenting all the texts together. However, the four LLMs, which were not pre-trained, were able to find a small number of errors. We, then, proposed the prompt in Italian again, repeating the instructions for each text. In this case, the LLMs identified types of errors that were not required. Following the recommendations from Kruijsbergen et al. (2024) on the prompt's language, the entire prompt was then given in English. The performance improved as a greater number of errors were identified, but still types of errors that were not required. Therefore, we gave a more detailed prompt in English following the recommendation of Coyne et al. (2023). Definitions of the four Italian PoS were provided. Further, we listed the eight error types with descriptions and examples. The texts were presented in numbered sentences. LLMs were instructed to classify each detected error and were informed that there could be more than one error in a sentence as well as no errors at all. The entire prompt was repeated for each text. This last version of the prompt was used for this study. Subsequently, we calculated the inter-annotator agreement between the four LLMs, which resulted to be weak (k = 0.21).

3.3.2. Human annotator groups

LLMs' performance was also compared to two human groups. Twenty-two L1 (age range: 19-50) and Twenty-seven L2 speakers (age range: 22-40) of Italian took part in the annotation task. They were undergraduate and postgraduate students in humanities and social studies. They were asked to annotate only the error types described above, with definition and examples provided for each type of error. They were also asked to report the incorrect form and to provide the correct one. Then, we calculated the inter-annotator agreement between the raters of the two groups. L1 speakers reached a good agreement (k = 0.52), while the agreement between L2 speakers was poor (k = 0.33).

4. Evaluation

Four measures were used to compare the performance of LLMs and human annotators in detecting errors: Accuracy, Precision (P), Recall (R) and F-score (F_β). Accuracy was calculated by dividing the number of correctly identified errors by the total number of annotated errors. To be consistent with previous works in GED (Volodina et al. 2023), F-score was set to 0.5 given that it weights P twice as much as R (i.e., it is more important that a system makes a correct prediction, than being able to detect all errors).

4.1. Overall error detection

Gemini outperformed the other three systems, demonstrating the highest accuracy (65,52%). In contrast, Llama 3 turned out to be less accurate in comparison to the others (51,72%). ChatGPT and Copilot behaved similarly in terms of accuracy (57,47%). LLMs were less accurate than human groups in detecting errors, as L1 and L2 speakers reached much higher values of accuracy (89,66% and 78,16% respectively).

When looking at AI performance, Copilot and Llama3 showed worse P than ChatGPT and Gemini, indicating that they had low ability in detecting true error instances. Conversely, Gemini and Copilot were able to detect a higher number of errors compared to ChatGPT and Llama3. ChatGPT made the best predictions, while Gemini had better R. Human groups outperformed AI systems for R, P, and F-score (Table 2). L1 speakers were able to detect almost all errors and to make correct predictions. On the contrary, L2 speakers had better P and worse R, suggesting they had lowest number of FP but a reduced ability to detect TP.

Figure 1 shows the performance of each group in terms of P and R.

	P (%)	R (%)	$F_{ß}$
ChatGPT	65.22	58.82	63.83
Copilot	34.78	69.56	66.75
Gemini	58.69	71.05	60.81
Llama3	45.65	55.26	47.29
L1	93.02	89.96	92.39
L2	93.55	63.04	85.29

Table 2. Groups' performance in the detection of the overall errors.

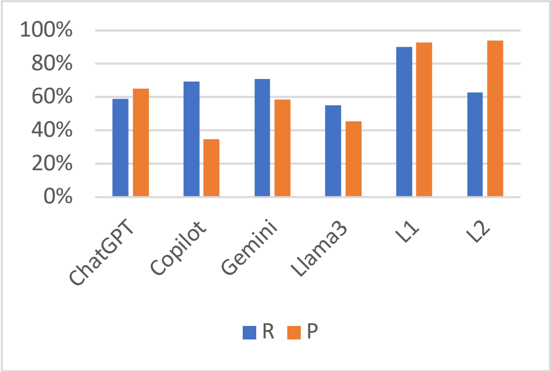

Figure 1. R and P for each group in the detection of overall errors.

4.2. Error type detection

To examine thoroughly the performance of the LLMs in GED, we calculated R, P and F-score metrics for each of the eight error types (Table 3).

Error type	P(%)	R(%)	$F_{ß}$ (%)
ChatGPT			
AO	50	100	55.56

PA	100	50	83.33
PS	100	47.06	81.63

Table 3. Human vs. AI in detecting different error types.

Copilot, Gemini, and Llama3 failed to detect various error types exhibiting a high number of FP without detecting true instances. Copilot showed a fair prediction of VE and PS errors. Gemini had better R and P in detecting and correctly predicting AO and VE errors. However, it performed worse on PS errors in terms of both P and R. Llama3 was able to predict AS, VE, and PS errors but showing low values of R. ChatGPT turned out to be the best in predicting all error types, except for the AA error. ChatGPT showed high values of P in the prediction of AO, PA, and PO errors and showed low values of P and R for PS errors.

Human groups performed better than LLMs in detecting each error type. L1 speakers exhibited high values of R and P in detecting all error types but performed less well in making correct predictions on PS errors. L2 speakers demonstrated better R and P in detecting AO and AS errors. Conversely, they were unable to identify all AA errors. Furthermore, they showed a reduced ability in detecting all PO errors and in predicting them correctly.

5. Discussion and conclusion

The main aim of our paper was to investigate whether AI can be a valid support for second language acquisition research, in learner error detection, with specific reference to a language other than English, i.e., Italian. Our study compared the performance of four LLMs among them and also compared with L1 and L2 annotators. A GS, produced by the annotations of three trained linguists, was adopted as benchmark. Given the richness of Italian morphosyntax and the variety of possible morphosyntactic errors that L2 Italian learners may produce, contrary to the few other studies on Italian, this study considered three different error types for two of the parts of speech listed in Table 1, i.e. article and preposition. This methodological novelty can potentially lead to much more fine-grained results, while counterbalancing, like in our case, the low number of annotated texts.

The general finding about human annotators performing better than LLMs, both in terms of overall error detection and in terms of error type detection, is particularly significant if we consider the structural differences between English and other languages. Italian, like many other languages, is characterised by rich morphosyntatic traits, which inevitably have a considerable impact on the computational processing of L1 and L2 texts. Our findings may thus be a reflection of the well-known language bias in NLP, linked to the dominance of English, which then leads to a number of scientific but also social inequalities (Søgaard 2022; Volodina et al. 2023). Repeating the study with pre-trained LLMs might improve their performance. At present, pivotal tasks such as automatic error detection and classification, performed on a morphologically rich language such as Italian, does not seem to be viable with LLMs, as they do not add effectiveness to the same task performed manually.Future developments of this study may also include fine-tuned models, which are generally indicated as potentially better-performing than non-tuned ones (Kruijsbergen et al. 2024), as well as an increased number of annotated texts and an even more fine-grained and extended error annotation scheme. Automatic error detection and classification can be crucial for both the development of online language assessment systems and for second language acquisition research as a whole. This is especially true for languages other than English, which continue to be severely under-represented in all domains of language sciences, including NLP.

Acknowledgements

This study was conducted in the context of *CARLA – Corpus Approaches to Research on Language*, a research group affiliated with the Department of Italian language, literature and arts in the world (University for Foreigners of Perugia, Italy).

Appendix A

The Prompt

In this task, we present a text in Italian, produced by a learner of L2 Italian at B1 proficiency level.

The text is numbered and divided into numbered sentences. For each sentence, you will have to identify specific errors, if any.

The errors considered in this task involve articles (in Italian "il, lo, la, i, gli, le, un, uno, una"), prepositions (in Italian "di, a, da, in, con, su, per, tra, fra", in their simple forms or associated with articles "del, dalla, negli, etc.", nouns, and verbs).

For each error, you will have to indicate the type, which you can choose from the following list:

1a: Article addition: the learner has added an article where it was not necessary (e.g. "Ho fatto la fatica a salire le scale": "la" should not have been used);

1b: Article omission: the learner did not use the article even though it was necessary (e.g. "Maria ha fatto compromesso con il suo capo": "un" should have been used before "compromesso");

1c: Article choice: the learner used the wrong article (e.g. "In montagna ci sono i alberi sempreverdi": "i" is wrong, the correct article is "gli");

2: Verb ending: the verb ending is incorrect (e.g. "Ieri Luca andavo al mare": "andavo" has the wrong ending "o", the correct one is "a" --> "andava");

3: Noun ending: the noun ending is incorrect (e.g. "Ho comprato tre mela gialle": "mela" has the wrong ending "a", the correct one is "e" --> "mele");

4a: Preposition addition: the learner added a preposition where it was not necessary (e.g. "Ho comprato a un libro": "a" should not have been used);

4b: Preposition omission: the learner did not use a preposition even though it was necessary (e.g. "Anna Ë andata casa": the preposition "a" is missing before "casa");

4c: Preposition choice: the learner used the wrong preposition (e.g. "Questo Ë il libro a mio professore": "a" is wrong, the right preposition was "del").

It is possible that there is more than one error in a sentence, but also that there are no errors at all.

If you find no errors, do not indicate anything and move on to the next sentence.

Here is the text with the numbered sentences.

Explainability for Speech Models: On the Challenges of Acoustic Feature Selection

Dennis Fucci[1,2], Beatrice Savoldi[2], Marco Gaido[2], Matteo Negri[2], Mauro Cettolo[2] and Luisa Bentivogli[2]

Abstract

Spurred by the demand for transparency and interpretability in Artificial Intelligence (AI), the field of eXplainable AI (XAI) has experienced significant growth, marked by both theoretical reflections and technical advancements. While various XAI techniques, especially feature attribution methods, have been extensively explored across diverse tasks, their adaptation for the *speech* modality is comparatively lagging behind. We argue that a key challenge in feature attribution for speech processing lies in identifying informative acoustic features. In this paper, we discuss the key challenges in selecting the features for speech explanations. Also, in light of existing research, we highlight current gaps and propose future avenues to enhance the depth and informativeness of explanations for speech.

Keywords

Speech Models, Explainability, Feature Attribution

1. Introduction

> *Models are only as interpretable as their features.* [1]

Spoken language—as perhaps our most natural form of interaction—is the foundational element of many technologies we interact with in our daily lives [2], from virtual assistants to voice dictation [3, 4, 5]. More recently, the emergence of highly capable speech foundation models [6, 7, 8, 9] has also facilitated and expanded the adoption of speech technologies on an unprecedented multilingual scale. In light of this proliferation, a need arises to prioritize transparency and interpretability, qualities already demanded in the growing landscape of Machine Learning (ML).

As a response, the field of eXplainable AI (XAI) has risen prominently, with the aim of facilitating understanding of the rationale behind model decisions and fostering users' trust [10, 11, 12, 13]. XAI is also reinforced by the establishment of norms and legal frameworks, as seen in the European Union's General Data Protection Regulation, which enshrines the 'right to explanation', and the AI Act, which emphasizes transparency as a pivotal component of ML applications [14].

XAI encompasses various tasks and methods, such as identifying relevant model components for specific predictions, understanding the information processed by these components, and determining which input elements guide the model's predictions [15]. The latter task is the focus of *feature attribution* methods, which provide intuitive explanations by visualizing which input elements (e.g., pixels in an image or words in a sentence) have influenced the model's predictions. These methods assign a score to each input feature, quantifying its importance or contribution to the output: higher scores indicate greater importance of the corresponding input features for generating the output [16, 17, 18, 19]. They can help identify potential causes for errors and unexpected behaviors, as well as analyze the model's response to specific input properties. Overall, these explainability methods serve to present the reason why models make specific predictions by establishing a connection between input and output as a form of intuitive explanation for humans, thereby enhancing interpretability.[1]

Over time, ongoing efforts have aimed to refine feature attribution techniques and provide more effective explanations [22, 23]. However, it is essential to recognize that the effectiveness of feature attribution explanations relies not only on the techniques themselves but also on the informativeness of the input features used as explanatory variables. If an explanation highlights unintelligible or poorly informative features, it does little to enhance the understanding of the model's behavior

[1] Despite numerous efforts to differentiate the closely related concepts of explainability and interpretability, no consensus exists in the literature on their definitions [20]. In this paper, we adopt a perspective similar to that of Saeed and Omlin [21], where *explainability* refers to the process of extracting insights from a model's workings through specific techniques, while *interpretability* refers to the understanding process of those insights, crucial to make them actionable.

[1]. This can undermine key principles in XAI, such as *accuracy*—the property of correctly reflecting the factors that led the model to a specific decision including all relevant information—and *meaningfulness*—the property of offering explanations that are comprehensible to the user [24].[2]

In fields involving images or texts, feature representations are typically constrained to pixels and words, respectively. However, for speech, multiple input representations can be adopted, each emphasizing different acoustic aspects. Indeed, a sequence of speech elements does not only convey the meaning of what is said (like words in a text) but also bears a wealth of additional information useful for both human understanding and automatic processing (e.g. intonation, loudness, speaking rate). Consequently, when employing feature attribution methods, the resulting explanations can vary significantly in shape and focus on more or less informative characteristics depending on the type of speech representation used. To date, research on feature attribution for speech is notably limited to few applications—including classification [27, 28] and generative tasks [29, 30, 31, 32]—which offer a somewhat fragmented picture in the choice of speech representations, thus providing limited insights on the relation between the features considered and the explanations based upon them.

In light of the above, this paper reflects on the impact of the chosen acoustic features in explaining the rationale behind speech models, aiming to gain a deeper understanding of the trade-offs associated with acoustic features. By first offering a gentle introduction to the rich and multidimensional nature of speech and its digital representation, we identify current gaps and potential avenues for effectively incorporating this multidimensionality into XAI for speech models. Our discussion will focus on two critical factors: i) the amount of information these features provide about the model's behavior, which influences the *richness* of the explanations, and ii) the level of detail of such information, which determines the *granularity* of the explanations. We will also explore how these aspects impact both the accuracy and meaningfulness of the explanations, ultimately shaping their overall interpretability.

2. The Correlates of Speech

To gain deeper insight into the complexities of defining informative features in speech, we explore key characteristics of speech and their implications for modeling.

Speech is a multifaceted phenomenon. It is grounded on the materiality of sound to convey linguistic content (i.e. *what is said*), which is modulated depending on several paralinguistic cues (i.e. *how is said*) entailing extensive variation—also for single individual speakers [33]. As such, it comprises several dimensions, which are hard to pin down individually, but collectively amount to what we intuitively and simply perceive as spoken language.

From a linguistic perspective, the spoken communication system consists of the combination of phonemes,[3] which are regarded as the smallest meaningful units of sounds [34, 35]. Physically, it involves the continuous flow of sounds shaped by the movements of our phonatory organs, transmitted as sound waves [36]. Perceptually, we process speech through three primary dimensions [37]: *i)* ***time***, or the sequential occurrence of sounds;[4] *ii)* ***intensity***, corresponding to the energy level of the wave due to the strength of molecular vibration, which we perceived as loudness; *iii)* ***frequency***, regarding the rate of vibrations produced by the vocal cords—interpreted as pitch—and whose modulation is responsible for shaping the type of speech sound.

These three elements, known as *acoustic correlates* [38], are specific to both speakers and phonemes. For example, speakers possess unique characteristics, including pitch and speaking rate [33], and also exhibit high variability stemming from various sociodemographic factors such as gender, age, and dialect [39]. In these cases, the speech content needs to be disentangled from the variability in its delivery. Conversely, language sounds exhibit variability in duration—e.g., /i/ in *ship* and *sheep*—and are distinguished by specific frequency ranges [36]. The frequency dimension also plays a vital role in shaping suprasegmental aspects of speech—broader phenomena that span multiple segments—such as intonation, obtained by varying pitch [40]. Pitch, for instance, has a distinctive function in tonal languages, where it is used to distinguish lexical or grammatical meaning [41]. But even in non-tonal languages, these prosodic elements are indispensable to delivering different meanings and intents, as the reader can perceive by reading out loud two contrastive sentences such as: "*You got the joke right*" and "*You got the joke, right?*", where pauses and prosody play pivotal roles.

All these factors add to the multidimensionality of speech, which feature engineering strives to encapsulate and that cannot be overlooked in the explanatory process.

3. Speech Representations

While various representations are used to encode speech in a digital format, three main types are commonly given

[2] The properties of *accuracy* and *meaningfulness* can be associated with those of *faithfulness* and *plausibility*, respectively [25, 26].

[3] Throughout the paper, we use the abstract category of *phoneme* to denote individual speech sounds. However, when discussing their actual realizations, it is more accurate to refer to them as *phones* [34].

[4] E.g. the order of sounds between /pɑt/ (*pot*) or /tɑp/ (*top*) differentiates two words.

as input to state-of-the-art speech models (for a review, see [42, 43]). Namely, waveforms, spectrograms, and mel-frequency cepstral coefficients (MFCCs), which are shown in Figure 1.

The ***waveform*** serves as the most fundamental representation of a signal, comprising sequences of samples (e.g., $16,000$ per second), each indicating the amplitude of the signal at a specific point in time—essentially, the fluctuations in air pressure over time. This type of representation is leveraged by models like Wav2vec [6].

The ***spectrogram*** results from feature engineering operations that decompose the speech signal into its frequencies, presenting a 2D visualization of frequency distributions over time. These representations are commonly depicted as heatmaps, where color intensity corresponds to the energy of a specific frequency at a given moment. The time unit in spectrograms is represented by a fixed-length window of a few milliseconds (e.g., 25), commonly referred to as a frame, whithin which a given number of waveform samples are encompassed. Notably, the articulation of sounds produces time-frequency patterns which are visible as darker regions [36]. Prominent examples of state-of-the-art models leveraging spectrograms are Whisper [9] and SeamlessM4T [44].

The ***MFCCs*** offer another 2D representation where each coefficient captures important details about how the frequency content of the signal changes over time. Like spectrograms, MFCCs offer information about both frequency and time, but in a more compact form. MFCCs are commonly used in the implementation of ASR models within popular toolkits like Kaldi[5] [45] and Mozilla DeepSpeech[6].

Overall, though different in nature, these three types of representations are all effectively exploited by current speech models.[7] For human understanding, however, they actually vary in terms of informativeness with respect to the acoustic correlates discussed in §2. Indeed, although both intensity and frequency are somewhat discernible in waveforms, qualitative distinctions of patterns specific to pitch or phoneme frequencies are rarely feasible [36]. Comparatively, spectrograms and MFCCs are richer and more descriptive, because they capture the multiple dimensions of time, frequency, and intensity with finer detail. Still, spectrograms are more conducive to phonetic analyses, given the established knowledge in analyzing frequency patterns over time within this representation [36] In contrast, MFCCs are rarely used for phonetic analysis [46].

Overall, while weighting the informativeness and selection of speech representations requires a certain expertise in speech processing, being aware of the trade-offs they intrinsically entail is crucial for carefully conducting XAI examination in speech. Indeed, it is precisely upon such input features—and their trade-offs—that explanations are built.

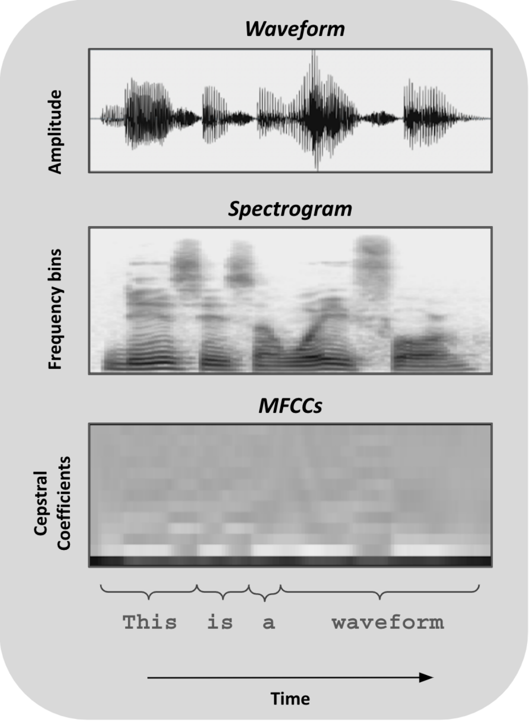

Figure 1: Schematic illustration of the primary speech representations used by state-of-the-art speech models for the utterance “This is a waveform”. The features were computed using Librosa 0.10.1 [47].

4. Richness of Explanations

Considering the foregoing, there is a causal relationship wherein explanatory possibilities in speech XAI are inherently limited by the richness of the audio features used, specifically the dimensions they encapsulate. This limitation directly correlates with the richness of the resulting explanations. Also, owing to the compatibility of current models with various representation types, the explanations generated are inevitably confined by the specific input features provided to the model. To exemplify, if models process audio as waverfoms—which poorly represent the frequency dimension for human understanding—explanations accounting for such a correlate will be out of reach. In fact, previous works by Wu et al. [31] and Wu et al. [32], based on waveforms solely focus on the temporal dimension to explain ASR.

[5] See https://kaldi-asr.org/doc/feat.html.

[6] See https://deepspeech.readthedocs.io/en/master/DeepSpeech.html.

[7] We are not aware of any recent study attributing higher systems performance depending on the used representation.

In these cases, to avoid limiting the understanding of the models' behavior to one single dimension it would be advisable to ***explore alternative techniques that offer deeper insights into how models process other acoustic correlates.*** For instance, Pastor et al. [28] integrated counterfactual explanations to specifically investigate whether selected paralinguistic features such as pitch, speaking rate, and background noise were influent for the model's prediction. Additionally, various techniques exist to analyze how models extract relevant patterns from waveforms through convolutions [48, 49, 50].

When the selected input features represent multiple dimensions, as in the case of spectrograms or MFCCs, the decision to only account for one of these dimensions becomes arbitrary. For example, two models tested by Wu et al. [31], namely, DeepSpeech [51] and Sphinx [52], are fed with spectrograms and MFCCs, respectively. However, explanations based on raw waveforms are provided for these models. This inconsistency between the features used in explanations and those used by the models inevitably offers only a partial overview of the models' behavior and limits the exploration of important acoustic aspects. This, in turn, can impact the accuracy of the explanations, which ideally should encompass all relevant information.

To prioritize explanation accuracy and conduct analyses considering the crucial role of acoustic correlates such as frequency, it is advisable to ***take into account all dimensions embedded in the speech representation***. This approach is exemplified by the works of Markert et al. [30], who provide explanations that account for the most influential elements in MFCCs, as well as Trinh and Mandel [29] and Becker et al. [27], who base the explanations on spectrograms. In the work by Markert et al. [30], however, it is challenging to connect the results with specific acoustic parameters due to the complexity of analyzing MFCCs (see §3), which significantly undermines the meaningfulness of the explanations. In contrast, explanations using spectrograms offer valuable insights into how machines process speech, producing both accurate and meaningful results. For instance, Trinh and Mandel [29] demonstrated that neural ASR models focus on high-energy time-frequency regions for transcription, while Becker et al. [27] found that lower frequency ranges, typically associated with pitch, exhibit higher attribution scores in speaker gender classification tasks [27], showing some alignment with human speech processing. However, interpreting these insights requires specialized expertise, which can reduce the meaningfulness of explanations for non-experts. This highlights that, even in speech, the balance between accuracy and meaningfulness can vary depending on the context [24].

5. Granularity of Explanations

Another critical factor concerning the informativeness of input features is the level of granularity at which the features are considered during the explanatory process. This decision affects the level of detail in the resulting explanations and, consequently, accuracy—as more detailed explanations may more accurately reflect the model's behavior—and their meaningfulness—as detailed and comprehensive explanations can be more difficult to interpret [12, 24].

In the time domain, for example, input features are highly fine-grained. As discussed in §2, spectrograms typically contain frames spanning tens of milliseconds, capturing detailed frequency content within each frame, whereas waveforms are composed of samples taken at much shorter time intervals—for instance, as mentioned in §2, there can be $16,000$ samples in just one second. This level of detail poses great challenges for (human) comprehension, particularly for a broader audience, since mapping groups of frames/samples in an explanation to recognizable speech units is highly time-consuming and requires specialized expertise.

Accordingly, to address the issue and make explanations for speech more broadly accessible, previous works have leveraged textual transcripts within the explanation process. More specifically, Wu et al. [32] and Pastor et al. [28] resort to the alignment of audio to text, either for individual phonemes or words, respectively, and apply explainability techniques to such units. While this approach helps decipher the contribution of input features based on more intuitive linguistic units, it diverges from how current models process speech features in small frames and samples [43]. This divergence risks overlooking the model's behavior and compromises the accuracy and effectiveness of the explanations. For instance, whether ASR systems rely on shorter or longer time intervals than individual words remains unclear [29]. Therefore, analyzing this aspect requires a more granular approach at the time level.

In light of the above, ***explanations should be obtained with low-level units*** to avoid biasing explanations towards human understanding. The use of audio-transcript alignment to aid analysis of explanations can be very useful but should occur downstream of the explanation process, not upstream. In this way, we can maximize the use of all available units to generate detailed and accurate explanations, and then aggregate scores from individual frames or samples to create more compact representations at the level of phonemes or words, ensuring flexibility in the meaningfulness of the explanations according to specific needs. This bottom-up approach mirrors practices in the text domain, providing adaptability in defining attribution units that can range from subwords to words or phrases [53, 54].

6. Conclusion

This paper has examined the role of acoustic features and their selection for explaining speech models. More specifically, we considered a specific subfield of XAI, namely, *feature attribution*, which connects input features to outputs as a form of explanation. Previous research has not explicitly addressed how to incorporate features into the explanation process within the speech domain, where input is encoded in more varied ways compared to other fields, such as text. This has led to diverse approaches, each with different implications for what can and cannot be explained about model behavior, and with the risk of not fully or accurately representing the model's functioning.

By discussing the key characteristics of speech and the properties of the most adopted acoustic features, we argue that explanations should ideally encompass all available dimensions, particularly time and frequency, as both are essential for a comprehensive understanding of the models' rationale. We have also discussed challenges associated with aligning explanations at high granularity with human understanding, emphasizing solutions that provide flexibility in the analysis, allowing for adjustments between more or less detail as needed.

Building on these insights, our ongoing research focuses on developing feature attribution techniques that operate on spectrograms at the finest possible unit level, integrating both time and frequency dimensions. Our aim is to generate explanations that are accurate and meaningful for experts, as well as adaptable for non-expert users. More broadly, we hope that our reflections will be beneficial and thought-provoking for researchers currently working in, or entering, the field of XAI for speech models, thereby contributing to a deeper understanding of the rationale behind these models.

7. Limitations

While exploring the relationship between the informativeness of speech features and explanations, we have deliberately not delved into the needs of specific stakeholders for XAI applications. Indeed, different stakeholders present varying needs [55, 56], and to consider them is a research avenue of paramount importance for the growth of XAI. As a nascent area of investigations, however, XAI for speech is still relatively in its infancy, we thus prioritized more fundamental methodological and design decisions which prioritize a comprehensive and detailed understanding at a low level of model's rationale. Accordingly, our reflections might be more appealing for a range of users who engage with speech models and possess expertise in machine learning and/or speech analysis, ranging from developers to speech therapists assisted by speech models [56].

The balance of richness and granularity—which also relates to the interplay between accuracy and meaningfulness—is also relevant to common users who interact with speech technologies. However, investigating how explanations can be effectively communicated to and understood by these users in the context of daily speech technology use exceeds the scope of this paper and warrants further exploration.

8. Acknowledgments

We acknowledge the support of the PNRR project FAIR - Future AI Research (PE00000013), under the NRRP MUR program funded by the NextGenerationEU. This paper has also received funding from the European Union's Horizon research and innovation programme under grant agreement No 101135798, project Meetween (My Personal AI Mediator for Virtual MEETtings BetWEEN People).

Abstract

Here we discuss strategies and results of a small-sized training program based on Italian child-directed speech (less than 3M tokens) for various network architectures. The rationale behind these experiments [1] lies in the attempt to understand the effect of this naturalistic training diet on different models' architecture. Preliminary findings lead us to conclude that: (i) different tokenization strategies produce mildly significant improvements overall, although segmentation aligns more closely with linguistic intuitions in some cases, but not in others; (ii) modified LSTM networks (eMG-RNN variant) with a single layer and a structurally more controlled cell state perform slightly worse in training loss (compared to standard one- and two-layered LSTM models) but better on linguistically critical contrasts. This suggests that standard loss/accuracy metrics in autoregressive training procedures are linguistically irrelevant and, more generally, misleading since the best-trained models produce poorer linguistic predictions ([2], pace [3]). Overall, the performance of these models remains significantly lower compared to that of 7-year-old native-speaker children in the relevant linguistic contrasts we considered [4].

1

1. Introduction

According to the mainstream LLM development pipeline, Transformer-based architectures [5] outperform sequential training models, like LSTM [6], in various NLP tasks. When small-sized training data are available, optimization becomes necessary [7], [8], but common optimization techniques neglect the linguistically relevant fact that these models (i) conflate semantic/world knowledge with morpho-syntactic competence, (ii) require unreasonable training data compared to that needed by children during language acquisition, (iii) the higher their performance, the lower their return in cognitive/linguistic terms [9]. In this paper we address these three issues, starting from the observation that while world knowledge uses all training data available, and the more the better, structural (morpho-syntactic and compositional semantic) knowledge might require a much smaller dataset (from 10 to 100 million words, according to [10]). We explore this intuition further and, based on prolific literature from the ‘80s showing that typical child errors are structurally sensitive and never random [11], we model networks' architecture to bias learning towards plausible structural configurations, possibly preventing these "small" language models (SLM) from producing wrong linguistic generalizations. We started from a mild revision of the LM training and evaluation pipeline for Italian including alternative approaches to tokenization based on pseudo-morphological decomposition (§2.2); we then approached a more structurally-driven update

of the cell state in LSTM networks, which we will call eMG-RNN variants (§2.3); we finally adopted a precise testing benchmark for specific linguistic contrasts in Italian following BLiMP design [12] (§2.4). We will first set the stage in section (§2) and discuss one alternative tokenization strategy (MorPiece). A simple modification to the gating system in LSTM is proposed that mimics certain linguistic constraints. Then, we will describe the relevant experiments we have run (§3) and draw some conclusions based on the observed results (§4). A general discussion with a description of the next steps will conclude this paper (§5).

2. Revisiting LM training pipeline

LM training pipeline is relatively rigid: after corpus cleaning (i), the data are prepared/optimized for tokenization (ii), then the tokenized input is batched for training autoregressive models (iii), mostly feeding transformer-based architectures (iv). Once the models are trained, the evaluation step requires their assessment using some standard tasks (v). In the next sub-sections, we will identify various criticalities in this pipeline, eventually proposing strategies to mitigate these problems and, in the end, training linguistically more informative SLM.

2.1. Corpus creation and cleaning

The primary data we collected for Italian replicates plausible linguistic input that children may be exposed to during acquisition, in line with [1]. It consists of about 3M tokens divided into child-directed speech (CHILDES Italian section), child movie subtitles (from OpenSubtitles), child songs (from Zecchino D'Oro repository), telephone conversations (VoLIP corpus, [13]), and fairy tales (all from copyright expired sources). Simple cleaning consisted of removing children's productions from CHILDES files as well as any other metalinguistic annotation (speakers' identification, headers, time stamps, tags, links, etc.). Dimension and rough lexical richness of each section are reported in Table 1 (Type-Token Ratio, TTR) before and after the cleaning procedure.

Table 1
Corpus profiling before (bc) and after (ac) cleaning.

Section	tokens bc	tokens ac	TTR
Childes	405892	346155	0.03
Subtitles	959026	700729	0.05
Conversations	80826	58039	0.11
Songs	240309	222572	0.08
Fairy tales	1103543	1287826	0.05
Total	2973879	2431038	0.03

2.2. Tokenization: MorPiece (MoP)

Popular vLLMs use either Byte-Pair Encoding (BPE) [14], [15] or (fast)WordPiece (fWP) [16] algorithms for tokenization. The simplicity and computational efficiency of these approaches contrast with the limited morphological analysis they provide. In rich inflectional languages (e.g., Italian) and agglutinative languages (e.g., Finnish), this might induce linguistically unsound generalizations. Here, we explore a more morphologically informed strategy, inspired by the Tolerance Principle (TP) and Sufficiency Principle (SP) [17], aiming to break words into potentially relevant morphemes without relying on morpheme tables [18]. The experiments we conduct compare the impact of different strategies when integrated into various network architectures. We refer to *MorPiece* (*MoP*) as a TP/SP-based strategy, which can be algorithmically described as follows: each token is traversed from left to right to create a "root trie," and from right to left to create an "inflectional trie" [19]. Each time a node *N* of the trie is traversed (corresponding to the current character path in the word), the frequency counter associated with this node (N_c) is updated (+1). Nodes corresponding to token endings (characters before white spaces or punctuation) are flagged. Once both tries are created, the optimization procedure explores each descendant, and for every daughter node D_k its frequency *k* is compared to H_N, the approximation of the harmonic number for *N* used both in TP and SP [17], where *c* is the frequency of the mother node N_c:

$$H_N = c/ln(c) \qquad \text{(F1)}$$

If $k > H_N$ and $c \neq k$, a productive boundary break is postulated (based on the inference that since there are different continuations and some of them are productive, i.e. sufficiently frequent according to SP, those might be real independent morphemes). We can check if this break respects H_D for the relevant nodes D_j and N_i in the "inflectional trie". This means there exists a path where the frequency *i* of the daughter node N_i (in the "inflectional trie" the dependency between D and N is reversed) is lower than *j/ln(j)*, where *j* is the frequency of the mother node D_j. If this is the case, the continuation is not considered "an exception", in the sense of TP [17], suggesting that the continuation is, in fact, a productive independent morpheme. A "++" root node is then activated, the node D_k linked to it, and so on recursively, following the FastWordPiece tokenization strategy [20]. During recognition, the LinMaxMatch identification approach is adopted, as in FastWordPiece. Figure 1 illustrates the relevant morpheme breaks (indicated as "||") obtained by applying this morpheme-breaking procedure in the *root* and *infl* tries fragments.

Various parametric controls have been considered to tune this procedure: (i) a *branching factor* (*bf*) parameter that excludes nodes with an excessively high number (> *bf*) of continuations (the rationale being that when too many continuations are present, they are unlikely to correspond to inflections; this often happens near the root of each trie); (ii) a *cutoff* parameter indicating the lower frequency boundary for a mother node (this is necessary to ensure a minimum number of observations; for example, if *cutoff* = 8, we exclude from the "root" trie any branching daughter with a frequency < 5). As in BPE, minimum frequency control for tokens is also implemented to exclude infrequent dictionary entries.

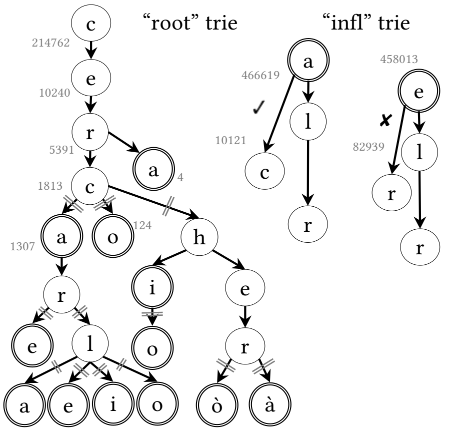

Figure 1: Visualization of a fragment of the "root" and the "infl(ectional)" trie created by MorPiece on our corpus (*cutoff*=100, *bf*=10).

Consider the word "cerca" ("to search for") represented in the "root" trie. In the last "c-a" the relation between H_{fc} and "a" frequency indicates that a break might exist between the nodes "c" (frequency=1813) and "a" (frequency=1307), since H_{fc} = 1813/ln(1813) and 1307 > H_{fc}. This hypothesis is confirmed by the failure of the H_{fc} check at the relevant "infl" "a-c" segment ("a" frequency=10121, "c" frequency=466619): 10121 < 466619/ln(466619). If H_{fc} had been greater than "a" frequency, then no segmentation advantage would have been observable.

The proposed algorithm has a linear time complexity of *O*(*2n*), as each trie must be explored deterministically exactly once to evaluate the H_N/D frequency relation. The best linguistic results (relatively linguistically coherent segmentations) for our Italian corpus were obtained with *cutoff*=100 and *bf*=10. We found that it was unnecessary to filter the proposed inflectional breaks using the *infl* trie double check (TP) since the LinMaxMatch strategy already efficiently filtered out initially overestimated breaks. However, as an anonymous reviewer correctly pointed out, this strategy does not guarantee total inclusion of every token of our training corpus (in contrast to BPE, for instance). We acknowledge this limitation, but we emphasize that our goal was to produce a smaller, potentially more efficient lexicon. In our experiments, while BPE generated a lexicon of 96028 tokens (67169 when the minimum lexical frequency was set to 2), MoP produced a lexicon of just 55049 tokens (*cutoff*=100, *bf*=10).

2.3. Revisiting LSTM architecture

Despite many variants of the standard LSTM architectures, notably Gated Recurrent Units [21] or LSTM augmented with peephole connections [22], and the discouraging equivalence results for these variations [23], we observe a recent revival of RNN-based model architectures [24]. We believe, in fact, that the core intuition behind the LSTM architecture may be linguistically relevant and worth exploring further, although generally more performant models (for instance in terms of GLUE benchmark, [25]) are usually preferred [26]. The linguistic intuition is that the "long-term memory" (cell state *C* in Figure 2) in LSTM networks could effectively model various types of non-local dependencies using a single mechanism. Linguistically speaking, filler-gap dependencies (1) and co-referential dependencies (2) are both "non-local dependencies" but they are subject to non-identical locality conditions:

(1) a. cosa$_{i}$ credi che abbia riposto _$_{i}$?
what (you) believe that (he) shelved?
what do you believe he shelved?
b. *cosa$_{i}$ credi che abbia riposto il libro [$_{AdvP}$ senza leggere _$_{i}$]]?
b'. cosa $_{i}$ credi che abbia riposto _ $_{i}$ [$_{AdvP}$ senza leggere _$_{i}$]]?
*what do you believe he shelved (*the book) without reading?*

(2) a. [il panino]$_{i}$, chi credi che lo$_{i}$ abbia mangiato?
the sandwich, who (you) believe it has eaten?
b. *[il panino]$_{i}$, chi credi che _$_{i}$ abbia mangiato?
the sandwich, who (you) believe has eaten?
*the sandwich, who do you believe have eaten *(it)?*

While both dependencies require C(onstituent)-command generalizations to be captured [27], the *adjunct island* in (1), [28], but not *clitic left-dislocation* in (2), [29], can, for instance, be licensed with a(n extra) gap (1).b'. Aware of these differences, we decided to simply alter the gating system to allow the LSTM to create distinct pathways: one to "merge" new tokens, the other to decide if a long-distance dependency is necessary, and subsequently to "move" the relevant items [30]. The processing implementation of these operations is inspired by expectation-based Minimalist Grammars formalism, eMG [31], and it is then named eMG-RNN.

Following this implementation, *merge* applies incrementally, token by token, and *move* means "retain in memory". In more detail, the cell of an eMG-RNN network performs the forward processing described in the computational graph in Figure 2: (i) the input at time *t* (x_t) is linearly transformed to a lower dimension vector (*E*, loosely used for "embedding"), then concatenated (*C*) with the previous hidden state/output, if any (h_{t-1}). Two pathways, both transformed using a sigmoid function (σ), lead, on the one hand, to the *move* gate, on the other, to the *merge* gate. In the first case, the result of the sigmoid transformation is multiplied (⨀, the Hadamard product) with the input (this either erases or allows some component of the original vector to be added (+) to the previous (if any) context/cell state (c_{t-1}) as in LSTM *forget* gate). The *merge* gate, on the other direction, will privilege the new token if the result of the sigmoid combination of the incoming token and the previous hidden state is low, otherwise (1 - this activation, as in GRUs *update* gate) will favor items in the context/cell state (transformed through a *tanh* function to simulate memory decay).

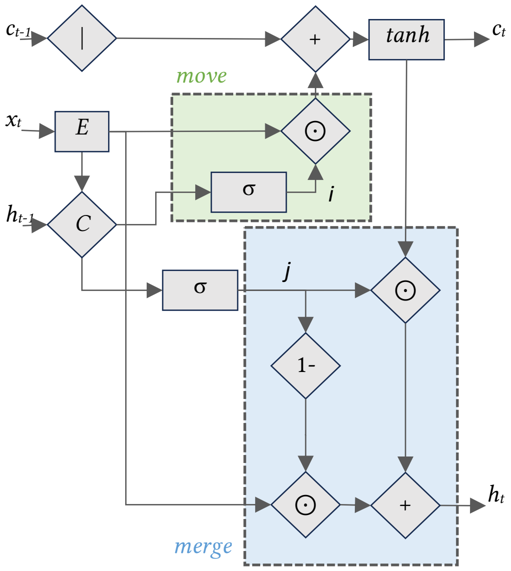

Figure 2: eMG-RNN cell computational graph.

This architecture is the most performant compared to various alternatives tested for the BabyLM 2024 challenge [32].

2.4. A linguistically informed evaluation

The last step in the pipeline requires a linguistically advanced set of oppositions to verify that the structural generalizations can be captured coherently. We adopted the lm-eval package [33] and we included a specific task based on English BLiMP [12]. Most of the contrasts are derived from the COnVERSA test [4]. They consist of minimal pairs ordered following an increasing complexity metric that considers the number of operations necessary to establish a dependency and the locality of such dependency. The examples below illustrate this point by comparing a local agreement dependency with, (3).b, or without, (3).a, a (linear) intervener and a more complex dependency that requires to process an object relative clause (4):

(3) a. Il piatto è pieno. Vs. Il piatto è piena.
the dish.S.M is full.S.M … full.S.F
b. Il muro della casa è rosso
the wall.S.M of the house is red.S.M
Vs. Il muro della casa è rossa.
the wall.S.M of the house is red.S.F

(4) Ci sono due maestri. Uno insegna ed è ascoltato dagli studenti, l'altro si riposa. Quale maestro insegna? *There are two teachers. One teaches and he's listened to by the students, the other rests. Which one teaches?*
Quello che gli studenti ascoltano.
The one who the students listen to
Vs. Quello che ascolta gli studenti.
The one who listens to the students

Four kinds of dependency (agreement, thematic role assignment, pronominal forms usage, questions formation and answering) are considered for a set of 32 distinct syntactic configurations (a total of 344 minimal pairs to be judged, [4]).

3. Materials and Methods

We trained our models on the IUSS High-Performance Cluster with 2 GPU nodes, each with 4 A100 NVIDIA devices and 1T RAM. Each network has been trained with the full corpus using various batched strategies. (i) *Naturalistic*, line-by-line, single exposure to each sentence in the corpus (each epoch corresponds to an exposure of about 3M tokens); (ii) *Conversational*, two sequential lines are used for the input, that is, [line 1, line 2], [line 2, line 3], etc. are batched; this guarantees that a minimal conversational context for each sentence is provided. In this case, each epoch corresponds to an exposure of 6M tokens; (iii) *fixed sequence length*, considering the average sentence length of 54 words per sentence, a window of 60 tokens is used, that is, [tok_1, tok_2 … tok_60], [tok_2, tok_3 … tok_61] … are batched; with this regimen, each epoch corresponds to an exposure of 180M tokens. Roughly speaking, the bare amount of data processed by a 7 y.o. child ranges from 7 to 70M tokens, [34], then training the networks with a *naturalistic* or *conversational* regimen for 3-10 epochs would result in a comparable exposure. We trained the networks using torch.optim.lr_scheduler (*step_size*=5, *gamma*=0.1) and Adam optimizer (*lr*=0.001) with 16-bit automatic mixed-precision to speed up the (parallel) training for a maximum of 100 epochs. The networks have been implemented in PyTorch (v2.3.1), wrapped in Transformers structures (4.42.4) to maximize compatibility in the lm-eval (v.0.4.3) environment. CUDA drivers v.12.4 were used. The most relevant configurations tested are discussed in the next session.

3.1. Configurations tested

Three different tokenization strategies (BPE, FastWordPiece, and MorPiece) are compared using the best-performing LSTM network [35] , which consists of 650 units for the embedding layer and 650 nodes for each of the two hidden layers. Five different network architectures are compared, with the GroNLP GPT-2-small pretrained model [36] constituting our "top LLM performer". This model was re-adapted to Italian from the GPT-2 English trained model, which was originally trained on approximately 10 billion token corpus, namely various orders of magnitude bigger than our corpus. We then trained on our corpus a comparable bidirectional transformer (BERT), two LSTM networks, respectively with 1 and 2 LSTM layers, and a one-layer eMG-RNN network (Table 2), as described in §2.3.

Table 2
Network architectures

Model	Parameters	Structure
GroNLP GPT-2 small	121M	12 Attention heads + 768 hidden units
BERT	113M	12 Attention heads + 768 hidden units
LSTMx2	65M	650 Embedding + 2 LSTM layers (650)
LSTMx1	36M	650 Embedding + 1 LSTM layers (650)
eMG-RNN	73M	650 Embedding + 1 eMG-RNN layer (650)

4. Results

Comparing BERT and LSTM architectures, LSTMx1 qualifies as the most performant configuration (both in training and in minimal pair judgments). Considering training, the only batching regimen performing sufficiently well is the *fixed sequence length* (*loss=0.8877* with LSTMx1 vs. conversational *loss*=4.0240 or naturalistic regimen *loss*=4.5884). All networks reached a learning plateau around 10-12 epochs. Comparing the performances on COnVERSA, we realized that the results does not improve after 3 epochs of *fixed sequence length* (60 tokens) training regimen (this result is compatible with the overfitting hypothesis, [37]). Focusing on tokenizer training results with LSTMx1, we observed that BPE and FastWordPiece have comparable performance. MorPiece performs slightly worse, even though the tokenization seems linguistically more coherent (e.g., "farlo" – "to do it" is tokenized both by BPE and fWP as a single token, while it is split in two in MorPiece: "far" "+lo") and the training faster (Table 3). This, however, only marginally impacts on minimal pairs contrast judgments, performing slightly better, overall, just in certain agreement cases.

Table 3
Impact of the tokenization strategy on LSTM training

Strategy	Vocab size	Training time x epoch	Loss
Corpus types	*72931*	*~1h*	*1.1520*
BPE	96028	*~4h*	*0.8877*
fWP	97162	*~4h*	*0.9491*
MoP	55049	*~3h*	*1.1151*

We then adopted the BPE tokenizer for architectural comparisons. Network training performances are summarized in Table 4 and graphically represented in Figure 3 for linguistic dimensions comparison.

Table 4
Network architectures and their performance on training (Loss/Accuracy) and COnVERSA test

Model	Loss/Accuracy	COnVERA
GroNLP GPT-2s		0.73 (±0.02)
BERT	4.5488/0.65471	0.43(±0.02)
LSTMx2	0.7849/0.8283	0.48(±0.03)
LSTMx1	0.8784/0.8103	0.52(±0.03)
eMG-RNN	0.9491/0.7815	0.61(±0.01)

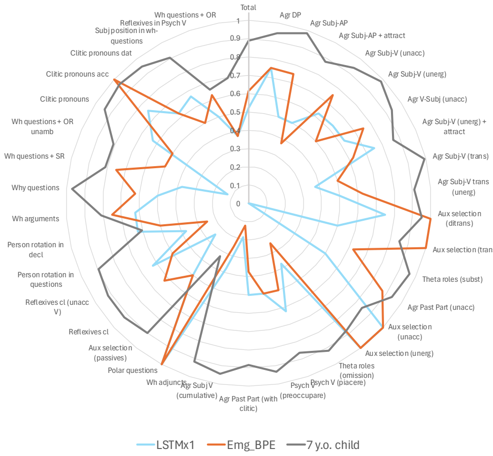

Figure 3: Performance of the 2 best RNN networks variants on COnVERSA compared to the 7 y.o. children.

5. Discussion

Overall, LSTM networks significantly outperform Bidirectional Transformers in this minimal pairs test on Italian. This finding is consistent with results previously discussed in the literature and suggests a clear advantage of recurrent, sequential model architectures (e.g., LSTM) over Bidirectional Transformers in terms of linguistic generalizations [38] and partially justify the renewed interest for RNN networks that we have been observed in the last couple of years [24], [26]. As far as the tokenization procedure is concerned, it is somewhat premature to draw definitive conclusions from our experiments, as MorPiece has not yet been fully optimized or tested. Specifically, the optimal cut-off threshold and minimum branching factor have not been systematically evaluated. Nevertheless, a more morphologically coherent segmentation is expected to enhance sensitivity in certain minimal contrasts.

Similarly, the eMG-RNN architecture could be further explored and optimized, particularly considering specific contrasts, which may help determine whether our linguistic modeling is on the right track. Evidence to the contrary is attested by the judgments of sentences with missing thematic roles, which are often incorrectly preferred by most models, including our eMG-RNN.

In the end, our results suggest that Loss/Accuracy performance registered in training is not a significant predictor of the performance on the COnVERSA test, or more generally, of the linguistic coherence of the LM trained. Likewise, the models' dimension is not a clear predictor either: Transformers trained on the same small dataset perform randomly (in all dimensions their performance is round 50%) while eMG-RNN, which has a number of parameters similar to LSTM-2, outperforms both LSTM-2 and LSTM-1 (half size of eMG-RNN). The training size remains a striking difference compared to the input received by children: this difference of one order of magnitude suggests that the bias considered in eMG-RNN are not yet satisfactory and that our Language Acquisition Device is still more efficient; in this sense, the Poverty of Stimulus Hypothesis remains unrefuted [39] by these results. Next steps will consider extending to 10M tokens the training corpus (to match the English counterpart [1]) and further exploring the effects of optimized tokenization procedures or other minimal modifications, and optimizations [24], of recurrent neural networks.

On Cross-Language Entity Label Projection and Recognition

Paolo Gajo[1,*], Alberto Barrón-Cedeño[1]

[1]Università di Bologna, Corso della Repubblica, 136, 47121, Forlì, Italy

Abstract

Most work on named entity recognition (NER) focuses solely on English. Through the use of training data augmentation via machine translation (MT), multilingual NER can become a powerful tool for information extraction in multilingual contexts. In this paper, we augment NER data from culinary recipe ingredient lists by means of MT and word alignment (WA), following two approaches: *(i)* translating each entity separately, while taking into account the full context of the list and *(ii)* translating the whole list of ingredients and then aligning entities using three types of WA models: Giza++, Fast Align, and BERT, fine-tuned using a novel entity-shuffling approach. We depart from English data and produce Italian versions via MT, span-annotated with the entities projected from English. Then, we use the data produced by the two approaches to train mono- and multilingual NER BERT models. We test the performance of the WA and NER models on an annotated dataset of ingredient lists, partially out-of-domain compared to the training data. The results show that shuffling entities leads to better BERT aligner models. The higher quality NER data created by these models enables NER models to achieve better results, with multilingual models reaching performances equal to or greater than their monolingual counterparts.

Keywords

information extraction, named entity recognition, cross-lingual label projection, data augmentation

1. Introduction

Named entity recognition (NER) is a sequence labeling task with a long history of works mainly focusing on the recognition of entities such as people, locations, and organizations. Multilingual NER has also attracted research efforts, with recent SemEval campaigns including tasks on multilingual complex NER (MultiCoNER) [1, 2]. Despite its popularity and various mono- and multilingual NER datasets being available, specific domains such as the culinary one likely require new annotated data. In addition, NER is often the first step in information extraction for knowledge graph construction and, to the best of our knowledge, all literature in the domain of cuisine on this topic solely focuses on English data [3, 4, 5, 6, 7]. Therefore we argue that, given cuisine's multicultural nature, more research in this direction is warranted.

Entity label projection [8] aims to address this scarcity by automating the data generation process for NER. This task consists in taking the labels associated with spans from a source text and automatically applying them to its translation in another language, i.e. the target text. Through this task, we attempt to find an efficient automatic way of developing models for entity projection across languages to produce high-quality multilingual data for recipe Named Entities (r-NE) [4]. Departing from an English-language dataset containing ingredients from culinary recipes, annotated at the span level with entity category labels, we first rely on a MT engine to translate each source entity s_i individually into Italian, while keeping the full context into account. This results in a first entity-wise (EW) translated EN–IT–ES dataset where entities are linked across languages.[1]

Using these synthetic alignments, we train BERT models to align source and target entities, shuffling the latter to prevent the model from learning to simply predict the original entity order. We then test the models on two novel entity alignment datasets, partially out-of-domain compared to the training data, e.g., as regards the used food products, units of measure, and cooking processes. As baselines to evaluate the BERT alignment models, we use Giza++ [9] and Fast Align [10], two statistical word alignment (WA) models. In order to produce higher-quality r-NE data, we translate the ingredient lists across their whole length, predicting target entity spans with the best BERT models from the previous step, along with the baseline models. We thus obtain various sentence-wise (SW) translated datasets in Italian, trading some alignment accuracy for better translations.

Both types of training data, EW and SW, are then used to fine-tune mono- and multilingual BERT NER models on the task of recognizing entities in food recipes. The models are trained on various combinations of mono- and multilingual data and are tested on the entity annotations from the two aforementioned novel testing datasets.

Our contribution is three-fold: *(i)* We show the efficacy of fine-tuning alignment models by shuffling entities in contexts where most of the information depends on the presence of lexical items rather than the dependencies

[1] Experiments on Spanish (ES) are included in Appendix A.

linking them. *(ii)* We showcase the performance delta between mono- and multilingual NER models when fine-tuning on the synthetic data produced by our alignment. These models can be used to label large datasets in multiple languages at a finer granularity level compared to currently available monolingual resources. *(iii)* We release code and data to produce data in multiple languages.[2]

The rest of the paper is structured as follows. Section 2 presents relevant past research on the subjects of cross-lingual entity alignment and recognition. Section 3 introduces the datasets and corpora used in the experiments, along with their annotation process. Section 4 presents architecture, training, and evaluation details for the models comprising our pipeline. Section 5 discusses the conducted experiments and their results. Finally, Section 6 summarizes the paper and draws conclusions. Appendix A shows further results including Spanish. Appendix B presents statistics and gives insight on the additional training data used. Appendix C lists information on the computational requirements.

2. Related Work

Word alignment was first approached for statistical MT, with models such as IBM 1-5 [11], used in well-known implementations such as Giza++ and Fast Align. With the advent of Transformers [12] and the BERT model [13], this task has been approached by employing both question answering [14] and token classification [15] models, trained on freely available resources, such as XL-WA [16].

A number of past works have studied label projection following a range of approaches. Jain et al. [8] project PER, ORG, LOC and MISC labels (person, organization, location, and miscellaneous) by translating sentences and then finding potential matches using glossaries. Fei et al. [17] align words using Fast Align and use POS tagging to enhance data for semantic role labeling. García-Ferrero et al. [18] use the AWESoME word alignment model [19] to align machine-translated data from NER datasets in seven languages. Li et al. [15] fine-tune a NER model on English PER, ORG, LOC, MISC data from CoNLL2003 [20] to infer on the source portion of parallel Opus corpora [21] with the aim of creating silver NER data. Subsequently, they train an XLM RoBERTa alignment model by using Wikipedia articles and project the labels on the target portion of the parallel corpus, which they use to train a target-language NER model.

NER can also be approached with large language models (LLM) [22, 23, 24] by prompting them to extract entities from a given text. For example, PromptNER [25] uses chain of thought [26] along with a list of entity definitions to prompt a variety of LLMs, obtaining results on par with SOTA supervised NER systems. Similarly, [27] use in-context learning [28] to evaluate GPT-3 [22] for NER on the CoNLL2003 [20] and OntoNotes5.0 [29] datasets by using retrieval-augmented generation [30] and comparing the results to BERT and models based on graph neural networks [31].

With regard to data specific to the culinary domain, many English-language resources exist in various forms. RecipeDB [32] is an ontology comprising $118\,k$ web recipes which can be used to relate foods and cooking processes to taste profiles and health data. FoodOn [33] is a "farm-to-fork" ontology which provides a structure of relationships between food products across the whole industrial supply chain. Bridging the gap between ontologies and NER datasets, FoodKG [34] is a knowledge graph which can be used to find ingredient substitutions based on dietary health requirements. It is built by leveraging FoodOn and Recipe1M+ [35], a dataset originally intended for learning joint text/image embeddings on over $1\,M$ culinary recipes. Expanding on Recipe1M+, Bień et al. [36] construct RecipeNLG, comprising more than $2\,M$ recipes. It is the biggest food NER dataset to date, but its granularity stops at the sole food product names. More fine-grained silver labels are obtained by Komariah et al. [37], who propose a new methodology to extract entities from AllRecipes.[3] Doing so, they construct FINER, a dataset comprising $64\,k$ recipes with labels predicted by what the authors refer to as a "semi-supervised multi-model prediction technique." The dataset also contains recipe tags such as `vegetarian` and `vegan`, which can be useful for training recipe classifiers. Leveraging RecipeDB [32], a large-scale structured corpus of recipes, [38] generate a synthetic dataset of augmented ingredient phrases and compare the NER performance of various rule-based and neural models.

Despite the wide availability of English-language resources in the culinary domain, other languages are largely understudied. To the best of our knowledge, the only study to approach this domain in a multilingual setting was conducted by Radu et al. [39], who obtain NER tags automatically in English, German, and French by using a regex-based tagger. Our work aims to partially address this gap in past research by focusing on Italian.

3. Data

The entity alignment data used for training is generated through MT starting from TASTEset [40], a dataset comprising ingredient lists from 700 food recipes, annotated at the span level. We use TASTEset because it is human-curated and its annotations are fine-grained. We translate each entity one by one with DeepL,[4] concurrently feeding the whole ingredient list and the single

[2] Resources available at https://github.com/paolo-gajo/food

[3] https://www.allrecipes.com

[4] https://www.deepl.com/en/docs-api

entity as two separate inputs. This provides DeepL with context, improving translation quality and retaining the start and end span indexes in the target text by simply concatenating each translated entity. To the best of our knowledge, DeepL is currently the only MT engine capable of contextually translating a substring taken from a sentence, which is why we are using it in this study. Doing this, we obtain an Entity-wise Machine-translated TASTEset (EMT). Since entities are automatically paired to the source label, the distribution across English and Italian is identical (Table 1).

We also generate shuffled variations of EMT, where the entities within a single ingredient have a probability $p \in \{0.1, 0.2, \ldots, 1.0\}$ of being shuffled, for a total of ten variations. Figure 1 shows an example where entities have been shuffled in the first and third target ingredients. The rationale behind this approach is that, when training on EMT, if the dataset were to be left as-is, the model would simply learn to associate a source entity to the target entity in the corresponding position, since entities are simply translated and replaced in EMT.

Overall, we have 22 different variations of EMT, i.e. the original and the 10 shuffled versions for each of the two types of tokenization (mBERT's WordPiece [13] vs mDeBERTa's SentencePiece [41]). The datasets have to be tokenized during the generation of the dataset because token indexes depend on the tokenizer being used when converted from character-level span annotations.

We produce a second kind of synthetic dataset by first translating the ingredient lists as a whole, and then aligning source and target entities by using the BERT, Giza++, and Fast Align models presented in Section 4. We refer to this type of dataset as Sentence-wise Machine-translated TASTEset (SMT). As Table 1 shows, the SMT dataset produced by the BERT model trained on both XL-WA and the shuffled version of EMT contains slightly fewer entities than the source material. This is due to the fact that at times the models produce impossible predictions, e.g. predicting the end of an entity to be before its start.[5] This problem does not exist with Giza++ and Fast Align, since their alignments are word-based. As additional training data for the BERT models, we use the EN–IT portion of XL-WA. Table 9 in Appendix B reports the size of each of the partitions we used.

Class	**EMT** (en/it)	**SMT** (it)	**GZ** (en)	**GZ**(it)

Figure 1: Aligning source s_i and shuffled target t_j entities.

For testing, we annotated an English–Italian dataset of recipes, obtained from GialloZafferano (where the English recipes are translated from the Italian ones).[6] For the annotation process, we recruited a professional translator who is a native speaker of Italian, with an MA in Specialized Translation in both English and Spanish. Figure 2 shows the instructions given for the first multi-class entity annotation task, which consider the same entities as TASTEset, and the second cross-language entity-linking annotation task, carried out by the same annotator at a later time. The annotation was carried out in Label Studio.[7]

The GialloZafferano (GZ) dataset comprises 597 recipes. The alignments were annotated manually on a subset of 300 recipes, with the possibility of more than one source entity being aligned with one target entity, and vice versa. This is because some recipes contain more than one ingredient option in English but not in Italian (and vice versa), e.g., `Cocomero (anguria) 1 fetta` vs `Watermelon 1 slice`. The GZ dataset contains a total of 46,903 NER annotations and 9,842 alignments.

We manually scrutinized GZ and found that the paired recipes do not always coincide completely. Some ingredients may be missing in either language or be an equivalent rather than the same food product. In order to avoid training the alignment models on excessively different recipes, we chose to avoid annotating alignments whenever the number of source ingredients missing from the target recipe surpassed a heuristic threshold of 1/3.

Note that in GZ quantities and units of measure are localized and are thus listed in both imperial and SI units. As shown in Table 1, this is reflected by the lower number of instances annotated as `quantity` and `unit` in the Italian portion of GZ, compared to its English portion.

[5] The effect on model performance upon training is negligible given that these predictions constitute less than 1% of the total.
[6] https://www.giallozafferano.it
[7] https://labelstud.io

Instructions for the multi-class entity annotation task.

Annotate the ingredients below by assigning to spans of text one of the following categories: `quantity`, `unit`, `food`, `color`, `part`, `physical quality`, `process`, `purpose`, `taste`. Use `quantity` for numerical values or expressions such as 'to taste', identifying the quantity of an ingredient. `Unit` stands for "unit of measure", such as grams (g) or ounces (oz). Use `color` for any color that is not part of a `food`'s own name (e.g. 'red' can be tagged in 'red wine', but not 'black' in 'blackberries'). `Part` refers to parts of an ingredient, such as 'wings' in 'chicken wings'. Use `physical quality` for attributes which already characterize an ingredient at the start of the preparation. `Process` refers to actions that the reader is supposed to carry out. The label `purpose` answers the question, "What is this entity used for?" Finally, use `taste` for words referring to a taste, such as 'unsweetened' or 'dry', with relation to a wine. N.B.: **The annotations cannot overlap**. You can either choose to annotate multiple spans with the same label, or avoid annotating one or more spans of text.

Instructions for the cross-lingual entity linking task.

Link each source language entity to its corresponding entity in the target language with an arrow. **Entities should only be linked if they share the same use.** For example, the "2" in "2 tablespoons chopped onions" does not have the same function as in "2 cebollas largas picadas", since one refers to tablespoons and other to the number of onions. However, "onions" and "chopped" could still be linked, as they are equivalent in the two sequences. Individual source entities can be linked to multiple target entities and vice versa. N.B.: **Entities can still be linked if they differ slightly in form or content** but still clearly perform the same function in the same ingredient context. For example, "340" and "450" could still be linked if they both refer to the quantity of grams of the same source and target food products.

Figure 2: Annotation task instructions.

4. Models

Entity Alignment As baselines, we use two statistical models: Giza++ [9] and Fast Align [10]. Giza++ combines a HMM [42] alignment model and IBM M1-5 [11]. Fast Align is much more lightweight, only leveraging IBM M2. We use two multilingual BERT models as well: mBERT [13] as the baseline multilingual Transformer model and mDeBERTa [43] because of its larger size ($276M$ vs $179M$ param.) and performance. When using the BERT models, we follow Nagata et al. [14] and treat entity alignment as a question-answering task, enclosing the source word to be aligned within rarely used characters, e.g., '•', feeding the model both the source sequence A and the target sequence B at once. Figure 1 exemplifies this, where the model $M_{aligner}$ is trained to predict an entity within a shuffled ingredient's boundaries.

Table 2
Exact metric results of the alignment task; averaged out of 5 random runs, besides the XL-WA baseline. Best in bold.

We train the models for up to 3 epochs on each dataset with a batch size of 16. The optimizer's learning rate is set at 3×10^{-4}, while ϵ is 10^{-8}. Each training run, we select the best model based on the Exact metric E [44]:

$$E = \frac{\sum_i^n exact(p_i, g_i)}{\|preds\|} \quad , \tag{1}$$

where $preds$ is a list of predictions and $exact(p_i, g_i)$ is the Kronecker delta:

$$exact(p_i, g_i) = \begin{cases} 1, & \text{if } p_i = g_i, \\ 0, & \text{if } p_i \neq g_i \end{cases} \tag{2}$$

with the predicted and gold strings p_i and g_i having been lowercased and stripped of excess punctuation and spaces. We calculate mean Exact and its standard deviation out of five random runs for each model.

In order to improve the models' ability to align entities, we optionally train them on an intermediary word-alignment task using the EN–IT training and dev sets of XL-WA. In addition, we train mBERT and mDeBERTa solely using said XL-WA partitions in order to test them directly on GZ. This serves as a baseline which will allow us to gauge the positive effects of fine-tuning on EMT.

Table 3
Exact metric results of the alignment task by class on GZ for the best models (trained on IT$\oplus$ES). Best in bold.

Entity Recognition For the NER task, treated as token classification, we once again use mBERT.[8] To test the efficacy of the multilingual approach, we also use the following monolingual models when training and testing on a single language: `bert-base-uncased` (henceforth "BERT$_\text{en}$") for English [13] and `bert-base-italian-uncased` ("BERT$_\text{it}$") [45] for Italian. We forgo mDeBERTa for this task, as the focus is showing a comparison between models of equivalent size and performance. Prior to training, the data is preprocessed and labeled using the BIO annotation scheme [46]. We ignore subword tokens when calculating cross-entropy loss, following established methodology.[9]

We train the models on the EN–IT, EN–ES, EN–IT–ES language subsets of EMT and of the four versions of SMT, produced by mBERT, mDeBERTa, Giza++, and Fast Align. For the BERT models, we use the same hyperparameters used for the alignment task, but with a lower learning rate of 2×10^{-4}. The models are evaluated using the macro F$_1$-measure. Details on the employed computational resources can be found in Appendix C.

5. Results and Discussion

Entity Alignment Table 2 reports the Exact scores for the entity alignment experiment. The entity shuffling approach appears to be very effective for creating data which can make the models better at generalizing. The performance of every single model is greatly enhanced when shuffling ingredients just 10% of the time, with increased shuffling frequency not leading to any significant further improvement. The increase in performance seems to be greater for models which have undergone intermediate training on XL-WA, with mDeBERTa$_\text{X}$ gaining almost 12 points in the Exact metric, when fine-tuned on shuffled data. Unsurprisingly, the larger mDeBERTa performs much better than the smaller mBERT across the board. Although the model obtaining the highest mean performance is obtained at $P = 0.8$, an overlap can be observed between all the confidence intervals for $P \geq 0.1$. However, this is not true when going from $P = 0$ to $P = 0.1$. Consequently, increased shuffling past 10% does not seem to provide a concrete performance gain, which is why we decided to produce SMT by using the BERT trained on the least-shuffled version of EMT.

In and of itself, the intermediary training step on XL-WA provides a slight performance boost when looking at mBERT vs mBERT$_\text{X}$ and mDeBERTa vs mDeBERTa$_\text{X}$. Still, this increase is much smaller compared to the one gained through shuffling. While fine-tuning the models on a general word-alignment task can be beneficial, the target domain is likely too different from the training data for this to produce a large performance boost. This is especially true as regards the structure of the sentences, since the test data is comprised by short lists of entities separated by semicolons, while the training data is a domain-balanced sample of sentences from Wikipedia. An additional performance boost is provided by multilingual fine-tuning, while cross-lingual settings (e.g., fine-tuning on ES and testing on IT) lead to worse outcomes. Table 6 (Appendix A) shows the results.

Table 3 reports the performance of the best overall models on each class. As the results show, the much lighter Giza++ model surpasses mBERT$_\text{X}$, only trailing behind mDeBERTa$_\text{X}$. The poor scores achieved by the two BERT models are largely attributable to their poor scores on the `unit` and `part` classes. We hypothesize that this poor class-specific performance has to do with units of measure often being very short strings. Training mDeBERTa only on the `unit` instances does not improve its performance, with the model scoring a lower 18.08 Exact metric. Inspecting its individual predictions in this single-class scenario, we noticed that the model does learn to always predict two consecutive tokens, but the enclosed token does not match the original text when converted into characters. This is due to two separate issues: *(i)* the model selects the wrong span, e.g., selecting an ingredient such as "carote" (carrots) rather than the unit "g" or *(ii)* the model's prediction is empty when converted to characters. Since mBERT and mDeBERTa both have poor performance on this class while using two different tokenization algorithms (WordPiece vs SentencePiece), the problem may lie in the models' tokenizer's token-to-character conversion method.[10] We plan to shed light on this in the future. As regards the `part` class, the poor performance could be explained by the small

[8] We do not use the larger mDeBERTa model due to the computational cost deriving from the number of language combinations.

Model performance for the entity recognition task, in terms of F_1 measure. All results are macro avg. out of 5 random runs.

number of training instances (55). However, the models obtain high scores on the purpose class, also just 94 instances (mBERT_x gets 94.87 Exact score). Unfortunately, repeating the approach we used for the unit class is not feasible, as fine-tuning the model on just 55 instances does not produce any reliable results ($E_{part} = 3.96$), meaning this will have to be left for future work.

The rest of the results from Table 3 are generally in line with the average results from Table 2. The scores achieved by the baselines for each class do not have any evident outliers, save for Fast Align scoring a 0 on taste. More generally, Fast Align, being the simplest and most lightweight model, performs on average well below the other more complex models.

Entity Recognition Table 4 reports the results for the NER task. The aligner column indicates which alignment model, out of the best ones listed in Table 3, has produced the SMT training data used to fine-tune the NER model. When no alignment model is specified, the training data being used is EMT. Note that in this case we are not using EMT's shuffled versions, as there is no relation between any two recipes when fine-tuning on the NER task.

When training and testing on Italian data, the best results are obtained for both mBERT and BERT_it when fine-tuning on SMT data produced by mDeBERTa. When fine-tuning them on EMT, the performance is noticeably lower, with a 5-point difference for mBERT and an 8-point difference for BERT_it. The data produced by mBERT also allows both models to outperform the EMT baseline, although by smaller amounts. Conversely, the data produced by Fast Align and Giza++ worsens the data quality in 75% of the cases. When fine-tuning mBERT on bilingual ES-IT data, the performance on the test set remains essentially unvaried (see Table 8 in Appendix A).

Looking at the baselines at the bottom of Table 4, we can see that fine-tuning mBERT on English data yields worse performance when testing on GZ, compared to fine-tuning on EMT's Italian data. Our data augmentation strategy is thus providing an evident performance boost, with entity alignment producing bigger improvements than machine-translating each entity individually.

In all settings, mBERT performs on par with the monolingual models. This shows that a single multilingual model can suffice when extracting entities from multilingual corpora, saving time and compute.

6. Conclusions

We explored a simple novel technique to automatically generate high-quality multilingual NER data by combining machine translation and cross-language entity linking. For our experiments, we relied on the English-language TASTEset dataset, which includes recipes whose lists of ingredients are span-annotated for entity recognition. Moreover, we manually curated a novel English–Italian cross-language dataset, featuring the same kind of annotation, with the addition of cross-language alignments.

We machine translated the entities in TASTEset's recipes individually and shuffled them within ingredient boundaries. Leveraging this augmented data, we then fine-tuned BERT entity-alignment models. Using statistical word-alignment models as baselines, we tested these BERT models on our English–Italian parallel corpus. The results showed that models fine-tuned using our novel approach consistently outperform those trained on unshuffled data, along with two statistical baselines.

We then created additional synthetic data by first translating TASTEset's recipes in their entirety, and then aligning the entities in the machine-translated target text using the best models obtained from the first part of the study. These data allowed us to obtain better NER models, compared to the ones we would have obtained by using the original recipes translated entity by entity. We tested monolingual English and Italian BERT models against mBERT, and showed that the latter is capable of obtaining the same performance as its monolingual counterparts when tested on monolingual NER data.

In future work, we plan to extend the annotation of our datasets, both in terms of number of instances and annotators. We will also prioritize solving the token-to-character conversion issues encountered in this study. Furthermore, we plan to leverage this data augmentation technique in order to improve multilingual text-to-graph models, since all of the literature in this regard focuses on English-only data [3, 4, 5, 6, 7].

A. Incorporating Spanish

In order to test more thoroughly the soundness of our approach, we carry out an equivalent study with Spanish.

A.1. Data

We annotated an English–Spanish dataset of recipes obtained from My Colombian Recipes,[11] which we refer to as MCR. MCR is translated from English to Spanish, which is evident from the fact that on the website all Spanish recipes have an English counterpart, but not vice versa. We believe approximately 5-10% of the dataset's instances to be possible MT. A good indication of this is the fact that the English "to taste" is sometimes translated as "para probar", likely an MT mistake, while other times the correct "al gusto" is used. Although using machine-translated data is not ideal, this was our best choice for a Spanish-language parallel recipe corpus, due to the lack of availability of similar online resources. The use of MT data has implications with respect to the evaluation of the models, as their performance would likely be lower in a real-world scenario involving recipes written directly in Spanish. Nonetheless, given the limited amount of data we hypothesize as being machine-translated, we believe the impact would not be large enough to discredit our results, which focus on the improvement over the cross-lingual EN–ES baseline, rather than the absolute performance of the best model.

MCR contains 276 recipes, 104 of which are bilingual and annotated with alignments. Due to this imbalance between the number of English and Spanish recipes, the number of entities is around 3x for the former, as shown in Table 5. In total, MCR contains annotations for 15,257 entities and 3,565 alignments. Along with the ingredient lists, MCR also contains cooking instructions for all its recipes, along with nutritional facts for 139 of them.

A.2. BERT Model

As a monolingual Spanish BERT model baseline to compare against mBERT, we use `bert-base-spanish-wwm-cased` ("BERT$_{\text{es}}$") [47].

A.3. Results

Entity Alignment Table 6 reports the results for the alignment task, complete with the settings including Spanish-language data.

Fine-tuning on the same language as the test set yields better results than cross-lingual scenarios. Furthermore, the best performance on MCR is obtained when fine-tuning mDeBERTa$_{\text{X}}$ on both Italian and Spanish.

This is not the case for mBERT$_{\text{X}}$ and mDeBERTa, whose performance is hindered by the addition of Italian training data. MCR is much narrower in terms of culinary variety, focusing solely on Colombian recipes. On the other hand, GZ contains not just traditional Italian recipes, but an international range of dishes. This is probably the reason why bilingual training is helpful on GZ, but is not beneficial with relation to MCR: adding data from a separate locale helps the models when approaching the more varied GZ, helping them generalize more effectively over its data. Conversely, they are thrown off

by the addition of out-of-domain data when tested on MCR's narrower domain.

Comparing the EMT fine-tuning results with the baselines at the bottom of Table 6, we can see that further fine-tuning on EMT does provide a boost, compared to training only on XL-WA. Nonetheless, the difference in performance is much greater when testing on GZ, compared to MCR. When looking at mBERT$_X$, fine-tuned on both Italian and Spanish, the model improves by more than 23 Exact points on GZ, while the gap in performance is just under 16 points on MCR. This effect is even more dramatic for mDeBERTa$_X$, with a difference of more than 25 points on GZ, but only 2.48 points on MCR.

Compounded with the fact that, in general, the metrics are much higher when testing on MCR compared to GZ, this points to MCR being a much less challenging test set, compared to GZ. As previously mentioned, part of the dataset is likely machine translated, and since an MT engine is more likely to follow rigidly defined patterns compared to a human translator, this might play a role into the alignment task being easier on these data.

Table 7 reports the performance of the best overall models on each of the individual classes, on both GZ and MCR. Giza++ essentially matches mDeBERTa's performance on MCR, which once again points to entities in MCR being easier to identify compared to GZ. However, the similar performance is largely due to mDeBERTa performing poorly on the `unit` and `part` classes, due to the reasons outlined in Section 4.

Entity Recognition Table 8 reports the results for the NER task for all language settings. For each language, we use the aligner models which obtained the highest results on the entity alignment task. Note that, since the aligner performance does not significantly improve with increased shuffling (see Section 5), we only train aligner models up to $P = 0.2$ for the Spanish setting due to computational constraints.

In the Spanish monolingual setting, both BERT$_{es}$ and mBERT obtain F$_1$ scores between 0.92 and 0.95 when fine-tuned on SMT, with the models fine-tuned on EMT trailing behind by 11 to 12 points. As all the models perform similarly and the standard deviation is also close to zero, it once again appears that the entities contained in the MCR dataset are not too challenging for both the mono- and multilingual models to identify.

Table 7
Results of the alignment task by class for the best models, using the Exact metric. Best on GZ in bold, best on MCR underlined.

In the bilingual fine-tuning scenario, the training data is a concatenation of the SMT datasets produced by the models obtaining the highest performance on the two test sets. Since this is a bilingual fine-tuning scenario, we only use mBERT, as the monolingual models would not be able to be fine-tuned appropriately on this multilingual data. In this setup, the usefulness of the BERT-based aligners becomes more evident. Indeed, while performance on MCR is largely similar to the other setups, with all models outperforming the baseline by a large amount, the same cannot be said for mBERT's performance on GZ. Fine-tuning mBERT on the combination of the Italian and Spanish data aligned by Fast Align and Giza++ makes the NER model considerably worse at identifying entities in GZ, with a performance decrease of 20 F_1 points with the data created by Fast Align and of 21 F_1 points with that created by Giza++. The opposite is true when fine-tuning the mBERT NER model on the SMT data created by mDeBERTa, with the model achieving an F_1 of 0.94, beating the baseline by 5 points. Compared to the model fine-tuned on data created by Giza++, this represents a 26 F_1 point increase in performance.

As regards the baseline model fine-tuned on TASTEset's English data and tested on MCR's Spanish entities, we can see that, unexpectedly, the model obtains a 0.88 F_1 score, outperforming the mBERT (0.83 F_1) and BERT$_{es}$ (0.84 F_1) models fine-tuned on the monolingual Spanish EMT data. Despite this, fine-tuning on SMT data produced through our alignment approach allows the NER models to beat this 0.88 F_1 baseline, reaching scores as high as 0.95 F_1, as previously mentioned.

In all three scenarios, mBERT achieves performances comparable to those of the monolingual models. This shows that, when inferring on multilingual corpora to extract entities, a single multilingual model can be used, saving time and computational resources both during training and inference.

B. XL-WA

As additional data for intermediate word-alignment training, we use XL-WA [16], a multilingual word-alignment dataset [16] built from WikiMatrix [48], [12] featuring 14 EN–XX language combinations. Its training set is composed of silver labels generated by a statistical model, while the development and test sets are manually annotated. Since XL-WA has a balanced domain distribution and can be considered representative of general language, it can be a good resource on which to train a baseline word-alignment model. Table 9 reports statistics for the EN–IT and EN–ES partitions used in this study.

[12] https://ai.meta.com/blog/wikimatrix/

	Sentences		Alignments	
Language	Train	Dev	Train	Dev
en–it	1,002	103	20,525	1,961
en–es	1,002	105	16,720	1,980

Table 9
Statistics for XL-WA's EN–IT and EN–ES subsets.

C. Computational Resources

All models are trained on a single NVIDIA RTX 5000 Ada Generation, with 32 GB of VRAM. The total training time is around 7-15 minutes for each alignment model, depending on the training data combination, plus 30-60 minutes for training each on XL-WA. Training each NER model takes around 6-7 minutes. All the training, including multiple models for standard deviation calculation, was carried out in under 48 hours.

NYTAC-CC: A Climate Change Subcorpus based on New York Times Articles

Francesca Grasso[1,*,†], Ronny Patz[2,†] and Manfred Stede[2,†]

[1] *University of Turin, Corso Svizzera 185, 10149, Turin, Italy*
[2] *University of Potsdam, Karl-Liebknecht-Str. 24-25, 14476, Potsdam, Germany*

Abstract

Over the past decade, the analysis of discourses on climate change (CC) has gained increased interest within the social sciences and the NLP community. Textual resources are crucial for understanding how narratives about this phenomenon are crafted and delivered. However, there still is a scarcity of datasets that cover CC in *news media* in a representative way. This paper presents a CC-specific subcorpus of 3,630 articles extracted from the 1.8 million New York Times Annotated Corpus, marking the first CC analysis on this data. The subcorpus was created by combining different methods for text selection to ensure representativeness and reliability, which is validated using ClimateBERT. To provide initial insights into the CC subcorpus, we discuss the results of a topic modeling experiment (LDA). These show the diversity of contexts in which CC is discussed in news media over time.

Keywords

Climate Change, Corpora, Topic Modeling

1. Introduction

We present NYTAC-CC, a topic-specific subcorpus with 3,630 articles addressing climate change (CC), derived from the *New York Times Annotated Corpus*. This subcorpus covers a 20-year period, drawing from NYTAC's collection of 1.8 million articles published between 1987 and 2007, which is available through the *Linguistic Data Consortium*. The original corpus, and thus also the subcorpus, includes a variety of metadata such as the 'desk' (the newspaper branch) and both manually- and automatically-labeled content categories, with many articles also featuring hand-written summaries. The extensive use of NYTAC in NLP research over the last 15 years (e.g., [1, 2]) benefits CC researchers, allowing for detailed historical analysis of CC discussions in news media. This includes exploring how CC debates were interwoven with topics like domestic and foreign policy, science reporting, and arts and culture coverage. Unlike other CC-focused resources that often contain shorter documents, the NYTAC-CC subcorpus offers a diverse array of articles with varying lengths and complex content, making it a unique resource for investigating the evolution of CC narratives over time.

The contribution of this paper is threefold:

(*i*) We present the NYTAC-CC subcorpus and its construction using blending of dictionary-based and supervised methods in order to ensure *representativeness* as well as *validity* and *reliability*, which are key in social science research [3]. This hybrid approach addresses the challenges of refining a topic-specific subcorpus from a larger corpus, aiming to mitigate the limitations of traditional keyword-based sampling that often results in false positives.

(*ii*) To demonstrate the validity of the subcorpus, and thus its reliability for further downstream tasks, we illustrate the results of a classification experiment using ClimateBERT [4]. While this experiment further validates that the articles in our NYTAC-CC subcorpus are, indeed, true positives, it also shows limitations of ClimateBERT. As ClimateBERT falsely classifies a number of true positives from our subcorpus as (false) negatives, we demonstrate that our approach achieves better results in ensuring recall of relevant CC articles from the NYTAC corpus.

(*iii*) To gain initial insights into the CC subcorpus coverage, we use keyword analysis and topic modeling (specifically LDA) to track specifics of CC reporting over the 1987-2007 time span. The results show important trends over time, including key periods of reporting and a large variety of contexts in which CC is discussed.

Thus, our goal is to provide a substantively new and relevant subcorpus, developed and validated in multiple iterations, and to then provide a first overview of the NYT's coverage of climate change during the time period covered in our corpus. Although several studies have explored U.S. print media's reporting on anthropogenic CC, we cover an important 20-year period in which much of today's climate change discourse evolved.

2. Related Work: CC in News

Despite the growing interest in addressing climate change among various academic communities, as pointed out by Luo et al. [5], the topic has so far received limited attention within the 'core' NLP community. This is largely due to the NLP field's focus on standardized datasets and shared tasks, where the topic of CC has been scarcely addressed.

Efforts can be observed within the context of social media, with datasets made available for CC-related tasks [6, 7]. However, there remains a scarcity of work addressing CC at the news article level, which is essential for the NLP community investigating CC narratives in media or performing downstream tasks involving longer texts. In contrast, the analysis of CC discourse on both social media and traditional media has been extensively studied in various social science disciplines [8, 9]. In the following, we will focus on prominent work targeting traditional news media.

A widely-cited early study by Trumbo [10] examined the framing techniques used by various ”claim makers” in the online editions of five U.S. newspapers. After querying with different terms and manually filtering the results, the remaining articles were thoroughly investigated. Boykoff [11] later studied the ”claims and frames” issue in a similar manner. Legagneux et al. [12] conducted a comparative study of scientific literature and press articles to investigate coverage differences between CC and biodiversity. They analyzed materials from the USA, Canada, and the United Kingdom spanning 1991 to 2016, using representative keywords to query and retrieve relevant content. Similarly, [13] examined how journalistic norms affected CC reporting in U.S. TV and newspapers. Other studies examined the frequency of CC mentions, or the 'attention cycle'. Brossard et al. [14] compared CC reporting between the NYT and the French *Le Monde*. Grundmann and Krishnamurthy [15] analyzed newspapers from four countries, enhancing article counts with word frequency and collocation analyses using corpus-linguistic tools, where the outcomes are manually interpreted. The work of [16] highlights one of the few instances where NLP technology is used to analyze CC in newspapers, where authors applied supervised classification to construct a corpus and identify frame categories within four U.S. papers. Continuing in the NLP domain, [4] utilized a specialized corpus that includes CC-related news articles, though details on data retrieval are not available. [17] compiled a dataset of 11k news articles from *Science Daily* through web scraping.

In conclusion, there remains a scarcity of available corpora containing larger text units like entire articles, which are essential for the NLP community investigating CC narratives in traditional media or performing various downstream tasks involving news articles.

3. Building the NYTAC-CC

3.1. Challenges in CC Text Selection

The New York Times Annotated Corpus (LDC release)[1] contains 1,855,658 articles (1987-2007), each formatted as a single XML file. Metadata include date, author, and newsroom desk. Articles are manually annotated with locations, people, organizations, and key topics. However, topic labels are generally not sufficient for our purpose, that is, finding all CC-related articles, because (i) not all articles are labeled; (ii) some labels of potentially CC-relevant text are overly broad, e.g., 'weather,' which also encompasses many non-CC topics; and (iii) some articles we consider CC-relevant are tagged with labels that do not relate to CC.

Our goal is to design a retrieval method that not only ensures *validity* and *reliability* but also emphasizes *representativeness*, ensuring that the corpus adequately covers content related to the specific subject it aims to represent. Traditional approaches, such as the use of keywords or n-grams, can be inadequate if used alone and can lead to misclassifications due to both false positives and false negatives. Crucially, this holds even with advanced models, particularly when tasked with processing large linguistic units such as entire articles [18]. The changing use of language in time-spanning corpora can further challenge single-method approaches, since they must handle texts that, although consistent in topic, may cover the phenomenon in varied ways over time.

Moreover, we aim for an approach that is reproducible, i.e., that can also be applied to other corpora that do not come with this type of metadata. We have therefore opted for a hybrid approach that combines the advantages of both keyword-based methods and automatic classification, while also aiming to overcome the weaknesses of both.

3.2. Our Hybrid Approach

Our subcorpus construction is built on text retrieval methods previously used in studies on CC discourse (see, e.g., Section 2), but merges them into a hybrid approach to address their strengths and weaknesses. In the literature, we identified the following approaches:

1. Search with bigrams: typically, this involves terms like “climate change,” sometimes accompanied by one or two others, notably “global warming” and ”greenhouse effect”; e.g., [10, 12];

2. Search with a longer list of keywords, followed by manual filtering; e.g., [19, 18];

[1] https://www.ldc.upenn.edu

3. Complex Boolean queries with keywords and operators (AND, OR, NOT); e.g., [20];

4. Manual annotation of training data followed by supervised classification; e.g., [16].

As a first exploratory step, we experimented with method (1), obtaining the expected unsatisfactory results. We subsequently refined our retrieval process from the NYTAC by extending methods (2) and (4). Texts that we consider relevant for the CC topic must not only merely mention CC in passing, but should discuss aspects of anthropogenic CC, relate substantial information, or convey a stance on its existence or urgency.

Bigram search. Initially, we experimented with a list of bigrams (see Appendix A) sourced from the BBC Climate Change Glossary[2]. This was done to cover terminologies used over the two decades spanned by the corpus. This method led to the retrieval of 10,707 articles. Upon manual inspection, we found that many were false positives, addressing general environmental issues but not specifically related to CC. Conversely, many articles we regarded as relevant did not contain the bigram ”climate change” (searching for this bigram yielded only 2,080 texts). Consequently, this led us to seek a more elaborate approach.

Keyword search. In response to the limited performance of the bigram search, we proceeded to extract CC-related articles using keywords that were employed by [19] to identify topic-relevant articles in *Nature* and *Science* (see Appendix B). To these, we added the keyword ”Kyoto”, given the specific time period of our corpus where the Kyoto conference had a similar importance as later the ”Paris agreement”. However, the resulting subcorpus still contained many false positives, primarily from long list-like articles combining various news items. To ensure homogeneity, we excluded these articles, resulting in an intermediate corpus of 12,883 articles.

Text ranking and supervised classification. To overcome the presence of false positives, we implemented an additional, more elaborate filtering step on the intermediate corpus. Initially, we heuristically ranked the articles for topic relevance, using a score based on accumulated keyword weights. This score reflects both the frequency of the keywords and their position within the article, as content in the beginning is generally considered most important. Specifically, we multiply the number of keyword occurrences per sentence by a score representing sentence prominence (1 for the first sentence, 0.9 for the second, 0.8 for the third, and so on). After automatically ranking the articles, we selected 450 articles for manual tagging: the top 150, the last 150, and 150 from the middle. We manually assessed them to determine if they were at least partially about CC, using the labels ’1’ (CC-related) or ’0’ (not CC-related).

We used the manually-annotated data to train and test an XGBoost classifier, configured to differentiate between CC-related and non-CC articles. The features used included keyword counts, (those from [21], plus ’Kyoto’), the 50 most frequent ’topic’ labels from the article metadata, and several binary features: whether an article was published by (i) the ’Dining’ or ’Style’ desks or by (ii) other desks; whether it was published on the weekend; whether a keyword appeared in the title or the first paragraph; and whether the article was (i) an opinion piece or a letter versus (ii) another type of article. The classifier achieved a precision score of 1.0 and a recall score of 0.94 on our held-out evaluation set of 100 texts. Subsequently, we used the classifier to label the entire intermediate corpus, labeling 9,253 articles as not CC-related and 3,630 CC-related, thus forming what we now refer to as our final ’NYTAC climate change subcorpus’ and make available as the list of document IDs.[3] Figure 1 illustrates the features that had the greatest impact on the classification decisions.

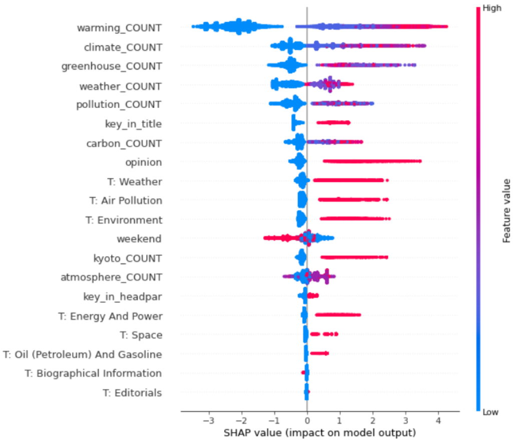

Figure 1: Key features in classifying ”climate change” articles

3.3. Evaluation with ClimateBERT

We aim to demonstrate (i) the relevance of our 3,630-article subcorpus in genuinely consisting of climate change (CC)-related articles and, thereby, (ii) the validity of our combined method for retrieving topic-consistent texts from a larger, heterogeneous collection while minimizing false positives. To perform that validation, we employed ClimateBERT, specifically $ClimateBert_F$ [4], a BERT-based model trained on CC-related texts. In particular, we used *distilroberta-base-climate-detector* from the

[2] https://www.bbc.com/news/science-environment-11833685

[3] https://github.com/discourse-lab/NYTAC-CC

Hugging Face platform[22], a fine-tuned version with a classification head for detecting climate-related paragraphs. Given its specialization in CC-related texts, we deemed ClimateBERT a very suitable tool to confirm the accuracy of our dataset. In doing so, we are also indirectly assessing the model's capability in detecting CC-related content within larger portions of texts. As the model's context length is limited to 512 tokens, we addressed this limitation by adopting two different approaches described below.

In the first approach, longer texts were truncated due to the model's limited context length. Of the 3,630 instances, the model recognized 3,468 articles as +climate. We manually inspected the remaining 162 texts classified as -climate, i.e., as false negatives. We found that the model clearly misclassified 75 texts, which included relevant CC content appearing beyond the initial 512 tokens. More qualitative insights on these 162 texts are provided in the subsection below.

In addition, we attempted a second approach to overcome the context length constraint by using a sliding window technique. This involved creating chunks of longer texts (> 512 tokens), classifying each chunk, and labeling the entire text as +climate if any of the chunks were labeled as such. This second approach led to significantly different results, as only 3 out of 3,630 instances were labeled -climate.

These results demonstrate both the representativeness of our corpus and the validity of our hybrid subcorpus selection method. In addition, we show how automatic classification models can be limiting when dealing with long text units, therefore reinforcing the need for a combined approach to build topic-relevant (sub)corpora.

3.4. Analysis of the ClimateBERT misclassifications

As discussed in Section 3.3, we manually inspected 162 articles that ClimateBERT initially classified as false negatives within our subcorpus. Of these, 75 were clearly related to CC. Specifically, 48 articles featured significant discussions on CC-related issues beyond the model's 512-token limit. Additionally, 27 articles contained detailed CC narratives within the first 512 tokens, often intersecting with other topics like politics (e.g., conferences on CC) and population (e.g., CC impacts on specific regions). This misclassification highlights the models' limitation extending beyond the mere input token limitation, underscoring the challenges in handling topic intersections.

Although not the primary focus, CC was still mentioned in the remaining articles. In particular, 51 articles included CC in contexts marginally related to their main narratives, integrating CC with other discussions. In another 36 articles, CC was a secondary topic, occasionally mentioned only in passing, such as references to the Kyoto Protocol or metaphorical uses of global warming.

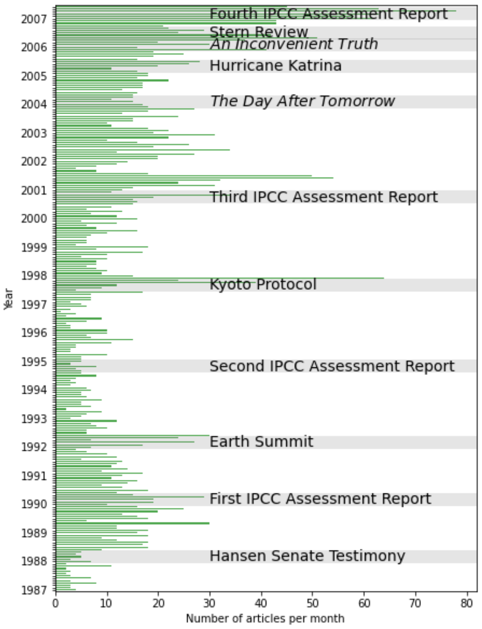

Figure 2: Monthly article count in CC subcorpus

4. Overview of NYTAC-CC

In this section, we provide an initial overview of the NYTAC-CC coverage, including the article distribution over time and a preliminary subtopics exploration.

4.1. Temporal and Keyword highlights

We examine the temporal distribution of articles and key lexical features in our corpus to illuminate trends and shifts in CC coverage over time (see Figure 2).

The analysis reveals a peak in articles during 1990, with up to 50 mentions per month, followed by a decline to 20 articles per month in the mid-90s. After the Kyoto Protocol in December 1997, the curve shows a steady rise with intermittent bursts in coverage. In the figure, we have marked important 'climate events' corresponding to the years they occurred.

The frequency ratios of the top eight lexical features determined by the classifier (cf. Figure 1) over time in Figure 3 illustrate the dominance of 'greenhouse' in the late 1980s. 'Warming' remains the most frequent term throughout, but in the final years, 'climate' gains prominence, suggesting a shift of term preference from 'global warming' to 'climate change'—a transition noted in various other studies as well. Also, the two 'Kyoto' events

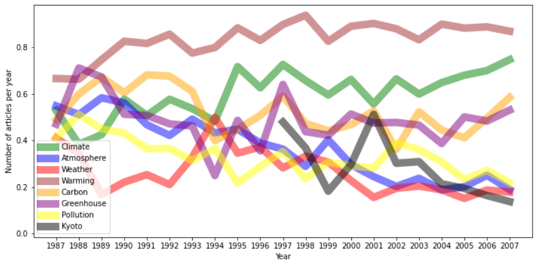

Figure 3: Keyword distributions over time

are clearly visible: the international accord was reached in 1997, and the Bush administration's decision not to ratify it occurred in 2001.

At the same time, we also find that many articles focused on weather or pollution primarily addressed these issues directly, mentioning climate change only tangentially. This reduces the co-occurence of other prominent CC terms in these articles.

4.2. Document Structuring with LDA

Building on the basic statistics discussed in the previous subsection, we delved deeper into the range of subtopics within the CC corpus using topic modeling, specifically Latent Dirichlet Allocation (LDA). This approach helps to uncover underlying thematic structures in the data, which are not immediately apparent from simple keyword analysis.

Preprocessing Steps To prepare the texts for LDA, we performed several preprocessing steps on article titles and bodies, including removing punctuation, lemmatizing words, and converting all text to lowercase to ensure consistency. We also joined frequently co-occurring bigrams into single terms to preserve important phrases. For our topic modeling, we focused on nouns and proper nouns that ranked among the top 10,000 by frequency and had more than two letters. This refinement allowed us to emphasize key entities and their relationships, central to the content of the articles, and avoid the dilution of thematic significance by less informative parts of speech, enhancing consistency through the use of pseudowords.

Model Selection The best LDA model was chosen based on the coherence score, calculated using the Python *Gensim* library. This ensures an objective selection process, minimizing subjective interpretation. We prioritized coherence to ensure that the topics generated by the model are interpretable and meaningful. The optimal model identified 18 topics, with a coherence score of .56, indicating a reasonable level of interpretability. We chose the highest-ranked term as the 'name' of each topic and listed five additional representative terms as follows:

1. **emission:** country, world, greenhouse_gas, carbon_dioxide, global_warming
2. **administration:** president, policy, white_house, bill, congress
3. **people:** time, life, book, world, earth
4. **scientist:** temperature, climate, study, research, university
5. **energy:** oil, fuel, gas, production, power
6. **city:** new_york, people, park, town, mayor, manhattan
7. **company:** business, project, program, group, director
8. **global_warming:** report, climate_change, scientist, panel, editor
9. **plant:** coal, company, emission, power, utility
10. **water:** area, land, river, population, fish
11. **state:** pollution, air, ozone, epa, smog
12. **china:** government, people, war, security, country
13. **car:** vehicle, fuel, gasoline, hydrogen, auto
14. **ice:** sea, arctic, ocean, glacier, bear
15. **forest:** tree, plant, species, fire, crop
16. **weather:** winter, temperature, snow, degree, heat
17. **storm:** el_nino, drought, hurricane, wind, flood
18. **island:** bird, beach, garden, long_island, sand

As is common with topic models, some overlap between topics can occasionally be observed when examining the complete top-30 term lists, for example, between topics *company* and *plant*. Additionally, we find some apparent 'outlier' terms in all the topics.

As a preliminary approximation, we tagged each text in the subcorpus with the predominant topic identified by the model, allowing us to track the evolution of topic coverage over time (see Figure 4). This LDA-based analysis highlights how the context of CC-related coverage in the NYTAC corpus shifts over time, for example from a framing within science and pollution debates to a discourse context in which greenhouse gas emissions were central. Further, our findings complement the manual inspection discussed in Section 3.3, illustrating how climate change discussions, while sometimes secondary in broader articles on government policy (topic 'administration'), are integral to discussions on foreign policy ('China') and cultural topics ('people').

5. Conclusion and Future Work

In this paper, we introduced the NYTAC-CC, a specialized subcorpus of 3,630 climate change articles from the New York Times Annotated Corpus spanning 1987 to 2007,

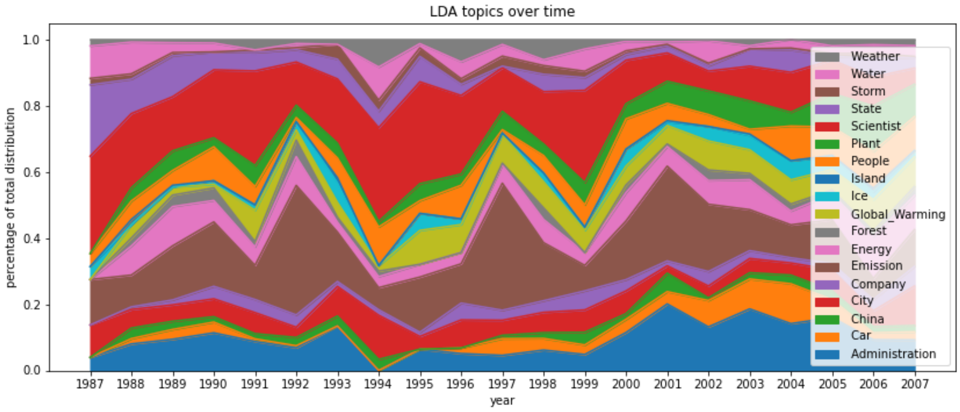

Figure 4: Topic coverage over the 20-year period

marking the first CC analysis with this dataset. Addressing the lack of available news-based textual resources for NLP tasks, we employed a hybrid method combining keyword-based prefiltering and automatic classification to optimize the corpus construction. The representativeness of the subcorpus was confirmed using ClimateBERT, but additional manual inspection of ClimateBERT's classification of a relevant amount of true positives as (false) negatives also showed the model's limitations and the benefits of the hybrid approach chosen.

Initial analyses of the subcorpus, including statistics, keyword searches, and topic modeling, highlight the corpus's potential for detailed diachronic and subtopic exploration.

Thus, the NYTAC-CC subcorpus can be a useful resource for examining the historical narrative of climate change in news media. As it builds on the NYTAC corpus, it adds to previous work on this data, providing valuable insights for social science research. It also serves as a beneficial dataset for developing NLP applications that require a deep understanding of climate-related discourse. While the size of the subcorpus may restrict certain quantitative analyses, its rich, concentrated content is ideal for qualitative studies. Furthermore, it offers the potential for expansion and further integration with additional sources to enhance its utility and relevance for ongoing climate change research. Future work will expand on these findings with advanced topic modeling techniques and integrate more recent articles to enrich the diachronic analysis.

Task-Incremental Learning on Long Text Sequences

Natalia Graziuso[1], Andrea Zugarini[2,*] and Stefano Melacci[1]

[1]Department of Information Engineering and Mathematics, University of Siena, Italy
[2]expert.ai, Italy

Abstract

The extraordinary results achieved by Large Language Models are paired with issues that are critical in real-world applications. The costs of inference and, in particular, training are extremely large, both in terms of time and computational resources, and they become prohibitive when working in dynamic environments, where data and tasks are progressively provided over time. The model must be able to adapt to new knowledge, new domains, new settings, without forgetting the previously learned skills. Retraining from scratch easily becomes too costly, thus Continual Learning strategies are of crucial importance. This is even more evident when data consist of "long" documents, that require several resources to be processed by modern neural models, leading to very long prompts. This paper investigates LLM-based Task-Incremental Learning in the case of tasks exploiting long sequences of text, as it is typical in summarization, question-answering on long documents, reviewing long contracts, and several others. We show how adapting the model by Task Arithmetic with LoRA, which was proposed for visual data, yields promising results also in the case of such "long" text data. To our best knowledge, this is the first work along this challenging direction. The outcome of the investigation of this paper is generic enough to represent an important starting point for further research in processing linguistic data in every language.

Keywords

Continual Learning, Task-Incremental Learning, Long Sequences of Text, Large Language Models

1. Introduction

The quality of Language Models (LMs) has been rapidly improving in the last decade, showing outstanding skills when scaled to large data and networks [1], leading to the nowadays popular Large Language Models (LLMs). Solving more complex tasks with LLMs often requires processing "long" documents and articulated long instructions. However, handling lengthy prompts can be a significant obstacle for real-world applications, raising costs and resources required during both inference and, in particular, training. This issue can become critical when the LLM needs to be specialized to many different tasks, domains, and, more generally, when it is applied to dynamic settings that require multiple adaptations. For instance, in real-world applications, models need to be re-trained from time to time, as new data/tasks become available. In such scenarios, the need for Continual Learning (CL) [2, 3] strategies becomes imperative. From a very generic perspective, CL focuses on the development of algorithms capable of sequentially learning from a stream of data, while preserving what was learnt in past experiences, avoiding catastrophic forgetting [4].

In this work, motivated by the aforementioned issues, we study the problem of Continual Learning from "long" sequences of text, exploiting LLMs. We investigate several strategies based on LoRA [5] to adapt an LLM to multiple tasks that are sequentially proposed over time. In particular, we first follow the route of training a single adapter in a sequential manner, then we explore Task Arithmetic to fuse multiple adapters trained independently [6]. We consider the possibility of assigning different weights to each task, and we shed some light on what are the factors that contribute the most to catastrophic forgetting and to effective task adaptation. The outcomes of such an investigation reveals that: (1) there is limited sensitivity to task-order, i.e., regardless of the sequence in which tasks are presented, the overall average performance remains relatively stable, a property that, to our best knowledge, was never evaluated in the case of tasks composed of long documents; (2) despite its simplicity, Task Arithmetic demonstrates effectiveness in addressing forgetting phenomena when learning from long texts, strongly reducing the gap from multiple models independently adapted to the task data. Moreover, (3) we are the first to evaluate a recently proposed benchmark (SCROLLS [7]) in a CL setting, offering reference results for further activity in processing long sequences of text. We remark that while our experiments are based on data in English language, the generic issues we explore about handling long sequences of text are intrinsically shared by every language.

2. Related Work

In the last few years, a variety of approaches were proposed by the scientific community in the context of CL (see [3] and references therein). The main goal is the one

CLiC-it 2024: Tenth Italian Conference on Computational Linguistics, Dec 04 — 06, 2024, Pisa, Italy

of learning from newly provided information, with models that are capable of acquiring new knowledge without forgetting the previously learned one, and, more importantly, without storing the full dataset and retraining from scratch every time [8]. Several efforts are dedicated to the case of lifelong Reinforcement Learning [9] and of Supervised Learning [10], distinguishing among scenarios and categories of approaches [11], ranging from parameter isolation, regularization methods, and replays [12]. Unsupervised or Self-Supervised Learning approaches are also becoming popular [13, 14, 15], and the case of adaptation of pre-trained backbones [16].

Of course, neural models for processing language are a subject of study in the context of CL [17]. We mention the case of language modeling in Lamol [18], which is trained to concurrently solve a task and mimic training examples, thereby preserving the distribution of previous tasks. Sun et al. [12] introduce Distill and Replay, which learns to solve the task, to generate training examples formatted as context-question-answer, and to distill knowledge from a model trained on the previous task(s). Differently, Reasoning-augmented Continual Learning [19] focuses on creating reasoning pathways to preserve and improve LLMs' reasoning abilities and information transfer.

Together with works that learn new models from scratch, several approaches devise fine-tuning strategies for pre-trained Transformers in language processing, that turn out to be efficiently adaptable to a downstream task by learning only a small number of task-specific parameters. It is the case of models that tune the input prompt [20] or of generic Adapters [21], such as the popular LoRA [5], which introduces new weight matrices, parametrized by the product of low-rank ones. Evaluating these models with long contexts [22] is not frequent in the scientific literature, especially in the case in which multiple fine-tunings are sequentially applied, typical of CL, which is the main focus of this paper. In particular, LoRA and Task Arithmetic [23] has been jointly studied to handle CL problems in vision [6], that is what this paper extends to the case of language and long sequences. We also mention works that focus instruction-based model for CL, such as ConTinTin [24], where each task is modelled by a specific instruction that directly defines the target concept along with a few instances that illustrate. Scialom et al. [25] and Luo et al. [4] investigate natural language instructions paired with memory buffers and replays.

3. Task-Incremental Learning on Long Sequences of Text

Task-Incremental Learning (TIL) is a continual learning scenario where the same model is trained on tasks that are presented in a sequential manner. The main challenge consists in profitably learning from the last-presented task without forgetting the previous ones [3]. In order to cope with TIL on Long Sequences of Text, specifically focusing on LLMs, we consider different learning strategies. In this Section we describe each of them in detail, after having formally introduce the TIL problem.

Problem. We are given a model parameterized by θ, which is a vector collecting the learnable variables. In TIL, a set $\mathcal{T}$ of k tasks is sequentially presented to the model, i.e. one at a time. Each task $t \in \mathcal{T}$, features data sampled from a task-specific distribution, collected into dataset $\mathcal{D}_t := (\mathcal{X}_t, \mathcal{Y}_t)$, composed of raw samples and labeling information, respectively. The model is not only expected to learn from $\mathcal{D}_t$, but also to not forget knowledge already acquired from the past tasks. In the following, to keep the notation simple, we indicate each task by a numerical index, thus $t \in \mathcal{T} = \{1, \ldots, k\}$. In this case of study, the model is a pre-trained LLM with billions of parameters, and all the TIL tasks are characterized by long input sequences. Such a combination constitutes a computationally demanding mix, making offline/joint training potentially very expensive, that is where CL solutions are very convenient. We consider the case in which LLMs are fine-tuned exploiting adapters [26]. In particular, we focus on LoRA [5], that introduces additional learnable parameters while keeping the rest of the network freezed. This is both less resource demanding, and it also alleviates catastrophic forgetting, since the LoRA weights θ^l are usually of a number that is a small fraction with respect to total model parameters, i.e. $|\theta^l| \ll |\theta|$. Hence, it is a perfect candidate for the experience of this paper.

Single-model TIL with LoRA (S-TIL). In the straightforward implementation of a TIL problem, tasks are presented to the model sequentially starting from the first one up to the k-th one. The order may be given a priori, or established according to some criteria, such as tasks similarity or difficulty (curriculum-like learning [27]). At the beginning, when considering the first task, $t = 1$, we start from a model with freezed parameters θ and additional trainable weights θ^l_1 initialized as described in [5]. At task t, with $t > 1$ instead, the LoRA weights are initialized with the LoRA parameters from previous step, i.e., θ^l_{t-1}. It is worth noticing that in such a way, at the end of the k tasks, the final model parameters will be constituted by the original θ, still unchanged, and a *single* set of adapter parameters θ^l_k, that was sequentially trained over all the tasks.

Multi-model TIL with LoRA (M-TIL). Another way to face the problem of learning the multiple tasks in TIL, is to build a specialized model per task, independently on the other ones. This usually yields strong performance on each sub-problem, guaranteeing no catastrophic forgetting issues, since the model to use is simply retrieved

Table 1
Selected datasets from the SCROLLS benchmark and their main features.

Dataset	*Task*	*Domain*	*Metric*	*#Examples*	
				Train	Validation
Contract NLI	Natural Language Inference	Legal	EM	7191	1097
Qasper	QA	Science	F1	2567	1726
QuALITY	Multi Choice QA	Literature, Misc	EM	2523	2086
QMSUM	Query-based Summarization	Meetings	ROUGE-L	1257	272
SummScreenFD	Summarization	TV	ROUGE-L	3673	338

in function of the task to solve. At the same time, such a strategy requires the storage, deployment and maintenance of k independent models, which is unsustainable with billion-sized models like current LLMs. Even when using adapters such as LoRA, maintaining many of them can be still hard to handle.

Task Arithmetic TIL with LoRA (TA). Based on the concept of "task vectors", Task Arithmetic (TA) [23] was proposed to combine together the weights learned in a multi-model continual learning scenario. A task vector represents the direction in the weights space of a pre-trained model toward a certain task. In TA, multiple directions are fused together via a simple linear combination of them. Similarly, LoRA adapters steers the model behavior to improve performance on a specific task. Therefore, LoRA weights trained separately (multi-model) can be updated with task arithmetic [6]:

$$\theta^l_{\text{final}} = \sum_{t \in \mathcal{T}} \lambda_t \theta^l_t, \quad (1)$$

where λ_t is a scalar weighting the importance of task t.

Fine-tuning by Memory Buffer (FTB). In principle, TA can be applied as it is, without requiring further fine-tuning. However, we also consider refining the parameters using a memory buffer with examples from all the tasks. Indeed, experience replay is a well-known and effective strategy in Reinforcement Learning and Continual Learning problems. Examples were chosen randomly, evenly distributed across the given tasks. Since we are dealing with long documents, we keep it small.

4. Experiments

We experimented LLMs in TIL exploiting sequences of long texts from a benchmark made public to the scientific community in the last few years [7]. Notice that these benchmarks *are not* designed for TIL. Thus, using them in TIL is indeed a novel experience off the beaten track.

4.1. Datasets

We consider five out of seven datasets of SCROLLS [7], that is the reference benchmark for tasks composed of long documents. Datasets belong to different domains, and they are about different tasks, that we adapted to TIL by means of instruction tuning. An overview of the benchmark is provided in Table 1, and here we briefly describe each dataset.

Qasper. Qasper [28] (QSPR) is Question Answering (QA) dataset on academic papers. Crafted by NLP experts, it contains questions based on title and abstract of the paper. There are different kind of inquiries: abstractive, extractive, yes/no questions, including unanswerable ones. To answer the question, the entire paper must be read.

QuaLITY. QuALITY [29] (QALT) is a multiple-choice QA dataset, drawing upon English source articles with an average length of about 5,000 tokens. Original texts are provided in HTML format, retaining paragraph breaks and basic formatting such as italics, but with images removed. Questions are designed to require details from different parts of the text to properly answer them.

QMSum. QMSum, presented in [30], is a question-based document summarization benchmark. The dataset is characterized by long meetings transcripts, collecting 1,808 query-summary pairs from 232 different meetings.

ContractNLI. Contract NLI [31] (CNLI) is the first dataset for Natural Language Inference in contracts. Given a premise and a contract, a model has to classify whether the premise is entailed by, contradicting to or not mentioned by the contract. There are 607 contracts and 17 unique hypotheses, combined to get 10,319 examples.

SummScreenFD. SummScreen [32] (SumScr) is a summarization dataset of TV series transcripts and human written recaps. Examples come from two different sources, but in SCROLLS, authors only kept ForeverDreaming (FD), due to its greater variety of shows.

4.2. Experimental Setup and Results

We consider Mistral-7B-v0.1 [33] as the backbone LLM for all the fine-tuned models in our TIL experiments. Albeit trained on a restricted context length of at most 8,192 tokens, it supports longer inputs of size up to 32,768. The LLM was quantized via 4-bit quantization in order to fit long sequences on a single A6000 GPU. During training, the micro batch size was set to 1, with 32 gradient accumulation steps. LoRA adapters were updated with AdamW for 3 epochs in all the experiments, regardless of the dataset. At inference time, outputs were generated using Beam Search with beam size set to 2. We compared: (*i*) Mistral-7B-v0.1-Instruct, the instruction-tuned version of mistral, referred to as Mistral-7b-instruct; (*ii*) The case of multiple independent LoRA adapters, each of them trained in a single dataset, i.e., M-TIL (Section 3); (*iii*) Classic TIL with a single model, progressively updated on the sequence of tasks, i.e., S-TIL (Section 3), considering both the case in which tasks are provided in a certain order (S-TIL$_\downarrow$) or in the opposite one (S-TIL$_\uparrow$); (*iv*) Task Arithmetic (Section 3) with evenly values λ's (TA) or with tasks-specific λ's based on prior knowledge (WTA).

Evaluation. Due to the different nature of each task in SCROLLS, there are different metrics to take into account for each of them. In particular, summarization-like tasks (QMSum and SummScreenFD) are evaluated with ROUGE score [34] (1,2 and L) , whereas, ContractNLI and QuaLITY are assessed with Exact Match (EM). Finally, results on Qasper are measured by F1. A global overview of the metrics can be found in Table 1. We indicate with S_i the score yielded by the associated metric for task i. Following the way the SCROLLS benchmark was proposed, scores are averaged to provide a unique index of Overall Performance OP. Since we focus on TIL, we evaluate OP after each task t, and we also compute the Overall Forgetting at task t (OF_t), also known as index of negative backward transfer [35], which tells how strongly the previously considered tasks have been negatively affected by learning from the current task t, i.e., a measure of catastrophic forgetting [4]. Formally,

$$OP_t = \frac{1}{t}\sum_{i=1}^{t} S_{t,i}, \quad OF_t = \left[\frac{1}{t-1}\sum_{i=1}^{t-1}(S_{i,i} - S_{t,i})\right]_+,$$

where $[\cdot]_+$ keeps the positive part, and $S_{t,i}$ is the score of task i after having learned from task $t \in \mathcal{T}$. Since the test set of SCROLLS is not public, we used the SCROLLS validation set as test set, and sampled a sub-portion of the training data to build a validation set. After cross-validation, we set the rank of LoRA to 8, dropout-rate to 0.05, and α to 16 (see [5] for param description) and learning rate $3 \cdot 10^{-4}$ (linearly decaying).

Investigating S-TIL. Dealing with long sequences of text might affect the TIL procedure in function of the order in which tasks are presented. We study different task orderings based on the average length of the sequences of text in each task, from tasks involving shorter output sequences to the ones involving longer sequences and vice-versa. As anticipated, we named them S-TIL$_\uparrow$ and S-TIL$_\downarrow$, respectively. Results of this experience are presented in detail in Table 2. The training order does strongly affect the final performance on single tasks, promoting higher scores on more recently seen datasets. On one hand, this is expected, since the older ones are more likely affected by catastrophic forgetting. Catastrophic forgetting (last columns of Table 2) at $t = k = 5$ is below 10% in both cases. On the other hand, there is an evident peak of forgetting in S-TIL$_\downarrow$ at $t = 3$, which is then reduced when learning from the following tasks. The peak is due to a strong reduction of performance in the first two tasks after having learned from Qasper (QSPR). We investigated this aspect, and found that the model fails in generating the perfectly-formatted output string that is then exploited in the EM metric. When moving to the following task, this skill is partially recovered. We hypothesize that the presence of unanswerable questions in Qasper negatively bias the types of answers in SummmScreenFD (SumScr) and QMSum, where all the questions have an answer instead.

Comparing Instances S-TIL and M-TIL. Figure 1 compares the models of Table 2 (for $t = k$) with M-TIL, which is composed of multiple adapters, each of them specifically trained on a task, and thus forgetting-free. Performance of both S-TIL's are lower of M-TIL, as expected, but sometimes not far from it. Comparing S-TIL$_\uparrow$ and S-TIL$_\downarrow$, we see that they get similar overall performances, but the latter yields better results in three out of five tasks. The quality of S-TIL$_\uparrow$ (w.r.t. S-TIL$_\downarrow$) improves going right-to-left, and, symmetrically, the one of S-TIL$_\downarrow$ increases going left-to-right, as expected, since they were trained in opposite order (relative gain is > 1 in SumScr due to forward transfer).

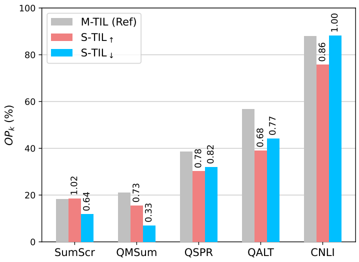

Figure 1: Test results in TIL: overall performance at $t = k = 5$, i.e., OP_k. We compare the cases of S-TIL$_\uparrow$ and S-TIL$_\downarrow$ (see Table 2), with the ones of multiple-independently trained adapters, i.e., M-TIL. **Relative Gain is indicated on the bars.**

The Role of TA. We compared all the introduced models with the case of merging independently-trained adapters with TA. Table 3 shows that TA results to be a simple yet competitive solution, with average performance on par with S-TIL$_\downarrow$. Actually, observing task-wise performance, we can see how TA outperforms S-TIL$_\downarrow$ across all the datasets, with the exception of ContractNLI

Table 2

Evaluation score (%) on test data, for each task, after having learned from task t (i.e., $S_{t,i}$) in S-TIL$_{\uparrow}$ (**left**) and S-TIL$_{\downarrow}$ (**right**). The order of columns (dataset names) reflect the task-order followed during training. Tasks becomes available in order, thus – indicate that the value cannot be computed yet. The OF_t column is about catastrophic forgetting (the lower the better).

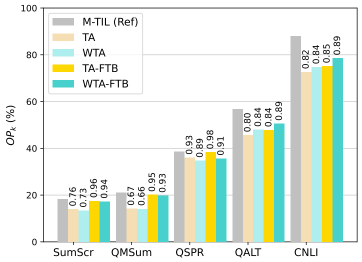

Figure 2: Test results in TIL with Task Arithmetic (TA). TA is explored with or without Fine-tuning by Memory Buffer (FTB), and also in the case of task-specific weights provided in advance (WTA). Same setting of Figure 1.

(CNLI), the last task in which S- TIL$_{\downarrow}$ was specialized. In WTA, λ's for non-QA datasets were halved, since there tasks involve generation of longer outputs that more strongly condition the behaviour of the LLM, as already discussed for Qasper. WTA yielded evident improvements in the last two datasets, despite being less weighed, keeping similar performance on the others. This suggests that appropriately weighing the task-vectors in Eq. 1 is a viable road to improve the model.

Impact of FTB. We also investigate the impact of rehashing the memory of the TA/WTA model via fine-tuning it on just 50 samples per the tasks (memory buffer). Despite being a simple refinement stage, results presented in Table 3 show a consistent boost of performance when using the memory buffer (FTB), reaching about 39.0 averaged score, when using the weighted TA version, significantly reducing the gap from the k-independent adapters solution of M-TIL. Figure 2 provides a quick view on the already presented results of all the TA methods we considered, reporting also the Relative Gain w.r.t. M-TIL. Indeed, we can observe that the relative drop in performance is always below the 11%.

5. Conclusions

We investigated Large Language Models in progressively learning from tasks involving long sequences of text. A pre-trained model was paired with one or more adapters (LoRA), and we analyzed the role of Task Arithmetic, showing that it yields performances that are not far from the ones of multiple models independently trained to solve each task. Our results suggests a viable road to mitigate the need of large computational resources when learning from tasks based on "long" documents. While we exploited data in English language, the experiences of this paper can be interpreted as generic attempts to leverage long sequences in Continual Learning, in a sense going beyond the language barrier. Future work will consider schemes to automatically tune the Task Arithmetic [36].

Abstract

This paper presents the Vulnerable Identities Recognition Corpus (VIRC), a novel resource designed to enhance hate speech analysis in Italian and Spanish news headlines. VIRC comprises 880 headlines, manually annotated for vulnerable identities, dangerous discourse, derogatory expressions, and entities. Our experiments reveal that recent large language models (LLMs) struggle with the fine-grained identification of these elements, underscoring the complexity of detecting hate speech. VIRC stands out as the first resource of its kind in these languages, offering a richer annotation scheme compared to existing corpora. The insights derived from VIRC can inform the development of sophisticated detection tools and the creation of policies and regulations to combat hate speech on social media, promoting a safer online environment. Future work will focus on expanding the corpus and refining annotation guidelines to further enhance its comprehensiveness and reliability.

Keywords

hate speech, vulnerable identities, annotated corpora

1. Introduction

Hate Speech (HS) detection is a task with a high social impact. Developing technologies that are able to recognize these forms of discrimination is not only crucial to enforce existing laws but it also supports important tasks like the moderation of social media contents. However, recognizing HS is challenging. Verbal discrimination takes different forms and involves a number of correlated phenomena that make difficult to reduce HS as a binary classification.

Analyzing the recent history of corpora annotated for HS it is possible to observe the shift from very broad categorizations of hatred contents to increasingly detailed annotation schemes aimed at understanding the complexity of this phenomenon. High-level schemes including dimensions like “hateful/offensiveness” [1] or “sexism/racism” [2] paved the way for more sophisticated attempts to formalize such concepts in different directions: exploring the interaction between HS and vulnerable targets [3, 4, 5]; studying the impact of subjectivity [6, 7]; identifying the triggers of HS in texts [8, 9].

Despite this trend, the complex semantics of HS in texts is far from being fully explored. Information Extraction (IE) approaches to HS annotation have been rarely implemented, yet. Therefore, corpora that includes fine-grained structured semantic representation of HS incidents are not available. The only notable exception is the recent work of Büyükdemirci et al. [10], which treat the identification of HS targets as a span-based task.

In order to fill this gap, we present the Vulnerable Identities Recognition Corpus (VIRC): a dataset of 880 Italian and Spanish headlines against migrants aimed at providing an event-centric representation of HS against vulnerable groups. The annotation scheme is built on four elements:

- **Named Entity Recognition (NER)**. All the named entities that are involved in a HS expression: ‘location’, ‘organization’, and ‘person’.
- **Vulnerable Identity mentions**. Generic mentions related to identities target of HS as they are defined by the international regulatory frameworks [1]: ‘women’, ‘LGBTQI’, ‘ethnic minority’, and ‘migrant’.
- **Derogatory mentions**. All mentions that negatively portray people belonging to vulnerable groups.
- **Dangerous speech**. The part of the message that is perceived as hateful against named entities or vulnerable identities.

In this paper we present a preliminary annotation experiment intended to validate the scheme and to assess the impact on disagreement in such a fine-grained task. The paper is structured as follows. In Section 2, we discuss related work, in Section 3, we describe the methodology used, in Section 4, we introduce the VIRC corpus, and in Section 5, we present the conclusions and discuss possible future work.

2. Related Work

Literature on automatic HS detection is vast and follows different research directions [11]: from the analysis of subjectivity in the perception of this phenomenon [12] to the definition of ever more refined categorizations of hateful contents [13]. In this section we focus on the approaches to HS detection that are aimed at studying the target of HS inspired by Information Extraction (IE) approaches. In Section 2.1 we review HS

resources inspired by this approach with a specific focus on span-based annotated corpora. In Section 2.2 we discuss the implementation of NER-based techniquest in the creation of HS corpora.

2.1. Hate Speech Detection

A large amount of work on HS detection focuses on classification, both binary (existence or not) and multi-labeled (misogyny, racism, xenophobia, etc.). This has led to the existence of large collections of datasets such as those grouped by [14]. One of the main problems is that most resources are in English, and for mid-to-low resource languages (e.g., Italian), some HS categories are not covered. This constraint is mitigated by cross-lingual transfer learning to exploit resources in other languages [15] and, although good results are achieved, the creation of resources for these languages is still necessary.

The main resources for the identification of HS are particularly focused on a target by identifying the presence or absence of HS in them. As in the work of [16], where in 1,100 tweets in Italian with special target on immigrants were annotated according to the presence of HS, irony, and the stance of the message's author on immigration matters. However, recently, there has been an increasing focus on identifying hateful expressions and their intended targets. The change in paradigm suggests that resources should be wider in scope and not focus on a particular discourse target. The main resources in this field have high linguistic diversity, although they do not all follow the same annotation scheme, with English being the most common language. We have found works in English [17]; Vietnamese[18]; Korean [19]; English and Turkish [10]; and English, French, and Arabic [20]. However, we have not found any in Italian or Spanish, which we believe makes this work the first to cover these languages for this task.

Two main annotation approaches can be drawn from these studies, those that annotate at the span level [17, 18, 19, 10] and those that annotate over the full text [20]. On the one hand, the work that follows the latter approach presents a corpus of 13.000 tweets (5.647 English, 4.014 French, and 3.353 Arabic) and notes the sentiment of the annotator (shock, sadness, disgust, etc.), hostility type (abusive, hateful, offensive, etc.), directness (direct or indirect), target attribute (gender, religion, disabled, etc.) and target group (individual, women, African, etc.).

On the other hand, works that follow the approach of span annotation design different annotation criteria. The simplest, [17, 18], only annotates one dimension. The first, [17], annotates the parts that make a comment toxic on a 30.000 English comments of the Civil Comments platform. The second, [18], annotates only the parts that make a comment offensive or hateful in 11.000 Vietnamese comments on Facebook and Youtube. The other papers, [19, 10], extend this approach and also label the span in which the target of the attack is mentioned. Moreover, [19] is not limited to that; they also annotate the target type (individual, group, other), the target attribute (gender, race, ethnic, etc.) and the target group (LGBTQ +, Muslims, feminists, etc.). Their final corpus has 20.130 annotated offensive Korean-language news and video comments.

However, the guidelines used by the different works sometimes present incompatibilities. Although some works use offensive and hateful labels in the same way [19, 18], others distinguish between these two types of expression [10]. This resource, the last one, has separately annotated hateful and offensive expressions, totaling 765 tweets in English and 765 tweets in Turkish.

2.2. Named Entity Recognition

Developed as a branch of Information Extraction (IE), Named Entity Recognition (NER) is a field of research aimed at detecting named entities in documents according to different schemes. Following the review of Jehangir et al. [21], it is possible to observe general-purpose schemes, which usually includes entities of the type 'person', 'location', 'organization' and 'time', and schemes defined for specific applications. OntoNotes [22] is an example of the first type of approach: a broad collection of documents gathered from different sources (e.g., newspaper, television news) annotated with a tagset that includes general categories of named entities. On the other hand, more specific applications include biomedical NER, which focuses on identifying entities relevant to the biomedical field, such as diseases, genes and chemicals. An example in this field is the JNLPBA dataset[23], which is derived from the GENIA corpus. This dataset consists of 2,000 biomedical abstracts from the MEDLINE database, annotated with detailed entity types such as proteins, DNA, RNA, cell lines and cell types.

NER-based approaches for HS detection and analysis are still few. ElSherief et al. [24] exploited Twitter users' mentions to distinguish between directed and generalized forms of HS. Rodríguez-Sánchez et al. [25] used derogatory expressions of women as seeds to collect misogynist messages according to a fine grained classification of this phenomenon. [26] adopted a similar methodology to collect tweets about 3 vulnerable groups to discrimination: ethnic minorities, religious minorities, and Roma communities. Piot et al. [14] analyzed the correlation between the presence of HS and named entities in 60 existing datasets. Despite these previous works, there are no attempts to define a NER-based scheme specifically intended for HS detection. Our work represents an attempt to fill this gap by combining categories from general-purpose NER and a taxonomy of vulnerable groups to discrimination in a common annotation scheme aimed at providing deeper insights about the targets of HS.

3. Methodology

3.1. Data Collection

We collect news from public Telegram channels with the *telegram-dataset-builder* [27]. The selected channels are shown in Table 1, they are in Spanish and Italian and aligned with the left and right wings of the political spectrum. The subset of Italian headlines was integrated with titles published on newspapers Facebook pages that have been collected in collaboration with the Italian Amnesty Task Force on HS, a group of activists that produce counter narratives against discriminatory contents spread by online newspapers and users comments[2]. We collected all the news headlines detected by activists in March 2020, 2021, 2022, and 2023, and added them to our corpus.

Given the large amount of news collected, we applied filters to the dataset to reduce it to its final size. We focus on news about racism; for this purpose, we applied the classifier *piuba-bigdata/beto-contextualized-hate-speech* to stick to news items labeled as racism. Since this classifier is trained on Spanish

texts, prior to this step we automatically translated Italian news with the model *facebook/nllb-200-distilled-600M*. This translation step is used only for the filtering process; once the news is selected, the translated text is no longer used. In the end, this process generates 532 news headlines classified as racist for Italian and 348 for Spanish, that have been selected for the annotation task.

3.2. Data Annotation

A comprehensive, span-based annotation scheme was developed to label vulnerable identities and entities present in the dataset. Annotators were provided with instructions and had to choose a label and highlight the word, phrase, or portion of text that best embodied the qualities of the chosen label in the text. It was possible to choose more than one label for the same portion of text. The instructions also provided annotators with some examples of annotated headlines.

The initial layer of annotation focuses on identifying vulnerable targets within the text and categorizing them into one of six predefined labels: **ethnic minority**, **migrant**, **religious minority**, **women**, **LGBTQ+ community**, and **other**. These labels represent vulnerable groups, as the vulnerability of the targets can often be traced back to their belonging to certain categories of people which are particularly exposed to discrimination, marginalisation, or prejudice in society. In cases where the targeted group didn't fit into one of the predefined labels, annotators were required to use the 'other' category. Then, for instances labeled as 'other', annotators were instructed to provide specific details regarding the group in a free-text field.

After categorizing vulnerable targets, the second layer involves annotating named entities. Annotators identify entities within the text and label them with one of five possible types: **person**, **group**, **organization**, **location**, and **other**. As in the first layer, instances labelled 'other' require annotators to provide details about the entity in a free-text field.

The final layers of the annotation scheme address the context in which these entities are mentioned, specifically focusing on identifying derogatory mentions and dangerous speech.

A derogatory mention is characterized by negative or disparaging remarks about the target. In these instances, explicit hate speech is absent, but the mention itself is discriminatory or offensive, often employing a tone intended to belittle or discredit the target. The label **derogatory** is used to mark these mentions.

Moreover, the annotation includes identifying dangerous elements: portions of text that, intentionally or unintentionally, could incite hate speech or increase the vulnerability of the target identity. Dangerous speech, which can be either explicit or implicit, promotes or perpetuates negative prejudices and stereotypes, potentially triggering harmful responses against the group. The label **dangerous** [28] is used to tag these segments. Annotators were encouraged to use free-text fields to provide details on implicit dangerous speech or recurring dangerous concepts.

The annotation guidelines provided annotators with specific criteria and with the following list of potential markers of dangerous speech to help their identification:

- **Incitement to violence**: the text explicitly encourages violence against the target group;
- **Open discrimination**: the text openly states or supports discrimination against the target group;
- **Ridicule**: the text ridicules the target in the eyes of the readers by belittling it or mocking it;
- **Stereotyping**: the text perpetuates negative stereotypes about the target group, contributing to a distorted view of it;
- **Disinformation**: the text spreads false or misleading information that can harm the target group;
- **Dehumanization**: the text dehumanizes the target group, using language that equates it with objects or animals;
- **Criminalization**: the text portrays the target group as inherently criminal or associates it with illegal activities, contributing to the perception that the group as a whole is dangerous.

However, a text may still be considered dangerous even if it does not explicitly include these markers, as they are intended as examples rather than strict requirements.

Figure 1 provides three examples of annotated headlines, two in Italian and one in Spanish, showing the application of the annotation scheme as described. In the figure, different colours highlight the various types of labels used. A vulnerable identity was detected in each headline: 'Migranti' in the first and in the third one and 'gitanos' in the second one, respectively labelled as 'vulnerable group - migrant' and

[2] "Migrants, an army of scroungers: 120,000 supported by the Italians' 8x1000 tax allocation".
[3] "Hordes of gypsies devastate Mercadona after 3000 euros were deposited in their solidarity cards".
[4] "This is Villa Aldini, the luxury residence that hosts rapist migrants in Bologna".

‘vulnerable group - ethnic minority’. The three examples all contain multiple elements of dangerous speech, highlighted in red, and the second text also contains an element which was marked with the derogatory label. Additionally, the second and the third headlines include examples of annotation for named entities, with ‘Mercadona’ labelled as ‘entity - organization’, and ‘Villa Aldini’ and ‘Bologna’ labelled as ‘entity - location’.

4. The VIRC Corpus

The VIRC corpus is a collection of 532 Italian and 348 Spanish news headlines annotated by 2 independent annotators for each language. Following the perspectivist paradigm [29], we both released the disaggregated annotations and the gold-standard corpus. The code used to generate the gold standard corpus, carry out experiments, and compile statistics can be accessed through the following GitHub repository[6]. In this Section we present an analysis of disagreement (Section 4.1) and relevant statistics about the corpus (Section 4.2).

4.1. Inter-Annotator Agreement

Since the span-based annotation task does not provide a fixed number of annotated items, we adopted the F-score metric to evaluate the agreement between annotators [30]. For each subset of the corpus we randomly chose one annotator as the gold standard set of labels and the other as the set of predictions. We then computed the F-score between the two distributions of labels in order to measure the agreement between the annotators. Table 2 shows the results of our analysis. In general, annotations always showed a fair or higher agreement, except for some entity-related labels and the “derogatory” one. There is also a low agreement in the Italian set on the labels “religious minority” and “women”.

	IAA (F-score)	
	Spanish	Italian
dangerous	0.49	0.57
derogatory	0.08	0.28
entity - group	0.0	0.00
entity - location	0.66	0.60
entity - organization	0.41	0.12
entity - other	0.0	0.10
entity - person	0.47	0.63
vulnerable entity	0.15	0.00
vulnerable group - ethnic minority	0.83	0.63
vulnerable group - lgbtq+ community	-	0.80
vulnerable group - migrant	0.96	0.86
vulnerable group - other	0.46	0.41
vulnerable group - religious minority	1.0	0.00
vulnerable group - women	0.6	0.22

Table 2
The annotators agreement measured through the F-score and broken down by label.

Although the overall results are positive, they show significant variations that can be quantitatively and qualitatively. Inclusion of overlapping spans was handled as follows: if one span fully included another, this was considered to be an agreement. In cases where the spans only partially overlapped, meaning there was some shared text but not full inclusion, this was treated as a partial agreement. For example, if one annotator labeled “All women” and another selected only “women”, this would be a full agreement (1 *true positive*). However, if the latter selected “women of Italy”, it would be a partial agreement (0.5 *true positive*).

Quantitative Analysis. The agreement on the annotation of entities is always moderate but differs between the Spanish and the Italian subsets. Annotators of Spanish headlines scored a higher agreement on ‘location’ (0.66 *vs* 0.60), ‘vulnerable’ (0.15 *vs* 0) and ‘organization’ (0.41 *vs* 0.12) while entities of the type ‘person’ (0.63 *vs* 0.47) and ‘other’ (0.1 *vs* 0) are better recognized in Italian headlines.

On average, the annotation of vulnerable identities resulted in a higher agreement between annotators in both subsets and at the same time confirmed an higher agreement of Spanish annotations that always outperforms Italian ones. The highest agreement emerges for the label ‘migrant’ on which annotators obtained an F-score of 0.86 for Italian and 0.96 for Spanish. The agreement on ‘ethnic minority’ is a bit lower but still significant, while Spanish headlines reached an F-score of 0.83 Italian ones only 0.63. An equally high agreement is on the ‘lgbtq+’ label, which is only present in Italian headlines with an F-score of 0.8. Among vulnerable groups, women scored the lowest F-score: 0.6 for Spanish, 0.22 for Italian. The largest observed discrepancy is with religious minorities, in Spanish an F-score of 1 is achieved while in Italian 0.

While the annotation of ‘dangerous’ spans achieves an acceptable agreement, the ‘derogatory’ annotation is characterized as the one that achieves the lowest agreement between annotators. Additionally, annotations of Italian headlines resulted in higher disagreement than Spanish ones, contrary to what we observed about ‘entities’ and ‘vulnerable identities’. Text spans expressing dangerous speech are recognized with an agreement of 0.57 for Italian and 0.49 for Spanish headlines. Agreement about ‘derogatory’ is low for Italian headlines (0.28) while Spanish ones show almost no agreement (0.08)

Qualitative Analysis. In summary, while the overall results of the annotation are positive, some categories show significant disagreement between annotators. These disagreements highlight the need to review and refine the annotation guidelines for problematic categories, and to provide more detailed instructions. The importance of reassessing the guidelines in order to make them clearer and more consistent is further underscored by the fact that, for Spanish headlines, the annotators agreed on both labels and intervals in only 67 cases, and for Italian headlines, agreement was reached in just 88 cases.

Since the annotation task was span-based, we opted not to use a confusion matrix to analyze the disagreement. A confusion matrix is not appropriate for span detection, as it assumes discrete labels applied to predefined items, whereas our task involved labeling spans of text that varied in length and context. Instead, we performed a qualitative analysis, examining specific cases of disagreement to understand their nature. This approach allowed us to explore not only how annotators differed in labeling spans but also why these differences emerged, providing a deeper insight into the underlying issues of interpretation and guidelines.

Looking more closely at the headlines where the annotations present inconsistencies, a variety of motivations behind discrepancies can be identified.

For instance, in the Italian title “Orrore nella casa occu-

[6] https://github.com/oeg-upm/virc

pata dagli immigrati: donna lanciata giù dal secondo piano"[7], 'donna' was marked as a vulnerable identity by only one of the annotators, suggesting maybe an erroneous focus on an individual target at a time ('immigrati') by the other annotator.

Another type of disagreement relates to the interpretation of derogatory mentions. An example can be found in "Un terzo dei reati sono commessi da stranieri (e gli africani hanno il record). Tutti i numeri"[8], where one annotator identified the term 'stranieri' as a derogatory mention, as well as representative of a vulnerable identity, while another annotator simply stuck to the second label, perhaps highlighting a divergence in the interpretation of the guidelines. Furthermore, it is interesting to observe the disagreement created by the headlines that use generic term 'stranieri' ('foreigners'), which was often labelled as 'vulnerable identity - ethnic minority' by one annotator and as 'vulnerable identity - migrant' by the other. This inconsistence between annotators can be identified in two headlines: "Ius soli e cittadinanza facile agli stranieri? Il sangue non è acqua"[9] and "Un terzo dei reati sono commessi da stranieri (e gli africani hanno il record). Tutti i numeri"[2]. In the first case, we can solve the disagreement by looking at the context: the explicit reference to the issue of granting citizenship suggests that the term 'foreigners' is more appropriately referred to the specific category of migrants. On the other hand, in the second headline, there is no direct reference to specifically migration-related issues and thus both interpretations in terms of the vulnerable category of belonging are acceptable.

Finally, some texts present a slight difference in the annotation spans of choice, as observed in "Più di 200mila case popolari agli immigrati"[10], where the annotators identified dangerous speech in the same section of text, but with differences in the number of highlighted words (first annotator labelled 'Più di 200mila'; second annotator labelled '200mila case popolari'), reflecting variations in the identification of relevant content for the analysis of dangerous speech.

In addition to the predefined labels, we also collected free-text fields as part of the annotation process. These comments offered an additional layer of granularity, allowing annotators to describe nuances not covered by the fixed categories. For example, in the Spanish headline "Dos menas marroquíes apuñalan a dos turistas para robarles en Salou"[11], both annotators used the two labels 'vulnerable identity - ethnic minority' and 'vulnerable identity - other' to annotate the span 'menas marroquíes'. Alongside the 'other' label, one annotator provided the comment 'Under 18', while the other one used 'young people' to describe the vulnerable group. Although stated differently, both comments highlight the specific vulnerability related to the age of the group, complementing the existing labels. As this example shows, the flexibility in the annotation process provided by free-text fields is useful to capture multi-categorical terms and to identify potential new categories that may not have been initially considered in the predefined labels.

	Spanish	Italian
dangerous	136	166
derogatory	3	16
entities	140	146
vulnerable groups	270	253

Table 3
The distribution of labels in the gold standard corpus.

4.2. Dataset Analysis

In this section we provide an analysis of the four label types that occur in the gold standard version of the VIRC corpus: 'derogatory', 'dangerous', 'named entities', 'vulnerable groups'. The analysis is twofold: first, we describe the distribution of these label types, then we present a zero-shot and a few-shot experiment aimed at understanding if existing LLMs (T5[31] and BART[32]) are able to recognize these labeled spans in news headlines by comparing their outputs to the gold standard annotations.

Corpus statistics. Table 3 shows the distribution of label types in the corpus. As it can be observed, mentions of vulnerable groups are the most present, with 270 occurrences in the Spanish subset and 253 in the Italian subset. This confirms the relevance of annotating vulnerable in the identification of discriminatory contents, which is tied to their high recognizability by annotators (Section 4.1). The role on named entities differs in the two subsets. Annotators labeled them with agreement 130 times in Spanish headlines and 67 times in Italian ones. This might be caused by their compositions. Since Italian headlines were partly collected from Facebook pages of mainstream newspapers, there was a higher number of named entities that were not relevant for the analysis of headlines' danger. The number of text spans labeled as dangerous is almost equivalent in the two subsets (136 for Spanish, 166 for Italian), showing a good presence of this label type despite the high disagreement between annotators. Finally, it is worth mentioning the almost total absence of text spans labeled as 'derogatory' with agreement (3 for Spanish, 16 for Italian) that suggests the high subjectivity of this phenomenon and also the need of better define its characteristics in annotation guidelines.

Corpus analysis with LLMs. We completed our analysis of the VIRC corpus through zero-shot experiments aimed at exploring the ability of existing LLMs to identify the four types of labelled spans in messages. We considered the detection of spans as an extractive Question Answering (QA) problem. For the task we adopted the T5[31] and BART[32] LLMs architectures for both languages. For Italian we employ [33] and [34] and for Spanish [35] and [36] models, respectively. The translations of the prompts used are the following (see Appendix A for the original ones):

- What part of the text is dangerous (criminalizes, ridicules, incites violence, ...) against vulnerable identities (women, migrants, ethnic minorities, ...)?
- What part of the text is derogatory (negative or pejorative comments about the victim without explicit hate speech, but the mention itself is discriminatory or offensive, and often uses a tone intended to denigrate or discredit the victim)?
- What named entity is mentioned in the sentence?

[7] "Atrocity in a house occupied by migrants: woman thrown from second floor".
[8] "One third of all crimes are committed by foreigners (and Africans hold the record). All the numbers".
[9] "Ius soli and easy citizenships for foreigners? Blood is not water".
[10] "More than 200,000 public housing units for immigrants".
[11] "Two Moroccan unaccompanied migrant minors stab two tourists to rob them in Salou".

	Non-Restictive Zero-Shot				Restictive Zero-Shot			
	T5		BART		T5		BART	
	Spanish	Italian	Spanish	Italian	Spanish	Italian	Spanish	Italian
dangerous	0.39	0.28	0.43	0.39	0.49	0.47	0.51	0.43
derogatory	0.02	0.05	0.03	0.04	0.67	0.43	0.50	0.33
entity	0.28	0.11	0.23	0.23	0.40	0.30	0.30	0.27
vulnerable identity	0.63	0.19	0.41	0.48	0.56	0.18	0.35	0.37

Table 4
F-score results of zero-shot experiments on the VIRC corpus with T5 and BART models for each label.

- Which hate speech vulnerable identity is mentioned in the sentence?

We designed two approaches for zero-shot experiments, restictive and non-restrictive. On the one hand, for the **non-restictive zero-shot** experiments, for each sentence in the dataset, we queried the model with the prompt of each label and extracted the three most confident results. Then, we filtered out those responses below the $\%0.02$ confidence of the model to limit the noise. Finally, all these annotations go through a majority vote (identical to the one used to build the aggregate dataset) to normalize the model response.

On the other hand, for the **restictive zero-shot** experiments, we queried the model with the prompts for each annotation present in the aggregated dataset. And, as there are sentences that have two equal labels in different spans, we request five different annotations from the model, ordered from most confident to least confident. If an annotation was already included, the next annotation is taken in order to avoid duplicating annotations in the model.

Table 4 presents the F-scores for each label type, experiment, and model. In general, T5 and BART tend to perform more effectively in Spanish compared to Italian. The models face noticeable challenges in identifying the labels 'dangerous', 'derogatory', and 'entity'. Nevertheless, when they are aware that the label exists within the sentence (restictive), they manage to recognize it with fairly good agreement. During annotation, the label 'derogatory' proves most challenging to identify. In the non-restrictive scenario, it scarcely receives any agreement, yet in the restictive scenario, it achieves a reasonable level, particularly in Spanish. This indicates that the model struggles to discern its presence initially but, once acknowledged, can recognise the expression.

The restictive method enhances performance over the non-restictive method for all labels except 'vulnerable identity.' This shows that models generally have a better comprehension and identification of vulnerable identities in sentences without restrictions compared to when they are restricted to specific mentions. It should also be noted that, in the Spanish context, T5 is more effective than BART in identifying 'vulnerable identity' labels for both approaches, while BART performs better in Italian.

These results show that a NER-based annotation scheme for HS detection is difficult to annotated but also to be automatically detected. Larger resources are necessary to develop models that are able to detect the complex semantics of HS.

5. Conclusions and Future Work

The Vulnerable Identities Recognition Corpus (VIRC), created in this work, reveals the challenge of identifying vulnerable identities due to the rapid evolution of language on social media. Our experiments indicate that large language models (LLMs) struggle significantly with this task.

VIRC provides a detailed and structured resource that enhances understanding of the extensive use of hate speech in Italian and Spanish news headlines. The corpus is particularly valuable as it includes more annotation dimensions compared to related studies in other languages, such as vulnerable identities, dangerous discourse, derogatory expressions, and entities. This differentiation between vulnerable identities and entities, as well as between dangerous and derogatory elements, enables the development of sophisticated detection tools that can facilitate large-scale actions to mitigate the impact of hate speech (e.g., moderation of messages and generation of counter-narratives that reduce the damage to the mental health of victims).

Future work will focus on expanding this resource by doubling the size of annotations for both languages and including non-racism-related phrases to ensure the resource is comprehensive. Additionally, we plan to refine the annotation guidelines to avoid low agreement on the derogatory label, enhancing the overall reliability and utility of the corpus. These efforts will further improve the effectiveness of hate speech detection and contribute to the development of policies and tools for a safer online environment.

A. LLMs Prompts

The prompts used are the same for each model but different for each language. For Spanish, the prompts used for each label are:

- **Dangerous:** "¿Qué parte del texto es peligroso (criminaliza, ridiculiza, incita a la violencia, ...) contra identidades vulnerables (mujeres, migrantes, minorías étnicas, ...)?"
- **Derogatory:** "¿Qué parte del texto es derogativo (comentarios negativos o despectivos sobre la víctima sin incitación explícita al odio, pero la mención en sí es discriminatoria u ofensiva, y a menudo emplea un tono destinado a menospreciar o desacreditar a la víctima)?"
- **Entity:** "¿Qué entidad nombrada se menciona en la frase?"
- **Vulnerable Identity:** "¿Qué identidad vulnerable al discurso de odio se menciona en la frase?"

For Italian:

- **Dangerous:** "Quale parte del testo è pericolosa (criminalizza, ridicolizza, incita alla violenza, ...) nei confronti di identità vulnerabili (donne, migranti, minoranze etniche, ...)?"
- **Derogatory:** "Quale parte del testo è dispregiativa (commenti negativi o denigratori sulla vittima senza un esplicito discorso d'odio, ma in cui la menzione stessa è discriminatoria o offensiva e spesso usa un tono volto a sminuire o screditare la vittima)?"
- **Entity:** "Quale entità nominata è menzionata nella frase?"
- **Vulnerable Identity:** "Quale identità vulnerabile ai discorsi d'odio è menzionata nella frase?"

The Self-Contained Italian Negation Test (SCIN)

Abstract

Recent research has focused extensively on state-of-the-art pretrained language models, particularly those based on Transformer architectures, and how well they account for negation and other linguistic phenomena in various tasks. This study aims to evaluate the understanding of negation in Italian bert- and robert-based models, contrasting the predominant English-focused prior research. We develop the SCIN Set, an Italian dataset designed to model the influence of polarity constraints on models in a masked predictions task. Applying the SCIN Set reveals that these models do not adjust their behaviour based on sentences polarity, even when the resulting sentence is contradictory. We conclude that the tested models lack a clear understanding of how negation alters sentence meaning.

Keywords

negation, Italian PLMs, testing, self-contained

1. Introduction

Compositionality is a fundamental feature of human language, based on the principle that the meaning of a complex expression derives from its parts and their respective arrangements.

One notable compositional phenomenon is negation, formally defined as a semantic operator (or function) that reverses the truth-value of a sentence [1].

Given its importance, understanding how well pretrained language models (PLMs) can grasp and apply this principle is crucial.

These models achieve impressive performance across a wide array of language modeling tasks. Nonetheless, they often reveal to rely on shallow heuristics or exhibit other issues in handling specific aspects of language.

A prominent bias in the body of research is that the vast majority of research on language models has predominantly concentrated on English. This focus raises concerns about the generalizability of findings to other languages which may be structurally different from English. Conducting similar experiments in other languages could provide valuable context and material for comparison, potentially highlighting language-specific effects or revealing new generalization. Therefore, we decide to undertake a new experiment focusing on Italian negation.

Thus, in this article, we aim to explore whether the behavior of PLMs accurately models the polarity of sentences. We will investigate how the addition of negation to a sentence can alter its overall meaning (demonstrating the models' capability to handle shifts in meaning due to structural changes).

Given the limitations explained above, our work has deliberately chosen to concentrate on Italian. This choice not only addresses the need to explore how these models perform with languages other than English but also serves as a critical test for PLMs dedicated to Italian. We suspect that these models may not be as advanced or effective as their English counterparts, highlighting the need for further developments outside English.

We adapt the test set developed for English by Kletz et al. [2] to Italian, creating the *Self-Contained Italian Neg Set* (SCIN Set). Using the dataset to evaluate bert- and roberta-based models for Italian, we find that these models are unable to adjust their prediction in response to constraints posed by negation, often generating contradictory text.

The article will be structured as follows. The rest of Section 1 will introduce compositional phenomena and Italian negation in particular. Section 2 will briefly review related work. Section 3 will detail the composition of the SCIN Set. Section 4 will present the tests conducted on several bert-based Italian models using the SCIN Set; in particular, we tested the following bert-base-cased models:

- bert-base for Italian, both in its basic and its XXL versions (bert-base-italian-cased,

2. Related work

Although negation plays an essential role in human communication, it appears to present challenges for PLMs. In recent years, much research has focused on this topic.

2.1. Effect of negation on the model's prediction

Kassner and Schütze [7] and Ettinger [8] analyzed to what extent Transformer-based language models' predictions are sensitive to the presence or absence of negation in sentences involving factual knowledge, such as (1-a-b):

(1) a. Birds can [MASK].
b. Birds cannot [MASK].

They found that in such pairs the top-1 predictions are unchanged most of the time: models do not seem to take into account the polarity of the environment (presence or absence of a negation in the surrounding sentence) to adapt their predictions. They concluded that models do not deal correctly with negation.

Gubelmann and Handschuh [9] criticized such studies, noting in particular that the pragmatic component was overlooked in Ettinger's experiments. They noted that a statement containing a negation stating a false fact (for example, *Birds cannot fly*) can be more plausible than a formally true but unusual statement (say, *Birds cannot breastfeed*). In fact, a vast number of words could potentially fit the negative statement, making it true, many of them with little association with the rest of the sentence. This makes it challenging for any single word to become the top prediction in the negative case.

Gubelmann and Handschuh [9] developed a more pragmatically informed test set, in which each instance is (in [2]'s terms) *self-contained.* This means that each item in the set includes some context information, allowing direct evaluation of the model's completion. Building on this work, [2] developed the *Self-Contained Neg Test*, which aimed to address some issues in the test set from [9] and more accurately determine the model's handling of negation without interference of world knowledge.

2.2. The *Self-Contained Neg Test*

The *Self-Contained Neg Test*, developed by Kletz et al. [2], is a set of pairs of sentences consisting of a context (C) and a target (T) sentence, either positive (p) or negative (n). The target sentence contains a masked position, syntactically constrained to be filled by a verb (2).

(2) Jessica is an architect who likes to dance. She isn't happy to [MASK].

The instances are designed in such a way that a model that predicts (in the masked position of T) the last verb of C will produce a semantically well-formed paragraph only if C and T have the same polarity. For instance, in (2), the context is positive (Cp), the target is negative (Tn), and as a consequence a model predicting *dance* in the masked position produces an ill-formed paragraph:

(3) #Jessica is an architect who likes to dance. She isn't happy to dance.

In contrast, a CnTn version of (3) would accept the verb *dance* in the same position:

(4) Jessica is an architect who doesn't like to dance. She isn't happy to dance.

To produce the sentences of the set, the pattern (5) is taken as a starting point, where NAME and PRON are substituted with a proper noun and a compatible third person pronoun, PRO is substituted with a profession name, and ACT is substituted with an action verb.

(5) NAME is a PROF who likes/doesn't like to ACT.
PRON is/isn't happy to [MASK].

A large number of triplets (NAME, PRO, ACT) are tested with each model, and the ones that are retained are the ones such that the model's top one prediction is the ACT verb itself when C and T are both positive (CpTp). Here for instance, assuming that (6) are a model's predictions, the triplet (Jessica, architect, dance) would be retained while the triplet (Luke, janitor, swim) would not.

(6) a. Jessica is an architect who likes to dance. She is happy to dance.
b. Luke is a janitor who likes to swim. He is happy to ski.

Once triplets have been selected (the set of all triplets such that the ACT verb is repeated in CpTp instances), CpTn and CnTp instances can be formed, and the expectation is that a model that "understands" negation should not predict the ACT verb in those cases since it would lead to contradictory instances. As a control, two additional confirgurations are considered: CnTn where it is expected that the repetition of ACT is possible (though

[1] https://huggingface.co/dbmdz/bert-base-italian-xxl-cased
[2] https://huggingface.co/bert-base-multilingual-cased
[3] https://github.com/marcopoli/AlBERTo-it
[4] https://github.com/musixmatchresearch/umberto

not required), and CpTv in which an adverb (*very*) is inserted in the positive target, which should not change the preferred prediction of ACT since both sentences are positive. The different configurations are illustrated below.

(7) CpTp Jessica is an architect who likes to dance. She is happy to [MASK].
CpTn Jessica is an architect who likes to dance. She isn't happy to [MASK].
CnTp Jessica is an architect who doesn't like to dance. She is happy to [MASK].
CnTn Jessica is an architect who doesn't like to dance. She isn't happy to [MASK].
CpTv Jessica is an architect who likes to dance. She is very happy to [MASK].

3. SCIN construction

In Italian, negation is most commonly expressed by the negative invariable proclitic *non* (not) [10].

It is this expression of negation that we use for the Italian adaptation of the *Self-Contained Neg Test* that we present in this section: the SCIN set.

3.1. Italian patterns

Following the preparation of the *Self-Contained Neg Test*, we collect a list of Italian verbs, professions and names that will be used to create the triplets to be tested. The verbs are taken from the *Dizionario Italiano Sabatini Coletti* 2022 (online version); only the intransitive (3138 verbs) are retained; among these, for each of the tested models we further exclude the verbs that are not tokenized as a single token. The selected names are the 100 most popular in Italy in 2024[5]. Lastly, the professions are taken from a site specializing in job searches in Italy[6]; of those present on the site, only those consisting of a single word have been selected.

The patterns cannot simply be a direct translation of English patterns into Italian. In fact, for the test to be adequate for evaluating models, we need the masked position to be syntactically constrained to be a verb. This would not be the case if we used a direct translation of the original sentences: for example, the sequence (8) can be completed with the token “questo” (= *PRON is happy to do this*).

(8) NAME è un PROF che ama ACT. È felice di MASK.
NAME is a PROF who loves to ACT. (PRON) is happy to MASK.

We choose instead to rely on the pair (9), involving a semantic inference relation.

(9) ha l'abitudine di / molto spesso
is used to / very often

The final form of the SCIN set is available in table 1. The shape of the contexts is given in row 1, that of the targets in row 2, and the test target Tv is added in row 3.

Our assumption is that, if the model repeats the ACT token in the CpTp configuration, it is proof that the model has resolved the *ha l'abitudine di / molto spesso* inference. When confronted with the CpTn or CnTp configuration, the model should have the addition of the negation as the only element that can explain the modification of its predictions. Finally, the CpTv control allows us to check the extent to which the addition of a different, non-negative adverb in the sequence modifies the model's predictions; we can assume that any modification of greater magnitude than that associated to CpTv are due to the influence of negation.

The complete list of new patterns is available in Table 1.

3.2. Pattern selection

The triplets (*name*, *profession*, *verb*) used for testing are selected by testing them on the CpTp configuration: only triplets leading to a repetition of the ACT token are retained (see Table 2). This ensures that only patterns for which the model is already biased towards repetition are tested, and the model has to understand the influence of negation on sentence semantics to reverse this tendency.

All available triplets are tested, i.e. all configurations between verbs monotokenized by the model, first names and occupations selected in subsection 3.1. As tokenization is model-dependent, the number of verbs tested is not the same for each model: details are available in the first row of table 3.

The results of this test are available in table 3. The results are highly model-dependent: while the bert-base-italian-cased model predicts the ACT token in almost 25% of cases, this is the case in only 0.03% of cases for alb3rt0.

4. Testing

4.1. Setup

Tests are performed as in Kletz et al. [11]. Contexts (C) and targets (T) are combined to create two test patterns CpTn, CnTp; in addition to these two, the test includes two control patterns CnTn and CpTv where the repetition of the ACT verb is not contradictory.

All selected triplets are then used to saturate the patterns, and the resulting patterns are provided as inputs to

Table 1
Complete list of contexts and targets used to build masked sequences in the SCIN dataset. Masks are always in the target. Contexts and targets can be either positive or negative, and the target can also have an adverb added which is not a negation cue. Patterns are made up of a context and a target, i.e. 5 possible patterns.

<table>
<tr><td colspan="3"><b>Instantiated NAME/PROF</b>:
<i>Jessica / Ballerina (Dancer)</i></td></tr>
<tr><td colspan="3"><b>Tested verb</b>: <i>Fumare (To smoke)</i></td></tr>
<tr><td colspan="3"><b>Tested example</b>: <i>Jessica è una ballerina che ha l'abitudine di fumare. Lei [MASK] spesso.</i></td></tr>
<tr><td>Model</td><td>Top 1 pred.</td><td>Retained?</td></tr>
<tr><td>b-b-italian-c</td><td><i>fuma</i></td><td>✓</td></tr>
<tr><td>b-b-italian-xxl-c</td><td><i>fuma</i></td><td>✓</td></tr>
<tr><td>m-bert</td><td><i>balla</i></td><td>no</td></tr>
<tr><td>alb3rt0</td><td><i>parla</i></td><td>no</td></tr>
</table>

Table 2
An example of selecting a triplet for testing. A NAME/PROF/VERB triplet is used to saturate the CpTp pattern of SCIN. The sequence contains a mask and is used as input to a PLM. If the model prediction is the ACT token, the triplet is retained (indicated by the ✓ symbol). In the name of the models given as examples, "b-b" means bert-base, "it" stands for italian and "c" for cased.

the models. Predictions at masked positions are collected.

We use *drop* as a measure of the models' performance: for each pattern, given the rate t_r of repetitions of the Act Token in the predictions, the drop is defined as $100 - t_r$. The higher the drop for the CpTn and CnTp patterns and the lower for the CnTn and CpTv controls, the better the model has understood the negation.

4.2. Results and Discussion

Results are shown in table 4.

In contrast with the observations made by [8] and [7], the models are not insensitive to the presence of negation in a sentence: all the models show a drop in both configurations CpTn and CnTp, showing an adaptation of their predictions to the presence of a negation cue. This observation is confirmed by the fact that the drops in the CpTv control are always lower than those observed in CpTn or CnTp.

This shows that simply adding an adverb is not sufficient to change the model's predictions. While we cannot definitively attribute this to its logical function, the negation marker does exert a distinct influence.

Nevertheless, it is important to emphasize the very clear limitations of these results. Firstly, the drops never exceed 25%, meaning that 75% of the times the model predicts a semantically prohibited token. On the other hand, with the exception of m-bert, all the models have a highe drop for the CnTn control than for the CnTp configuration, thus indicating that even though the models have acquired a certain understanding of negation, this remains superficial and does not, for example, clearly include an understanding of the positive value of a double negation.

A broader examination of the results reveals that while the drops in CpTn and CnTp configurations increase together, the CnTn controls also show a corresponding increase.

Finally, the training corpus of the models seems to have an influence on their performance. For example, note that the alb3rt0 model is the model obtaining the results least in line with our expectations, while bert-base-italian-xxl-cased and bert-base-italian-cased had better drop values, with the former performing better than the latter. However, these three models have identical numbers of layers, attention heads and hidden sizes, the difference between them only consisting in their training data. The alb3rt0 model was trained exclusively on tweets, which likely limits the diversity of its data, particularly with respect negation. In contrast, bert-base-italian-cased and bert-base-italian-xxl-cased models were trained on more varied corpora, with the latter featuring a larger dataset.

In the future, this should lead us to study the correlation between the performance of the models and the fine-grained distribution of negative and affirmative contexts in their training corpus.

5. Comparison with English

In this section we compare the results obtained with the SCIN Set with those observed by [2] in English.

Model	b-b-it-c	b-b-it-xxl	m-bert	alb3rt0	UmBERTo
# tested contexts	5880000	5880000	780000	18800000	280000
Repetitions	1498456	1236899	141609	5464	93284
%	25.48	21.03	18.16	0.03	33.31
# retained contexts	20000	20000	19973	2088	20000

Table 3
Details of the verb sets created for each model. The first line shows the number of triples available per model, the second the number of these triples which, in a CpTp configuration, led to a repetition (prediction by the ACT token model), and line 3 the percentage of triples this represents.) The last line shows how many of the triplets leading to a repeat were retained, the maximum for one model being 20,000. In the column titles, "b-b" means bert-base, "it" stands for italian and "c" for cased

Pattern	b-b-it-c	b-b-it-xxl	m-bert	alb3rt0	UmBERTo
CpTn	16.5	**22.1**	23.0	9.7	9.9
CnTp	11.0	14.5	**19.7**	4.4	11.9
CnTn	11.6	14.6	18.6	**9.3**	20.6
CpTv	1.3	14.3	1.0	**0.2**	1.7

Table 4
Drops of Italian pretrained language models on the SCIN Set, for each pattern type. In the two first rows, a high number is expected — the higher number of each row in bold face; in the two last rows, a lower number is expected. In the column titles "b-b" means bert-base, "it" stands for italian and "c" for cased

The scale of the drops in the two articles is notably very different: the maximum drop observed in Italian is 23% (CpTn m-bert), while in English it's 82.8%. Similarly, the CpTv drops of Italian-speaking models hardly exceed 15%, while those of English-speaking models are never less than 25%.

On the other hand, model architecture and type of training do not seem to have a major influence: Umberto has the same architecture as roberta-base, but while the latter is the best performing model in [2], the former's drops are the lowest for all configurations of the SCIN Set. Conversely, the other Italian models are built with the same architecture as bert-base-cased, i.e. the worst performing model for English; however, even the worst performing Italian model, namely alb3rt0, features higher drops than bert-base-cased. This confirms the observation from the previous section, that while architecture is indeed a limiting criterion, training data probably plays a significant role.

In general, we note that none of these models, neither for Italian nor for English, shows definitive drops compatible with a full understanding of the semantic constraints of negation.

6. Conclusion

In this paper, we investigated the ability of several Italian PLMs to take negation into account in their predictions. To do this, we adapted to Italian the *Self-Contained Neg Test* proposed by Kletz et al. [2], which is based on minimal pairs of aligned sentences.

Applying this test to six models enabled us to show that negation modifies their predictions, but that this does not happen consistently or in a way that is always coherent with the semantic effect that we expect negation to have on sentences. These results suggest a strong need to adapt these models to make them more sensitive to negation and its semantic consequences.

Nevertheless, we also noted a fairly marked difference in performance from one model to another, correlated with the different corpora used to train them. We thus suggest that a lexical and statistical study of these corpora could shed further light on the behavior of the models.

Lastly, it would be interesting to compare these results with the performance of generative models, in order to study the relative importance of the number of model parameters in relation to their architecture.

Acknowledgments

We would like to express our gratitude to Marie Candito for her valuable assistance and guidance throughout the course of this study.

Abstract

This paper investigates the ability of Large Language Models (LLMs) to differentiate between canonical and non-canonical sentences in Italian, employing advanced neural architectures like LLaMA and its adaptations. Canonical sentences adhere to the standard Subject-Verb-Object (SVO) structure. We hypothesize that recent generative LLMs are influenced heavily by the English language, where non-canonical structures are very rare. Using the in-context learning technique, we probe these models and further fine-tune them for this specific task. Initial results indicate that these models continue to struggle with this task even after fine-tuning. Additionally, we introduce a test set comprising several hundred sentences from the poetry domain, which presents significant challenges for the canonical structure task.

Keywords

Large Language Models, Italian Sentence Structure, Non-Canonical Structures, In-Context Learning

1. Introduction

Unlike contemporary English, which primarily follows a Subject-Verb-Object (SVO) structure, Italian exhibits a rich variety of non-canonical syntactic structures that deviate from this pattern[1] [1, 2]. Italian is generally considered a configurational language with a neutral or canonical SVO sentence structure. However, it also displays characteristics of a weak non-configurational language due to several typological parameters: free subject inversion, pro-drop, and nonlexical expletives. Additionally, Italian lacks wh- in situ, preposition stranding, deletable complementizers, impersonal passives, and parasitic gaps with the same argument [3].

In cognitive linguistic terms, the use of surface or syntactic constituency and word order in non-canonical sentences in Italian reflects its informational structure. As an example, the first sentence "*Sempre caro mi fu quest'ermo colle e questa siepe che da tanta parte de l'ultimo orizzonte il guardo esclude*"[2] of Leopardi's famous *L'infinito* is a typical example of a non-canonical sentence: the complement is fronted and the subject is in post-verbal position, also known as complete argument inversion, for letting the reader focus on the subject and main verb rather than the complement.

The functional or relational interpretation of these syntactic structures, along with semantic processing, is essential to understanding the semantic roles associated with displaced grammatical functions. For instance, when a subject appears in an inverted position, it indicates a pragmatically motivated displacement, emphasizing focus over an otherwise topic-related function. Typically, subjects, understood as topics or "what the sentence is about" and constituting old information, precede the verb. This is consistent with Italian and English, both of which follow an SVO structure. Conversely, focus, defined as "the essential piece of new information carried by a sentence," usually follows the verb in the "comment" portion of the sentence.

We consider complexity measures sensitive to non-canonical structures (NCS), which are pragmatically motivated and used to encode structured meaning with high informational content, related to the FOCUS/TOPIC non-argument functions in Lexical-Functional Grammar (LFG) [4, 5]. Non-canonical structures can aid the reader or interlocutor in better understanding the pragmatically relevant meaning in context [6].

Italian NCS are relatively frequent in text. In [7], the authors analyzed the VIT (Venice Italian Treebank) by manually annotating non-canonical structures and inflected propositions in Italian. The study found that Left Dislocated Complements, where a complement of the main verb according to subcategorization restrictions occurs, appear in 0.03% of cases. Dislocated Subjects, indicating any NP subject not followed by the main verb, occur in 0.28% of cases. The overall percentage of non-

[1] Elizabethan English was more similar to Italian in its variety of syntactic structures.

[2] In English: "*Always dear to me was this solitary hill and this hedge which from large side of the ultimate horizon the gaze excludes*"

projectivity in written texts is 7%, based on 230, 629 constituents. Compared to Latin, where the non-projectivity index is 6.65% in the Latin Dependency Treebank containing about 55, 000 tokens, Italian and Latin are quite similar. In contrast, English tree projectivity in the Penn Treebank (PT), where the majority of data corresponds to the articles of Wall Street Journal (WSJ), shows much lower numbers: with 720, 086 constituents, the non-projectivity index is 0.01004%.

Thus, Italian speakers have high expectancies for the presence of an NCS due to processing difficulties also raised by the number of unexpressed subjects: 61% of all Inflected Propositions lack a lexically expressed subject. This does not apply to English speakers, for whom NCS are infrequent and context-specific. In this view, Italian is considered unique for its use of many of the non-canonical structures found in contemporary poetry and examined in this experiment. The richness and freedom of the language give the speakers the ability to produce such a diverse typology of non-canonical structures, which stems from its Latin heritage, with the Null Subject being one of the most well-known features. Like many other languages, including Spanish, Portuguese, and Catalan, as well as Chinese, Japanese, Slavic languages, Greek, and Hebrew, Italian is a Null Subject Language. However, this parameter alone does not fully explain the richness and complexity of syntactic structures seen in Italian poetry. While other Romance languages share similar syntactic traits, the specific linguistic legacy and poetic traditions of Italian give it a unique character in this regard.

In this paper, we want to analyze the ability of recently proposed Large Language Models to detect non-canonical sentences in Italian. Our hypothesis is that, given the very large percentage of English training data (usually more than 90%) and the very low percentage of Italian training data (usually less than 1%), these models have a limited capacity to process such structures and they rely mostly on the English writing structures. On the other hand, the models that have been specifically adapted or fine-tuned on Italian data should show a better understanding of the canonicity in Italian.

In the rest, Section 2 describes the related work, Section 3 shows the approach in recognizing the canonical structures, Section 4 presents and discusses the results, while Section 5 derives the conclusions.

2. Related Work

Our approach has been previously adopted by other researchers but with slightly different aims, as described below. Initial attempts at parsing Italian treebanks of constituent structures focused on two small treebanks: TUT [8, 9] and ISST [10], containing approximately 3, 500 and 3, 000 sentences, respectively. *Illo tempore*, these efforts yielded an F1 score of 82.96%, while comparable parsers (Stanford, Collins, and MaltParser) achieved about 92.10% on the WSJ treebank. The lower performance in Italian was primarily due to two factors: a higher number of non-canonical structures (i.e., word order variations) and the presence of pro-drop clauses, where the subject is lexically omitted — a challenge also documented for other similar languages [11].

Significant improvements in parsing performance were noted in a paper on the EVALITA shared task on constituency parsing, where the best F1 score increased from 70% to 84% [12], attributed to the nearly doubling of training samples between 2007 and 2011. In [13], the authors presented a new dataset of Italian based on "marked" sentences to test the performance of the neural parser TINT. The result for LAS dependency structures was 77% accuracy, three points below the best results on the UD corpus of Italian, which was 80%. This outcome confirmed previous findings with a small dataset of strongly marked sentences, where accuracy was below 50%. The authors detailed seven types of marked structures in their treebank corpus: cleft, left-dislocated, right-dislocated, presentative "*ci*" (*there* in English), inverted subject, pseudo-clefts, and hanging topic, with cleft and left-dislocated sentences being the most common.

In this context, it is interesting to explore the capabilities of state-of-the-art methods for addressing the problem of distinguishing between canonical and non-canonical sentences in Italian. This exploration is motivated by the complexity and richness of Italian syntax, which presents unique challenges for natural language processing models. Mostly all actual state-of-the-art models are based on the Transformer architecture [14]. This game-changer model comprises two main components, leading to different model families. The encoder, used in models like BERT [15], RoBERTa [16], and Sentence BERT [17], encodes input sequences using self-attention. In contrast, decoders, such as GPT [18], GPT-3 [19], and LLaMA [20], generate output sequences auto-regressively. Beyond these, encoder-decoder models like T5 [21] and BART [22] integrate both components, excelling in tasks such as translation, summarization, and question-answering.

One notable Transformer-based architecture is the LLaMA foundational model [20]. LLaMA is a large model with billions of parameters that generates output sequences auto-regressively based on the input and previously generated tokens. It has been recently applied to a variety of linguistic tasks by instruction-tuning a monolithic architecture to solve them all [23]. This family of models is promising as they rely on auto-regressive generation methods and, thanks to their massive amount of training data and parameters, can solve a plethora of linguistic tasks. Additionally, [24] demonstrated the application of LLaMA-family models for syntactic parsing across multiple languages, highlighting the capability of the model to analyze and detect sentence structures. This work underscores the versatility of large language models in handling diverse syntactic frameworks, further probing their performance in cross-linguistic scenarios. Finally, architectures specifically adapted for Italian, such as Camoscio [25] and LLaMAntino [26], are tuned with instruction datasets for the Italian language, starting from the original LLaMA model and its second variant, LLaMA2-chat, respectively. They demonstrate a strong understanding of the language and an excellent ability to generate appropriate responses.

In this paper, we aim to explore the ability of Large Language Models (LLMs) to distinguish between canonical and non-canonical sentences in Italian using neural architectures such as LLaMA and its various adaptations, as discussed in the next Section. It's interesting to note that in the future one might explore the applications of probing syntax at the intermediate layers of various models.

3. Recognizing Canonical structures through LLMs

To address the capabilities of Large Language Models in recognizing the canonical structures, they can be utilized through In-Context Learning techniques [27] or by directly fine-tuning the model for specific downstream tasks. In-context learning relies on the model's pre-existing knowledge acquired during pre-training and on instructions provided in natural language at inference time. This method does not involve additional training and can be categorized based on the number of examples provided: *i)* **0-shot Learning**, where no examples are given, and the model generates responses based solely on its pre-existing knowledge and the provided instructions; *ii)* **1-shot Learning**, where one example per class (positive and negative in our case) is added to provide a more precise context, these examples help the model better understand the task by offering a concrete reference point; *iii)* **Few-shot Learning**, where more than one example per class is provided to give the model additional contextual information during decision-making. This approach is particularly effective when very few examples (such as 2 or 4) are given, but it can be extended up to the maximum input context length.

For both one-shot and few-shot learning approaches, a key challenge is selecting the most informative examples to provide during inference. One effective strategy is to retrieve examples that are most similar to the current sequence to be classified, focusing on those with a similar structure or meaning. A commonly used method for this is to generate vector embeddings of sentences using a model like sBERT [17]. This model produces a contextualized vector that represents the information contained in a sentence. By applying Cosine Similarity, we can rank these vectors and select the training examples most similar to the input sequence. This process ensures that the model is supplied with the most relevant solved examples for a given input. It's important to note that these examples may not always capture the same explicit syntax representation as a Tree Kernel [28] function would, in which every word of the sentence is explicitly annotated with syntactic information and linked to each other. However, the crucial aspect is that the examples provided are sufficiently similar in meaning and context, and the sBERT architecture is very effective.

When the model's pre-existing knowledge is insufficient, we can fine-tune it on the downstream task. Fine-tuning involves training the model in a traditional manner using input-output pairs (training data) to adjust its parameters. This process improves the model's performance on specific tasks, allowing it to learn from a more extensive set of examples. As a result, the model becomes more adept at handling similar queries in the future, with a focus on the specific task at hand. By leveraging these techniques, LLMs can recognize and respond to canonical structures with varying degrees of efficiency and accuracy.

3.1. Training LLMs against non-Canonical structures

To interact with the models, we need a sufficiently detailed prompt, which includes a natural language description of the task (i.e., the rules to determine whether an Italian sentence follows the canonical structure) and specifies the type of answer we expect the LLM to produce: *Sì* (*Yes* in English) if the sentence is canonical and follows the rules, or *No* otherwise. For the training and the 0-shot strategy, we used the following prompt:

> *"Dimmi se la seguente frase ha una struttura canonica o meno. Per Canonica si intende una frase che segue una struttura standard per ogni verbo presente. Più nello specifico, le frasi canoniche seguono queste regole: contengono SOLO sequenze del tipo nome o strutture nominali SEGUITE da struttura verbale a sua volta seguita (oppure no) da complementi OPPURE contengono SOLO sequenze composte da struttura verbale seguita da complementi, dove: STRUTTURE VERBALI sono sequenze composte da ausiliare o/e modale e verbo, e tra i due ci può essere un avverbio oppure strutture preposizionali COMPLEMENTI sono strutture nominali oppure strutture preposizionali*

oppure strutture frasali oppure strutture infinitivali. Tutte le altre frasi sono da considerarsi come Non Canoniche. Riguardo il prossimo input, rispondi 'sì' se è 'canonico', 'no' se è 'non canonico'."

For the 1-shot scenario, immediately after the above prompt, we append the following instruction, where the two provided examples are selected as the most relevant for the input example:

> Ti faccio un paio di esempi:
> <POSITIVE_EXAMPLE> e devi rispondere sì.
> <NEGATIVE_EXAMPLE> e devi rispondere no.

When fine-tuning a model, a highly detailed prompt might seem excessive, especially since traditional training involves repeating the prompt multiple times. However, our hypothesis is that clearly explaining the task to the model aids in faster convergence of the parameters and a more rapid reduction in loss during training. Therefore, this is the reason why our prompt includes a comprehensive description of the canonical sentence structure. This description details that each verb must adhere to specified constraints, the types of sequences they can contain, the verbal structures, and the order of complements. If a verb does not adhere to these constraints, it should be classified as Non-Canonical.

3.2. LLM architectures of non-Canonical structures

Today, the landscape of Large Language Models (LLMs) is vast, making it challenging to choose the most suitable model. In this paper, we focus on several well-known models from the LLaMA family: LLaMA1 [20], the first in the series; LLaMA2 [29], which introduced minor improvements in Transformer architecture; Camoscio [25], an instruction-tuned LLaMA model fine-tuned on Italian data; ExtremITA [23], an architecture designed for a wide range of Italian tasks; and LLaMAntino [26], an adaptation of the original LLaMA2 model for the Italian language.

We expect the best-performing models to be those specifically adapted or fine-tuned on Italian data, such as Camoscio, ExtremITA, or LLaMAntino. One significant issue with the English models is that non-canonicity is very rare in English, as the language predominantly follows the Subject-Verb-Object structure, which is canonical, with very few (grammatically correct) non-canonical examples.

4. Empirical Investigation

In this setup, the models trained and those utilized in the k-shot scenario are required to answer Yes if the given text is canonical and follows the rules, or No otherwise.

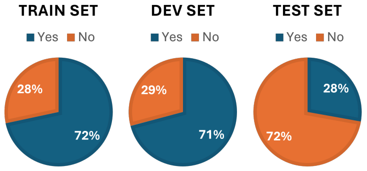

Figure 1: Statistics about the class distribution in the Training, Development and Poetry Test sets. 'Yes' refers to the positive class (i.e. the example is Canonical) and 'No' to the negative one.

For training, we used the VIT Treebank [30], which contains approximately $320,000$ words. Among other information, each sentence is categorized into canonical or not. The dataset was divided into a Training set and a Development set with a 90/10 ratio. The class distribution is shown in Figure 1, where it is evident that the vast majority of the sentences are canonical, reflecting the natural usage patterns of Italian speakers.

We employed the LoRA [31] technique and the Peft package on a single Tesla T4 GPU to train the models for 3 epochs, with a learning rate of 3^{-4} and using a linear scheduler with 10% warmup. The LoRA R parameter was set to 8, α to 16, and all available layers were involved (for more details, refer to the original paper [31]). For computational efficiency, the floating-point precision of the parameters was set to 8 bits, allowing the use of a single GPU.

For the Test set, we used a collection of Italian poetry comprising 51 texts with a total of 303 sentences. For the same reason that people still regard Dante as the greatest Italian poet and students are required to learn his best poems by heart, we have chosen what is regarded as the best Contemporary Italian poetry: a manually curated collection of excerpts from Italian poems from the late 19th and early 20th centuries. In particular, we used poems from the 1975 Nobel Prize Eugenio Montale, with about one hundred excerpts taken from the volume "*Ossi di Seppia*". The class distribution of this test set is shown in Figure 1. Notably, the distribution of Yes (the sentence is canonical) and No (the sentence is non-canonical) is reversed compared to the Training and Development sets, due to poetic license and rhyming constraints. This reversal poses a significant challenge for the models we trained, but it presents an interesting test case. More details about this and a simple Error Analysis are presented in the Appendix B.

In this context, it is important to note that the consideration of structures which, in Chomskyan transformational theory, were once viewed as surface-level realizations of deep canonical structures has not been a deliberate focus of this experiment. The first reason for

Table 1
Classification results on the Test Dataset. FT for each model here refers to the Fine-Tuning procedure, 0s for the 0-shot and 1s for the 1-shot In-context Learning technique.

Model Type	**Precision**				**Recall**				**F1-Score**			
	Yes	**No**	**Macro**	**Micro**	**Yes**	**No**	**Macro**	**Micro**	**Yes**	**No**	**Macro**	**Micro**

excluding structures like passives, interrogatives, relative clauses, cleft sentences, tough constructions, and others, is their relative scarcity in poetry, though they are more frequent in prose. A second reason, closely tied to the first, is that these common structures do not add an element of surprise, given their frequency in everyday language use. That said, some of these common non-canonical structures can still be found in Italian literary prose, but not all are represented in the examples we studied. On the other hand, focus fronting (also referred to as object preposing, complement preposing, or full argument inversion, depending on the constituent being fronted) is prevalent in the examples included in the experiment. An exemplar list of such structures can be found in Appendix C.

4.1. Results and Discussion

The models used in this paper are those already anticipated in Section 3.2, available from Huggingface, using the prompt described in Section 3.1. The results are available in Table 1. Given the distribution of the sentences of the Training set, we report a simple but informed `Yes-Baseline`. This baseline cannot perform well on the inverted distribution of the Test Set, as it always answers `Yes`. We first used the LLMs anticipated in Section 3.2 in a 0-shot manner and you can notice an overall good ability to detect the non-canonical sentences reaching a 73% of Precision and 93% of Recall for Camoscio, but still struggles to identify the canonical ones. We hoped to heavily boost the performances of the model in the 1-shot scenario[3], but it seemed to decrease in performance. The same trend can be noted for all the other models. As a second comparison, we train an Italian BERT model for 3 epochs which starts showing some awareness of the task and reaching an overall 40% of Micro-F1. Using our Development set we selected only the best LLM to report here for space constraints, which is based on Camoscio [25]. Finally, the Fine-Tuned model reaches the best performance with a very good Precision (98%) for the non-canonical sentences and very good Recall (98%) for the canonical ones, with a final 60% of both Macro and Micro F1.

4.2. Corpus Analysis

For a better insight into the current measured performance, we studied the role of training material as representative of the adopted test dataset. We analyzed the test dataset used in terms of the average word frequencies, as observed on the ITWaC corpus[4]. This corpus provides pre-computed frequencies for each word: for comparative reasons, we normalized in $[0, 1]$ and measured them for each sentence in terms of the mean frequency, i.e., the sum of the word frequencies over each sentence. By independently averaging frequencies of canonical and non-canonical sentences, we obtained the following figures:

- Canonical Sentences, AVG frequency: 0.38
- Non-Canonical Sentences, AVG frequency: 0.24

Intuitively, a value approaching 1 characterizes highly frequent words in ITWaC: this suggests that they are well-represented in the original LLM. Conversely, values closer to 0 characterize less represented sentences. Notice that only canonical sentences (AVG 0.38) are represented, although in a limited manner, in standard Italian texts. This result sheds light on the specific relationship

[3] We experimented with more than 1 example per class, increasing the number of samples up to a 16-shot scenario. Unfortunately, the performance was not increasing but stale around 60% of Micro-F1. We didn't report such results here for space constraints.

[4] https://www.sketchengine.eu/itwac-italian-corpus/

Table 2
Classification results in a 5-fold cross-validation scenario, where the performance for all the splits is merged together.

Model Type	Precision				Recall				F1-Score			
	Yes	No	Macro	Micro	Yes	No	Macro	Micro	Yes	No	Macro	Micro
Yes-Baseline	0,72	0,00	0,36	0,72	**1,00**	0,00	0,50	0,72	0,84	0,00	0,42	0,72
Camoscio FT	**0,93**	**0,83**	**0,88**	**0,90**	**0,93**	**0,84**	**0,88**	**0,90**	**0,93**	**0,83**	**0,88**	**0,90**

between word frequencies and training: LLMs, particularly *Camoscio*, are more "confident" with words they encountered during pre-training or fine-tuning. It is noticeable that almost 50% of our test set words (adjectives, verbs, nouns) do not even occur in the ITWaC and, in fact, they are also absent in any canonical sentence of the training set. Another issue lies in the pre-training data of these LLMs. Since most of the data is in English (over 88%) and non-canonical sentences are extremely rare in English, models like LLaMA or Camoscio have rarely encountered such data, leading to suboptimal performance. Moreover, the length of the sentence could be a factor that may influence the performance of LLMs, specifically in poetry, in the ability to detect canonical or non-canonical sentences.

Therefore, to achieve a more balanced evaluation, we merged the Training, Development, and Testing sets into a single dataset to balance the classes and ensure that the model learns to recognize non-canonical sentences. We then performed an N-Fold Cross-Validation ($N = 5$). Only the trained model was re-evaluated, and the results are presented in Table 2. We maintained the simple and informed `Yes-Baseline` for comparison and recomputed its performance. In this setting, the class distribution aligns again with the Training set. The fine-tuned Camoscio model now shows very good performance in distinguishing canonical sentences, achieving a Macro-F1 of 88% and a Micro-F1 of 90%.

5. Conclusions

In this study, we have shown the potential of Large Language Models, particularly the LLaMA architecture and its Italian adaptations, in distinguishing between canonical and non-canonical sentences in Italian. Our experiments indicate that instruction-tuned models specifically for Italian, such as Camoscio and LLaMAntino, exhibit a strong grasp of Italian syntax and can effectively handle diverse sentence structures. However, the performance for this task is still penalized by the large portion of English data they ingest during pre-training. The findings underscore the importance of tailored language models for specific languages and the benefits of incorporating extensive syntactic variations into training datasets. Future work should focus on expanding the training datasets with more diverse syntactic structures and improving model architectures to better capture the nuances of non-canonical sentences.

A. Limitations

In assessing the data distribution disparities between languages in the pre-training phase of the LLaMA family models, we provide an illustrative breakdown in Table 3, where English accounts for nearly 90% of the data, while Italian is present in less than 1%.

Table 3
Data distribution.

Code	Language	Percentage
en	English	**89,70%**
unk	unknown	8,38%
de	German	0,17%
fr	French	0,16%
sv	Swedish	0,15%
zh	Chinese	0,13%
ru	Russian	0,13%
es	Spanish	0,13%
nl	Dutch	0,12%
it	Italian	0,11%
ja	Japanese	0,10%
pl	Polish	0,09%
pt	Portuguese	0,09%
vi	Vietnamese	0,08%
uk	Ukrainian	0,07%
ko	Korean	0,06%
ca	Catalan	0,04%
sr	Serbian	0,04%
cs	Czech	0,03%
fi	Finnish	0,03%
hu	Hungarian	0,03%
id	Indonesian	0,03%
no	Norwegian	0,03%
ro	Romanian	0,03%
bg	Bulgarian	0,02%
da	Danish	0,02%
hr	Croatian	0,01%
sl	Slovenian	0,01%

Among the limitations of the proposed model, the computational costs associated with training a model like LLaMA are undoubtedly significant, requiring hundreds of hours on a GPU. We have implemented methods to streamline this process, but the computational expenditure for training on a 16GB GPU remains high. This becomes even more pronounced considering the model's sentence processing time, which is slightly less than half a second per sentence. Given the required computational power to run the model, this duration is relatively long.

Regarding the model's application, since it heavily relies on an LLM, it might be susceptible to hallucination — generating non-existent sentences or fragments. However, during inference (few-shot or training), it seems to always answer in the request format, very rarely (especially in 0-shot) adding some explanation for its decision after a `Yes` or `No`.

Additional experiments might be necessary to ensure that pollution effects don't unduly influence the evaluation process: the VIT dataset might have been encountered during the pre-training phase. Although this might have occurred, certainly the model did not have the opportunity to observe sentences from the poetry domain associated with the canonical or non-canonical label.

B. Error Analysis

In this section, we present a simple Error Analysis with two different cases: *i)* a sentence from the Development set, which should reflect the distribution of the training data for the models introduced in Section 3.2; a sentence from the poetry domain that is radically different from the training data. We will then report the answer for each model specifying the modality (in-context learning or training) and eventually the number of shots used for inference.

As a first example, consider "*Difficile tenersi in quel cammino*"[5], which is non-canonical as the main verb "è" is missing. The models answered as follows:

- LLaMA1 0s: canonical
- LLaMA1 1s: canonical
- LLaMA2 0s: canonical
- LLaMA2 1s: canonical
- ExtremITA 0s: canonical
- ExtremITA 1s: non-canonical
- LLaMAntino 0s: canonical
- LLaMAntino 1s: non-canonical
- Camoscio 0s: non-canonical
- Camoscio 1s: non-canonical
- BERT FT: non-canonical
- Camoscio FT: non-canonical

This example is interesting because all the Italian adapted models in some way (1-shot or Fine-Tuned) answered correctly, thus recognizing that the sentence was missing the main verb, given the initial prompt. Notice that only Camoscio answered correctly both in 0-shot and 1-shot

As a second and more difficult example, consider the sentence "*Zacinto mio che te specchi nell'onde del greco mar da cui vergine nacque Venere*"[6], taken from the poetry test set. This example is very hard to comprehend as some words are very rare in spoken/written Italian (*nell'onde*), the usage of the uncommon *te* to express that the city is actively mirroring in the sea, and the reversed order of the last words. In this case, all the models answered that the sentence is non-canonical, recognizing the strange structure of the sentence, except for BERT FT which classified this sentence as canonical.

C. Typical Non-Canonical Structures

In this section, we report a list of typical non-canonical structures as an example of the complexity the models are dealing with.

1. Inversion of the complete argument, where the complement is fronted, and the subject follows the verb.
2. Subject inversion, positioning the subject after the main verb.
3. Fronting of the object, moving the object to the beginning of the sentence before the subject.
4. Extraction of the object from an infinitival clause, placing it at the beginning of the sentence.
5. Preposing of a prepositional adjunct from a participial clause, moving the prepositional complement of a past participle to a position before the verb.
6. Leftward extraction of the lexical verb, where the untensed, non-finite main verb precedes the auxiliary or modal verb.
7. Right dislocation of the subject, placing the subject after the complements of the sentence.
8. Fronting of both the subject and the object, positioning them before the main verb, with the subject preceding the object.
9. Fronting of a prepositional specification, often introduced by "of", extracting it from the noun phrase and positioning it at the front.
10. Right dislocation of the clitic, where a clitic pronoun attached to the main verb corefers to an object noun phrase positioned later in the sentence.
11. Right dislocation of the object, placing the object after indirect objects, adjuncts, or an inverted subject.
12. Insertion of parentheticals or adjuncts between the subject and the main verb.
13. Rightward extraction of the adjective from the noun phrase, positioning it after any noun adjuncts.
14. Right stranding of a prepositional specification, such as "of", leaving it at the end of the sentence, separate from the noun phrase.
15. Rightward extraction of the lexical verb, positioning the untensed, non-finite main verb after the complements of the sentence.
16. Right stranding of the predicate's head noun, leaving it after two adjuncts.

Abstract

In the modern labour market, taxonomies such the *European Skills, Competences, Qualifications and Occupations* (ESCO) classification are used as an *interlingua* to match job postings with job seeker profiles. Both are classified with respect to ESCO *occupations*, and match if they align with the same occupation and the same skills assigned to the occupation. However, matching models usually struggle with the classification because of overlapping skills and similar definitions of occupations defined in the ESCO taxonomy. This often leads to imprecise classification outcomes. In this paper, we focus on the challenge of the classification of job postings written in Italian or Spanish against ESCO occupations written in English. We experiment with multilingual embeddings, zero-shot classification, and use of a large language model (LLM) and show that the use of an LLM leads to best results. Furthermore, we also explore an alternative automatic labeling method by prompting three top-performing LLMs to annotate the test dataset. This approach serves both as an experiment on the usability of automatic labeling and as an evaluation of the reliability of the automatically assigned labels, involving human annotators.

Keywords

ESCO labour market taxonomy, job posting classification, class embeddings, text embeddings, LLM

1. Introduction

The modern labour market becomes more and more diverse. High-tech jobs demand novel skills and competences, which in their turn keep undergoing adaptations and modifications. Under these circumstances, accurately classifying job postings and CVs of job seekers (henceforth *candidate experiences*) that contain detailed technological specifications with remarkably similar yet distinct skills and experiences has evolved into a complex challenge.

The overwhelming majority of job portals and employment agencies use either the *European Skills, Competences, Qualifications and Occupations* (ESCO) taxonomy[1] or its US equivalent O*Net taxonomy[2] to classify job postings and candidate experiences in terms of job title labeled ESCO/O*Net occupations. Most of the proposals to automatic alignment of job postings with candidate experiences (or vice versa) also use ESCO or O*Net [1, 2, 3]. However, despite their wide use, both ESCO and O*Net taxonomies exhibit principle limitations for the task of automatic classification of job postings and candidate experiences because due to their tree structure they often fail to adequately distinguish between occupations that exhibit substantial skill overlaps. For instance, two job postings labeled as 'data analyst' may appear similar but require different skills if one focuses on market research while the other concentrates on healthcare trends analysis. This issue is particularly pronounced when classification relies on a single label, such as the job title of an ESCO occupation, where skill overlaps undermine precise classification. Hence, employing multiple job titles and framing the problem as a multi-label classification task is imperative.

This paper addresses the challenge of multilingual multi-label classification using Large Language Models (LLMs) for the alignment of Italian and Spanish job postings with English job titles encountered in the ESCO taxonomy. Multilingual class embeddings are explored to improve classification accuracy, aiming to provide the necessary contextual awareness and addressing the core limitations of taxonomies such as ESCO.

Furthermore, we explore an alternative automatic labeling method by prompting three top-performing LLMs to annotate the test dataset. This approach serves both as an experiment on the usability of automatic labeling and as an evaluation of the reliability of the automatically assigned labels, involving human annotators.

To provide LLMs with domain-specific information and to mitigate hallucinations in the course of the classification of the job postings, we employ Retrieval Augmented Generation (RAG) [4], which combines information retrieval with a generative model. RAG serves

[2] https://www.onetonline.org/

two critical functions in our methodology. Firstly, it provides detailed definitions, including essential skills and synonyms for each ESCO occupation, selected through vector similarity as outlined in [5]. Secondly, it ensures that the assigned job titles are restricted to titles within our predefined label space, i.e., standardized job titles defined in the ESCO taxonomy.

The contributions of our work are:

• We explore the impact of using multilingual class embeddings derived from the ESCO taxonomy for the task of job posting classification.

• We integrate RAG to provide LLMs with domain-specific information and eliminate the dependency on fine-tuning;

• We show how the LLM response can be restricted to standardized job titles and thus how LLMs can be used for high quality job title classification that outperforms state-of-the-art proposals for this task.

The remainder of the paper is structured as follows. In Section 2, we present a concise overview of the related work. In Section 3, the model on which our work is based is outlined. Section 4 describes the experiments we carried out, the results we obtained in these experiments, and their discussion. In Section 5, finally, draws some conclusions from the presented work and outlines some directions for future research. In Appendix A, we present an ablation study in which we assess the comprehension of English ESCO job titles and its Spanish equivalents by our model. Appendix B provides, for illustration, examples of Italian job postings and predicted ESCO job titles. In Appendix E, we present the signature used to prompt Large Language Models for pre-processing.

2. Related Work

A number of works have been carried out in the domain of job title classification, focusing on various facets of the problem. Shi et al. [6] introduce Job2Skills, a model developed for LinkedIn. The model significantly improves job recommendation performance metrics, however, raises questions about its effectiveness beyond LinkedIn. Li et al. [7] proposes a two-step job title normalization, also in LinkedIn, which is based on tokenization and matching of the original job title provided by the user with a lookup table. The use of a lookup table instead of a standard occupation taxonomy such as ESCO or O*Net significantly limits the generalization potential of this strategy. Zhang et al. [8] extract soft and hard skills from job posting descriptions, showing that domain-specific pre-training significantly enhances performance in skills and knowledge extraction. Javed et al. [3] introduce a semi-supervised machine learning approach that utilizes hierarchical classifiers and the O*NET *Standard Occupational Classification* (SOC) taxonomy for the classification of online recruitment data. Similarly, Wang et al. [9] propose a model based on multi-stream convolutional neural networks, aiming to classify noisy user-generated job titles by considering different elements such as characters and words within job titles. Yamashita et al. [10] and Zbib et al. [1] conduct studies on the classification of job titles, focusing on job title alignment and job similarity training, respectively. JobBERT Decorte et al. [2] classifies job titles against the ESCO taxonomy, treating the task as a semantic text similarity (STS) exercise. In particular, JobBERT emphasizes the understanding of the semantics of job titles through the skills inferred from the associated vacancies and descriptions, thus alleviating the need for an extensive labeled dataset or a continuously updated list of standardized titles. Before the recent proposals [11] and [12], JobBERT used to be referenced as the state-of-the-art baseline. In general, all of these works draw upon some of the information encoded in the ESCO taxonomy. However, none of them uses detailed descriptions of ESCO occupations, as we propose.

3. The Model

3.1. The Basics

The proposed model is based on the notion of *distinctiveness*, which specifies the difference between the prompt concept θ^* and other concepts within the conceptual space Θ [13]. The notion is crucial for distinguishing in-context learning concepts that are aimed to be learned by analogy. θ^* acts as a latent parameter in a Hidden Markov Model that defines a distribution over observed tokens, represented by selected ESCO job titles as labels. As proposed by Xie et al. [13], the error of the in-context predictor approaches optimality under the condition that θ^* is distinguishable from other concepts in $\Theta \setminus \{\theta^*\}$. When RAG is adapted as a few-shot reasoning (or in-context learning) framework for job posting classification [14] , θ^* is represented by the top-selected ESCO labels and ensures that the LLM can effectively differentiate between closely related job categories.

The explanation enriched prompts enhance the LLM's ability to learn more from each example. According to Xie et al. [13], the expected error decreases as the length and informational content of each example increase, contributing to the richness of the input–output mapping for a more robust in-context learning environment. This assumption is proven to be true under the condition of distinguishability of in-context examples and can be mathematically expressed as a reduction of the expected error $E[\epsilon]$, correlated with an increase in the information content I of the examples:

$$E[\epsilon] \propto \frac{1}{I(S_n, x_{\text{test}})} \tag{1}$$

    )
```

Figure 2: Prompt Template

where S_n represents the sequence of training examples in the prompt and x_{test} is the test input.

The use of RAG helps avoid hallucination since when directly prompted with job postings, LLMs have been observed to sometimes produce non-existent labels [5].

3.2. Design of the Model

The proposed model (see Figure 1) uses multilingual class embeddings of the E5-large model[15] to retrieve pertinent ESCO occupation definitions in English. The definitions serve as contextual information to prompt language models for selection of the most suitable job titles. To this end, we incorporate the DSPy library's Chain-of-Thought mechanism,[3] augmented by a hint to restrict the model output to a specified list of job titles. The signature used in this methodology (cf. Figure 2) is inspired by [16].

To implement the RAG model, we initially established a vector database,[4] in which English ESCO occupation definitions were inserted as multilingual embedding vectors. Acknowledging the reported significance of chunking in many NLP applications, we conducted a series of ablation studies to determine the optimal chunk size. These studies revealed that subdividing the ESCO occupation definitions into smaller segments adversely affects the performance of vector-based similarity matching. Therefore, we opted for storing each of the 3,015 occupations represented in the ESCO taxonomy in its entirety.

Table 1
Recall values for classification with E5-large Text Embeddings vector similarity

Precision @ K	@5	@10	@30	@40
Value	0.4238	0.9004	0.9627	0.9817

To accurately classify a given job posting with respect to the ESCO taxonomy, we include 30 ESCO occupation documents (i.e., 30 nodes of the taxonomy) into the LLM's context as potential job titles. The rationale for choosing 30 documents is that we aim to strike a balance between computational efficiency and the accuracy of the retrieved documents. The precision of the LLM would naturally decrease when it is presented with inaccurate labels. Although, as shown in Table 1, the precision of the model slightly increases with 40 documents in the context, we accepted this trade-off in favor of a lower VRAM requirement.

Upon the retrieval of the 30 ESCO occupations that are most closely aligned with a given job posting description, a composite prompt (see Figure 2) is constructed as input to the LLM. The prompt integrates the actual text data encompassing job titles, descriptions, and skills pertinent to the selected occupations. The design of the simplified composite prompt aims to minimize the bias by focusing only on the core elements. The prompt is then processed by using a locally stored Llama-3 LLM[5] in an isolated environment[6].

As a few-show predictor, the LLM evaluates the composite prompt to accurately classify job postings by examining the semantic nuances of the selected ESCO occupations, aligning them with the actual job titles within the offers. To quantitatively assess the alignment between a job posting vector J and each occupation embedding E_{ESCO} derived from the ESCO taxonomy, cosine similarity $a(J, E_{\text{ESCO}})$ is used:

$$a(J, E_{\text{ESCO}}) = \frac{J \cdot E_{\text{ESCO}}}{\|J\| \|E_{\text{ESCO}}\|} \tag{2}$$

The similarity scores yielded through $a(J, E_{\text{ESCO}})$ for each E_{ESCO} facilitate the identification and selection of

[3] https://github.com/stanfordnlp/dspy

[5] https://llama.meta.com/llama3/
[6] We use dockerized models from the open-source Ollama library https://ollama.com/ for all experiments

the ESCO occupation embeddings that are most pertinent to the job posting in question. Armed with this information, the LLM proceeds to classify the job posting by selecting the ESCO occupation that exhibits the highest degree of semantic and contextual relevance.

For a specific job posting J, an embedding function E is employed, such that $E(J)$ produces the corresponding embedding for J. The degree of similarity between the job posting's embedding $E(J)$ and any ESCO occupation embedding e_i from E_{ESCO} (where E_{ESCO} stands for the ensemble of occupation embeddings derived from the ESCO taxonomy) is determined through the similarity function $S(E(J), e_i)$ (in our case cosine).

The similarity scores for each occupation embedding e_i within E_{ESCO} relative to $E(J)$ are computed. The ten class embeddings that exhibit the highest similarity to $E(J)$, denoted as E_{top}, are selected. Formally, E_{top} is defined as the subset $\{e_1, e_2, \ldots, e_{10}\}$ from E_{ESCO}, where each e_i is selected based on the top 10 similarity scores $S(E(J), e_i)$.

The last stage entails a decision-making process enacted by the Llama-3 LLM, represented by the function D. This function accepts the composite prompt including candidates $\{e_1, e_2, \ldots, e_{10}\}$ accumulated to E_{top} and the job posting J, to render the final selected occupation embedding. The chosen occupation embedding e^* is determined by $e^* = D(E_{\text{top}}, J)$, representing the ESCO occupation best matched by the model.

The entire algorithm can be presented by the following equation, which encapsulates the embedding generation, similarity assessment, and decision-making process by the LLM, culminating in the selection of the most suitable ESCO occupation embedding e^* for the given job posting description.

$$e^* = D(\{e_1, e_2, \ldots, e_k \mid e_i \in E_{\text{ESCO}}; \\ \text{top k by } S(E(J), e_i)\}, J) \quad (3)$$

4. Experiments

To evaluate the effectiveness of the proposed model in handling multilingual job postings, experiments were conducted separately on Italian and Spanish datasets.

4.1. Test dataset

To have a reliable test dataset, we use three high performing LLMs as initial annotators of real-world 100 Italian and 100 Spanish job postings with the most extensive descriptions from the InfoJobs [7] database. Non-informative elements such as company descriptions and promotional content where removed using a DSPy module (cf. Appendix E for prompt), which employs zero-shot LLama-3 LM inference to anonymize sensitive information in job postings and candidate experiences. The preprocessed postings were annotated by the top three performing LLMs: GPT-4o[8], Gemini 1.5 Pro[9], and Claude 3.5 Sonnet[10], according to LmSys Arena[17]. In this context, the ESCO job titles are presented to each model separately, requesting them to select the appropriate job titles, and then measure their level of agreement on these labels. The agreement between LLM models was assessed using Cohen's kappa coefficient[18]. The average kappa score between Gemini and GPT-4o was found to be 0.6386, indicating a substantial level of agreement. The agreement between Gemini and Claude was lower, with an average kappa of 0.5798, suggesting a moderate level of agreement. Similarly, the kappa score between GPT-4o and Claude was 0.6497, also indicative of substantial agreement. Overall, the average kappa score across all "annotators" was 0.6227, reflecting a general trend towards substantial inter-annotator agreement among the models.

To establish ground truth labels, we incorporated a dual-layer labelling process. Although the test set consists of only 200 items, labeling them from scratch would be time-consuming due to the complexity of the ESCO taxonomy, which includes 3,015 distinct occupations. Human annotators would require extensive training to accurately navigate this taxonomy. Therefore, we first annotate the occupations automatically using LLMs and then let the initial annotations cross-examine by human expert annotator. Since each data point was reviewed by one annotator only, inter-annotator agreement among human annotators was not quantified. Instead, we conducted an analysis to identify job titles that consistently showed agreement or disagreement across the three LLMs, where domain-specific professionals from InfoJobs reviewed label discrepancies. This analysis, detailed in Appendix C, suggests that certain occupations are inherently more challenging to classify, possibly due to overlapping skills or ambiguous descriptions.

Furthermore, we repeated experiments using ground truth labels where any two of the three automatic LLMs agreed on the label. The results showed alignment between the models' predictions and the automatic labeling process, indicating consistency with the patterns recognized by the automatic methods when there is partial agreement. A detailed analysis of this alignment can be found in Appendix D.

4.2. Baselines

4.2.1. SkillGPT

SkillGPT [5] has been introduced as a tool for skill extraction and classification, with vector similarity search against LLM-precomputed ESCO embeddings. The authors employ embeddings generated by an LLM, although they do not directly use LLM to select among candidate embeddings. Instead, they rely on embedding similarity to assign the most closely related ESCO class to job descriptions under consideration.

4.2.2. Zero-Shot Classification

By transforming the classification task into a Natural Language Inference (NLI) problem, any model pretrained on NLI tasks can be utilized as a text classifier without the need for fine-tuning, effectively achieving zero-shot text classification. This is particularly beneficial when we deal with classes unseen during training, making it a robust solution for a variety of text classification scenarios [19].

In our implementation that we use as baseline, we utilize the BART-MNLI model [20] that showed high performance in summarization tasks when pretrained for various NLI tasks on an MNLI dataset [21] that is leveraged for its capability to understand entailment relations for classification of the given sequence into one of the specified categories. We also apply the same methodology with the Llama-3 model.

4.3. Model Optimization

To optimize LLMs with a minimal set of manually crafted examples, we use the DSPy library [22]. We initialize the classifier module with a Llama-3 model and use a GPT-4o model as the teacher. Our optimization of the classification is aimed at achieving high F1 scores for each dataset individually. In each run, we use 10 labeled training examples and 30 labeled validation examples. We employ DSPy's *BootstrapFewShot*, configuring it to perform a maximum of 2 rounds with up to 8 bootstrapped demonstrations. We define a custom metric—the F1 score—to guide the bootstrapping process. For the optimization of the LLMs, we use data points that had high inter-agreement among the automatic methods and were reviewed by human annotators. We perform a validation/test split to ensure that the optimization did not bias the evaluation results.

4.4. Outcome of the experiments

For the evaluation of the results of the experiments, we used the *micro recall* and *micro precision* metrics, which are suitable for our multi-class classification task. We report evaluation scores seperately on Spanish and Italian test sets.

Table 2
Italian Performance Metrics for Top 5 and Top 10 Predictions

Model	Precision		Recall	
	@5	@10	@5	@10
llama-3-8b (CoT opt.)	**0.32**	0.13	**0.76**	0.80
llama-3-8b (CoT)	0.26	0.12	0.62	0.64
llama-3-8b (SkillGPT)	0.19	0.19	0.36	0.82
mBart-large-mnli (0-shot)	0.13	0.12	0.29	0.58
multilingual-e5-large	0.16	0.19	0.36	0.88

Table 3
Spanish Performance Metrics for Top 5 and Top 10 Predictions

Model	Precision		Recall	
	@5	@10	@5	@10
llama-3-8b (CoT opt.)	0.28	**0.20**	0.72	**0.90**
llama-3-8b (CoT)	0.26	0.16	0.64	0.68
llama-3-8b (SkillGPT)	0.09	0.12	0.36	0.62
mBart-large-mnli (0-shot)	0.15	0.14	0.39	0.70
multilingual-e5-large	0.20	0.19	0.48	**0.92**

Tables 2 and 3 display the results on the Italian and Spanish datasets, respectively. The results indicate that prompting techniques outperform SkillGPT in both languages. Specifically, the optimized Llama-3-8b model with chain-of-thought (CoT) achieves the highest precision and recall at @5 for Italian, with values of 0.32 and 0.76, respectively, and for Spanish, with values of 0.28 and 0.72. This supports our assumption that optimization enhances performance. The multilingual E5-large model achieves the highest precision at @10 for Italian (0.19) and the highest recall at @10 for Spanish (0.92), underscoring the efficacy of embeddings in classification. This implies that semantically less similar labels can confuse models, whereas embeddings ensure higher recall accuracy, particularly in wider retrieval scenarios. Although both models exhibit similar precision, indicating comparable accuracy in their predictions, the optimized model's capacity to capture a broader range of relevant job titles ensures greater alignment with expert human preferences. This enhances the model's ability to make relevant job title suggestions, thereby improving the overall matching process.

4.5. Discussion

In Tables 2 and3 we observe that the combined use of general text embeddings and language models significantly outperforms current classification techniques, which rely on language models specifically tailored to the field of the labour market, such as [12]. We see that using vector similarity with the text embeddings created by the E5-large text embedings model alone does not surpass the baseline. However, it is worth noting that the results are quite close, despite the fact that this model was not specifically fine-tuned on labour market data or adapted to the ESCO taxonomy, as is the case of [12]. Furthermore, we can observe how text embeddings indeed provide a significant value for filtering *n* occupations closest to a job posting within the taxonomy. Using these *k* professions as input to various language models for few-shot classification significantly improves over the baselines. Table 6 in the Appendix illustrates the decisions of the LLMs in the case of four sample job postings.

We also evaluated the effectiveness of a large language model for classification of job titles based on provided descriptions, as shown in Table 4 even when the correct titles were not explicitly listed among the initial ESCO job titles. The model's ability to select accurate titles reflects its functionality in processing and understanding the contextual and semantic aspects of the job descriptions. For instance, when presented with a job description focused on the management of comprehensive water and wastewater services, the model correctly identified "Operations Manager" as the correct title. This identification was made despite the presence of several closely related but distinct labels (such as, "Water treatment plant manager") within the pool of ESCO job titles. This indicates that the model's decisions are more influenced by a comprehensive understanding of the job responsibilities and sectors than by the mere presence of keywords or phrases in the ESCO job titles.

The model's capacity to differentiate between job titles with more specific definitions enhances its comprehension of job postings and assigned labels, thereby improving the precision of suggesting relevant skills. Upon integration into an operational job platform, this model will better understand the requirements of job postings and accurately assign job titles that align with the specific needs of companies. Similarly, in the context of parsing of job candidate experiences, keywords tend to appear more frequently in semantically related ESCO definitions, enabling parsers to incorporate these keywords to enhance parsing performance.

Overall, we can thus state that the integration of class embeddings generated using the multilingual E5-large model, with subsequent application of few-shot classification techniques through LLMs, significantly improves the accuracy of job title classification, clearly surpassing those of the baselines.

4.6. Computational Cost of Compared Methods

In addition to evaluating performance metrics, we analyzed the computational cost and environmental impact of each method. The *Llama-3-8b* model, with 8 billion parameters, requires significant resources for inference, necessitating a GPU with at least 16 GB of VRAM (e.g., NVIDIA RTX 3090). Its average inference time per job posting is approximately 1.5 seconds, and its high energy consumption leads to increased CO_2 emissions, making large-scale deployment less environmentally sustainable without optimizations.

In contrast, the *mBART-large-mnli* model has about 610 million parameters and operates on GPUs with 8 GB of VRAM, offering faster inference times under 0.5 seconds per job posting. The embeddings-based method using the *multilingual E5-large* model, with 330 million parameters, allows for precomputed embeddings and efficient CPU-based vector similarity searches, reducing inference time to less than 0.2 seconds per job posting. These smaller models consume less energy, providing more resource-efficient and eco-friendly alternatives suitable for production environments where computational cost and environmental impact are critical considerations.

5. Conclusions and future work

In this paper, we argued that the use of multilingual embeddings in combination with LLMs significantly enhances our ability to distinguish between very similar (or even identical) job titles that suggest different skills and competencies. Our experiments have shown that this is indeed the case, demonstrating that the combination of multilingual text embeddings similarity with the Llama-3 markedly exceeds the performance of other leading approaches in the field.

In the future, we plan to apply the same approach to the analysis and classification of job candidate experiences. Once it is ensured that both job postings and candidate experiences can accurately be modeled using the embedded representation of the ESCO taxonomy, we plan to set the stage for a more direct and efficient alignment process between job postings and experiences of job seekers.

Another interesting direction for future research is to analyze the lexical overlap between English domain-specific terms that appear in Italian and Spanish job postings and the English occupation descriptions in the ESCO taxonomy. Such an analysis would reveal whether job types with higher lexical overlap affect model accuracy, providing deeper insights into the multilingual nature of the task.

determine the best job title for a person who manages operations in a quick service restaurant.

1. Exclude options that are not relevant to managing a quick service restaurant:
* Business manager and hospitality revenue manager are broader terms that could apply to various types of businesses, not just quick service restaurants. Therefore, we can exclude these two options.
* Accommodation manager is typically used for hotels or other lodging establishments, so we can also exclude this option.
* Delicatessen shop manager and rooms division manager are specific to different types of businesses, so we can exclude those as well.
* Customer experience manager could be a relevant term, but it's more focused on the overall customer experience rather than managing day-to-day operations in a quick service restaurant. Therefore, we can also exclude this option.
1. Consider synonyms for the remaining options:
* Restaurant manager is a broad term that could apply to various types of restaurants, not just quick service ones. However, it's still a relevant option.
* Quick service restaurant team leader and fast food shift team leader are similar terms that refer to leading a team in a quick service restaurant. They are specific to the type of restaurant we're considering, so they could be good options.
* Destination manager is not relevant to managing a quick service restaurant.
* Membership manager is also not relevant to managing a quick service restaurant.
1. Evaluate the remaining options based on their relevance and specificity:
* Restaurant manager is a broad term that could apply to various types of restaurants, but it's still relevant. However, it may not be as specific as other options.
* Quick service restaurant team leader and fast food shift team leader are more specific terms that refer to leading a team in a quick service restaurant. They are relevant options.

Based on this reasoning, the best job title for a person who manages operations in a quick service restaurant would be either "quick service restaurant team leader" or "fast food shift team leader." These terms are specific to the type of restaurant we're considering and highlight the leadership aspect of the role.

Figure 3: LLM's Rationale

A. Ablation Study

In our ablation study, we pursued two primary objectives. Firstly, to evaluate the model's comprehension of ESCO job titles and its decision-making process. To achieve this, we prompted the model to articulate its underlying rationale. Secondly, so far we reported the performance of our model when Italian and Spanish data were matched against English job titles and occupations in the ESCO taxonomy. Here we wanted to explore whether its comprehension was extendable to data in different languages. We selected Spanish for this purpose and discovered that the model's understanding was consistent, irrespective of the language; see Table 4.

As illustrated in Figure 3, the LLM showcases a comprehensive understanding of the task at hand, effectively narrowing down potential ESCO job titles to identify the most suitable label. Additionally, the LLM is observed to generate a novel job title, referred to as "fast food shift team leader". This can be attributed to the absence of contstraints imposed on the LLM regarding structured output for classification, thereby granting it to autonomy to propose the most fitting job title. The analysis initially excludes broader or less related job titles such as "bussiness manager", "hospitality revenue manager", and "accomodation manager", which are not spesific to quick-service restaurant operations. Subsequently, the model considers and ultimately selects titles that emphasize leadership within this spesific restaurant context, narrowing down to "quick service restaurant team leader" and "fast food shift team leader" as the most apt job titles. The reasoning of the model is correct on chosing these titles for their precise reflection of the managerial and leadership responsibilities pertinent to the restaurant environment.

B. Job postings and Predicted ESCO job titles

The following tables provide examples of job titles, job posting descriptions, and the corresponding gold labels in Table 5 and optimized LLama-3 job titles in Table 6. These examples illustrate how the job titles assigned by recruiters may not always capture the specific nature of the job described in the postings. The gold labels and the optimized LLama-3 job titles offer a more accurate representation of the job roles based on the detailed job descriptions.

The job title "Commessa" (Salesperson) is generic and does not specify the specialization required for the job. The gold label "telecommunications equipment specialised seller" fits better because the job description clearly focuses on selling telecommunications equipment, which requires specific knowledge and skills related to this type of product. The gold label accurately reflects the specialized nature of the role. The job title "Project engineer" given by the recruiter suggests a technical and

Gold Label Job Title
Quick Service Restaurant Team Leader
Posting Job Title Encargado de Franquicias **Posting Description:** - Responsable de garantizar la satisfacción de los huéspedes y de gestionar y superar los objetivos financieros y operativos de los restaurantes a mi cargo. - Garantizar una excelente atención a los huéspedes en base a las promesas y estándares definidos. - Liderar, motivar y desarrollar equipos. - Facilitar los recursos y el apoyo necesario a los equipos en sus restaurantes. - Utilizar de manera eficaz los diferentes recursos de la Compañía. - Identificar oportunidades y amenazas de negocio en el mercado. - Aportar ideas y ejecutando proyectos en el corto y medio plazo. - Difundir las mejores practicas y resolver problemas comunes en los restaurantes. - Cumplir los protocolos y políticas de la Marca y la Compañía. - Garantizar y difundir los valores y principios definidos por la Compañía. **Skills:** SAP Girnet Gtock, Cuiner
ESCO Job Titles: Restaurant Manager, Business Manager, Hospitality Revenue Manager, Accommodation Manager, Delicatessen Shop Manager, Rooms Division Manager, Customer Experience Manager, Quick Service Restaurant Team Leader, Destination Manager, Membership Manager

Table 4
Spanish job posting Example

Posting Job Title	**Job Posting Description**	**Gold Labels**
Commessa	Commessa; Commessa; - Presentazione e vendita di attrezzature per telecomunicazioni ai clienti; - Servizio e supporto clienti; - Gestione delle transazioni di vendita; - Gestione dello stock e dell'inventario.	Telecommunications equipment specialised seller
Project Engineer	Project Engineer; Project Engineer; PROJECT MANAGER / PROJECT ENGINEER Divisione: Amministrazione Tecnica - Coordinamento delle attività di gestione progetti in ambito tecnico; - Supporto al Product Development; - Pianificazione e monitoraggio delle attività progettuali; - Supervisione del team tecnico; - Assistenza alla gestione dei fornitori e del budget di progetto.	Project manager, Product development manager

Table 5
Examples of Job Titles, Descriptions, and Gold Labels

engineering-focused role. However, the job description emphasizes project management, coordination of project activities, support to product development, and supervision of the technical team. The gold label "project manager" fits better as it captures the overall management and coordination responsibilities described, which are more aligned with the duties of a project manager than just a project engineer.

The job title "Addetto alle vendite" (Sales Assistant) is too generic and does not capture the specialized nature of the role described in the vacancy. The description specifies duties typical of a deli worker, such as serving customers, slicing cheeses and cured meats, preparing packages, and managing the deli counter. Our model's titles "meat and meat products specialised seller" and "deli worker" are more precise, indicating a specialized role in food handling and customer service, which goes beyond the general sales assistant title. This demonstrates our model's ability to interpret the specific context and responsibilities of the job accurately.

The job title "IT Specialist" is generic and could encompass various IT roles. However, the job description clearly indicates responsibilities such as managing ICT projects, coordinating a software development team, planning and monitoring development activities, managing ICT resources and budget, and providing advanced techni-

Posting Job Title	Job Posting Description	Optimized LLama-3 Job Titles
Addetto alle vendite	Addetto alle vendite; Addetto alle vendite; Salumiere: servizio clientela, tagli di formaggi e salumi, preparazione confezioni, gestione banco gastronomia.	Meat and meat products specialised seller, Deli worker, Food and beverage server
IT Specialist	IT Specialist; IT Specialist; Responsabile della gestione dei progetti ICT; Coordinamento del team di sviluppo software; Pianificazione e monitoraggio delle attività di sviluppo; Gestione delle risorse ICT e del budget; Assistenza tecnica avanzata e risoluzione dei problemi.	ICT project manager, Software development manager
Sales Manager	Sales Manager; Sales Manager; Sviluppo del business aziendale; Definizione delle strategie di vendita; Gestione del team di vendita; Monitoraggio delle performance e raggiungimento degli obiettivi di vendita; Gestione delle relazioni con i clienti chiave e i partner strategici.	Business development manager, Sales director

Table 6
Examples of Job Titles, Descriptions, and Optimized Job Titles

Table 7
Examples of Job Postings with Ambiguous Classification due to Multilingual and Contextual Challenges

Job Title	Description Excerpt	Labels Suggested
Junior Project Manager	Applicare i metodi e gli strumenti propri del Project Management a commesse specifiche per il settore dell'automazione industriale, di cui l'azienda fornisce sistemi di visione artificiale.	Project Manager, ICT Project Manager, Programme Manager
Assistente Amministrativo (Healthcare)	Gestione dei flussi delle segnalazioni dei cittadini per prenotazioni vaccinazioni e assistenza pandemica, inclusa la verifica del "certificato verde" per la conformità alle normative sanitarie.	Healthcare Assistant, Administrative Assistant, Contact Tracing Agent
Commesso di Negozio (Retail)	Creazione di vetrine accattivanti con abbinamenti di tendenza e assistenza alla clientela nella scelta dei prodotti.	Shop Assistant, Sales Assistant, Visual Merchandiser
Team Leader (Energy Sector)	Predisposizione documenti formativi e aggiornamento processi operativi presso sede Enel, inclusa l'implementazione e il collaudo di software per la gestione energetica.	Team Leader, Energy Analyst, Business Process Analyst
Assistente Amministrativo (Legal and Fiscal)	Compiti legati al Registro Nazionale delle Varietà Vegetali e mansioni fiscali complesse come Dichiarazioni IRAP.	Accounting Assistant, Administrative Assistant, Compliance Officer

cal support. The optimized titles “ICT project manager” and “software development manager” are more accurate as they reflect the leadership, coordination, and project management aspects of the role, which go beyond the scope of a general IT specialist.

The job title “Sales Manager” suggests a mid-level management role. However, the job description highlights responsibilities such as business development, defining sales strategies, managing the sales team, monitoring performance, and managing relationships with key clients and strategic partners. These responsibilities are more aligned with a higher-level role such as “business development manager” or “sales director”, which involve strategic planning and high-level management.

C. Ambiguity from Specialized and Contextual Factors

To further understand the complexity of job classification in a multilingual context, we conducted an ablation study focusing on cases where both human annotators and LLMs demonstrated shared uncertainty in assigning definitive labels. These cases were particularly challenging due to specialized terminology, regional language variations, or overlapping responsibilities within job postings. Table 7 highlights key examples where annotators, despite their recruitment expertise, aligned with the LLMs in experiencing ambiguity.

As presented in Table 7, each example illustrates specific challenges encountered in classifying job postings across multilingual and sector-specific contexts. The *Junior Project Manager* job posting, for instance, combines general project management with specialized tasks such as machine vision, but without enough specific context, it is unclear whether the focus should be on technical expertise or managerial skills. The *Project Engineer* example shows the impact of technical terminology and sector-spesific language on classification. Terms such as “SCADA” and “Modbus TCP” are common in international engineering contexts but may not align with typical understanding of recruiters, leading to the selection of varied labels by both LLMs and annotators. The example of the *Assistente Amministrativo* with a legal and fiscal focus involves highly specialized processes such as “Registro Nazionale delle Varietà Vegetali” and complex fiscal duties like “Dichiarazioni IRAP.” These terms relate to specific Italian government and regulatory compliance, which could exceed the annotators’ typical recruitment experience, thus resulting in generalized labels that do not fully capture the compliance and accounting complexity.

These cases emphasize that job postings, as human-created documents, often do not provide enough context for a definitive classification, resulting in ambiguity across specialized and regional terms.

D. Analysis of Model Alignment with Partial Agreement Ground Truth Labels

Table 8
Performance Metrics for Top 5 and Top 10 Predictions

Model	Precision		Recall	
	@5	@10	@5	@10
Spanish (SPA)				
llama-3-8b (CoT opt.)	0.12	0.06	0.58	0.62
llama-3-8b (CoT)	0.22	0.16	0.64	0.68
llama-3-8b (SkillGPT)	0.19	0.12	0.36	0.62
mBart-large-mnli (0-shot)	0.15	0.14	0.39	0.70
multilingual-e5-large	0.20	0.19	0.48	0.92
Italian (ITA)				
llama-3-8b (CoT opt.)	0.12	0.06	0.56	0.60
llama-3-8b (CoT)	0.23	0.07	0.55	0.59
llama-3-8b (SkillGPT)	0.22	0.06	0.53	0.59
mBart-large-mnli (0-shot)	0.27	0.06	0.31	0.58
multilingual-e5-large	0.35	0.08	0.39	0.79

In our evaluation, we established two levels of ground truth labels: *gold* and *silver*. Gold labels represent unanimous agreement among all three annotators (GPT-4o, Gemini 1.5 Pro, and Claude 3.5 Sonnet), validated by human experts. Silver labels indicate a strong majority consensus, assigned when any two annotators agree, even if the third disagrees.

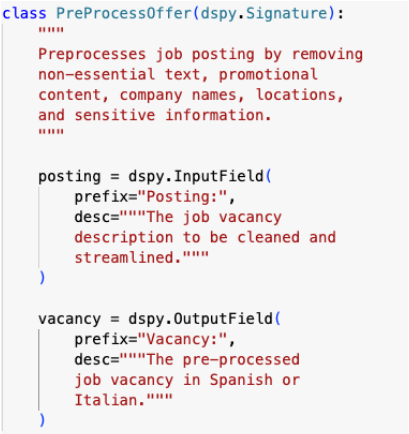
We assessed our model’s performance on both silver and gold labels to understand its effectiveness under different levels of agreement. We had reported results for gold labels in Table 2 and 3, results for silver label are presented in Table 8. For the Spanish dataset, the model’s performance was relatively consistent between silver and gold labels, with only minor variations in precision and recall. This consistency suggests that the model robustly captures underlying patterns in the job postings, regardless of labeling strictness.

In contrast, the Italian dataset exhibited more significant differences between performances on silver and gold labels. For example, in some cases, the precision was higher for silver labels while recall was higher for gold labels. This disparity may indicate that the model better captures broader classifications aligning with majority consensus in Italian but struggles with the stricter criteria required for unanimous agreement.

An interesting observation is that optimization using gold label ground truth data had a negative effect on the models’ scores derived from silver labels. This could be explained by the fact that during optimization, the language models became more attuned to the patterns present in the gold labels, potentially diverging from those in the silver labels. As a result, the models may have become less effective at predicting labels where only partial agreement (silver labels) was present among the automatic methods.

E. DSPy Signature

We utilize DSPy signatures to prompt large language models (LLMs) for performing downstream tasks. To optimize the script, recursive LLM calls were employed, resulting in its final form based on empirical observations.



```
class PreProcessOffer(dspy.Signature):
    """
    Preprocesses job posting by removing
    non-essential text, promotional
    content, company names, locations,
    and sensitive information.

Divergent Discourses: A Comparative Examination of Blackout Tuesday and #BlackLivesMatter on Instagram

Knierim, Aenne[1,*,†], Michael Achmann[2,**,‡], Ulrich Heid[1,*,†] and Christian Wolff[2,*,†]

[1]Universität Hildesheim, Universitätsplatz 1, 31134 Hildesheim
[2]Universität Regensburg, Universitätsstraße 31, 93035 Regensburg

Abstract

On May 25th, 2020, a viral eleven-minute clip showing the murder of George Floyd sparked international outrage and solidarity, leading to the digital memorial event Blackout Tuesday on Instagram. We analyzed posts to compare Blackout Tuesday discourse with #blacklivesmatter movement conversations. Using topic modeling, we identified dominant themes and counter-narratives in Blackout Tuesday and #blacklivesmatter captions. Using hashtag co-occurrence analysis, we investigate hashtag networks to situate the discourses within spheres of Instagram activism. Our findings indicate that both corpora share themes like ”calls to action”, but Blackout Tuesday posts are shorter and solidarity-focused, while #blacklivesmatter posts are longer and address white privilege more explicitly. #blacklivesmatter is linked to anti-racist activism hashtags, while Blackout Tuesday connects more with popular culture and #Alllivesmatter. This supports qualitative research on Blackout Tuesday’s performative allyship, adding a quantitative perspective to existing research.

Keywords

Blackout Tuesday, #blacklivesmatter, Instagram, Cultural Analytics

1. Introduction

The number of posts from the #blacklivesmatter movement (#blm) is estimated to be 28 million, which exemplifies the movement’s impact on society [1, 2]. However, the popularity of the movement reached a peak when “Blackout Tuesday” (BT) took place, a digital memorial day on Instagram [1, 2]. BT was caused by a wave of outrage about the murder of George Floyd, an African American who was killed on May 25, 2020 by two white police officers in Minneapolis. The outrage was sparked by an 11-minute clip of the murder which went viral in social media. The video was posted in the context of the #blm movement and in a cultural setting where African Americans perceived law enforcement as agents of brutality [3]. To postulate solidarity with African Americans in their fight for racial justice, social media users posted a black square and added a post caption with the hashtag #blackouttuesday. Given the cultural context, the video supported the perception of white police brutality, white supremacy, and systemic injustice against African Americans. While #blm needed years to gain a large international audience, BT reached millions within a day.

The #blm movement has received significant attention in research and has had a strong impact on discussions in mainstream media; however, little attention has been paid to BT to date. Most existing research on BT has been conducted using interview studies and hermeneutic methodologies. In addition, there is one quantitative study by Chang et al. [7] which examines the contents of images, focusing on visual and geographic analyses. Because a large share of the posts related to BT feature a black tile rather than an image, it is also important to examine the text in the post, the caption.

To fill this gap, this study used text mining to investigate the content of posts on BT. We examined the interrelations between BT and #blm by applying topic modeling and hashtag co-occurrence analysis to both discourses within the same period of time. Our aim was to understand how BT has impacted the #blm discourse. We also wanted to compare the different types of discourse, as BT is a digital memorial day, whereas #blm is a new social movement.

2. BT and #blm on Instagram

#blm is a movement started by the three African American women Alicia Garza, Patrisse Cullors, and Opal Tomet. It is described as: ”an ideological and political intervention in a world where Black lives are systematically and intentionally targeted for demise. It is an affirmation of Black folks’ contributions to this society, our humanity, and our resilience in the face of deadly oppression” [4]. The number of posts from the #blm movement is estimated to be 28 million, which exemplifies the movement’s impact on society [1, 2]. #blm is a *new-new social movement*: hierarchical, participatory and decentralized, deeply mediated, accommodating both online and offline

CLiC-it 2024: Tenth Italian Conference on Computational Linguistics, Dec 04 — 06, 2024, Pisa, Italy

knierim@uni-hildesheim.de (K. Aenne); michael.achmann@informatik.uni-regensburg.de (M. Achmann); heidul@uni-hildesheim.de (U. Heid); christian.wolff@ur.de (C. Wolff)

repertoires, combining connective with collective action [5, 6]. In the summer of 2020, 20 million people joined protests to address racial injustice and demand accountability for the murder of countless Black people at the hands of law enforcement [7, 8].

BT was part of the campaign #TheShowMustBePaused, spreading from the music industry to social media [9, 10]. It was started by Jamila Thomas and Brianna Agyemang, both female music executives at major record companies in the U.S. [10]. The campaign was opened in response to the murders of George Floyd, Breonna Taylor, Ahmaud Arbery and other Black citizens at the hands of police [11]. Thomas and Agyemang encouraged music industry professionals to halt business operations for the duration of June 2, 2020 to prompt conversation about financial empowerment of Blacks in the music industry [10, 11]. The campaign involved posting a black square on Instagram, while refraining other social media activity that day [10]. Soon, the hashtag morphed and circulated, with posts being different than intended [9, 10]: the hashtag was used to postulate solidarity with George Floyd, instead of encouraging financial empowerment of Blacks in the music industry. This also impacted the #blm conversation on Instagram.

Often, users posted the hashtag #blm in #blackouttuesday posts. Hashtags allow users to find specific information or to monitor a situation because they serve to structure discourse centered around a specific topic in social media platforms like Instagram [12, 13]. In table 2, we show that nearly 10% of #blackouttuesday posts were tagged with the hashtag #blm. Using #blm in BT posts concealed #blm posts with social justice information, hindering critical collective organization [10, 13]. Therefore, #blm called not to use the hashtag along with BT posts. Next to concealing #blm posts, BT critics called it “white guilt day” [14]. Posts were considered as empty gestures [15, 10]. This accusation was not made in the context of #blm.

With a bird’s eye view on hashtag relations and topics, we hope to gain insight into differences between BT posts and #blm. Thus, we investigated the following research questions:

1. **Topic prevalence and significance:** What are the dominant themes and topics in the #blackouttuesday and #blm Instagram captions? Comparing the two, what are the core concerns?
2. **Counter speech:** Which counter narratives appear?
3. **Hashtag co-occurences** Which hashtags co-occurring in the #blackouttuesday and #blm feeds are most prevalent, and do their interconnections form distinct clusters? What do these hashtag networks suggest about the broader contexts and intersections within the sphere of black activism?
4. **Digital memorial day versus new social movement:** BT and #BlackLivesMatter constitute different forms of political participation in social media. Is this visible in the posts, topical clusters and networks of hashtags? If so, can we draw conclusions about how discussions are led differently depending on the type of participation, in this case a memorial day versus a new social movement?

3. Data Collection and Description

Building on the framework of *Cultural Analytics*, we base our analysis on cultural sampling [16]. Because hashtags structure online discourse [12], we used the hashtags #blackouttuesday and #blm to create our cultural sample. Manovich highlights that current humanities research follows ”Close Reading” [17] as the dominant paradigm of textual analysis which puts single artifacts by professional authors at the center of research [16, 18]. Using cultural samples allows to investigate nonprofessional vernacular created by ”regular” people [16]. We add a distant reading perspective to existing research on racial justice movements by extracting a cultural sample of #blm and BT from Instagram posts.

We collected our corpus retrospectively using CrowdTangle[1]. We used the two search terms #blacklivesmatter and #blackouttuesday to find public Instagram posts published within a three month period following the death of George Floyd. Our corpus comprises posts from 05/24/2020 11:59 pm to 08/24/2020 12:00 am. We exported the data in two batches, as CrowdTangle’s search limits exports to a maximum of 300,000 posts. Using this method, we collected 548,249 posts for #blm, and 305,344 posts for #blackouttuesday. The CrowdTangle dataframes contain posts as a link to one image per post and the ”description” column that contains the caption of the post. In addition, the exported data includes metadata for each post: The timestamp when the post was published, the username and name of the creator, and interaction metrics for likes and comments. Our analysis concentrates on captions, the textual part of Instagram posts. Additionally, we use the timestamps for a descriptive analysis of trends within our corpus.

We collected the top hashtags and sorted them by usage in Table 2. Expectedly, #blm posts referenced BT, with #georgefloyd, #blackouttuesday and #icantbreathe in the top twenty hashtags. Unlike #blackouttuesday, #blm contains no references to the original campaign #theshowmustbepaused in the top hashtags. #blackouttuesday also includes #alllivesmatter, a hashtag signaling counterdiscourse. Breonna Taylor, another victim of police brutality, is referenced in the #blm corpus.

#vidrasnegasimportam	2725	0.89%	#justice	15364	2.76%
#stopracism	2665	0.87%	#breonnataylor	14953	2.69%
#icantbreathe	2523	0.82%	#blackgirlmagic	14821	2.67%
#blackout	2382	0.78%	#justiceforbreonnataylor	14768	2.66%

The type-token density is a measure for language complexity. It allows insight into the complexity of both discourses, which we present in Table 1. Expectedly, type-token density is high in both discourses when measured including hashtags. We attribute this to special characteristics of social media language, such as frequent use of hashtags, non-standardized spelling and the use of emojis. While BT has a higher type-token density than #blm when hashtags are included (0,96 vs 0,88), we can see that #blm has a higher type-token density when hashtags are excluded (0.79 vs 0.56 without hashtags). This shows that more different hashtags are used in #blackouttuesday posts than in #blm posts. At the same time, the text without hashtags is less lexically diverse than in #blm posts. The type-token density in #blackouttuesday is only slighty above average (0.56), while #blm has a type-token ratio that is quite high (0.79). #blm posts are also longer than #blackouttuesday posts. On average, #blm post lengthis three times longer than that of #blackouttuesday posts (69 tokens incl. hashtags to 19 tokens). This ratio remains consistent when substracting hashtags (60 vs 16 tokens).

4. Hashtag Co-Occurences

Omena introduces hashtags as natively digital objects that enable users to join debates on the local and global scale through their indexing function [19]. Following Roger's digital methods approach [20], we use these hashtags as digital traces [21] to study the #blm movement in the light of BT. Co-occurrence analysis allows to extract a network of hashtags, which gives insight into the movements' relations to other activist discourses indexed by hashtags.

For the co-occurence analysis, we preprocessed both corpora in the same way. We extracted the hashtags from each caption using regex, lowercased the hashtags and counted the occurences of each hashtag. We selected the top 1,000 hashtags for each corpus and created a co-occurrence network, counting the co-occurence for each hashtag pair. Each network was imported to Gephi, where we used the modularity algorithm [22] to find hashtag clusters [23]. In a last step, we plotted the network for each modularity class within each of the two networks. These plots were the basis for our qualitative exploration of the hashtag clusters. Through this exploration, we were able to name each cluster based on the hashtags they contain. We extracted the modularity classes associated with each hashtag to conduct a quantitative assessment of the hashtag clusters. We excluded the search hashtag from each network during this mapping process to mitigate potential biases (#blackouttuesday for the one, #blm for the other). Each post was then assigned to a specific class based on a majority rule approach which considered the hashtags present in the post. We labeled cases as 'ambigious' where a clear majority for a particular modularity class was not evident. The hashtag clusters are saved in a digital repository.[2]

5. Topic Modeling

Topic modeling is a method to cluster themes in large corpora that is widely applied in the digital humanities. Typical for social media data, our posts are quite short, with post length ranging from $\bar{x}$= 19 token for BT posts to $\bar{x}$ = 69 token for #blm posts. Therefore, we chose to employ BERTopic [24] for the topic modeling due to its ability to handle sparse data.

We applied only minimal preprocessing. We removed @mentions for privacy protection and deleted 29 post duplications that are a result of the scraping process. Next to this, we removed words with two or less letters, stopwords and the hashtags.

After preprocessing and topic modeling, we assigned labels to the 100 most frequent topics of each dataset (postprocessing). For a human eye, it becomes clear that many topics follow broader themes. Therefore, we add an additional step by identifying broader themes consisting of similar topics after the postprocessing.

Firstly, we apply the baseline application of BERTopic [24], using UMAP for dimensionality reduction and the HBDSCAN minimal cluster size to 30 [25, 26]. This reduced the amount of topics drastically, which is why we set the minimal cluster size to 150 items. Although the baseline application of BERTopic [24] yields good results in terms of readibility and topic diversity, we conducted an experimental study for finetuning on samples of both datasets to increase topic diversity (n=0,1%). Maximal Marginal Relevance considers the similarity of tokens with the document, along with the similarity of already selected keywords and keyphrase [27, 24]. We found that topic words consisted of two words instead of one in many cases, but would sometimes contain the same word twice. The application of MMR did not increase topic diversity. We found that the right preprocessing is more important to obtain high topic diversity.

6. Results

6.1. Core concerns and narratives

We visualize the most frequent themes occuring in the datasets in figure 1 and figure 2, with the bubble size representing the relative frequency within the 100 most frequent topics. The colors for shared topics in both discourses correspond. The datasets share many common themes. We identify that both datasets contain many "calls to action". Apparently, many posts aim to activate readers politically, for example by joining protests or signing petitions. Other calls to action are more generic, manifesting in topic words like *fight* or *change*. Other posts ask readers to become conscious of racism and white privilege. In the #blm dataset, 30% of posts are "calls to action", while only 13 % of the BT posts fall into this category.

We identified the theme "voice-of-color" in the topics. The voice-of-color is an established thesis from critical race theory. It holds that alleged minority status brings with it a presumed competence to speak about race and racism [28]. The speech act of "breaking the silence" appears in both corpora. It is more present in the #blm dataset (for a comparison, see figure 1 and figure 2). Within the BT dataset, this becomes visible with topics that include words such as *voice, heard, voices, use, space*. Within the #blm dataset, this becomes even more clear, with topics such as *Silent, silence, quiet, staying, silenced, Voice, voices, heard, amplify, use.*

Both corpora share themes, but we identify two big differences. Common themes are mentions of other antiracist movements, references to African American artists and musicians, or references to platform affordances. A difference lies in internationality. 21% of BT topics are written in other languages than English, such as Spanish, German, French or Russian which points to the international character of BT (considering the 100 most frequent topics). In contrast, #blm is rooted in the English speaking countries U.S., Canada, and Australia [29]. Another difference between the corpora is the perspective of solidarity which is prevalent in BT posts. 7% of topics relate to solidarity, using hashtags like #icare or #togetherforchange. In contrast, the #blm dataset thematizes equality and privilege, calling out white privilege (3% of topics). While solidarity expresses the perspective of an outsider, the corresponding #blm theme expresses a deeper understanding of racism and systems of oppression.

6.2. Connection with other spheres of Black activism

The modularity algorithm discovered five communities within the hashtag co-occurences for #blm, and six for BT. In case of BT, hashtags were split unevenly between

[2] https://osf.io/cu2bj/?view_only=bc770f9539c64682a0bd477d5bd6bb99

the classes: Classes 2–4 contained between 3.6% (n=33, class 3) and 5.8% (n=53, class 4) of all hashtags, while the classes 0, 1, and 5 contained between 16.6% (n=152, class 0) and 35.4% (n=325, class 1) of all hashtags. The smallest cluster contains hashtags referring to food and animals. Class 4 contains references to sport and class 5 the #blackgirlmagic and #blackbusiness theme. The classes 0, 1, and 5 contain political hashtags, multilingual hashtags, and content-related hashtags (like #portrait). The hashtag #blackouttuesday appears in class 0, the multi-lingual class, possibly as the unique bridge to the other clusters. When mapping posts to modularity classes based on the top 1000 hashtags, 71.6% (n=56783) of all posts were identified to belong to class 1, the cluster that contains most hashtags related to the movement, like #theshowmustbepaused and #justiceforgeorgefloyd. 10.6% of posts (n=8371) were mapped to the multilingual cluster (0), 8.21% (n=6507) to cluster 5, and 6.28% (n=4975) of posts were classified as ambiguous, as they did not show a clear majority for the one or the other cluster. A minority of posts was mapped to classes 2–4.

The hastags co-occuring in the #blm network are more evenly split into four clusters: from 37.3% (n=373) in class 3 to 13.7% (n=137) in class 2. Hashtags contained in the largest cluster (3) are mostly non-political and mundane (#family, #food, #college, #followme). The smallest class (2) contains #black+x hashtags, like #blackqueen, #blacknews, #blackbloggers. Class 0 (24.4%, n=244) contains hashtags revolving around justice in combination with different topics, as well as allyship hashtags (e.g. #istandwithyou), while class 1 (24.6%, n=24.6) clusters hashtags related to politics and policy issues (e.g #notmypresident, #guncontrol). The classification based on the hashtag mapping for posts shows a more even distribution for the #blm hashtag which is congruent with the hashtag distribution across clusters. Most posts were mapped to cluster 1 (31.1%, n=127410), with the ambiguous classification coming second (19.2%, n =78706). 17.5% (n =71907) posts were mapped to the mundane class 3, and 17.3% (n =70947) to class 0. Finally, the smallest amount of posts (15.0%, n =61308) were classified to cluster 2.

In general, the #blm co-occurence network shows that the social movement is closely related to other hashtags of Black activism, while also containing links to popular culture that are common to Instagram, such as art or photography. In the aftermath of George Floyd's death, the hashtags #justiceforgeorgefloyd, #protest, #policebrutality, #justiceforbreonnataylor and the German hashtag #gegenrassismus ("against racism"), are closest to different spellings of #blm. An example of the hashtag's relatedness to other movements of Black activism are empowerment hashtags, such as #blackexellencexx, #unapologeticallyBlack and #BlackGirlMagic.

While BT co-occurence networks contain hashtags from a wider political spectrum than #blm, they are also related to off-topic hashtags. For example, two hashtag networks contain mundane content related to the food blogging and wildlife, such as #animalsofinsta, #animallover or #wildlifeonearth. Another network revolves purely around U.S. sports men and basketball. Unlike the comparable co-occurence network at #blm, these networks do not contain any other hashtags from African-American communities except for #blm and #blackexcellence within the animal topics. This shows the mainstream character of BT compared to #blm. This is supported by the wide political spectrum visible in solidarity hashtags, referencing conservative and republican hashtags alongside hashtags on the political left such as #socialist or contents related to the democratic party.

A shared topic are support networks for black businesses and empowerment content of black women, related to hashtags such as #BlackGirlMagic, #BlackEmpowerment or #melaninpoppin. Scholars have established that empowerment occurs within the realm of social media. For example, #BlackGirlMagic, introduced by CaShawn Thompson, negotiates societal presentations of Black women [30]. Black women-centered discourse achieves empowerment by highlighting their experiences in ways that are often neglected or distorted in traditional media outlets [31]. Within the #blm corpus, these hashtags are closely connected to mental health content. In the BT context, hashtags are connected to support hashtags for Black businesses.

6.3. Counter Speech

Another hashtag shared by both #blm and BT is the colorblind hashtag #alllivesmatter. #Alllivesmatter is a counter-protest hashtag whose content argues that equal attention should be given to all lives regardless of race [32]. The "All Lives Matter" movement is, "one of the primary ways in which people resisted the #blm movement [...] in the form of [...] a counterslogan to undermine the purpose and message of the #blm call to action" [33]. Powell et al. have shown that the use of #blm or #AllLivesMatter are signals of political identity [34].

6.4. Political Hashtags

Several political hashtags appear close to #blm, like #berniesanders, #NeverTrump, #NeverBiden and #Progressives. A number of city hashtags are close to these hashtags, namely #LosAngeles, #Hollywood, #Brooklyn, #Atlanta, and #Chicago. A study analyzing Twitter profile information found that the #blm movement is largely ignored in places with a large percentage of white or Hispanic populations, compared to places with smaller percentages of these groups [35]. Published in 2019, the study was conducted before BT which gave the #blm movement a new spark both in the U.S. and internationally. A geospatial analysis could provide insight into whether this finding remains true after BT and if it is true for both #blm and BT posts.

7. Discussion: Digital memorial day versus new social movement

Previous work has investigated visual aspects of BT, studied posting motivations and the the role of celebrities, while we studied Instagram post captions [36, 37, 14]. We contrasted topics and hashtag co-occurences of the digital memorial event BT and the impactful movement #blm. We found that they share many similar topics, such as calls to action, mentions and thoughts of George Floyd, and connections to other antiracist movements. However, BT posts were posted from the solidarity perspective, while #blm discourse broaches the issue of white privilege. Moreover, #blm is more closely related to other hashtags of Black activism, while BT posts are more frequently connected to posts related to popular culture, underscoring its place in mainstream micro-activism. Nevertheless, topic modeling results show that many BT posts seek to mobilize people or express solidarity towards the murder or police brutality (see figure 2, figure 1).

We gain insight into networks of Black activism on Instagram. #blm is embedded in a network of anti-racist activism. Posts with the hashtag are on average more than twice as long and have a higher type-token ratio. In contrast, BT posts are shorter and contain many different hashtags. Posts in various languages characterize the memorial day as an international event. BT is an international spark of outrage – and in its nature more superficial than #blm. We point to Wellman's study, who investigates BT in the light of performative allyship [37]. Next to this, future work should compare the contents of #alllivesmatter and BT posts.

8. Ethics

This paper is based on a poster created for the 8th annual conference of the association *Digital Humanities im deutschsprachigen Raum*, which called for papers with the topic "Kulturen des digitalen Gedächtnisses", engl. *Cultures of digital memory* [38]. We researched #Blackouttuesday due to the actuality of the topic and the true interest in the memorial culture of Blackout Tuesday, an international memorial day to the African American victims of white police brutality in the U.S.. This paper is limited due to the authors' outsider perspective. As white Europeans, we can in no way comprehend the intersectional discrimination of African Americans and carry unconscious biases that are potentially harmful.

THAVQA: a German task-oriented VQA dataset annotated with human visual attention

Moritz Kronberger[1,†], Viviana Ventura[1,*,†]

[1] Technische Hochschule Augsburg, An der Hochschule 1, 86161 Augsburg, Germany

Abstract

Video question answering (VQA) is a challenging task that requires models to generate answers by using both information from text and video. We present Task-oriented Human Attention Video Question Answering (THAVQA), a new VQA dataset consisting of third- and first- person videos of an instructor using a sewing machine. The sewing task is formalized step-by-step in a script: each step consists of a video annotated with German language open-ended question and answer (QA) pairs and with human visual attention. The paper also includes a first assessment of the performance of a pre-trained Multimodal Large Language Model (MLLM) in generating answers to the questions of our dataset across different experimental settings. Results show that our task-oriented dataset is challenging for pre-trained models. Specifically, the model struggles to answer questions requiring technical knowledge or spatio-temporal reasoning.

Keywords

video question answering, human visual attention, multimodal large language model

1. Introduction

This paper presents a new VQA dataset based on demonstrating basic sewing machine operations. To our knowledge, THAVQA[1], which is also annotated with human visual attention, is the first task-oriented VQA dataset in German language.

The dataset building is a first step in the larger project aimed at developing an AI-assistant for a sewing machine workshop held at the Technische Hochschule Augsburg. This AI-assistant would support students when using sewing machines for the first time. For example, this could mean answering questions about basic machine settings or explaining fundamental sewing skills. Our dataset poses unique challenges for VQA models and is almost unique in the state-of-the-art VQA datasets since it is user- and task-oriented: the questions collected are those that a real user would ask for help while using the sewing machine. The process of operating the sewing machine was decomposed in a script into steps and sub-steps that were recorded and on which questions and answers were annotated. Specialized knowledge of the process and understanding of spatial and temporal relationships is required for answering the questions collected. In addition, the limited visual variety of the video scenes and the specialized language and dictionary challenge the models for VQA.
