The paradigm of ICL (Brown et al., 2020a) is rapidly gaining importance. Studies have demonstrated that the generalization of LLMs to various downstream NLP tasks, such as MMLU (Hendrycks et al., 2021b), is significantly enhanced when provided with a small number of examples as prompts (Brown et al., 2020a; Chowdhery et al., 2022; Hoffmann et al., 2022; Rae et al., 2022; Anil et al., 2023; Touvron et al., 2023; OpenAI, 2022, 2023). Recent research has extensively evaluated the performance of LLMs across a spectrum of language-related tasks, spanning from text generation to understanding input sequences. This assessment contains a wide array of benchmarks, including SUPER-GLUE (Wang et al., 2019; Laskar et al.,

2023), and tasks such as question answering, information retrieval, sentiment analysis (Bang et al., 2023b; Liang et al., 2022), dialogue (Heck et al., 2023), and text classification (Yang and Menczer, 2023).

## 2.2 Model Compression for LLMs

Model compression techniques can be broadly categorized into three main approaches: compression during training, compression associated with fine-tuning, and post-training methods. In terms of quantization during training, this technique enables LLMs to adapt to low-precision representations during the training process (Liu et al., 2023). Model compression with fine-tuning involves quantization awareness into the fine-tuning stage (Kim et al., 2023; Dettmers et al., 2023). Post-training techniques, on the other hand, are applied after the completion of an LLMs training phase and typically involve the use of calibration data. This category comprises two primary approaches: pruning, which removes redundant or non-salient weights to induce sparsity (Frantar and Alistarh, 2023), and quantization, which employs low-precision numeric representations of weights and activations (Nagel et al., 2020; Frantar et al., 2022; Yuan et al., 2023). Prior research shows that quantization outperforms pruning in several settings (Kuzmin et al., 2023), thus in this work, we focus on model quantization and its impact on the selected context-aware tasks.

## 3 Task Selection & Design

Our contextual understanding benchmark includes four tasks with nine datasets, as presented in Figure 1. In the following sections, we provide detailed explanations of each task and the corresponding datasets, along with the designed prompts for ICL evaluations.

### 3.1 Coreference Resolution

The coreference resolution (CR) task contributes to achieving a coherent understanding of the overall meaning conveyed within the text. Thus, it plays a critical role in diving into language models’ capability to grasp coreference relations as well as contextual nuances within documents. We select two coreference datasets: WSC273 (Levesque et al., 2012) and OntoNotes 5.0 (Pradhan et al., 2013).

WSC273, which contains the first 273 examples from the Winograd Schema Challenge, is a dataset that requires the system to read a sentence with

---

**Instruction:** Please carefully read the following passages. For each passage and the options, you must identify which option the mention marked in **\*bold\*** refers to. If the marked mention does not have any antecedent, please select “no antecedent”.

**Context:** ... To express **\*its\*** determination ... the Chinese securities regulatory department ... this stock reform ...

**Choices:**

- A. no antecedent
- B. the Chinese securities regulatory department
- C. this stock reform

...

**Question:** What does **\*its\*** refer to?

**Answer:** B

---

Table 1: An OntoNotes example of prompt and *answer*.

an ambiguous pronoun and select the referent of that pronoun from two choices. OntoNotes is a human-annotated corpus of documents annotated with multiple layers of linguistic information including syntax, propositions, named entities, word sense, and in-document coreference. As it is one of the most frequently used datasets for training coreference models, prior research has achieved significant advancements under the supervised fine-tuning paradigm (Lee et al., 2017; Joshi et al., 2020; Bohnet et al., 2023). However, these model designs cannot be extended to generative models under ICL settings. Recently, Le and Ritter (2023) have leveraged document templates for LLMs; however, their evaluation is confined to prominent models such as InstructGPT (Ouyang et al., 2022), neglecting the fact that smaller models lack the generative capacity required to accomplish such tasks. Due to these limitations, we propose a novel multiple-choice task design. In this design, we provide the mentions and evaluate the model on resolution. Each option represents a potentially markable span.<sup>2</sup> Table 1 presents an example of the input to the model<sup>3</sup>. The entire prompt consists of five parts: (1) an instruction that provides guidance to the model for the task, (2) a document containing plain text with a selected mention span highlighted using a bold symbol, (3) a list of choices, which includes all the gold mentions present in the document, (4) a question that directs the model’s attention, and (5) a guiding word *answer* that prompts for the output. We experiment with multiple instructions and prompts and provide the one with the best performance. Linking scores are computed for each ques-

<sup>2</sup>Considering the inferior performance of small models on the mention detection task, we utilize gold markable spans coreference linking.

<sup>3</sup>Detailed examples for each task design can be found in Appendix A.

---

**Ontology:**  
 {"slots": {"restaurant-pricerange": "price budget for the restaurant", ... },  
 "categorical": {"restaurant-pricerange": ['cheap', 'expensive', 'moderate'], ... }  
**Instruction:** Now consider the following dialogue between two parties called the "system" and "user". Can you tell me which of the "slot" was updated by the "user" in its latest response to the "system"? Present the updates in JSON format. If no "slots" were updates, return an empty JSON list. If you encounter "slot" that was requested by the "user" then fill them with "?". If a user does not seem to care about a discussed "slot" fill it with "dontcare".  
**[Previous Dialogue State]**  
**[Conversation]:**  
 "system": ""  
 "user": "I'm looking for a moderately priced place to eat that's in the centre of town."  
**Output:** {"restaurant-pricerange": "moderate", "restaurant-area": "centre"}  

---

Table 2: A DST example of prompt and *answer*.

tion and the results are subsequently aggregated for evaluation. We utilize the official evaluation metrics from the CoNLL-2012 shared task (Pradhan et al., 2012), which employs the CoNLL F1 score, derived from the averaging of three coreference metrics: MUC, B<sup>3</sup>, and CEAF<sub>φ4</sub>.

### 3.2 Dialogue State Tracking

Dialogue state tracking (DST) is an important task in the area of task-oriented dialogue (TOD) modeling (Young et al., 2013), where the dialogue agent tracks the key information provided by the user as the conversation progresses. Table 2 provides an example from MultiWOZ (Budzianowski et al., 2018) where the user expresses the constraints when looking for a restaurant. The output of DST is typically maintained in slot-value pair format.

Previous research has explored ICL capabilities on MultiWOZ and demonstrated promising results compared to fine-tuning models (Hu et al., 2022; Heck et al., 2023). However, these studies either involve partial training or are untested with smaller and quantized models. Here we adopt a straightforward and simplified ICL approach proposed by Heck et al. (2023), and test it on MultiWOZ v2.2 (Zang et al., 2020). The prompt to the model consists of domain knowledge from ontology, an instruction, previous dialogue state (the belief state accumulated until the previous user turn) and the conversation proceeding to the current turn. The ontology could be lengthy if considering all domains in the dataset. Thus, given the input length constraint of LLMs, only the knowledge relevant to the conversation is provided. Following literature,

---

**Instruction:** Given two arguments and a list of connective words, please select the most likely connective between two arguments.

**[Relation Description]**

**Input:**

Arg 1: Amcore, also a bank holding company, has assets of \$1.06 billion.

Arg 2: Central’s assets are \$240 million.

**Question:** What is the connective that best describes the relation between two arguments?

**Choices:**

A. Temporal B. Contingency C. Comparison D. Expansion

**Answer:** C  

---

Table 3: A PDTB example of prompt and *answer*.

we report joint goal accuracy (JGA) (Mrkšić et al., 2017) for evaluating the performance of DST.

### 3.3 Implicit Discourse Relation Classification

Discourse demonstrates its importance beyond individual sentences, which emphasizes the ways in which different segments of a text interconnect and structure themselves to convey a coherent and meaningful message. The PDTB-3 corpus, as introduced by Webber et al. (2019), annotates implicit discourse relations across elementary discourse units (EDUs)<sup>4</sup>. These relations imply connections between EDUs and may be made explicit by inserting a connective. Within the context of the understanding benchmark, we opt for the implicit discourse relation classification task for two primary reasons. Firstly, the order of the two EDUs is provided, enabling the model to directly utilize this information. Secondly, the connective triggering the relation is implicit, increasing the task’s complexity. In this task, two EDUs are fed as input, and the objective is to correctly identify the relation between them. Due to the nuanced differences between each relation and the demand for annotators with rich linguistic knowledge and extensive annotation training, the classification task poses challenges to fine-tuned classification models.

The PDTB3 corpus classifies discourse relations into four categories - Temporal, Contingency, Comparison, and Expansion. We convert this task into a multiple-choice question and experiment with *classes* as options. In the *classes* scenario, the task offers four options, each representing a distinct discourse relation class. Table 3 exhibits the components of the prompt. It includes an instruction at the beginning, followed by a concise description of each relation, a context with two arguments, a

<sup>4</sup>EDU refers to the smallest segment of a text that conveys a complete and coherent meaning within larger discourse.

---

**Instruction:** Rewrite the last query following interaction into a well-formed, context independent query. Resolve any disfluencies or grammatical errors in the query.

**Input:**  
 User: Try to reach Forbes now .  
 Bot: Forbes at Washington Post ? Or Forbes of Publishing Division ?  
 User: Publishing Division .

---

**Rewrite:** *Forbes of Publishing Division*

---

Table 4: A query rewriting example of prompt and answer.

question along with answer choices, and a trigger word. We evaluate each model’s performance on this dataset using accuracy as the metric.

### 3.4 Query Rewriting

While document-based CR (OntoNotes, Section 3.1) covers various types of coreference relations across multiple genres, it does not allow the ability to evaluate certain aspects which are important to understand context. Firstly, the CR task typically focuses on document-based coreference chains, neglecting mention resolution in dialogues. Secondly, ellipsis, which is the omission of one or more words from a clause, is a crucial linguistic phenomenon in speech and conversation. It is essential for language models to grasp and accurately identify ellipses within context. Incorporating these features into the benchmark is thus pivotal when evaluating context understanding.

Query Rewriting (QR) is a task of rewriting the last utterance of a user in a conversation into a context-free, independent utterance that can be interpreted without dialog context. It requires the model to identify the entity or events references from context and further generate a complete utterance with resolved coreference or ellipsis.

We incorporate five QR datasets in the proposed benchmark: MuDoCo with QR annotations (Martin et al., 2020; Tseng et al., 2021), QReCC (Anantha et al., 2021), InCar (Regan et al., 2019), GECOR (Quan et al., 2019), and CANARD (Elgohary et al., 2019). These datasets span multiple genres and domains in dialogues. We experiment with various prompts used for fine-tuning models and present the results with the best selections. Table 4 presents a concise prompt comprising an instruction along with context for each dialogue. To assess the quality of generated queries, we follow the metrics from previous research, particularly BLEU (Papineni et al., 2002) and ROUGE (Lin, 2004).

## 4 Experiments

### 4.1 Implementation Details

Evaluation was conducted on a computational infrastructure comprising  $8 \times$  A100 GPUs. We experiment with three model families. For smaller models, we consider OPT (Zhang et al., 2022), ranging from 125M to 2.7B. Although OPT also offers larger models, we opt for LLaMA (Touvron et al., 2023) as the mid-sized LMs, spanning from 7B to 65B parameters, due to showcased superior performance by prior works. For large-scale LMs, we leverage GPT-3.5-turbo<sup>5</sup>. For each model, on every dataset, we assess five different settings: zero-shot, one-shot, 5-shot, 8-shot, and 10-shot. We randomly select the examples from the training set for the few-shot prompting.<sup>6</sup>

### 4.2 Dense Model

Results of the three model families are reported in Table 5, along with results of fine-tuned (FT) models to help better interpret how well the pre-trained models behave with ICL. Figure 2 also visualizes the gap between various commercial/non-commercial language models and fine-tuning models that achieve the best performance on these tasks. For each, we present the N-shot setting that yields the highest score (see Appendix B for details). Overall, performance improves as the model size increases and pre-trained models with ICL struggle to catch up with FT models on most tasks.

**Coreference Resolution** Larger models exhibit promising performance on the WSC273 task, indicating that LLMs can effectively handle "simple" coreference relations within limited contexts and mentions. However, when it comes to document-based CR with complex clusters, their performance substantially drops<sup>7</sup>. Even on providing ground-truth mentions, the highest-performing GPT is only on par with rule-based coreference systems (Manning et al., 2014) and is far from the end-to-end fine-tuned SpanBERT (Joshi et al., 2020). The gap

<sup>5</sup><https://platform.openai.com/docs/models/gpt-3-5>

<sup>6</sup>WSC273 itself is a test set and thus has no fine-tuning results. We only report the zero-shot results.

<sup>7</sup>Note that the OntoNotes dataset is substantially larger than the others. We observe that inference on the entire test set becomes extremely time-consuming, particularly with the larger models; further, the cost of running inference on GPT-3.5 starts becoming non-negligible. Consequently, we propose limiting the OntoNotes test set to a 10% sub-sample, which is the setting we consistently adopt.

Task	Dataset	Metrics	OPT				LLaMA			GPT	FT
			125M	350M	1.3B	2.7B	7B	13B	30B	3.5-turbo	
CR	WSC273	Acc	58.24	66.67	76.19	77.66	86.81	89.38	89.01	88.64	N/A

		ROUGE	9.82	45.63	49.36	62.73	38.17	46.61	69.73	74.61	81.06

Table 5: Few-shot results of two open-sourced models and GPT-3.5 on the context understanding benchmark. The results with the best number of few-shot examples are reported for each task. Fine-tuning (FT) results serves as a reference when evaluating LLMs’ capability under ICL setup.

between ICL and FT results highlights that under the ICL setting, LLMs struggle to build coreference chains without adequate domain-specific examples. Specifically, models except GPT perform significantly worse on the MUC metric. Error analysis reveals that these models are inclined to create more clusters, including singleton clusters. This implies that pre-trained LLMs encounter difficulties in understanding long-range contextual information.

**DST** A similar trend is observed as CR where OPT and LLaMA models fall behind GPT-3.5 significantly. This suggests that these models fail to extract key information as the conversation proceeds, even with the provision of 5 to 10 demonstrations and the distilled relevant domain ontology in prompt. Our error analysis indicates that most of the errors happen due to the misdetection of slots or the wrong predicted value in a slot-value pair. Only GPT-3.5 reaches the level of FT results which is a fine-tuned T5 base model (Bang et al., 2023a).

**Implicit Discourse Relation Classification** We observe an increase in scores when the model size exceeds 7B. However, even the best-performing LLM, GPT, performs worse than the SOTA fine-tuned model (Liu and Strube, 2023) with the drop of 32% accuracy. We carefully examine the predictions for each model and found that all models tend to predict the same relation class for every example, albeit with their individual preferences

for the selected relation. In addition, because of an imbalanced distribution of classes, these models potentially perform worse than random chance (25%). This suggests that the models struggle to distinguish the nuances between different relation classes and fail to correctly identify relations across EDUs within context.

**Query Rewriting** The gap between small and large models is significantly huge, compared to the other tasks. For instance, OPT-125M cannot even complete the rewriting task. Analysis on predictions of small models indicates that the model is not capable of following the instructions or learning patterns from the few-shot examples. We identify a few major error types: (1) generating the next sentence, instead of rewriting; (2) rewriting the wrong user turn from the conversation; (3) copying the last user utterance without any rewriting. These errors get reduced as the model size increases. However, similar to the previous three tasks, the best ICL results achieved by GPT is far from the fine-tuned models.<sup>8</sup> It is worth noting that OPT-2.7B performs on par or notably better than LLaMA-7B, which is somewhat not aligned with the findings in Beeching et al. (2023) where LLaMA-7B even outperforms OPT-66B in many tasks, including ARC (Clark

<sup>8</sup>In literature, the best FT results come from different models across five QR datasets, where some are not even LLM based. To ensure fair comparison, we fine-tuned a T5 large model on each QR dataset.

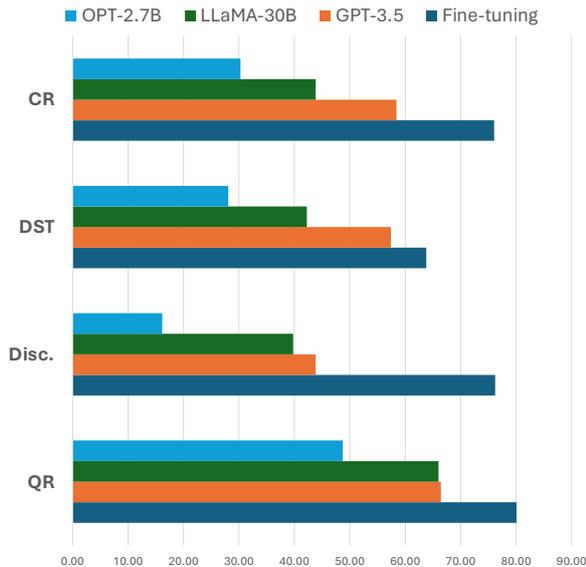

Figure 2: Comparison between commercial/non-commercial models and fine-tuning models for each task in the context understanding benchmark.

et al., 2018), HellaSwag (Zellers et al., 2019), and MMLU (Hendrycks et al., 2021b).

All in all, this section presents a holistic comparison of LLMs’ behaviors on the target context understanding tasks. On the tasks with structured outputs such as CR or DST, even small models show a certain level of context understanding and seem to follow the task instruction. Classification tasks such as discourse relation selection are deemed the easiest among all tasks; however, the small models are even worse than a random guess (25%). As for the generative task, the ability to complete query rewriting can be only observed in the case of larger models, as the model has the freedom to generate arbitrary content that does not follow the prompt. We notice that OPT-2.7B outperforms LLaMA-7B in multiple QR datasets, including MuDoCo, QReCC, and CANARD. We carefully compare the outputs between the two models. As an example, QReCC, a QA-based conversational dataset, consists of several QA pairs as context and a last query to be rewritten. We observe that LLaMA-7B tends to rewrite the question in context instead of rewriting the last target query, which is not frequent in OPT-2.7B. It is also noted that except for DST, FT models demonstrate marked superiority over pre-trained models, highlighting the potential for improving LLMs’ competence on these context understanding tasks.

Dataset	Metrics	7B-D	30B-Q	30B-D
WSC273	Acc	86.81	87.18	89.01
	MUC	10.31	25.37	33.56
	B <sup>3</sup>	52.20	56.80	58.66
	CEAF <sub>φ4</sub>	32.63	36.93	39.27
	Avg. F1	31.71	39.70	43.83
MultiWOZ	JGA	32.30	41.99	42.24
PDTB-3	Acc	17.16	31.29	39.77

	ROUGE	38.17	67.15	69.73

Table 6: Comparison between dense and quantized models. Dense LLaMA-7B and 3-bit quantized LLaMA-30B share similar memory and disk requirements. **D** represents dense model and **Q** denotes quantized model.

### 4.3 Model Compression Technique

As we focus on evaluating context understanding of LLMs in an ICL setup, we evaluate models quantized using GPTQ (Frantar et al., 2022), which is an efficient one-shot weight quantization algorithm based on approximate second-order information that compresses the model post-training. It enables a reduction in memory and disk requirements by up to 80%, compared to the pre-quantized model.

### 4.4 Quantized Model Results

GPTQ (Frantar et al., 2022) has been shown to effectively reduce the model size to 3 bits without incurring substantial performance losses across a range of NLP tasks, such as MMLU, ARC, StoryCloze. However, whether this performance preservation can be extended to contextual understanding was unclear.

Table 6 presents the comparison between the dense and 3-bit quantized LLaMA models. In contrast to previous studies on 3-bit quantization, we observed that quantization leads to fluctuated drops in performance across the four tasks. Specifically, in WSC273, MultiWOZ, and CANARD, post-training quantization incurs only a marginal performance drop ( $\sim 1.7$  points). However, in the remaining datasets, quantization results in significant performance drops.

The results further show that the quantized LLaMA-30B model consistently outperforms the

dense LLaMA-7B model across all tasks despite being comparable in disk and memory requirements. For CR, the 30B quantized model achieves significantly higher scores on the OntoNotes dataset across all metrics. The MUC metric shows the most substantial improvement, indicating that the quantized 30B model partially overcomes the tendency to create small clusters for mentions. For DST on MultiWOZ, the 30B quantized model show a 30% relative improvement over the 7B model in JGA. On discourse parsing with PDTB-3, the accuracy of quantized 30B model is almost double, 17.16% vs 31.29%. Across all QR datasets, the quantized 30B model substantially improves NLG scores compared to the dense 7B model, with relative gains ranging from 15-50%. The largest gap is observed on GECOR.

In general, we show that the quantized 30B LLaMA model consistently and significantly outperforms the dense 7B model as a result of the increased scale, despite using 3-bit quantization. The benefits of greater model scale thus outweigh the impacts of quantization in understanding discourse. We believe this finding would be beneficial when deploying LLMs in real-world applications with disk and runtime constraints.

## 5 Case Study: Query Rewriting

In this section, we provide in-depth analysis by comparing the two open-sourced model families OPT and LLaMA, and the impact of quantization, using query rewriting as the target task.

We conduct a careful inspection of the query rewriting task because of three reasons: (1) by the nature of the task, query rewriting is the only one with free-form generation, while the others effectively are either classification-based tasks or heavily constrained in their possible output predictions. The generation task allows us to explore the LLMs’ output in more detail, and to provide more interesting insights; (2) the manual analysis of errors is a time-consuming process, making it challenging to conduct such an in-depth analysis across all four tasks; (3) the query rewriting task covers a diverse range of five datasets, enabling us to compare differences between each dataset and to thereby gain a deeper understanding.

### 5.1 OPT vs. LLaMA

Prior works (Beeching et al., 2023) have consistently shown that, under the same model size,

Dataset	6.7/7B		13B		30B	
	O.	L.	O.	L.	O.	L.
Mudoco	53.1	41.1	55.2	61.1	55.2	66.5
	71.8	56.0	72.1	74.7	71.5	77.8
QReCC	46.6	28.1	43.7	38.6	43.8	58.6
	73.4	48.2	71.6	56.4	71.9	78.7
InCar	40.3	28.2	41.9	42.1	44.6	48.5
	64.8	49.9	62.6	56.7	65.3	64.1
GECOR	58.8	53.2	60.9	66.3	58.2	73.8
	75.7	69.2	78.3	80.9	76.1	86.0
CANARD	43.8	21.3	37.5	29.3	41.3	47.2
	72.0	38.1	66.0	46.6	69.3	69.7

Table 7: Comparison between OPT (O.) and LLaMA (L.) across five query rewrite datasets. For each dataset, the first and second rows represent BLEU and ROUGE scores respectively.

Context
User: what is the name of india pakistan border line
Bot: The Radcliffe Line was the boundary demarcation line between the Indian and Pakistani portions of the Punjab and Bengal provinces of British India.
User: who created the radcliffe line
Bot: The Radcliffe Line was named after its architect, Sir Cyril Radcliffe, who was the joint chairman of the two boundary commissions for the two provinces.
User: when was the line published
<b>Gold answer:</b> when was the <u>radcliffe</u> line published
<b>Prediction 1 (repeat the last query):</b> when was the line published
<b>Prediction 2 (language modeling):</b> 1947

Table 8: An example of two major types of errors found in the query rewriting task.

LLaMA outperforms OPT. However, their performance on QR, as shown in Table 7, does not follow this pattern.

When the model size is around 7B, OPT consistently performs better than LLaMA by a significant margin across the five QR datasets. The two models perform on par with each other at 13B. The superiority of LLaMA is only obvious with 30B model size. From another perspective, although we expect performance to improve as model size increases, we observe this trend on LLaMA, but not on OPT. These results suggest that it may not be correct to conclude the overall superiority between two model families by only comparing on a certain range of model sizes or on a certain set of tasks.

### 5.2 Dense vs. Quantized

We conduct a quantitative analysis on the error types of query rewriting to investigate the performance gap between dense and quantized models.

Type	Dataset	7B D	30B Q	30B D
Repeat	MuDoCo	260	247	194
	QReCC	86	90	26
	InCar	17	15	8
	GECOR	59	62	37
	CANARD	47	44	32

Table 9: Number of the major two types errors on three LLaMA models (7B dense, 30B quantized, and 30B dense) found in query rewriting. *Repeat* stands for repeat-the-last-query error and *LM* denotes language modeling error.

Across the five datasets, we identify two main error types that account for nearly 80% of the total errors, with examples shown in Table 8. First, the model *repeats* the last query without resolving any referred entity or ellipsis. In this case, the model seems to understand the instruction but fails at rewriting. This type of error can be primarily associated with the model’s context understanding capability. Second, the model treats the task as a language modeling (*LM*) task, where it provides a response to the last query. In this scenario, the model appears to struggle to understand the task instruction, even with several few-shot examples. We classify this error type as more related to the model’s ICL ability.

We perform manual error annotations on the five QR datasets<sup>9</sup>. Table 9 illustrates the number of errors of the three selected models on each dataset. A consistent trend is observed across all QR datasets. In terms of *repeat* errors, the 30B dense model exhibits significantly fewer errors compared to the 7B dense model (297 vs. 469). However, 3-bit GPTQ quantization leads to an increase in this type of error, reaching a similar error count to the 7B dense model (458 vs. 469). This implies that 3-bit quantization reduces the model’s ability to comprehend the context. Regarding *LM* errors, the 30B dense model also significantly outperforms the 7B dense model, with 106 errors compared to 232. It is to be noted that the quantized model generates only 125 *LM* errors, slightly more than the 30B dense model. However, it generates significantly fewer (around

50%) errors compared to the 7B dense model (125 vs. 232). This indicates that 3-bit quantization maintains the ICL capability that allows models to rewrite the user query successfully rather than performing language modeling task.

## 6 Conclusion

This paper introduces a contextual understanding benchmark designed to assess the performance of LLMs. We collect nine existing datasets spanning four tasks, each carefully tailored to suit generative models. This benchmark encompasses essential elements for assessing linguistic comprehension within context, including both document and dialog based contextual understanding. Experimental results reveal that LLMs under in-context learning struggle with nuanced linguistic features within this challenging benchmark, exhibiting inconsistencies with other benchmarks that emphasize other aspects of language. To the best of our knowledge, we are also the first to compare dense models and post-training quantization models in contextual understanding tasks. This comparison highlights that 3-bit post-training quantization reduces the general understanding capacity of context to different extent across the 4 tasks. The proposed contextual comprehension benchmark thus provides a unique perspective on the contextual dimension of language understanding and offers a valuable addition to existing LLM evaluations.

## Limitations

This work provides an evaluation of various pre-trained LLMs, including OPT, LLaMA, and GPT, on our understanding benchmark. However, we have not evaluated other LLMs designed for longer input scenarios, such as LongLLaMA (Tworowski et al., 2023).

In our evaluation, we focus on the GPTQ quantization method, analyzing its performance on our benchmark. We do not include other post-training quantization techniques, such as RPTQ (Yuan et al., 2023), in this work.

Our evaluation concentrates on English datasets, primarily utilizing LLMs pre-trained with English data. All of the four tasks on our benchmark have datasets from other languages. The coreference dataset OntoNotes 5.0 contains annotations of Arabic and Chinese. In addition, recent releases such as CorefUD (Nedoluzhko et al., 2022) promote standardization of multilingual coreference anno-

<sup>9</sup>10% test data on QReCC and CANARD was graded.

tations. In DST, CrossWOZ (Zhu et al., 2020) is a cross-domain wizard-of-oz task-oriented dataset. Long et al. (2020) develop TED-CDB, a Chinese discourse relation dataset. The query rewriting task also has datasets in other languages, such as REWRITE (Su et al., 2019) and Restoration-200K (Pan et al., 2019). Finally, specific LLMs optimized for individual languages, such as ChatGLM (Du et al., 2022), exist and are not a part of our evaluation.

## Acknowledgements

The authors would like to thank Jeffrey Nichols, Russ Webb and the anonymous reviewers for their help and feedback.

## A Task Design Examples

Table 10 presents the input example for each task. For CR, we only show examples from OntoNotes.

## B Few-shot Settings

Table 11 shows the number of examples for each dataset that yields the best scores. All datasets except WSC273 and PDTB3 use randomly selected examples from the training set. Since WSC273 does not include any train or validation set, we use the zero-shot setting, as scores presented in Table 5. For each class in PDTB3, we randomly select two examples from the training set for prompting. For some particular datasets, such as OntoNotes, experiments are only performed in the zero-shot and one-shot settings due to the limitation on input length.

## C Reliability of Experiment Results

For each task, we have randomly run several experimental setups with multiple rounds, with over 10 settings in total. However, due to the challenges posed by limited time, budget, and computing resources, it is very difficult to run multiple rounds for every single experiment, given the complexity of our experimental setup. In addition, for existing experiments with multiple rounds, we empirically observe that there is low variance across the rounds, which leads us to assume that performing the remaining experiments with a single run does not significantly impact the arguments presented in this paper.

### Coreference Resolution

Instructions: Please carefully read the following passages. For each passage and the options, you must identify which option the mention marked in \*bold\* refers to. If the marked mention does not have any antecedent, please select "no antecedent".

[Few-shot examples]

Context: — basically , it was unanimously agreed upon by the various relevant parties . To express \*its\* determination , the Chinese securities regulatory department compares this stock reform to a die that has been cast . It takes time to prove whether the stock reform can really meet expectations , and whether any deviations that arise during the stock reform can be promptly corrected . Dear viewers , the China News program will end here . This is Xu Li . Thank you everyone for watching . Coming up is the Focus Today program hosted by Wang Shilin . Good-bye , dear viewers .

Choice:

- A. the Chinese securities regulatory department
- B. this stock reform
- C. the stock reform
- D. you
- E. everyone
- F. no antecedent

Question: What does \*its\* refers to?

Answer: A

---

### Dialogue State Tracking

Consider the following list of concepts, called "slots" provided to you as a json list.

```
"slots": [{"restaurant-pricerange": "price budget for the restaurant",
"restaurant-area": "area or place of the restaurant",
"restaurant-food": "the cuisine of the restaurant you are looking for",
...
"hotel-postcode": "postal code of the hotel",
"hotel-ref": "reference number of the hotel booking"
}]
```

Some "slots" can only take a value from predefined list:

```
"categorical": [{"restaurant-pricerange": ['cheap', 'expensive', 'moderate'],
"restaurant-area": ['centre', 'east', 'north', 'south', 'west'],
"restaurant-bookday": ['monday', 'tuesday', 'wednesday', 'thursday', 'friday', 'saturday', 'sunday'],
...
"hotel-internet": ['free', 'no', 'yes'], "hotel-area": ['centre', 'east', 'north', 'south', 'west']
}]
```

Now consider the following dialogue between two parties called the "system" and "user". Can you tell me which of the "slot" was updated by the "user" in its latest response to the "system"? Present the updates in JSON format. If no "slots" were updates, return an empty JSON list. If you encounter "slot" that was requested by the "user" then fill them with "?". If a user does not seem to care about a discussed "slot" fill it with "dontcare".

Input:

Previous state: {}

"system": ""

"user": "I'm looking for a moderately priced place to eat that's in the centre of town."

Output: [{"restaurant-pricerange": "moderate", "restaurant-area": "centre"}]

---

### Implicit Discourse Relation Classification

Instructions: Given two arguments and a list of connective words, please select the most likely connective between two arguments.

Below are the descriptions of four discourse relation labels. Please find the correct label for each example.

Temporal: The tag temporal is used when the situations described in the arguments are intended to be related temporally.

Contingency: The tag Contingency is used when the situation described by one argument provides the reason, explanation or justification for the situation described by the other.

Comparison: The tag Comparison is used when the discourse relation between two arguments highlights their differences or similarities, including differences between expected consequences and actual ones.

Expansion: The label Expansion is used for relations that expand the discourse and move its narrative or exposition forward.

[Few-shot examples]

Input:

Arg 1: Amcore, also a bank holding company, has assets of \$1.06 billion.

Arg 2: Central's assets are \$240 million.

Question: What is the connective that best describes the relation between two arguments?

- A. Temporal
- B. Contingency
- C. Comparison
- D. Expansion

Answer: C

---

### Query Rewrite

Instructions: Rewrite the last query following interaction into a well-formed, context independent query. Resolve any disfluencies or grammatical errors in the query.

[Few-shot examples]

Input:

User: Try to reach Forbes now .

Bot: Forbes at Washington Post ? Or Forbes of Publishing Division ?

User: Publishing Division .

Rewrite: *Forbes of Publishing Division*

Table 10: Examples of task design for each task in the context understanding benchmark.

Task	Coreference		DST	Discourse	Query Rewriting				
Dataset	WSC273	OntoNotes	MultiWOZ	PDTB3	MuDoCo	QReCC	InCar	GECOR	CANARD
N-shot	Zero-shot	One-shot	5-shot	8-shot	10-shot	5-shot	10-shot	10-shot	5-shot

Table 11: N-shot settings for each task & dataset that yields the highest scores. For each task and model, we use consistent N-shot settings for comparison.

# Let's Negotiate! A Survey of Negotiation Dialogue Systems

## Abstract

Negotiation is a crucial ability in human communication. Recently, there has been a resurgent research interest in negotiation dialogue systems, whose goal is to create intelligent agents that can assist people in resolving conflicts or reaching agreements. Although there have been many explorations into negotiation dialogue systems, a systematic review of this task has not been performed to date. We aim to fill this gap by investigating recent studies in the field of negotiation dialogue systems, and covering benchmarks, evaluations and methodologies within the literature. We also discuss potential future directions, including multi-modal, multi-party and cross-cultural negotiation scenarios. Our goal is to provide the community with a systematic overview of negotiation dialogue systems and to inspire future research.

## 1 Introduction

Negotiation involves two or more individuals discussing goals and tactics to resolve conflicts, achieve mutual benefit, or find mutually acceptable solutions (Fershtman, 1990; Bazerman and Neale, 1993; Lewicki et al., 2011). It is commonly used to manage conflict and is the primary give-and-take process by which people try to reach an agreement (Fisher et al., 2011; Lewicki et al., 2011). Negotiations can be cooperative or competitive and are used in various social settings such as informal, peer to peer, organizational, and diplomatic country to country settings (Cano-Basave and He, 2016) and thus the implications for enhancing outcomes are vast. However, humans are naturally subject to various biases and can be swayed by emotion during negotiations, making them inclined to overlook useful implicit information from other participants in the negotiation process and hindering optimal outcomes. Negotiators also often lack the necessary skills, training and knowledge to achieve their desired goals (Walton and McKersie, 1991).

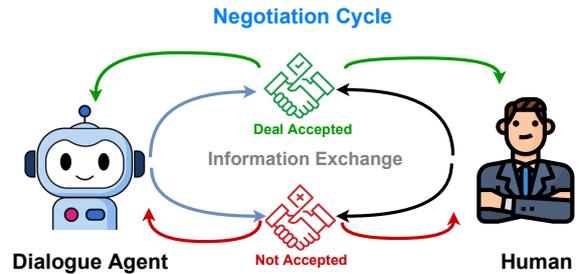

Figure 1: A typical negotiation dialogue involves a multi-turn interaction between agent and human. They exchange information about their deals and end up with accepting or declining deals.

To facilitate human negotiation processes, previous researchers (Lewandowska, 1982; Lambert and Carberry, 1992; Chawla et al., 2021b) have aimed to build intelligent negotiation agents that can aid humans or even directly negotiate with humans in multi-turn interactions (Figure 1). Effective agents could yield significant benefits in many real-world scenarios, ranging from bargaining prices in everyday life (He et al., 2018) to higher-stakes political or legal situations (Cano-Basave and He, 2016).

Research on negotiation has been conducted for almost 60 years in the field of psychology, political science, and communication. It has evolved over the past decades from exploring game theory (Walton and McKersie, 1991), behavior decisions driven by the cognitive revolution in psychology (Bazerman and Neale, 1993), to cultural differences in the 2000s (Bazerman et al., 2000). Negotiation research, however, is now forced to confront the implications of human/AI collaborations given recent advancements in machine learning (Bazerman et al., 2000; Ouali et al., 2017). Research has focused on establishing new benchmarks and testing environments for various negotiation dialogue scenarios, including product price bargaining (Lewis et al., 2017; Heddaya et al., 2023), multiple player strategic games (Asher et al., 2016) and job interviews (Zhou et al., 2019). Other research has at-

tempted to propose new methodologies and frameworks to model the negotiation process, including various negotiation policy learning, negotiator mental status modeling and negotiation decision making. Converging efforts from social scientists and data scientists which incorporate insights from both fields will thus be fruitful in maximizing processes and outcomes in negotiations.

Despite the significant amount of research that has been conducted, we are not aware of a systematic review on the topic. In this work, we aim to fill this gap by reviewing contemporary research efforts in the field of negotiation dialogue systems from the dimensions of datasets, evaluation metrics and modeling approaches. We first briefly explore human negotiations and corresponding limitations, and propose how dialogue agents may supplement human negotiation processes. We then discuss the popular negotiation dialogue modeling methods, including *Strategy modeling*, *Negotiator modeling* and *Action modeling*. We further introduce existing datasets according to their negotiation scenarios. Finally, we give an overview for three major types of evaluation metrics, i.e., *goal-based metrics*, *game-based metrics* and *human evaluation*, used in negotiation dialogue systems.

In summary, our contributions are three-fold: (i) we point out human limitations in negotiation and systematically summarize the existing AI solutions aiming to address those limitations; (ii) we systematically categorize current negotiation dialogue benchmarks from a distributive and integrative perspective, and provide an overview of evaluation methods; (iii) we point out current limitations and promising future research directions.

## 2 Negotiations from a Social Science Perspective

In this section, we will first introduce a framework for human negotiation from social sciences, then discuss human limitations in negotiation, which motivates NLP researchers/practitioners to develop strong negotiation dialogue systems.

### 2.1 Understanding of Human Negotiations

Brett and Thompson (2016) propose a comprehensive framework for a two-party negotiation process, as shown in Figure 2. Preferences and strategies of the negotiators determine the potential outcomes and the interaction of the negotiation process. The preferences of both negotiators create the poten-

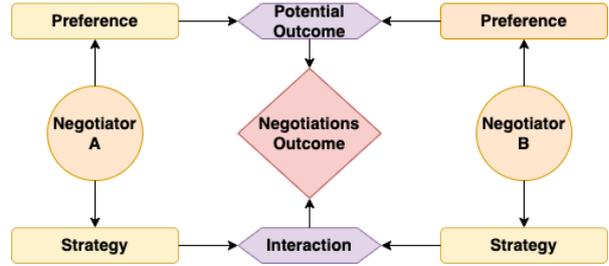

Figure 2: Negotiation Framework for two negotiator scenario from Brett and Thompson (2016).

tial outcome that may be reached by them. The negotiators’ strategies, defined as the goal-directed behaviors that are used in order to reach an agreement (Weingart et al., 1990), affect the interaction, ultimately determining how much of that potential outcome created by the negotiators’ preferences is obtained.

### 2.2 Human limitations in Negotiation

Although negotiations are commonly found in daily life (e.g., price bargaining), it is still a challenging task. Without professional training, people often lack the negotiation skills to achieve their desirable goals. They may not know what *strategies* to be used and how to implement these *strategies*. It is also challenging to identify and process implicit information about other negotiators’ interests and preferences in the negotiation. Often times, people view negotiation as a competition and may not even be motivated to seek or express this information (Brett and Thompson, 2016). Finally, human cognitive heuristics, biases and emotionality may prove a hindrance in negotiation scenarios. For example, people view themselves, the world and the future as being more positive than in reality (Taylor, 1989), which may lead to overestimation and optimism in negotiations (Crocker, 1982). The negotiation could also lead participants to be emotionally engaged and make it more difficult to process information rationally (Pinkley and Northcraft, 1994). Thus, developing effective negotiation conversational dialogue agents can be beneficial for understanding and controlling for these various factors, and optimizing the negotiation.

## 3 Methodology Overviews

In negotiation dialogues, negotiators interact with each other in a strategic discussion to reach a final goal. As discussed above, *strategies* and *preferences* significantly affect the negotiation outcomes.

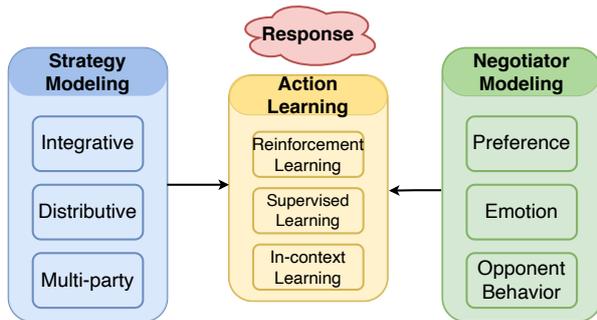

Figure 3: An overview architecture of method section. The *strategy* and *negotiator* modules collect information from the negotiation dialogue, and the *action learning* module conditions on the information and produce responses to push the negotiation forward.

To effectively assist people in this process, as shown in Figure 3, existing research on negotiation dialogues can be categorized into *a) Negotiator Modeling*; *b) Strategy Modeling*; *c) Action Learning*. Herein, *Negotiator Modeling* aims to infer the *explicit information* from other negotiators based on a dialogue context. *Strategy Modeling* learns to select strategies to use given the current dialogue context. Finally, the *Action Learning* incorporates the above negotiation information to map strategies into observable actions or responses, e.g. utterances, by developing dialogue models within the existing machine learning frameworks.

### 3.1 Problem Formulation

Formally, a negotiation dialogue process can be formally characterized as a tuple  $(n, \mathcal{K}, \mathcal{S}, \mathcal{U}, \pi, g)$ . Herein,  $n$  refers to the number of negotiation party ( $n \geq 2$ ),  $\mathcal{K}$  refers to the background information for a negotiation dialogue, such as negotiator’s preferences and demands towards items. This information may not be transparent to others in a dialogue.  $\mathcal{S}$  denotes a strategy trajectory  $\{s_1, s_2, \dots\}$  used during the negotiation process.  $\mathcal{U} = \{u_1, u_2, \dots\}$  is a sequence of dialogue utterances or actions in a negotiation process. A policy  $\pi_\theta(\mathcal{K}, \mathcal{S}, \mathcal{U})$  is a distribution of actions or a mapping to determine which actions or utterances to produce in order to reach the final negotiation goal  $g$ .

### 3.2 Strategy Modeling

In negotiations, people use a wide range of tactics and approaches to achieve their goals  $g$ . Many previous research efforts have focused on modeling these strategies  $\mathcal{S}$ . They can be categorized into three aspects: *integrative* (win-win), such as max-

imizing unilateral interests (Bazerman and Neale, 1993), and *distributive* (win-lost), such as bargaining (Fershtman, 1990), and *multi-party* (Li et al., 2021).

#### 3.2.1 Integrative Strategy

Integrative strategy (known as *win-win*) modeling aims to achieve mutual gains among participants. For instance, Zhao et al. (2019) propose to model the discourse-level strategy using a latent action reinforcement learning (LaRL) framework. LaRL can model strategy transition within a latent space. However, due to the lack of explicit strategy labels, LaRL can only analyze strategies in implicit space. To resolve this problem, Chawla et al. (2021b) define a series of explicit strategies such as *Elicit-Preference*, *Coordination* and *Empathy*. While *Elicit-Preference* is a strategy attempting to discover the preference of an opponent, *Coordination* promotes mutual benefits through an explicit offer or implicit suggestion. In order to capture user’s preference, Chawla et al. (2022) utilize those strategies using a hierarchical neural model. Yamaguchi et al. (2021) also present another collaborative strategy set to negotiate workload and salaries during the interview, whose goal is to reach an agreement between an employer and employee, recommending, for example, to communicate politely, address concerns, and provide side offers.

#### 3.2.2 Distributive Strategy

Distributive strategy (known as *win-loss*) modeling focuses on achieving one’s own goals and maximizing unilateral interests over mutual benefits. Distributive strategy is used when one insists on their own position or resists the opponent’s deal (Zhou et al., 2019). For example, to persuade others to donate to a charity, Wang et al. (2019) propose a set of persuasion strategies containing 10 different strategies, including logical appeal, emotional appeal, source-related inquiry and others. Further exploration on the role of structure (e.g., facing act, emotion) (Li et al., 2020a; Dutt et al., 2020) helps utilize strategy modeling between asymmetrical roles. Another line of research focuses on the adversarial attack strategy. Dutt et al. (2021a) investigate four resisting categories, namely contesting, empowerment, biased processing, and avoidance (Fransen et al., 2015). Each individual category contains fine-grained strategic behaviors. For example, contesting refers to attacking the message source, and empowerment implies reinforcing per-

sonal preference to contradict a claim (*Attitude Bolstering*) or attempting to arouse guilt in the opponent (*Self Pity*).

### 3.2.3 Multi-party Strategy

While the previously mentioned work on integrative and distributive strategy modeling mainly relates to two-party negotiations, multi-party strategy modeling is slightly different. In multi-party situations, strategy modeling needs to consider different attitudes and complex relationships among individual participants, whole groups, and subgroups (Traum et al., 2008). Georgila et al. (2014) attempt to model multi-party negotiation using a multi-agent RL framework. Furthermore, Shi and Huang (2019) propose to construct a discourse dependency tree to predict relation dependency among multi-parties. Li et al. (2021) disclose relations between multi-parties using a graph neural network. However, research in multi-party strategies is currently hindered by limited relevant datasets and benchmarks.

## 3.3 Negotiator Modeling

Negotiation dialogues are affected by various features of negotiators. There is psychological evidence showing that, for example, a negotiation process is affected by personality (Sharma et al., 2013), relationships (Olekals and Smith, 2003), social status (Blader and Chen, 2012) and cultural background (Leung and Cohen, 2011). We thus summarize the existing works on modeling negotiators from following three perspectives: *Preference*, *Emotion*, and *Opponent Behavior*.

### 3.3.1 Preference Modeling

Preference estimation helps an agent infer the intention of their opponents and guess how their own utterances would affect the opponents' preference. Nazari et al. (2015) propose a simple heuristic frequency-based method to estimate the negotiator's preference. However, a critical challenge for preference modeling in negotiation is that it usually requires complete dialogues, so it is difficult to predict those preferences precisely from a partial dialogue. Therefore, Langlet and Clavel (2018) consider a rule-based system to carefully analyze linguistic features from partial dialogue to identify user's preference. In further, to enhance preference modeling in those partial dialogues, which widely exist in real-world applications, Chawla et al. (2022) formulate preference estimation as

a ranking task and propose a transformer-based model that can be trained directly on partial dialogues.

### 3.3.2 Emotion Modeling

Emotion modeling refers to recognizing emotions or emotional changes of negotiators. Explicit modeling of emotions throughout a conversation is crucial to capture and estimate reactions from opponents. To study emotional feelings and expressions in negotiation dialogues, Chawla et al. (2021a) explore the prediction of two important subjective goals, including outcome satisfaction and partner perception. Liu et al. (2021) provide explicit modeling on emotion transition engaged using pre-trained language models (e.g., DialoGPT), to support patients. Further, Dutt et al. (2020) propose a novel set of dialogue acts modeling *face*, which refers to the public self-image of an individual, in persuasive discussion scenarios. Mishra et al. (2022) utilize a reinforcement learning framework to elicit emotions in persuasive messages.

### 3.3.3 Opponent Behavior Modeling

Opponent behavior modeling refers to detecting and predicting opponents' behaviors during a negotiation process. For example, fine-grained dialogue act labels are provided in the Craigslist dataset (He et al., 2018), to help track the behaviors of buyers and sellers. Based on this information, Zhang et al. (2020) propose an opposite behavior modeling framework to estimate opposite action using DQN-based policy learning. Tran et al. (2022) leverage dialogue acts to identify optimal strategies for persuading people to donate. He et al. (2018) firstly propose a framework to decouple the opponent behavior modeling with utterance generation, which allows negotiation systems to manage opponent modeling in a precise manner. Yang et al. (2021) further improve the negotiation system with a first-order model based on the theory of Mind (Frith and Frith, 2005), which allows agents to compute an expected value for each mental state. They provided two variants of ToM-based dialogue agents: explicit and implicit, which can fit both pipeline and end-to-end systems.

## 3.4 Action Learning

Action learning empowers negotiation dialogue systems to properly incorporate previous strategies and other negotiator information to generate high-quality responses. Existing research on policy

learning can be broadly categorized into *reinforcement learning*, *supervised learning* and *in-context learning*.

### 3.4.1 Reinforcement Learning

English and Heeman (2005) pioneer applying reinforcement learning (RL) techniques to negotiation dialogue systems. They propose a single-agent RL framework that learns the policy of two participants individually. However, the single-agent framework is not feasible for situations where two agents interact frequently in a continuously changing environment. Georgila et al. (2014) further propose to use multi-agent RL techniques and provide a way to deal with multi-issue negotiation scenarios. Furthermore, Keizer et al. (2017) propose to learn about the actions of negotiators with a Q-learning reward function. They use a Random Forest model trained on a large human negotiation corpus from (Afantenos et al., 2012).

Most recent works have tried to build negotiation dialogue models using RL techniques with deep learning. Zhang et al. (2020) propose OPPA, which utilizes the system actions to estimate how a target agent behaves. The system actions are predicted based on the target agent’s actions. The reward of the executed actions is obtained by predicting a structured output given a whole dialogue. Additionally, Shi et al. (2021) use a modular framework containing a language model to generate responses. A response detector would automatically annotate the response with a negotiation strategy and an RL-based reward function to assign a score to the strategy. However, this modular framework separates policy learning from response generation. Gao et al. (2021) propose an integrated framework with deep Q-learning, which includes multiple channel negotiation skills. It allows agents to leverage parameterized DQN to learn a comprehensive negotiation strategy that integrates linguistic communication skills and bidding strategies.

### 3.4.2 Supervised Learning

Supervised learning (SL) is another popular paradigm for policy learning. Lewis et al. (2017) adopt a Seq2Seq model to learn what action should be taken by maximizing the likelihood of the training data. However, supervised learning only aims to mimic the average human behavior, so He et al. (2018) propose to apply a supervised model to directly optimize a particular dialogue reward function, which is characterized by i) the utility function

of the final price for the buyer and seller ii) the differences between two agents’ utilities iii) the number of utterances in the dialogue. Zhou et al. (2020) first train a strategy predictor to predict whether a certain negotiation strategy occurred in the next utterance using supervised training. Then, the response generation conditions on the predicted negotiation strategy, as well as user utterance and dialogue context. In addition, Joshi et al. (2021) incorporate a pragmatic strategies graph network with the seq2seq model to create an interpretable policy learning paradigm. Recently, Dutt et al. (2021b) propose a generalized framework for identifying resisting strategies in persuasive negotiations using a pre-trained BERT model (Devlin et al., 2019). In addition, there are also research attempts to jointly train several sub-tasks simultaneously. Li et al. (2020b) propose an end-to-end framework that integrates several sub-tasks, including intent and semantic slot classification, response generation and filtering tasks in a Transformer-based pre-trained model. Zhou et al. (2020) propose jointly modelling semantic and strategy history using finite state transducers (FSTs) with hierarchical neural models. Chawla et al. (2022) integrate a preference-guided response generation model with a ranking module to identify opponents’ priority.

### 3.4.3 In-context Learning

With the recent emergence of large language models such as GPT-3.5 and GPT-4<sup>1</sup>, a few studies have applied zero-shot and few-shot in-context learning. These techniques leverage the inherent knowledge of LLMs to predict agent behaviors and generate utterances. Fu et al. (2023) utilize LLMs in the context of bargaining, while Xu et al. (2023) employ them for the popular game “Werewolf”. Besides, Chen et al. (2023) propose a framework to evaluate strategic planning and execution of LLM agents. In both tasks, the LLMs act as agents, negotiating with other LLMs under specific scenarios to achieve pre-defined goals.

## 4 Negotiation Datasets

In this section, we summarize the existing negotiation datasets and resources. Table 1 shows all of the 14 collected benchmarks, along with their negotiation types, scenarios, data scale and modality. We categorize these benchmarks based on their negotiation types, namely, *integrative* negotiation

<sup>1</sup><https://platform.openai.com/docs/models/>

DataSet	Negotiation Type	Scenario	# Dialogue	# Avg. Turns	# Party	# Modality
InitiativeTalking (Nouri and Traum (2014))	Integrative	Fruit Assignment	41	-	Multi	-
STAC (Asher et al. (2016))	Integrative	Strategy Games	1081	8.5	Two	-
DealorNoDeal (Lewis et al. (2017))	Integrative	Item Assignment	5808	6.6	Two	-
Craigslis (He et al. (2018))	Distributive	Price Bargain	6682	9.2	Two	-
M3 (Kontogiorgos et al. (2018))	Integrative	Object Moving	15	-	Multi	MultiModal
Niki & Julie (Artstein et al. (2018))	Integrative	Item Ranking	600	-	Two	MultiModal
NegoCoach (Zhou et al. (2019))	Distributive	Price Bargain	300	-	Two	-
PersuasionforGood (Wang et al. (2019))	Distributive	Donation	1017	10.43	Two	-
FaceAct (Dutt et al. (2020))	Distributive	Donation	299	35.8	Two	-
AntiScam (Li et al. (2020b))	Distributive	Privacy Protection	220	12.45	Two	-
CaSiNo (Chawla et al. (2021b))	Integrative	Item Assignment	1030	11.6	Two	-
JobInterview (Yamaguchi et al. (2021))	Integrative	Job Interview	2639	12.7	Two	-
DelIData (Karadzhov et al. (2021))	Integrative	Puzzle Game	500	28	Multi	-
DinG (Boritchev and Amblard (2022))	Integrative	Strategy Game	10	2357.5	Multi	-
NegoBar (Heddaya et al. (2023))	Distributive	Price Bargain	408	35.85	Two	-

Table 1: Negotiation dialogues benchmarks are sorted by their publication time. For each dataset, we present the negotiation type, scenario, the number of dialogues and corresponding average turns, and party attributes.

and *distributive* negotiation.

#### 4.1 Integrative Negotiation Datasets

In integrative negotiations, there is normally more than one issue being negotiated. To achieve optimal negotiation goals, the involved players should make trade-offs for these multiple issues.

**Multi-player Strategy Games** Strategy video games provide ideal platforms for people to verbally communicate with other players to accomplish their missions and goals. Asher et al. (2016) propose the STAC benchmark, which is based on the game of Catan. In this game, players need to gather resources, including wood, wheat, sheep, and more, with each other to purchase settlements, roads and cities. As each player only has access to their own resources, they have to communicate with each other. To investigate the linguistic strategies used in this situation, STAC also includes an SDRT-styled discourse structure. Boritchev and Amblard (2022) also collect a *DinG* dataset from French-speaking players in this game. The participants are instructed to focus on the game, rather than talk about themselves. As a result, the collected dialogues can better reflect the negotiation strategy used in the game process.

**Negotiation for Item Assignment** Item assignment scenarios involve a fixed set of items as well as a predefined priority for each player in the dialogue. As the players only have access to their own priority, they need to negotiate with each other to exchange the items they prefer. Nouri and Traum (2014) propose *InitiativeTalking*, occurring between the owners of two restaurants. They discuss how to distribute the fruits (i.e., apples, bananas, and strawberries) and try to reach an agreement. Lewis et al. (2017) propose *DealorNoDeal*, a

similar two-party negotiation dialogue benchmark where both participants are only shown their own sets of items with a value for each and both of them are asked to maximize their total score after negotiation. Chawla et al. (2021b) propose *CaSiNo*, a dataset on campsite scenarios involving campsite neighbors negotiating for additional food, water, and firewood packages. Both parties have different priorities over different items.

**Negotiation for Job Interview** Another commonly encountered negotiation scenario is job offer negotiation with recruiters. Yamaguchi et al. (2021) fill this gap and propose the *JobInterview* dataset. *JobInterview* includes recruiter-applicant interactions over salary, day off, position, and workplace. Participants are informed with opposite’s preferences and the corresponding issues. Feedback from the opposites will be forwarded to participants during the negotiation process.

#### 4.2 Distributive Negotiation Datasets

Distributive negotiation is a discussion over a fixed amount of value (i.e., slicing up the pie). In such negotiation, the involved people normally talk about a single issue (e.g., item price) and therefore, there are hardly trade-offs between multiple issues in such a negotiation.

**Persuasion For Donation** Persuasion, convincing others to take specific actions, is a necessary required skill for negotiation dialogue (Sycara, 1990; Sierra et al., 1997). Wang et al. (2019) focus on persuasion and propose *PersuasionforGood*, two-party persuasion conversations about charity donations. In the data annotation process, the persuaders are provided some persuasion tips and example sentences, while the persuaders are only told that this conversation is about charity. The annotators are

required to complete at least ten utterances in a dialogue and are encouraged to reach an agreement at the end of the conversations. [Dutt et al. \(2020\)](#) further extend *PersuasionforGood* by adding the utterance-level annotations that change the positive and/or the negative face acts of the participants in a conversation. A face act can either raise or attack the positive or negative face of opponents in the conversation.

**Negotiation For Product Price** Negotiations over product prices can be observed on a daily basis. [He et al. \(2018\)](#) propose *CraigslistBargain*, a negotiation benchmark based on a realistic item price bargaining scenario. In *CraigslistBargain*, two agents, a buyer and a seller, are required to negotiate the price of a given item. The listing price is available to both sides, but the buyer has a private price. Two agents chat freely to decide on a final price. The conversation is completed when both agents agree on a price or one of the agents quits. [Zhou et al. \(2019\)](#) propose *NegoCoach* benchmark on similar scenarios, but with an additional negotiation coach who monitors messages between the two annotators and recommends tactics in real-time to the seller to get a better deal.

**User Privacy Protection** Privacy protection of negotiators has become more and more vital. Participant (e.g., attackers and defenders) goals are also conflicting. [Li et al. \(2020b\)](#) propose *Anti-Scam* benchmark which focuses on online customer service. In *Anti-Scam*, users try to defend themselves by identifying whether their components are attackers who try to steal sensitive personal information. *Anti-Scam* provides an opportunity to study human elicitation strategies in this scenario.

## 5 Evaluation

We categorize the methods for evaluating the negotiation dialogue systems into three types: *goal-oriented* evaluation, *game-based* evaluation and *human* evaluation. Table 2 summarizes the evaluation metrics that are introduced in our survey.

### 5.1 Goal-based Metrics

Goal-oriented metrics mainly refer to the quantifiable measures on evaluating agent’s proximity to the negotiation goals from the perspective of strategy modeling, task fulfillment, and sentence realization. *Success Rate (SR)* ([Zhao et al., 2019](#)) is the most widely used metric to measure

Goal-based Metrics	SR (2019); PA (2014; 2019; 2020); Average F1 score (2021b); Macro F1 score (2019; 2020); ROC-AUC, CM, AP (2021); IRT (2022); Naturalness (2015); PPL, BLEU-2, ROUGE-L, Extrema (2017)
Game-based Metrics	WinRate, AvgVPs (2017); Utility, Fairness, Length (2018); Avg. Sale-to-list Ratio, Task Completion Rate (2019); Robustness (2019)
Human Evaluation	Customer satisfaction, Purchase decision, Correct response rate (2015); Achieved agreement rate, Pareto optimality rate (2017); Likert score (2018)

Table 2: Various Metrics used in the existing negotiation dialogues benchmarks.

how frequently an agent completes the task within their goals. Meanwhile, *Prediction Accuracy (PA)* and *macro/average F1 score* are also employed to evaluate the accuracy of agent’s strategy predictions ([Nouri and Traum, 2014](#); [Wang et al., 2019](#); [Dutt et al., 2020](#); [Chawla et al., 2021b](#)). Specifically, [Yamaguchi et al. \(2021\)](#) present a task where the model is required to label the human-human negotiation outcomes as either a success or a breakdown, and use following metrics: *area under the curve* (ROC-AUC), *confusion matrix* (CM), and *average precision* (AP) to evaluate the model. Moreover, [Kornilova et al. \(2022\)](#) introduce Item Response Theory (IRT) to analyze the effectiveness of persuasion on the audience.

In terms of language realization for negotiation dialogue, [Hiraoka et al. \(2015\)](#) employ a pre-defined naturalness metric (i.g., a bi-gram overlap between the prediction and ground-truth) as part of the reward to evaluate policies in negotiation dialogues. Other classical metrics for evaluating the quality of response are also used, i.e., perplexity (PPL), BLEU-2, ROUGE-L, and BOW Embedding-based Extrema matching score ([Lewis et al., 2017](#)).

### 5.2 Game-based Metrics

Different from the goal-oriented metrics that focus on measuring how successful an agent achieves the negotiation goals, game-based evaluation provides a user-centric perspective to evaluate systems. [Keizer et al. \(2017\)](#) measure agent’s ability on negotiation strategy prediction within the online game “*Settlers of Catan*”. They propose the metrics *WinRate* and *AvgVPs* to evaluate the success of human and agent separately. [He et al. \(2018\)](#) present a task where two agents bargain to get the best deal using natural language. They use task-specific scores to test the performance of the agents, including: *utility*, *fairness*, and *length*. [Zhou et al. \(2019\)](#) design a task where a seller and a buyer try to achieve a mutually acceptable price through a natural language negotiation. They adopt *average sale-to-list ratio* and *task completion rate* to evaluate agent performance. Besides, [Cheng et al. \(2019\)](#) propose

an adversarial attacking evaluation approach to test the *robustness* of negotiation systems.

### 5.3 Human Evaluation

To evaluate the users' satisfaction with the dialogue systems, human judgment is employed as a subjective evaluation of agent performance. Hiraoka et al. (2015) use a user simulator as the salesperson to bargain with customers in real and have the users annotate subjective *customer satisfaction* (a five-level score), the final decision of making a purchase (a binary number indicating whether persuasion is successful), and the *correct response rate* in the dialogues. Lewis et al. (2017) employ crowd-sourcing workers to highlight that essential information when bargaining with negotiation systems, covering the percentage of dialogues where both interlocutors finally achieve an agreement, and *Pareto optimality*, i.e., the percentage of the Pareto optimal solutions in all the agreed deals. He et al. (2018) propose human likeness as a metric in evaluating how well the dialogue system is doing in a bargain. They ask workers to manually score the dialogue agent using a *Likert* metric to judge whether the agent acts like a real human or not.

## 6 New Frontiers and Challenges

The previous sections summarize the prominent achievements of previous work in negotiation dialogue, including benchmarks, evaluation metrics, and methodology. In this section, we will discuss some new frontiers that allow negotiation dialogue systems to be fit to actual application needs and to be applied in real-world scenarios.

**Multi-modal Negotiation Dialogue** Existing research works in negotiation dialogue rarely consider multi-modality. However, humans tend to perceive the world in multi-modal patterns, not limited to text but also including audio and visual information. For example, the facial expressions and emotions of participants in a negotiation dialogue could be important cues for making negotiation decisions. Further work can consider adding this non-text-based information into the negotiation.

**Multi-Party Negotiation Dialogue** Although some work sheds light on multi-party negotiation, most current negotiation dialogue benchmarks and methods predominantly focus on two-party settings. Therefore, multi-party negotiation dialogues are underexplored. Future work can consider collecting

dialogues in multi-party negotiation scenarios, including *General multi-party negotiation* and *Team negotiation*. Specifically, *General multi-party negotiation* is a type of bargaining where more than two parties negotiate toward an agreement. For example, next-year budget discussion with multiple department leaders in a large company. *Team negotiation* is a team of people with different relationships and roles. It is normally associated with large business deals and highlights the significance of relationships between multi-parties. There could be several roles, including leader, recorder, and examiner, in a negotiation team (Halevy, 2008).

**Cross-Culture & Multi-lingual Negotiation Dialogue** Existing negotiation dialogue benchmarks overwhelmingly focus on English while leaving other languages and cultures under-explored. With the acceleration of globalization, a dialogue involving individuals from different cultural backgrounds (Chawla et al., 2023; Zhan et al., 2023; Joshi et al., 2024) becomes increasingly important and necessary. There is an urgent need to provide people with a negotiation dialogue system that is multicultural and multi-lingual. Further works can consider incorporating multi-lingual utterances and social norms among different countries into negotiation dialogue benchmarks.

**Negotiation Dialogue in Real-world Scenarios** As discussed in Section 4, previous works have already proposed many negotiation dialogue benchmarks in various scenarios. However, we notice that most of these benchmarks are created through human crowd-sourcing. Participants are often invited to play specific roles in the negotiation dialogue. The resulting dialogues may not perfectly reflect the negotiations in real-world scenarios (e.g., politics, business). Therefore, it could be a promising research direction to collect real-world negotiation dialogues. For example, one could collect recorded business meetings or phone calls.

## 7 Conclusion

This paper presents the first systematic review on the progress of negotiation dialogue systems. We firstly provide an understanding of negotiation between humans from a social science perspective. Then we thoroughly summarize the existing works, which covers various domains and highlight their challenges, respectively. We additionally summarize currently available methodologies, bench-

marks, and evaluation methods. We also shed light on some new trends in this research field. We hope this survey inspires and facilitates future research on negotiation dialogue systems.

## Limitations

This survey briefly introduced the motivation and limitation of human negotiation from social science perspectives, and summarized methodology, dataset and evaluation methods in the field of computational linguistics. The limitation relays on that we only have brief investigation on the human negotiation. Further, we will conduct a comprehensive investigation from the social science perspectives and then motivate our future work in the dialogue research. In further, we will summarize the details of each paper and illustrate the difference between these papers. Nevertheless, we hope that our survey will inspire and facilitate future research as a good foundation.

# Towards Understanding Counseling Conversations: Domain Knowledge and Large Language Models

Younghun Lee<sup>†</sup>, Dan Goldwasser<sup>†</sup>, Laura Schwab Reese<sup>‡</sup>

<sup>†</sup>Department of Computer Science

<sup>‡</sup>Department of Public Health

Purdue University

{younghun, dgoldwas, lschwabr}@purdue.edu

## Abstract

Understanding the dynamics of counseling conversations is an important task, yet it is a challenging NLP problem regardless of the recent advance of Transformer-based pre-trained language models. This paper proposes a systematic approach to examine the efficacy of domain knowledge and large language models (LLMs) in better representing conversations between a crisis counselor and a help seeker. We empirically show that state-of-the-art language models such as Transformer-based models and GPT models fail to predict the conversation outcome. To provide richer context to conversations, we incorporate human-annotated domain knowledge and LLM-generated features; simple integration of domain knowledge and LLM features improves the model performance by approximately 15%. We argue that both domain knowledge and LLM-generated features can be exploited to better characterize counseling conversations when they are used as an additional context to conversations.

## 1 Introduction

Online counseling has become a more significant part of mental health services over the last couple of decades as younger generations feel more emotionally safe with digital communication (Murphy and Mitchell, 1998; King et al., 2006). Although building therapeutic relationships and social presence through written communication may exhibit significant challenges compared to in-person services (King et al., 2006; Norwood et al., 2018), text or chat based counseling services are irreplaceable; nearly 50% of the United States population reside in a mental health shortage area where there are less than two psychiatrists per 100,000 residents (Morales et al., 2020; Cheng and Mohiuddin, 2021).

The conversation dynamics and therapeutic relationship between mental health providers and

clients have been actively studied in the health science field, mainly analyzing mutual trust (Torous and Hsin, 2018), empathy (Nienhuis et al., 2018), social presence (Gunawardena, 1995), and rapport-building (Bantjes and Slabbert, 2022). Despite its importance, there’s relatively little work done in analyzing linguistic components of counseling conversations and characterizing them to better understand the conversation dynamics.

Throughout this research, we aim to propose a systematic approach to better characterize counseling conversations. We hypothesize that the current state-of-the-art language models contain insufficient knowledge of the counseling domain in their parameters. Motivated by existing works using external knowledge for solving tasks such as question answering (Ma et al., 2022), commonsense reasoning (Schick et al., 2023), and language generation (Peng et al., 2023), this paper studies whether additional knowledge helps characterize counseling conversations. We suggest two different ways of obtaining this additional knowledge: human annotation and large language model (LLM) prompting.

In this paper, we measure the level of understanding counseling conversations by predicting conversation outcomes, i.e., whether the help seeker would feel more positive after the conversation or not. We empirically show that Transformer-based classifiers as well as state-of-the-art LLMs exhibit sub-optimal performances despite their strong ability on many downstream tasks. The paper then describes how domain knowledge is obtained in order to further emphasize the counselor’s strategic utterances and the help seeker’s perspectives. We show that the additional knowledge helps pre-trained language models better fit the dataset and perform well in predicting the conversation outcomes—simple integration of the knowledge and feature ensembling improves the model performance by approximately 15%. We further analyze the efficacy of different features and explain how these features

help classifiers better predict the outcome.

**Key Contributions:** To the best of our knowledge, this is the first attempt to exploit LLMs as a knowledge extractor to better characterize counseling conversations. With better prompting, we expect LLMs to generate more meaningful knowledge and explanations to assess the help seeker’s perspectives. These knowledge-infused language models can be further used to generate evidence of how the conversation is going and how the help seekers may feel in real-time during the conversation, and ultimately assist human counselors in providing better counseling.

## 2 Counseling Conversation Analysis

In chat based services for crisis counseling, a help seeker starts a session seeking help and a counselor replies to it. There are two speakers in these chat sessions, a help seeker and a counselor. Following previous works in analyzing such conversations (Sharma et al., 2020; Grespan et al., 2023), we aim to analyze counseling conversations by observing two different levels of features—utterance level features and session level features. Utterance level features examine the characteristics of conversation turns (i.e. messages), whereas session level features consider different aspects that can be found throughout the whole conversation.

### 2.1 Problem Formulation

One of the main goals of this research is to train a model that understands the conversation text between a counselor and a help seeker. Existing works on counseling conversations measure the level of language understanding by evaluating the quality of language generation; the models are trained with language model objectives and they generate the most likely utterance given a snippet of a conversation history. However, widely-used metrics for language generation such as ROUGE (Lin, 2004) and BLEU (Papineni et al., 2002) do not accurately assess the model’s language understanding in this domain because defining the correct utterance given the conversation context is unclear; given the same conversation context, both an empathetic text and a solution-driven text can be considered as a good response at the same time. Alternatively, language models can be evaluated by asking humans to choose better generations from different models. However, this does not guarantee fair evaluations because humans who evaluate

generated texts cannot fully understand the help seekers’ perspectives.

Thus in this paper, we use a more easy-to-understand feature to define the level of understanding. We choose the help seeker’s post-conversation survey answer to a question, “*Do you feel more positive after this conversation?*”, as an output of each conversation instance. We train the model to solve a classification task to predict whether the help seeker has become more positive after having a conversation session.

Regardless of a simple classification pipeline, this is a challenging NLP task as it requires models to understand the context of a conversation session and to read between the lines to assess the help seekers’ feelings throughout the conversation. The help seeker’s perspectives on the counseling session can be affected by many factors such as their situations, needs, the type of abuse, the counselor’s tone, rapport-building strategies, the solutions suggested by the counselor, etc. Moreover, help seekers rarely express their negative emotions about how the counselor is doing during the conversation (e.g. “*You are not helping.*”). In most cases, the help seekers rather show their gratitude to the counselor as a courtesy (e.g. “*Thanks for the help.*”), yet respond to the post-conversation survey that they don’t feel more positive after the conversation. Thus the models need to analyze not only the direct meanings of what help seekers say, but also identify different aspects such as whether the help seekers’ needs are met, if the solutions are specific to the help seekers’ situations, whether the counselors express their empathy, etc.

### 2.2 Human-annotated Domain Knowledge

To better characterize the conversation and predict whether the help seeker has become more positive, we first obtain domain knowledge from human annotation. One of the main research questions we aim to solve in this paper is whether domain-specific knowledge helps understand counseling conversations. We qualitatively analyze around 200 counseling conversation sessions from The Childhelp National Child Abuse Hotline<sup>1</sup> and annotate utterance level features with pre-defined counseling strategies; we focus on annotating utterances from the counselors and investigate the effects of counseling strategies on the help seekers.

Both inductive and deductive processes are used

<sup>1</sup><https://childhelphotline.org>

to explore the counseling strategies; the first draft of the feature set was based on existing conversations related to child maltreatment (Cash et al., 2020; Schwab-Reese et al., 2019, 2022), then it was revised based on the content of the conversations. The overall feature development process follows the adaptation of grounded theory described by Schreier (2012). The annotators identify patterns that are not covered by the features used in the first draft, then they discuss differences, refine the annotation framework, and apply the new features to small batches of the data (30 instances). By iteratively following this process, the annotators have come to identify various emotional attending strategies such as active listening (Ivey et al., 1992), validation (Linehan, 1997), unconditional positive regard (Wilkins, 2000), and evaluation-based language (Brummelman et al., 2016). After the inter-annotator agreement score reaches 95% in assessing the small batches, the annotators identify utterance level features for the rest of the data.

### 2.3 LLM-generated Features

Recent studies show that LLMs can solve many different NLP tasks including summarization, classification, generation, and question answering (Chintagunta et al., 2021; Chiu et al., 2021; Goyal et al., 2022; Lee et al., 2022; Liu et al., 2022), suggesting these models are capable of understanding natural language and reasoning with world knowledge. As our task not only requires language understanding but also applying real-world knowledge, we aim to explore whether LLMs can comprehend counseling conversations and provide meaningful features that can later be used to characterize them. As we focus on obtaining utterance level features from human annotation, we put more emphasis on retrieving session level features and the help seekers' perspectives using LLMs.

It is also beneficial to study the role of LLMs in representing conversation text regarding training efficiency. Analyzing multi-turn conversations using Transformer-based models often encounters trade-offs between maximum token limits and model complexity; smaller models could easily reach their maximum token limits to encode the whole conversation text and bigger models like LongFormer (Beltagy et al., 2020) require a larger number of training instances to fine-tune their parameters. LLM-generated features have the potential to replace the lengthy conversation text and ultimately help reduce possible issues in training, especially

when the number of training instances is not large enough to tune a complex model.

### 2.4 Data

The data for this study comes from the text and chat channel of The Childhelp National Child Abuse Hotline. The crisis counselors are professionals with specialized training in hotline services and child maltreatment, rather than volunteers or peers like 7cups<sup>2</sup>, TalkLife<sup>3</sup>, or other mental health related online communities<sup>4</sup>. We gained access to de-identified transcripts and metadata that anonymized and normalized all names and street addresses which relieves ethical concerns.

This research studies two streams of data.  $\mathcal{D}_{small}$  refers to the dataset we purposely select for annotating utterance level features. We select 236 conversation instances out of 1,153 total conversations recorded during July 2020. The selection criteria were designed to have a more diverse demographic background of the help seekers and more number of conversation sessions with valid post-conversation survey answers. We have another stream of data,  $\mathcal{D}_{large}$ , which includes additional conversation sessions from August 2021 to December 2022 where the help seekers provided valid post-conversation survey answers. The major difference between  $\mathcal{D}_{small}$  and  $\mathcal{D}_{large}$  is that the former has annotated utterance level features and demographically diverse distributions among help seekers, while the latter has more number of conversation sessions.

All counseling conversations are recorded in English. For  $\mathcal{D}_{small}$ , around 70% of the help seeker was female, and 55% of the help seeker was the maltreated child. About 60% of the help seekers are younger than 17 years old.

The annotation team includes one of the authors, a graduate research assistant, and two collaborators at Childhelp. The author is a family violence prevention researcher with a Ph.D. in public health and a Master of Arts in counseling. The author also has experience conducting qualitative analyses of written hotline transcripts. The graduate research assistant was a Master of Public Health student and had worked on the author's research team for three years. The research assistant had experience with qualitative child maltreatment research. The Childhelp collaborators have substantial experience

Class distribution (neg/neu/pos)	31 / 104 / 101
Date range	30
Avg/Max number of tokens per session	1,075 / 4,773
Avg/Max number of turns per session	27 / 143
Avg/Max number of annotated utterance level features per session	11 / 45
$\mathcal{D}_{large}$	
Number of sessions	1,469
Class distribution (neg/neu/pos)	238 / 627 / 604
Date range	300
Avg/Max number of tokens per session	1,034 / 5,253
Avg/Max number of turns per session	26 / 234

Table 1: Statistics of the two datasets. Only  $\mathcal{D}_{small}$  contains human annotated utterance level features.

in hotline counseling and leadership. One has a Master of Science in Counseling Psychology. The second has a Master of Science in Family and Human Development and a Master of Education in Guidance Counseling.

As mentioned in 2.1, we consider the help seekers’ post-conversation survey answers as a class. We take the answer to a question, “*Do you feel more positive after this conversation?*”, as output and discard instances where the help seekers answered ‘Prefer not to answer’. The remaining classes are ‘A lot (positive)’, ‘A little (neutral)’, and ‘Not at all (negative)’. Detailed statics of the datasets and the class distributions are described in Table 1.

### 3 Models

We implement baseline models with the conversation text and integrate varying features to evaluate their efficacy.

#### 3.1 Baseline

Baseline models are implemented to measure the difficulty of predicting conversation outcomes. In this setting, we only provide the conversation text between the counselor and the help seeker, and the model is trained to infer a conversation outcome (i.e. whether the help seeker has become more positive). Baseline models are pre-trained BERT-based sequence classifiers that are fine-tuned on the dataset. We implement BERT (Devlin et al., 2019), DistilBERT (Sanh et al., 2019), and RoBERTa (Liu et al., 2019) sequence classifiers from the huggingface distributions<sup>5</sup>.

The average number of tokens in a conversation session is over a thousand (see Table 1), whereas

<sup>5</sup><https://huggingface.co/docs/transformers>

the aforementioned pre-trained classifiers can encode up to 512 tokens. Thus we truncate the conversation text; the model takes the first and the last  $k$ -turns of the conversation<sup>6</sup>. In general, the beginning of the conversation includes the reason why the help seeker reached out, and the conversation develops into solutions and suggestions towards the end of the conversation. From this observation, we hypothesize that the beginning and the end of the conversation can better characterize the content rather than letting the model encode the text from the beginning and truncate the rest of the text when it reaches the maximum token limits. We have experimented with different encoding approaches to test the hypothesis and found out that our encoding approach (i.e. using the first and the last  $k$ -turns) outperforms the plain encoding approach (i.e. encoding from the beginning until the token limit) by 4~9% in macro F1 score.

Another baseline model we evaluate is the state-of-the-art LLMs. We prompt ChatGPT<sup>7</sup> in a zero-shot setting to predict the conversation outcome. Unlike BERT-based classifiers, ChatGPT can take up to 4,096 tokens and there are less than 10 instances that exceed this limit in the dataset. Thus in using ChatGPT, we only remove a couple of utterances for the conversation sessions exceeding the maximum token limit and use the whole conversation for the rest of the sessions.

#### 3.2 Integrating Utterance-level Features

Counseling strategies (i.e. utterance level features) are annotated for only a partial amount (i.e.  $\mathcal{D}_{small}$ ) of the full dataset (i.e.  $\mathcal{D}_{all} = \mathcal{D}_{small} \cup \mathcal{D}_{large}$ ). To fully integrate utterance level features into conversation text, we implement simple classifiers that identify strategies in a counselor’s utterance. Given a counselor’s utterance and its previous  $k$ -turns of the conversation, classifiers assign correct utterance level features. Note that this is a multi-label classification as a counselor’s utterance can exhibit multiple strategies at the same time.

There are 18 distinct features identified from the annotation framework described in 2.2, yet we categorize them into 4 groups, ‘*Emotional Attending*’, ‘*Fact Related*’, ‘*Problem Solving*’, and ‘*Resources*’. The performance of different classifiers in predicting utterance level features in Table 2 shows trade-

<sup>6</sup>We compare this method to other alternatives such as using LongFormer or LSTM-based models, yet truncation works the best.

<sup>7</sup>We use version gpt-3.5-turbo-0613

Utterance-level Feature Prediction	
<i>Fine-grained Feature Classification</i>	
BERT-based end-to-end classifier	F1 55.03
BERT-based 2-step hierarchical classifier	<b>56.49</b>
text-davinci-003, few-shot (2 samples) prompt	48.87
text-davinci-003, few-shot (3 samples) prompt	56.2
<i>Grouped Feature Classification</i>	
BERT-based end-to-end classifier	<b>69.22</b>
text-davinci-003, few-shot (3 samples) prompt	61.12

Table 2: Utterance level feature prediction results of BERT-based classifiers and LLM-based classifiers. Fine-grained feature classification models infer among 18 classes while grouped feature classification models assign classes from the grouped features (4 classes).

offs between the feature’s expressibility and the model’s faithfulness; when a more fine-grained set of features is used, more diverse utterance level information is added but the accuracy of the inferred features from the classifier is likely to be lower. Given the classification results, we choose to use groups of features for weak supervision. More details of the features and how they are grouped are described in Appendix A.2.

Using the BERT-based classifier for grouped utterance features, we automatically annotate the counselors’ utterances that are not annotated by humans (i.e.  $\mathcal{D}_{large}$ ). In order to better represent the conversation text, we integrate utterance level features into the existing text data. Specifically, we add this additional knowledge as special tokens that further explain the message that follows. Refer to a short snippet of a conversation and the same conversation with utterance level features added, for instance.

[Original Conversation]  
 Help seeker: I am abused by my parents.  
 Counselor: I am sorry that happened.

[Conversation with Utterance Features]  
 Help seeker: I am abused by my parents.  
 Counselor: <Emotional Attending> I am sorry that happened.

Using the inputs with utterance feature addition, we train BERT-based classifiers to predict conversation outcomes and compare their performance with the baseline models.

### 3.3 Extracting Session-level Features using LLMs

The main advantages of using LLMs to extract relevant features from conversation text are two-fold: compressing lengthy conversation text, and cost efficiency. When LLM-generated features exhibit

representation power comparable to the original conversation text, we can compress the lengthy conversation input by replacing it with LLM-generated features. Also, annotating domain knowledge following the process we perform in 2.2 is costly and time-consuming, thus it would be cost efficient if LLMs are able to provide useful knowledge to characterize conversation text without having human annotators trained to analyze the data.

We first evaluate an LLM’s ability to predict utterance level features. Table 2 illustrates that the performance of prompting the text-davinci-003<sup>8</sup> model in both zero-shot and few-shot settings is worse than BERT-based classifiers. From the observation, we hypothesize that identifying utterance level features from the conversation is highly contextual and it requires fine-tuning rather than prompting LLMs. Thus we focus on retrieving session level features that are less contextual but meaningful in order to better understand the help seekers’ perspectives.

We design 12 questions that cover a sufficient range of understanding how the conversation went and what the help seeker would have thought, and prompt ChatGPT in a zero-shot setting to get the answers to the questions. The questions focus on analyzing the help seekers’ needs, the corresponding solutions suggested by the counselors, and also observe both of their attitudes. We consider the answers generated from these questions as session level features as they need to be answered by reading the whole conversation text. To alleviate the issues of providing generic answers or being hallucinated, we force ChatGPT to answer the questions by selecting from pre-defined choices. We have 60 choices (i.e. features) in total and Table 3 shows examples of the questions and their corresponding features.

Having features selected by ChatGPT, we first process them as one-hot vectors and train machine learning models to predict conversation outcomes. Various models including Logistic Regression, Support Vector Classifier, Gaussian Naïve Bayes, and ensemble models such as Random Forest (Ho, 1995) and AdaBoost (Freund and Schapire, 1997) are implemented.

Another way to utilize the session level features is to express them as a natural language explanation and encode them with BERT-based models. The

<sup>8</sup>We use the largest model at the time of running experiments. Note that the results might change with the most recent models.

Prompt Type	Feature Examples
Help seeker's identity	{Maltreated child, Family member, Peer/Friend, Other known adult, Unknown person, Other}
Perpetrator's identity	{Parents, Siblings, Step-parents, Ex-partners, Other family member, Peer/Friend, Other}
Type of abuse	{Physical, Verbal/Emotional, Neglect/Careless, Stress from family/friends/school}
Severity of abuse	{Imminent danger, Persistent abuse, Poor care, Casual behavior}
Help seeker's needs	{Seeking resources, Getting emotional support, Reporting the situation, Practical advice, Not clear}
Counselor's response	{Providing resources, Reflection of feelings, Affirmation or reassurance, Providing advice, Not clear}
Counselor's strategies	{Interpreting, Reflecting feelings, Asking questions, Validating, Providing information}
What's been tried	{Contacting authorities, Talking to professionals, Talking to others, Self care methods, Others, None}
Counselor's advice	{Contacting authorities, Talking to professionals, Talking to others, Self care methods, Others}
Help seeker's reaction	{Accepting, Accepting with concern, Doubting, Has already been tried, Denying}
Counselor's negative attitudes	{Trivializing issues, Lacking validation, Pushy tone, Lacking exploration, Lacking solutions}
Help seeker's negative attitudes	{Yes, No}

Table 3: Main features we aim to retrieve from LLMs. Detailed design of each prompt is described in Appendix A.3

following paragraph illustrates an example.

[LLM-generated Features]  
 Help seeker's identity: Maltreated child  
 Perpetrator's identity: Parents  
 Type of abuse: Physical  
 ...  
 [Natural Language Explanation of Features]  
 A **maltreated child** has been experiencing **physical** abuse by their **parents**...

One of the advantages of this approach is that these textualized features can be added to the conversation text and provide more parameterized information when BERT-based classifiers are trained. We concatenate the last hidden state representation of the two inputs (i.e. conversation text and session feature text) and train a classifier.

### 3.4 Free-form LLM Generation

In order to examine the efficacy of asking pre-defined questions in characterizing counseling conversations, we compare the features generated in 3.3 with free-form generation from LLMs. Instead of asking specific questions, we simply ask the ChatGPT model to summarize the conversation. We obtain two different summaries; one generates a plain summary, and the other is prompted to generate summaries, *focusing on whether the help seeker would have felt more positive after the conversation*. The former contains information about the conversation only, while the latter includes ChatGPT's stance on whether the conversation affected the help seeker in a more positive way. When the summary is fed into the model with conversation text, the last hidden state of summary text from a BERT encoder is concatenated.

## 4 Experimental Settings

Very little difference exists between 'positive' and 'neutral' conversation outcomes. We combine these

two classes and make the task as a binary classification task (i.e. 'negative' v. 'non-negative'). To evaluate and compare different models, we compute macro F1 scores and the recall values of the minority class (i.e. 'negative' class). Models can achieve a satisfactory macro F1 score by minimally assigning minority class to test instances. In such cases, these models will score low recall on the minority class. However, models with higher recall on the 'negative' class are more desirable in a real use case, as they identify more instances where the help seekers do not feel positive, and one can further assess what can be done alternatively.

The reported results are from DistilBERT-based uncased classifier which works the best among all BERT based classifiers we implemented. Conversation text includes  $k = 4$  turns in the beginning and the end. We use the union of  $\mathcal{D}_{small}$  and  $\mathcal{D}_{large}$  as our main dataset,  $\mathcal{D}_{all}$ , with 60/20/20 splits of training, evaluation, and testing sets. All models are experimented with 10-fold cross validation.

Table 4 illustrates the conversation outcome prediction results of various models and inputs. In the table, inputs are abbreviated as follows: Conv is conversation text, Utter means utterance level features are added to the conversation text, Session is natural language explanation of ChatGPT generations about session level features, Summary means plain summaries generated from ChatGPT, and Stance is ChatGPT's summary with a stance on whether the help seeker feels positive or not.

## 5 Discussion

In this section, we further diagnose the model outputs and their relatedness to the features.

### 5.1 Model Performance

We empirically show that predicting the conversation outcome is not a trivial task regardless of its simple training pipelines. The first two rows

Conversation Outcome Prediction		
Input $\Rightarrow$ Model	F1	Recall
<i>Baseline Models</i>		
Conv $\Rightarrow$ DistilBERT	61.91	31.39
Conv $\Rightarrow$ ChatGPT	63.23	25.28
<i>Utterance-level Features</i>		
★ Utter $\Rightarrow$ DistilBERT	62.84	37.04
Utter $\Rightarrow$ ChatGPT	62.09	24.39
<i>Session-level Features</i>		
Session one-hot vector $\Rightarrow$ AdaBoost	63.84	24.82
Session $\Rightarrow$ DistilBERT	63.80	27.37
Conv+Session $\Rightarrow$ DistilBERT	63.97	30.11
★ Utter+Session $\Rightarrow$ DistilBERT	64.60	41.24
<i>Features from Summaries</i>		
Summary $\Rightarrow$ DistilBERT	62.36	29.56
Utter+Summary $\Rightarrow$ DistilBERT	65.53	32.85
Utter+Session+Summary $\Rightarrow$ DistilBERT	65.32	41.06
Stance $\Rightarrow$ DistilBERT	68.46	37.59
★ Utter+Stance $\Rightarrow$ DistilBERT	69.88	41.42
Utter+Session+Stance $\Rightarrow$ DistilBERT	66.88	36.50
<i>Feature Ensembling</i>		
★ Utter+Session+Summary +Stance $\Rightarrow$ Ensemble	<b>71.29</b>	<b>49.27</b>

Table 4: Macro F1 scores and recall values of the ‘negative’ class. The input to the AdaBoost models are one-hot encoded vectors of session level features, and all other DistilBERT models get text inputs. Ensemble model stacks logits from different classifiers and learn a final Logistic Regression classifier. A leading star sign indicates the model with the best F1 and recall score within the same category.

in Table 4 show that the baseline models lack in performance. Although the ChatGPT model scores a higher macro F1 score, its low recall implies that the model predicts fewer conversation instances as ‘negative’. This validates our argument described in 2.1; predicting the conversation outcome is a challenging task and it requires more domain-specific knowledge rather than relying on the knowledge encoded in language model parameters.

Overall, the performance of language models incrementally improves by adding more features—utterance level features, session level features, and features from summaries—except for the case where Utter+Stance shows better performance than Utter+Session+Stance. While the efficacy of session level features is not clear when it is used with summaries with stance, it helps the language model better perform when used with other features. Ensembling classifiers trained with different features not only mitigates the potential class imbalance issues but also produces the best F1 and recall scores.

## 5.2 Effectiveness of Utterance-level Features

Utterance level features can enhance the model’s accuracy in general as well as its ability to identify ‘negative’ class instances. Simple integration of utterance level features to the conversation (i.e. Utter) improves the F1 score by 1.5% and minority class recall by 18% compared to the original conversation (i.e. Conv). We observe that utterance level features also improve when both conversation text and session level features are used together; Utter+Session enhances the minority class recall by 37% than Conv+Session, while maintaining F1 scores.

We compute the Shapley values and observe how utterance level features contribute differently to the classifier following the approaches proposed in SHAP (Lundberg and Lee, 2017). Compared to the original conversation input, utterances that are integrated with features tend to contribute more to the inference, which potentially leads models to identify more ‘negative’ instances. For instance, the counselor’s utterance, “*It must be very hard for you to ...*” in Figure 1 contributes more to the final prediction when it appears with the utterance feature indicators, and it ultimately leads the model to infer a correct class, ‘negative’.

## 5.3 Effectiveness of Session-level Features

Session level features show sufficient representation abilities compared to the original conversation text. Using session level features, either one-hot encoded or represented by BERT-based encoders, shows better performance in predicting the outcome even without considering the original conversation text.

The effectiveness of session level features is arguable when it is used with features from summaries. While session level features improve the minority class recall for the plain summary features, summaries with stance can perform best without having session level features at all. This observation raises a question, “*Are session level features essential when we have summaries with stance?*”.

We further diagnose the performance of the two models, one using session level features and the other using features with stance with respect to the length of the conversation text. When the context is lengthy, we hypothesize that LLMs are susceptible to having more insufficient or incorrect generations in producing general summaries, compared to answering questions focusing on specific aspects.

Context: Help seeker wants to support their friend who is being physically and emotionally abused by her dad	
[Original Conversation]	
<SEP> Counselor: It must be very hard for you to see your friend go through this. When does she turn 18? <SEP> Counselor: It sounds like it is a hard spot for your friend and for you as wel. *well <SEP> HelpSeeker: It really doesn't matter how it is for me, she's the one stuck there	<SEP> HelpSeeker: I'm useless to her for it though At
<SEP> Counselor: I can see where you are coming from. It is hard to see a friend going through such things as you described. <SEP> HelpSeeker: I'm useless to her for it though At	I'll go try and come up with something else *no it Thank you again Have a good night
[Original Conversation] + [Utterance-level Features]	
<SEP> Counselor: [Emotional] [Factual] It must be very hard for you to see your friend go through this. When does she turn 18?	<SEP> Counselor: [Emotional] I can see where you are coming from. It is hard to see a friend going through such things as you described. <SEP> HelpSeeker: I'm useless to her for it though At
<SEP> Counselor: [Emotional] It sounds like it is a hard spot for your friend and for you as wel. *well <SEP> HelpSeeker: It really doesn't matter how it is for me, she's the one stuck there	I'll go try and come up with something else *no it Thank you again Have a good night

Figure 1: Shapley value of phrases in the counseling conversation (upper) and the conversation with utterance level features (lower). Highlighted area in red contributes the models to predict ‘negative’ class, and area in blue contributes the opposite.

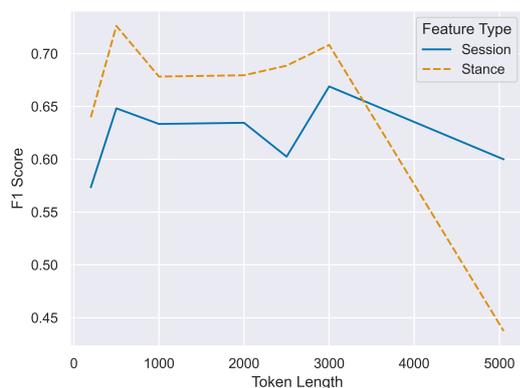

Figure 2: F1 score comparison between session level feature input and summaries with stance. Performance of summary with stance decreases when the length of the counseling conversation exceeds 3K tokens, while session level feature input shows more consistent performance.

Figure 2 shows the F1 score of the two models with respect to the length of the conversation. As the conversation gets longer than 3K tokens, the performance of summaries with stance decreases while session level feature input shows consistency. This implies that obtaining summaries and using them as features becomes less consistent when the input conversation is lengthy, thus using session level features is more beneficial.

#### 5.4 Plain Summary v. Summary with Stance

The difference between generating plain summary and summary with stance is very minimal in the prompts, yet their effectiveness varies significantly; using Stance improves the macro F1 by 12% and the minority class recall by 27%, compared to using Summary. To further examine the commonalities and differences of the summaries generated by the two approaches, we identify distinct aspects that are captured in the summaries through clustering.

We split the summaries into sentences and run k-means clustering to group similar sentences together. Qualitative analysis shows that the plain summary generates more sentences mentioning the help seeker expressing gratitude at the end of the conversation, while the summary with stance generates whether the help seeker would feel more positive after the conversation. We argue that this difference leads the Summary model to have a low recall on the ‘negative’ class; having a summary sentence about the help seeker being thankful makes the classifier more likely to infer an instance as ‘positive’, yet the expression of gratitude should not be considered as a significant feature as described in 2.1. Another difference is that the plain summary generates more details of the help seekers’ situations, particularly about their parents being abusive, while the summary with stance focuses more on whether the counselor empathizes with the help seeker’s situation. Figure 4 in Appendix B illustrates the clustered sentences in the summaries and co-occurring themes in each cluster.

## 6 Related Work

Several recent NLP works looked at analyzing counseling conversations and predicting their outcomes (Althoff et al., 2016; Pérez-Rosas et al., 2018, 2019; Grespan et al., 2023; Li et al., 2023). Similar to our approach, several work relied on domain knowledge to identify counseling strategies and conversational actions (Lee et al., 2019; Park et al., 2019; Cao et al., 2019a). For example, Cao et al. (2019b) employed behavioral codes of clients and therapists to provide real-time feedback to a therapist about the category of the current utterance and suggest the next category to apply.

Other works analyzed the conversational style of counselors, how it changes over time (Zhang et al., 2019; Zhang and Danescu-Niculescu-Mizil, 2020)

and the emotional support they provide (Pérez-Rosas et al., 2017; Sharma et al., 2020). For example, Sharma et al. (2020) proposed an empathy-based approach in understanding counseling conversations between a help seeker and peer supporters on TalkLife and r/depression subreddits (Sharma and De Choudhury, 2018). Liu et al. (2021) worked on guiding dialog models with emotional support strategy chains using 7cups dataset (Baumel, 2015). The authors evaluated the framework on BlenderBot (Roller et al., 2021) and DialoGPT (Zhang et al., 2020).

As counseling conversation analysis has been improving with the help of more representative language models over time, our research poses the initial attempt to utilize LLMs for reasoning about features relevant to conversational dynamics, and their relatedness to conversation outcomes.

## 7 Conclusion

We study the dynamics of conversations between crisis counselors and help seekers. Transformer-based models and the ChatGPT fail to predict whether the help seeker feels positive after the conversation. To better characterize counseling conversations, we integrate domain-specific knowledge, human-annotated utterance level features identifying counseling strategies, and LLM generated session level features portraying help seekers' perspectives. We show that ensembling additional features improves performance in predicting conversation outcomes. Analyses suggest that the features lead the model to focus more on the counselor's strategy-related utterances, and better represent lengthy conversations with session level features.

## Limitations

This paper shows the effectiveness of domain-specific knowledge and LLM generations in understanding counseling conversations. One of the major limitations of this work is the sub-optimal performance of LLM generated features. LLMs show great performances in many downstream tasks, especially when prompted with additional knowledge. Studying more approaches in prompt engineering to get more meaningful session level features with the help of human annotated features would be beneficial. Additionally, evaluating the quality of LLM generated features would improve the effectiveness of the features.

We did not fully explore the most efficient model

structure to combine utterance level features and session level features. Multi-task learning objectives for utterance level features and session level features to be benefited from each other used in Grespan et al. (2023) can be a future work we can consider.

Another approach is to minimize the use of LLMs and train a model to generate features. One of the future approaches can be adopting the On Policy Learning framework and training a tunable language model, such as FLAN-T5 (Chung et al., 2022), to generate session level features given a conversation, that maximizes the rewards (i.e. the outcome prediction performance).

The effectiveness of the domain knowledge in understanding counseling conversations was shown in one data source. Due to their sensitivity, access to such conversation is often limited, and experimenting with additional datasets would help demonstrate the generalizability of our approach.

## Ethics Statement

To the best of our knowledge, this work has not violated any code of ethics. As the data of this research includes human subjects and their behaviors, this research has been approved by the Institutional Review Board. The annotators as well as the researchers signed data confidentiality agreements and received an online education regarding ethical guidelines. The personal information of help seekers, such as names and street addresses, is anonymized and normalized prior to the researchers obtaining the data. Sample conversations described in 2.2 and 3.3 are synthetic examples. This paper illustrates a real example of a conversation snippet in Figure 1. We replace the details of the conversation with 'Context', and erased some parts from the help seeker's utterances that are unnecessary in evaluating the models. We provide the code for future reproducibility of the work. The data will not be publicly shared or posted anywhere.

## Acknowledgments

This project is mainly supported by the Children's Bureau (CB), Administration for Children and Families (ACF) of the US Department of Health and Human Services (HHS) as part of a financial assistance award in the amount of \$6 million with 100% percent funded by CB/ACF/HHS, and partially funded by NSF IIS-2048001 and DARPA CCU pro-

gram. The contents are those of the author(s) and do not necessarily represent the official views of, nor an endorsement by, CB/ACF/HHS/DARPA, or the US Government. For more information, please visit Administrative and National Policy Requirements.

## A Experiment Details

### A.1 Baseline experiments

All baseline models are first implemented to search the best set of parameters without incorporating any features. We have searched training batch size, learning rate, weight decay, and warm up steps for each of the BERT-family classifiers. The best working model was with DistilBERT-base-uncased sequence classifier with 16 training batch size, learning rate as  $3.44 \times 10^{-5}$ , weight decay as  $3.61 \times 10^{-6}$ , and warm up steps as 30. We also searched the optimal value of  $k$  for selecting utterances in the beginning and in the end, trying various number of turns. The performance gradually improves from encoding  $k = 0$  turn to  $k = 4$  turns, and it starts decreasing from encoding  $k \geq 5$  turns. The number of parameters for the classifier is about 67M and training the classifier with 10 epochs takes roughly 7 minutes on NVIDIA Tesla V100 GPU with 32GB RAM. As all experiments are conducted with 10-fold cross validation, the total running time of the model with a specific input type is around 70 minutes.

### A.2 Utterance-level Feature Codebook

Table 5 illustrates the codebook that the annotators have used for labeling utterance level features for

Abstract Category	Feature	Description
Emotional Attending	Paraphrasing	Repeats what was said by the help seeker in a way that hones the focus of the conversation.
	Interpreting	Offers a coherent overview of the situation and supports the help seeker to see new patterns or ideas.
	Reflecting feelings	Distills the help seeker’s feelings to support in identifying what is most bothering them about the situation.
	Validating	Affirms the help seeker, their feelings, and their thoughts to ensure that they are important.
	Unconditional positive regard	Provides support of the help seeker, regardless of their behavior or things that have been done to them.
	Open questions	Invites the help seeker to share about the experience that helps exploring the issues and eliciting details.
	Praise	Approves the help seeker or their behavior.
	Apology	Apologizes about technical difficulties or expresses their compassion for the help seeker and their situations.
Fact Related	Fact seeking	Asks questions about specific situations to get better understandings
	Fact giving	Provides factual knowledge based on the help seeker’s questions or their situations
Problem Solving	Asks what has been tried	Asks help seeker what they have tried to resolve the issue
	Asks about supports/resources	Asks help seeker which resources they tried or considered trying
	Advice/idea giving	Suggests solutions to resolve the help seeker’s issues
	Pushes advice/resources	Continuously mentions the same advice/idea regardless of the help seeker’s thoughts or previous experience
Resources	CPS	Suggests contacting CPS for help
	Counseling	Suggests getting counseling
	Police	Suggests contacting police and/or higher authorities
	Other online services	Suggests other online services

Table 5: Counseling strategy features used to annotate conversation instances.

System Message
You are a helpful assistant to help me understand the chat conversation between HelpSeeker and Counselor. Briefly answer questions about the conversation. + {Conversation}
<b>Instruction:</b> “Don’t answer in sentences and answer by only choosing one from the given categories”
<b>Categories:</b> Pre-defined feature examples described in Table 3
<b>Feature Generating Prompts</b>
<ul style="list-style-type: none"> <li>• Help seeker’s identity: “Who is the HelpSeeker? + {Instruction} + {Categories}”</li> <li>• Perpetrator’s identity: “Who is the perpetrator? + {Instruction} + {Categories}”</li> <li>• Type of abuse: “What is the type of the abuse or the stress? + {Instruction} + {Categories}”</li> <li>• Severity of abuse: “What is the nature and severity of the abuse or the stress? + {Instruction} + {Categories}”</li> <li>• Help seeker’s needs: “Why does the HelpSeeker come talk to the Counselor? + {Instruction} + {Categories}”</li> <li>• Counselor’s response: “How does the Counselor help the HelpSeeker? + {Instruction} + {Categories}”</li> <li>• Counselor’s strategies: “How does the Counselor explore the issue? + {Instruction} + {Categories}”</li> <li>• What’s been tried: “What are the things that have previously done by the HelpSeeker to resolve the situation? + {Instruction} + {Categories}”</li> <li>• Counselor’s advice: “What are the things suggested by the Counselor to resolve the situation? + {Instruction} + {Categories}”</li> <li>• Help seeker’s reaction: “What is the HelpSeeker’s reaction to the Counselor’s suggestion? + {Instruction} + {Categories}”</li> <li>• Counselor’s negative attitudes: “Are there any indications that the Counselor hurt the HelpSeeker’s feelings? + {Instruction} + {Categories}”</li> <li>• Help seeker’s negative attitudes: “Are there any indications that the HelpSeeker didn’t like the chat? Consider if they are being hopeless, doubtful, denial, dissatisfied, etc. + {Instruction} + {Categories}”</li> </ul>
<b>Prompts for Summaries</b>
<ul style="list-style-type: none"> <li>• Plain summary: “Summarize the conversation in 150 words.”</li> <li>• Summary with stance: “Summarize the conversation in 150 words, focusing on whether the help seeker would have felt more positive after the conversation.”</li> </ul>
<b>Prompts for Conversation Outcome Prediction</b>
Would the help seeker have felt more positive after the conversation? Answer ‘0’ if they would not feel more positive at all, and answer ‘1’ otherwise.

Table 6: LLM prompt design for obtaining session level features, summaries, and conversation outcome prediction.

conversation instances in  $\mathcal{D}_{small}$ . The column **Feature** and **Description** shows a set of fine-grained 18 classes we used for annotation and the description of each feature. In order to apply semi-supervised approach for annotating utterance level features in  $\mathcal{D}_{large}$ , the utterance level feature identification should be accurate, yet using a 18-class feature set does not exhibit reliable results. To this end, we categorize features into 4 groups that are described in the **Abstract Category** column. We apply this 4-class feature group to train an utterance level feature predictor model and use the model to automatically annotate  $\mathcal{D}_{large}$ .

### A.3 LLM prompts for session level features

All session level features are obtained through asking one question at a time and no questions are asked as a chain. This is to minimize potential issues of ChatGPT being hallucinated by its own previous generations. Table 6 describes the prompts we provide to the ChatGPT model. We also illustrate prompts that are used to generate summaries about the conversation, as well as prompts that are used to evaluate the ChatGPT model’s performance on conversation outcome prediction.

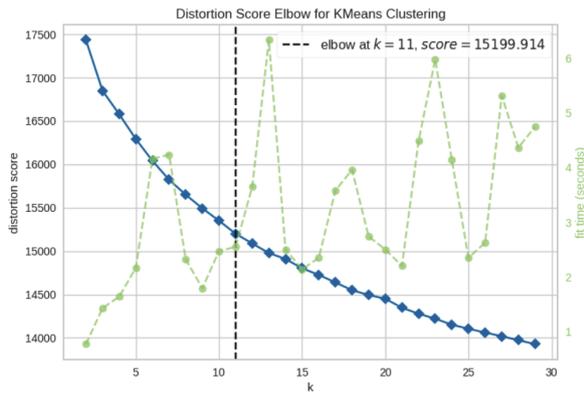

Figure 3: Distortion values of different number of clusters. Blue line indicates distortion values

#### A.4 Session level features to natural language explanation

Given a set of session level features, we use a pre-defined template to convert the features into natural language explanation. We tried an alternative approach to convert features into natural language explanation by prompting ChatGPT; we prompt ChatGPT to generate explanations using a given set of features. However, the conversation outcome prediction models better fit when we use templates to convert features, thus our final method becomes using templates. Following paragraph is the template we used.

An [help seeker's identity] is seeking for [help seeker's needs] regarding the situation where there has been [type and severity of abuse] by [perpetrator's identity]. The counselor explores the issues with [counselor's strategies] and focuses on [counselor's response]. The help seeker tried [what's been tried] to resolve the situation and the counselor suggests [counselor's advice]. About the suggestion, the help seeker is [help seeker's reaction]. In the chat, the help seeker shows [help seeker's negative attitudes]. The counselor's attitudes seems to be [counselor's negative attitudes] in the conversation.

## B Clustering results

To qualitatively analyze the difference between plain summary and summary with stance, we perform clustering on the sentences generated by these two approaches. We first combine all summaries from the two approaches, split the sentences, encode sentences using SentenceTransformers (Reimers and Gurevych, 2019), and perform  $k$ -means clustering. The optimal  $k$  is derived by comparing distortion values of different number of clusters (Figure 3).

Figure 4 illustrates clustered results after mapping sentence representations into 2d through T-distributed Stochastic Neighbor Embedding (t-SNE). The closest items to each cluster centroid and the distribution of two different summaries in each cluster are described in Table 7.

<p><b>Cluster 0:</b> Help seeker shares negative emotions Summary: 47%, Stance: 53%</p> <ul style="list-style-type: none"> <li>● HelpSeeker reaches out to the Counselor, expressing their struggles with depression, anxiety, and suicidal thoughts.</li> <li>● HelpSeeker expresses their depression and feeling of helplessness.</li> <li>● HelpSeeker expressed feelings of sadness, wanting to end their life, and self-harm tendencies.</li> </ul>	<p><b>Cluster 1:</b> Counselor empathizing Summary: 40.67%, Stance: 59.33%</p> <ul style="list-style-type: none"> <li>● The Counselor provided support and empathized with the HelpSeeker's concerns.</li> <li>● The Counselor empathizes with the situation, reassuring HelpSeeker and offering support.</li> <li>● The counselor empathizes with HelpSeeker's situation and offers support.</li> </ul>
<p><b>Cluster 2:</b> CPS as a solution Summary: 50%, Stance: 50%</p> <ul style="list-style-type: none"> <li>● The counselor provides the CPS phone number and advises HelpSeeker to explain their situation honestly.</li> <li>● The counselor provides the CPS number and encourages HelpSeeker to contact them to document the situation.</li> <li>● The counselor sympathized and encouraged HelpSeeker to contact Child Protective Services (CPS).</li> </ul>	<p><b>Cluster 3:</b> Parents being abusive Summary: 57.33%, Stance: 42.67%</p> <ul style="list-style-type: none"> <li>● HelpSeeker explains their situation, detailing how their mother has physically abused them in the past.</li> <li>● During the conversation, HelpSeeker shares concerns about their mom's physical abuse and erratic behavior.</li> <li>● HelpSeeker reveals that their mother is defensive about her actions, believing that she has never abused them.</li> </ul>
<p><b>Cluster 4:</b> Help seeker's positivity Summary: 0%, Stance: 100%</p> <ul style="list-style-type: none"> <li>● It is likely that HelpSeeker felt more positive after the conversation, as they were provided with validation, guidance, and resources to seek help.</li> <li>● Overall, it is likely that HelpSeeker would have felt more positive after the conversation due to receiving validation, resources, and a supportive response from the counselor.</li> <li>● Based on the conversation, it is likely that HelpSeeker would have felt more positive after the conversation as they received empathy, understanding, and resources for help.</li> </ul>	<p><b>Cluster 5:</b> Help seeker expressing gratitude Summary: 60%, Stance: 40%</p> <ul style="list-style-type: none"> <li>● The HelpSeeker expresses gratitude for the help and the conversation concludes with the Counselor offering further assistance if needed.</li> <li>● HelpSeeker expresses gratitude, and the conversation concludes with the Counselor encouraging HelpSeeker to reach out for further assistance if needed.</li> <li>● HelpSeeker expresses gratitude and the conversation ends on a positive note, with the counselor offering further assistance if needed.</li> </ul>
<p><b>Cluster 6:</b> Reason for seeking help Summary: 57.33%, Stance: 42.67%</p> <ul style="list-style-type: none"> <li>● HelpSeeker reached out to Counselor to discuss their concerns about being emotionally abused.</li> <li>● HelpSeeker reaches out to the counselor to understand what constitutes abuse.</li> <li>● HelpSeeker reached out to the Counselor seeking advice regarding their experience with child abuse.</li> </ul>	<p><b>Cluster 7:</b> Different types of concerns Summary: 56.67%, Stance: 43.33%</p> <ul style="list-style-type: none"> <li>● HelpSeeker expresses concern and seeks advice on whether they should report the situation.</li> <li>● HelpSeeker is unsure whether they should report the situation.</li> <li>● HelpSeeker asked if they could report the incident and get help.</li> </ul>
<p><b>Cluster 8:</b> Parents being abusive Summary: 60%, Stance: 40%</p> <ul style="list-style-type: none"> <li>● HelpSeeker explained that their mom constantly belittles them and their dad has physically harmed them in the past.</li> <li>● They also mentioned experiencing abuse and feeling scared of their mom.</li> <li>● They explain that they are having issues with their family, particularly with their disrespectful mother.</li> </ul>	<p><b>Cluster 9:</b> Reason for seeking help Summary: 53%, Stance: 47%</p> <ul style="list-style-type: none"> <li>● HelpSeeker reached out to the counselor seeking advice and clarification on their parents' behavior.</li> <li>● HelpSeeker reaches out to the Counselor with concerns about their mother's behavior.</li> <li>● HelpSeeker reached out to the counselor to discuss the problems they were having with their mom.</li> </ul>
<p><b>Cluster 10:</b> CPS as a solution Summary: 53%, Stance: 47%</p> <ul style="list-style-type: none"> <li>● The Counselor provides guidance to HelpSeeker and suggests contacting Child Protective Services to report the situation.</li> <li>● Counselor acknowledges HelpSeeker's concerns and suggests contacting child protective services to report the situation.</li> <li>● Counselor advised HelpSeeker to document their observations and report the situation to Child Protective Services.</li> </ul>	

Table 7: Each cluster's topic, most representative situation examples, and the distribution of plain summary and summary with stance within the cluster.

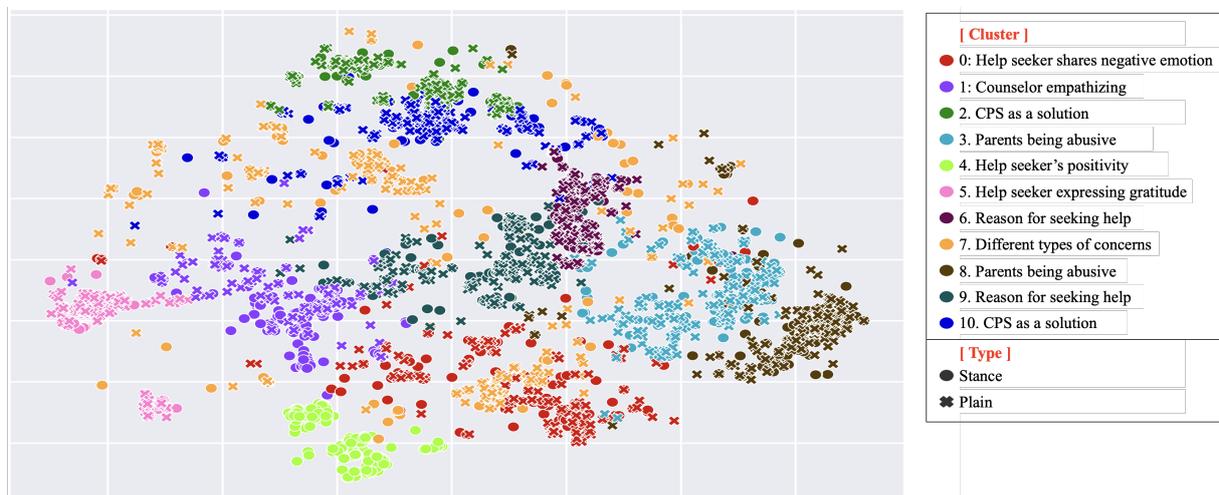

Figure 4: Clustered sentences from two types of summaries. In most case, plain summary and summary with stance produces similar aspects regarding the conversation. There are a few clusters where the portion of one summary type is meaningfully larger than the other type. Cluster 3, 5, 8 consists of around 60% of plain summary items, while cluster 1 has the opposite distribution. Cluster 4, describing the stance of the help seeker, only contains summary with stance items.

# Better Explain Transformers by Illuminating Important Information

## Abstract

Transformer-based models excel in various natural language processing (NLP) tasks, attracting countless efforts to explain their inner workings. Prior methods explain Transformers by focusing on the raw gradient and attention as token attribution scores, where non-relevant information is often considered during explanation computation, resulting in confusing results. In this work, we propose highlighting the important information and eliminating irrelevant information by a refined information flow on top of the layer-wise relevance propagation (LRP) method. Specifically, we consider identifying syntactic and positional heads as important attention heads and focus on the relevance obtained from these important heads. Experimental results demonstrate that irrelevant information does distort output attribution scores and then should be masked during explanation computation. Compared to eight baselines on both classification and question-answering datasets, our method consistently outperforms with over 3% to 33% improvement on explanation metrics, providing superior explanation performance. Our anonymous code repository is available at: <https://github.com/LinxinS97/Mask-LRP>

## 1 Introduction

Transformer (Vaswani et al., 2017) currently serves as the fundamental structure for state-of-the-art models (Kenton and Toutanova, 2019; Radford et al., 2019; Liu et al., 2020; Touvron et al., 2023a,b). The power of these models provides convincing results in multiple Natural Language Processing (NLP) tasks. However, building a robust Transformer-based model to assist trustworthy human decision-making processes requires an understanding of the internal mechanisms of the Transformers (Kovaleva et al., 2019; Jain and Wallace, 2019; Qiang et al., 2022a).

In NLP tasks, tokens are prevalently utilized to signify a word or a fragment of a word (also known

as a *subword*), serving as the input for Transformers. To comprehend the influence of input tokens on a Transformer, helping us to understand which part of input the Transformer is most interested in, a typical approach involves determining the *attribution score* of input tokens by leveraging the information captured by the attention matrix obtained from each attention head (Bach et al., 2015; Barkan et al., 2021; Voita et al., 2019; Chefer et al., 2021b,a). A high attribution score signifies that the input token likely plays a pivotal role in the model’s decision-making process for a specific class, output word, or answer index.

To derive attribution scores for each input token, recent approaches utilized information within a trained Transformer, such as input-gradients (Shrikumar et al., 2017; Ancona et al., 2019), raw attention matrices (Abnar and Zuidema, 2020) or the combination of input-gradients and attention matrix (Barkan et al., 2021; Qiang et al., 2022b). The underlying premise for those methods is that input token gradients reflect the token’s significance during backpropagation, while attention mechanisms capture the between-token interactions. However, both theoretical and empirical results (Chefer et al., 2021b; Qiang et al., 2022b; Ali et al., 2022) indicate that not all types of information embedded within the gradient and attention mechanisms contribute towards the explanations. They either fail to or can only partially aid in understanding which token primarily contributes to the Transformer’s decision-making process.

To solve this issue, we follow the line of work known as Layer-wise Relevance Propagation (LRP, Bach et al. (2015)) with refined information flow to derive compelling attribution scores for each token. The information flow within LRP parameterized by each attention head mirrors that of the Transformer, concentrating on distinct portions of the input tokens, and attention heads focusing on irrelevant information can disrupt this flow, causing

explanation confusion. We refine the information flow within LRP by illuminating the attention head that focuses on important information and reducing the attention head that zeroes in on less important information.

To achieve this, we illuminate the important attention head by adopting a head mask generated from dataset statistics. We first label the attention heads concentrating on a specific syntactic relationship as *syntactic* attention heads. Syntactic relations (e.g., nominal subject) are extensively utilized to define the relations between tokens in NLP (Voita et al., 2019), which establish a directional relation between two words. Furthermore, we designate the attention head that predominantly centers on a fixed relative position as a *positional* attention head, which reflects the internal feature (e.g., spatial position) of token embedding. We encapsulate *syntactic* and *positional* within a head mask, which we use to refine the information flow during the LRP process. To further reduce the irrelevant information, we obtain the attribution score by rolling out the relevance of the attention head from each attention blocks with the corresponding gradient (Chefer et al., 2021b).

To evaluate the performance of our method, we compared it with eight strong baselines across five classification datasets and two question-answering datasets. The results reveal that our method outperforms others in explanation performance, demonstrating a distinguished capacity to assign influential tokens from both interaction and internal perspectives. Furthermore, an ablation study uncovers that irrelevant information can obfuscate the LRP process, subsequently leading to a biased explanation of input tokens. The key contributions of our work can be summarized as follows:

1. We refine the information flow within the LRP process by illuminating two types of important information.
2. Through experiments, we demonstrated that irrelevant information hampers the LRP process.
3. Compared to previous state-of-the-art methods, our approach significantly improves explanation performance, achieving over 3.56% improvement in AOPC and LOdds for classification tasks and 33.02% for Precision@20 in question answering tasks.

## 2 Related Works

To explain a Transformer in NLP tasks, one common approach involves providing a post-hoc interpretable description of the Transformer’s behavior. This approach assists users in understanding which input tokens most significantly influence the model’s decision-making process. Abnar and Zuidema (2020) achieve this by leveraging the attention heads for defining more elaborate explanation mechanisms, while Wallace et al. (2019) and Atanasova et al. (2020) accomplish this by involving the Integrated Gradients or Input Gradients. Numerous models and domains have employed gradient methods such as Saliency Maps (Zhou et al., 2016; Barkan et al., 2021), Gradient $\times$ Input (Shrikumar et al., 2017; Srinivas and Fleuret, 2019; Hesse et al., 2021; Qiang et al., 2022b), or Guided Backpropagation (Zeiler and Fergus, 2014), and these methods have also been effectively transposed and applied to Transformers.

Concurrently, there have been several attempts to implement Layer-Wise Relevance Propagation (LRP, Bach et al. (2015)) in Transformers (Voita et al., 2019; Ali et al., 2022) and other attention-based models (Ding et al., 2017). LRP has been used to explain predictions of diverse models on NLP tasks, including BERT (Kenton and Toutanova, 2019). Other methodologies for LRP / gradient propagation in Transformer blocks can be found in (Chefer et al., 2021b,a), where the relevance scores are determined by combining attention scores with LRP or attention gradients.

Additionally, a few instances exist where perturbation-based methods have employed input reductions (Feng et al., 2018; Prabhakaran et al., 2019), aiming to identify the most relevant parts of the input by observing changes in model confidence or leveraging Shapley values (Lundberg and Lee, 2017; Atanasova et al., 2020). Furthermore, a line of work using tensor decomposition to decompose the attention matrix for a faithful Transformer explanation (Kobayashi et al., 2020, 2021; Modarressi et al., 2022; Ferrando et al., 2022).

## 3 Preliminary

### 3.1 Problem Formulation

This work focuses on post-hoc explanations of Transformer-based models, like BERT (Kenton and Toutanova, 2019; Liu et al., 2020) and GPT (Radford et al., 2019), across various NLP tasks. Given

a dataset  $D$  with each input  $x_i$  consisting of  $T$  tokens, we use a fine-tuned Transformer-based language model,  $f(\cdot; \theta)$ , composed of  $B$  self-attention blocks with  $M$  attention heads each. We extract each model layer’s output for analysis, with layer input denoted as  $x^{(n)}$  and  $n$  ranging from 1 to  $N$ . Here,  $x^{(N)}$  and  $x^{(1)}$  signify the model input and output, respectively, as information propagation starts from the output to the input.

We aim to understand the attribution of input  $x^{(N)} \in D$  to the output  $x^{(1)} \in \{c_1 \dots c_K\}$  ( $K$  denoting classification task classes or question answering task tokens). We seek an attribution function  $\mathbf{R}^{(N)} = R(x^{(N)})$  evaluating each token’s contribution to output  $x^{(N)}$ . An ideal  $\mathbf{R}^{(N)}$  assigns high attribution scores to influential tokens, causing output confidence to flatten or predictions to flip when these tokens are removed or masked.

### 3.2 Layer-wise Relevance Propagation

The Layer-wise Relevance Propagation (LRP, Bach et al. (2015)) is used to compute the attribution score  $\mathbf{R}^{(N)}$  of each input token, propagating relevance from the predicted class or index backward to the input tokens.

The LRP applies the chain rule to propagate gradients with respect to the output  $x^{(1)}$  at index  $c$ , denoted as  $x_c^{(1)}$ :

$$\nabla x_j^{(n)} = \frac{\partial x_c^{(1)}}{\partial x_j^{(n)}} = \sum_i \frac{\partial x_c^{(1)}}{\partial x_i^{(n-1)}} \frac{\partial x_i^{(n-1)}}{\partial x_j^{(n)}}, \quad (1)$$

where  $j$  and  $i$  are element indices in  $x^{(n)}$  and  $x^{(n-1)}$  respectively. The layer operation on two tensors  $\mathbf{X}$  and  $\mathbf{Y}$  is denoted as  $L^{(n)}$ , typically indicating the input feature map and weights for layer  $n$ . The relevance propagation follows the Deep Taylor Decomposition (Montavon et al., 2017):

$$\begin{aligned} R_j^{(n)} &= \mathcal{G}(\mathbf{X}, \mathbf{Y}, \mathbf{R}^{(n-1)}) \\ &= \sum_i X_j \frac{\partial L_i^{(n)}(\mathbf{X}, \mathbf{Y})}{\partial X_j} \frac{R_i^{(n-1)}}{L_i^{(n)}(\mathbf{X}, \mathbf{Y})}, \end{aligned} \quad (2)$$

with  $j$  and  $i$  denoting elements in  $R^{(n)}$  and  $R^{(n-1)}$  respectively. This equation obeys the conservation rule:

$$\sum_j R_j^{(n)} = \sum_i R_i^{(n-1)}. \quad (3)$$

We begin relevance propagation with  $R^{(0)}$  as a one-hot vector indicating the target class or index  $c \in x^{(1)}$ .

LRP presumes non-negative activation functions and is incompatible with functions outputting both positive and negative values, like GELU (Hendrycks and Gimpel, 2016). As Chefer et al. (2021b) done, we overcome this by filtering out negative values and selecting the positive subset of indices  $q = \{(i, j) | x_i w_{ij} \geq 0\}$  for relevance propagation:

$$\begin{aligned} R_j^{(n)} &= \mathcal{G}(x, w, q, R^{(n-1)}) \\ &= \sum_{\{i | (i, j) \in q\}} \frac{x_j w_{ji}}{\sum_{\{j' | (j', i) \in q\}} x_{j'} w_{j'i}} R_i^{(n-1)}. \end{aligned} \quad (4)$$

## 4 Layer-wise Relevance Propagation Through Important Attention Head

In this work, we empirically show that irrelevant information can detrimentally impact the LRP process. Therefore, our focus should be directed toward the important information while concurrently eliminating irrelevant information within the LRP process. In this section, we initially classify two kinds of important information (Sec.4.1), followed by introducing the method to extract this information in each layer (Sec.4.2). Subsequently, we illustrate the technique of concentrating on the important information extracted during Layer-wise Relevance Propagation (LRP, Sec. 4.3).

### 4.1 Important Information Flows in Transformer

Understanding Transformer-based models in NLP tasks entails grasping the important information each attention head prioritizes. This information in an input sentence comprises internal and interaction information (Voita et al., 2019; Qiang et al., 2022b). Interaction information explores if Transformer’s encoder heads focus on tokens tied to core syntactic relationships, while internal information refers to an input where an attention head focuses on a fixed position for token embedding (Voita et al., 2019). In this work, to capture the above types of information, we identify two functions that attention heads might be playing: (1) syntactic: the head points to tokens in a specific syntactic relation, and (2) positional: the head points to a specific relative position. Not all syntactic relations are suitable for defining the core component of a sentence. De Marneffe et al. (2014) classifies the syntactic relations into nominal, clauses, modifier words, and function words. While nominal (subject,

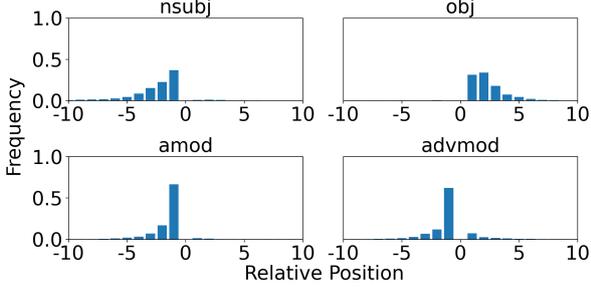

Figure 1: Distributions of the relative positions dependent for different syntactic relations in SST2.

object) and modifier words (adverb, adjectival modifier) are frequent, others like vocatives (common in conversations), expletives (e.g., "it" and "their" in English), and dislocated elements (frequent in Japanese) don't define a sentence's core and explain on them can confuse human understanding. Therefore, we identify four core syntactic relations: nominal subject (*nsubj*), direct object (*obj*), adjectival modifier (*amod*), and adverbial modifier (*advmod*), which contains the core information of a whole sentence. The selected syntactic relations establish directional links between two words or linguistic units. For example, in "*The car is red*", *car* is the *nsubj* target for *red*. Hence, in LRP, important information the relevance contains of a layer input  $x^{(n_b)}$  in the self-attention block  $b$  at layer  $n_b$  can be decomposed as:

$$\mathbf{R}_{\text{imp}}^{(n_b)} = \mathbf{R}_{\text{synt}}^{(n_b)} + \mathbf{R}_{\text{pos}}^{(n_b)}, \quad (5)$$

where  $\mathbf{R}_{\text{imp}}^{(n_b)}$  denotes the important information,  $\mathbf{R}_{\text{synt}}^{(n_b)}$  and  $\mathbf{R}_{\text{pos}}^{(n_b)}$  the information from syntactic relations and relative positions, respectively. The next section will detail preserving important information in the LRP process by identifying the important attention heads.

## 4.2 Identifying Important Heads

To illuminate the influence of the attention heads that are oriented towards important information, we create a head mask denoted as  $\mathcal{M} \in \mathbb{R}^{B \times M}$  by combining two separate masks:  $\mathcal{M}_{\text{synt}}$  and  $\mathcal{M}_{\text{pos}}$ . The mask  $\mathcal{M}$  is constructed as follows:

$$\mathcal{M} = \mathcal{M}_{\text{synt}} + \mathcal{M}_{\text{pos}}. \quad (6)$$

$\mathcal{M}_{\text{synt}}$  represents the syntactic mask generated based on the statistical analysis of syntactic relations within each text, while the positional mask  $\mathcal{M}_{\text{pos}}$  is derived from the positional analysis of the

specific Transformer-based model chosen for the study.

**Syntactic mask.** We first obtain the distribution of the  $k$ -th syntactic relation at each token position, denoted as  $\lambda_k$ . Here,  $\lambda_k^i$  represents the probability of the  $k$ -th syntactic relation appearing at position  $i$  (as depicted in Fig. 1). The attention head mask for syntactic relations, denoted as  $\mathcal{M}_{\text{synt}}^{(b,m)}$ , can be derived as follows:

$$\mathcal{M}_{\text{synt}}^{(b,m)} = \sum_{k \in K} \mathbb{1}_{\{\alpha_k^{(b,m)} > \max(\lambda_k) + \xi_{\text{synt}}\}}, \quad (7)$$

where  $K = \{\text{nsubj}, \text{obj}, \text{amod}, \text{advmod}\}$  represents the set of core syntactic relations,  $\alpha_k^{(b,m)} \in [0, 1]$  denotes the frequency of the  $m$ -th attention head at block  $b$  assigning its highest attention weight to the  $k$ -th syntactic relation. The threshold  $\xi_{\text{synt}}$  determines the level of probability at which an attention head is considered syntactic relation-specific. In this work, we set  $\xi_{\text{synt}} = 0.1$  to ensure that the selected attention head is not solely focused on a specific token position but exhibits a substantial probability of capturing syntactic relations.

**Positional mask.** We also examine attention heads that exhibit a high degree of focus on specific relative positions (e.g., ...,  $-1, +1, +2, \dots$ ). We refer to these attention heads as "positional" if, most of the time, their maximum attention weight is assigned to a specific relative position. To identify these attention heads, we utilize a positional mask denoted as  $\mathcal{M}_{\text{pos}}^{(b,m)}$ , which collects the indices of attention heads that satisfy the positional criteria. The positional mask is defined as follows:

$$\mathcal{M}_{\text{pos}}^{(b,m)} = \sum_{i \in I} \mathbb{1}_{\{\alpha_i^{(b,m)} > \xi_{\text{pos}}\}}, \quad (8)$$

where  $\alpha_i^{(b,m)} \in [0, 1]$  denotes the frequency of the  $m$ -th attention head at block  $b$  assigning its highest attention weight to the  $i$ -th relative position,  $I = \{\dots, -1, +1, \dots\}$  denotes the set of relative positions and  $\xi_{\text{pos}}$  is set to 0.8, as previously mentioned, to ensure that we capture attention heads primarily focusing on the positional information.

## 4.3 Layer-wise Relevance Propagation Through Important Heads

To gain deeper insights into the important information within the Transformer model, we specifically focus on the Layer-wise Relevance Propagation

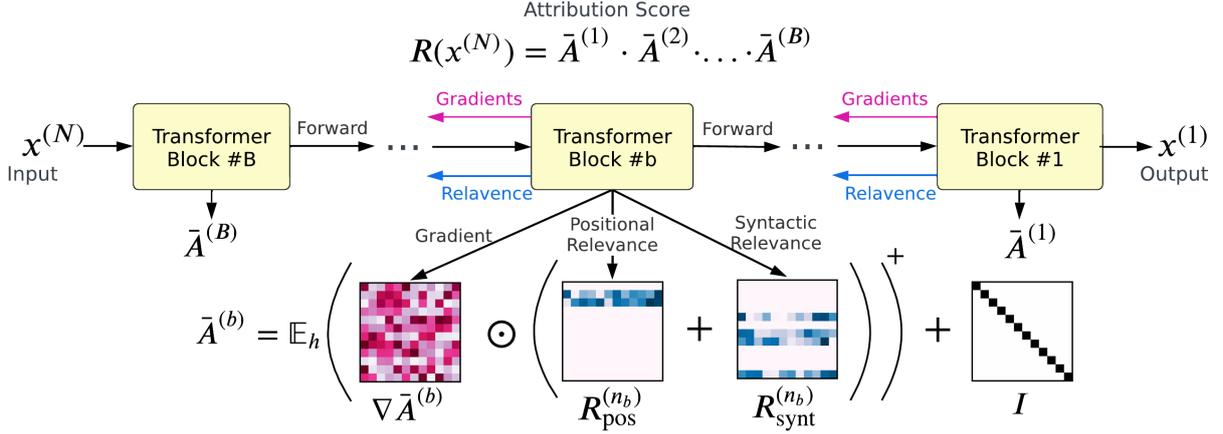

Figure 2: Illustration of our method. Gradients and relevance are propagated through the Transformer block from the final layer to the first layer. We extract two types of important information during the LRP process in all blocks by identifying the important heads.

(LRP) process between important attention heads across different layers and obtain the final attribution score. The process of our proposed method is illustrated in Fig. 2.

According to the type of information a relevance contains, the relevance of each attention head in the self-attention block at layer  $n_b$  can be defined as a combination of two types of relevance w.r.t. attention heads: important relevance and irrelevant relevance. Recalling the Eq. (2) and (5), we have:

$$\begin{aligned} \mathbf{R}^{(n_b)} &= \mathcal{G}(\mathbf{X}, \mathbf{Y}, \mathbf{R}_{\text{imp}}^{(n_b-1)} + \mathbf{R}_{\text{others}}^{(n_b-1)}) \\ &= \mathcal{G}(\mathbf{X}, \mathbf{Y}, \mathbf{R}_{\text{synt}}^{(n_b-1)} + \mathbf{R}_{\text{pos}}^{(n_b-1)} + \mathbf{R}_{\text{others}}^{(n_b-1)}), \end{aligned} \quad (9)$$

in each Transformer block. Here,  $\mathbf{R}_{\text{others}}^{(n_b-1)}$  corresponds to the relevance output from attention heads that are not specific to important information. To highlight the important relevance  $\mathbf{R}_{\text{imp}}^{(n_b-1)}$  in the LRP process, we employ the  $b$ -th block's mask  $\mathcal{M}^{(b)}$  obtaining from Eq. (6):

$$\mathbf{R}^{(n_b)} := \mathbf{R}_{\text{synt}}^{(n_b)} + \mathbf{R}_{\text{pos}}^{(n_b)} = \mathcal{G}(\mathbf{X}, \mathbf{Y}, \mathcal{M}^{(b)} \mathbf{R}^{(n_b-1)}).$$

To keep the conservation after adopting the mask, we apply normalization to  $\mathbf{R}_{\text{synt}}^{(n_b)}$  and  $\mathbf{R}_{\text{pos}}^{(n_b)}$  as follows:

$$\begin{aligned} \mathbf{R}_{\text{synt}}^{(n_b)} &:= \mathbf{R}_{\text{synt}}^{(n_b)} \frac{|\sum \mathbf{R}_{\text{synt}}^{(n_b)}|}{|\sum \mathbf{R}^{(n_b)}|} \cdot \frac{\sum \mathbf{R}^{(n_b-1)}}{\sum \mathbf{R}_{\text{synt}}^{(n_b)}}, \\ \mathbf{R}_{\text{pos}}^{(n_b)} &:= \mathbf{R}_{\text{pos}}^{(n_b)} \frac{|\sum \mathbf{R}_{\text{pos}}^{(n_b)}|}{|\sum \mathbf{R}^{(n_b)}|} \cdot \frac{\sum \mathbf{R}^{(n_b-1)}}{\sum \mathbf{R}_{\text{pos}}^{(n_b)}}. \end{aligned}$$

The normalization step ensures the conservation rule is maintained, i.e.,  $\sum \mathbf{R}_{\text{synt}}^{(n_b)} + \sum \mathbf{R}_{\text{pos}}^{(n_b)} = \sum \mathbf{R}^{(n_b-1)}$ . Note that we have omitted the subscript of the index (e.g.,  $i, j$ ) to enhance readability.

We output the final attribution  $\mathbf{R}^{(N)}$  by leveraging the rollout of weighted attention relevance (Chefer et al., 2021b) of each block  $b$ :

$$\bar{\mathbf{A}}^{(b)} = \mathbb{E}_h \left( \nabla \mathbf{A}^{(b)} \odot \left( \mathbf{R}_{\text{synt}}^{(n_b)} + \mathbf{R}_{\text{pos}}^{(n_b)} \right) \right)^+ + \mathbf{I} \quad (10)$$

$$\mathbf{R}(x^{(N)}) = \bar{\mathbf{A}}^{(1)} \cdot \bar{\mathbf{A}}^{(2)} \cdot \dots \cdot \bar{\mathbf{A}}^{(B)}, \quad (11)$$

where  $\odot$  denotes the Hadamard product,  $\mathbf{A}^{(b)} = \text{softmax}(\mathbf{Q}^{(b)} \cdot \mathbf{K}^{(b)\top} / \sqrt{d_h})$  is the attention matrix obtain from query  $\mathbf{Q}$  and key  $\mathbf{K}$  in block  $b$ , and  $\nabla \mathbf{A}^{(b)}$  denotes the corresponding gradient. We use the superscript  $a^+$  to denote the operation  $\max(0, a)$ .

## 5 Experiment

### 5.1 Experiment Setup

**Implementation details.** For the classification task, we use pretrained BERT<sub>base</sub> (Kenton and Toutanova, 2019) with a 512 token input limit and attribute the [CLS] token as the classifier input. For question answering, we compare our method with three baselines using pretrained BERT<sub>base</sub>, GPT-2 (Radford et al., 2019), and RoBERTa (Liu et al., 2020), assessing the effect of model scale and tokenizer on information flow. We evaluate the attribution of the start and end answer indices.

Our model-agnostic method can apply to various Transformer-based models with minimal modifications. We obtain all results from the validation set

across all methods, focusing on the post-hoc explanation with fixed model parameters. Variance is limited to the baseline using a randomly generated mask.

**Datasets.** We choose the validation set on seven datasets across the sentiment classification: SST-2 (Socher et al., 2013), IMDB (Maas et al., 2011), Yelp Polarity (Zhang et al., 2015), duplicated question classification: QQP (Chen et al., 2018), natural language inference: MNLI (Williams et al., 2018) and question answering: SQuADv1 (Rajpurkar et al., 2016) and SQuADv2 (Rajpurkar et al., 2018) to evaluate all methods. SST-2, IMDB, and Yelp Polarity take a single sentence as input, while QQP and MNLI use a pair of sentences for their target. Specifically, we extract the data marked as *duplicate* (with ground truth label 1) in QQP for evaluation. Details of the model and datasets are in Appendix C.

**Evaluation metrics.** We use AOPC and LOdds for classification evaluation, and precision@20 for question-answering evaluation. To evaluate post-hoc explanation interpretability in a classification task, we measure model confidence for a specific class before and after masking influential tokens, using both linear (AOPC) and non-linear (LOdds) metrics (Qiang et al., 2022b). AOPC and LOdds aim to detect the change of confidence before and after the influential tokens are removed, which are formularized as:

$$\text{AOPC}(k) = \frac{1}{T} \sum_{t=1}^T f_{\hat{y}}(\mathbf{x}_i; \boldsymbol{\theta}) - f_{\hat{y}}(\tilde{\mathbf{x}}_i^k; \boldsymbol{\theta}), \quad (12)$$

$$\text{LOdds}(k) = \frac{1}{T} \sum_{t=1}^T \log \frac{f(\tilde{\mathbf{x}}_i^k; \boldsymbol{\theta})}{f(\mathbf{x}_i; \boldsymbol{\theta})}, \quad (13)$$

where  $\tilde{\mathbf{x}}_i^k$  denotes the top- $k\%$  masked input tokens ranked by the attribution score  $R(\mathbf{x}_i^{(N)})$ .  $f_{\hat{y}}(\cdot; \boldsymbol{\theta})$  denotes the model’s max confidence w.r.t label  $\hat{y}$ . Furthermore, we use precision@20 to evaluate the question answering task (SQuADv1 and SQuADv2). In QA tasks, precision@20 will not introduce bias because it will not remove the ground truth answer from the input, and the model that has a low precision@20 means that the model cannot capture a correct mapping between the answer part and the ground truth index.

**Hyperparameters** In this work, we use two hyperparameters:  $\xi_{\text{synt}}$  and  $\xi_{\text{pos}}$  for the corresponding

masks. As we mentioned in the main context, we choose 0.1 for  $\xi_{\text{synt}}$  and 0.8 for  $\xi_{\text{pos}}$ . One reason why we choose these values is that we empirically found that the highest frequency for the syntactic relations is almost lower than 0.7 for a specific relative position. Therefore,  $\xi_{\text{synt}} = 0.1$  ensure the syntactic mask effectively filters out the attention head, which is focusing on irrelevant information, or just focusing on a specific position, and  $\xi_{\text{pos}} = 0.8$  help us to capture the rest attention heads that are focusing mainly on a specific relative position, which is filtered by the syntactic mask. Although the two masks are complementary, many attention heads still focus on various relative positions so that we cannot identify their function and mark them as irrelevant attention heads.

## 5.2 Baselines

We categorize eight baselines into three groups based on their characteristics with one additional random baseline:

**Attention maps** : **RawAtt** (Abnar and Zuidema, 2020) uses the mean attention weights from the final Transformer block as attribution scores, while **Rollout** (Abnar and Zuidema, 2020) rolls out average attention weights from all Transformer blocks.

**Relevance-based** : **LRP** (Bach et al., 2015) uses output-to-input layer relevance as attribution scores. **PartialLRP** (Voita et al., 2019) calculates relevance at the model’s final layer. **GAE** (Chefer et al., 2021a) propagates attention gradients to the final layer to obtain attribution scores.

**Gradient-based** : **CAM** (Zhou et al., 2016) and **GradCAM** (Barkun et al., 2021) use the final layer gradient and its weighted version by final layer attention respectively as attribution scores. **AttCAT** (Qiang et al., 2022b) combines the summation of attention weight from each Transformer block with input gradient.

In addition, we include **Random**, a baseline using a randomly generated mask (maintaining the same mask rate, i.e.,  $\|\mathcal{M}_{\text{random}}\| = \|\mathcal{M}_{\text{ours}}\|$ , as our method) to show that our method effectively identifies the crucial head in the Transformer model.

## 5.3 Results

We assessed the explanation performance of each method within classification tasks by computing mean AOPC and LOdds across five benchmark

Methods	SST-2		IMDB		Yelp		MNLI		QQP	
	AOPC $\uparrow$	LOdds $\downarrow$								
RawAtt	0.374	-0.992	0.354	-1.593	0.376	-1.513	0.135	-0.399	0.447	-5.828
Rollout	0.337	-0.911	0.334	-1.456	0.244	-0.770	0.137	-0.396	0.437	-5.489

Table 1: AOPC and LOdds results of all methods in explaining BERT<sub>base</sub> model on each dataset. The best results are marked in bold. Note that a method with high AOPC and low LOdds is desirable, indicating a strong ability to mark influential tokens. The results of the Random mask are average and standard deviation between five runs. We also provide the comparison with SOTA tensor decomposition method in Appendix B.

Method	SQuADv1			SQuADv2		
	BERT <sub>base</sub>	GPT-2	RoBERTa	BERT <sub>base</sub>	GPT-2	RoBERTa
Rollout	4.62	5.86	8.04	6.15	5.54	5.87
RawAtt	36.33	28.97	45.61	4.69	27.85	18.09
AttCAT	31.44	17.53	47.32	18.81	16.99	23.39
Ours	<b>52.97</b>	<b>51.62</b>	<b>67.31</b>	<b>27.03</b>	<b>49.63</b>	<b>56.41</b>

Table 2: Precision@20 results of the selected explanation methods on SQuAD datasets. Higher Precision@20 is better, indicating the marked influential tokens highly overlap with the answer text.

datasets, detailed in Tab.1. Remarkably, the performance across all post-hoc explanation methods remained stable, independent of random initialization, except for a randomly initialized mask method. Our approach generally surpassed others, achieving the highest AOPC and lowest LOdds, indicating superior accuracy in identifying influential tokens. Fig.3 displays performance curves against pruning rate  $k$ , endorsing our method’s performance at every rate. It consistently outperformed gradient-based methods, particularly in handling lengthy token lists. Attention information from larger matrices often includes irrelevant details that assign high attribution to non-influential tokens, reducing the quality of explanations (see Sec.5.4 for more). For the question-answering task, we evaluated Precision@20 on two SQuAD datasets. As per Tab.2, our method consistently outperformed the baselines, demonstrating accurate attribution to influential answer tokens.

#### 5.4 Assessing the Impact of Important and Irrelevant Information

In this section, we seek to address two key questions: (1) does our method effectively identify the

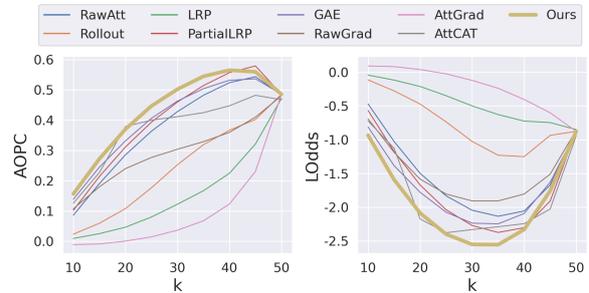

Figure 3: AOPC and LOdds scores of different methods in explaining BERT<sub>base</sub> against the corruption rate  $k$  on SST-2. Note that higher AOPC and lower LOdds scores are better.

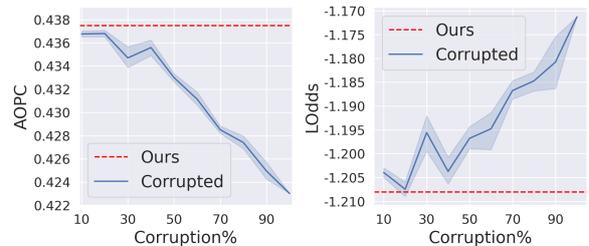

Figure 4: Comparison before and after corrupting the generated mask on SST-2. The blue line combines the solid line (average values) and shadow areas (standard deviation). The method’s ability to explain becomes dropped after adding corruption.

attention head that focuses on important information? and (2) does the residual, irrelevant information that other heads concentrate on adversely affect the explanation?

To answer the first question, we carry out an ablation study where we replace our mask with a randomly generated mask, maintaining the same mask rate as discussed in Sec.5.2, to examine if this

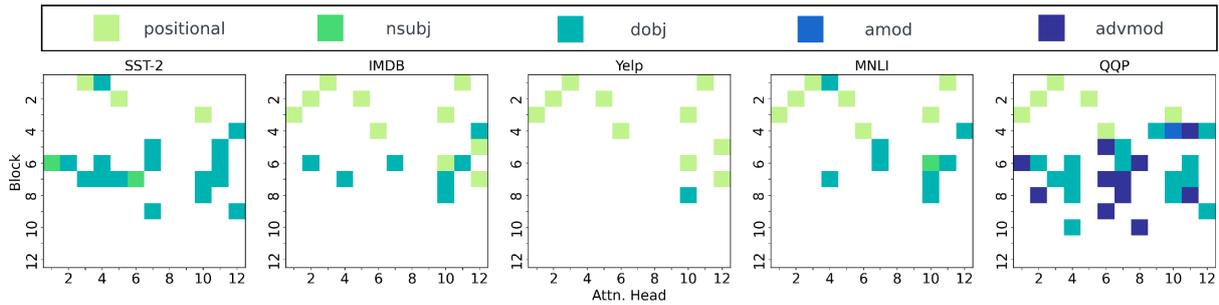

Figure 5: Different types of important heads in BERT<sub>base</sub> model cross different dataset. The  $x$ -axis denotes the position of the attention head, while the  $y$ -axis is the position of the Transformer block. It is obvious that attention heads in previous blocks tend to focus on simple internal information (e.g., position), while attention heads in later blocks tend to focus on the complex interactions between tokens (e.g., syntactic relations).

Attribution score for a positive classified sentence in SST-2	
Visualization of our attribution score, darker is higher.	
Ours [CLS] it ' s a charming and often affecting journey . [SEP]	
Visualization of our scores minus baseline scores.	
is positive and is negative, darker indicates higher absolute value.	
$\Delta$ Ours w/o $\mathcal{M}_{pos}$	[CLS] it ' s a charming and often affecting journey . [SEP]
$\Delta$ Ours w/o $\mathcal{M}_{synt}$	[CLS] it ' s a charming and often affecting journey . [SEP]
$\Delta$ Rollout	[CLS] it ' s a charming and often affecting journey . [SEP]
$\Delta$ RawAtt	[CLS] it ' s a charming and often affecting journey . [SEP]
$\Delta$ AttCAT	[CLS] it ' s a charming and often affecting journey . [SEP]
$\Delta$ LRP	[CLS] it ' s a charming and often affecting journey . [SEP]
$\Delta$ GAE	[CLS] it ' s a charming and often affecting journey . [SEP]

Figure 6: The comparison of attribution scores between our method (shown in the first line) and baselines on a positive classified sentence. Tokens highlighted in green represent those receiving more attention from our method than the baseline, while those in red signify the opposite. Our method emphasizes more on both internal and interaction information. We put results of other datasets in Appendix.D

alteration impacts the explanatory capacity. The results, as reported on line 12 in Tab.1, clearly demonstrate that our method consistently outperforms the variant with a randomly generated mask. This underscores that our method is capable of identifying a set of attention heads that can robustly explain the information flow within a Transformer.

For the second question, we derive our answer by collating findings from Tab.1 and Fig.4. We discover from Tab. 1 that even with a random mask, our method exhibits superior explanation performance than other relevance-based methods such as GAE because of the less focus on irrelevant information. This suggests that irrelevant information flow in the Transformer greatly affects the LRP, thereby confusing the explanation of input tokens. In addition, we conducted another ablation study where we randomly switched a portion of the remaining zeros in  $\mathcal{M}_{ours}$ . These zeros in the

mask correspond to the irrelevant information the Transformer focuses on, and their alteration can be interpreted as a corruption of the generated mask. If our method employs a 100% corrupted mask (a mask filled with ones), it degenerates to GAE. We observed the variance in explanation performance at different corruption rates (ranging from 10% to 100%) on SST-2, the results of which are displayed in Fig. 4. Notably, it is clear that the rate of performance decline is closely related to the corruption rate and ultimately converges to the performance of GAE. This evidence substantiates the notion that irrelevant information can interfere with the LRP process at each layer, thereby resulting in a perplexing explanation.

## 5.5 Visualizing and Analyzing Extracted Attention Heads

We visualize both  $\mathcal{M}_{synt}$  and  $\mathcal{M}_{pos}$  that our method extracted from BERT<sub>base</sub> according to each dataset. The resulting visualizations are presented in Fig. 5. We discovered that positional attention heads are predominantly concentrated in the earlier blocks, whereas syntactic attention heads tend to gather in the later blocks. This observed phenomenon suggests that Transformers initially learn the simplistic internal information and subsequently propagate this internal information to the subsequent layers. This aids the attention heads in these later layers in capturing the interaction information between tokens. Additionally, we found that during model training on more datasets with long input tokens, such as IMDB and Yelp, there are only a few heads with unipolar function, that is, a head focusing solely on a single pattern, and those heads are filtered by our mask. Yet, as the experiment results in Sec. 5.3 illustrate, the attribution scores assigned

Method	SST-2		QQP	
	AOPC	LOdds	AOPC	LOdds
Ours	0.438	-1.208	0.451	-6.001
Ours w/o $\mathcal{M}_{\text{pos}}$	0.438	-1.208	0.450	-6.001
Ours w/o $\mathcal{M}_{\text{synt}}$	0.437	-1.205	0.449	-5.998

Table 3: Explanation performance comparison of different masks. Only use  $\mathcal{M}_{\text{pos}}$  or  $\mathcal{M}_{\text{synt}}$  still have strong explanation performance.

solely by these heads are representative enough to provide a persuasive explanation. This implies that for binary classification tasks, the important information flow can be remarkably simple, even in the context of complex inputs. We also examine the explanation performance differences when using  $\mathcal{M}$  compared to solely utilizing  $\mathcal{M}_{\text{pos}}$  or  $\mathcal{M}_{\text{synt}}$  in Tab. 3. Interestingly, we discover that eliminating one type of mask doesn’t substantially impact the explanation performance. This can be attributed to the fact that a single mask type does not alter the ranking of output attribution but rather enriches its detail. Additional insights are provided in the subsequent paragraph.

To delve deeper into the attributions assigned by these important heads, we visualized the difference in attribution scores allocated by our method and other baseline methods in Fig. 6. The sentence, randomly selected from the SST-2 dataset and depicted in Fig.6, is annotated with a positive sentiment. Compared to attention-based methods (Rollout, RawAtt, AttCAT), our approach de-emphasizes less crucial tokens like *affecting*, emphasizing important ones like *charming*. Also, unlike relevance-based methods (LRP, GAE) that overlook *journey*, our method pays attention to it due to its link with *charming* via *and*. Thus, our method successfully extracts interaction information, attributing scores based on both single tokens’ internal information and their interplay.

## 6 Conclusion

In this study, we propose that irrelevant information in the gradient and attention hampers the explanation process. To address this, we improve the information flow in the LRP process by masking irrelevant attention heads. By illuminating the important information, we show that explanations become more convincing. Our method outperforms nine baseline methods in classification and question answering tasks, consistently delivering better explanation performance.

## Limitations

Though our method is model-agnostic, limitations in computational resources prevent us from fully exploring its implications for Large Language Models (LLMs) like LLAMA and LLAMA-2 (Touvron et al., 2023a,b), but we provided the implementation in our repository. We conjecture that LLMs may learn advanced interaction information surpassing the syntactic relationships we defined. This high-level interaction information could potentially allow LLMs to grasp the interplay between sentences or even broader structures like topics, complementing existing research on Transformers’ topic learning capability via self-attention mechanisms (Li et al., 2023). Additionally, while we’ve empirically shown that irrelevant information hinders the LRP process, the origins and contents of this irrelevant information remain obscure. We will delve deeper into the nature of such information in future work.

## A Why do we choose *nsubj*, *dobj*, *amod*, and *advmod*?

Many syntactic relations exist, but not all are suitable for defining the core component of a sentence. De Marneffe et al. (2014) classifies the syntactic relations into nominals, clauses, modifier words, and function words. While nominals (subject, object) and modifier words (adverb, adjectival modifier) are frequent, others like vocatives (common in conversations), expletives (e.g., "it" and "their" in English), and dislocated elements (frequent in Japanese) don't define a sentence's core and explain on them can confuse human understanding.

## B Extra experiment comparing with tensor decomposition method

We provide the comparison results between ours and the SOTA tensor decomposition method ALTC (Ferrando et al., 2022) in Table 4.

Methods	SST-2		IMDB		Yelp	
	AOPC $\uparrow$	LOdds $\downarrow$	AOPC $\uparrow$	LOdds $\downarrow$	AOPC $\uparrow$	LOdds $\downarrow$
ALTC	0.369	-0.866	0.342	-0.748	0.363	-1.428
Ours	<b>0.438</b>	<b>-1.208</b>	<b>0.392</b>	<b>-1.906</b>	<b>0.434</b>	<b>-1.898</b>

Table 4: AOPC and LOdds results of ALTC and ours in explaining BERT<sub>base</sub> model on SST-2, IMDB, and Yelp. The best results are marked in bold. Note that a method with high AOPC and low LOdds is desirable, indicating a strong ability to mark influential tokens.

## C Extra Implementation Details

**Environment** We run all experiments on the device with the following specs:

- System: Ubuntu 20.04.4 LTS
- CPU: Intel(R) Xeon(R) Platinum 8368 @ 2.40GHz (36 Cores / 72 Threads)
- GPU: NVIDIA A100 SXM4 40GB
- Memory: 230GB

With the above specs, we can complete the evaluation of one dataset within one hour by adopting the multi-process.

**Datasets** The task, amount of training, validation, and testing set numbers are shown in Tab. 5. Note that the dataset of IMDB and Yelp Polarity does not contain a validation set, so we use the test set for our experiment. Moreover, in QQP, data points are annotated with a binary label as *duplicated*

or *not duplicated*. If we remove the influential tokens in those data marked as *not duplicated*, the model's prediction does not change because the two questions remain different. Therefore, we select the data marked as *duplicated* for our experiments to see the changing of the model's prediction from *duplicated* to *not duplicated*.

Dataset	Task	Train	Valid	Test
SST-2	Classification	6,920	872	1,821
IMDB	Classification	25,000	-	25,000
Yelp Polarity	Classification	560,000	-	38,000
QQP	Question Paring	363,846	40,430	390,965
MNLI	Natural Language Inference	392,702	20,000	20,000
SQuADv1	Question Answering	87,599	10,570	9,533
SQuADv2	Question Answering	130,319	11,873	8,862

Table 5: Statistics for the benchmark dataset we used in this work. Note that IMDB and Yelp Polarity only contains training and test set.

**Models** In this work, we use different pretrained models archived in Hugging Face<sup>1</sup> for each task and modify them to adjust for LRP in our implementation. The models we use for different tasks are shown in Tab. 6. Note that there does not exist GPT-2 model pretrained on SQuADv2, so we adopt the model trained on SQuADv1 for SQuADv2 experiments, which also provides convincing performance.

Dataset	Model	Huggingface Repo
SST-2	BERT <sub>base</sub>	textattack/bert-base-uncased-SST-2
IMDB	BERT <sub>base</sub>	textattack/bert-base-uncased-imdb
Yelp	BERT <sub>base</sub>	abriceyh/bert-base-uncased-yelp_polarity
QQP	BERT <sub>base</sub>	modeltc/bert-base-uncased-qqp

	GPT-2	anas-awadalla/gpt2-span-head-finetuned-squad
	RoBERTa	2liridescent/roberta-base-finetuned-squad2-lwt

Table 6: Baseline models of different datasets and their Hugging Face repositories.

## D Additional Visualization Results

In this section, we provide visualization results of the attribution score difference in MNLI (Fig. 7, 8 and 9), IMDB (Fig. 10 and 11), and Yelp (Fig. 12 and 13), which include the task of classification of sentence pair and long text and each dataset, we randomly obtain a data from each class. For all of the above figures, as we mentioned in Fig. 6, tokens highlighted in green represent those receiving more attention from our method than the baseline,

# Testing the Depth of ChatGPT’s Comprehension via Cross-Modal Tasks Based on ASCII-Art: GPT3.5’s Native Abilities in Regard to Recognizing and Generating ASCII-Art Are Not Totally Lacking

David Bayani<sup>[000-0001-5811-6792]</sup>

Inpleo, Inc

david.bayani@inpleo.com

## Abstract

In the months since its release, ChatGPT and its underlying model, GPT3.5, have garnered massive attention, due to their potent mix of capability and accessibility. While a niche industry of papers have emerged examining the scope of capabilities these models possess, language — whether natural or stylized like code — has been the vehicle to exchange information with the network. Drawing inspiration from the multi-modal knowledge we’d expect an agent with true understanding to possess, we examine GPT3.5’s aptitude for visual tasks, where the inputs feature ASCII-art without overt distillation into a lingual summary. In particular, we scrutinize its performance on carefully designed image recognition and generation tasks.<sup>1</sup>

## 1 Introduction

ChatGPT has rapidly been adopted since its release in November 2022. This large language model (LLM) builds off of version 3.5 of the Generative Pre-trained Transformer model family developed by OpenAI, a child whose lineage has been marked by one massive step after another in regard to the size of LLM networks and their training data. Active utilization in industry (Marr, 2023) and education (Brown, 2023) are already a reality, though with growing concerns on the impacts on the workforce and academic integrity. Fueled by the model’s unprecedented popularity, accessibility, and power, a niche industry of papers attempting to rigorously investigate the abilities of ChatGPT — and the GPT3/GPT3.5 family underlying it more broadly — have materialized in short order. However, efforts thus far have almost exclusively focused on language-centric tasks (Liu et al., 2023). Filling this gap, we explore GPT3.5’s abilities to “see” and

“draw” — critically, doing so without first summarizing the inputs into a verbal description for the model. Our vehicle in order to conduct this analysis is ASCII-art (AArt) (O’Riordan, 2014). Ultimately, GPT3.5 demonstrates noticeable visual acumen. We uncover that GPT3.5 has subtly more vision-related acumen than has been appreciated.

## 2 Related Work

Most work on ChatGPT has considered canonical NLP problems (Zhang et al., 2023; Liu et al., 2023; Zhong et al., 2023). As pointed out in (Liu et al., 2023), ChatGPT’s diverse capabilities and accessibility have fueled a deluge of papers exploring its potential and limitations. The model has proven performant in areas ranging from poetry (Cushman, 2022) to programming (Sadik et al., 2023) to verbally-enabled room navigation (Joublin et al., 2023). Within this space, most relevant to us are efforts treating ChatGPT’s spatial reasoning, as well as those exploring its integration into multi-component pipelines geared toward text-based image recognition, manipulation, or generation.

Both (Deshpande and Szefer, 2023) and (Zhang et al., 2023) — examining, respectively, the network’s performance in an introductory engineering course and from surveying across the literature — observed limitations in GPT3.5’s abilities to handle “diagrams or figures” and to “perform spatial, temporal, or physical inferences”. Muddying their conclusions, however, are a subset of reported instances where the network produced AArt— but with major qualifiers of being rare and generic enough to likely be rote memorization.

There have been attempts to integrate recent GPT-family models into VQA (Yang et al., 2022; Bongini et al., 2022; Si et al., 2023; Yang et al., 2022; Chalvatzaki et al., 2023; Tiong et al., 2022; Li et al., 2023; Huang et al., 2023; Mu et al., 2023; Srivastava et al., 2023b), image generation (Yang

<sup>1</sup>An extended version of this write-up is available at: <https://arxiv.org/abs/2307.16806>.

et al., 2023; Maddigan and Susnjak, 2023; Nanwani et al., 2023; Qin et al., 2023; Todd et al., 2023), graph analysis (ex., layout descriptions, scene graphs, etc.) (Zhang, 2023; Wang et al., 2023a; Guo et al., 2023; Shi et al., 2023; Zhu et al., 2023; Bartolomeo et al., 2023), and in other problem settings where visual-content could play either input or output roles (Shen et al., 2023; Wu et al., 2023). The diversity of implementation-specifics notwithstanding, the takeaways are largely the same: these works either (1) prior to querying the LLM, summarize context verbally or in a human-readable data structure via different foundation model specifically engineered for image-related tasks or (2) modify the language models in question to explicitly include visual knowledge, often coupling this with additional training of parts that are woven intimately into the LLMs. For our purposes, adopting either strategy disqualifies a work from bearing fully on our main question. That is, many existing works simply “let GPT3.5 see” by either modifying it to the point of being a fundamentally different model, or giving it a seeing-eye dog (i.e., another foundation model that addresses all the seeing and manipulation). Each of (Ye et al., 2023), (Chen et al., 2023), and (Joublin et al., 2023) examine GPT3.5’s spatial reasoning, navigation, and interaction tasks, but yet again all exchanges were mediated through verbal descriptions of the world state and action space, though sparing the use of a separate foundation model to produce the words. We comment further on the nature of this distinction in Appendix A.

The aforementioned aside, some substantive works exist that somewhat resonate with our work.

Under the impetus of differentiating content generated by ChatGPT versus humans, (Wang et al., 2023b) curated questions that emphasized the areas where LLMs’ aptitude most differed — for better or worse — from that of a human. Among the eight tests considered, identification of AArt was one, exposing a patent gap between human and ChatGPT performance — 94% and 8% accuracy respectively on 50 cataloged drawings. In addition to the limited show-verbatim-and-describe nature of these trials, we highlight that all samples came from a public website existent for years before ChatGPT’s release, the ASCII Art Archive,<sup>2</sup> risking membership in GPT3.5’s training data; moreover, the images’

<sup>2</sup><https://web.archive.org/web/20180305160309/https://www.asciart.eu/>.

online popularity may predate their inclusion in the catalog. While 8% accuracy is not astounding, it is not nothing; questions remain as to how much is from memorization, actual recognition ability, and random chance.

Under similar inspiration, the massive, collaborative effort of the “BIG Benchmark” (Srivastava et al., 2023a) showcases 204 diverse tasks examining language model’s capabilities. Three such tasks nominally featured AArt, but all concerned the recognition of text that was “rendered” in that fashion. The only other germane task we saw was the “text navigation game”,<sup>3</sup> which featured a small input grid containing an AArt “maze”, requiring the models to verbally specify moves from the start to the goal; no instances of “success” were observed by any model for board sizes above 5-by-5, and moreover the authors made reference to success rates on smaller boards being on par with random movement. Overall, we find a lack of sufficient subtlety in the benchmark’s pertinent tasks, them failing to be sensitive enough — at least as explored — to detect all but the most obvious performance. Furthermore, probing specific to evaluating vision systems — such as robustness to rotation, noise or translation — were not carried out, leaving insights only at the high-level outcomes of the raw tests. Both of these aspects help distinguish our work from theirs, not to mention the fact that we examine generation of visual content in addition to its recognition.

Like us, (Dabkowski and Begus, 2023) study capabilities of OpenAI’s GPT model family, version 3.5 and 4 in their case,<sup>4</sup> using a series of prompts without additional training or system modifications. Their endeavor partially examined rudimentary AArt produced to explore the models’ recursive generation abilities — however, whether this is a “visual” task or essentially an algebraic computation is debatable. The authors note that certain examples displayed are likely memorized from training data, but also point out (rightfully) that the more exotic figures produced are less subject to this concern. Either way, the concern underscores the fact that their prompts for AArt did not (obviously) impose novelty-constraints on the output, thus failing to rule out preprepared responses as “correct”

<sup>3</sup>[https://github.com/google/BIG-bench/tree/main/bigbench/benchmark\\_tasks/text\\_navigation\\_game](https://github.com/google/BIG-bench/tree/main/bigbench/benchmark_tasks/text_navigation_game)

<sup>4</sup>Note that GPT4 is not relevant to our focus since that model was explicitly designed to include visual processing.

outputs. In contrast, our experiments require responses to correspond with unique, freshly generated structures provided in our prompts, reducing the feasibility of context-independent, pre-canned responses passing scrutiny.

Finally, we remark on a certain degree of “folk knowledge” about ChatGPT’s drawing abilities — for instance (Wetrorave, 2022; Arora, 2022; Blocks, 2022). However, exchanges in this category directly featuring AArt (i.e., not code for diagrams, etc.) were mostly sporadic acts, not systematic or deep explorations. A theme throughout is the appearance of AArt of reasonable quality, but occurring at inappropriate times in respect to the prompts — hallmarks of shallow memorization, repeating training examples without deeper, semantically-meaningful interpretation or modification. As a result, the casual consensus judges ChatGPT’s abilities in this regard as poor. We endeavor to perform more rigorous analysis than the loose folk-perceptions.

### 3 The ASCII-Art Used in Experiments

We use AArt of box diagrams (AADs) to nontrivially probe GPT3.5’s vision-related capabilities. We briefly share the inspiration for this particular choice, since we believe the observations valuable:

First, we realized that AADs are used as illustrations in many settings — e.g., electrical-circuit diagrams, placement charts, and flowcharts online. Indeed, mini-languages like PIC (Kernighan, 1982) exist to aid their creation, though manual drawing is rarely difficult. GPT3.5 may therefore have a substantial amount of varied training data available for these drawings, e.g., as part of Common-Crawl.<sup>5</sup> Additionally, owing to their common role as a visual aids accompanying verbal descriptions, these depictions likely have appreciable amounts of granular visio-lingual coupled data.

Second, we encountered quite promising results during early investigations into ChatGPT’s germane abilities. In a trial, we requested drawings of several town layouts, each with certain buildings and accompanying labels. Illustrations were generated that matched our specification, a feat not easily dismissed as mere memorization. Reasonable success continued during additional requests (e.g., for roads) that followed.

Following these leads, we have run experiments featuring randomly generated AADs to gauge Chat-

GPT’s aptitude in typical vision-related tasks: content recognition despite changes due to rotation, scale, “pixel” noise, and translation. If GPT3.5 can handle these tasks, then it suffices to say it is not *entirely* incapable of “doing well at AArt”, despite impressions held in folk knowledge.

#### 3.1 Generation of AADs

Our AADs start with a blank 24-by-24 character canvas to which boxes are progressively added. Per box, five values are needed: two values per lower-left and top-right vertex — all constrained to stay on canvas — and a name comprised of a single ASCII alphanumeric character which is optionally displayed. A box is added after two-phases: proposal then, as needed, rejection.

During proposal, a start position and length are chosen for each axis independently, the former uniformly over the canvas, the latter via draw from a Poisson distribution. Using  $\lambda = 8$  for the Poisson made reasonable illustrations with an appealing variation in layout and complexity — for instance, results can range from well-aligned rows of roughly uniform boxes, to nested complexes arranged in a scattered fashion. Lengths are required to be at least 3 — the minimum to fit a name and boundary lines — and are resampled until then.

In the rejection phase, we throw out boxes that run off the canvas or overlap existing boxes. Additionally, to reserve space for potential names, we reject boxes that are tightly nested in the corner of another box. Upon rejection, we sample a new box until either 1000 tries have failed or 14 boxes are established, after which results go forward to the next phase.

Having abstractly determined box placement, we place characters to reflect it. We attempt reasonable diligence in ensuring the network cannot cheat through trivial illustration artifacts. As one precaution, for experiments that require comparing multiple AADs, each option has the same number of each type of character present.<sup>6</sup> Proposed AADs that fail to have character counts matching earlier drawings are rejected; we then make another generation attempt. To improve acceptance rates, we clip box lengths post-draw to ensure that the number of proposed characters never exceeds constraints.

Box boundaries are drawn using dashes (“-”) for the horizontal (x) length and pipe symbols (“|”) for the vertical (y) length. We considered adding “+” at

<sup>5</sup><https://commoncrawl.org/big-picture/>

<sup>6</sup>An exception in some trials being added noise characters.

vertices, but character-matching constraints would then require all drawings to have an equal number of boxes — a needless restriction on the possible outcomes. Instead, corners are left unfilled.

By default, we pad the right-margin of the AArt with spaces so that all lines are the same length, the alternative having been to leave the right-edge ragged. We choose this default since, on balance, the added uniformity boosts our confidence that any positive outcomes are not the result of leveraging non-visible structure, e.g. a unique right-edge. Also, we suspect that this provides the best chance for the model to demonstrate any ability it truly has, it not having to contend with additional environmental instability.<sup>7</sup>

Names are drawn inside boxes in one corner selected at random. Within an experiment trial, if we show multiple AADs (e.g., in Section 4) each drawing must use the same set of names, a fact also requiring that the number of boxes in each picture match. The assignment of names to boxes is randomized. By default, names are not in AADs, since lack of such identifiers should increase difficulty; while we do not want to set the model up for failure, we deemed this a reasonable difficulty-threshold to start with for the inherently easier tasks (looking ahead: image recognition versus generation) which we can relax should the barrier prove too high to detect anything non-trivial.

We overview our experiments next. In addition to the below, we ran trials to verify that GPT3.5 was performant at recognizing and generating provided AArt *verbatim*; this sanity-check was of interest since the LLM was not trained to handle large sections of such non-lingual content. Results for those trials were near perfection and largely as hoped — thus, to respect space, we limit their discussion to this note.

## 4 Recognition Experiments

### 4.1 Setup

We ran experiments to gauge GPT3.5’s native image recognition abilities. The model was given a prompt displaying a reference AArt, followed by a request to select from among three randomly-ordered choices one depiction that corresponds to the reference in a way matching the prompt. While one can imagine trials where multiple options are

<sup>7</sup>I.e., if performance is good, we may have more trust cheating did not occur, and if it is poor, we may have greater confidence that the model categorically lacks those abilities.

based on the reference but only one corresponds to the correct transform — for example, each being a different rotation, with the goal to find the 90° turn — it is imprudent to start with such added difficulty. Overall, we are interesting in judging GPT3.5’s ability to identify an image after it has undergone typical vision-related changes — e.g., translation, enlargement, rotation, etc. If it is unable to succeed when only one option is derived from the reference art, then it seems reasonable to suppose having more derived choices would cause performance to degrade even further.

```
Instructions: I am about to show you a reference ASCII-art
image, and then ask you a question about it in
relation to three choices -labeled choice A, choice B
, and choice C. Note that in each illustration, the
objects depicted are labeled with a unique name, which
consists of an alphanumeric character and which
appears inside the object they label next to one of
the object's boundaries.
Your job is to do the following, in order:
(1) Describe the reference ASCII-art image.
(2) Describe each of the ASCII-art choices, A, B, and C.
(3) Describe how you would go about answering the question
posed about the ASCII-art images to determine which
choice is correct.
(4) Name which choice you believe is correct, only stating
the name of the choice and nothing else.

Reference ASCII-art Image:
...
[...]
```

Figure 1: The prompt we used for recognition experiments that featured scaling. AArt would be placed where the bolded, bracketed ellipsis ([...]) are shown. In the limits of space, we display only Choice A; Choice B and Choice C follow the same pattern, going to the end of the prompt. The highlighted text is only present for experiments that label AADs with names.

Taking the cue from Chain-of-Thought (CoT) Prompting (Wei et al., 2022), we asked the model warm-up questions to facilitate examination of the AArt provided, build up focus towards facets of the depiction pertinent to the main query. See Figure 1.

Queries are issued once for each prompt using OpenAI’s API for gpt-3.5-turbo with no additional context maintained between calls. Responses are drawn with a temperature of zero, since the space of correct answers is small. Despite this temperature, preliminary trials showed that responses were meaningfully diverse, including differences in response to the main question. We query once per prompt since that suffices to produce the statistics of interest, and also avoids de-

dependencies that would muddy interpretation.

Responses we received reliably had answers located next to their corresponding subquestion number, for instance, “(1) *The reference looks like[...](2)[...](3) To determine which, I would[...](4) The answer is Choice A because [...]*”. Basic string parsing (e.g. regular expressions) was able to consistently extract the primary response (i.e., which option corresponds to the reference); see Appendix C for more comments in this regard.

In most cases, our prompts did not give any information about the AArt’s content, either in terms of the objects shown (boxes) or the meaning of characters. For instance, in trials involving (geometric) translation, we only ask which option matches the target if it was shifted horizontally or vertically — we do not indicate the amounts shifted. Additional details are at Appendix B.

#### 4.1.1 Matching After Translation

To test the model’s ability to match images after translation, we embed our AArt into a larger canvas and pick a random position for the inner-canvas’s bottom-left corner. Specifically, the larger canvas is 48-by-48 and the offset is drawn from  $\text{Uniform}(\mathbb{Z} \cap [0, 23])$  for each dimension.<sup>8</sup> We force the offsets for the reference image and the correct choice to be different, ensuring all queries are nontrivial. We place no such constraints on the other choices.

#### 4.1.2 Matching After Rotation

For rotation, we have the reference image undergo a 90° clockwise turn. Early trials suggested that this task is difficult, which is unsurprising since the transform changes character locations in a fashion atypical for prose. Attempting due diligence in detecting any aptitude GPT3.5 has for this task, we tried several settings of the drawings’ side-length ( $s$ ), maximum number of boxes ( $B$ ) and Poisson parameter ( $\lambda$ ), specifically  $(s, B, \lambda) \in \{(24, 14, 8), (15, 9, 5), (8, 5, 3)\}$ . These settings reflect scaling the values to 1.0 (the default), roughly 0.6, and roughly 0.3; Table 1 refers to them as such. Under the same motivation, trials were carried out with box names present.

#### 4.1.3 Matching Despite Noise

Images commonly have pixel noise — small-scale, random alterations that are neither attributed to obvious geometric transforms nor are semantically

<sup>8</sup>GPT3.5’s tokenizer captures whitespace verbatim — e.g., newlines and multi-spaces are not substituted out.

impactful. Investigating GPT3.5’s robustness to this ubiquitous phenomenon, we inject randomly drawn characters into the AArt— both the reference and, sampled independently, each choice — then ask the LLM to find the match. We use a small set of otherwise unused ASCII special characters as noise elements,<sup>9</sup> and place them where spaces initially were. By only replacing whitespace, we ensure that a drawing’s main structures are unambiguously visible, preventing critical information loss that could otherwise set the model up to fail.<sup>10</sup>

We use two noise levels: 0.04 — that for each space, there is a 4% chance that it will be replaced by a noise character — and 0.32. We repeat the injection process until at least one noise character is added. In combination with this, we experiment with either the default padding (i.e., guaranteed 24 characters per line) and maximum number of boxes (14), or with a ragged right-edge and at most six boxes; this explores the performance impacts of additional variation in token structure combined with “less signal” due to fewer boxes.

#### 4.1.4 Matching After Rescaling

Image recognition requires detecting a pattern despite changes in its scale. To study this, we generate AArt at half its typical size then decide to display either the reference or the choices, but not both, at double their initial size; the choice of which is a parameter. The initial art generated has a 12-by-12 canvas, at most 7 boxes, and  $\lambda$  of 4; when enlarged, the canvas is the standard 24-by-24 size. In addition to choosing the target of scaling, we examine the impact of naming boxes, resulting in a total of four different experiment settings.

## 4.2 Results

In Table 1, we list the observed accuracy for each setting and  $\alpha = 5\%$  Clopper-Pearson confidence intervals (CIs) on them. Random guessing would have an expected performance of 33.3%.<sup>11</sup> We see that all raw observations exceed this measure save one, and the majority of CIs are strictly above it.

While we did not make family-wise significance corrections to the individual intervals, given the

<sup>9</sup>Specifically, chars in the set:  $\{", @, *, ., ,\}$ .

<sup>10</sup>Though a somewhat fanciful comparison, an analogous requirement is that adversarial injections to modern CV systems do not, to humans, add overt changes (Eykholt et al., 2018; Khalid et al., 2021).

<sup>11</sup>A one-sided hypothesis test based on our CIs would have a significance-level of  $\alpha/2$ , which is *more* conservative (rejects the null less often) than a  $\alpha = 5\%$  test.

12 independent CIs of  $\alpha \leq 0.05$ , the probability that three or more fail to contain the parameter is less than a threshold of 5% (in fact  $< 2\%$ ); this and the fact that 7 CIs are strictly above  $\frac{1}{3}$  — the performance if purely guessing — support the idea that the figures are not purely the outcome of guessing, aiding the notion that GPT3.5 does have some acumen for distinguishing between AADs.

We observe an appreciable performance boost for translation, which we speculate results from prose often being indented, thus making it likely that the training set had many pertinent examples. Also, for English, whitespace rarely carries semantic value, thus making it more obviously ignorable.

Our results also do suggest that, all else equal, recognition is aided by the presence of names and more boxes with uniform padding to the right margin — however, this should be taken with reservation, since the CIs overlap in the comparisons. With a similar caveat, performance degrades with higher noise levels, as one would expect, while (less reservedly) AAD size does not obviously impact accuracy on rotation. Additionally, we notice that when the choices in the rescaling-trials are enlarged, the raw performance drops, though comparable CIs continue to intersect.

Exp.	Params	GPT3.5 Acc. (%)		Sample Size
		Obs.	CI, $\alpha = 0.05$	
Rotat.	scaling: 0.3	34.0	[ 29.4, 38.9 ]	397
	scaling: 0.6	35.2	[ 30.5, 40.1 ]	395
	scaling: 1.0	34.5	[ 29.8, 39.4 ]	397
Tr.	—	90.5	[ 87.2, 93.2 ]	399
Scale	ref., -name	39.6	[ 34.8, 44.7 ]	396
	ref., +name	42.4	[ 37.5, 47.4 ]	401
	cho., -name	31.5	[ 27.0, 36.3 ]	400
	cho., +name	38.0	[ 33.2, 43.0 ]	400
Noise	0.04, +pad.	44.0	[ 39.0, 49.0 ]	398
	0.04, -pad.	42.1	[ 37.2, 47.1 ]	399
	0.32, +pad.	40.5	[ 35.6, 45.5 ]	398
	0.32, -pad.	39.9	[ 35.0, 44.9 ]	396

Table 1: Results for recognizing AADs. + or - indicate, respectively, presence or absence; “pad.” stands for padding and “name” for names. In the parameters, “ref.” indicates the reference was shown at 24-by-24 scale and the options where 12-by-12, while “cho.” means the reverse assignment of sizes. For noise trials, 0.04 and 0.32 indicate the noise level.

## 5 Generation Experiments

We examine GPT3.5’s ability to generate AArt, tasking it to transform input images as specified.

### 5.1 AArt Used and Queries Issued

To access the model’s AArt generation abilities while anchoring to something we can access, we follow a modification of the prompt-with-image-reference scheme detailed in Section 3.1 and 4.1, using the same process to form the references. Again leveraging CoT reasoning, we issue warm-up questions leading to the ultimate request. We tried to avoid revealing excessive, step-by-step instructions in order to better gauge the degree to which GPT3.5 already had a notion of what our queries involved; nonetheless, some transforms required more details than others to be specified unambiguously and in reasonably pithy ways. See Appendix D for the prompts used in this section.

Before proceeding, we detail the parameters used in generating experiments. In contrast to most earlier probing (e.g., Section 4), *all* AADs in this section contain name labels. This was motivated by the belief that (1) the generation task is inherently harder than the recognition task, and (2) providing names to anchor and minimally queue GPT3.5 as to structure would reduce the chance of “missing interesting behavior” by setting the LLM up for failure (i.e., starting with unnecessary difficulty). For translation we asked the model to return the image without the extras spaces (we explicitly stated it this way), and for the rescaling-trials, we displayed a half-size image and tasked the model to scale it up by two. Noise trials were conducted at the 0.04 level with padding retained, and rotations were done at size 1.0; see Table 1. Unlike in the recognition experiments, we informed GPT3.5 of what characters were non-noise, as can be seen in Figure 3c.

As before, the network’s output was consistently structured well enough to extract content automatically with simple string parsing and lightweight heuristics. More details are in Appendix C.

In order to get a sense of GPT3.5’s behavior on these tasks, we manually examined outcomes from randomly generated queries for each of the transforms under analysis. While we considered judging “correctness” with more ridged and mechanical approaches,<sup>12</sup> we observed that GPT3.5 did not simply fail or succeed at tasks, but appreciably often generated content along an orthogonal axis, where the outputs were not wrong per se, but also were not quite what we envisioned. Notwithstanding

<sup>12</sup>Ex: AuROC of a simple model’s distance measure between generated content, expected results, and alternatives.

refinements to the prompts we attempted to narrow conceivable ambiguity after observing this behavior during preliminary investigations, the potential for meaningful nuances warrants the examination by a reasonably context-informed human.

In the rest of this section, we summarize the outcomes on 30 randomly selected queries per transform, and attempt to give a sense of successes, difficulties, and curiosities. As with the recognition experiments, our focus will be on the final outcome, which here is the AArt returned by the network, not the verbal responses provided in reply to our CoT prompting preceding it. Figure 2 shows examples of middle-grade outcomes from each of the experiments we run; they are neither the best nor the worst instances observed, but are in the representative “middle”, illustrative of general trends.

## 5.2 An Overall Trend: No Hallucinations

Across our experiments, we observed that GPT3.5 did not invent nonexistent box names; for some experiments, while names may be *lost*, there did not appear to be “hallucinations” (Ji et al., 2023) where names not present in the reference were newly added. In respect to entire boxes, while some trials showed duplication or templating from the reference content (ex, Figure 2a), boxes by and large did not seem invented whole cloth. Given general concerns of LLMs concocting answers, this “honesty” in respect to the reference is worth noting.

## 5.3 Translation Trials

On the whole, translation results showed a mixed success, instances spanning from near perfection, to irrelevant output, and everywhere between. Only 8 cases had seemingly random code or prose mixed with the art, of which only 3 had images failing to clearly reflect the reference. Most commonly, excess whitespace on the periphery was trimmed, as desired. This success was tempered by certain “failure modes,” namely loss of boxes, distortion of inner-distances, or muddling of box boundary alignments. In all such cases, remnants of the reference image remained clearly visible, with a minimum of one to two boxes intact. Finally, we noted 3 results very close to perfect, preserving the boxes almost exactly (a few boundaries were mildly misaligned) and performing close to the full translation desired (all having  $\leq 2$  extra left-aligned spaces), while 2 others retained the image structure, but kept excess left-padding. Overall, while the network was

not spot-on completing this task, some nontrivial achievement of the visual manipulation requested was witnessed.

## 5.4 Noise Trials

Over the 30 noise trials studied, results tended to be reasonable but incomplete or mildly flawed. As to reasonableness, unlike the “squashing” or loss of boxes that occurred in a number of translation trials, the result boxes aligned with the reference, save a minority of rows that on occasion were visibly shifted, more often left than right; this shifting is predominately responsible for the “mild flaws” we saw. Another type of mistake was the removal of box names in addition to noise characters: only 1 occasion had all names removed, but 20 instances had at least one name missing.

As to the removal of noise characters, we observed the following: We did not see any example where all noise characters were removed, though there was at least one case where the input was cleaned of all such marking (originally 16 characters) and retained only one. Every observed instance removed at least some of the undesired characters. No case that we saw added more noise than was originally present, and moreover the strict subset of noise remaining was located in the same position in the result as the original, save a handful of cases where the entire row was shifted one space left or right. The treatment of undesired characters did not obviously correlate with the type of noise character, location in the image, or whether it shared a row or column with other noise characters.

Taken together, this consistent decrease of noise in an image while failing to totally remove it causes us to label the outcomes as “incomplete.” In light of the amount of structure retained while noise is reduced, however, a reasonable interpretation suggests GPT3.5 does not lack all prowess here.

## 5.5 Rescaling Trials

The 30 rescaling-trials we scrutinized were diverse and, of our experiments, most subject to the moniker “not wrong per se, but not what was initially envisioned.” Indeed, it was these experiments that initially lead us to more fully appreciate the modalities of pronounced, arguably-correct behavior that would otherwise be underappreciated by more rigid, narrowly focused analysis.

We rarely saw instances where images were scaled by *exactly* double. GPT3.5 did display, however, a consistent ability to enlarge images along at

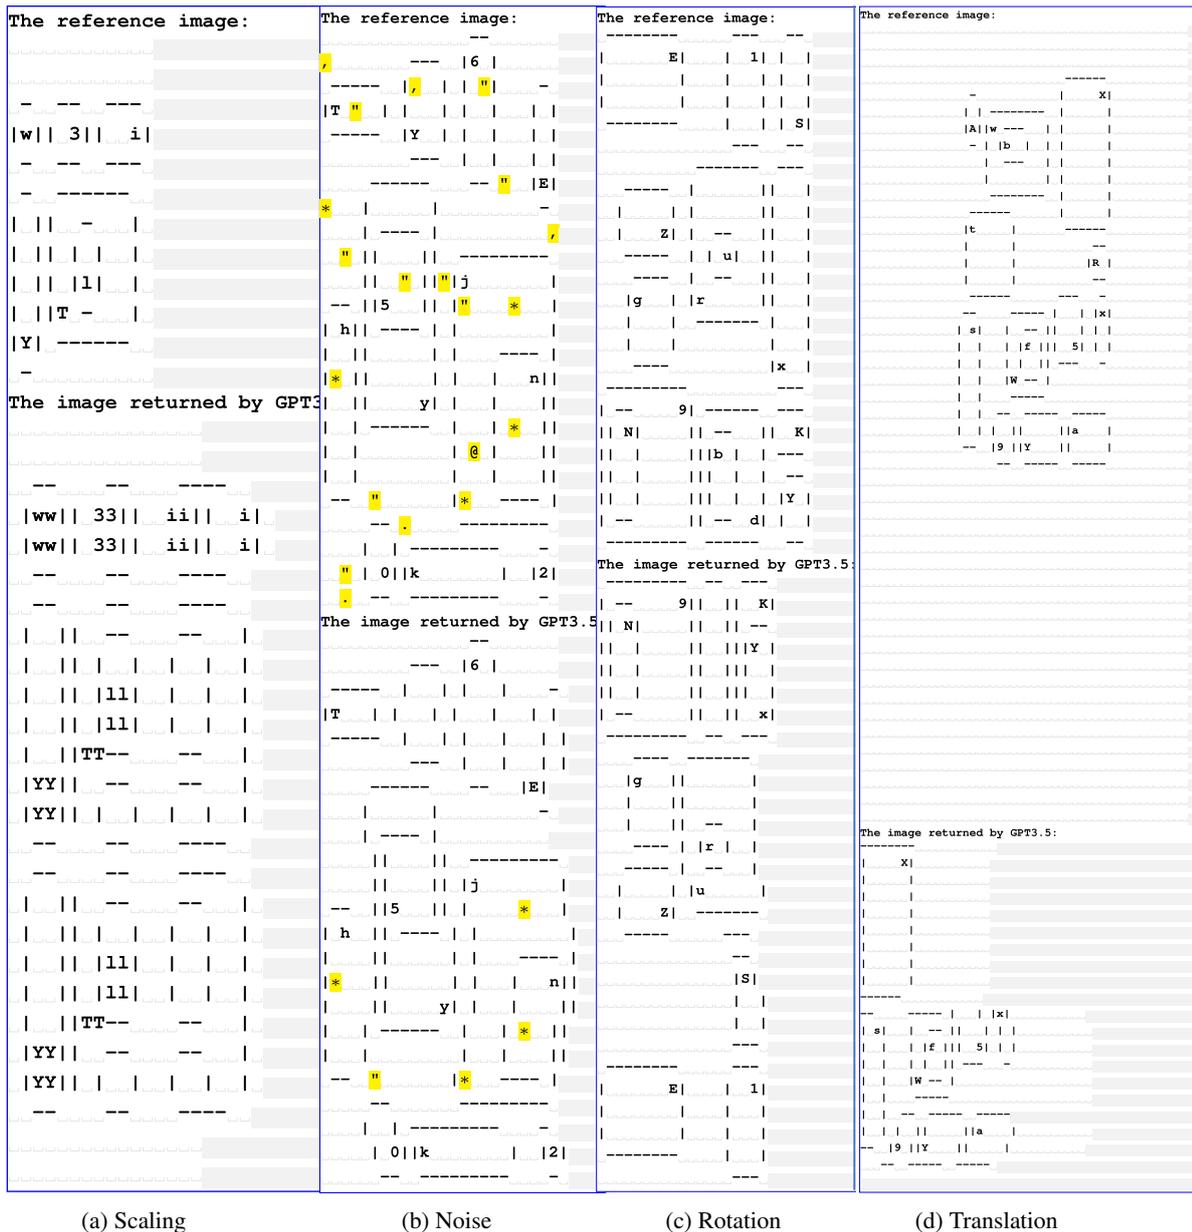

Figure 2: Representative, middle-grade examples of results generated by GPT3.5. The subcaptions indicate the trial from which an example is drawn. To make visible any patterns on the right-edge, we add gray blocks at the line endings. Individual spaces are distinguished with gray under-brackets. For 2b, we highlight the noise characters in yellow to ease interpretation.

least one axis or “enlarge by doubling” the picture in reasonable but unexpected ways. In the case of the first, we note that precise arithmetic is appreciated as difficult for NLP LLMs. Exactness notwithstanding, within an image, one axis generally grew while the other was kept the same size.<sup>13</sup> The fact scaling occurred along either axis, sometimes vertically and sometimes horizontally (and

<sup>13</sup>In fairness to the model, we did accidentally use the singular form of “axis” in our prompt (see Figure 3d), whereas we meant the plural “axes” — the rest of the query’s language hopefully conveyed what we intended despite this oversight.

certainly at times both), is of some interest since GPT3.5 was trained mostly on languages that are read horizontally; that said, horizontal expansion appeared more frequent. Results appreciably often had a mix of boxes that were enlarged and those that retained their original size. Reductions in size were rare. This mix of behaviors across (and at times within) the instances leaves us uncomfortable commenting on the prevalence of each mode, beyond noting that each occurred appreciably often, except for the rarity of shrinking.

Consecutive repetition of names was common,

either horizontally (most prominent), vertically, or, at times, in a rectangular patch within their box. 19 cases exhibited this phenomena. Name repetition tended to coincide with growth by the corresponding box. Speaking on an opposite phenomena, 15 instances lacked at least one name from the input — though not always lacking the corresponding box (which would be displayed without its label). Of these, only 7 were missing more than one name, with an observable skew towards lower counts of names missing.

As alluded to, a common modality of expansion was to repeat reference boxes, most frequently doing so in some structure-informed way (e.g. same inner-distances to copied landmarks, not thrown in haphazardly). For instance, content could be copied and translated straight down or across. Relatedly, 5 instances of the 30 featured repetition of characters until the context window end, either repeating boundaries of boxes that extended indefinitely downward or as a subset of the boxes tessellated. Of these, all but one was missing a box label; that is, they contributed 4 to the aforementioned 15 where the outputs had certain names absent.

Only a handful of times ( $\approx 3$ ) did the output seem largely divorced from the structure and naming of the input. Name placement in the outputs roughly matched the reference in respect to relative positioning; similar can be said of the boxes, though it appeared their size and *absolute* location varied more. All unforeseen nuances weighed, it is fair to say that certain substantive visually information was retained in the typical case, as visible in Figure 2a.

## 5.6 Rotation Trials

In this setting, we found two undesired modes to comprised virtually all instances, and the remaining handful not being more successful: 1. repetition of boundary marks until the end of the context window, at times preceded by a few boxes that appeared to be copied from the reference image, 2. some shuffling of content — primarily names among structure that otherwise was a copy of the reference. Case 2 had subcases which seemingly contained content flipped over an axis (ex: Figure 2c), though it is unclear what extent that holds for most instances, and may be apophenia. Another fairly common subcase, accounting for 8 instances, was that names were moved, though the boxes present (shapes and positions) matched the input. 11 instances fell into case 1, displaying a

large quantity of repeated vertical or horizontal box side-markers.

In an appreciable chunk of cases (perhaps a non-simple majority) box naming underwent some changes that might constitute a partially successful flip, or two such flips along perpendicular axes; while we believe there is enough evidence to not dismiss the idea, future work is necessary to move it outside of speculation. Names did not appear to be consistently moved to destination boxes whose distance from the image boundary was qualitatively similar to the origin box’s boundary distance in the reference; e.g., names from toward the center sometimes were moved to boxes touching the borders and vice versa.

Ultimately, we did not deem a single result of the 30 to be totally or largely a correct rotation. This is not surprising: neither the poor performance observed in the recognition experiments for rotations nor preliminary analysis we conducted during development provided fuel for optimism. This all said, a comfortable majority of the time we observed that substantial visual substructures were preserved, and moreover that the model made some attempt to shuffle or alter the image while preserving its rough scale and origin.

## 6 Conclusion

Drawing inspiration from the comprehension we’d expect an intelligent agent to possess across multiple signal modalities, in this work we examined GPT3.5’s aptitude for visual tasks, where the inputs featured diagrams rendered as ASCII-art. In sharp contrast to the large majority of prior works, we made no attempt to overtly distill the image content into a lingual summary. We conducted experiments analyzing the model’s performance on image matching tasks after various transforms typical in visual settings, as well as tasks requesting such transforms be generated. In each of these categories of experiment, we found that while GPT3.5 had room for notable improvement, results suggested it was not totally lacking in regard to visual and pictorial aptitude. Given that GPT3.5 is a model nominally trained on text-only input, we were pleasantly intrigued by these outcomes.

## 7 Limitations

We have not investigated the mechanisms by which ChatGPT achieves any visual performance. While we considered ways the LLM could “cheat” when

we were constructing the experiments, that was as an attempt to diligently weed out artifacts and confounding factors. In respect to how GPT3.5 actually operates, we provide few insights into what it actually does to “compare between images”, what it “pays most attention to” while “deciding”, or “looks at” while “drawing boxes”. These are all interesting avenues of future work, for which ideally we would conduct additional controlled experiments and, OpenAI’s API then permitting, apply some of the latest methods of XAI (Explainable AI, (Gunning, 2019)) available. Considering the initial motivation of this work, resources available, and space to discuss, establishing that this is even a direction of potential interest is progress over previous perceptions.

As to our tests, more are possible and could provide additional insights. For instance, one could study whether GPT3.5 can identify subset relationships between boxes, or identify matches despite perturbing internal positions slightly (distortions, etc.); while we believe that our selection of experiments hit on the primary axes of consideration, certainly there exist additional minor axes over which experiments can be considered to ensure GPT3.5 behaves as expected.

Additional types of trials aside, those already in existence could be extended to probe further into the landscape of the network’s performance. For instance, in the recognition trials, only one answer is based on the reference image, all others are freshly generated; one could consider circumstances where multiple choices are based on the reference and the network must select which corresponds to a particular transform — e.g., rotated a half turn left instead of a half turn right. As we discussed, part of our aim was to undertake experiments that were sensitive to any visual acumen GPT3.5 did possess, so the modifications would be worthwhile, but risked missing the phenomena of interest had we undertaken them *instead* of the arrangement used. Now, having established that —in contrast to general perceptions — there may be something of interest to study in this space, these additional experiments of added difficulty may provide additional insights as to the extent of GPT3.5’s visual understanding.

In regard to our examination of AADs the model generated, we took strides to provide numeric descriptions as frequently as possible, while also providing what we believe is worthwhile, level-handed qualitative analysis. As we remarked in the text, we had weighed using a more cut-and-dry approach,

such as training a classifier to distinguish between the generated results, the expected results, and some other, “negative” class. Such results could perhaps be an interesting complement to what we present, but would not be superior to them. Of particular concern is that much of the nuance we wished to expose may have been too easily missed by generic automated evaluation. That said, we recognize that such material could provide benefits in respect to exactness, digestibility (for readers), and quantifiable summarization.

In potential contrast to automated means, it may be possible that more nuance could be had with human trials, particularly by leveraging a comprehensive series of survey questions (in contrast to just manually performed image matching tasks, say). In particular, gathering detailed impressions from neutral arbiters as to the qualitative properties of outcomes would help further gauge GPT3.5 successfulness (rare as such surveys may be for accessing image generation systems ). Outside of that, arrangements similar to blind A/B-testing could be performed where, given a pair of AADs prepared by some variety of means — separate random draws, input and results from GPT3.5, and perhaps other near-alternatives — must select how they relate (rotation, scaling, unrelated, etc.); this however runs into the issue of missing subtly, hence the suggestion for more detailed and expansive surveying.

Finally, while the data we generated to perform analysis has many merits, certainly there are limitations. Most obviously, the data is ultimately patterned after the shared, fundamental structure of AADs. In the same spirit of exploring the space over which GPT3.5 is visually performant, more varied datasets could be used, which would also boost confidence that outcomes are not special to our setting. Risk of the model secretly exploiting artifacts and biases specific to the generative process should be borne in mind, particularly since we mechanically generate our data.<sup>14</sup> This all said, however, works like (Ribeiro et al., 2016; Khalid et al., 2021) and (Eykholt et al., 2018) show that even “more respectable” CV systems and datasets are subject to similar categories of concern, if not comparable degrees of it.

---

<sup>14</sup>It is possible that the degree of hesitation one has should also correlate with the size of the AADs used, however we are not yet promoting that stance.

## A Additional Comments In Regards to the Gap in Ability Between Utilizing Verbal Summaries of Images and Being Able to Directly Process Images

Handling symbolic structures that happen to be derived from spatial data may be more akin to an “algebraic computation” than “visual understanding” (using those phrases connotatively if not a firm distinction). For instance, from group theory alone, one knows that applying a transformation  $T$  followed by  $-T$  results in the identity. It may well be that  $T$  is translating a triangle 10 meters left and  $-T$  moves the same distance right; an LLM could conclude that  $T$  then  $-T$  results in no change completely

divorced from whatever  $T$  is meant to represent. In that process, though, the model wouldn’t necessarily know how vertices of the triangle move over the course of the transformation — and moreover, it doesn’t mean that the model could derive the vertices from a bitmap image, or even be able to recognize a triangle in the picture.  $T$  and  $-T$  could just as well be depositing then withdrawing money from a bank account. The LLM may be able to handle the high-level summary of what an image contains, but by the time such a description is produced, much of what makes it a visual problem is already treated. As a historical footnote, popular perception about the difficulties symbolic AI had for processing raw visual input (e.g., Moravec’s Paradox) bolster the position that this gap is not to be taken for granted; see, for instance, (Brooks, 1991; Moravec, 1993; Sutton, 2019) for a couple critical takes.

## B More Details About Information We Provide in Prompts for Recognition Experiments

As noted, in general we keep the details of what we inform the model of in the AADs to a minimum. In the following circumstances, we provide a few more words which may reveal additional — albeit minimal — aspects of the AAD: 1. *When names are used*: We indicate names are alphanumeric and occur on the inside boundary of objects. 2. *Noise trials*: We explicitly refer to “boxes” being present. We do not indicate what characters comprise them or the noise. 3. *Size trials*: We specify whether the choices are scaled up or scaled down in respect to the reference.

## C Regarding String Parsing to Extract Content

For recognition experiments: Basic string parsing (e.g. using regular expressions) was able to consistently extract the primary response (i.e., which option corresponds to the reference); our code flagged instances of unexpected content and separated them for manual review, but ultimately that only triggered seven times out of several thousand cases; in light of their minimal impact, we ultimately disregarded them, finding that the benefit of their use was outweighed by the added methodological cleanliness.

For generation experiments: In preliminary trials, we found that a fraction of the time GPT3.5

would reply to our prompt solely with text<sup>15</sup> or other non-AArt content. In order to ease planned downstream analysis, we opted to add a lightweight mechanism for detecting such cases and reissuing the query. The heuristic deployed checked that the response was at least of minimal feasible length to contain an image and at least one arrangement of characters that looked like a potential box corner (i.e., “-” on one line, “|” adjacent on a line above or below).

The illustrations we share were extracted with a two-step, heuristic process: (1) return the content in the last pair of triple back-ticks (“` ` `”) present in the output, (2) if the first option does not extract content seemingly containing a box<sup>16</sup> return everything after the last line holding at least two consecutive alphanumeric characters. The second step, when invoked, aims to cut out anything that may loosely look like text/words. We consider the lack of human effort in the extraction process to be both convenient and reassuring, the latter as it mitigates concern over human biases impacting output characteristics like tabbing or presence of excess whitespace margins.

## **D Prompts Used for AArt-Generation Trials**

---

<sup>15</sup>A paraphrased example of those occasional replies: “I’m sorry, but as an LLM, I can’t process ASCII-art.”

<sup>16</sup>Using the method of the prior paragraph.

Instructions: I am about to show you a reference ASCII-art image, and then ask you questions about it and a task you must complete. The questions are numbered 1, 2, *and* 3, and the task is indicated separately. The ASCII-art depicts a collection of boxes, some of which may be nested inside of other boxes. Note that in the ASCII-art, each box depicted is labeled with a unique name, which consists of an alphanumeric character and which appears in one of the box's corners.

Reference ASCII-art Image:

```
....  
[...]  
..
```

(a) Preamble text with overview of the tasks GPT3.5 is requested to complete, followed by the placement of where ASCII-art would be, as indicated by the bolded, bracketed ellipsis ([...]). The bolded, italicized text in the preamble is substituted with “3 and 4,” whenever the experiment involves four such questions.

**[...Preamble from Figure 3a...]**

Your job is to do the following, in order:

- (1) Describe the reference ASCII-art image.
- (2) What would you do in order to form a piece of ASCII-art that matches what the reference ASCII-art would look like if it had no blank areas at the top of it and no empty left margin? That is, how would you change the reference ASCII-art to look like it was translated so that there was not unneeded empty space around it (while preserving all internal spacing and structured)?
- (3) What would the reference ASCII-art look like if it had no blank areas at the top of it and no empty left margin? That is, what would the reference ASCII-art look like after it has been translated so that there was not unneeded empty space around it?

Task: Provide ASCII-art that matches what the reference ASCII-art would look like if it was translated to have no blank areas at the top of it and no empty left margin. That is, show a modified version of the reference ASCII-art that has been translated so that there is no unneeded empty space around it (while preserving internal spacing and structure).

(b) Prompt used for trials of generating image translations.

**[...Preamble from Figure 3a...]**

Your job is to do the following, in order:

- (1) Describe the reference ASCII-art image.
- (2) In the reference ASCII-art, the only characters that should be present are ``|'', ``-'', alphanumeric characters, or whitespace. All other characters are noise that should not be present. List what characters are present in the reference ASCII-art that are noise.
- (3) How would you remove noise from the reference ASCII-art so that only the characters that should be there are present?
- (4) What would the ASCII-art look like if each character that is noise was replaced with a single space character?

Task: Provide what the reference ASCII-art would look like if you remove the noise and only leave the characters that should be present. Any single character you remove should be replaced by a single space character.

(c) Prompt used for trials of generating de-noised versions of reference images.

**[...Preamble from Figure 3a...]**

Your job is to do the following, in order:

- (1) Describe the reference ASCII-art image.
- (2) What would you do in order to form a piece of ASCII-art that matches what the reference ASCII-art would look like if it was scaled up to double the size?
- (3) What would the reference ASCII-art look like if it was enlarged by a factor of two? That is, what would the reference ASCII-art look like if it was made twice as large?

Task you must complete after answering the questions: Provide ASCII-art that matches what the reference ASCII-art would look like if we scaled the reference ASCII-art to double its size. That is, produce ASCII-art that has axis which are double the length of the reference, and which the images shown are enlarged respectively.

(d) Prompt used for trials of generating enlarged copies of images.

**[...Preamble from Figure 3a...]**

Your job is to do the following, in order:

- (1) Describe the reference ASCII-art image.
- (2) What would you do in order to form a piece of ASCII-art that matches what the reference ASCII-art would look like if it was rotated 90 degrees clockwise? That is, what you you do in order to depict the reference image after a quarter-turn clockwise?
- (3) What would the reference ASCII-art look like if it was rotated 90 degrees clockwise? That is, what would the reference image look like after a quarter-turn clockwise?

Task: Provide ASCII-art that matches what the reference ASCII-art would look like if it was rotated 90 degrees clockwise. That is, show the reference ASCII-art after it has been rotated a quarter-turn clockwise.

(e) Prompts used for trials of generating image rotations.

Figure 3: Prompts Used for AArt-Generation Trials. By the nature of the generation task compared to recognition, some trials required more information be specified in the prompt to more narrowly specify the set of assemble outcomes. Compare, for instance, to the overview provided in Section 4.1 and Appendix B.

# Cross-lingual Editing in Multilingual Language Models

Himanshu Beniwal<sup>†\*</sup>, Kowsik Nandagopan D\*, Mayank Singh

Department of Computer Science and Engineering

Indian Institute of Technology Gandhinagar

{himanshubeniwal, dkowsik, singh.mayank}@iitgn.ac.in

## Abstract

The training of large language models (LLMs) necessitates substantial data and computational resources, and updating outdated LLMs entails significant efforts and resources. While numerous model editing techniques (METs) have emerged to efficiently update model outputs without retraining, their effectiveness in multilingual LLMs, where knowledge is stored in diverse languages, remains an underexplored research area. This research paper introduces the cross-lingual model editing (XME) paradigm, wherein a fact is edited in one language, and the subsequent update propagation is observed across other languages. To investigate the XME paradigm, we conducted experiments using BLOOM, mBERT, and XLM-RoBERTa using the two writing scripts: *Latin* (English, French, and Spanish) and *Indic* (Hindi, Gujarati, and Bengali). The results reveal notable performance limitations of state-of-the-art METs under the XME setting, mainly when the languages involved belong to two distinct script families. These findings highlight the need for further research and development of XME techniques to address these challenges. For more comprehensive information, the dataset used in this research and the associated code are publicly available at the following URL<sup>1</sup>.

## 1 Introduction

The introduction of large language models (LLMs) has revolutionized tasks such as dialogue generation, question-answering, and contextual reasoning (Brants et al., 2007; Touvron et al., 2023; Scao et al., 2022). LLMs are trained on massive datasets, but this unsupervised data can potentially contain biased or incorrect information. For example, an LLM trained on a dataset of news articles might

learn that: *Apple iPhones are the best phones* or that *Mumbai is the capital of India*. This issue becomes problematic because retraining an LLM with equivalent computational power and environmental impact is impractical (Madaan et al., 2022; Si et al., 2023). To address this problem, researchers have proposed several Model-Editing Techniques (hereafter referred as METs, Dai et al. (2022); De Cao et al. (2021)). METs focus on updating the knowledge within existing LLMs rather than undergoing complete retraining. However, these METs have been evaluated predominantly in monolingual settings, where editing and evaluation occur within a single language, typically English. This paper aims to explore an alternative scenario, as depicted in Figure 1. For example, we consider the task of updating a language model (in the English language) to reflect the transition of presidential power from Donald Trump to Joe Biden in the United States, using established model editing techniques. Subsequently, we prompt the updated model with the following French query: *Donald Trump est le président des États-Unis d'Amérique?* (Donald Trump is the President of the United States of America?), expecting the model to correctly predict 'REFUTES'. We term this new editing paradigm as **Cross Lingual Model Editing (XME)**.

We evaluate a specific family of METs that leverage a hypernetwork, an additional model, to update the parameters of a base LLM within the framework of XME. The primary objective is to address the following research questions: [Q1] What is the effectiveness of hypernetwork-based editing techniques in cross-lingual settings? [Q2] Do different architectures store knowledge at different locations? [Q3] How does language selection in the initial fine-tuning stage affect editing performance? [Q4] Is the traditional fine-tuning approach more effective than METs in achieving higher performance in the cross-lingual setting?

In our research, we present the following key

<sup>†</sup>This work is supported by the Prime Minister Research Fellowship.

\*Equal Contribution.

<sup>1</sup><https://github.com/lingo-iitgn/XME>

Figure 1: XME pipeline: we update a fact in one language (say English) and check whether the same fact is updated in different languages.

contributions:

- We explore the cross-lingual editing paradigm on existing METs over two distinct language writing scripts encompassing six languages (both high and low resources).
- We uncover a substantial editing performance disparity between monolingual and cross-lingual contexts with exhaustive 9,936 experiments in 69 configurations (Language Pairs x Models x METs).
- We provide robust evidence of distinct knowledge localizations in multilingual encoder-only and decoder-only LLMs.

## 2 Related Work

We classify previous works into two distinct categories: (i) *Parameter-Updating* techniques involve actively updating and modifying the parameters of the LLM. These approaches aim to adapt and fine-tune the LLM’s parameters according to the specific requirements of the editing task. These techniques involve the use of additional feed-forward network architectures. Notably, **KnowledgeEditor** (De Cao et al., 2021) and **KnowledgeNeurons** (Dai et al., 2022) leverage the gradients of the base model and a hypernetwork to identify the weights that require updating (Ha et al., 2017). Another prominent technique, **MEND** (Mitchell et al., 2022a), employs gradient updates from multiple feed-forward networks to update the parameters of the base model. Numerous *Locate-then-Edit* techniques, exemplified as **ROME** (Meng et al., 2022a) and **MEMIT** (Meng et al., 2022b), initially localize the knowledge within the model and then update the base model accordingly.

On the other hand, (ii) *Parameter-Preserving* techniques refer to methods that aim to maintain the original parameters of the LLM during the editing process (Madaan et al., 2022; Dong et al., 2022; Huang et al., 2023). The focus is on preserving the

existing knowledge and capabilities of the LLM while incorporating specific modifications for the desired task. **SERAC** (Mitchell et al., 2022b) incorporates an explicit memory to store edits, enabling the model to reason over them and modulate the predictions of the base model accordingly. Another approach, **GRACE** by Hartvigsen et al. (2022), introduces a key-value model editor that learns to cache and retrieve activations for selected layers based solely on observed errors during deployment.

The preference for hypernetwork-based approaches over other METs arises regarding the effective generability and localization of knowledge, albeit requiring additional memory (Yao et al., 2023; Xu et al., 2023). A study conducted by Hase et al. (2023) reveals that localization techniques do not provide further insights into determining the most suitable MLP layer within the base model for overriding an existing stored fact with a new one. Further, the time required to perform an edit in hypernetwork-based techniques is lesser, and the inaccessibility of ROME and MEMIT over different architectures reasons to choose hypernetwork-based techniques over other METs in our experiments (Yao et al., 2023).

## 3 Cross-lingual Model Editing (XME)

The cross-lingual model editing problem can be explained by leveraging notations from monolingual model editing. Given a fine-tuned model  $f$  with its parameter  $\theta$ , the prediction or label  $y$  can be computed as  $y = f(x; \theta)$ , where  $x$  represents the input sentence. Our objective is to update the model’s parameter to  $\theta'$  in order to modify the label for input  $x$  to a new value  $a$ , denoted as  $a = f(x; \theta')$ . However, for the remaining information  $\hat{x}$  where  $\hat{x} \neq x$ , the label remains unchanged as  $y$ . Let’s consider an example: when presented with input  $x$  as *Donald Trump is the President of the USA?* and its semantically equivalent input  $x'$  as *USA’s Presi-*

dent is Donald Trump a fact verification model  $f$  outputs  $y$  as “SUPPORTS”. Now, assuming that the fact is updated and model parameters are changed from  $\theta$  to  $\theta'$ , for the same inputs  $x$  and  $x'$ , the updated output becomes ‘REFUTES’ ( $a$ ), where  $a = f(x, \theta') = f(x', \theta')$ . Furthermore, the unrelated information  $\hat{x}$  remains the same as before editing; for instance, *The capital of France is Paris* should still yield the answer “SUPPORTS”. Therefore,  $y = f(\hat{x}; \theta) = f(\hat{x}; \theta')$ . In contrast to the monolingual model editing, in XME, the inputs  $x$ ,  $x'$ , and  $\hat{x}$  belong to different languages.

## 4 Experiments

This section details the experiments performed for XME and highlights the dataset, architectures, and evaluation strategies.

### 4.1 Language Selection

We have selected a diverse set of languages from the two distinct scripts: *Latin* and *Indic*. From the *Latin* branch family, we have chosen three widely spoken languages: English (**en**), French (**fr**), and Spanish (**es**). These languages have significant global influence and are among the top 10 most spoken languages worldwide (Lobachev, 2008). Additionally, we have included three languages from the *Indic* script family: Hindi (**hi**), Bengali (**bn**), and Gujarati (**gu**). Hindi and Bengali are among the top 10 most widely spoken languages globally.

### 4.2 Dataset

In our experimental setup, we focus on a closed-book fact verification task using a modified version of the binary FEVER dataset (Thorne et al., 2018). This modified dataset, as described in (De Cao et al., 2021; Mitchell et al., 2022a), includes the original instances and 1 to 25 human-created semantically similar paraphrases for each instance. The dataset consists of 104,966 training instances and 10,444 validation instances. The facts are updated by flipping the label. There are 1,200 instances with flipped labels that were used for editing and subsequent evaluation. On average, each instance has ten semantically similar paraphrases (refer to §A.1 for more details). We translate<sup>2</sup> each training, validation, edited instance and the corresponding paraphrases (originally in **en**) into five languages described above, creating six snapshots

<sup>2</sup>The translation was performed using Google’s Translate API: <https://cloud.google.com/translate>

of the same data one for each language. Note that, in our experiments, we performed editing and evaluation on 1193 (out of originally 1200 instances) instances, as the rest led to translation errors.

**Quality Assessment of Translations:** For the five selected languages (other than English), two annotators per language were chosen to verify and annotate the randomly chosen 150 correct translations. All the annotators were native in their assigned languages and fluent in English. The average accuracy and Inter-Annotator Agreement (IAA) over all languages are 88.07% and 77.8%, respectively. The details for the average annotator’s accuracy and IAA per language are added in §A.2.

### 4.3 Pretrained Language Models (PLMs)

Our research paper investigates the performance of two distinct families of multilingual PLMs: encoder- and decoder-only models. As a representative decoder-only PLM, we choose BLOOM (Scao et al., 2022). BLOOM is a massive language model trained on the extensive ROOTS corpus (Laurençon et al., 2022), encompassing 46 diverse natural languages. For the encoder-only category, we selected mBERT (bert-base-multilingual-uncased) (Devlin et al., 2019) and XLM-RoBERTa (Conneau et al., 2020) as representative models based on their well-established performance in multilingual NLP tasks. mBERT, pre-trained on the 104 languages with the largest Wikipedia, offers comprehensive language coverage. On the other hand, XLM-RoBERTa was trained on filtered CommonCrawl data (Wenzek et al., 2020), enabling robust performance across one hundred languages. Considering the limitations imposed by computational resources, we opted to employ a downsized variant of BLOOM, namely BLOOM-560M (hereafter referred to as BLOOM), for our research. Additionally, we utilized uncased versions of mBERT and the base-sized model variant of XLM-RoBERTa in our experiments.

### 4.4 Model Editing Techniques (METs)

We conducted the experiments on two state-of-the-art hypernetwork-based MET techniques along with the standard fine-tuning technique. The hypernetwork-based MET includes Model Editor Networks using Gradient Decomposition (MEND, Mitchell et al. (2022a)) and Knowledge Editor (KE, De Cao et al. (2021)). Both techniques used an additional model, referred to as hypernetwork, to update the weights of the base PLM model.

The hypernetwork is trained with constrained optimization to modify a fact without affecting the rest of the knowledge. In addition, we employed a standard fine-tuning approach (**FT**) as a baseline approach, which does not require an additional network for the base PLM update.

#### 4.5 Evaluation

The above three techniques are evaluated using two metrics as described below:

**The Generability Score** ( $G_S$ ) assesses the ability of the MET to predict updated facts on semantically equivalent inputs accurately. To illustrate this, let’s consider an example scenario: initially, given an input  $x$  such as *The President of the USA is Donald Trump*, the model predicts a label of ‘SUPPORTS’. Subsequently, the label for  $x$  is updated to ‘REFUTES’. Following the editing of the model parameters, we consider the edit successful if, when presented with semantically equivalent inputs ( $x'$ ) (e.g., *Donald Trump is the President of the USA*), the model correctly outputs ‘REFUTES’.  $G_S$  quantifies the proportion of successfully edited inputs where the model predicts the updated fact label on the corresponding semantically equivalent input. In our experiments, we randomly select one  $x'$  among several semantically equivalent inputs of  $x$ .

**The Specificity Score** ( $S_S$ ) evaluates the MET’s ability to avoid updating unrelated information. In this context, we define an unrelated input as  $\hat{x}$ , where  $\hat{x}$  is irrelevant to the editing fact  $x$ . For instance, let’s consider the initial input  $x$  as *The President of the USA is Donald Trump*, and the model predicts a label as ‘SUPPORTS’. Subsequently, the label for  $x$  is updated to ‘REFUTES’. Now, if we present an unrelated input  $\hat{x}$ , such as *The capital of France is Paris*, the model should still predict ‘SUPPORTS’.  $S_S$  measures the proportion of unrelated inputs for which the model correctly maintains the original prediction label for an irrelevant input.

It is essential to note that in the metric definitions mentioned above, we have considered  $x$ ,  $x'$ , and  $\hat{x}$  within the same language to keep it simple. However, in the actual XME setting,  $x$ ,  $x'$ , or  $\hat{x}$  can belong to multiple languages simultaneously.

#### 4.6 Experimental Settings

In our research methodology, we fine-tune the models described in Section 4.3 for each specific language. Following the fine-tuning process, we apply model editing techniques, as detailed in Section 4.4, by passing individual inputs to the fine-tuned mod-

els. The performance of these edited models is then evaluated using the metrics defined in Section 4.5.

To implement the Knowledge Editor and Fine-Tuning techniques, we utilize the implementation provided by **MEND** (Mitchell et al., 2022a). Consistent with the experimental settings of **MEND**, we selectively update only four layers of each PLM. The same set of layers is updated by both **KE** and **FT**. For the decoder-only models, we designate layers 1–4 as initial layers (**IL**), 14–17 as middle layers (**ML**), 21–24 as last layers (**LL**), and we randomly select layers 9, 14, 18, and 22 as random layers (**RL**). Similarly, for the encoder-only models, we assign layers 1-4 as **IL**, 5–8 as **ML**, 9–12 as **LL**, and 3, 5, 7, and 10 as **RL**. We have utilized the default hyperparameters as implemented in the **MEND**’s implementation for **MEND**, **KE**, and **FT**. All experiments were completed on 4 V100 GPUs (Each consisting of 32GB).

### 5 Results

In this section, we present and analyze the key findings and address the research questions posed in Introduction Section (see Section 1 for more details). To accomplish this, we examine a total of 69<sup>3</sup> configurations, which are derived from combining six languages, three PLMs, and three METs. For each configuration, we present the results in tabular form. For instance, Table 1 showcases the performance measured by  $G_S$  obtained from fine-tuning the mBERT (left) and BLOOM (right) on an **en** dataset and subsequently applying the **MEND**’s editing technique. The rows of the table represent the editing languages, while the columns represent the languages used for evaluation. The diagonal values represent monolingual  $G_S$ , whereas off-diagonal entries show cross-lingual  $G_S$ . Similarly, Table 2 showcases the performance measured by  $S_S$  for mBERT when fine-tuned on **en** (left) and **hi** (right) and edited using **MEND**. In our experimental analysis, we observe consistent trends for both the **MEND** and **KE** techniques. However, due to space limitations, we focus on reporting the results obtained using the **MEND** approach. The performance scores for the **KE** technique can be found in §A.6. Next, we answer the posed research questions.

<sup>3</sup>The combination is (6 languages + mixed configuration + inverse configuration) x 3 models x 3 METs = 72 configurations. Three configurations corresponding to mBERT are unavailable (the inverse proportion for three METs). Hence summing up to 69 configurations.

### 5.1 What is the effectiveness of hypernetwork-based editing techniques in cross-lingual settings?

Table 1 and 2 elucidates notable trends observed in evaluating existing METs. Table 1 demonstrates high values of  $G_S$  (above 90%) along the diagonal entries, providing empirical evidence for the effectiveness of METs when applied to mBERT in monolingual contexts. Conversely, **a noticeable decrease in the  $G_S$  scores becomes evident as one moves away from the diagonal, indicating the relative inefficiency of METs in cross-lingual scenarios.** Language pairs within the same script family, such as **en**→**es**, **en**→**fr**, or **hi**→**bn**, achieve higher  $G_S$  values compared to pairs belonging to different script families, such as **en**→**hi** or **es**→**bn**. The average  $G_S$  (excluding the diagonal entries) for editing in the *Latin* family (90.04%) is significantly higher than in the *Indic* family (78.38%). However, the two branches do not significantly differ in the average  $G_S$  under a monolingual setting. Similar trends are observed for fine-tuning mBERT in other languages (refer to §A.5.2, §A.6.2, and §A.7.2 for detailed results). Comparable patterns were also identified for XML-RoBERTa (refer to §A.5.3, §A.6.3, §A.7.3 for detailed results). The observations derived from the analysis of the BLOOM model reveal notable distinctions. The metric  $G_S$  strongly depends on the fine-tuning language script, irrespective of the employed editing language. Specifically, when examining the **en** language, a significant disparity in  $G_S$  values is observed between the *Latin* and *Indic* script families, as evident in Table 1. For instance, the average  $G_S$  (including the diagonal entries) for the *Latin* and *Indic* families is 94.14% and 84.32%, respectively. Additional results pertaining to BLOOM can be found in §A.5.1, §A.6.1, and §A.7.1.

Unexpectedly, the  $S_S$  metric presents contrasting findings compared to the  $G_S$  metric. Encoder-only models’  $S_S$  mainly depend on the fine-tuning language script irrespective of the editing language. For example, in Table 2, average  $S_S$  (including the diagonal entries) for the *Latin* family (97.63%) is sufficiently higher than *Indic* family (91.06%), when mBERT is finetuned on **en**. But when fine-tuned on **hi**, the average  $S_S$  for *Indic* family (98.58%) is higher than the *Latin* family (85.85%). XLM-RoBERTa follows similar trends (See §A.5.3, §A.6.3, §A.7.3 for more details). In contrast, BLOOM shows a very distinct trend. It

results in high  $S_S$  for the *Latin* script family, irrespective of fine-tuning or editing language selection (refer §A.5.1, §A.6.1, and §A.7.1). **Lastly, editing and verifying the edit in the same written script family yields better results.**

**Inference 1** In our analysis, let us consider that we fine-tune using the ‘en’ dataset, and later we perform the XME. If we look at Table 1, for BLOOM (right), the maximum  $G_S$  for en-en is seen in the Middle layers (93.04%), while for the last layers, the reported  $G_S$  is 85.83%. This shows that it is possible that the model stores the facts at different locations. Similarly, let us consider when we fine-tune using ‘en’ (In the same table) and edit and verify in Spanish (es-es); in this case, the reported  $G_S$  is 89.1% in the middle layer and 87.26% in last layers. The information is significantly (different from nearly 2%) available across the sets of layers. We have extended the research question by exploring if the fine-tuning language also has any impact on the editing and if it shifts the information from the middle layers to other sets of layers.

**Inference 2** Referring to Table 12, we fine-tune the BLOOM model on the ‘hi’ dataset. The  $G_S$  score for hi-hi in the initial layer (92.37) is higher than the middle layers (85.58%), which tells us that when we fine-tuned the model on the Hindi dataset, the information is majorly stored in the initial layers rather than our previous assumption of middle layers.

### 5.2 Do different architectures store factual knowledge at different locations?

We have observed that **different architectures store factual knowledge in distinct locations.** Specifically, in the case of encoder-only models, a significant proportion of factual knowledge is found in the Last Layers (LL). Table 1 illustrates that the LL exhibits the highest average  $G_S$  score (78.74%) compared to other layer sets (IL=70.23%, ML=77.93%, and RL=69.32%). In contrast, for BLOOM (decoder-based), factual knowledge is concentrated in the Middle Layers (ML). The ML achieves a notably higher average  $G_S$  score (69.99%) than other layer sets (IL=61.16%, LL=59.19%, and RL=60.73%). This finding aligns with the observations made in (Meng et al., 2022a), which identified similar trends in GPT-2 (Radford et al., 2019), decoder-only model (Qi et al., 2023). Notably, the initial layers demonstrate the lowest  $G_S$  scores for both encoder- and decoder-only models.

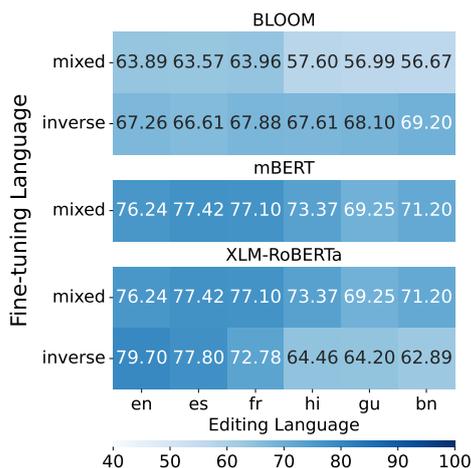

Figure 6: The figure illustrates  $G_S$  given the editing language (x-axis) and fine-tuning datasets (y-axis) for all the three models BLOOM (top), mBERT (middle) and XLM-RoBERTa (right) when edited using MEND.

### 5.3 How does language selection in the initial fine-tuning affect editing performance?

Figure 2 shows the effect of initial fine-tuning performed using six languages. Columns represent average  $G_S$  scores for each editing language. As illustrated, language selection during initial fine-tuning significantly impacts the editing performance for the decoder-only model BLOOM. For instance, fine-tuning on the *Latin* script family led to poor  $G_S$  for the *Indic* script family. Similar trends can be observed when fine-tuning is performed on *Indic* script families. However, in the latter case, the difference of  $G_S$  between the two families is not as high as observed in the former scenario. In the case of encoder-only models, we see a similar performance in both families for *Latin* scripts fine-tuning. **In the case of *Indic* family fine-tuning, the performance of *Latin* scripts is marginally poor than that of *Indic* family.** We attribute this to the effect of editing performance on the disproportionate pretraining on different languages.

We performed additional experiments involving two alternative fine-tuning settings. We created two snapshots of the fine-tuning data: (i) “mixed”, which contained an equal distribution of languages, and (ii) “inverse”, where the languages were represented inversely proportional to their respective pretraining language proportions. It is important to note that a single instance of the mixed dataset was generated for PLMs, while the inverse datasets were specific to each PLM. Since BLOOM and XLM-RoBERTa provide language representation

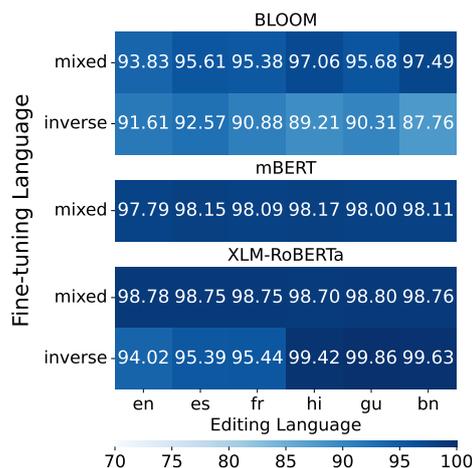

Figure 7: The figure illustrates  $S_S$  given the editing language (x-axis) and fine-tuning datasets (y-axis) for all the three models BLOOM (top), mBERT (middle) and XLM-RoBERTa (right) when edited using MEND.

information, we only created inverse datasets for these PLMs. Figure 6 illustrates the results obtained from the mixed and inverse datasets. Notably, the inverse dataset consistently exhibited performance improvements for the BLOOM model (aka decoder-based). However, the mixed fine-tuning approach performs poorly than the monolingual fine-tuning method. Lastly, in the case of encoder-only models, the mixed and inverse fine-tuning approaches decreased performance compared to the monolingual fine-tuning method.

Intriguingly, the  $S_S$  metric reveals contrasting findings compared to the  $G_S$  metric. Figure 3 demonstrates that **the initial fine-tuning significantly impacts the  $S_S$  scores of encoder-only models, whereas this observation is not observed for decoder-only models.** Similarly, Figure 7 highlights that encoder-only models trained on the mixed dataset exhibit improved  $S_S$  scores compared to monolingual fine-tuning. However, the mixed and inverse datasets do not result in any performance gain for the BLOOM model.

### 5.4 Is the traditional fine-tuning approach more effective than METs in achieving higher performance in the cross-lingual setting?

**Figures 4 and 5 demonstrate that traditional fine-tuning approaches perform comparably to METs in cross-lingual settings.** This observation contrasts the previous claim that shows the significantly low performance of METs in the monolingual setting (Xu et al., 2023; Meng et al., 2022a).

## 6 Conclusion and Future Directions

Our research focuses on conducting rigorous experiments with state-of-the-art hypernetwork-based model editing techniques within cross-lingual settings. Specifically, we investigate the storage patterns of factual associations in encoder-only and decoder-only models, using two distinct language families as our experimental basis. Additionally, we establish a clear dependency between the fine-tuning language selection and the editing tasks' performance.

To further advance the XME paradigm, we plan to utilize parameter-preserving and localized editing techniques. Furthermore, we intend to extend our investigations to encompass other NLP tasks, such as Machine Translation or question-answering. By expanding our research, we aim to enhance our understanding of the capabilities and limitations of hypernetwork-based model editing techniques in diverse cross-lingual settings.

### Limitations

The performance of METs including **KN** (Dai et al., 2022), **SERAC** (Mitchell et al., 2022b), **CaliNet** (Dong et al., 2022), **Transformer-Patching** (Murty et al., 2022), **KAFT** (Li et al., 2022), **Patcher** (Huang et al., 2023), is limited when the information is distributed across layers. Our experiments' findings indicate that the information in different languages is dispensed across types of architectures. While our work focuses on encoder-based and decoder-based architectures, we intend to incorporate encoder-decoder architectures in future research. The objective is to enhance the localizing and efficient updating of factual information in tasks such as generation, translation, and others. To assess the cross-linguality in METs, we aim to propose a dataset to evaluate whether facts dependent on the edited information also undergo changes. For instance, does the fact 'Where is the President of the USA's hometown?' also change when we edit the information about the 'President of USA'.

### Ethics and Potential Risks

The model-editing techniques are designed to edit or delete the information from the LLMs. The editing techniques can be used to modify the model's parameters and can be adversely used. We do not show such harm and intend to show cross-lingual model editing. We carefully adhere to the ethics

and guidelines and ensure our work is ethically correct.

### Acknowledgements

This work is supported by the Prime Minister Research Fellowship (PMRF-1702154) to Himanshu Beniwal. We want to thank Mansi Rana, Anant Kumar, Mihir Patel, Shikhar Nigam, Akbar Ali, Hitesh Lodwal, Indrani Zamindar, Krishna Satish, and Ariana Villegas who helped in verifying the translations. A part of our work was supported by Microsoft's Accelerate Foundation Models Research grant. Lastly, we would like to thank the PARAM Ananta Supercomputing facility under the National Supercomputing Mission coordinated by the Ministry of Electronics and Information Technology (MeitY) and Department of Science and Technology (DST), Government of India, hosted at IIT Gandhinagar.

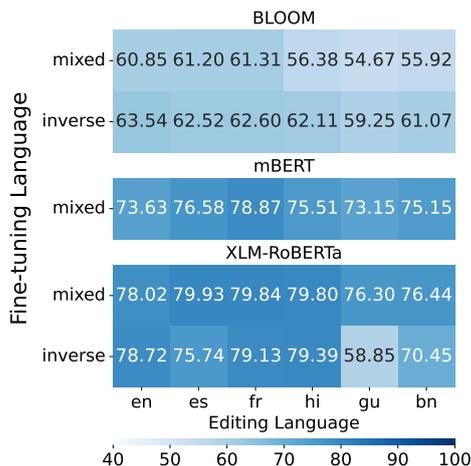

Figure 8: The figure illustrates  $G_S$  given the editing language (x-axis) and fine-tuning datasets (y-axis) for all the three models BLOOM (top), mBERT (middle) and XLM-RoBERTa (right) when edited using **KE**.

## A Appendix

This section contains all the  $G_S$  and  $S_S$  experiments using different ME techniques for different architectures.

### A.1 Dataset

The complete dataset statistic regarding the cross-lingual dataset and Average Lengths (AL) for encoder-only and decoder-only models are shown in Table 6. We considered the samples overlapping in all six languages (not including mixed and inverse) from the train, validation, and test splits. Table 7 and 8 report the inverse proportion of languages for BLOOM and XLM-RoBERTa.

### A.2 Quality Assessment of Translations

We randomly selected 150 instances from the English-FEVER dataset (Thorne et al., 2018) and the corresponding translations and then assigned them to the human annotators. There were two annotators per language; each was a native speaker of the language assigned to them and proficient in English. We recruited language experts who voluntarily helped in the annotation process without pay.

Table 4 shows the individual annotation accuracy and inter-annotation agreement (IAA). In the table, the IAA column represents scores computed from Cohen’s Kappa coefficient, computed between two annotators for the respective language. While computing the IAA, annotators verified that the translated sentences were syntactically and semantically

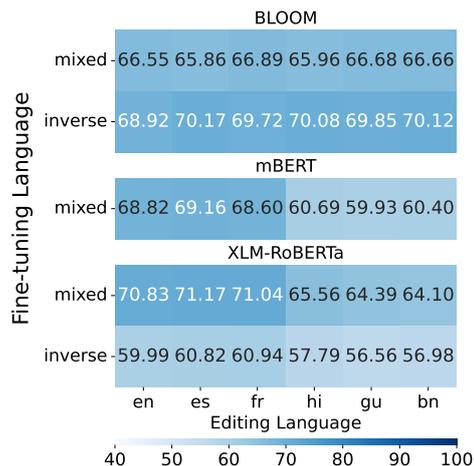

Figure 9: The figure illustrates  $G_S$  given the editing language (x-axis) and fine-tuning datasets (y-axis) for all the three models BLOOM (top), mBERT (middle) and XLM-RoBERTa (right) when edited using **FT**.

correct (No code-switching or code-mixing was allowed). Considering the Relaxed-IAA (R-IAA), code-mixed and code-switched transitions were assumed to be relaxed and surpassed (Correct semantics were verified). Further,  $acc_{a1}$  and  $acc_{a2}$  represent the accuracy<sup>4</sup> of annotators one and two with strict instructions. Lastly, R- $acc_{a1}$  and R- $acc_{a2}$  represent the accuracy with the relaxed instructions from both annotators. Accuracy for individual annotators was over 80 percent in all the cases.

### A.3 Model Editing Techniques

Table 5 reports the 24 editing techniques introduced in top venues over the recent years. The techniques are classified into different editing approaches. From the literature review, the editing techniques have gained popularity and trends to become a focused problem for the future never-aging LLMs. Figure 10 shows the average  $G_S$  for all three models for **KE**. Furthermore, Figure 8 shows the mixed and inverse proportion results for the **KE** and **FT**. Similarly, Figures 13 and 5 show the average  $S_S$  for all three models for **KE** and **FT**. Furthermore, Figure 11 and 12 shows the mixed and inverse proportion results for the **KE** and **FT**.

### A.4 Implementation Details

We utilized the Mitchell et al. (2022a)’s implementation of **MEND**, **KE**, and **FT**. We used the default hyperparameters to fine-tune the base model and the MLPs as specified in MEND’s implementation.

<sup>4</sup>We have computed average accuracy as the ratio of correct translations annotated with the total number of instances.

MET	Model	en	fr	es	hi	gu	bn	mixed	inverse
MEND	BLOOM	9	10	11	12	13	14	15	16
	mBERT	17	18	19	20	21	22	23	-
	XLM-RoBERTa	24	25	26	27	28	29	30	31
KE	BLOOM	32	33	34	35	36	37	38	39
	mBERT	40	41	42	43	44	45	46	-
	XLM-RoBERTa	47	48	49	50	51	52	53	54
FT	BLOOM	55	56	57	58	59	60	61	62
	mBERT	63	64	65	66	67	68	69	-
	XLM-RoBERTa	70	71	72	73	74	75	76	77

Table 3: The table contains the index for all the configurations for ME techniques, models, and fine-tuning data.

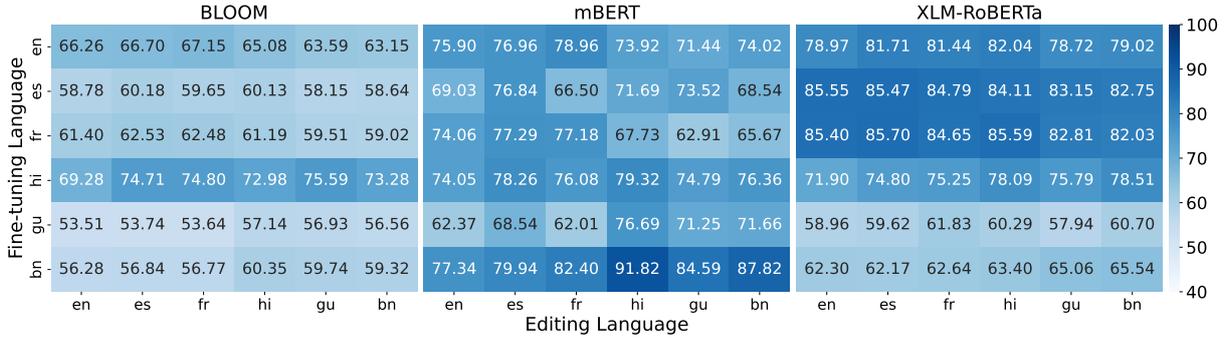

Figure 10: The figure illustrates  $G_S$  given the editing language (x-axis) and fine-tuning languages (y-axis) for all the three models BLOOM (left), mBERT (middle) and XLM-RoBERTa (right) when edited using KE.

Language	IAA	R-IAA	$acc_{a1}$	$acc_{a2}$	Avg. Acc.	R- $acc_{a1}$	R- $acc_{a2}$	R-Avg. Acc.
French	67.00	80.00	88.67	94	91.33	92.00	93.33	92.66
Spanish	66.00	74.00	76.67	84.67	80.67	87.33	90.00	88.66
Hindi	63.00	85.00	75.33	76.67	76.00	93.33	92.67	93.00
Bengali	70.00	76.00	80.67	80.67	80.67	92.67	92.00	92.335
Gujarati	56.00	74.00	66.67	59.33	63.00	74.00	73.33	73.66
<b>Average</b>	64.4	77.8	77.60	79.07	78.33	87.87	88.27	88.07

Table 4: Inter-Annotator Agreement (IAA), Relaxed-IAA, and average accuracy per language the annotators assign for both standard and relaxed configurations (Reported numbers are percentages over 150 instances). In our experiments, two annotators represented as  $a1$  and  $a2$  were asked to annotate the correct translations. Standard accuracy per language by annotator is represented with  $acc_{a1}$  and  $acc_{a2}$ , whereas relaxed accuracy is denoted with R- $acc_{a1}$  and R- $acc_{a2}$  for annotators one and two.

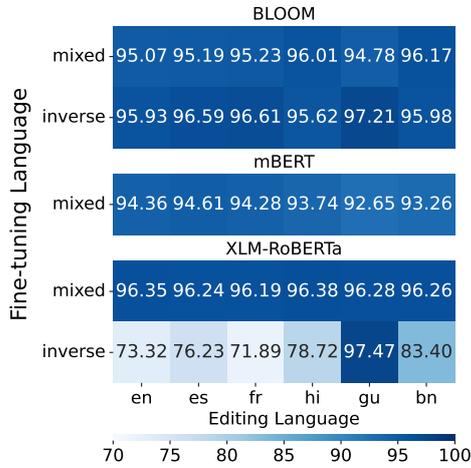

Figure 11: The figure illustrates  $S_S$  given the editing language (x-axis) and fine-tuning datasets (y-axis) for all the three models BLOOM (top), mBERT (middle) and XLM-RoBERTa (right) when edited using **KE**.

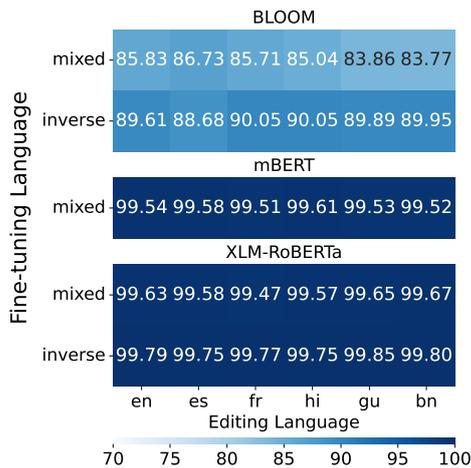

Figure 12: The figure illustrates  $S_S$  given the editing language (x-axis) and fine-tuning datasets (y-axis) for all the three models BLOOM (top), mBERT (middle) and XLM-RoBERTa (right) when edited using **FT**.

We edit one instance per batch. For all 69 configurations with Language Pairs x Models x METs, a total of 9,936 experiments were performed. From the tables indexed in 3, one experiment is computed as  $G_S$  and  $S_S$  for one configuration, say, in Table 9, for IL, when  $x$  is **en**, and  $x'$  is **en** for both  $G_S$  and  $S_S$ . Similarly, for one set of layers (36 values), there are a total of 4 sets and 69 configurations, which sums to  $36 \times 4 \times 69 = 9,936$  experiments.

## A.5 MEND

### A.5.1 BLOOM

Tables 9, 10, 11, 12, 13, 14, 15, and 16 shows the experiments on BLOOM when fine-tuned on **en**, **fr**, **es**, **hi**, **gu**, **bn**, **mixed**, and **inverse**, respectively using **MEND**.

### A.5.2 mBERT

Tables 17, 18, 19, 20, 21, 22, and 23, shows the experiments on mBERT when fine-tuned on **en**, **fr**, **es**, **hi**, **gu**, **bn**, and **mixed**, respectively using **MEND**.

### A.5.3 XLM-RoBERTa

Tables 24, 25, 26, 27, 28, 29, 30, and 31, shows the experiments on XLM-RoBERTa when fine-tuned on **en**, **fr**, **es**, **hi**, **gu**, **bn**, and **mixed**, respectively using **MEND**.

## A.6 KE

### A.6.1 BLOOM

Tables 32, 33, 34, 35, 36, 37, 38, and 39 shows the experiments on BLOOM when fine-tuned on **en**, **fr**, **es**, **hi**, **gu**, **bn**, **mixed**, and **inverse**, respectively using **KE**.

### A.6.2 mBERT

Tables 40, 41, 42, 43, 44, 45, and 46, shows the experiments on mBERT when fine-tuned on **en**, **fr**, **es**, **hi**, **gu**, **bn**, and **mixed**, respectively using **ke**.

### A.6.3 XLM-RoBERTa

Tables 47, 48, 49, 50, 51, 52, 53, and 54, shows the experiments on XLM-RoBERTa when fine-tuned on **en**, **fr**, **es**, **hi**, **gu**, **bn**, and **mixed**, respectively using **MEND**.

## A.7 FT

### A.7.1 BLOOM

Tables 55, 56, 57, 58, 59, 60, 61, and 62 shows the experiments on BLOOM when fine-tuned on **en**, **fr**, **es**, **hi**, **gu**, **bn**, **mixed**, and **inverse**, respectively using **FT**.

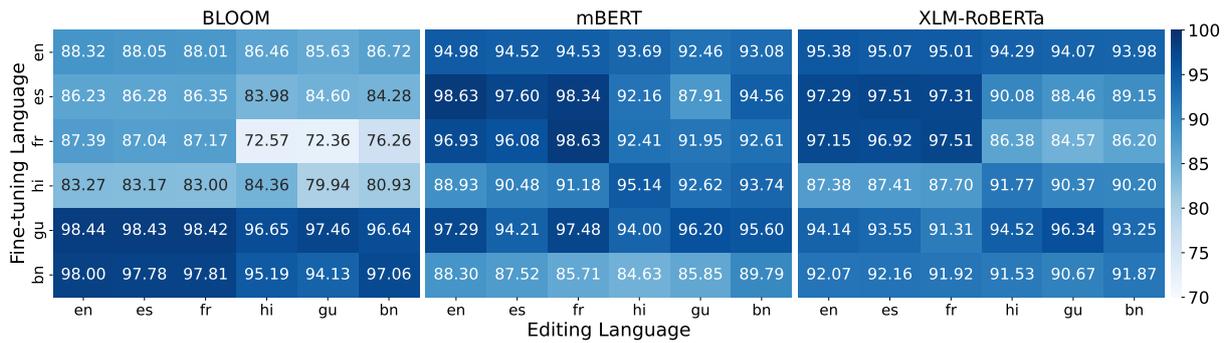

Figure 13: The figure illustrates  $S_S$  given the editing language (x-axis) and fine-tuning languages (y-axis) for all the three models BLOOM (left), mBERT (middle) and XLM-RoBERTa (right) when edited using **KE**.

### A.7.2 mBERT

Tables 40, 41, 42, 43, 44, 45, and 46, shows the experiments on mBERT when fine-tuned on en, fr, es, hi, gu, bn, and mixed, respectively using **FT**.

### A.7.3 XLM-RoBERTa

Tables 70, 71, 72, 73, 74, 75, 76, and 77, shows the experiments on XLM-RoBERTa when fine-tuned on en, fr, es, hi, gu, bn, and mixed, respectively using **FT**.

All 69 configurations for ME techniques, models, and languages are indexed to Table 3. The normalized  $G_S$  for **KE** and **FT** are shown in Figure 10 and 4, respectively. Furthermore, Figures 8 and 9 show the normalized  $G_S$  for **KE** and **FT** for mixed and inverse configurations, respectively using **MEND**.

$Inv_{xlm}$	-	-	11.95	104966	10.8483	10.3747

Table 6: Dataset statistics in different languages. Note TFR and VFR are the average length of training-filtered and validation filtered rephrases, respectively.  $Inv_{bloom}$  and  $Inv_{xlm}$  are the inverse proportion of BLOOM and XLM-RoBERTa. We do not include the inverse proportion of mBERT. Lastly, in all the languages, the size of validation and test remains 10444 and 1193, respectively.

## Abstract

Large language models (LLMs) have revolutionized natural language processing (NLP) by excelling at understanding and generating human-like text. However, their widespread deployment can be prohibitively expensive. SortedNet is a recent training technique for enabling dynamic inference by leveraging the modularity in networks and sorting sub-models based on computation/accuracy in a nested manner. We extend SortedNet to generative NLP tasks, making large language models dynamic without any Pre-Training and by only replacing Standard Fine-Tuning (SFT) with Sorted Fine-Tuning (SoFT). Our approach boosts model efficiency, eliminating the need for multiple models for various scenarios during inference. We show that this approach can unlock the potential of intermediate layers of transformers in generating the target output. Our sub-models remain integral components of the original model, minimizing storage requirements and transition costs between different computational/latency budgets. The efficacy of our proposed method was demonstrated by applying it to tune LLaMA 2 13B on the Stanford Alpaca dataset for instruction following and TriviaQA for closed-book question answering. Our results show the superior performance of sub-models in comparison to Standard Fine-Tuning and SFT+ICT (Early-Exit), all achieved with very efficient tuning and without additional memory usage during inference.

## 1 Introduction

Large language models are revolutionizing the way we interact with information in today's world (Hoffmann et al., 2022; Brown et al., 2020; Penedo et al., 2023; Scao et al., 2022). New models are continually emerging, demonstrating their capabilities in understanding and, more importantly, in generating human-like text. Notably, models such as ChatGPT, LLaMA 2 70B (Touvron et al., 2023b), and Falcon 180B (Almazrouei et al., 2023) have had a profound

impact on the applicability of large language models (LLMs). However, deploying these expansive language models can become prohibitively expensive.

What distinguishes this new era of ChatGPT-like models is their ability to perform an extraordinarily wide array of tasks in natural language processing (NLP), reasoning, and more, all through behavior cloning (Wei et al., 2021; Wang et al., 2022). In fact, a single model can leverage the strong contextual learning ability offered by Standard Fine-Tuning to address numerous tasks, spanning from language comprehension to complex reasoning. While this unified usage simplifies the deployment of these models as general assistants, it remains highly inefficient. Enabling dynamic inference, where the computational resources allocated to a given query vary at inference time, can significantly enhance the practicality of employing such models in real-time scenarios. This enables the use of smaller models when the budget is limited or latency is critical. It is important to note that dynamic inference strategies for large models with a substantial number of parameters should not require loading different models during inference.

Previous research has explored methods for training dynamic models capable of adapting to evolving resource constraints (Cai et al., 2019; Hou et al., 2020; Xin et al., 2020; Fan et al., 2019). However, existing approaches often rely on complex training procedures or necessitate modifications to the original model architecture. SortedNet (Valipour et al., 2023) introduces a novel approach to training deep neural networks that leverages the inherent modularity of these networks to construct sub-models with varying computational loads. This method sorts sub-models hierarchically based on their computation/accuracy characteristics, facilitating efficient deployment during inference. Furthermore, it employs an efficient updating scheme combining random sub-model sampling with gradient accumu-

lation to minimize the training cost. Consequently, with a single round of training, numerous models can be obtained within a single model.

While the SortedNet approach has primarily been applied to vision and language understanding tasks, given the significant impact of generative language models in today’s AI landscape, the efficacy of this method for generative tasks in NLP is of considerable interest. In fact, being able to make a large language model dynamic without the need for Pre-Training and only at the cost of a round of Standard Fine-Tuning can open doors to efficient inference of these models without incurring additional expenses associated with common model compression methods like knowledge distillation and pruning, among others. Moreover, since all the resultant models are components of the original model, the storage requirements and the cost associated with transitioning between different computation demands become minimal. Otherwise, managing multiple models for various scenarios during inference becomes impractical.

In this study, we challenge the conventional approach of relying solely on the last layer’s contextual embeddings and use Sorted Fine-Tuning (SoFT) in place of Standard Fine-Tuning to enhance the performance of these models across multiple layers. By doing so, we aim to provide new insights into the efficiency and effectiveness of middle layers in producing high-quality results for specific downstream tasks. Our proposed approach can potentially optimize these sub-models in addition to the main model, ultimately enhancing their overall performance. In this paper, we seek to answer the following questions through systematic evaluation:

i) Do the intermediate layers resulting from Standard Fine-Tuning of a large language model generate accurate and meaningful outputs? ii) Does Standard Fine-Tuning exhibit a sorted behavior, meaning that later layers produce more accurate and meaningful results than earlier layers? If so, to what extent? iii) How can we enhance this sorted behavior with minimal cost?

To answer these questions, we employ LLaMA 2 13B and perform both Standard Fine-Tuning (SFT) and Sorted Fine-Tuning (SoFT) on the Stanford Alpaca (Taori et al., 2023) and TriviaQA (Joshi et al., 2017) datasets. For Sorted Fine-Tuning, we target 8 sub-models and share the LLM head among them to ensure cost parity. We utilize the PandaLM benchmark (Wang et al., 2023) to assess the perfor-

mance of the sub-models on Alpaca dataset. Our findings demonstrate the superior performance of SoFT in comparison to SFT and even to memory-demanding methods like Early Exit (Xin et al., 2020). The contributions of this paper can be summarized as follows:

- Extending the SortedNet method for tuning auto-regressive language models for generative tasks by sharing a single LLM head layer among sub-models.
- Generating 8 nested sub-models, ranging from 12 to 40 layers, from LLaMA2 13B by applying Sorted Fine-Tuning on the Stanford Alpaca dataset and TriviaQA benchmarks and at a cost equivalent to Standard Fine-Tuning.
- Evaluating the performance of the sub-models of a LLaMA 2 and demonstrating the effectiveness of SoFT in enhancing the ability of intermediate layers for text generation and question answering through extensive evaluation.

## 2 Related Work

This section briefly introduces the most relevant papers to our work.

**Many-in-One Models** Deep neural networks (DNNs) are often overparameterized, motivating researchers to explore ways to use the parameters of the models more efficiently. More number of parameters lead to higher costs of deployment for neural networks. Moreover, in practice, these overparametrized DNNs are expected to accommodate customers with varying requirements and computational resources. To address these diverse demands, one can think of training models of different sizes, which can be prohibitively costly (in terms of training and memory), or another alternative is to train many-in-one networks (Cai et al., 2019). Many-in-one solutions aim to train a network along with some of its sub-networks simultaneously for specific tasks. For example, we can consider the *Early-Exit* method (Xin et al., 2020), wherein a prediction head is fine-tuned on top of specific intermediate layers within a network. Another approach is *Layer Drop* (Fan et al., 2019), which trains a network in any depth by randomly dropping the layers during training. While both Early-Exit and Layer Drop are simple solutions, they are not state-of-the-art in terms of performance. In Early-Exit, we only train the output prediction layer on top of each intermediate layer, and this layer might not have enough

capacity to retain a good performance. Layer Drop, conversely, suffers from the abundant number of possible sub-models in training, which makes the training process exhaustive and sub-optimal. Furthermore, this approach requires tuning the extent of dropping layers during training. This additional hyper-parameter, layer drop rate during training determines the best size and setting of the model at the inference time. Deviating from the training drop rate at the inference time can result in a significant drop in performance.

Cai et al. (2019) in *Once for All (OFA)* proposed an alternative solution to neural architecture search (NAS). OFA requires training the model and all possible sub-models in an arbitrary progressive way followed by a separate search phase. Dyna-BERT (Hou et al., 2020) is another work that targets training Dynamic pre-trained many-in-one BERT models in two stages: first, distilling from the main network to the width adaptive networks and then distilling from the width adaptive networks to depth adaptive networks. Both width adaptive and depth adaptive networks have a limited pre-defined set of width and depth for the sub-models. While both OFA and DynaBERT have shown successful results, their solutions are hardly applicable to multi-billion-parameter LLMs because of their complicated multi-stage training process and their search and knowledge distillation requirements. SortedNet (Valipour et al., 2023) is a recent method that forms and trains sub-models of a network in a sorted manner while not requiring any search during training or inference. SortedNet has shown superior performance compared to other previously mentioned methods in terms of simplicity, performance, scalability, and generalization. Considering these benefits, we target deploying the SortedNet training algorithm for developing many-in-one LLMs.

### Many-in-One Large Language Models (LLMs)

Large language models have recently gained significant attention in the literature (Touvron et al., 2023a; Brown et al., 2020; OpenAI, 2023; Chowdhery et al., 2022; Ouyang et al., 2022). In practice, these LLMs serve users with different tasks, expectations, and computational budget requirements (Sun et al., 2022). There are two types of adaptation approaches to make LLMs suitable for customer requirements: first is the so-called parameter efficient tuning (PEFT), and second is model compression. In PEFT, the

core backbone model remains the same, and we just update much smaller adapter parameters (e.g. LoRA (Hu et al., 2021), KRONA (Edalati et al., 2022), Adapter (Houlsby et al., 2019; Pfeiffer et al., 2020), DyLoRA (Valipour et al., 2022), Ladder Side-Tuning (Sung et al., 2022)) and Compacter (Karimi Mahabadi et al., 2021). In model compression, the larger model is compressed using any model compression solutions such as knowledge distillation (Hinton et al., 2015; Hsieh et al., 2023; Wu et al., 2023), pruning (Bansal et al., 2023), and quantization (Prato et al., 2019; Dettmers et al., 2023), a good related survey can be found in (Zhu et al., 2023). Even though PEFT solutions are pretty popular with LLMs, they do not provide dynamic-size LLMs. Model compression solutions can provide models with different sizes, but they need to train each compressed model separately, and they are not many-in-one models.

To the best of our knowledge, this work is the first attempt to obtain many-in-one generative LLMs by applying the Sorted Fine-Tuning to the LLaMA 13B model. Considering the benefits of many-in-one networks and the growing application of LLMs, we are hoping that this will help the community to build more efficient large language models that can be deployed adaptive during inference using methods such as SoFT.

## 3 Methodology

This paper focuses on making generative LLMs many-in-one by unlocking the potential of intermediate layers through the SortedNet approach (Valipour et al., 2023).

Let's consider a language model  $f(x; \theta)$  with the parameters  $\theta$  and the input  $x$ . The following is the sorted training procedure:

**Forming Sub-Networks** First, we need to form the sub-networks of the LLM. For the sake of simplicity and without loss of generality, we focus on the depth-wise sub-networks. Supposed that the sub-network  $f_n(x; \theta_n)$  refers to the first  $n$  layers of  $f(x; \theta)$ . In this paper, the language model is considered to be LLaMA2 13B. Since LLaMA2 comprises 40 layers, we define the sub-networks as  $n \in \mathbf{B} = \{12, 16, 20, 24, 28, 32, 36, 40\}$ .

**Calculating the Output of Sub-Networks** Each sub-model's output will be predicted using the shared output prediction head from the last layer (original network). Remember that in the LLaMA

40	At the meeting, Rose presented the analysis of the data and shared her findings with the team. John proposed a new idea that he believed could benefit the company. Jane was appointed to head a new project that the company had recently taken on. Tom, however, requested more time to fix a software bug that had been discovered. The team discussed the importance of the bug fix and agreed to give Tom the additional time he needed.	In the meeting, Rose analyzed data and presented her findings. John proposed a new idea, and Jane was appointed to head the project. Tom requested more time to fix the software bug.

Table 1: Generated responses in different layers of LLaMA (Early Exit) and Sorted LLaMA for two samples from PandaLM validation set. Black phrases mean the answer is following the instruction and **Red** ones demonstrate errors and hallucinations.

model, there is an RMSNorm layer (Zhang and Sennrich, 2019) before the output prediction head. This RMSNorm is added before the shared prediction head of every sub-model. This normalization may be an important factor that helps Sorted LLaMA to generalize better for all sub-models.

**Objective Function** Let  $L_n(x; \theta_n)$  be the loss for the  $n^{\text{th}}$  sub-model for input batch  $x$ . To train the network, we define the loss as the summation of the losses of all these sub-models:

$$\mathcal{L} = \frac{\sum_{n \in \mathbf{B}} L_n(x; \theta_n)}{|\mathbf{B}|} \quad (1)$$

For the experiments conducted in the paper,  $|\mathbf{B}| = 8$ . Note that these sub-models have shared parameters through a nested style i.e.  $\theta_1 \subset \theta_2 \dots \subset \theta_n$ .

**Training Dataset** We utilized the Stanford Alpaca dataset (Taori et al., 2023), which includes demonstrations of 52K instruction-following examples. We also used TriviaQA open-domain QA benchmark (Joshi et al., 2017) including 110K closed-book question-answer pairs.

**Evaluation** In this paper, in addition to embedding the last layer, we evaluate the quality of the embeddings of intermediate outputs spanning from block 1 to  $n$ . PandaLM benchmark (Wang et al., 2023) compares the output of different sub-models. PandaLM deploys a large language model (Fine-Tuned LLaMA 7b) to judge the quality of generated text from two sources. PandaLM provides a valida-

SFT

Figure 1: SoFT vs. SFT + ICT (Early-Exit) (Left) and SoFT vs. SFT (Right). Note that for our SoFT method, the output prediction layer is shared between all sub-models whereas, for Early-Exit, a separate prediction head is learned per sub-model, making inference inefficient. Both SoFT and SFT had equivalent training time (2 Epochs) in this experiment. The number in each cell is calculated by considering wins as the times SoFT sub-models (rows) were preferred, losses as the times SFT sub-models (columns) were preferred and ties when non of them were preferred (Equation 2).

tion set consisting of 170 instructions<sup>1</sup>, to evaluate target models for instruction-following tasks. To ensure that the order of the models’ responses does not influence the judgment of the PandaLM evaluator, we reported an average score under both the Model 1 first and the Model 2 first scenarios. The output of the PandaLM evaluation is the number of wins, denoted as  $W$ , the number of losses, denoted as  $L$ , and the number of ties, denoted as  $T$ , in the validation set. The final reported score has been calculated using the following formula:

$$Score = \frac{(W - L)}{T} \quad (2)$$

The final score is a number between -1 and 1, in which 1 represents a strong win rate and -1 means a poor performance of the model.

We used accuracy (exact match) as the evaluation metric for the TriviaQA benchmark.

**Baseline** The primary objective of the LLM in this paper is to follow the provided instructions by a query. Therefore, following the setup of Alpaca (Taori et al., 2023), we fine-tuned LLaMA2 13B on the Stanford Alpaca Dataset with two setups: (1) Regular Standard Fine-Tuning (SFT) as the baseline, focusing only on the training of the last layer of the network as the common practice in the literature; (2) Sorted Fine-Tuning (SoFT), calculating loss for multiple outputs from layer 12 to layer 40 (last layer) with four intervals, and train-

ing multiple models simultaneously as explained in the previous section.

## 4 Experiments

This section delves into the experiments’ specifics and the analysis provided to understand better the effect of Sorted Fine-Tuning over the performance of a large language model like LLaMA2 (Touvron et al., 2023b). Before diving into results, we are going to define certain notations that we used for different setups in our experiments:

- **SoFT/SFT:** We first train the model with SoFT or SFT paradigms and use the sub-models after training without any further training of the language model head for intermediate layers.
- **SFT+Intermediate Classifier Tuning (ICT):** We first train the model with SFT paradigm and then further fine-tune the language model head exclusively for each sub-model while keeping their weights frozen. The SFT+ICT is also known as Early-Exit (Xin et al., 2020) in the literature.
- **Extracted Fine-Tuning:** When we extract the sub-models from the learned weights of the pre-trained original model and train each sub-model separately.

### 4.1 Experimental Setup

We used the pre-trained LLaMA2 13b weights, publicly available on Hugging Face, as our starting point. For SFT+ICT (Early-Exit) setup, we froze the parameters of the transformer blocks and only

<sup>1</sup>github.com/WeOpenML/PandaLM/blob/main/data/testset-inference-v1.json

further trained the weights of the language model head classifier for one additional epoch. We used a batch size of 32 and gradient accumulation of 8. The learning scheduler was cosine annealing. The learning rate was set to  $2e-5$  and seed to 42. We trained the models on 8 V100 32GB GPUs. The same GPUs were used during inference time. The training maximum input sequence length was 2024, with a maximum of 50 (TriviaQA) and 256 (PandaLM) generated tokens during inference. Additionally, we used greedy search as the decoding strategy in all of our experiments. We also extended the huggingface assisted decoding code to implement Speculative Decoding and Instance-Aware Adaptive Inference. In Speculative Decoding, we used adaptive K window-size (the same as huggingface) starting with  $K=4$ . In Instance-Aware Dynamic Inference, we set the confidence thresholds of intermediate layers as follow: Layer 12 = 0.95, Layer 16 = 0.95, Layer 20 = 0.9, Layer 24 = 0.9, Layer 28 = 0.8, Layer 32 = 0.8 and Layer 36 = 0.7.

## 4.2 What is the effect of sorting information across layers of a generative model?

As mentioned before, we generated responses for all the layers  $n \in \mathbf{B}$  for both SFT and SoFT-based trained models. Then, we conducted a pair-wise comparison between all the sub-models in the two trained models using the PandaLM evaluator. As the results suggest in Figure 1, sorted training significantly unlocks the potential of intermediate layers in generating the desired output.

Sorted LLaMA (aka SoFT) is outperforming regular fine-tuning (SFT) in nearly all layer comparisons by a meaningful margin, as shown through automated evaluation in Figure 1.

It might be noted that the Layer 12 performance of SFT is slightly better compared to Layer 12 of Sorted LLaMA. We argue this is happening because the outputs of early layers in SFT are mostly gibberish (see Table 1 as an example), and the PandaLM evaluator has not been trained on such data. Hence the automatic evaluation results for this layer are not meaningful. To further investigate the reason behind the results for early sub-models, we conducted human evaluation on 6 cells of two tables in Figure 1 (Layer 12 of SFT and SFT+ICT vs Layers 12,16, and 20 SoFT) to verify our claim. We observed that SoFT early sub-models could significantly outperform sub-model layer 12 of both SFT and SFT+ICT models, proving the negative

impact of gibberish text on PandaLM evaluator performance. As we go to higher layers in SFT, the generated text becomes meaningful, which makes the comparison with the Sorted LLaMA layer counterpart more reasonable.

Moreover, to improve SFT results, inspired by Early-Exit (Xin et al., 2020), we also tried the scenario in which a separate classifier head is dedicated to all sub-models of SFT. This method has been introduced in the notation section as SFT+ICT. These classification heads have been trained an additional epoch after SFT tuning while keeping the base model frozen. Note that this setting suffers from significant memory overhead during tuning and inference compared to our SoFT method. In fact, the extra number of parameters for SFT+ICT (Early Exit) is  $|B| - 1 \times D \times V$ , where  $|B|$  is the number of sub-models,  $D$  is the hidden size of the model, and  $V$  is the vocabulary size. For LLaMA 2 13B, this is equivalent to 1B extra parameters.

The results of comparing sorted with the early exit are shown in figure 1 (Left). Despite having far more parameters, SFT+ICT (Early-Exit) underperforms our sorted tuning for most sub-models. According to the results, the sub-model in Sorted LLaMA with 36 layers performs almost as well as regular fine-tuning of the full-size model. This showcases the impressive ability of our proposed paradigm to generate powerful, small sub-models that perform similarly to the original model. Another experiment that has been conducted in appendix A.2, further investigated the impact of longer training time for SoFT. The results show that our model was still under-trained, and we could observe a significant improvement in Sorted LLaMA performance with longer training time.

Moreover, we compared the performance of Sorted LLaMA sub-models with the actual capacity of these models by fine-tuning the sub-models separately and reporting the results in both equal training time and more training time for SoFT. We extracted 4 sub-models (Layer 12, Layer 20, Layer 28, and Layer 36) and each time fully fine-tuned the extracted sub-model separately for two epochs on the Alpaca dataset. Figure 2 and Table 9 shows the comparison between Extracted Fine-Tuned and SoFT sub-models. The first part in Table 9 shows the equal training budget setup (2 Epochs) comparison in which SFT demonstrates slightly better performance compared to the similar SoFT sub-models. Further training SoFT will lead to better sorted sub-models in which SoFT outperforms the

fully fine-tuned sub-models, proving the positive impact of SoFT on the performance of lower sub-models.

	12	20	28	36		12	20	28	36

Figure 2: SoFT vs. Extracted Fine-Tuning. The left figure shows an equal training time setup (2 epochs), and the figure on the right considers two extra training epochs for SoFT.

### 4.3 How does SoFT work for other domains?

We further evaluated Sorted LLaMA in a different domain from the instruction following, selecting the TriviaQA (Joshi et al., 2017) benchmark to assess the sub-models performance in open-domain closed-book questions answering.

Figure 3 shows the performance of SoFT and three SFT, Extracted Fine-Tuning and SFT+ICT baselines in different checkpoints through the training procedure on the TriviaQA benchmark. SoFT sub-models show significant superior performance compared to SFT and SFT+ICT counterparts in all sub-models. Similar to PandaLM, the gap between SoFT and SFT full-model performance is small in TriviaQA, which can underscore the SoFT capability in maintaining full-model performance compared to SFT. We also did Extracted Fine-Tuning on intermediate sub-models for 2 Epochs and results demonstrate close performance of SoFT intermediate layers to Extracted Fine-Tuning counterparts.

### 4.4 How can SoFT accelerate text generation?

**Improving Speculative Sampling** Speculative Decoding (SD) is a technique introduced by (Chen et al., 2023) to increase the speed of text decoding in large models. The method utilizes a large target and smaller draft models to generate tokens faster. We can verify the generated tokens by the large model in parallel. We used the same paradigm for Sorted LLaMA as we used earlier sub-models as

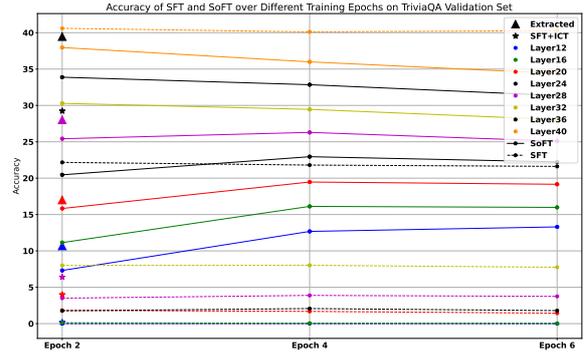

Figure 3: The results of TriviaQA. We reported case-sensitive exact match accuracy as the main metric. SFT+ICT and Extracted Fine-Tuning results can be found in Epochs 2, as we found Epoch 2 checkpoint saturated for the original SFT experiment (main LLaMA2 13b model with 40 layers).

draft and the full-size model as the target model. As the parameters have been shared between the large and draft models in this setup, we can avoid any extra memory overhead, unlike the standard Speculative Sampling. Table 2 reports the results of using speculative decoding on Alpaca and TriviaQA benchmarks in inference in SoFT by using three different sub-models as drafts (Layer 12, 16, and 20). Using Speculative decoding in Sorted LLaMA can speed up the token generation up to  $1.16\times$  compared to normal auto-regressive decoding in PandaLM with negligible performance drop compared. Due to the short average length of answers in TriviaQA, speculative decoding does not result in speed up in this benchmark as the draft generation process does not find any opportunity to accelerate inference.

**Instance-Aware Dynamic Inference** We also dynamically utilize SoFT sub-models to increase text generation speed during inference. Based on the confidence of the sub-model’s predicted tokens, we decide which sub-model needs to generate each token during inference. Given each token during inference, the sub-models would process the token in size order (first smallest sub-model 12, then 16, and so on). Wherever in this procedure, the confidence of the predicted token by a sub-model is higher than the defined confidence threshold, the predicted token would be chosen as the next token and exit the model. We also implemented an adaptive caching mechanism in order to utilize KV caching in this non-trivial scenario where each token can exit from a different layer. Table 2 shows that Instance-Aware Dynamic Inference can speed up the normal auto-regressive approach in all benchmarks up to  $1.34\times$  in PandaLM and  $1.12\times$  in TriviaQA. Furthermore

PandaLM				TriviaQA		
<b>Auto-regressive Decoding</b>						
Model	Time per Token (ms)	Score	Rejection Ratio	Time per Token (ms)	Accuracy	Rejection Ratio
Layer 40 (full)	94.07	-	-	91.27	37.95	-
<b>Speculative Decoding</b>						
Draft Model	Time per Token (ms)	Score	Rejection Ratio	Time per Token (ms)	Accuracy	Rejection Ratio
Layer 12	80.86 (1.16 $\times$ )	-0.144	0.37	110.50 (0.82 $\times$ )	34.36	0.72
Layer 16	84.10 (1.11 $\times$ )	-0.211	0.31	118.92 (0.76 $\times$ )	34.16	0.70
Layer 20	84.50 (1.11 $\times$ )	-0.144	0.26	139.78 (0.65 $\times$ )	34.19	0.66
<b>Instance-Aware Dynamic Inference</b>						
Model	Time per Token (ms)	Score	Rejection Ratio	Time per Token (ms)	Accuracy	Rejection Ratio
Layer 12:40	69.91 (1.34 $\times$ )	-0.050	-	81.01 (1.12 $\times$ )	36.53	-

Table 2: Speed-up in inference time on three PandaLM and TriviaQA benchmarks by utilizing Speculative Decoding and Instance-Aware Dynamic Inference techniques. Score column in PandaLM section means the score of the model versus the Auto-regressive generated results based on Equation 2.

dynamic inference can result in better performance in PandaLM and TriviaQA compared to speculative decoding.

## 4.5 Analysis

### 4.5.1 A comparison between the learned probability distribution of SoFT versus SFT

Sorted tuning aims to make sub-models performance similar to the full model. To explore the efficacy of the SoFT in closing the gap between sub-models and the full model in instruction following task, we measure the similarity between probability distributions of each token in each sub-model versus the full model using the Kullback–Leibler (KL) divergence. Figure 4 (Left) compares the probability distribution of Sorted LLaMA and SFT sub-models at different output positions.

Figure 4a (Left) compares different SFT layers and the last Sorted LLaMA layer. The figure shows that only SFT’s full-size output distribution is close to the sorted full-size model, while the other layers’ distribution diverges faster in the initial steps compared to the SoFT. This is expected as the language model head is unfamiliar with the learned representation of the middle layers in SFT. In the next section, we compared the learned representations of different sub-models to understand SoFT’s impact better.

Figure 4b (Left) compares the output distribution of all sorted layers to the last SFT layer. Compared to Figure 4a (Left), Figure 4b (Left) Sorted LLaMA can preserve the output distribution close to the SFT full-size model even in lower layers for initial output tokens.

The comparison between the last layer and the layers 12 to 36 in the SFT model is shown in Figure

5a (Left). It is clear from this figure that the output distribution diverges quickly compared to the last layer after generating a few initial tokens, even in higher layers like 36 and 32. It is important to note that this evaluation was generated without adjusting the classifier head.

Finally, Figure 5b (Left) demonstrates that in Sorted LLaMA, the likelihood distribution of the produced outcome becomes increasingly more similar to the full-size model as we get closer to the last layer.

### 4.5.2 A comparison between the learned representation of SoFT versus SFT

During regular fine-tuning, no connection between the language model head and sub-models can intensify the divergence of probability distributions in Figure 4 (Left). To overcome this, we conducted another experiment to compare the hidden state representation in the last and middle layers just before passing the hidden states to the language model head. Figure 4 (Right) compares the learned hidden state representation of SFT and Sorted LLaMA sub-models at various positions in the output. This will make the analysis independent of the language model head. We used cosine similarity to measure the difference between the two representations. As shown using heatmaps, the cosine similarities are highly correlated to the KL-Divergence comparison explained in the previous section.

Figure 4a (Right) compares all SFT sub-models with the Sorted last layer regarding hidden representation similarity. Again, similar to probability distribution analysis, the similarity between the SFT sub-model and Sorted last layer tends to fade immediately after generating the first few tokens, while

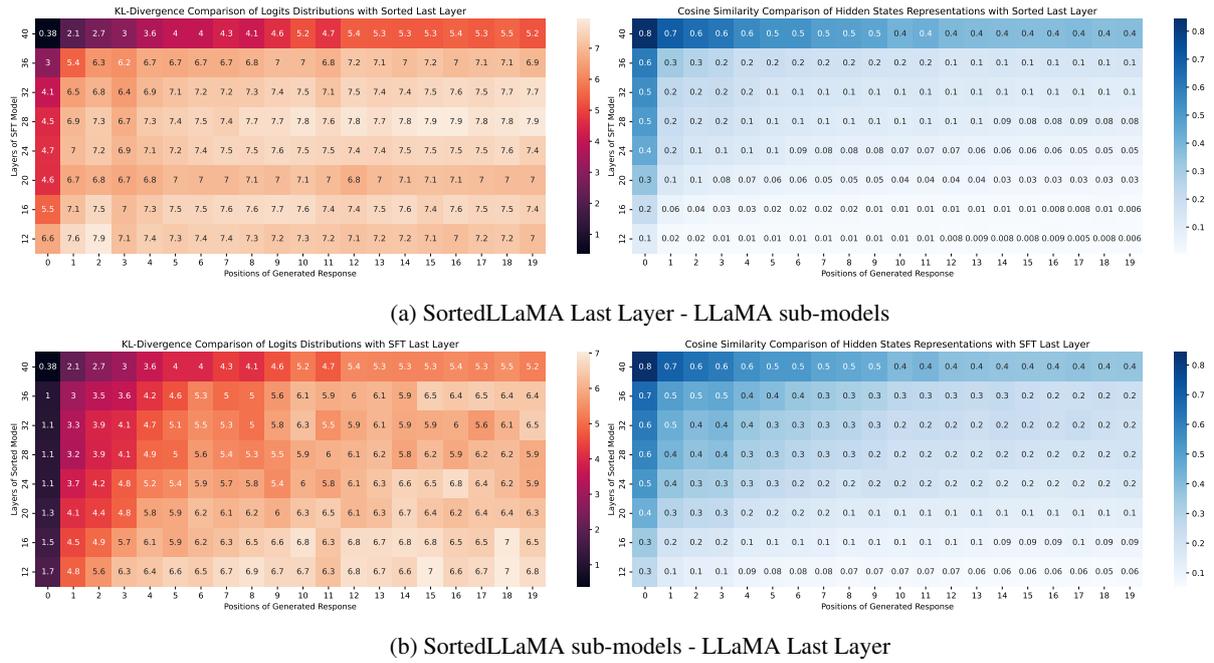

Figure 4: A sub-model comparison based on output logits and hidden state cosine similarity. The numbers are average of all 170 samples in the PandaLM validation set.

Figure 4b demonstrates the capability of Sorted LLaMA sub-models in preserving the learned representations closely similar to the SFT last layer hidden states.

Figure 5a (Right) depicts the heatmap of hidden states cosine similarity among different SFT sub-models compared to the SFT last layer. Similar to its left plot, the similarity quickly diminishes after a few tokens, and this fade is more considerable in earlier layers.

On the other hand, Figure 5b (Right) shows that the representations of Sorted sub-models stay similar to the Sorted last layer even after generating multiple initial tokens.

### 4.5.3 Case Specific Analysis

Table 1 shows a sample of instructions from the PandaLM benchmark and the generated responses by SFT+ICT (Early-Exit) and Sorted LLaMA sub-models. Sorted LLaMA performs better in preserving and transferring the last layer performance to earlier sub-models based on the information made visible by black (related to the query) and red (hallucinations, irrelevant, etc.) colors.

Sorted sub-models generate almost correct answers from the 20 layers sub-model, while the first meaningful result from SFT+ICT sub-models appears in layer 28. Other samples generated by SoFT and Early-Exit can be found in A.3.

## 5 Conclusion

This work presents sorted LLaMA, a many-in-one language model for dynamic inference obtained using Sorted Fine-Tuning (SoFT) instead of Standard Fine-tuning. Sorted LLaMA unlocks the potential capability of intermediate layers, offering dynamic adaptation without pre-training or additional expenses related to model compression. It presents a promising avenue for optimizing generative language models in NLP. Our approach makes the deployment of these models far more efficient. As all sub-models remain integral components of the original model, the burden of storage requirements and transition costs between different computational demands is minimized, making the management of multiple models during inference a practical reality.

Our systematic evaluation of instruction following and questions answering benchmarks challenged conventional wisdom by empowering middle layers to produce high-quality results. This, in turn, enables dynamic inference of LLMs with a highly efficient tuning method (SoFT), ultimately optimizing the usage of LLMs. Our encouraging results show the promising capability of SortedNet (Valipour et al., 2023) to train multiple language models with different sizes at once without incurring expensive costs.

## 6 Limitations

Despite showing the effectiveness of the Sorted-Net approach for large language models, further research is necessary to better understand the scope of its applicability in LLMs. For example, applying this method during pre-training, sorting other model dimensions such as attention heads and hidden dimensions, and investigating the impact of choosing a specific architecture could offer potential avenues for future research. Our study might be slightly biased to automated evaluation, requiring further investigation through human evaluation.

Method	Avg Time per Epoch (s)	Avg Memory Usage per Epoch (MB)
SFT	25,765.95	99,168
SoFT	25,269.87 (0.98×)	125,682

Table 3: Training Time and Memory Usage comparison of SoFT and SFT on Alpaca dataset.

## A Appendix

### A.1 Computational Overhead of SoFT

Given the nested pattern of sub-models and the fact that we share the language model head across sub-models, we do not expect to see any computation overhead for SoFT versus SFT. To validate this claim, we compared SoFT and SFT regarding training time and memory usage in our experiment on the Alpaca dataset (Table 3). Here is the result for two main experiments of SoFT and SFT. As expected, training with SoFT leads to equal training time compared to SFT. During training, SoFT has about 25% memory overhead in PyTorch compared to SFT, which only provides a single full model at the end.

### A.2 Additional Experiments

Table 4 shows the detailed results of the Sorted LLaMA and SFT performance on the PandaLM benchmark in different setup in equal training time (2 Epochs for both SFT and SoFT). As we can see, sorted sub-models outperform their SFT counterparts (and even higher sub-models), while in SFT+ICT (Early-Exit), as we go higher in sub-models (e.g. layer 36), we can see a noticeable improvement in the performance compared to the SFT. This can demonstrate the importance of tuning the language model classifier in improving text generation capability in the latest layers in the standard fine-tuning format.

Table 5 shows the SoFT and SFT comparison in a different training time setup in which SoFT has access to doubled training time (4 Epochs). Results show that Sorted LLaMA can outperform standard fine-tuned LLaMA further by continuing the SoFT process. The improvement in Sorted LLaMA sub-models performance can be observed specifically in intermediate layers.

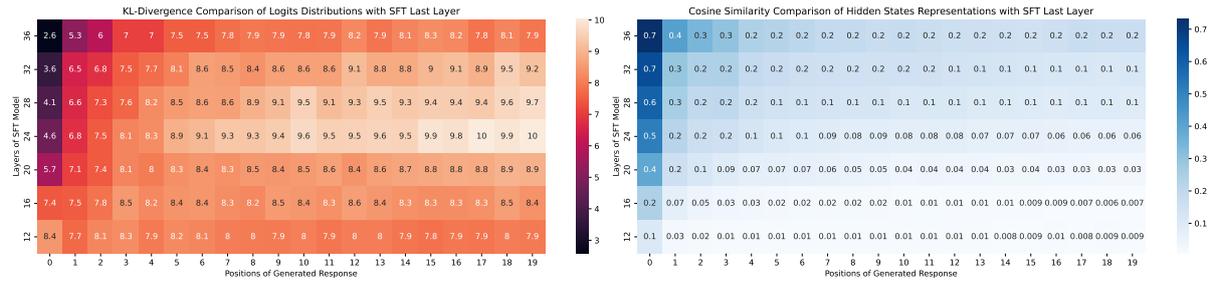

### A.3 Analysis

Table 6 and 7 show some samples generated by sub-models of LLaMA (SFT+ICT) and SoFT on PandaLM evaluation set. In the first query of Table 6, LLaMA sub-models until layer 36 struggle to generate relevant responses about books in the

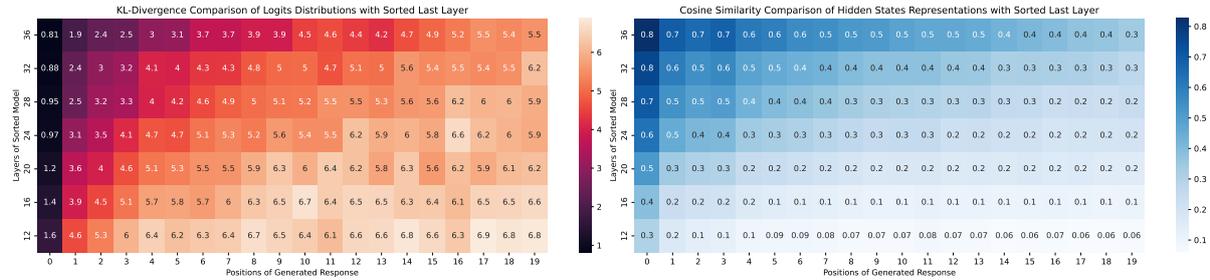

Crime and Mystery genre. While Sorted LLaMA sub-models start to address the related novels from layer 24. The second query in the table is a simpler instruction, which is a multi-label classification problem. Again Sorted LLaMA sub-models start to generate the correct label in much earlier layers (layer 20) compared to the LLaMA sub-models (layer 24). Table 7 first example shows the performance gap of the LLaMA and Sorted LLaMA intermediate sub-models even in a more severe case. To write a review about a restaurant with certain aspects, LLaMA sub-models before layer 32 hallucinate or generate gibberish, while Sorted LLaMA starts to generate a complete review addressing key points mentioned in the instruction even in the first sub-model (layer 16). In the second example, the same pattern occurs where SoFT sub-models can generate meaningful response starting from layer 16 while LLaMA first reasonable text happens at layer 36.

Table 8 shows an example of SFT and SoFT performance on TriviaQA benchmark. While LLaMA struggles to generate single answer token even in the sub-models close to the last layer, SoFT could transfer the question answering ability until sub-layer 20 and generate the correct final answer.

After all, Sorted LLaMA sub-models demonstrate the ability to generate more comprehensive (Table 6 example 1 and Table 7 example 1) and informative (Table 6 example 2) answers in earlier layers compared to LLaMA. Based on our observation, LLaMA sub-models mostly tend to generate irrelevant or even gibberish in earlier blocks (layers 12 to 24), while the generated texts by Sorted LLaMA exhibit sufficient learned information to answer the input instruction despite having much fewer parameters.

(a) LLaMA sub-models vs LLaMA Last Layer

(b) SortedLLaMA sub-models - SortedLLaMA Last Layer

Figure 5: A comparison of sub-models based on output logits and hidden state cosine similarity.

Sorted LLaMA/LLaMA	12 (4.1B)	16 (5.4B)	20 (6.6B)	24 (7.9B)	28 (9.2B)	32 (10.4B)	36 (11.7B)	40 (13B)

Table 4: Pair-wise comparison for different layers (sub-models) in Standard Fine-Tuning and SoFT at equal training cost (2 Epochs). Each cell consists of three values: Wins, Losses, Ties. Wins demonstrate the number of times that the generated text of the sub-model in row (sorted) is preferred to the sub-model in column (Fine-Tuned) and Losses is the opposite. Numbers are average of two separate experiments with different order of inputs to evaluator in order to neutralize the order bias.

## Abstract

Despite advancements in speech recognition, accented speech remains challenging. While previous approaches have focused on modeling techniques or creating accented speech datasets, gathering sufficient data for the multitude of accents, particularly in the African context, remains impractical due to their sheer diversity and associated budget constraints. To address these challenges, we propose *AccentFold*, a method that exploits spatial relationships between learned accent embeddings to improve downstream Automatic Speech Recognition (ASR). Our exploratory analysis of speech embeddings representing 100+ African accents reveals interesting spatial accent relationships highlighting geographic and genealogical similarities, capturing consistent phonological, and morphological regularities, all learned empirically from speech. Furthermore, we discover accent relationships previously uncharacterized by the Ethnologue. Through empirical evaluation, we demonstrate the effectiveness of *AccentFold* by showing that, for out-of-distribution (OOD) accents, sampling accent subsets for training based on *AccentFold* information outperforms strong baselines with a relative WER improvement of 4.6%. *AccentFold* presents a promising approach for improving ASR performance on accented speech, particularly in the context of African accents, where data scarcity and budget constraints pose significant challenges. Our findings emphasize the potential of leveraging linguistic relationships to improve zero-shot ASR adaptation to target accents. Please find our code for this work here.<sup>1</sup>

## 1 Introduction

English language is spoken in 88 countries and territories as either an official, administrative, or

<sup>1</sup>[https://github.com/intron-innovation/accent\\_folds](https://github.com/intron-innovation/accent_folds)

\* Authors contributed equally

cultural language, estimated at over 2 billion speakers with non-native speakers outnumbering native speakers by a ratio of 3:1.

Despite considerable advancements, automatic speech recognition (ASR) technology still faces challenges with accented speech (Yadavalli et al., 2022b; Szalay et al., 2022; Sanabria et al., 2023). Speakers whose first language (L1) is not English have high word error rate for their audio samples (DiChristofano et al., 2022). Koenecke et al. (2020) showed that existing ASR systems struggle with speakers of African American Vernacular English (AAVE) when compared with speech from rural White Californians.

The dominant methods for improving speech recognition for accented speech have conventionally involved modeling techniques and algorithmic enhancements such as multitask learning (Jain et al., 2018; Zhang et al., 2021; Yadavalli et al., 2022a; Li et al., 2018), domain adversarial training (Feng et al., 2021; Li et al., 2021a), active learning (Chellapriyadharshini et al., 2018), and weak supervision (Khandelwal et al., 2020). Despite some progress in ASR performance, performance still degrades significantly for out-of-distribution (OOD) accents, making the application of these techniques in real-world scenarios challenging. To enhance generalizability, datasets that incorporate accented speech have been developed (Ardila et al., 2019; Sanabria et al., 2023). However, given the sheer number of accents, it is currently infeasible to obtain a sufficient amount of data that comprehensively covers each distinct accent.

In contrast, there has been a relatively smaller focus on exploring linguistic aspects, accent relationships, and harnessing that knowledge to enhance ASR performance. Previous research in language modeling (Nzeyimana and Rubungo, 2022), intent classification (Sharma et al., 2021) and speech recognition (Toshniwal et al., 2018; Li et al., 2021b; Jain et al., 2023) have demonstrated that incorpo-

rating linguistic information in NLP tasks generally yields downstream improvements, especially for languages with limited resources and restricted data availability – a situation pertinent to African languages. Consequently, we opine that a deeper understanding of geographical and linguistic similarities, encompassing syntactic, phonological, and morphological aspects, among different accents can potentially enhance ASR for accented speech.

We believe embeddings offer a principled and quantitative approach to investigate linguistic, geographic and other global connections (Mikolov et al., 2013; Garg et al., 2018), and form the framework of our paper. Our contribution involves the development of AccentFold, a network of learned accent embeddings through which we explore possible linguistic and geographic relationships among African accents. We report the insights from our linguistic analysis in Section 4.

By conducting empirical analysis, we demonstrate the informative nature and practical significance of the the accent folds. Concretely, in Section 5, we show that for a given target OOD accent, fine-tuning on a dataset generated from a subset of accents obtained through AccentFold leads to improved performance compared to strong baselines.

## 2 Related Work

Using existing state-of-art pre-trained models to probe for linguistic information and using that to improve models’ performance has gained interest in the community recently. Prasad and Jyothi (2020) use various probing techniques on the DeepSpeech 2 model (Amodei et al., 2015). They find that first few layers encode most of the accent related information. Bartelds and Wieling (2022) quantify language variation in Dutch using a combination of XLS-53 (Conneau et al., 2020) embeddings and Dynamic Time Warping (Sakoe and Chiba, 1978). They show that this leads to a Dutch dialect identification system that is better than a system dependent on the phonetic transcriptions with just six seconds of speech. Thus, proving that pre-trained models such as the one proposed by Conneau et al. (2020) indeed capture rich linguistic information in their representations. Jain et al. (2018); Li et al. (2021a) extract accent embeddings learnt from a separate network and input those embeddings along with other features. They show that this leads to a superior accented ASR model. Our work is most closely related to (Kothawade et al.,

2023), where the authors explore various statistical methods such as *Submodular Mutual Information* in combination with hand-crafted features to select a subset of data to improve accented ASR. Our work differs from previous works in two important ways (1) we take a different approach and use the extracted accent embeddings from a pre-trained model to decide what subset of data to use to build an ASR that performs the best on a target accent in a cost-effective manner (2) we do this at a much larger scale of 41 African English accents. Note that the previous highest was 21 English accents by Li et al. (2021a).

## 3 AccentFold

This section outlines the procedures involved in the development of AccentFold.

### 3.1 The Dataset

We use the Afrispeech-200 dataset (Olatunji et al., 2023b) for this work, an accented Pan-African speech corpus with over 200 hours of audio recording, 120 accents, 2463 unique speakers, 57% female, from 13 countries for clinical and general domain ASR. To the best of our knowledge, it is the most diverse collection of African accents and is thus the focus of our work. Table 1 shows the statistics of the full dataset and Table 3 focuses on the accentual statistics of the Afrispeech-200 dataset. With 120 accents, the dataset covers a wide range of African accents. The entire dataset can be split, in terms of accents, into 71 accents in the train set, 45 accents in the dev set and 108 accents in the test set, of which 41 accents are only present in the test set (see Figure 1). The presence of unique accents in the test split enables us to model them as Out Of Distribution (OOD) accents: a situation beneficial for evaluating how well our work generalizes to unseen accents.

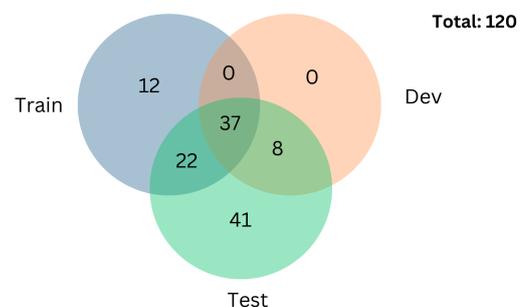

Figure 1: Venn diagram of the accent splits

Speaker Gender Ratios	No. of Utterances %
Female	57.11%
Male	42.41%
Other/Unknown	0.48%
Speaker Age Groups	No. of Utterances %
<18yrs	1,264 (1.88%)
19-25	36,728 (54.58%)
26-40	18,366 (27.29%)
41-55	10,374 (15.42%)
>56yrs	563 (0.84%)
Domain	No. of Utterances %
Clinical	41,765 (61.80%)
General	25,812 (38.20%)

Table 1: Afrispeech-200 Dataset statistics

### 3.2 Creating AccentFold

#### Obtaining and visualizing accent embeddings:

AccentFold is made up of learned accent embeddings. To create the embeddings, we follow the work of Anonymous (2023). This is a multitask learning model (MTL) on top of a pre-trained XLS-R model (Conneau et al., 2020). The MTL model contains a shared encoder with three heads : (1) ASR head (2) Accent classification head, and (3) Domain classification head. The **accent classification** head predicts over 71 accents while the **Domain classification** head predicts (binary) if a sample is from the clinical or general domain. The ASR head is trained with the Connectionist Temporal Classification (CTC) loss (Graves et al., 2006) using the same hyperparameters as Conneau et al. (2020). For the domain and accent heads, we perform mean pooling on the encoder output and pass this to the dense layers in each corresponding head. The **accent classification** head predicts over 71 accents with cross-entropy loss. Extreme class imbalance further makes the task challenging. Therefore, we add a dense layer to our accent classification head to model this complexity. **Domain classification** uses a single dense layer with binary cross-entropy loss. The 3 tasks are jointly optimized as follows:

$$L_{MTL} = 0.7p_{ctc}(y|x) + 0.2p_{acc}(a|x) + 0.1p_{dom}(d|x)$$

We found the above relative weights to give us the best results. For all the experiments, we train the models with a batch size of 16 for 10 epochs. Following Conneau et al. (2020), we use Adam optimizer (Kingma and Ba, 2014) where the learning rate is warmed up for the first 10% of updates to a

peak of  $3e-4$ , and then linearly decayed over a total of 30,740 updates. We use Huggingface Transformers to implement this (Wolf et al., 2020).

We train this model on the AfriSpeech-200 corpus (Olatunji et al., 2023b). We then extract internal representations of the last Transformer layer in the shared encoder model and use these as our *AccentFold* embeddings. For all samples for a given accent, we run inference using the MTL model and obtain corresponding *AccentFold* embeddings. For a given set of accent embeddings, we create a centroid represented by its element-wise medians. We select the median over the mean because of its robustness to outliers.

To visualize these embeddings we use t-distributed stochastic neighbor embedding (t-SNE) (van der Maaten and Hinton, 2008) with a perplexity of 30 and early aggregation of 12 to transform the embeddings to 2 dimensions. Initially, we apply the t-SNE transformation to the entire AfriSpeech dataset and create plots based on the resulting two-dimensional embeddings. This step enables us to visualize the overall structure and patterns present in the dataset. Subsequently, we repeat the transformation and plotting process specifically for the test split of the dataset. This evaluation allows us to determine if the quality of the t-SNE fitting and transformation extends to samples with unseen accents.

### 4 What information does AccentFold capture?

In this section, we delve into an exploratory analysis of the t-SNE visualizations for all the accents in AccentFold. Our aim is to gain a deep understanding of the intricate connections and patterns that emerge among these diverse accents. The t-SNE visualizations of the accent in AccentFold can be found in Figures 2, 3, 4. We also present some more Figures (8, 9, 10, 11) in the Appendix.

**Language Families:** Figure 10 presents a t-SNE visualization of the learned accent embeddings, where color coding is utilized to distinguish language families, and varying levels of transparency ensure distinct colors for each accent. Each point in the figure corresponds to an accent embedding obtained through AccentFold, allowing us to convey two pieces of information: the distribution of accents and their respective language families.

Through an exploratory analysis of Figure 10, we observe that the accent embeddings tend to

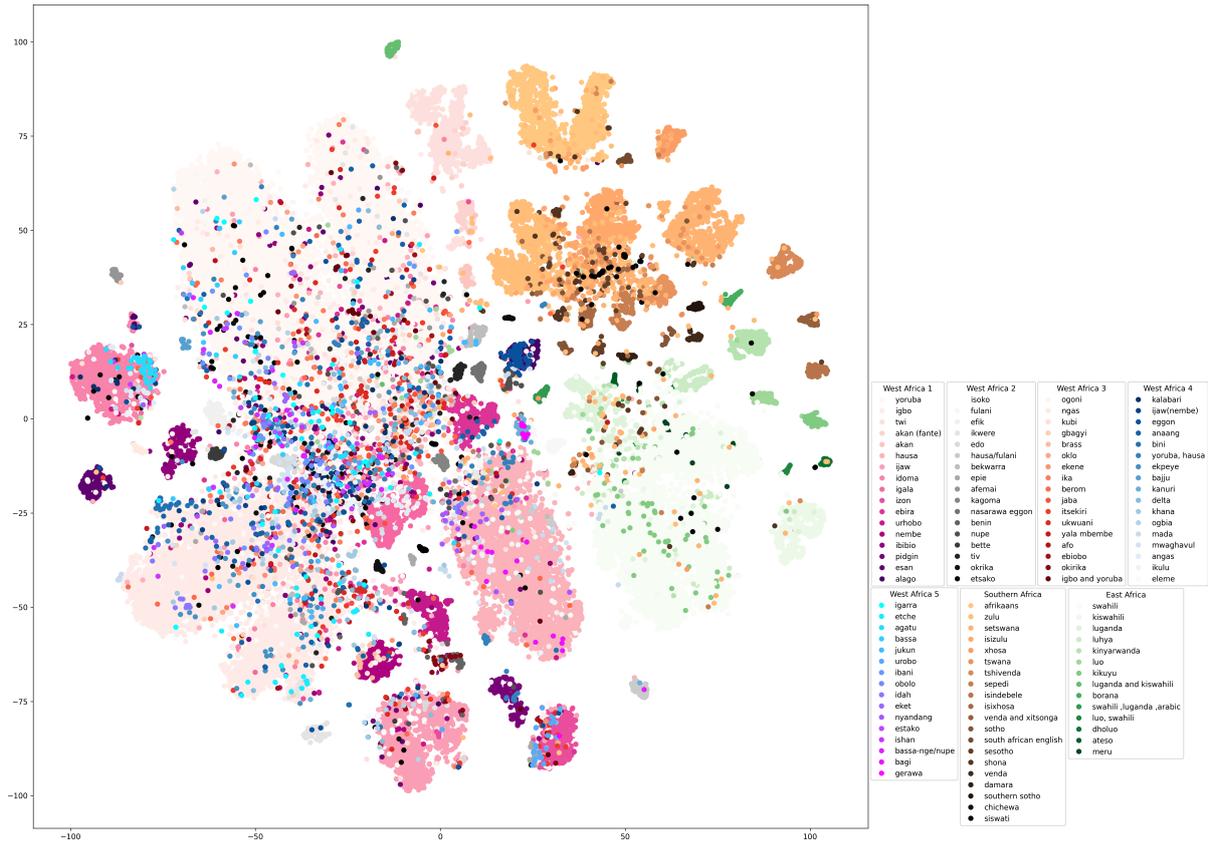

Figure 2: t-SNE visualization of the learned accent embeddings in AccentFold: embeddings of the entire Afrispeech-200 data. In this figure, each accent is encoded with one color. We use the color transparency to differentiate the accents, while the color categories represent the geographical region.

group together (forming what we refer to as “accent folds”) based on language family similarities. Language families represent the genetic connections between languages, as they consist of languages that descended from a common ancestor (Comrie, 1987). These language families exhibit syntactic, phonological, and morphological relationships (de Marneffe and Nivre, 2019). Based on these observations, we hypothesize that AccentFold captures linguistic regularities within accents.

**Geographically Consistent Clusters:** Although the majority of the data comes from Nigeria, Figure 3 plots all test samples with their country labels showing spatial relationships between countries. The t-SNE plots generally align with geographical disposition, accents from Nigeria (Orange) are closer in vector space to Ghana (blue) but further from Kenya, Uganda, Rwanda, and South Africa likely reflecting the distinct languages spoken across these countries. However, where similar languages (e.g. Swahili) are spoken across countries (e.g. Botswana and South Africa), the spatial distinction is less apparent. Uganda, Kenya,

and Tanzania cluster together while Botswana and South Africa cluster together and Rwandan embeddings fall between both regions. This demonstrates that the learned embeddings do encode some geographical information extracted entirely from speech and accent labels.

**Accent disposition:** In Figure 8, Ghanaian accents - Twi and Akan (Fante), cluster closer together and are distinct from Nigerian neighbors. South African accents Zulu, Afrikaans, and Tswana cluster together. Similarly, Kinyarwanda, Luganda, Luganda, Swahili, Luhya and other East African accents cluster together. In Nigeria, Northern accents Hausa and Fulani cluster together and are closer to middle belt accents than South-Eastern and South-Western Nigerian accents. Accents spoken in South-Eastern Nigeria, which make up the majority of West African accents in this dataset, represent the collection of embeddings with indistinguishable margins, representing the close relationship between these accents.

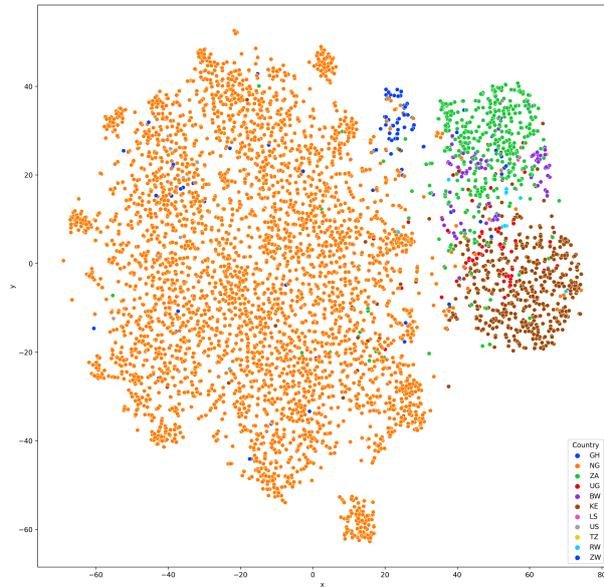

Figure 3: t-SNE visualization of embeddings by country from the Afrispeech test split.

**Peripheral West African Clusters:** Figure 3 shows a distinct pattern in the Nigerian accents. There are 10 distinct peripheral subclusters surrounding a more homogenous core. These may represent accents with very distinct linguistic or tonal characteristics from various parts of the country. Some of these accents include Okirika, Bajju, Brass, Agatu, Eggon, Mada, Ikulu Hausa and Urobo.

**Dual Accents:** Figure 4 shows a really interesting phenomenon with speakers with self-reported dual accents. Sample embeddings for dual accents "Igbo and Yoruba" (orange) fall between the Igbo (blue) and Yoruba (green) clusters. Although Yoruba (green) and Hausa (red) are very distinct accents, speakers with dual accents (purple) fall somewhat between both clusters. This trend is consistent with Yoruba/Hausa and Hausa/Fulani accents.

#### 4.1 Contrasting with the Ethnologue

According to Ethnologue (Campbell, 2008) there are 7,151 living human languages distributed in 142 different language families, 6 of which are assigned to Africa, based on historically accepted language ancestry. Although the empirically learned embeddings generally support this classification, they reveal 2 interesting possibilities that remain uncharacterized by the Ethnologue.

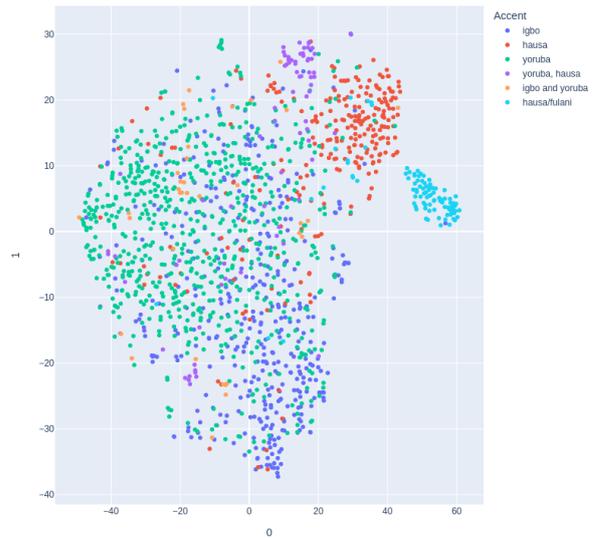

Figure 4: Analysis of Dual Accents

**Kwa-Bantu Relationship:** Although the Ghanaian Kwa languages are traditionally separated from the Bantu languages in South Africa and are geographically very distant, our embeddings suggest they may be more similar than earlier proposed and possibly share similar ancestry. This line of reasoning is supported by Güldemann (2018) reclassification of African languages.

**Niger-Congo Subfamilies.** Although there have been attempts to better categorize the large Niger-Congo family, Güldemann (2018)'s work, based on basic classificatory units and genealogical relations, rethinks traditional classification. The spatial disposition shown in Figure 9 also suggests possible sub-families based on speech representations empirically learned by optimizing the MTL objective function.

#### 4.2 Accent Normalization and Re-identification

User reported accents are sometimes noisy. In the Afrispeech dataset, we encountered 4 strange accent labels where their groupings shed more light on possible true accent labels. 11 speakers located in Nigeria reported their accent as "English". Although the centroid for this group is closest to the "Berom" accent, all samples for this group fall within clusters occupied by speakers from South-eastern Nigeria. Another group of 20 speakers reported a "pidgin" accent. Embedding for speech for speakers are nearest to clusters from Ijaw, Delta,

Edo, and other Nigerian accents where pidgin accent is prevalent. 2 speakers self-identified their accents as “South African English”. However embeddings are closest to Afrikaans speakers. Embeddings for a group of “Portugese” speakers located in South Africa also fall very close to Zulu and Tswana, both south African accents. Embedding/Accent distances were also very valuable with normalizing dialects or misspelled accents for example “luo” and “dholuo”, “Twi” and “Akan”, “kiswahili” and “swahili” and many others.

## 5 Empirical study of AccentFold

### 5.1 Problem Formulation

In this empirical study, we set out to understand how informative the accent folds are for accent-level zero shot ASR performance. To achieve this, we designed our experimental task as follows: Assume we have the below oracle data set generator:

$$F(a_k) \longrightarrow \{(x_i, y_i)\}_{i=1}^{N_k}, \quad (1)$$

such that when  $\mathbb{F}$  is given an accent  $a_k \in A := \{a_1, a_2, a_3, \dots, a_n\}$ , it returns a data set of  $N_k$  audio-text pairs where the audio samples are from speakers of accent  $a_k$ .  $A$  is a finite set of possible accents from which the generator can give us data samples. Also,  $N_k$  varies for each accent  $a_k$ . We have a target OOD accent  $a_{OOD} \notin A$  for which we want to improve ASR performance. For every given OOD target accent  $a_{OOD}$ , we can only select  $s \ll n$  accents from  $A$ , i.e  $A_s = \{a_1, \dots, a_s\}$ , with which we can obtain data samples from  $\mathbb{F}$  and finetune our model. The problem then becomes how to choose  $A_s$  for a given  $a_{OOD}$ .

As a practical example of the problem above, consider a company that wants to improve their speech recognition performance on  $a_{OOD}$ . They therefore hire recorders with various accents ( $A$ ) to record given texts, but do not have access to recorders with accent  $a_{OOD}$  perhaps due to geographical reasons (a company based in the USA would find it difficult to find speakers with *afante* accent). Due to constraints (perhaps budget, time) they can not engage all the recorders in the recording task. So it is imperative to choose which accents to use to create the training dataset for their ASR system. This is an important problem in the real world, where accents are abound and resource constraints are highly limited (Aks nova et al., 2022; Hinsvark et al., 2021).

The approach we adopt as our baseline is to select  $A_s$  randomly. AccentFold offers another approach to selecting  $A_s$ : by selecting accents from  $A$  that share geographic and linguistic similarities with  $a_{OOD}$ .

### 5.2 Experimental Setup

For our experimental setup, we interpret the Afrispeech-200 dataset as our oracle dataset and design a function,  $\mathbb{F}(\triangleright\lrcorner)$ , that returns the speech-text samples from Afrispeech-200 which are spoken with accent  $a_k$ .  $A$  then represents the distinct set of accents in Afrispeech-200. We visualize in Figure 1 a Venn diagram showing how the accents intersect within the train, test and dev splits.

**Target accents ( $a_{OOD}$ ):** Based on Figure 1, we note the presence of 41 accents within the test split that are not found in either the train or dev splits. As a result, we choose these 41 accents to represent our target the out-of-distribution (OOD) accents for our experimental setup. We choose our  $s$  to be 20.

**Selecting  $A_s$  and obtaining fine-tuning dataset:** Our experimental setting is hinged on how we select the accent subset,  $A_s$ , from which the data generator retrieves the fine-tuning dataset will be used. For our first baseline, we implement a random selection of  $s$  accents from  $A$ . Sampling is done uniformly and without replacement.

For our second baseline (GeoProx), we leverage the real-world geographical proximity of the accents. Concretely speaking, for a given target OOD accent,  $a_{OOD}$ , we extract its country information and compare this information with that of the other accents in  $A$ , taking the  $s$  accents that are geographically closest to  $a_{OOD}$ . We leverage the geocoding Python package called *geopy*<sup>2</sup> for this process.

With the utilization of AccentFold, we extract the centroids of the accents in  $A$ , as well as a given OOD accent  $a_{OOD}$ . Leveraging the vectorial representation of accents, determining their similarities becomes straightforward using the cosine distance metric. Consequently, we compute the cosine similarity between the embedding vector of the OOD target accent and that of each accent in  $A$ . We subsequently arrange the accents in  $A$  in ascending order based on their cosine similarity and select the top  $s$  accents, resulting in the formation of  $A_s$  for

<sup>2</sup><https://github.com/geopy/geopy>

a given  $a_{OOD}$ . We perform this operation for each of the 41 accents in our target accent set.

Then for each  $a_{OOD}$  we utilize our data generator to obtain a training dataset  $\mathbb{D} = \{(x_i, y_i)\}_{i=1}^{N_k}$  of speech-text samples based on accents in  $A_s$ . This dataset is then used for our fine-tuning experiment which is explained in more detail below.

**Fine-tuning Details:** We use a pre-trained XLSR model (Conneau et al., 2020) for our experiments. The XLSR model extends the wav2vec 2.0 (Baevski et al., 2020) model to the cross-lingual setting and was trained to acquire cross-lingual speech representations through the utilization of a singular model that is pre-trained using raw speech waveforms from various languages. The fact that this model is cross-lingual makes it a good fit for our experiments.

During the fine-tuning of our pre-trained model, we follow the hyperparameter settings of Olatunji et al. (2023a). These include setting the dropout rates for attention and hidden layers to 0.1, while keeping the feature projection dropout at 0.0. We also employ a mask probability of 0.05 and a layer-drop rate of 0.1. Additionally, we enable gradient checkpointing to reduce memory usage. The learning rate is set to  $3e-4$ , with a warm-up period of 1541 steps. The batch sizes for training and validation are 16 and 8, respectively, and we train the model for ten epochs.

For each of the 41 target accents, we finetune our pre-trained model on its corresponding dataset and evaluate the word error rate on the test set comprising audio samples containing only the target accent. We run all our experiments using a 40GB NVIDIA A100 SXM GPU, which enables parallel use of its GPU nodes.

**Evaluation procedure:** It is important to note that although the training dataset size  $N_k$  depends on the target accent  $a_{OOD}$  in consideration, the test set used to evaluate all our experiments is fixed: it comprises the samples from the test split of the Afrispeech-200. Using Figure 1 the test set are samples from all the 108 accents of the test split. By keeping the test set constant, we can assess the model’s performance on our intended accent  $a_{OOD}$  in an out-of-distribution (OOD) scenario. This is because the training and development splits do not include any audio-speech samples from these accents. Additionally, this procedure enables us to evaluate the model’s capacity to generalize to other accent samples, resulting in a highly resilient eval-

uation.

### 5.3 Results and Discussion

Table 2: Test WER on target OOD accent compared by subset selection using AccentFold, GeoProx, and random sampling. Average and standard deviation are taken over the 41 accents of our target. We also report p-value from a 1-sample, two-sided t-test.

Model	Test WER ↓
AccentFold	<b>0.332 ± 0.013</b>
GeoProx	0.348 ± 0.007
Random	0.367 ± 0.034

Table 2 presents the results of a test Word Error Rate (WER) comparison between three different approaches for subset selection: AccentFold, GeoProx, and random sampling. The table displays the average and standard deviation of the WER values over the 41 target OOD accents. The results show that the AccentFold approach achieves the lowest test WER of 0.332 with a standard deviation of 0.013. In contrast, the random sampling approach yields the highest test WER of 0.367 with a larger standard deviation of 0.034. GeoProx, which uses real-world geographical proximity of the accents, performs better than random sampling but still under-performs when compared to AccentFold. To better understand this, we investigate the accents selected by AccentFold and GeoProx and analyse their non-overlapping accents in Figure 6. The histogram reveals that many of the accents selected by AccentFold for any given target OOD accent,  $a_{OOD}$ , are not necessarily those geographically closest to  $a_{OOD}$ . This insight suggests that the learned embeddings in AccentFold encompass much more than geographical proximity of accents.

Figure 5 visualizes the test WER obtained by AccentFold and random sampling for each of the 41 accents. We see that in majority of the accents, AccentFold leads to improved performance in terms of WER compared to random sampling. These findings indicate that AccentFold effectively captures linguistic relationships among accents, allowing for more accurate recognition of the target OOD accent when used to build the fine-tuning dataset. This demonstrates the usefulness of leveraging linguistic information and accent embeddings provided by AccentFold in the context of automatic speech recognition tasks.

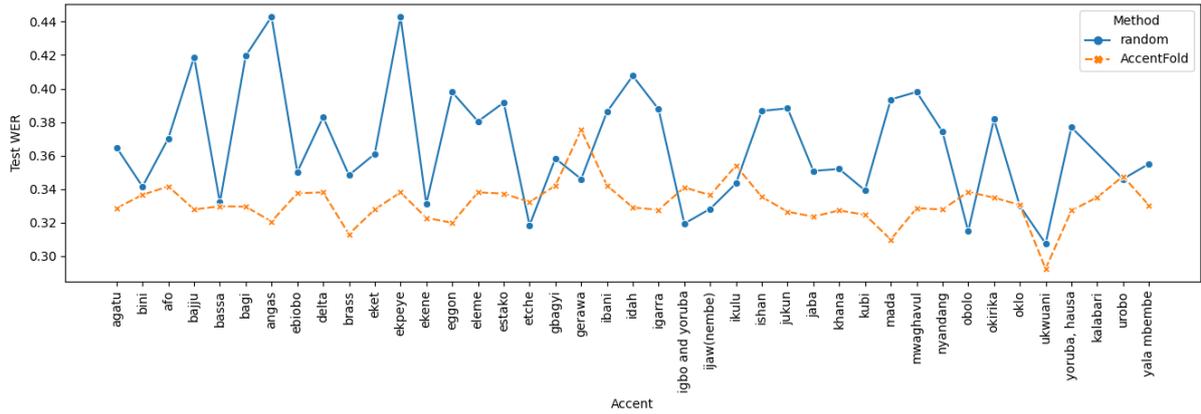

Figure 5: Test WER across all 41 OOD accents. We compare AccentFold with random sampling.

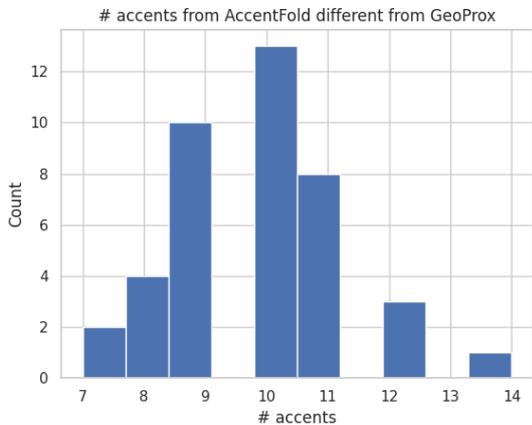

Figure 6: Histogram of number of accents from AccentFold that are non-overlapping with GeoProx.

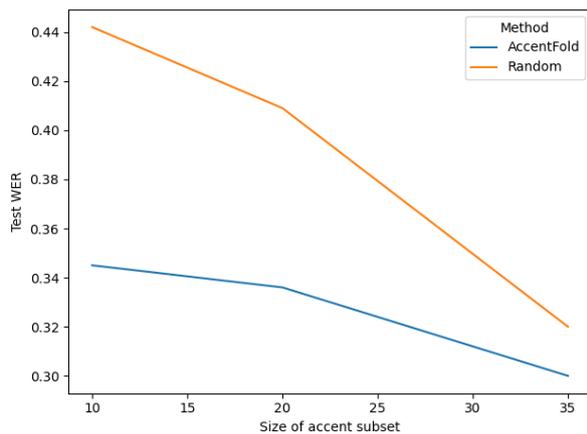

Figure 7: Test WER on Bini accent for different accent subset sizes (different values of  $s$  for  $A_s$ ).

We notice a pattern, as shown in Figure 7, where increasing the value of  $s$ , which corresponds to a larger training dataset size  $N_k$ , results in minimal variation in the selection of accent subsets. This

convergence of test WER implies that as the sample size increases, the specific choice of accent subsets becomes less influential in determining the performance.

## 6 Conclusion

In conclusion, our research addresses the challenge of speech recognition for African accented speech by exploring the linguistic relationships of accent embeddings obtained through AccentFold. Our exploratory analysis of AccentFold provides insights into the spatial relationships between accents and reveals that accent embeddings group together based on geographic and language family similarities, capturing phonological, and morphological regularities based on language families. Furthermore, we reveal, in Section 4.1, two interesting relationships in some African accents that have been uncharacterized by the Ethnologue. Our experimental setup demonstrates the practicality of AccentFold as an accent subset selection method for adapting ASR models to targeted accents. With a WER improvement of 3.5%, AccentFold presents a promising approach for improving ASR performance on accented speech, particularly in the context of African accents, where data scarcity and budget constraints pose significant challenges. Our research paves the way for a deeper understanding of accent diversity and linguistic affiliations, thereby opening new avenues for leveraging linguistic knowledge in adapting ASR systems to target accents.

## Limitations

One limitation of our study is the utilization of a single pre-trained model for fine-tuning in our ex-

periments. While the chosen model demonstrated promising performance, this approach may the generalizability and robustness of our findings. Incorporating multiple pre-trained models with varying architectures and configurations would provide a more comprehensive evaluation of the ASR system's performance.

Furthermore, our study primarily focuses on improving the ASR performance for English with a focus on African accents. Consequently, the findings and outcomes may not be directly transferable to languages outside of the African continent. The characteristics and phonetic variations inherent in non-African accents require tailored approaches to improve ASR systems in different linguistic contexts. Future studies should expand the scope to encompass a broader range of languages and accents to enhance the generalizability of our method beyond African languages.

t-SNE, a stochastic dimensionality reduction algorithm, is highly effective in preserving local structures and representing non-linear relationships in data (Roca et al., 2023). Hence it serves as a versatile and robust tool for visualizing high-dimensional data and has been used extensively in myriad domains: for example in the medical domain it is used in visualizing and understanding single-cell sequencing data (Becht et al., 2019; Kobak and Berens, 2019). However, it should be noted that t-SNE is primarily used for data visualization purposes. Therefore, the insights discussed in Section 4 are solely derived from the exploratory analysis conducted using AccentFold and are not based on the inherent capabilities of t-SNE itself. The results obtained from t-SNE analysis should be interpreted with caution, as previous research has demonstrated (Roca et al., 2023; Becht et al., 2018).

## Ethics Statement

We use AfriSpeech-200 dataset (Olatunji et al., 2023b) in this paper to run our experiments. This dataset is released under CC BY-NC-SA 4.0. As we use it only for research purpose or not for any commercial purpose, we do not go against the license. We do not foresee any harmful effects or usages of the methodology proposed or the models. We release all the artefacts created as part of this work under CC BY-NC-SA 4.0.

# Hierarchical and Dynamic Prompt Compression for Efficient Zero-shot API Usage

Yichen Jiang<sup>\*1</sup> Marco Del Vecchio<sup>2</sup> Mohit Bansal<sup>1</sup> Anders Johannsen<sup>2</sup>

<sup>1</sup>UNC Chapel Hill <sup>2</sup>Apple

{yichenj}@cs.unc.edu

## Abstract

Long prompts present a significant challenge for practical LLM-based systems that need to operate with low latency and limited resources. We investigate prompt compression for zero-shot dialogue systems that learn to use unseen APIs directly in-context from their documentation, which may take up hundreds of prompt tokens per API. We start from a recently introduced approach (Mu et al., 2023) that learns to compress the prompt into a few “gist token” activations during finetuning. However, this simple idea is ineffective in compressing API documentation, resulting in low accuracy compared to the baseline using an uncompressed prompt. In this work, we introduce two major improvements. First, we specialize gist tokens for different hierarchies within an API: we use one  $\text{Gist}_{\text{arg}}$  token for compressing an argument and one  $\text{Gist}_{\text{value}}$  token for compressing an acceptable value of a categorical argument. We then dynamically reveal  $\text{Gist}_{\text{value}}$  tokens only when they are needed. Second, we add a reconstruction loss to predict the API documentation from the gist tokens. On multiple API-calling tasks, our proposed system keeps the simplicity, efficiency, and large compression factor (20x on SGD) of the gist token approach while achieving significantly better accuracy.<sup>1</sup>

## 1 Introduction

Large Language Models (LLM) have been shown to be able to use external tools or APIs in a zero-shot manner by in-context learning from APIs’ documentation (Shen et al., 2023). Specifically, the LLM is given a prompt that includes a detailed description of an API’s functionality and its acceptable arguments and values. It is also presented with a user’s request or a conversation between the user and the system. The model is then asked to gener-

ate an API call that covers all the user’s requests so far. We show an example in Fig. 1.

Despite the benefits of learning new APIs in-context, deploying such a model is challenging for latency-critical and resource-constrained settings. This is partially because of the time and memory it takes to compute the attention weights between the newly generated token and all tokens in the API documentation (Pope et al., 2023). For example, generating an API from the documentation of 103 tokens using LLaMA (Touvron et al., 2023) 7B costs an extra of 42 ms, 1729 GFLOPS of compute and 9.1 GB memory compared to generating it without the documentation.<sup>2</sup> In this work, we aim to accelerate the generation of the API call by compressing the documentation into **Hierarchical and Dynamic “HD-Gist tokens”**. *First, we propose a scheme to compress an API documentation hierarchically*: we insert one “argument gist token” ( $\text{Gist}_{\text{arg}}$  in Fig. 2b) after every argument’s description; for those categorical arguments, we additionally insert one “value gist token” ( $\text{Gist}_{\text{value}}$  in Fig. 2b) after every acceptable value of the argument. Intuitively, each argument is coarsely encoded into a  $\text{Gist}_{\text{arg}}$  token, while a categorical argument’s values are additionally encoded into a set of  $\text{Gist}_{\text{value}}$  tokens. We can train the proposed hierarchical HD-Gist model with no additional cost over the standard finetuning (following Mu et al. (2023)), by simply modifying the attention mask. The model first encodes the API documentation with the inserted gist tokens from left to right normally. Then, as the model encodes the user’s conversation and generates the API call, we mask out all but those  $\text{Gist}_{\text{arg}}$  tokens. This encourages the model to compress the API documentation into gist tokens, that can then be attended to during the generation of the API call.

*Second, we allow the model to ‘zoom’ in/out of a*

<sup>\*</sup>Work partially done while at Apple.

<sup>1</sup>Our code is publicly available at <https://github.com/jiangycTarheel/HD-Gist>.

<sup>2</sup>Benchmarked on a single NVIDIA A100 40GB.

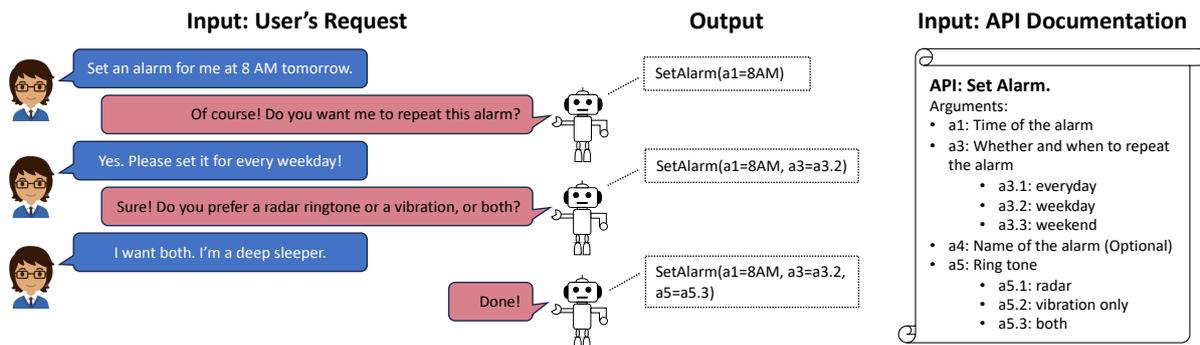

Figure 1: An example of the task discussed in this work. The model is given its conversation with the user and the API documentation. It then predicts the API call to fulfill the user's request.

*compressed, categorical argument by dynamically adjusting the gist mask:* the model unmask the  $Gist_{value}$  tokens of an argument right after it has generated this argument in the API call, and re-masks these tokens after it has predicted the value. Finally, we also optimize the model to **reconstruct the API documentation from the HD-Gist tokens only**. We again only unmask the  $Gist_{value}$  tokens of an argument when the model is reconstructing its description and acceptable values. This reconstruction objective regularizes the model to hierarchically compress all crucial information about the arguments and values into the HD-Gist tokens.

We finetune a LLaMA 7B model (Touvron et al., 2023) with different compression methods to generate the API call in the SGD training set (Rastogi et al., 2020). We then evaluate the model on unseen APIs and conversations on the SGD and SGD-X (Lee et al., 2022) test sets. First, the proposed model with HD-Gist tokens obtains higher accuracy (56.68% on SGD and 54.83% on SGD-X) than any models with a fixed number of static gist tokens (41.43% on SGD and 39.53% on SGD-X with 20 gist tokens). Next, our experiments show that our reconstruction objective improves the accuracy of both the static gist model and HD-Gist model, while the HD-Gist model still maintains a sizable advantage (71.22% VS 46.47% on SGD). Notably, the proposed HD-Gist model is only 1.44% lower than the LLaMA baseline with uncompressed documentation. On the SGD-X test set, it even outperforms the LLaMA baseline by 4.5% in the accuracy, suggesting that compressing the documentation can even act as a regularizer to improve the out-of-domain generalization. We further show that HD-Gist is generalizable: on the APIBench dataset (Patil et al., 2023), it again achieves stronger results than all static gist models. Last but not least, the proposed method maintains

a similar amount of compute and memory usage to the static gist model (Mu et al., 2023). Compared to the LLaMA baseline with uncompressed API documentation, using HD-Gist tokens achieves a 5.6% speedup in CUDA time, 29.9% reduction in compute, and 32.5% reduction in memory usage.

To understand the improvement of the proposed model, we also perform an error analysis on the SGD validation set. First and foremost, we find that static gist baseline predicts a wrong value for a categorical argument in more than 46% of the examples. Using the HD-Gist tokens can significantly reduce this error to 17% and adding the reconstruction loss further reduce it to 14%. Moreover, our proposed model also makes fewer errors in missing arguments, generating extra arguments, and hallucinating arguments that is not in the documentation.

Overall, by only attending to an average of 5.08 tokens in the API documentation per generation step, our proposed HD-Gist model significantly improves upon the previous state-of-the-art compression method. It closes the accuracy gap to the baseline that needs to attend to an average of 108.94 tokens in the API documentation, while requiring 30% less compute and memory usage.

## 2 Background and Related Work

**Language models using external tools.** With the recent tide of advancement in large language models (LLMs) comes further investigations into their weaknesses (e.g., incapability in math (Cobbe et al., 2021), hallucinating contents (Dziri et al., 2022), etc). Researchers have been trying to augment LLMs with external tools including web browsing (Nakano et al., 2021; Lazaridou et al., 2022; Komeili et al., 2022), calculators (Cobbe et al., 2021; He-Yueya et al., 2023), translation, code interpreters (Gao et al., 2023), or a combination of them (Thoppilan et al., 2022; Schick et al., 2023).

These preliminary efforts mostly focus on training/prompting LLMs to use a single tool or a limited pool of tools and cannot generalize to unseen tools without retraining or prompt engineering.

**Zero-shot API usage by in-context learning from API documentation.** More recent works (Shen et al., 2023; Liang et al., 2023) try to enable LLMs to use an infinite set of tools by exploring their ability to learn API documentation in-context and make API calls. Patil et al. (2023) introduced the APIBench dataset consisting of APIs from HuggingFace, TorchHub, and TensorHub and user requests. In this work, we also use the Schema-guided Dialogue (SGD) dataset (Rastogi et al., 2020) that challenges models to track dialogue states from a user-system dialogue following a schema of the service required. Based on the SGD dataset, Lee et al. (2022) further introduced SGD-X by rephrasing the API/argument’s name and description. We use the schema of a specific intent (e.g., FindHotel) as the API documentation and ask the model to predict the value of all active arguments (e.g., check-in date) of the API.

**Compressing prompts into gist tokens.** In-context learning from API documentation enables LLMs to use potentially any tools. However, the length of API documentation grows with its complexity, including the number of acceptable arguments, different use cases, and so on. There has been a series of works that aim to compress Transformer’s information-redundant, hidden activations into a small set of soft, compact vectors that can be used as the attention’s keys and values in processing later tokens. Rae et al. (2020) first tried to compress activations using compression functions like pooling and convolution. Later works instead rely on the Transformer itself to compress a long sequence of activations into a shorter sequence of activations. Mu et al. (2023) proposed to append a few special “gist” tokens after the prompt and compress the prompt into the gist tokens’ activations. The model can only attend to the gist tokens when encoding and decoding later context. This significantly speeds up the decoding, but at the cost of accuracy for knowledge-intensive tasks like API calling. More concurrent works (Jiang et al., 2023; Zhang et al., 2024) further improved upon gist-tokens in multiple aspects. For example, Ren et al. (2023) proposed to use a pair of sentinel tokens (similar to gist tokens) to mark the boundary of the span to be compressed, and achieve a wide

range of compression ratios in a longer context. Chevalier et al. (2023) finetuned LLMs to compress segments of long context into individual memory vectors. To reduce information loss in compression, Ge et al. (2023) compressed long context into a few “memory tokens” using an additional LLM encoder. They pretrained this encoder with a fixed LLM decoder on language modeling and reconstruction objectives. They then finetuned the encoder on instruction-following data. In an alternative direction, Li et al. (2023) proposed “Selective Context” to directly prune redundant content in a given input context. Jung and Kim (2023) compressed the prompts with reinforcement learning.

In a parallel direction, Xiao et al. (2023) proposed to keep a sliding window plus the 4 initial tokens’ Key-Values in the cache as an “attention sink” during the inference. This method specializes in local language modeling at the cost of losing direct attention to distant contexts. In comparison, the gist-tokens methods focus on providing efficient but fine-grained access to distant context, which is essential in API-calling that requires copying specific parameter names. In this work, we inherit the lightweight compression method from Mu et al. (2023) that simply modifies the attention masks of tokens after the documentation without introducing a separate encoder. We further incorporate the auto-encoding objective (Ge et al., 2023) to improve the quality of compressed gist representations. Different from recent works that compress activations into static “gist” vectors, we introduce multiple sets of hierarchical and dynamic gist tokens to encode information at different granularities, and further allow automatic switching on/off a set to zoom in/out.

### 3 Method

In this section, we first explain the data preprocessing steps (Sec. 3.1). We then introduce the details about the HD-Gist tokens (Sec. 3.2) and reconstruct the API Documentation from HD-Gist (Sec. 3.3).

#### 3.1 Preprocessing

**Indexing the arguments and categorical values.** When training a language model to follow API documentation, the model could quickly memorize the APIs in parameters and then operate independently of the documentation. This overfitting to seen APIs significantly harms the model’s generalization to call unseen APIs at test time. To overcome this

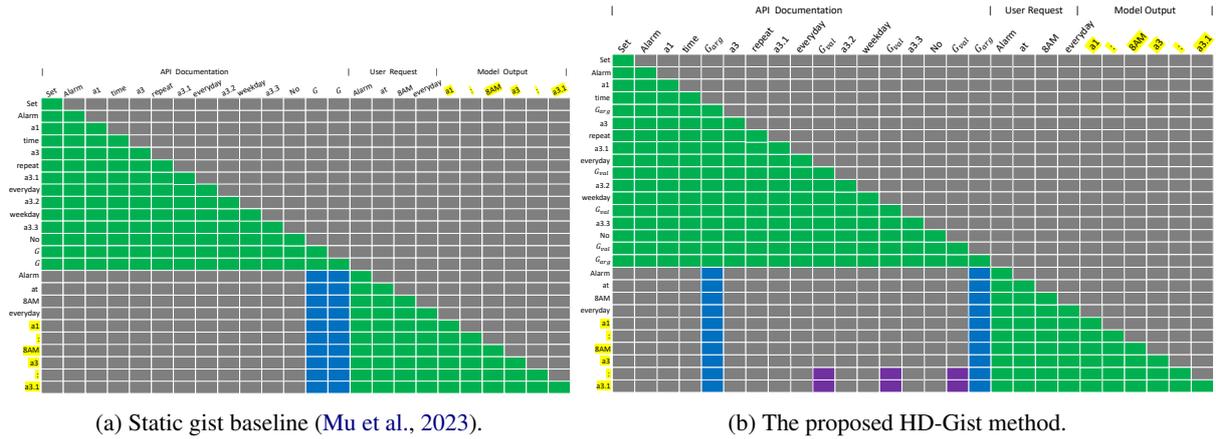

Figure 2: The modified attention mask from the model with static gist ( $G$ ) tokens (Mu et al., 2023) and our proposed model with HD-Gist tokens (including **hierarchical**  $Gist_{arg}$  and  $Gist_{value}$ ). The causal attention mask shown is for a decoder-only model (e.g., LLaMA). Gray cells are zeros in the mask and other colored cells are ones in the mask. Blue cells represent attention to static gist tokens and argument-level  $Gist_{arg}$  tokens. Purple cells represent attention to the **dynamic**, value-level  $Gist_{value}$  tokens. Model outputs are highlighted in curly brackets and yellow. We show the modified attention mask from HD-Gist model trained with the **reconstruction** loss in Fig. 3.

problem, we convert argument names and categorical values into structured indexes (e.g., “a1: Destination, a3: The number of stops in the itinerary, values=[a3.1: 1, a3.2: 0]”). The model is then asked to predict argument indices paired with either textual values or indexed categorical values (“a1=‘NYC’, a3=a3.2”). This indexing scheme is based on the fact that argument and value names are simply *symbols* that can be replaced with anything, and it is the descriptions that actually encodes their meanings (Zhao et al., 2022).

**Randomizing argument and value orders.** Within an API documentation, we randomize the order of the arguments as well as the acceptable values of categorical arguments across different examples that share this API. This further prevents the model from memorizing the API documentation and helps the model to generalize.

### 3.2 Hierarchical and Dynamic Gist Token

**Motivation.** Recently, Mu et al. (2023) proposed to compress instructions into the activations of a few “gist tokens” inserted between the instruction (“Translate this into Spanish”) and the input (“I like to play tennis.”), by masking out the entire instruction after encoding the gist tokens. This method is lightweight as it only added an embedding vector of the gist token to the model parameters. However, we argue that appending all gist tokens sequentially after the API documentation may result in a loss of the hierarchical information. For example, for the SetAlarm API, the list of acceptable

values “everyday; weekday; No” is relevant to the argument “repeat” only and is irrelevant to other arguments. Such hierarchy is originally encoded by the attention to the API documentation, but may get lost after being compressed into the gist tokens. We will later support this argument with a detailed error analysis (Sec. 5.3).

In order to retain this important hierarchy of API documentations during the compression, we introduce two major improvements to the static, sequential gist token method. *First, we propose a scheme to compress an API documentation hierarchically:* we insert one “argument gist token” ( $Gist_{arg}$  in Fig. 2b) after every argument’s description; for those categorical arguments (e.g., the “repeat” argument in the SetAlarm API), we additionally insert one “value gist token” ( $Gist_{value}$  in Fig. 2b) after every acceptable value of the argument. Intuitively, each argument is coarsely encoded into a  $Gist_{arg}$  token, while a categorical argument’s values is additionally encoded into a set of  $Gist_{value}$  tokens. Following Mu et al. (2023), we can train the proposed hierarchical HD-Gist model with no additional cost over the standard finetuning, by simply modifying the attention mask. The model encodes the API documentation with the inserted gist tokens from left to right normally. Therefore, each gist token can possibly encode all preceding arguments. However, when the model encodes the user’s conversation and generates the API call, we mask out all but those  $Gist_{arg}$  tokens. This encourages the model to compress the API documentation

into gist tokens, that can then be attended to during the generation of the API call.

*Second, we allow the model to ‘zoom’ in/out of a compressed, categorical argument by **dynamically adjusting the gist mask**. When the model starts to generate the value for a categorical argument (e.g., it has generated “a3: ”), it un.masks the  $\text{Gist}_{\text{value}}$  tokens after every acceptable value (e.g., purple cells in Fig. 2). It then re.masks these  $\text{Gist}_{\text{value}}$  tokens after predicting the value (e.g., it has generated “a3: a3.1”). This in-context retrieval of  $\text{Gist}_{\text{value}}$  tokens has two benefits: (1) it encourages the model to encode the fine-grained information about one categorical argument, exclusive of other arguments, into its  $\text{Gist}_{\text{value}}$  tokens; (2) it avoids feeding the model with redundant tokens that would unnecessarily occupy memory and computation.*

In summary, we insert HD-Gist tokens after different structures of the API hierarchy, and allow the model to dynamically switch on a set of  $\text{Gist}_{\text{value}}$  tokens to zoom into a categorical argument.

### 3.3 Improving Compression Coverage by Learning to Reconstruct API

The existing objective supervises the model to generate the correct API call given the conversation with the user and the API documentation. However, in most examples, the API call only invokes some, but not all of the arguments in the documentation. Therefore, the existing objective does not provide the incentive for the model to compress all arguments in the gist token representations. To improve the completeness of the compressed API documentation, we add a second objective that trains the model to reconstruct the original API documentation given the argument-gist and dynamic value-gist tokens. Specifically, in all training examples, the model is given the API documentation and the conversation with the user and predicts the API call. In some training examples, we append a copy of the API documentation after the ground truth API call and a separator ([SEP]) token. When predicting the API documentation, the model can only attend to the argument and value gist tokens, while the model can additionally attend to the conversation when predicting the API call. We show the modified attention mask for an example with the reconstruction objective in Fig. 3.

## 4 Experiments

### 4.1 Experimental Setup

We adopt a unified setting across all datasets used in this work, in prompting an LLM to make API calls. The model’s input consists of the API documentation and then the user request in the form of a single sentence or a conversation between the user and the system. Unlike the previous work (Patil et al., 2023), we put documentation before the user request because we need a static documentation representation that is independent of the user request. The model needs to generate a list of argument-value pairs that include all API arguments that the user has given a value. We conduct experiments in an oracle setting where the ground-truth API’s documentation<sup>3</sup> is always given to the model in both training and evaluation without delegating to a API retrieval system as the impact of retrieval in a setting where the model is shown the k-best APIs is outside the scope of this work.

### 4.2 Datasets

**SGD** (Schema-Guided Dialogue) (Rastogi et al., 2020) is a public dataset in English that challenges models to perform dialogue state tracking (DST) by following a schema. We convert the original DST task into an API prediction task by (1) discarding arguments not used by the current API from the output and (2) giving the model the documentation of an API instead of a whole service. We train the model to predict an API call using the API documentation and the conversation between the user and the system. In both training and test, we also include intermediate turns where the user has not yet provided all arguments’ values. In these turns, we ask the model to generate a partial API call with only those arguments mentioned by the user so far.

**SGD-X** (Lee et al., 2022) is created from SGD by asking human annotators to paraphrase the original arguments’ names and descriptions into semantically similar yet stylistically diverse variants. SGD-X further evaluates models’ robustness to linguistic variations in API documentation. We use the SGD-X/v5, which is the version with the most variation, as the extra test set to evaluate models trained on the original SGD training set.

<sup>3</sup>“Ground-truth API” refers to the API that can fulfill the user’s request.

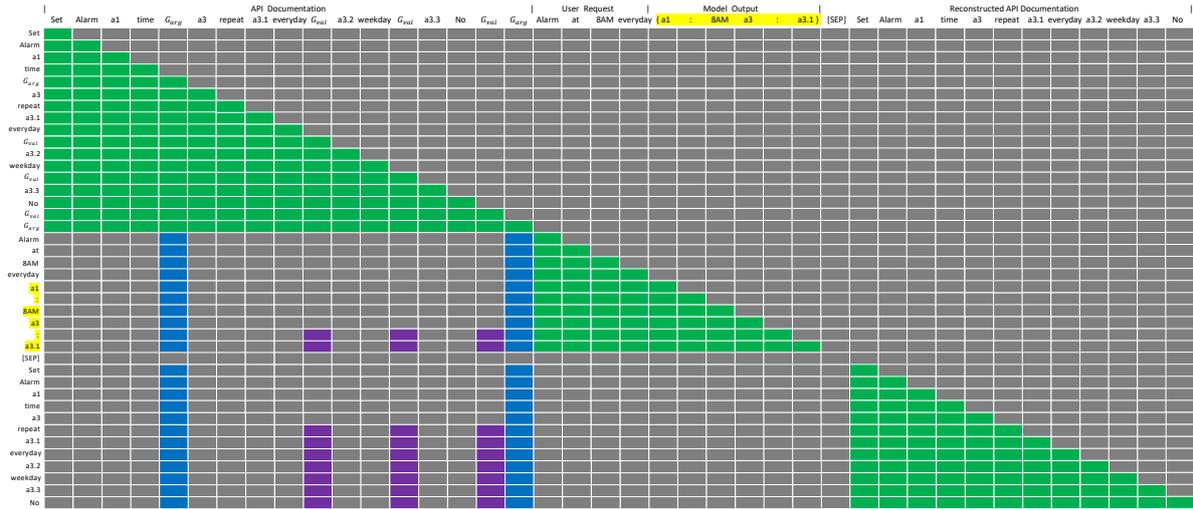

Figure 3: The modified attention mask from the model with the HD-Gist gist tokens that also reconstructs API documentation. There is a special token [SEP] that separates the API call and the reconstruction. After [SEP], the model can only attend to the  $Gist_{arg}$  tokens (blue cells) and preceding reconstruction (green cells). After the model has reconstructed the name of a categorical argument (a3), we unmask its  $Gist_{value}$  tokens (purple cells) so that the model can access the encoded fine-grained information when generating its details, including all acceptable values.

**APIBench** (Patil et al., 2023) is a public dataset consisting of APIs from HuggingFace, TorchHub, and TensorHub as well as user question prompts in English generated from Self-Instruct (Wang et al., 2023). Because the sole purpose of this work is to train and evaluate models to follow API documentation, we discard the undocumented arguments of the API calls and only ask the model to predict (1) one out of three available APIs (HuggingFace, TorchHub, TensorHub), and (2) the value (pretrained model card’s url) of the only argument of an API. Therefore, we insert an API-level gist token after every API, insert a  $Gist_{value}$  token after the description of every model card, and omit the  $Gist_{arg}$  token since there is only one argument per API. We provide more details regarding the SGD and APIBench datasets in Appendix B.1.

### 4.3 Evaluation Metrics

Following Rastogi et al. (2020), we evaluate models on SGD and SGD-X using joint-goal accuracy. For arguments that are both in the ground truth and the predicted API call, we calculate the exact-match scores for values of categorical arguments, and calculate fuzzy soft-matching scores<sup>4</sup> for other arguments. A matching score of 0 is assigned for both of the following errors: (i) arguments that in the ground truth but missed in the prediction, (ii) arguments in the prediction but not the ground truth.

<sup>4</sup>For example, predicting “New York” while the ground-truth is “New York City” results in a fuzzy-matching score of 0.76.

The joint-goal accuracy is the product of matching scores of all arguments in the API documentation. For APIBench that has no non-categorical argument, we use the exact-match accuracy only.

## 5 Results

### 5.1 Results on the SGD Datasets

Based on the results shown in Table 1, we can observe that the model with the argument-level gist tokens ( $Gist_{arg}$ ) outperforms all static gist models (Mu et al., 2023) with up to 40 gist tokens (41.43% on SGD and 39.53% on SGD-X with 20 gist tokens). The proposed model with HD-Gist tokens obtains even better accuracy (56.68% on SGD and 54.83% on SGD-X) than all other models with compressed API documentation. This model only needs to store an average of 10.84  $Gist_{arg}$  and  $Gist_{value}$  tokens in memory, and attend to an average of 5.08 gist tokens per generation step. This is a significant reduction from the more than 108 tokens that need to be kept in memory and attended by the LLaMA baseline. We further supervise the models to reconstruct the API documentation from the gist tokens in 30% of the training examples. We observe that both the static and HD-Gist models benefit from this extra objective, while the proposed HD-Gist model still maintains a significant advantage (71.22% VS 46.47% on SGD and 69.24% VS 41.52% on SGD-X).

Models	API Doc Tokens in		Accuracy	
	Attn	Memory	SGD	SGD-X
LLaMA	108.94	108.94	72.66 $\pm$ 1.7	64.78 $\pm$ 0.7
Without Reconstruction Objective

Table 1: Joint-goal accuracy on SGD (Rastogi et al., 2020) and SGD-X/v5 (Lee et al., 2022) test sets. All models are finetuned from a LLaMA 7B (Touvron et al., 2023) model. We report the results of static gist model (Mu et al., 2023) with up to 40 gist tokens. The best results from a model using the compressed API documentation are in bold. We report the mean and standard deviation across three random seeds.

Models	API Doc Tokens In		Accuracy
	Attention	Memory	
LLaMA	551.75	551.75	84.38
With Reconstruction Objective			
2 Gist	2	2	33.51
5 Gist	5	2	36.42
10 Gist	10	10	45.14
20 Gist	20	20	33.77
40 Gist	40	40	35.78
HD-Gist	4.15	12	<b>55.64</b>

Table 2: Accuracy of predicting the API and the model card on the APIBench (Patil et al., 2023) evaluation set.

## 5.2 Results on the APIBench Dataset

Next, we discuss the results on the APIBench (Patil et al., 2023) dataset. As shown in Table 2, the proposed HD-Gist model achieves a higher accuracy (55.65%) than all static gist-token models (45.14%). However, the gap (29%) to the LLaMA baseline with uncompressed API doc (84.38%) is much larger than it is on the SGD datasets. We believe this is because the documentation (e.g., descriptions of AI models) in APIBench is much longer than the documentation in SGD, which is demonstrated by the average number of tokens in the uncompressed API documentation (108.94 VS 551.75). In terms of the average compression ratio (original token to gist token ratio), one Gist<sub>value</sub> token of the lowest hierarchy only needs to encode

a single value (e.g., “everyday” in Fig. 3) in SGD, while a same token of the lowest hierarchy is expected to encode the description of a model card (61.3 tokens on average) in APIBench. Given these difficulties, our proposed HD-Gist method still achieves decent performance gain, which demonstrates the generalizability of our method and intuition. The noticeable gap between the model with a full context raises another research question: when the lowest hierarchy of the input is still very long, it is necessary to either increase the capacity of the gist compression (more than 1 gist tokens) or introduce a finer-grained hierarchy (e.g., sentence) in the compression. We leave the exploration of this question to future work.

## 5.3 Error Analysis

We break down 5 different types of errors that models make on SGD and count the percentage of validation examples where the model makes a specific error. We divide the 5 errors into two categories: argument error and value error. Argument error is when a model (I) misses an argument that is in the ground-truth API call, (II) predicts an extra argument from the documentation but is not in the ground-truth API call, or (III) hallucinates an argument that is not even in the documentation.

The second category, value error (IV), is when a model predicts the wrong value for a categorical argument, or (V) it predicts the wrong value for a regular argument. For Type IV error, the model could predict the wrong category (e.g., “s3.1 instead of s3.2”, or predict a value instead of the desired index. We show the results in Table 3. We can observe that all static gist models (row 2-4) as well as the Gist<sub>arg</sub> model predict the wrong value for a categorical argument (Type IV error) in more than 44% of the examples. The addition of the dynamic Gist<sub>value</sub> tokens significantly reduces the type IV error rate to 17.1% and adding reconstruction loss further reduces it to only 2.4%. This evidence corroborates our argument that the model can utilize more fine-grained information about an argument (e.g., its acceptable values) from the dynamic Gist<sub>value</sub> gist tokens.

## 5.4 Study on the Reconstruction Frequency

We then conduct a study on the percentage of training examples with the reconstruction loss. The results are shown in Table 4. On SGD-X, HD-Gist model achieves the best performance when we add the reconstruction loss in 10% of the training ex-

Models	Argument Error (%)			Value Error (%)	
	Miss (I)	Extra (II)	Hallu. (III)	Categorical (IV)	Regular (V)
LLaMA 7B	5.5	2.5	0.02	0.1	6.7
Append 2 Gist	11.3	8.5	1.1	47.0	15.8
Append 5 Gist	14.9	8.2	2.2	46.2	13.6
Append 10 Gist	9.9	3.2	1.3	46.6	7.4
Gist <sub>arg</sub> Only	7.5	2.5	0.9	44.9	<b>6.9</b>
HD-Gist	10.5	2.8	0.3	17.1	7.2
+Reconstruction	6.7	<b>0.0</b>	2.7	<b>2.4</b>	7.2

Table 3: The absolute percentage of different errors made by different models on SGD validation set.

Rec. Ratio	HD-Gist		10 Gist	
	SGD	SGD-X	SGD	SGD-X
0.0	70.47 $\pm$ 3.2	60.38 $\pm$ 2.8	45.36 $\pm$ 0.4	36.18 $\pm$ 1.6
0.1	87.81 $\pm$ 2.4	<b>83.37</b> $\pm$ 1.0	56.78 $\pm$ 1.3	43.47 $\pm$ 0.4

0.5	87.98 $\pm$ 1.0	75.36 $\pm$ 2.3	63.52 $\pm$ 3.2	47.34 $\pm$ 0.7
0.9	87.36 $\pm$ 2.0	70.61 $\pm$ 2.8	49.23 $\pm$ 6.9	37.48 $\pm$ 5.1
1.0	<b>89.98</b> $\pm$ 0.8	72.94 $\pm$ 4.2	61.87 $\pm$ 3.5	43.32 $\pm$ 9.6

Table 4: Joint-goal accuracy (average and standard deviation over 3 seeds) of the models trained with different ratios of examples with reconstruction. We report the model with 10 static gist tokens and the model with HD-Gist, evaluated on SGD and SGD-X validation sets.

Caching Strategy	Time (ms)	Compute (GFLOPS)	Memory (GB)
None	743.4	5788.7	26.5
API Doc	727.6	4079.1	21.8
Static Gist Caching			
2 Gist	704.9	4059.0	17.6
5 Gist	706.0	4059.5	17.7
10 Gist	711.6	4060.3	17.8
20 Gist	710.7	4061.9	18.1
40 Gist	710.0	4065.1	18.8
Dynamic Gist Caching			
HD-Gist	705.7	4060.6	17.9

Table 5: Efficiency of different caching methods, evaluated on 100 SGD validation examples. We report the average CUDA time (millisecond), computation (giga-FLOPS), and memory usage (gigabyte) for generating the ground-truth API call.

amples, while the static gist model achieves the best performance with 30% training examples with reconstruction. Reconstructing in more or less examples also achieves improvements on the baseline with no reconstruction.

## 6 Efficiency Evaluation

### 6.1 Benchmarking Setup

In this section, we compare the efficiency of the HD-Gist model to the static gist-token model as well as the baseline with no prompt compression. We aim to answer one important question: does our

proposed method still maintain the efficiency of the static gist-token model in terms of its compute, memory, and storage requirements? To answer this question, we compare the compute requirements (CUDA wall time, FLOPs) and memory usage during inference using different models and strategies to cache the API documentation:

- **No Caching.** We just encode the API documentation from scratch for every example.
- **API Doc Caching.** We cache the activations of the full API documentation (keys and values for all layers). This is the KV caching commonly used in the inference of a decoder-only Transformer (Pope et al., 2023).
- **Static Gist Caching** (Mu et al., 2023) compresses the API documentation into N gist tokens, and caches their activations.
- **Dynamic Gist Caching** compresses the API documentation into the proposed HD-Gist tokens, and caches their activations as well as a dictionary that maps a categorical argument’s name (e.g., “s3:”) to an attention mask that unmask its Gist<sub>value</sub> tokens.

We benchmark the prediction step that generates an entire output instead of a single forward pass (at the first decoding step) as is done in Mu et al. (2023). This is because we want to take into account the extra time to switch between the general attention mask that only unmask Gist<sub>arg</sub> and targeted masks that additionally unmask a set of Gist<sub>value</sub> for a categorical argument. Since we aim to benchmark different models (LLaMA 7B with no compression, static gist-token model, and our proposed model), and each model may generate an output of different lengths, we benchmark these models for generating the same, ground-truth API call instead of actually decoding them. This enables us to make a fair comparison between the

efficiency of these models. We benchmark on a single NVIDIA A100 40GB and report the GPU time, compute and memory usage.

## 6.2 Benchmarking Results

Table 5 shows the results of profiling an entire prediction step with PyTorch (Paszke et al., 2019) 2.0, averaged across 100 random validation examples. First, we note that all caching methods achieve significant speedup, less compute and memory than “No Caching” that encodes the API documentation from scratch for every example. This demonstrates the efficiency of caching and reusing the API documentation’s encodings.

Second, we observe that all static gist caching as well as the proposed dynamic gist caching only obtains a small speedup and reduction of compute compared to the “API Doc Caching”. A similar trend is also observed in Mu et al. (2023) and it is because the FLOPs required for a Transformer forward pass is dominated by encoding the newly generated token (e.g., passing it through feed-forward layers), which is unchanged across all caching strategies, rather than computing the self-attention weights with the cached key-values. Although the improvements in speed are limited, using “Dynamic Gist caching” reduces memory usage by 17.9%. As is shown in Table 1, caching the entire API documentation requires caching the activations of 108.94 tokens on average, while the dynamic gist method only requires caching the activations of 10.84 gist tokens on average.

## 7 Discussion

In this section, we discuss HD-Gist’s strong performance that even beats LLaMA with uncompressed API in SGD-X, and its potential of generalizing to compress any APIs and free text.

**Compression as Regularization.** One unexpected, but interesting finding in this work is that LLaMA with HD-Gist-compressed documentation outperforms LLaMA with uncompressed documentation in SGD-X (Table 1), whose arguments’ names and descriptions are paraphrased by human annotators. The opposite is observed in the original SGD test set whose arguments’ names and descriptions follow the same annotation as the training set. We believe this is because, after finetuning, LLaMA with uncompressed documentation overfits to the training examples. Therefore, when the arguments are paraphrased in the test set, the model is still

predicting based on its memory of training APIs. LLaMA with HD-Gist-compressed documentation, on the other hand, is exposed to a minimum but sufficient amount of information about the API through HD-Gist tokens during training. Thus it is more robust to test-time variations in APIs and generalizes better according to the information bottleneck theory (Tishby and Zaslavsky, 2015).

**Generalizing to Compress any APIs.** In the real world, API documentations mostly follow a similar hierarchical structure: starting with a coarse-grained API description, then a list of arguments and their descriptions, and further fine-grained descriptions of acceptable values for categorical arguments. Therefore, for any API documentations, we can append a  $\text{Gist}_{\text{value}}$  token after the description of a value, and append an  $\text{Gist}_{\text{arg}}$  token after the description of an argument. If the model needs to chain multiple API calls in the same expression, we can also append an API-level Gist token after an API documentation and hence include multiple APIs in the context. This allows HD-Gist to be generalized to compress any APIs.

**Generalizing to Compress Free Text.** We argue that HD-Gist can also be applied to compress free text where we have the ground-truth label on which part of the text the model should be attending. For example, in Multi-Hop Question Answering (Yang et al., 2018) with a long context containing multiple paragraphs, we know the golden paragraphs that contain the intermediate and final answers. Therefore we can add paragraph-level and sentence-level gist tokens to the context. The model only attends to paragraph-level gist tokens for the best efficiency, and then unmask the sentence-level gist tokens once it predicts to use a certain paragraph in a chain-of-thought reasoning step.

## 8 Conclusion

In this work, we propose to compress API documentation into a few sets of hierarchical and dynamic gist tokens. We enable the model to unmask value-level gist tokens to zoom into more details of a categorical argument. We further present a reconstruction objective that improves the compressed gist representation. Empirical results on multiple datasets demonstrate the significant improvement upon a single set of static gist tokens without sacrificing the speed or incrementing FLOPs.

## 9 Limitations

**Generalization to compress other texts.** In this work, we propose to hierarchically compress an API documentation into a set of  $Gist_{arg}$  tokens and a sets of  $Gist_{value}$  tokens. Each  $Gist_{arg}$  token is appended after the description of an argument and coarsely encodes this argument, while  $Gist_{value}$  token is appended after an acceptable value of a categorical argument and finely encodes this specific value. The model can automatically zoom into/out of information about an argument of interest by dynamically unmasking and remasking its  $Gist_{value}$  tokens. The decision of when to unmask and remask the  $Gist_{value}$  tokens of a categorical argument and which argument’s  $Gist_{value}$  tokens to unmask is solely based on the partially generated API call (output). For example, when the partial output ends with a categorical argument “a3: ”, we unmask the  $Gist_{value}$  tokens after every possible value of a3 (e.g., “[a3.0: 1  $Gist_{value}$ , a3.1: 0  $Gist_{value}$ ]”). After the model finishes predicting the value (“a3=a3.0,”), we mask these  $Gist_{value}$  tokens again. Therefore, our method can be applied to compress any API documentation (e.g., python, pytorch, etc.) that has a naturally hierarchical structure.<sup>5</sup> As long as the API call output refers to the argument name as it is in the documentation, which is true in almost all programming languages, the model can automatically decide when to unmask the  $Gist_{value}$  tokens of which argument.

One future direction is to extend the proposed hierarchical gist to compress unstructured, long context. To achieve this, one can explore some natural hierarchy (article, paragraph, sentence) within unstructured text and define and place gist tokens of different hierarchies. However, the output of a general prompt does not include signal tokens (e.g., argument names in API) that can be used to match to a component within the prompt hierarchy. Therefore, a crucial challenge is to let the model decide which paragraphs/sentences are relevant to the current decoding step and hence unmask the corresponding gist tokens. A potential solution is to quantify the “importance” of each paragraph/sentence within an article/paragraph using the attention weights on the paragraph/sentence gist tokens. We can then unmask the gist tokens in the most “important” paragraph/sentence to the

<sup>5</sup>Each API has multiple required and optional arguments, among which some arguments are categorical and have a finite set of acceptable values.

current step.

**Pretraining with compressed context.** Another potentially impactful direction is to incorporate the gist compression into the pretraining language modeling objective, instead of finetuning a pre-trained model to compress the context as is done in this work and [Mu et al. \(2023\)](#). This can significantly increase the length of the context window, which is a crucial factor in the pretraining of LLMs as the memory usage scales quadratically with the context length. For example, the longest context length of LLaMA is 2048 and further context longer than 2048 has to be truncated. Assume each paragraph in a corpus has 100 tokens. We can train the LLaMA model to attend to a token that is 409600 ahead by compressing each paragraph into a gist token.

## Ethical Considerations

In this work, we finetune a LLaMA 7B ([Touvron et al., 2023](#)) model to compress the API documentation and then predict the API call based on the user’s request. All training data are open-sourced, and hence do not contain any private or sensitive information. Nonetheless, previous work has shown that models trained with these large corpora can sometimes generate outputs that are toxic ([Dinan et al., 2019](#)) or reflect gender bias ([Dinan et al., 2020](#)) that might be offensive to certain users. As we are solely interested in having the model to predict the API call, we do not assess the toxicity or faithfulness of the model in generating free-form responses. Therefore, the model presented is only intended to predict an API call from the API documentation and user’s request. It is not intended to act as a chat agent on its own and we do not recommend prompting this model to generate free-form content.

## Appendix

### A Method

In Fig. 3, we show an example with the modified attention mask from the model with HD-Gist tokens that is also supervised to reconstruct the API documentation. During reconstruction, the model can only attend to the  $Gist_{arg}$  tokens. When it starts reconstructing a categorical argument, we unmask the  $Gist_{value}$  tokens associated with that argument, so that the model can learn to encode the fine-grained information (the list of all acceptable values) of the categorical argument into these  $Gist_{value}$  tokens.

### B Experimental Setup

#### B.1 Datasets

**SGD** (Schema-Guided Dialogue) (Rastogi et al., 2020) dataset challenges models to perform dialogue state tracking (DST) by following a schema. It has 143,346 training examples, 21,026 validation examples, and 36,129 test examples. The schema consists of multiple services (e.g., Hotel), where each service includes multiple intents (e.g., FindHotel) that can be invoked to fulfill a user’s request. Each intent is like an API and takes a number of arguments (e.g., location of hotel), including categorical arguments (e.g., “Number of guests per room”) that have a list of acceptable values (“[1, 2, 3]”). We convert the original DST task into an API prediction task by (1) discarding arguments that are not used by the currently active intent from the output<sup>6</sup> and (2) giving the model documentation of intent instead of the whole service. In both training and test, we also include intermediate turns where the user has not yet provided all arguments’ values. In these turns, we ask the model to generate a partial API call with only those arguments mentioned by the user so far. This increases the size of the training set at zero cost by utilizing the supervision from a dialogue state tracking dataset with labels of active arguments after every user’s turn. The dataset does not include any information that would leak the unique identity of individuals.

**SGD-X** (Lee et al., 2022) is created from SGD by asking human annotators to paraphrase the original arguments’ names and descriptions into se-

<sup>6</sup>For example, the DST task tracks the argument “location of hotel” specified by the user for the previous intent “FindHotel” but is not relevant to the current intent “BookHotel”.

manically similar yet stylistically diverse variants. For example, the argument “RequestPayment: Request payment from someone” is rewritten as “TransferRequest: Ask for a money transfer from a contact”. SGD-X further evaluates models’ robustness to linguistic variations in API documentation. We use the SGD-X/v5, which is the version with the most variation, as the extra test set to evaluate models trained on the original SGD training set.

**APIBench** (Patil et al., 2023) is a dataset consisting of APIs from HuggingFace, TorchHub, and TensorHub as well as 10 user question prompts generated from Self-Instruct (Wang et al., 2023). The documentation in APIBench only include the 3 API that construct a pretrained model (e.g., AutoModel.frompretrained in pytorch) and the acceptable values (model card’s url and description) of the first argument. There is no documentation on how to further use the constructed model to process inputs provided by users. Because the sole purpose of this work is to train and evaluate models to follow a compressed documentation, we discard the undocumented parts of API calls and only ask the model to predict (1) one out of three available APIs (HuggingFace, TorchHub, TensorHub), and (2) the value (model card’s url) of the first and only argument of an API. Therefore, we insert an API-level gist token after every API, insert a value-level gist token after the description of every model card, and omit the argument-level gist token since there is only one argument to predict.

We further observe that some user request does not specify which API they want to use, and all three APIs have at least one AI model that suffices the request. To eliminate the ambiguity, we add a prompt “I want to use TensorHub/TorchHub/Huggingface” to the user’s request. For each example, we sample 2 distracting model cards from the different categories of same API and 3 distracting model cards from the other two APIs. For example, if the ground-truth model card is a sentiment analysis model from TorchHub, we will not sample distracting model cards from the sentiment analysis category of TorchHub. However, we might sample a sentiment analysis model from Huggingface or TensorHub as a distractor. We repeat this sampling process 5 times per example to create 5 training instances with different distracting model cards. The resulting dataset has 48,750 training examples and 1,143 evaluation examples.

Models	API Doc Tokens in		Accuracy

Table 6: Joint-goal accuracy of single models on SGD (Rastogi et al., 2020) and SGD-X/v5 (Lee et al., 2022) validation sets. The best results from a model using the compressed API documentation are in bold.

## B.2 Training Details

We finetune every model on 8 NVIDIA A100 40GB GPUs for a single epoch, which takes around 16-18 hours to finish.

## B.3 Evaluation Metrics

Following Rastogi et al. (2020), we evaluate models on SGD and SGD-X using joint-goal accuracy. For arguments that are both in the ground truth and the predicted API call, we calculate the exact-match scores for values of categorical arguments, and calculate fuzzy soft-matching scores<sup>7</sup> for other arguments. For example, predicting “New York” while the ground-truth is “New York City” results in a fuzzy-matching score of 0.76. A matching score of 0 is assigned for both of the following errors: (i) arguments that in the ground truth but missed in the prediction, (ii) arguments in the prediction but not the ground truth. The joint-goal accuracy is the product of matching scores of all arguments in the API documentation. For APIBench that has no non-categorical argument, we use the exact-match accuracy only.

## C Extra Results

In Table 6, we report the models’ joint-goal accuracy on the SGD and SGD-X validation sets. The results are evaluated on the single model trained with seed 42.

## Abstract

Contrastive language-image pre-training (CLIP) models have demonstrated considerable success across various vision-language tasks, such as text-to-image retrieval, where the model is required to effectively process natural language input to produce an accurate visual output. However, current models still face limitations in dealing with linguistic variations in input queries, such as paraphrases, making it challenging to handle a broad range of user queries in real-world applications. In this study, we introduce a straightforward fine-tuning approach to enhance the representations of CLIP models for paraphrases. Our approach involves a two-step paraphrase generation process, where we automatically create two categories of paraphrases from web-scale image captions by leveraging large language models. Subsequently, we fine-tune the CLIP text encoder using these generated paraphrases while freezing the image encoder. Our resulting model, which we call ParaCLIP, exhibits significant improvements over baseline CLIP models across various tasks, including paraphrased retrieval (with rank similarity scores improved by up to 2.0% and 5.6%), Visual Genome Relation and Attribution, as well as seven semantic textual similarity tasks.

## 1 Introduction

Contrastive language-image pre-training (CLIP) models (Radford et al., 2021) have gained significant attention in the fields of computer vision and natural language processing for their remarkable capacity to understand the relationship between text and images. They have been widely used in various vision-language applications, including image classification (Deng et al., 2009), image retrieval (Lin et al., 2014; Plummer et al., 2015), and text-to-image generation (Saharia et al., 2022; Rombach et al., 2022), where the model should return desired visual outputs for a given text, and vice versa.

(Top-3) Retrieved Images by CLIP

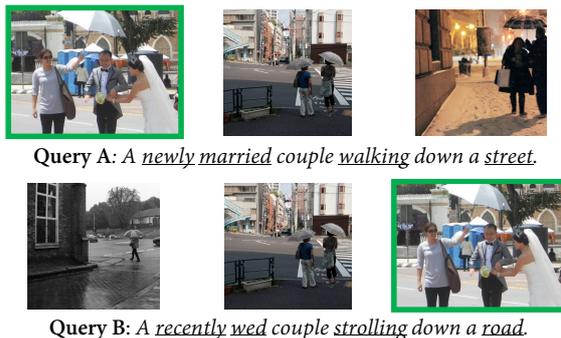

Figure 1: Image retrieval results of CLIP (Radford et al., 2021) for two different queries (the gold image is denoted by a bold border). Despite their comparable meanings, the model yields dissimilar retrieval results, highlighting the model’s struggle with linguistic variations.

An inherent challenge in vision-language tasks lies in the variability of text inputs. Even when conveying similar meanings and intentions, they can exhibit variations in vocabulary and structure depending on the particular user. Consequently, it becomes crucial to ensure that CLIP’s text encoders are robust enough to handle diverse synonyms and paraphrases in practical scenarios. However, current text encoders exhibit limited proficiency in comprehending linguistic variations, resulting in different retrieval results for user queries with similar meanings (Figure 1).

To address this challenge, we introduce a straightforward method to improve CLIP’s text encoders. Specifically, we generated two categories of paraphrases for image captions sourced from the web, leveraging recent large language models (LLM) such as ChatGPT (OpenAI, 2022) and LLaMA (Touvron et al., 2023). Subsequently, we utilized image captions and their corresponding paraphrases to fine-tune the text encoder, which ensures that the representations of captions and paraphrases cluster in a similar vector space.

We validated the effectiveness of our approach

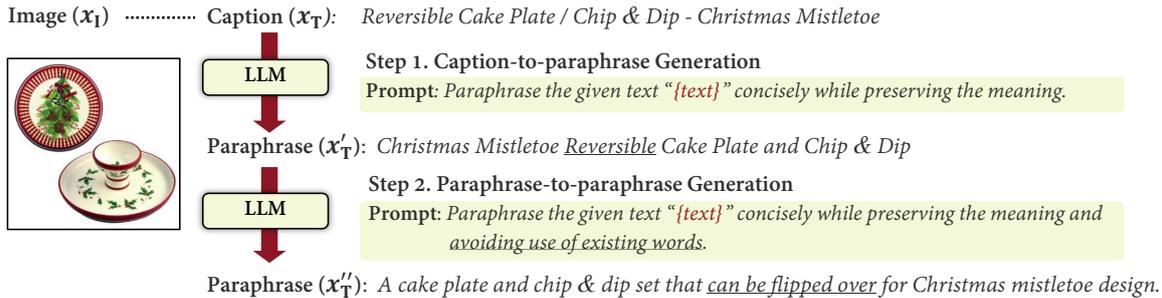

Figure 2: Overview of our two-step paraphrasing process. (1) In caption-to-paraphrase generation, the first paraphrase is generated by removing noise from the original caption and converting it into a more plain language. (2) In paraphrase-to-paraphrase generation, the second paraphrase is generated from the first paraphrase, where the word “reversible” is changed to a semantically similar expression “can be flipped over.”

using evaluation tasks that assess models’ understanding of language semantics and composition: paraphrased retrieval, Visual Genome Relation (VG-R), Visual Genome Attribution (VG-A) (Yuksekgonul et al., 2023), and semantic textual similarity (STS) tasks (Agirre et al., 2012). Our models, ParaCLIP, significantly outperformed baseline CLIP models, while maintaining or sometimes improving its robust performance on zero-shot image classification (Deng et al., 2009), as well as text and image retrieval (Lin et al., 2014). We emphasize that this is the first study to improve the representations of CLIP’s text encoders during the fine-tuning stage using synthetic paraphrases.

## 2 Method

Our objective is to refine the CLIP model’s training process, enabling its text encoder to produce consistent representations for various semantically similar textual inputs that the model might encounter in real-world scenarios. Certain image-captioning datasets provide multiple captions for a single image (Lin et al., 2014; Plummer et al., 2015), which might be utilized as semantically similar text pairs during training. However, the volume of these datasets is limited, which presents a challenge in terms of exposing models to diverse language patterns. Therefore, we automatically generated semantically similar pairs (i.e., paraphrases) for millions of image captions sourced from the web.

### 2.1 Paraphrase Generation

An image-captioning dataset typically comprises a collection of image-caption pairs ( $x_I, x_T$ ), where  $x_I$  and  $x_T$  represent an image and the corresponding caption, respectively. For each caption  $x_T$ , we created two categories of para-

phrases through a two-step paraphrasing process, caption-to-paraphrase generation and paraphrase-to-paraphrase generation, as illustrated in Figure 2.

**Caption-to-paraphrase generation** This process directly rewrites original captions. Image captions on the web often contain considerable noise, such as superfluous punctuation, product codes, and file extensions, which differ from typical queries. This step can be seen as responsible for converting these noisy captions into a more straightforward text format commonly used in everyday language. Using the power of LLMs, we synthesized paraphrases  $x'_T$  for each caption with the following prompt: “*Paraphrase the given caption “text” concisely while preserving the meaning.*”, where `text` is substituted with a given caption.

**Paraphrase-to-paraphrase generation** In this step, additional paraphrases,  $x''_T$ , are generated for each generated paraphrase,  $x'_T$ . The paraphrasing process is similar to the previous step, but with some differences in the prompt as follows: “*Paraphrase the given text “text” concisely while preserving the meaning and avoiding use of existing words.*”, where the underlined text is used to prompt the model to produce morphologically diverse expressions.

### 2.2 Training Objectives

Let  $\mathbf{X}_I$ ,  $\mathbf{X}_T$ ,  $\mathbf{X}'_T$ , and  $\mathbf{X}''_T$  be mini-batches of  $N$  examples of an image  $x_I$ , caption  $x_T$ , and two types of paraphrases,  $x'_T$  and  $x''_T$ . The final loss is calculated as the summation of three sub-losses as follows:  $\mathcal{L}_{\text{total}} := \mathcal{L}_1(\mathbf{X}_I, \mathbf{X}''_T) + \mathcal{L}_2(\mathbf{X}_T, \mathbf{X}'_T) + \mathcal{L}_3(\mathbf{X}'_T, \mathbf{X}''_T)$ . The first term,  $\mathcal{L}_1$ , represents the InfoNCE loss function that operates between images and text (Oord et al., 2018). This loss function is

crucial in the prevention of forgetting CLIP’s representations and knowledge acquired during pre-training. We used the paraphrased version of text input  $\mathbf{X}_T''$  rather than the original captions  $\mathbf{X}_T$  because user queries often resemble plain text rather than the original captions. This choice led to improved performance on the benchmark datasets during our preliminary experiment. If the target domain involves dealing with noisy text inputs, such as in an online shopping mall context, employing the original captions may be more effective.

The second term,  $\mathcal{L}_2$ , accounts for the relationship between captions and their paraphrases. Conceptually, it serves to establish a connection within the vector space between the representation of noisy captions and the plain text commonly used in everyday language. Lastly,  $\mathcal{L}_3$  serves to bring together various semantically similar plain texts within a vector space. For  $\mathcal{L}_2$  and  $\mathcal{L}_3$ , we used the InfoNCE loss. The resulting CLIP model fine-tuned using these three losses is called ParaCLIP.

### 3 Experimental Setups

We obtained image-caption pairs using LAION-400M (Schuhmann et al., 2021). We initially generated 300K paraphrases using ChatGPT and instruction-tuned an open-sourced LLM named LLaMA (7B) (Touvron et al., 2023) using these 300K data to generate additional paraphrases.<sup>1</sup> Our final dataset comprises 5M examples of  $x_I$ ,  $x_T$ ,  $x_I'$ , and  $x_T''$ . More details and hyperparameters are described in Appendix A.

#### 3.1 Baseline Models

We used the following CLIP models as baseline models, all built upon the ViT-B/32 architecture (Dosovitskiy et al., 2021). (1) OpenAI’s CLIP (Radford et al., 2021) was trained using a private dataset comprising 400M image-text pairs sourced from the web. (2) OpenCLIP models (Cherti et al., 2023) were trained using the largest open-sourced datasets, LAION-400M and LAION-2B (Schuhmann et al., 2022). (3) OpenCLIP-RoBERTa was pre-trained using LAION-2B. In contrast to the usual practice where text encoders are initialized with random weights and subsequently trained from scratch, its text en-

<sup>1</sup>We verified that the data generated by LLaMA exhibited comparable quality to that of ChatGPT. Additionally, when training the model using 300K paraphrases from LLaMA and an additional 300K paraphrases from ChatGPT, respectively, we observed similar performance in both cases.

coder was initialized with the weights of RoBERTa-base (Liu et al., 2019) for better linguistic comprehension capabilities. (4) LaCLIP (Fan et al., 2023) was pre-trained using the LAION-400m dataset augmented with automatically generated paraphrases.<sup>2</sup> Specifically, a small number of original caption and paraphrase pairs were obtained from COCO text descriptions, or created by ChatGPT, Google BARD, and humans. These seed examples were used to prompt an LLaMA 7B model through a in-context learning approach, which then generated paraphrases for the entire LAION-400m dataset. During pre-training, a standard InfoNCE loss was computed using these paraphrases and corresponding images in combination with original caption and image pairs. While our method shares some similarities with LaCLIP in the use of model-generated paraphrases, it should be noted that ours has unique advantages. First, we enhance CLIP models through fine-tuning the text encoders while freezing the image encoders, which is significantly more efficient compared to pre-training the entire model from scratch. Despite its efficiency, our method is significantly more effective to improve the CLIP’s robustness to paraphrases, improving the performance in paraphrased retrieval by a large margin (see Section 4 for details).

#### 3.2 Evaluation

We evaluated models on the following tasks in a zero-shot manner, without fine-tuning them on the target tasks. (1) Paraphrased retrieval (Cheng et al., 2024) involves retrieving identical images for both 4,155 original queries and their corresponding paraphrases from the image set of the COCO 2017 validation set (Lin et al., 2014). Paraphrases were generated using GPT-3 (Brown et al., 2020) and subsequently verified by humans. This task is well-suited for assessing models’ ability to effectively handle user queries expressed in diverse forms. For metrics, we used the top-10 average overlap (AO@10) and Jaccard similarity (JS@10) scores, which measure the degree of rank similarity between the top 10 images retrieved for the original query and paraphrased query. Detailed descriptions of the metrics can be found in Appendix B.

(2) VG-R and (3) VG-A (Yuksekgonul et al., 2023) are devised to assess relational and attributive understanding of vision-language models, respectively. They involve determining the correct

Table 1: Zero-shot performance of baseline CLIP models and our ParaCLIP models. The best scores are represented in bold. “Acc”: Accuracy. “Avg.”: Macro average of Spearman’s rank correlations across all STS tasks. “Clsf.”: Image classification. “T Rtrv.”: Text retrieval. “I Rtrv.”: Image retrieval.

caption for a given image from two candidate captions, where negative captions are generated by interchanging objects based on their relational context or interchanging attributes of objects. For instance, given the correct caption “the *dog* is behind the *tree*,” a negative counterpart could be formulated as follows: “the *tree* is behind the *dog*.” The VG-R and VG-A datasets comprise 23,937 and 28,748 test examples, respectively.

(4) STS has been widely employed to evaluate the text representations of encoders (Conneau et al., 2017; Reimers and Gurevych, 2019; Chuang et al., 2022). This task involves measuring semantic similarity or relatedness between pairs of text. Following Gao et al. (2021), we measured Spearman’s correlation for each task in the “all” aggregation setting and reported macro-averaged scores across the seven STS tasks (Agirre et al., 2012, 2013, 2014, 2015, 2016; Cer et al., 2017; Marelli et al., 2014).

Additionally, we assessed whether our models can maintain or even improve their performance on standard vision or vision-language tasks after being fine-tuned, including zero-shot image classification on the ImageNet-1K validation set (Deng et al., 2009), and image-to-text retrieval and text-to-image retrieval on the COCO validation set (Lin et al., 2014). For metrics, top-1 accuracy (Acc) and top-5 recall (R@5) were used in the classification and retrieval tasks, respectively.

## 4 Results and Discussion

### 4.1 Main Results

Table 1 shows the zero-shot performance of the baseline and our models in the evaluation tasks.

**Effect of fine-tuning using paraphrases** Across all CLIP models, our approach consistently demonstrated improved performance in the four primary tasks. Notably, the most significant improvements were observed in the paraphrased retrieval task, where our ParaCLIP model achieved 72.2% and 63.3% in AO@10 and JS@10 scores, increasing the performance of OpenAI’s CLIP by 5.0% and 5.6%, respectively.<sup>3</sup> The improvements in the STS tasks are also noticeable, with the macro-average score improving by 7.1%. Although not in all cases, our approach generally enhances performance in the text retrieval task. This is attributed to our model’s capability to encode texts that shares semantic similarity with a given input image closely within the vector space.

**Effect of initialization with RoBERTa** The OpenCLIP-RoBERTa model significantly outperformed the OpenCLIP (2B) model in paraphrased retrieval and STS, highlighting the benefits of leveraging pre-trained language models over randomly initialized text encoders. However, even with these advancements, there is substantial room for improvement in performance on these tasks. Our fine-tuning approach further refined the RoBERTa text encoder, leading to notable achievements across the four primary tasks, with 2.0% (AO@10) and 2.2% (JS@10) scores in paraphrased retrieval.

**Comparison with LaCLIP** While LaCLIP exhibited superior performance compared to the OpenCLIP (400M) model in image classification, paraphrased retrieval, VG-R, and VG-A, its per-

<sup>3</sup>A case study comparing CLIP and ParaCLIP in the paraphrased retrieval task can be found in Appendix C.

+ $\mathcal{L}''_1 + \mathcal{L}_2 + \mathcal{L}_3$ (Ours)	<b>72.2</b>	<b>63.3</b>	<u>60.4</u>	<u>64.2</u>	72.2	63.5	<b>77.0</b>	<b>58.8</b>

Table 2: Zero-shot performance of OpenAI’s CLIP (400M) with different loss functions applied. The best scores are represented in bold and the second best scores are underlined. “Paraphrased Rtrv.”: Paraphrased retrieval. “Acc”: Accuracy. “Avg.”: Macro average of Spearman’s rank correlations across all STS tasks. “Clsf.”: Image classification. “T Rtrv.”: Text retrieval. “I Rtrv.”: Image retrieval.

formance in the text/image retrieval and STS tasks witnessed a decline. This indicates that augmenting paraphrased text data may not consistently yield improvements, without incorporating effective loss functions such as  $\mathcal{L}_2$  and  $\mathcal{L}_3$ . Conversely, our fine-tuning method dramatically enhanced LaCLIP’s performance in paraphrased retrieval (+ 3.6% in AO@10 and 3.7% in JS@10), VG-R (+ 10.0%), VG-A (+ 1.0%), STS (+ 12.6%), and even on text retrieval (+ 5.5%) and image retrieval (+ 2.5%), highlighting that our method can complement LaCLIP to achieve optimal performance.

**Lack of compositional understanding** All CLIP models exhibited significant deficiencies in the VG-R and VG-A tasks. These limitations in compositional understanding can lead to errors in downstream tasks such as text-to-image synthesis, including unintentional attribute interchanges or the omission of objects in generated images (Feng et al., 2023). In future research, we plan to conduct a more in-depth analysis to explore the potential of our approach to mitigate these issues.

## 4.2 Ablation Study

We conducted an ablation study to closely examine the individual contributions of each loss term (Table 2). In this section, we simplify the notation  $\mathcal{L}_1(\mathbf{X}_I, \mathbf{X}_T)$ ,  $\mathcal{L}_1(\mathbf{X}_I, \mathbf{X}'_T)$ , and  $\mathcal{L}_1(\mathbf{X}_I, \mathbf{X}''_T)$  to  $\mathcal{L}_1$ ,  $\mathcal{L}'_1$ , and  $\mathcal{L}''_1$ , respectively. Note that our ParaCLIP model was trained using the combined loss functions,  $\mathcal{L}''_1 + \mathcal{L}_2 + \mathcal{L}_3$ , as detailed in Section 2.2.

First, we fine-tuned the OpenAI’s CLIP model using the same set of image-caption pairs in LAION-400M as our model, excluding paraphrases (referred to as “ $\mathcal{L}_1$ ”). While there was an overall improvement in performance, it still fell short of

our ParaCLIP model’s performance. When  $\mathcal{L}''_1$  was omitted (i.g.,  $\mathcal{L}_2 + \mathcal{L}_3$ ), the model showed the best performance on the VG-R, VG-A, and STS tasks, but the performance on image classification and standard text and image retrieval significantly degraded. This indicates that  $\mathcal{L}''_1$  was crucial in preserving the representations of CLIP acquired during pre-training. Although simply augmenting training data with synthetic paraphrases (i.e.,  $\mathcal{L}_1 + \mathcal{L}'_1$  and  $\mathcal{L}_1 + \mathcal{L}'_1 + \mathcal{L}''_1$ ) generally led to performance improvements, the improvements in the STS tasks were not substantial compared to the models with the  $\mathcal{L}_2$  and  $\mathcal{L}_3$  losses. Applying  $\mathcal{L}_3$  was particularly effective for STS because it involved comparing pairs of semantically similar “plain” text (not pairs of noisy caption and plain text), which aligns well with the goal of STS. Finally, our ParaCLIP model, incorporating three losses (i.e.,  $\mathcal{L}''_1 + \mathcal{L}_2 + \mathcal{L}_3$ ), showed the most balanced performance across all tasks among the various models evaluated. In particular, applying  $\mathcal{L}''_1$  instead of  $\mathcal{L}_1$  proved to be generally effective.

## 5 Conclusion

In this study, we proposed a two-step paraphrasing approach for enhancing the representations of CLIP for paraphrases that may occur in text inputs in real-world applications. Our ParaCLIP models, fine-tuned using synthetic paraphrases, outperformed baseline models by a large margin on various tasks requiring language semantics and compositional understanding, including paraphrased retrieval.

## Limitations

Our method sometimes degrades the performance of CLIP on conventional vision and vision-

language tasks such as zero-shot classification and image retrieval. A significant factor contributing to this performance variation may be the sensitivity of the infoNCE loss to changes in batch size. We observed consistent improvements in the image classification and text/image retrieval tasks by scaling up the batch size from 256 to 3K. Unfortunately, due to constraints in computational resources, we were unable to match the batch size to the scale of CLIP hyperparameters (e.g., OpenAI’s CLIP was pre-trained using a batch size of 32K). As a result, the effect of batch size in causing the observed performance degradation has not been thoroughly validated in this study. Although the primary goal of this paper was to showcase the potential improvements in the CLIP model through synthetic paraphrasing and better generalization ability across various input queries, a comprehensive investigation into the factors contributing to performance degradation should be conducted in future research.

## Acknowledgements

We thank Fabian Caba Heilbron and Donghee Choi for their help and insightful discussions. This research was supported by (1) National Research Foundation of Korea (NRF-2023R1A2C3004176), (2) ICT Creative Consilience Program through the Institute of Information & Communications Technology Planning & Evaluation(IITP) grant funded by the Korea government(MSIT)(IITP-2024-2020-0-01819), and (3) a Korea University Grant.

## A Implementation Details

In the data generation process, we used the `gpt-35-turbo-0301` model with the temperature of 1.0 and top-p of 0.1. We paid approximately 130 USD for using ChatGPT to generate 300K paraphrases for captions and 300K additional paraphrases for generated paraphrases.

We used the checkpoints of CLIP models provided in the official OpenCLIP GitHub repository.<sup>4</sup> We used `openai` for OpenAI’s CLIP, `laion400m_e32` for OpenCLIP (400M), `laion2b_s34b_b79k` for OpenCLIP (2B), and `laion2b_s12b_b32k` for OpenCLIP-RoBERTa. Our ParaCLIP models were trained for one epoch using the AdamW optimizer (Loshchilov and Hutter, 2019), coupled with a cosine annealing scheduler, on eight A100 80G GPUs. For fine-tuning, a learning rate of  $5e-7$ , a batch size of 3,072, and a weight decay rate of 0.001 were used. All reported scores were measured on a single run.

## B Metrics in Paraphrased Retrieval

**Average overlap** The top-k average overlap (AO@k) (Fagin et al., 2003) quantifies the rank similarity between the top-k elements of the two lists. Let  $L_a$  and  $L_b$  be ordered lists of retrieved images for two different queries. AO@k between the two lists is calculated based on the weighted sum of intersections of truncated lists as follows:

$$\text{AO@k}(L_a, L_b) := \frac{1}{k} \sum_{d=1}^k \frac{|L_a^d \cap L_b^d|}{d}, \quad (1)$$

where  $L_a^d = L_a[1 : d]$  and  $L_b^d = L_b[1 : d]$  represent the truncated lists at depth  $d$  and  $|L_a^d \cap L_b^d|$  indicates the cardinality of the set intersection between these truncated lists. When AO@k equals 1, it means that the top-k elements of  $L_a$  and  $L_b$  are exactly the same. Conversely, when AO@k equals 0, it implies that there is no overlap whatsoever between the top-k elements of  $L_a$  and  $L_b$ . AO@k gives more weight to the higher-ranked retrieval results because they contribute to more terms in the overall summation compared to lower-ranked results.

**Jaccard similarity** The top-k Jaccard similarity (JS@k) (Jaccard, 1912) is calculated as the ratio of the intersection to the union of the top-k elements

in two lists as follows:

$$\text{JS@k}(L_a, L_b) := \frac{|L_a^k \cap L_b^k|}{|L_a^k \cup L_b^k|}, \quad (2)$$

where  $|L_a^k \cup L_b^k|$  is the cardinality of the set union between  $L_a^k$  and  $L_b^k$ . JS@k equals 0 when  $L_a^k$  and  $L_b^k$  are disjoint and equals 1 when  $L_a^k$  and  $L_b^k$  contain the same retrieval results (although not necessarily in the same order). Unlike the average overlap, the Jaccard similarity does not assign more weight to the higher-ranked retrieval results.

## C Case Study

Figure 3 shows several examples where our ParaCLIP model yielded better retrieval results than OpenAI’s CLIP for paraphrased queries. In the first example, the paraphrased query (query B) contained several synonyms such as “picture,” “guy,” “cutting,” and “tiny,” replacing the words “image,” “man,” “slicing,” and “small,” respectively. While the CLIP model output dissimilar results for the given two queries, resulting in a performance drop for query B, ParaCLIP consistently produced identical results for both queries. In the second example, the only difference between the queries was the word “was.” Despite this minor variation, CLIP generated different sets of images. On the other hand, ParaCLIP returned the same images for both queries and achieved a better recall for query B, although the recall score for query A was slightly lower than that of CLIP. In the last example, query B was created by expanding the short query A into longer expressions. For instance, the concise phrase “a remote control” was transformed into the more elaborate phrase “a controller for a television that is wirelessly operated.” While CLIP exhibited high sensitivity to this long paraphrased query, ParaCLIP demonstrated greater robustness, resulting in more consistent results and superior recall scores.

<sup>4</sup>[https://github.com/mlfoundations/open\\_clip](https://github.com/mlfoundations/open_clip)

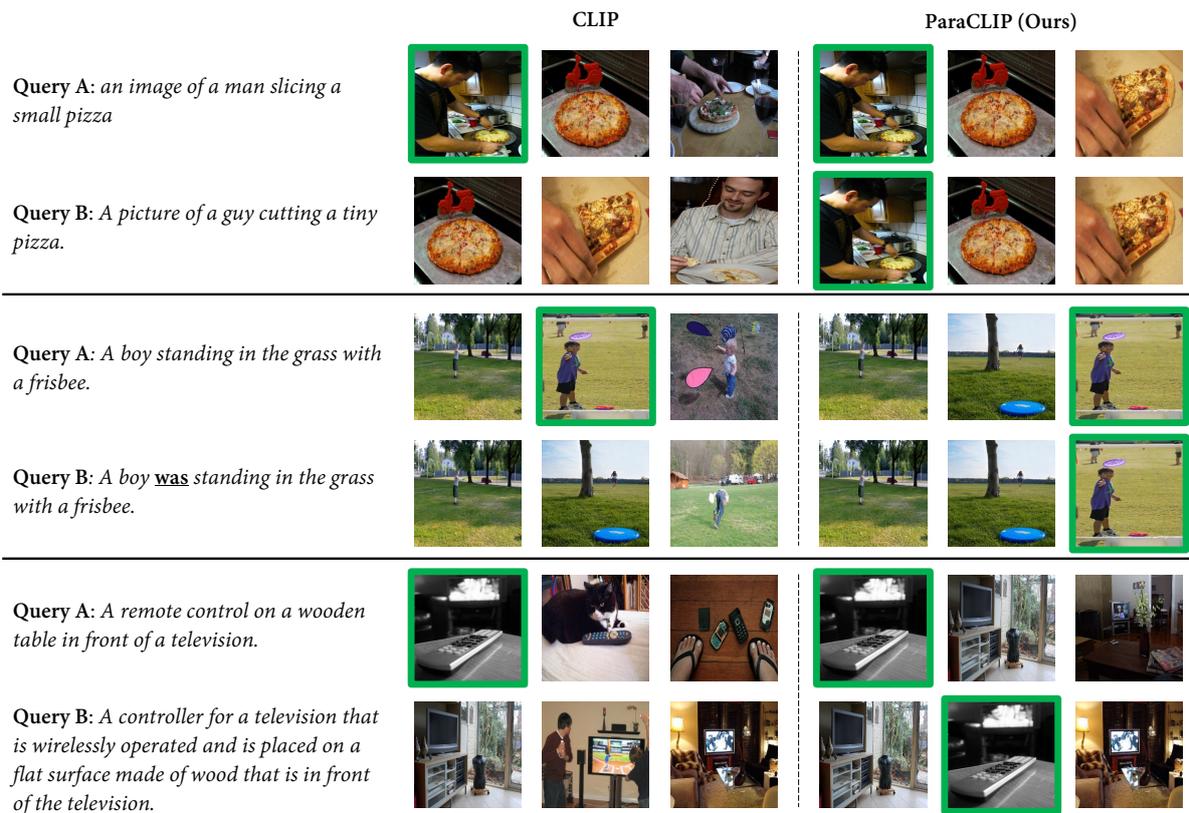

Figure 3: Examples of retrieved images by the CLIP (Radford et al., 2021) and our ParaCLIP models for two different queries. Note that the queries are obtained from the paraphrased retrieval dataset, and query B is a paraphrase for query A. The gold images are denoted by a bold border.

# Generative Interpretation: Toward Human-Like Evaluation for Educational Question-Answer Pair Generation

## Abstract

Educational question-answer generation has been extensively researched owing to its practical applicability. However, we have identified a persistent challenge concerning the evaluation of such systems. Existing evaluation methods often fail to produce objective results and instead exhibit a bias towards favoring high similarity to the ground-truth question-answer pairs. In this study, we demonstrate that these evaluation methods yield low human alignment and propose an alternative approach called **Generative Interpretation (GI)** to achieve more objective evaluations. Through experimental analysis, we reveal that **GI** outperforms existing evaluation methods in terms of human alignment, and even shows comparable performance with GPT3.5, only with BART-large.

## 1 Introduction

*Asking questions about the passage enhances children’s literacy development* (Blewitt et al., 2009; Sim and Berthelsen, 2014). In the context of children’s learning, educational question-answer generation (QAG) has gained considerable attention due to its practical utility (Xu et al., 2022; Dugan et al., 2022; Yao et al., 2022). QAG frameworks aim to generate relevant question-answer (QA) pairs based on a given story passage. With the significant research focus on QAG, numerous frameworks have been proposed to generate diverse and accurate QA pairs (Lee et al., 2020; Johnson et al., 2022; Eo et al., 2023)

While the generation capability of QAG has witnessed significant advancements, precise automatic evaluation remains a challenge. Current automatic evaluation metrics for QAG primarily rely on assessing textual similarity, such as ROUGE(Lin, 2004), and BERTscore(Zhang et al.), with respect to the ground-truth(GT) QA pairs (Dugan et al., 2022; Yao et al., 2022). However, we have observed that GT similarity seldom poses high score

for the high relevancy to the given passage, but only prefer GT similar QA pair, which follows misalignment with human assessment (Graham, 2015).

We consider *evaluation* to be a crucial factor in education of QAG, as inaccurate assessments can result in improper guidance (Shanmugavelu et al., 2020). Considering the role of QAG in the educational field, automatic evaluation methods serve as substitutes for human judgment that discriminate the most appropriate QA pair for the given passage. In such setting, an improper evaluation approach may restrict creative responses (Bullough Jr, 1992) and skew the purpose of the education towards mimicking answers from the GT QA dataset.

In an effort to mitigate such limitations, we propose a more objective and precise evaluation method, **Generative Interpretation (GI)**. **GI** employs a generative QAG model trained with GT QA pairs and selectively measures teacher-forced logits that are highly relevant in evaluating QA pairs. By evaluating each QA pair in a reference-free manner, **GI** enables even objective assessment that cannot be figured out via comparison between GT QA pairs. We figure out that **GI** can yield even higher human correlation, compared with the existing evaluation method. In particular, we demonstrate that only with utilizing the BART-large model structure (Lewis et al., 2020), **GI** can offer comparable performance to the ChatGPT (GPT3.5) evaluation (OpenAI-Blog, 2022).

## 2 Related Works

QAG frameworks aim to generate numerous QA pairs by given a passage (Xu et al., 2022; Liu et al., 2020; Jerome et al., 2021). In considering diversity in QA even enhances children’s intellectual and literacy development (Dillon, 2006; Shanmugavelu et al., 2020), current QAG studies mainly focus on enhancing diversity of the generating QA pairs (Yao et al., 2022; Zhao et al., 2022; Eo et al., 2023),

without harming relevancy to the given passage (Dugan et al., 2022; Lee et al., 2020). However, such methods only adopt the GT-similarity based evaluation method, which can yield biased results toward GT similar QA pairs (Graham, 2015).

### 3 Preliminary

The evaluation on the QAG framework is performed by measuring the quality of the candidate QA set  $C = \{(q_j^c, a_j^c)\}_{j=1}^{N_c}$ , generated by the QAG framework given a passage  $P$ . Existing methods measure the textual similarity between the  $C$  and the GT QA set  $R = \{(q_i^r, a_i^r)\}_{i=1}^{N_r}$ . We denote the textual similarity metric as **Metric**, where existing studies primarily adopt two measures, ROUGE and BERTscore. Considering multi-reference and multi-candidate setting, we can find two strategies in evaluating  $C$ .

**Concat-Metric** For the comprehensive evaluation, Zhao et al. (2022) concatenates all the QA pairs in a single sequence for each QA pair set, and estimates **Metric** between them. In this case, estimated quality of  $C$ , denoted as  $s_{\text{Concat}}$ , can be computed as equation (1). We denote  $[\dots]$  as a sequentialized concatenation of all elements.

$$\begin{aligned} r_i &= [q_i^r \ a_i^r], \quad r = [r_1, \dots, r_{n_r}] \\ c_j &= [q_j^c \ a_j^c], \quad c = [c_1, \dots, c_{n_c}] \quad (1) \\ s_{\text{Concat}} &= \mathbf{Metric}(r, c) \end{aligned}$$

**MAP@N-Metric** Yao et al. (2022); Eo et al. (2023); Xu et al. (2022) find the most similar QA pair in  $C$ , for each QA pair in  $R^1$ . In other words, we calculate the highest **Metric** for each QA pair in  $R$ , that can be derived by comparison with any QA pair in  $C$ . We can compute the estimated quality of  $C$ , denoted as  $s_{\text{MAP}}$ , as shown in equation (2).

$$\begin{aligned} \text{metric}_{i,j} &= \mathbf{Metric}([q_i^r \ a_i^r], [q_j^c \ a_j^c]) \\ s_{\text{MAP}} &= \frac{1}{N_r} \sum_{i=1}^{N_r} \max_j \{\text{metric}_{i,j}\}_{j=1}^{N_c} \quad (2) \end{aligned}$$

**Challenges in Evaluation** In applying human evaluation, QAG systems are generally estimated by the following aspects (Dugan et al., 2022; Eo et al., 2023; Zhao et al., 2022): (i) **Relevancy to**

<sup>1</sup>Xu et al. (2022) inversely matched the most appropriate reference for each candidate. However, as noted in Yao et al. (2022) and Eo et al. (2023), we find that such setting may bear unfair results, and set the baseline as in Yao et al. (2022).

**the passage** that determines whether the QA pair is relevant to the passage, (ii) **Answerability of the answer** that shows whether the answer can be regarded as an appropriate response to the question, and (iii) **Grammatical plausibility** of the generated QA pair. However, we argue that the existing automatic evaluation method of measuring similarity to GT has limitations in satisfying the above requirements and only evaluates whether the QA is similar to GT without evaluating the objective quality of the QA.

### 4 Generative Interpretation (GI)

**GI** estimates the adequacy of the generated QA pair, which encompasses relevancy to the passage and the connectivity between the QA. Similar with BARTscore (Yuan et al., 2021), we adopt QA generation model and take teacher-forced logits of the QA generation. In particular, we train the QA generation model  $\theta$  to return concatenated sequence of the QA pair, by feeding passage and the question start tokens, with  $\mathcal{L}_{CE}$  shown in equation (3).

$$\mathcal{L}_{CE} = -\frac{1}{N_r} \sum_{i=1}^{N_r} \prod_{l=1}^{N_{r_i}} \mathbf{P}_{\theta}(r_{i,l} | r_{i,<l}, q_{i,<n_s}^r, P) \quad (3)$$

The number of question start tokens are priorly set by a hyper-parameter  $n_s$ . We feed start tokens of each question as a part of input sequence, to alleviate the question type bias<sup>2</sup>. In utilizing  $\theta$ , we can estimate **GI** as follows:

#### 4.1 Teacher-Forced Inference

**GI** is estimated by the teacher-forced logits of the candidate QA pair, calculated by  $\theta$ . Precisely, we denote the probability of  $l^{\text{th}}$  token in  $c_j = [c_{j,1}, \dots, c_{j,n_c}]$ , to be generated by  $\theta$  as  $\text{prob}_{j,l}^c$ . Then we calculate the score for  $C$ ,  $s_{\text{GI}}$ , as follows:

$$\text{prob}_{j,l}^c = \mathbf{P}_{\theta}(c_{j,l} | c_{j,<l}, q_{j,<n_s}^c, P) \quad (4)$$

$$s_{\text{GI}} = \frac{1}{N_c} \sum_{j=1}^{N_c} \left[ \frac{1}{N_{c_j}} \sum_{l=2}^{N_{c_j}-1} \text{prob}_{j,l}^c \right] \quad (5)$$

<sup>2</sup>We argue that, in estimating the relevancy of the question to the given passage, question types that generally determined by the preceding tokens of the question should not be considered. For instance, "why" question can be generated for any passage. In this regard, we hypothesize that relevancy of the question to the passage is only determined by the preceding sequences

CLASS	Evaluation Method	Rel P-QA	Rel Q-A	Rel Avg	Usb	Rdb	Overall Avg
(a) GT Similarity	MAP@N-ROUGE	0.25708	0.28495	0.27101	0.44938	0.27702	0.31711
	Concat-ROUGE	0.23987	0.29014	0.26501	0.44401	0.27455	0.31214
	MAP@N-BS	0.31421	0.34464	0.32943	0.45315	0.33133	0.36083
	Concat-BS	0.30326	0.31240	0.30783	0.44174	0.33771	0.34878
(b) ChatGPT	GPT3.5 (P)	0.71699	0.36462	0.54080	0.13104	<b>0.43409</b>	0.41168
	GPT3.5 (QA)	0.73321	0.44916	0.59118	0.36482	0.35204	0.47481
	GPT4 (P)	0.70115	0.50391	0.60253	0.41532	0.14611	0.44162
	GPT4 (QA)	<b>0.78532</b>	<b>0.64633</b>	<b>0.71583</b>	<b>0.47354</b>	0.39561	<b>0.57520</b>

	GI - BART	<b>0.64525</b>	<b>0.46689</b>	<b>0.55607</b>	<b>0.40833</b>	<b>0.44438</b>	<b>0.49121</b>
	GI <sub>SS</sub> - T5	0.28245	0.23667	0.25956	0.25465	0.29370	0.26687
	GI <sub>SS</sub> - BART	0.17870	0.19743	0.18806	0.15051	0.33684	0.21587

Table 1: Experimental results in the respect of the human correlation (pearson-r). We denote **BS** as BERTscore, (P) as content-wise evaluation, (QA) as QA-wise evaluation, and **Rel Avg** as the average of the **Rel P-QA** and **Rel Q-A**. In estimating **GI**, we set  $n_s$  as 4.

**GI** works as a reference-free evaluation method, that can evaluate any QA pairs GT-independently. In particular, logits of question position in  $c_j$  determines the relevancy of the QA pair to the given passage, and answer position in  $c_j$  reflects the answerability of answer in  $c_j$ . Additionally, as logit reflects generation possibility, we can also judge the readability of QA pair via **GI**.

Unlike in training phase, **GI** is calculated as the mean of probabilities to prevent probability deterioration led by a single outlier. Also, the probability at the [BOS] and [EOS] position are excluded from the calculation for mitigating unintended bias.

## 4.2 Syntactic Similarity with Inference Output

The high performance of **GI** may solely contributed to the vast linguistic capability of  $\theta$ . For clarifying the validity of **GI**, we establish another baseline evaluation method, **GI<sub>SS</sub>**, that estimates the textual similarity between the generation output of  $\theta$  with  $C$ . By comparing **GI** with **GI<sub>SS</sub>**, we verify the effectiveness of **GI** in evaluating QAG, with relieved dependency on QAG model capacity. More details are described in Appendix F

## 5 Experiments

### 5.1 Experimental Settings

We adopt Fairytale QA dataset (Xu et al., 2022) in our experiments, as we find it as the most appropriate dataset fitted in educational purpose and is constructed by the human experts. We proceed

human evaluation on QA pairs for 20 passages, generated by four QAG systems, including gold QA pair. As in Eo et al. (2023), we evaluate four aspects: **Relevancy P-QA (Rel P-QA)** that estimates the relevance between QA pairs and a passage, **Relevancy Q-A (Rel Q-A)** that evaluates whether a question and its corresponding answer are correctly matched, **Usability (Usb)** estimating practical usability of the QA pair in educational field, **Readability (Rdb)** that indicates grammatical correctness. More precise details are dealt with Appendix A.

Adequacy for each metric is estimated by the pearson-r and kendall-tau correlation with human evaluation score (Koo and Li, 2016). Main results report pearson-r results (Freitag et al., 2021), and kendall-tau is dealt in the Appendix D. We adopt two pretrained language models in establishing **GI**: T5 (Raffel et al., 2020) and BART (Lewis et al., 2020), and measure ROUGE-L F1-score in estimating ROUGE, and F1-score for BERTscore. More extensive details about training and experimental settings are described in Appendix B.

### 5.2 ChatGPT as an Evaluator

One may wonder that all the evaluation process can be charged to ChatGPT owing to its extraordinarily high performance (Peng et al., 2023; Ouyang et al., 2022). In particular, several other tasks such as essay assessment (Chiang and Lee, 2023; Liu et al., 2023) adopted ChatGPT (OpenAI-Blog, 2022) in evaluation and show high human alignment. Con-

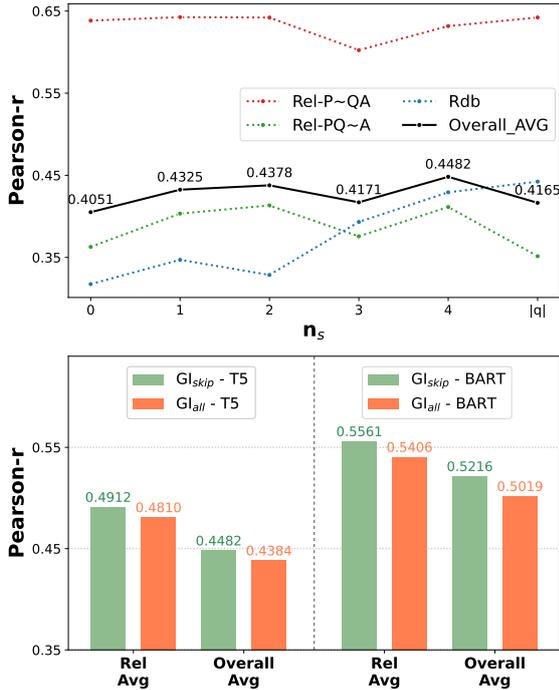

Figure 1: Case studies considering  $GI$ . Upper figure shows the human alignment variants depending on ( $n_s$ ), where  $|q|$  denotes the full length of question. Below figure demonstrates the effect of the logits in BOS and EOS position, where "skip" denotes the intended  $GI$ , and "all" considers all the logits, including BOS and EOS position.

Considering these, we check the performance of ChatGPT in evaluation of QAG, and verify the difficulty of evaluation in QAG and the effectiveness of  $GI$ .

In utilizing ChatGPT, we adopt the prompts and human instructions adopted to the prior studies (Yuan et al., 2022; Eo et al., 2023). As current evaluation protocol encompasses passage-wise evaluation (Eo et al., 2023) and QA-wise evaluation (Dugan et al., 2022; Xu et al., 2022), we experiment both of settings with specialized prompts. More details about the prompt engineering is described in Appendix C.

### 5.3 Main Results

**Estimating similarity between GT may bear suspicious results** As shown in class (a) of Table 1, we find that GT similarity based metrics shows even low human alignment especially for the relevancy aspects. This implies that similarity between GT suffers severe challenge in determining whether the QA pair is relevant to the given passage. Rather, it shows unexpectedly high correlation with usability aspect. These results indicate that existing

evaluation methods can be regarded as suspicious evaluators.

**ChatGPT is a decent evaluator** Results in class (b) of Table 1 shows that ChatGPT is a decent evaluator for the QAG. We find that QA-wise evaluation (*i.e.* GPT#(QA)) highly promote the evaluation performance of ChatGPT. Specifically, GPT4 shows the prominent performance, while GPT3.5 demonstrates relatively moderate performance, which implies the difficulty of evaluation for QAG.

**GI is a trust-worthy evaluator** Considering all the results in Table 1, specifically in the respect of class (C), we find that  $GI$  shows great human alignment (More details are in Appendix E).  $GI$  - BART outperforms existing evaluation methods, and even surpasses the performance of GPT3.5.

In particular, while  $GI$  shows comparable performance with GPT3.5,  $GI_{SS}$  does not even outperform ROUGE. This result indicates the methodologies applied in  $GI$  enables more objective and human-like evaluation of each QA pair.

### 5.4 Case Study

In estimating  $GI$ , we exclude "question start tokens" by feed it as an input, and dismiss logits in [BOS] and [EOS] positions, considering them as spurious factor that may lead to unintended bias. Figure 1 demonstrates case studies regarding them. We find that adjusting the number of question start tokens ( $n_s$ ) lead to even higher performance, by dismissing irrelevant logits in evaluating QA pairs. Similarly, we find that logits in [BOS] and [EOS] position also lead to unintended bias and decreases human alignment. More detailed results are described in Appendix D.4.

## 6 Conclusion

In this study, we focus on challenges in existing evaluation methods of educational QAG that measuring quality based on the similarity with GT QA pairs. We find out that existing automatic evaluation methods show inferior human alignment especially in measuring relevancy to the passage and question-answer pair. As alternatives, we propose more objective evaluation methodology,  $GI$ , that can relieve several challenges in existing metrics. We shows that  $GI$  demonstrates even higher human alignment than GPT3.5, only with BART-large. We plan to extend  $GI$  to more general metric that can cover more generalized question generation tasks.

## 7 Limitations

We find the effective of GI is only verified by the two model structures. We argue that GI can be applied to any large language models and more objective evaluation can be exploited by adopting more powerful language models. While this works only deals with BART-large and T5-base models due to the resource limitation, we plan to extend our experiments and urge future studies regarding model extension.

Additionally, we hope to clarify that our human evaluation was conducted with 240 QA pairs. Though it may seem small, we consider it to be a sufficient number for drawing general conclusions as compared to other studies that conducted human evaluations on approximately 100 QA pairs (Dugan et al., 2022). Notably, even on relatively ambiguous evaluation criteria, the achieved Krippendorff’s alpha score of 0.59 indicates our results are sufficiently reproducible and reliable.

## 8 Ethics Statement

We recruited participants by posting an announcement on a university community site that can be viewed by all members of the university; the individuals who participated in the experiment have no relationship with the authors outside of the present study. All the participants were provided with full disclosure about the purpose and process of the experiment before proceeding. We required from them official English proficiency scores (TOEIC, TOEFL), and only invited as evaluators those who had scores equivalent to or higher than 90 out of 100. All of the participants were asked for a B.A degree certificate in Education, ensuring that the evaluators had comparable levels of understanding in English and educational theory. In this process, all personally identifiable information from the human evaluators was immediately discarded after verification.

We paid the evaluators \$0.34 per evaluated QA, and we asked each evaluator to conduct a total evaluation on 240 QA pairs. We awarded a week for the evaluation period, and granted them autonomy in setting their own start and end times of evaluation. All evaluations were conducted on identical UI sites and everyone evaluated the same passage and same QA. We clearly state that there were absolutely no ethical issues that could be raised related to the human evaluation.

## A Dataset Details

For constructing our test dataset for the verification, we randomly extract 20 passages from Fairytale QA test dataset. Then we adopt three QAG systems: Yao et al. (2022)(FQAG), (Dugan et al., 2022)(SQG) and Eo et al. (2023)(DQAG). Then we generate three QA pairs for each passage with each QAG system. Additionally, we select three QA pairs from QA pair set that linked to the corresponding passage.

Subsequently, we proceeded human evaluation for each systems, including GT QA pairs. Human evaluation processes are the same as Eo et al. (2023). All human evaluators hold a bachelor’s degree in education. We assess the following four aspects estimating the quality of the QA pairs.

- **Relevancy P-QA:** This evaluates the relevance between a passage and a QA pair. If either question or answer is not relevant, it is irrelevant.
- **Relevancy Q-A:** This evaluates whether a question and its corresponding answer are correctly generated. If either of them is awkward, it is considered.
- **Usability:** This evaluates whether the generated QA pairs can be used for education purposes.
- **Readability:** This evaluates whether the generated QA pairs are grammatically right.

In this study, we revised notation utilized in Eo et al. (2023), for alleviating confusion with the educational domains (Miltenberger, 1990). We amend

the term "Acceptability" to "Relevancy Q-A", and subsequently replace the term "Relevancy" to "Relevancy P-QA". We got 0.5900 krippendorff’s alpha score over all the human evaluation results, and obtained the maximum score for the **Relevancy Q-A** (0.6355) (Krippendorff, 2011).

## B Training Details

For implementing **GI**, we adopt BART-large and T5-base model structure provided by the Huggingface(Wolf et al., 2020) framework (under Apache License 2.0). In training models for **GI**, we utilize a single RTX A6000 GPU. Each training is proceeded with AdamW optimizer(Loshchilov and Hutter, 2017) with learning rate  $1e - 04$  and batch size 32. We select the best performing model among different learning rate settings:  $\{2e - 04, 1e - 04, 3e - 05, 1e - 05\}$ .

## C ChatGPT Details

For the implementation of ChatGPT in our experiments, we utilize GPT-3.5(gpt-3.5-turbo-0301) (Ouyang et al., 2022) and GPT-4(gpt-4-0314) (OpenAI, 2023) and applied 0.7 temperature. We establish our prompts inspired by the previous works (Yuan et al., 2022), which aims at question generation utilizing LLM. Following Liu et al. (2023) and Mehri and Eskenazi (2020), we compose our prompt to include the human instruction for each aspect. In particular, we construct two types of the prompts that (1) evaluating each QA pair (**QA-wise**), and (2) evaluating QA pairs that correspond to the same passage (**content-wise**).

For **QA-wise**, each evaluation factor was scored on a 5-point Likert scale ranging from 1 to 5, which was then averaged across passages to obtain a final score, and **content-wise** was scored on a scale ranging from 0-3, with 1 point for each of the 3 QA pairs generated from a passage that met the criteria. All scores were re-scaled to values between 0 and 1. Utilized prompts are shown in figure 2 and figure 3.

## D Detailed Experimental Results

### D.1 Case Studies for ROUGE, BERTscore

Several existing QAG studies report ROUGE-L or BERTscore measured with precision or recall (Yao et al., 2022; Dugan et al., 2022). In this study, we point out that there is no clear standard in selecting one among precision, recall, or F1, and clarify human alignments of these methods in QAG. Experi-

Table 2: Experimental results on the variants of the existing methods, in the respect of the human correlation (pearson-r). We denote **BS** as BERTscore, **P** as a precision, **R** as a recall, and **F** as a F1-measure.

mental results are described in Table 2 and Table 3.

Experimental results shows that precision can be a more human-like measure compared with F1 measures, depending on its evaluating method. However, we argue that these results still cannot give considerable human alignments compared with **GI**.

## D.2 Experimental Results on the Kendall-tau Correlation

In our main results, we only report pearson-r correlation which indicates high correlation. For more objective verification, we additionally implement kendall-tau (Koo and Li, 2016) verification. Experimental results are shown in Table 4. We view the kendall-tau result as an auxiliary indicator as in Freitag et al. (2021).

## D.3 Results of GI variants

We report detailed experimental results regarding the Section 5.4. In this section, we demonstrate that discriminating "necessary part" in generating and accumulating logits of  $\theta$  is the essential part in estimating **GI**.

Table 5 describes the whole results of the experiments on the variant of  $\mathbf{n}_s$ .  $\mathbf{n}_s$  determines the extent of the information fed to the generative model  $\theta$ . Note that  $\theta$  is supervised to return the generation probability of QA pair. We hypothesize that question start tokens (which can include interrogative) determines the category of the corresponding question (Eo et al., 2023), and hardly related to the

relevancy between passage. In this regard, we find that feeding question start tokens to the  $\theta$  can yield more objective generation probability in judging "whether the question is relevant to the given passage". If  $\mathbf{n}_s$  is zero, generated probability can be influenced by the interrogative distribution of the training data, which may lead to unintended bias in estimating relevancy of the QA pair to the given passage. On the contrary, if  $\mathbf{n}_s$  is equal to the length of question, we find that  $\theta$  cannot properly identify the relationship between questions and answers, as the whole sequence of question is granted as input. Experimental results on Table 5 support our claims, which demonstrates the best performance when  $\mathbf{n}_s$  is set to 4.

Table 6 implies the reason we established the calculation process of **GI** as in Equation (5). In accumulating teacher-forced logits for calculating **GI**, we exclude probability yielded by decoding [BOS] and [EOS] positions. Note that the motivation of **GI** is estimating the plausibility of each QA pair, given a corresponding passage. In considering this, we find that probability obtained from [BOS] and [EOS] positions does not give meaningful information in estimating relevancy. As described in Table 6, we find that by following our intuition, we can enhance human alignment of **GI** (**GI** with **Skip**).

## D.4 System-level Evaluation

For better elaborate the practical utility of **GI**, we implement system-level evaluation, and the followings Table 7 reveal our results. For the human

Table 7: System level evaluation results

evaluation results, we measured average score for the four aspect we guaged (i.e. Rel P-QA, Rel Q-A, Usb, Rdb)

Our experiments reveal that **GI** attains high alignment with human evaluation, and gives informative results. While ROUGE and BERTscore yield mere difference across different systems, **GI** shows distinctive measure. More detailed evaluation results for each datapoint (i.e. evaluation for each QA set) are described in Figure 4.

## E Qualitative Analysis

To verify the practical usability of **GI**, we qualitatively analyze evaluation results proceeded in this study. We randomly extract three representative samples from our test dataset. As shown in Figure 4, **GI** shows high human alignment and similar tendency with GPT3.5 and GPT4. However, ROUGE shows even contrary results with human evaluation results, as it only reflects similarity with GT QA pairs. BERTscore provided high score with greater than 0.95 for all the QA pairs, that we can hardly determine which QA pair is decent or not. Our qualitative analysis support our main results, and further implies practical utility of **GI**.

## F Detailed Description of $GI_{SS}$

The method  $GI_{SS}$ , being experimented for illustration in our proposal, signifies that the effectiveness of  $GI$  is not merely reliant on the language un-

derstanding capability of the trained model itself. Essentially, the evaluation model  $\theta$  is trained to generate QAs by taking inputs from the passage and question start tokens.

In utilizing  $\theta$ ,  $GI$  is estimated by utilizing logit values. On the other hand,  $GI_{SS}$  evaluates the appropriateness of the generated output by comparing it with the candidate QAs.

Consider an evaluation candidate QA set  $[(q_1, a_1), \dots, (q_n, a_n)]$  for passage  $P$ . By utilizing the trained model  $\theta$ , we induce generation of answer  $a'_i$  by taking  $P$  and each  $q_i$  as inputs. Afterwards, we compare the textual similarity (ROUGE-L) between each  $a_i$  and  $a'_i$ . Using this generation-based evaluation method  $GI_{SS}$ , we observed significantly lower performance than  $GI$ . This experiment can essentially be regarded as a demonstration that, even when using the same evaluation model, the logit-based evaluation method we proposed is even more effective.

- (a) You will be given a passage from a story, a question about its content, and an answer to the question. Your task is to score the given passage, question, and answer on the five evaluation factors below.
- (b) You must use the 5-point Likert scale below to output your score for each factor, and you must not make any comments other than your score.  
(1) Strongly Disagree; (2) Disagree; (3) Neutral; (4) Agree; (5) Strongly Agree;
- (c) The five evaluation factors are described below.
- Relevancy: This evaluates whether the [question]-[answer] pair was generated with reference to the content of the [passage]. If either the [question] or the [answer] is not relevant, it is considered irrelevant.
  - Acceptability: This evaluates whether [answer] references [passage] and is appropriate as an answer to what [question] is asking. If [answer] is an answer that does not reference [passage], or if [answer] is not appropriate as an answer to [question], whichever is the case, it is unacceptable.
  - Usability: This evaluates whether the generated QA pairs can be used for education purposes.
  - Readability: This evaluates whether the generated QA pairs are grammatically right.
  - Difficulty: This evaluates whether the generated QA pairs are excessively easy.
- (d) The output only contain the score and NEVER contain any comments other than the score.

Figure 2: Prompts utilized in QA-wise evaluation of ChatGPT

- (a) You are given a passage from a story and "3 pairs" of questions and answers generated from that passage. Your task is to score the given passage and the 3 QA pairs according to the evaluation factors given below.
- (b) When calculating the evaluation score, you count one point for each QA pair that meets the factor. For example, for a criterion A, if only two out of three QA pairs meet the factor, the score is 2.
- (c) There are 5 evaluation factors: Relevancy, Acceptability, Usability, Readability, Difficulty. The output format of the score for all factors is "n/3" (n is the number of satisfying QA pairs).
- Relevancy: This evaluates whether the QA pair was generated with reference to the content of the [passage]. If either the Question or Answer is not relevant, it is considered irrelevant.
  - Acceptability: This evaluates whether Answer references Passage and is appropriate as an answer to what is asking. If Answer does not reference [passage], or if Answer is not appropriate as an answer to Question, whichever is the case, it is unacceptable.
  - Usability: This evaluates whether the generated QA pairs can be used for education purposes.
  - Readability: This evaluates whether the generated QA pairs are grammatically right.
  - Difficulty: This evaluates whether the difficulty of the QA pair is too easy or too hard. If it is too simple, it is not "difficulty".
- (d) The output only contain the score and NEVER contain any comments other than the score.

Figure 3: Prompts utilized in content-wise evaluation of ChatGPT

**Passage:**

a young man was out walking one day in erin , leading a stout cart - horse by the bridle . he was thinking of his mother and how poor they were since his father , who was a fisherman , had been drowned at sea , and wondering what he should do to earn a living for both of them . suddenly a hand was laid on his shoulder , and a voice said to him : ' will you sell me your horse , son of the fisherman ? ' and looking up he beheld a man standing in the road with a gun in his hand , a falcon on his shoulder , and a dog by his side . ' what will you give me for my horse ? ' asked the youth . ' will you give me your gun , and your dog , and your falcon ? '

**QA pairs:**

Q: who was drowned at sea ?  
A: his father

Q: what did a young man ask of his father ?  
A: will you sell me your horse

Q: what animal was on the shoulder of a young man walking in erin ?  
A: falcon

## Abstract

Pre-trained language models (LMs) perform well in In-Topic setups, where training and testing data come from the same topics. However, they face challenges in Cross-Topic scenarios where testing data is derived from distinct topics - such as *Gun Control*. This study analyzes various LMs with three probing-based experiments to shed light on the reasons behind the In-vs. Cross-Topic generalization gap. Thereby, we demonstrate, for the first time, that generalization gaps and the robustness of the embedding space vary significantly across LMs. Additionally, we assess larger LMs and underscore the relevance of our analysis for recent models. Overall, diverse pre-training objectives, architectural regularization, or data deduplication contribute to more robust LMs and diminish generalization gaps. Our research contributes to a deeper understanding and comparison of language models across different generalization scenarios.<sup>1</sup>

## 1 Introduction

Probing (Belinkov et al., 2017; Conneau et al., 2018a) is widely used to analyze pre-trained language models (LMs) (Devlin et al., 2019; Liu et al., 2019; He et al., 2021; Radford et al., 2019). It enables a better understanding of how LMs encode information and how it evolves in the architecture by studying linguistic properties such as part-of-speech or dependency-tree parsing (Tenney et al., 2019a,b). However, probing methods (Hewitt and Liang, 2019a; Hewitt and Manning, 2019; Voita and Titov, 2020a; Elazar et al., 2021) mainly rely on the general In-Distribution (ID) scenario, where we distribute train and test instances independent and identically. As a result, other more realistic Out-of-Distribution (OOD) scenarios (Shen et al., 2021), like generalizations regarding forthcoming

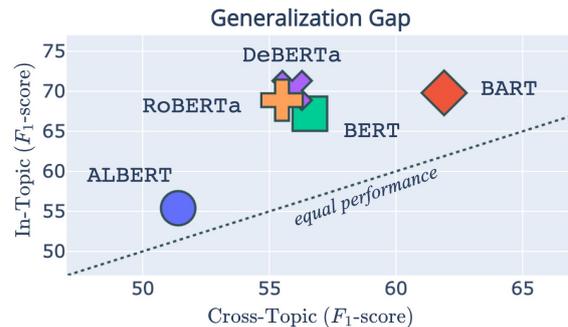

Figure 1: Generalization gap of fine-tuning LMs on argumentative *stance detection* (Stab et al., 2018) in the In- or Cross-Topic evaluation setup. The dashed line marks the ideal case of equal performance.

topics or temporal changes in the language, remain underexplored by probing.

Addressing this research gap, we propose - for the first time - a probing-based approach to comprehensively analyze LMs in a challenging OOD setup. More precisely, we rely on Cross-Topic<sup>2</sup> evaluation where we deliberately withhold instances from specific topics for testing. Following (Habernal and Gurevych, 2016; Stab et al., 2018), we define *topic* as the query used to compose a specific dataset - such as arguments covering *gun control* or *marijuana legalization*. This evaluation setup is highly relevant for challenging Argument Mining (AM) downstream tasks (Slonim et al., 2021). It allows for simulating, in a controlled setup, how well LMs handle topic-shifts when unseen semantic features (such as topic-specific vocabulary) arise in future and new topics. Previous studies found that Cross-Topic argument mining is challenging compared to the In-Topic setup (Stab et al., 2018; Waldis and Gurevych, 2023). The major reason lies in the apparent generalization gaps between randomly composing training and testing data (In-Topic) and using distinct groups of topics for training and testing

<sup>2</sup>Also known as Cross-Target in *Stance Detection* research.

(Cross-Topic). [Figure 1](#) shows such performance gap when fine-tuning on the *UKP ArgMin* dataset (Stab et al., 2018) - labeling arguments as in favor, against, or neutral to one of eight topics. Notably, we observe gaps between In- and Cross-Topic varying considerably across LMs - with BART outperforming the others in the Cross-Topic setup.

Such inconsistencies underline the need to investigate such crucial generalization capabilities. Thus, we propose extensive probing-based experiments to examine the gap between In- and Cross-Topic generalization and show that embedding spaces of LMs vary considerably regarding their generalizability and robustness. In detail, we propose three probing-based experiments to answer the following research questions, considering three linguistic probes (dependency-tree parsing, part-of-speech tagging, and named-entity recognition) based on *UKP ArgMin* dataset:

***How do generalization gaps of LMs differ after pre-training? (§ 4)*** We find generalization gaps substantially differ across LMs while becoming more prominent for tasks with more semantically difficulties, such as NER. In addition, we crucially observe that probing generally underperforms on lexical unseen instances (like highly rare entities), and deduplicating pre-training data provides more robust embedding space when evaluating larger and more recent LMs.

***How do LMs depend on topic-specific vocabulary? (§ 5)*** Next, we assess the influence of topic-specific tokens by removing them using amnesic probing and LMs significantly differing in their reliance on and robustness concerning such semantic features. Interestingly, pre-training objectives or architectural regularization influence robustness, suggesting their potential importance in building robust and competitive LMs.

***How do generalization gaps evolve during fine-tuning? (§ 6)*** Finally, we re-probe tuned LMs on the *UKP ArgMin* dataset and find that In-Topic fine-tuning erases more linguistic properties than Cross-Topic fine-tuning.

To sum up, we expand the probing scope to Cross-Topic generalization and highlight probing as a universal tool complementing the study of language models beyond general evaluation setups. While we focus on an in-depth analysis of In- vs. Cross-Topic generalization gaps, our experimental

setup generalizes to other types of OOD scenarios where one verifies generalization regarding other text genres (like the *social media* domain), languages, or temporal changes in the languages (Conneau et al., 2018b; Hardalov et al., 2021; Röttger and Pierrehumbert, 2021; Yang et al., 2023).

## 2 In- and Cross-Topic Probing

The following section formally outlines the probing setup and tasks before elaborating on the generalization gap and comparing the evaluation of In- and Cross-Topic probing.

### 2.1 Probing Setup and Tasks

We define a probe  $f_p$  comprised of a frozen encoder  $h$  and linear classifier  $c$  without any intermediate layer. This classifier is trained to map instances  $X = \{x_1, \dots, x_n\}$  to targets  $Y = \{y_1, \dots, y_n\}$  for a given probing task. Using a frozen LM as  $h$ , the probe converts  $x_i$  into a vector  $h_i$ . In detail, we encode the entire sentence, which wraps  $x_i$ , and average relevant positions of  $x_i$  to find  $h_i$ . Relevant positions for the considered probing task are either single tokens for *part-of-speech tagging (POS)*, a span for *named entity recognition (NER)*, or the concatenation of two tokens for *dependency tree parsing (DEP)*. Then, the classifier  $c$  utilizes  $h_i$  to generate a prediction  $\hat{y}_i$ , as shown in [Equation 1](#).

$$\hat{y}_i = f_p(x_i) = c(h(x_i)) \quad (1)$$

### 2.2 Generalization Gap

Generalization gaps arise when comparing evaluation setups focusing on different capabilities for the same task. This work focuses on gaps in using data from the same (In-Topic) or different topics (Cross-Topic) for training and testing. We define such topics  $T = \{t_1, \dots, t_m\}$  as the query to collect instances and thereby given by specific datasets (Habernal and Gurevych, 2016; Stab et al., 2018) - such as arguments covering *gun control* or *marijuana legalization*. The In- vs. Cross-Topic gap is visible in [Figure 2](#), which shows how NER instances (in blue) are distributed in the semantic space. For Cross-Topic, entities cover only specific topics and thereby are less broadly spread, while In-Topic ones are spread more broadly since they cover all datasets' topics. Simultaneously, we note more lexically *unseen* entities (in red) during training for Cross-Topic. Ideally, generalization gaps do not exist since pre-trained language models (LMs)

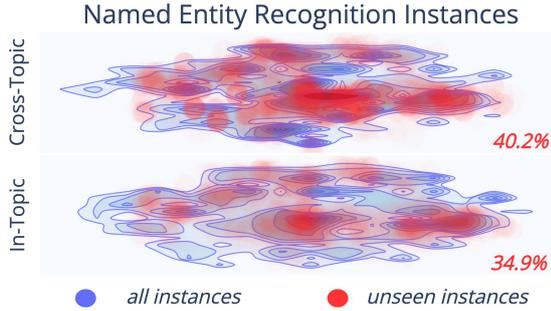

Figure 2: Density plot of In- and Cross-Topic NER test instances (blue), encoded with *bert-base-uncased* and reduced with the same t-SNE model (van der Maaten and Hinton, 2008). While the number of instances is the same, Cross-Topic embodies, with 40.2%, more *unseen* instances than In-Topic (34.9%).

overcome such distribution shifts between different evaluation setups. However, practically, these gaps vary for different models (Figure 1).

### 2.3 Difference between In- and Cross-Topic Evaluation

By evaluating probing tasks for In- and Cross-Topic, we examine the varying generalization gaps between these setups across different LMs.

**Cross-Topic** With Cross-Topic evaluation, we investigate how well a probe generalizes when the train, dev, and test instances cover distinct sets of topics  $\{T^{(train)}, T^{(dev)}, T^{(test)}\}$ . A probe  $f_p$  must generalize across the distribution shift in this setup. This shift originates because distinct topics cover different specific vocabulary  $Z$  - i.e.,  $Z^{(test)}$  for topics in  $T^{(test)}$ . We formally describe this shift, denoted as  $\Delta Z$ , as the relative complement between topic-specific vocabulary from train and test instances -  $\Delta Z = Z^{(train)} \setminus Z^{(test)}$ . For Cross-Topic, we expect  $\Delta Z$  to be large (Figure 2).

**In-Topic** In contrast,  $\Delta Z$  is smaller for the In-Topic setup because instances from every split (train/dev/test) cover the same topics. We expect similar topic distribution and minor semantic differences within these splits compared to Cross-Topic (Figure 2). Thus, we see fewer difficulties for In-Topic because a classifier does not need to generalize across a large distribution shift  $\Delta Z$ .

**Topic-Specific Vocabulary** As discussed previously, we see topic-specific vocabulary as one main reason for generalization gaps between In- and Cross-Topic because  $\Delta Z$  differs for these setups considering a dataset  $d$  covering topics  $T =$

Model	# Params	Objectives	Data
ALBERT (Lan et al., 2020)	12M	MLM + SOP	16GB
BART (Lewis et al., 2020)	121M	DAE	160GB
BERT (Devlin et al., 2019)	110M	MLM + NSP	16GB
DeBERTa (He et al., 2021)	100M	MLM	80GB
RoBERTa (Liu et al., 2019)	110M	MLM	160GB
ELECTRA (Clark et al., 2020)	110M	MLM+DISC	16GB
GPT-2 (Radford et al., 2019)	117M	LM	40GB

Table 1: Overview of the used LMs trained on MLM, LM, DISC, NSP, SOP, or DAE objectives.

$t_1, \dots, t_m$ . The topic-specificity of a token  $z_i$  is a latently encoded property within the encodings  $h_i$  for a token  $w_i$ . To capture this property on the token level, we adopt the approach of Kawin-tiranon and Singh (2021) and use the maximum log-odds-ratio  $r_i$  of a token regarding a set of topics  $T$ . Firstly, we calculate the odds of finding the token  $w_i$  in a topic  $t_j$  as  $o(w_i, t_j) = \frac{n(w_i, t_j)}{n(-w_i, t_j)}$ , where  $n(w_i, t_j)$  is the number of occurrences of  $w_i$  in  $t_j$ , and  $n(-w_i, t_j)$  is the number of occurrences of every other token  $-w_i$  in  $t_j$ . We then compute  $r$  as the maximum log-odds ratio of  $w_i$  for all topics in  $T$  as  $r(w_i, T) = \max_{t_j \in T} (\log(\frac{o(w_i, t_j)}{o(w_i, -t_j)}))$ .

## 3 Experimental Setup

We propose three experiments to analyze the varying generalization gap between LMs after pre-training (§ 4), their dependence on topic-specific vocabulary (§ 5), and the evolution of these gaps during fine-tuning (§ 6). We outline general details about these experiments, while details and results are provided in the subsequent sections.

**Models** We examine how various LMs (Table 1) with varying pre-training objectives or architectural designs differ regarding our probing tasks. We cover LMs pre-trained using masked language modeling (MLM), next sentence prediction (NSP), sentence order prediction (SOP), language modeling (LM), discriminator (DISC), and denoising autoencoder (DAE) objectives. As in previous work (Koto et al., 2021), we group them into the ones pre-trained using token- (MLM) and sentence-objectives (NSP, SOP, or DAE) and four purely token-based pre-trained (MLM, LM, DISC). We consider the base-sized variations to compare their specialties in a controlled setup. Apart from these seven contextualized LMs, we use a static LM with GloVe (Pennington et al., 2014).

**Data** We require a dataset with distinguishable topic annotations to evaluate probing tasks in the In- and Cross-Topic evaluation setup. Therefore, we mainly<sup>3</sup> rely on the *UKP ArgMin* dataset (Stab et al., 2018), which provides 25,492 arguments annotated for their argumentative stance (*pro*, *con*, or *neutral*) towards one of eight distinct topics like *Nuclear Energy* or *Gun Control*. Using these instances, we heuristically generate at most 40,000 instances for the three linguistic properties *dependency tree parsing* (**DEP**), *part-of-speech tagging* (**POS**), or *named entity recognition* (**NER**) using spaCy.<sup>4</sup> Additionally, we consider the main task of the *UKP ArgMin* dataset (Stab et al., 2018) - *argumentative stance detection* (**Stance**). Therefore, we have a topic-dependent reference probe to relate the results of other probes and evaluate the generalization ability of LMs on real-world tasks after pre-training. We use a three-folded setup for all these four probing tasks to consider the full data variability for both In- and Cross-Topic evaluation. Details about the compositions of these folds and how we ensure a fair comparison between In- and Cross-Topic are provided in the Appendix (§ A.2) as well as examples for probing tasks (Appendix § A.1).

**Evaluation** We primarily report the macro  $F_1$  score averaged over the results of evaluating each of the three folds three times using different random seeds. Following recent work (Voita and Titov, 2020b; Pimentel et al., 2020), we additionally report information compression  $I$  (Voita and Titov, 2020b) for a holistic evaluation. It measures the effectiveness of a probe as the ratio ( $\frac{u}{mdl}$ ) between uniform code length  $u = n * \log_2(K)$  and minimum description length  $mdl$ , where  $u$  denotes how many bits are needed to encode  $n$  instances with label space of  $K$ . We follow *online* variation of  $mdl$  and use the same ten-time steps  $t_{1:11} = \{\frac{1}{1024}, \frac{1}{512}, \dots, \frac{1}{2}\}$ , where we train a probe for every  $t_j$  with a fraction of instances and evaluate with the same fraction of non-overlapping instances. Exemplary, for,  $t_9$  we use the first fraction of  $\frac{1}{4}$  instances to train and another fraction of  $\frac{1}{4}$  to evaluate. We find the final  $mdl$  as the sum of the evaluation losses of every time step  $t_{1:11}$ . For Cross-Topic, we group training instances into two

<sup>3</sup>We verified our findings with another dataset in the Appendix § B.1.

<sup>4</sup>We show in the Appendix (§ B.8) that the heuristically generated labels are reliable, and our results are well aligned with previous work.

Table 2: In- and Cross-Topic probing results for eight LMs. We report the macro  $F_1$  over three random seeds, the average difference between the two setups (last row), and their average per LM (last three columns). The best results within a gap of 1.0 are marked by columns.

groups of distinct topics and sample the same fraction of instances to train and evaluate. Thus, we ensure a similar distribution shift between training and evaluation fractions as in all instances.

## 4 The Generalization Gap of LMs

The first experiment shows that the generalization gap already exists after pre-training and varies regarding specific LMs and probing tasks. We analyze general (Table 2 and Figure 3) and fine-grained (Table 3) results and discuss them for the different evaluating setups, probing tasks, and LMs. While firstly focusing on mid-size LMs usable for fine-tuning, we close how probing performance scales to large LMs in § 4.

**Design** We probe eight LMs on the probing tasks DEP, POS, NER, and Stance and verify them by observing significant performance drains using random initialized LMs (Appendix § B.2). For a holistic evaluation, we provide general results and group instances into two categories: *seen* and *unseen*. We define *seen* instances as already processed during training but in another context. For example, the pronoun *he* might appear in both training and test data, but in distinct sentences. By evaluating the LMs on *seen* instances, we gain insights into the influence of token-level lexical information versus context information from surrounding tokens. In contrast, *unseen* instances were not encountered during the training of a probe. They allow assessing whether LMs generalize to tokens that are similar to some extent (such as *Berlin* and *Washington*) but not seen during training.

**Results for Evaluation Setups** Upon analyzing Table 2, we observe clear generalization gaps between In- and Cross-Topic evaluation for all tasks and LMs. As in Figure 3, the magnitude of this gap

	DEP			POS			NER			
	<i>all</i>	$\Delta$ <i>seen</i>	$\Delta$ <i>unseen</i>	<i>all</i>	$\Delta$ <i>seen</i>	$\Delta$ <i>unseen</i>	<i>all</i>	$\Delta$ <i>seen</i>	$\Delta$ <i>unseen</i>	
	-	85%	15%	-	86%	14%	-	65%	35%	
<i>In-Topic</i>	<i>Instance Ratio</i>	-	85%	15%	-	86%	14%	-	65%	35%
	ALBERT	43.8	+0.21	-3.2	80.2	+0.41	-17.7	48.6	+1.1	-5.8
	BART	36.5	+0.13	-3.0	75.4	+0.20	-16.5	48.7	+1.3	-7.0

	DeBERTa	32.8	+0.07	-1.5	73.7	+0.09	-12.7	48.8	+1.0	-5.6
	RoBERTa	25.1	-0.01	-0.9	64.0	-0.04	-15.5	48.4	+1.0	-5.7
	<i>Average</i>	-	-0.08	-1.9	-	+0.17	-15.8	-	+1.1	-6.0
<i>Cross-Topic</i>	<i>Instance Ratio</i>	-	78%	22%	-	81%	19%	-	51%	49%
	ALBERT	39.5	+0.03	-2.3	78.0	+0.51	-12.9	45.8	+2.2	-5.3
	BART	36.9	+0.01	-4.0	74.1	+0.24	-16.5	45.3	+2.4	-5.8
	BERT	25.6	-0.09	-0.7	67.5	+0.20	-14.0	41.6	+1.9	-5.1
	DeBERTa	29.9	-0.07	-1.3	74.6	+0.14	-11.7	42.4	+2.0	-5.2
	RoBERTa	23.6	-0.22	-0.3	65.5	+0.00	-14.7	42.1	+1.9	-5.2
	<i>Average</i>	-	-0.08	-1.7	-	+0.22	-14.0	-	+2.1	-5.3

Table 3: Performance difference of *seen* and *unseen* instances compared to the full set (*all*). We report for ALBERT, BART, BERT, DeBERTa, & RoBERTa, and include the ratio of *seen* and *unseen* instances.

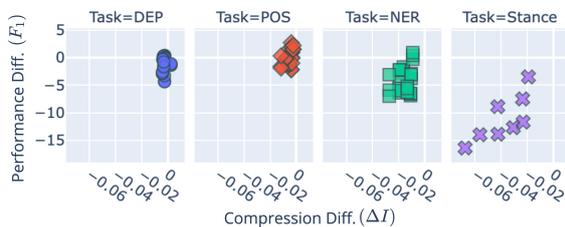

Figure 3: Comparison of the difference in  $\Delta F_1$  and  $\Delta I$  between Cross-Topic and In-Topic for all eight LMs on the four probing tasks.

( $\Delta F_1$ ) correlates with the difference in compression ( $\Delta I$ ). Interestingly, we find a stronger correlation between  $F_1$  and  $I$  for Cross-Topic ( $\rho = 0.72$ ) as compared to In-Topic ( $\rho = 0.69$ ). Thus, a higher performance level, like for In-Topic, leaves less room for compression improvements.

Further, we examine the performance of *seen* and *unseen* instances in Table 3. It shows that *seen* performs slightly better than *all*, while *unseen* ones underperform the complete set (*all*) and *seen* instances. Considering the average over LMs, there are fewer relative gains for *seen* for In-Topic and more loss for *unseen* instances (+1.2, -6.0 for NER) compared to Cross-Topic (+2.0, -5.3 for NER). This observation relates to the lower percentage of *unseen* instances (i.e., made of topic-specific terms) for In- compared to Cross-Topic. We see *unseen* instances on In-Topic are harder and cover rare vocabulary, and *seen* instances on Cross-Topic are easier and made of general terms - which confirm our theoretical and semantic assumptions (§ 2).

**Results for Probing Tasks** Considering Table 2 and Figure 3, we note higher generalization gaps (Avg.  $\Delta$  of -4.5 and -11.0) for semantic tasks (NER and Stance) than for syntactic ones (DEP and POS)

- Avg.  $\Delta$  of -1.2 and -0.5. We verify this trend with results by observing a more pronounced gap for semantic NER classes (like ORG) than for syntactic ones (like ORDINAL) in the Appendix (§ B.5).

Next, we separately compare tasks for *seen* and *unseen* instances. DEP shows the slightest performance difference compared to *all*. We assume that the pairwise nature of the task leads to a larger shared vocabulary between *unseen* and training instances - since a pair can be *unseen*, but it may contain a frequent word like *of*. In contrast, apparent differences between NER and POS are visible - with less performance drain on *unseen* instances for NER than POS. Therefore, we assume for NER a higher semantic overlap with training instances since they could include - as being an n-gram - words from the training vocabulary. In contrast, tokens of *unseen* POS instances are always single words; thus, we assume a smaller semantic overlap with the training.

**Results for Encoding Models** We now compare LMs amongst themselves. The four best-performing LMs of In-Topic differ up to 7.6 (ALBERT - BERT), while for Cross-Topic, this difference narrows to 4.1 (ALBERT - ELECTRA). These results confirm the varying generalization gap between them and, again, that we can not transfer conclusions from one evaluation setup to another. For example, the probing performance of BART for In-Topic Stance is the best and the third best for Cross-Topic.

Generally, we do not see a clear correlation between better average performance and a smaller generalization gap. LMs like DeBERTa perform better for In- and Cross-Topic but show a bigger gap (-5.1) compared to lower performing LMs like ELECTRA (-1.0), but there are also worse LMs with a bigger gap (GPT-2, -5.6) or better ones with a smaller gap (ALBERT, -4.6). Overall, we see the generalization gap being more pronounced for better-performing LMs.

Considering absolute performance, ALBERT and BART performs the best for both evaluation setups, while ELECTRA excels POS and DEP, and DeBERTa performs for NER and Stance. In contrast, BERT, RoBERTa, GPT-2, and GloVe underperform the others. Thus, LMs with architectural regularization, such as layer-wise parameter sharing (ALBERT), encoder-decoder layers (BART), disentangled attention (DeBERTa), or discriminator (ELECTRA), tend to provide

	DEP		POS		NER		Stance		Average		
	In	Cross	$\Delta$								
ALBERT	43.8	39.5	<b>80.2</b>	78.0	48.6	45.8	54.8	45.9	56.9	52.3	-4.6
BART	36.5	36.9	75.4	74.1	48.7	45.3	60.8	44.4	55.3	50.2	-5.1
PYTHIA (12B)	38.3	35.4	79.5	77.7	57.3	50.5	65.2	41.6	60.1	51.3	-8.8
PYTHIA-DD (12B)	<b>45.3</b>	<b>45.4</b>	79.8	79.2	<b>64.5</b>	<b>55.8</b>	66.1	<b>50.4</b>	<b>63.4</b>	<b>57.9</b>	-6.2
LLAMA-2 (13B)	<b>44.4</b>	41.8	<b>81.0</b>	<b>80.6</b>	48.7	45.3	<b>66.8</b>	44.2	60.2	53.0	-7.2
LLAMA-2 Chat (13B)	<b>45.4</b>	41.7	<b>80.7</b>	<b>80.1</b>	49.2	42.9	<b>67.2</b>	43.2	60.6	52.0	-8.7

Table 4: Results (macro  $F_1$ ) of the four probing tasks using the two overall best-performing LMs (ALBERT and BART) in the In- and Cross-Topic setup based on the *ArgMin* dataset (Table 2) and three large LMs.

higher Cross-Topic performance. Similarly, ALBERT or DeBERTa generally achieve more performance gains for *seen* instances and fewer performance drops for *unseen* ones than models without regularization such as BERT or RoBERTa. We hypothesize that architectural and regularization aspects give LMs a more generalizable and robust encoding space.

**Results for Larger Models** We compare in Table 4 four open accessible large LMs with the two best performing models (ALBERT and BART). In general, we see the performance scales with the higher number of parameters, but more noticeable for In- than Cross-Topic tasks. Therefore, the generalization gap of large LMs tend to be bigger than for LMs. Regarding the different large LMs, PYTHIA (Biderman et al., 2023) and LLAMA-2 (Touvron et al., 2023) outperform the others on In-Topic tasks while performing on par with ALBERT. Further, we notice data deduplication during pre-training (PYTHIA-DD) results in the best performing model and actively reduces the generalization gap from 8.8 to 6.2. In addition, instruction fine-tuning does not heavily affect the performance but tends to increase the generalization gap from 7.2 (LLAMA-2) to 8.7 (LLAMA-2 Chat).

## 5 The Dependence on Topic-Specific Vocabulary

To this point, we saw that the generalization gap varies between different LMs and probing tasks. Since topic-specific vocabulary crucially affects generalization gaps, we analyze the varying dependence on the topic-specific vocabulary of LMs using *Amnesic Probing* (Elazar et al., 2021). We observe apparent differences among LMs and assume their embedding space clearly differs beyond single evaluation metrics. Therefore, we emphasize considering various LMs when using *Amnesic Probing*. Additional insights of comparing *seen*

and *unseen* instance and distinct NER classes are provided in the Appendix (§ B.4, § B.6).

**Design** To measure how LMs depend on topic-specific vocabulary, we employ *Amnesic Probing* (Elazar et al., 2021) to remove the latently encoded topic-specificity  $z_i$  from the embeddings  $h_i$  of a token  $w_i$ . More precisely, we compare how the performance of a probing task (like NER) changes when we remove  $z_i$ . A more negative effect indicates a higher dependence on topic-specific vocabulary, while this property is a hurdle when performance improves. We first train a linear model on token-level topic-specificity  $r$  (§ 2.3). To shape it as a classification task, we categorize  $r$  into three classes (*low*, *medium*, *high*).<sup>5</sup> Next, we find a projection matrix  $P$  that projects all embeddings  $h_i$  - gathered as  $H$  - using the learned weights  $W_l$  of  $l$  to the null space as  $W_l P H = 0$ . Using  $P$  we update  $h_i$  by neutralizing topic-specificity from the input as  $h'_i = P h_i$  before training the probe. Following (Elazar et al., 2021), we verified our results by measuring less effect of removing random information from  $h_i$  (see Appendix § B.3).

**Results** Considering Figure 4, we see ALBERT, BART, and BERT depend less on topic-specific vocabulary. Their diverse pre-training (token- and sentence-objectives or sentence denoising) results in a more robust embedding space. Surprisingly, they show positive effects (3.2 for DEP for BART) when removing topic-specificity. This could remove potentially disturbing parts of the embedding space. Similarly, GPT-2 is less affected by the removal - we assume this is due to its generally lower performance level. Therefore, it has less room for performance drain, and capturing topic-specificity is less powerful.

Comparing In- and Cross-Topic setups shows a narrowing generalization gap for more affected models (like RoBERTa and GloVe on NER or NER). Simultaneously, less affected LMs either maintain the gap or enlarge it slightly - like BART on DEP, NER, or NER. Further, DeBERTa, RoBERTa, ELECTRA, and GloVe rely more on topic-specific vocabulary since they show significant performance loss (up to 34.6 for GloVe on POS) when removing this information. Specifically, GloVe as a static language model, and RoBERTa is affected the highest for all tasks. ELECTRA shows similar behavior but is less pro-

<sup>5</sup>Please find examples in the Appendix § A.6.

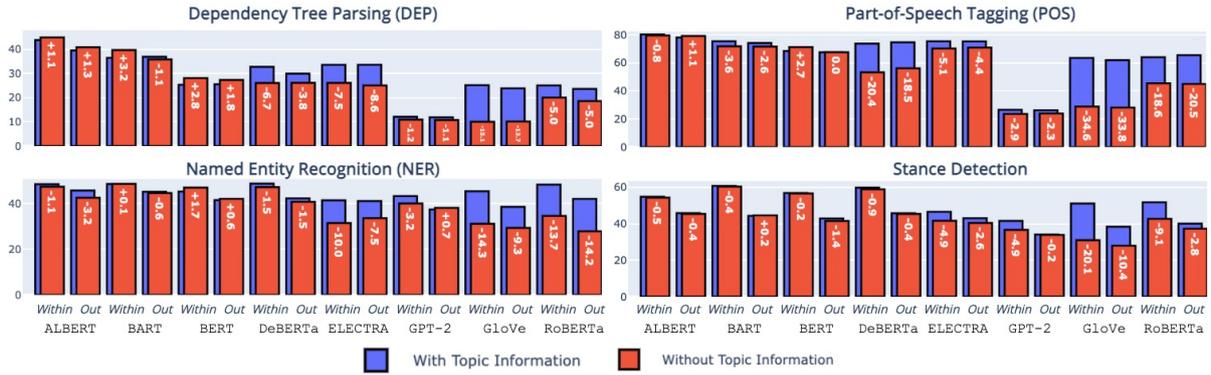

Figure 4: Comparison of the probing results with (blue bars) or without (red bars) topic information. The white text indicates the difference between these two scenarios ( $\Delta F_1^T$ ).

nounced for POS. Thus, its reconstruction pre-training objective provides a more robust embedding space than purely MLM (DeBERTa or RoBERTa). Comparing DeBERTa and RoBERTa, DeBERTa is less affected by the removal of semantic tasks (NER and NER). We hypothesize that distinguishing between token content and token position via disentangled attention makes DeBERTa more robust for the semantic than for syntactic tasks (DEP and POS).

## 6 The Evolution of the Generalization Gap during Fine-Tuning

Finally, we re-evaluate fine-tuned LMs using our proposed probing setups and show that fine-tuning leads to a drain in probing performance. We use these results to retrace apparent differences between evaluation setups and the varying generalization gap between LMs. This is relevant for a broader understanding of how fine-tuning affects LMs (Mosbach et al., 2020; Kumar et al., 2022a), and what they learn during fine-tuning (Merendi et al., 2022; Ravichander et al., 2021).

**Design** We fine-tune the LMs on an argumentative *stance detection* task and re-evaluate them on DEP, POS, and NER probing tasks. To be consistent with our probing setup, we used the same folds for fine-tuning. Further details are in the Appendix (§ A.5). We compare these results with the probing performance of their pre-trained counterparts (§ 4 and § 5) and correlate this change with the generalization gap observed on the downstream task. We limit our analysis to ALBERT, BERT, BART, DeBERTa, and RoBERTa.

**Results** Table 5 shows that fine-tuning clearly boost the performance on NER compared to the

		<i>Stance</i>	DEP	POS	NER	Avg.	DEP	POS	NER
		$F_1$ fine-tuned	$\Delta F_1$ probing				$\Delta F_1^T$		
In-Topic	ALBERT	55.4 +0.6	-27.3	-40.2	-25.0	-30.8	-0.6	-3.0	-0.1
	BART	69.8 +9.0	-17.3	-32.2	-4.0	-17.8	-0.8	-4.0	+0.3
	BERT	67.2 +10.3	-7.5	-24.8	+1.0	-10.4	+0.4	+0.7	+1.1
	DeBERTa	<b>70.1 +10.3</b>	-13.2	-25.3	-8.8	-15.8	-0.8	-3.8	-0.4
	RoBERTa	68.9 +17.1	-19.7	-48.6	-29.7	-27.2	-0.8	-3.0	-0.7
	Avg.	66.3 +9.5	-16.6	-32.6	-12.1	-20.4	-0.5	-2.6	+0.1
Cross-Topic	ALBERT	51.4 +5.5	-14.4	-20.3	-12.6	-15.8	+1.6	-1.3	+2.1
	BART	<b>61.9 +17.5</b>	-16.5	-33.9	-5.4	-18.6	-1.0	-3.5	-1.6
	BERT	56.6 +13.6	-5.7	-19.5	+0.6	-8.2	+0.7	+0.6	+1.2
	DeBERTa	55.9 +10.1	-13.4	-33.4	-11.8	-19.5	-1.2	-8.6	+1.6
	RoBERTa	55.5 +15.4	-16.6	-48.3	-23.1	-23.5	-1.9	-4.8	-0.3
	Avg.	56.3 +12.6	-13.0	-29.3	-9.1	-17.1	-0.4	-3.5	+0.6

Table 5: Results of evaluating our probing setup on fine-tuned LMs on NER. The first column shows these fine-tuned results and the gained improvement compared to probing for NER on pre-trained LMs (Table 2). Next, we show performance differences between pre-trained and fine-tuned LMs ( $\Delta F_1$  probing) and how removing topic-specificity affects the fine-tuned LMs ( $\Delta F_1^T$ ).

probing performance (§ 4) but leads to a clear performance drop ( $\Delta F_1$ ) for both evaluation setups and the probing tasks. Cross-Topic achieved more gains on average (+12.6) and fewer drains (-17.1) on the three linguistic properties than In-Topic (+9.5, -20.4). On average, we assume that In-Topic fine-tuning affects the encoding space of LMs more heavily than Cross-Topic. Regarding the different probing tasks, the performance drain is more pronounced for syntactic tasks (DEP and POS) than semantic tasks (NER). This hints that LMs acquire competencies of a semantic nature - which holds for *stance detection*. Similarly, removing topic-specificity influences fine-tuned LMs the least for NER. At the same time, this removal is more pronounced for Cross-Topic. This confirms the assumption that the Cross-Topic setup has smaller effects on LMs internals since we saw

big impacts of this removal (§ 5).

Considering the single LMs, we see apparent differences. For example, ALBERT, with its shared architecture and priorly best-performing LM, experiences big probing performance drains and the smallest fine-tuning gains (+0.6, +5.5). In contrast, we note effective fine-tuning of BERT with +10.3 for In- and +13.6 for Cross-Topic, and that it lost the least probing performance. Comparing RoBERTa and DeBERTa reveals again the effectiveness of architectural regularization of DeBERTa. RoBERTa shows the most gains when fine-tuning on NER and almost catching up with DeBERTa. However, it experiences a more clear performance drain (-27.2, -23.5) regarding the probing tasks for In- and Cross-Topic compared to DeBERTa (-15.8, -19.5). Next, we focus on BART and its superior Cross-Topic performance on NER. It seems already well-equipped for this downstream task due to its high In-Topic probing performance on NER. Therefore, it can learn the task more robustly during fine-tuning.

## 7 Related Work

The rise of LMs (Devlin et al., 2019; Liu et al., 2019; Radford et al., 2019; He et al., 2021) enabled big success on a wide range of tasks (Wang et al., 2018, 2019). Nevertheless, they still fall behind on more realistic Cross-Topic, like generalizing towards unseen topics (Stab et al., 2018; Gulrajani and Lopez-Paz, 2021; Allaway and McKeown, 2020). One primary reason is that LMs often rely on unwanted spurious correlations. Despite LMs seeing such vocabulary during pre-training, they failed to consider test vocabulary in the required fine-grained way (Thorn Jakobsen et al., 2021; Reuver et al., 2021). Further, Kumar et al. (2022b) found linear models can outperform fine-tuning LMs when considering out-of-distribution data. Thus, a broader understanding of LMs in challenging evaluation setups is crucial.

Probing (Belinkov et al., 2017; Conneau et al., 2018a; Peters et al., 2018) helps to analyze innards of LMs. This includes to examine how linguistic (Tenney et al., 2019a,c), numeric (Wallace et al., 2019), reasoning (Talmor et al., 2020), or discourse (Koto et al., 2021) properties are encoded. Other works focus on specific properties used for other tasks (Elazar et al., 2021; Lasri et al., 2022), or fine-tuning dynamics (Merchant et al., 2020; Zhou and Srikumar, 2022; Kumar et al., 2022b). However,

these works target the commonly used *In-Topic* setup and less work considering Cross-Topic setups. Aghazadeh et al. (2022) analyzed metaphors across domains and language, or Zhu et al. (2022) cross-distribution probing for visual tasks. They found that models generalize to some extent across distribution shifts in probing-based evaluation. Nevertheless, these works focus on specialized tasks and consider the generalizations across distributions in isolation. In contrast, we propose with our experiments a more holistic probing-based evaluation of LMs, covering different generalization aspects after pre-training and fine-tuning.

## 8 Conclusion

**Discussion** We analyzed and compared In- and Cross-Topic evaluation setups and found generalization gaps significantly differing regarding specific LMs and probing tasks.<sup>6</sup> Further, we make various crucial observations contributing to a better understanding of the generalizability of LMs: (1) diverse pre-training objectives and architectural regularization tend to positively affect the robustness of LMs and their embedding space, such as depending less on topic-specific vocabulary; (2) probing performance falls short for rare vocabulary, underscoring the need to explore token-level properties; (3) probing performance, but also generalization gaps, tend to scale for larger LMs, while deduplication of pre-training data improves their robustness and narrows these gaps; and (4) In-Topic fine-tuning tend to vanish linguistic properties more prominently than for the Cross-Topic setup.

To conclude, we highlight the practical utility of probing to analyze and compare the capacities of various LMs from a different perspective - considering different generalization scenarios. Thereby, our work points out the importance of probing as a universally applicable method, regardless of size or being static or contextualized, to complement existing work on analyzing language models (Wang et al., 2018; Liang et al., 2022).

**Outlook** With our findings in mind, we regularly see probing LMs and large LMs and consider forthcoming learning paradigms as indispensable for a holistic evaluation of their verity and multiplicity. Therefore, we will continue to analyze language models, including a broader set of tasks and focus-

<sup>6</sup>We verified our results using a second dataset from the social media domain (Conforti et al., 2020) - details in the Appendix § B.1.

ing on general and rare vocabulary to increase our understanding of how, why, and where they differ.

## Ethical Considerations and Limitations

**Automatic Annotations for Linguistic Properties** Our experiments require all instances origin in the same datasets with topic annotations. Thanks to this condition, we align all our experiments, like probing LMs, with the same data as they got pre-trained. Therefore, we minimize other influences like semantic shifts of other datasets. However, there are no corresponding annotations for linguistic properties, which forces us to rely on automatically gathered annotations. This work addresses this issue by transparently stating the libraries and models we used to derive these annotations and providing the source code and the extracted labels in our repository. We compared our results (§ B.8) with previous work (Tenney et al., 2019a,c; Hewitt and Liang, 2019b) and found our results well aligned. Further, we verify the probing task results on the different LMs with randomly initialized counter-parts (§ B.2) and confirm our findings with a second dataset (§ B.1).

**Definition of Topic-Specific Vocabulary** This work considers a topic as a semantic grouping provided by a given dataset. As previously mentioned, this focus on the context of one dataset allows in-depth and controlled analysis, like examining the change of LMs during fine-tuning. On the other hand, we need to re-evaluate other datasets since the semantic space and granularity of the topic are different in almost every other dataset. Nevertheless, results in the Appendix (§ B.1) let us assume that our findings correlate with other datasets and domains. Further, we consider only token-level specific vocabulary, as done previously in literature (Kawintiranon and Singh, 2021). We think that considering n-grams could give a better approximation of topic-specific terms. Still, we do not consider them because *Amnesic Probing* (Elazar et al., 2021) require token-level properties to apply resulting intervention on token-level tasks like POS.

**Impact of LMs Design choices** This work analyzes LMs regarding different properties like pre-training objectives or architectural regularization. However, we do not claim the completeness of these aspects nor a clear causal relationship. Making such a final causal statement would require significant computational resources to pre-train models to verify single properties with full certainty. Instead, we use same-sized model variations, evaluate all probes on three folds and three random seeds to account for data variability and random processes, and verify our results on a second dataset. Nevertheless, we use them to correlate results on aggregated properties (like having diverse pre-training objectives or not) and not on single aspects, like the usefulness of the *Sentence-Order* objective.

## A Additional Details of the Experiments

### A.1 Probing Tasks

Table 6 shows examples and additional details of the different probing tasks.

### A.2 Fold Composition

We rely on a three-folded evaluation for In- and Cross-Topic for a generalized performance measure. These folds cover every instance exactly once in a test split. In addition, we require that In- and Cross-Topic train/dev/test splits have the same number of instances for a fair comparison, as visualized in Figure 5. For Cross-Topic, we make sure that every topic  $\{t_1, \dots, t_m\}$  is covered precisely once by one of the three test splits  $X_{cross}^{(test)}$ . To compose  $X_{cross}^{(train)}$  and  $X_{cross}^{(dev)}$ , we randomly distribute the remaining topics for every fold. For In-Topic, we randomly<sup>7</sup> form subsequent test splits  $X_{in}^{(test)}$  for every fold from all instances  $\{x_1, \dots, x_m\}$ .  $X_{in}^{(train)}$  and  $X_{in}^{(dev)}$  are then randomly composed for every fold using the remaining instance set following the dimension of  $X_{cross}^{(train)}$  and  $X_{cross}^{(dev)}$ .

### A.3 Training Setup

For all our experiments, we use NVIDIA RTX A6000 GPUs, python (3.8.10), transformers (4.9.12), and PyTorch (1.11.0).

### A.4 Probing Hyperparameters

Further, we use for the training of the probes the following fixed hyperparameters: 20 epochs, where we find the best one using dev instances; AdamW (Loshchilov and Hutter, 2019) as optimizer; a batch size of 64; a learning rate of 0.0005; a dropout rate of 0.2; a warmup rate of 10% of the steps; random seeds: [0, 1, 2]

In addition, we use the following tags from the huggingface model hub:

- [albert-base-v2](#)
- [bert-base-uncased](#)
- [facebook/bart-base](#)
- [microsoft/deberta-base](#)
- [roberta-base](#)

<sup>7</sup>We expect that all folds cover all topics given the small number of topics (8) and the big number of instances.

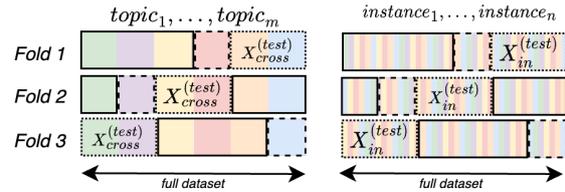

Figure 5: Overview of the In- and Cross-Topic setup using three folds. The colour indicates a topic; solid lines train-, dotted lines dev-, and dashed lines test-splits.

- [meta-llama/Llama-2-13b-chat-hf](#)
- [google/t5-xxl-lm-adapt](#)
- [allenai/tk-instruct-11b-def](#)

### A.5 Fine-Tuning Hyperparameters

To fine-tune on *stance detection*, we use the following setup: 5 epochs, where we find the best one using dev instances; AdamW (Loshchilov and Hutter, 2019) as optimizer; a batch size of 16; a learning rate of 0.00002; a warmup rate of 10% of the steps; random seeds: [0, 1, 2].

### A.6 Token-Level Examples for Topic Relevance

In § 5, we use the binned topic-specificity (§ 5) for each token. We show in Table 7 examples for three bins *low*, *medium*, and *high*. The first bin (*low*) is made of tokens, which barely occur in the dataset. The second one (*medium*) consists of tokens which are part of most topics. Finally, the last bin (*high*) includes tokens with a high topic relevance for ones like *Cloning* or *Minimum Wage*.

## B Further Results

### B.1 Generalization Across Datasets

With Table 8, and Figure 6 we verify the results of § 4, § 5, and § 4 using another *stance detection*

Task	Example	Label	# Instances	# Labels
DEP	I think there is a lot <u>we</u> can <u>learn</u> from Colorado and Washington State.	<i>nsubj</i>	40,000	41
POS	I think there is a lot <u>we</u> can learn from Colorado and <u>Washington State</u> .	<i>PRON</i>	40,000	17
NER	I think there is a lot we can learn from Colorado and <u>Washington State</u> .	<i>PERS</i>	25,892	17
Stance	I think there is a lot we can learn from Colorado and <u>Washington State</u> .	<i>PRO</i>	25,492	3

Table 8: Results of the four probing tasks using eight LMs in the In- and Cross-Topic setup. We report the mean  $F_1$  (macro averaged) over three random seeds, the average difference between the two evaluation setups per task (last row), and their average per LM (last two columns). Best-performing results within a margin of 1pp are marked for every task and setup.

dataset. Namely, we use the *wtwt* (*will-they-wont-they*) (Conforti et al., 2020) dataset which covers 51,284 tweets annotated either *support*, *refute*, *comment*, or *unrelated* towards five financial topics. The overall performance comparison between In- and Cross-Topic shows the same trend as we already saw in § 4, but on a lower level. We assume this is mainly due to this dataset’s more specific domain (twitter) compared to *UKP ArgMin*. Focusing on the influence of topic-specific vocabulary verifies the previously presented results (§ 5) again. LMs pre-trained with purely token-based objectives highly depend on topic-specific vocabulary.

## B.2 Comparison of Probing Tasks against Random Initialized LMs

We show in Table 9 and Table 10 the results of running the three linguistic probes on the seven contextualized LMs in their random initialized version. For In- and Cross-Topic, there is a clear perfor-

mance drop of having random initialized models.

	DEP		POS		NER	
	<i>Random</i>	$\Delta$	<i>Random</i>	$\Delta$	<i>Random</i>	$\Delta$
ALBERT	1.4	-42.4	6.8	-41.8	3.4	-76.8
BART	1.4	-35.1	5.0	-43.7	2.7	-72.7
BERT	2.7	-22.7	9.4	-36.0	4.6	-63.9
DeBERTa	7.0	-25.8	16.3	-32.5	16.1	-57.6
RoBERTa	2.2	-22.9	11.0	-37.4	4.7	-59.3
ELECTRA	1.7	-31.9	8.4	-33.1	3.8	-71.5
GPT-2	5.8	-19.4	12.3	-33.2	12.5	-51.0

Table 9: Results of evaluating DEP, POS, and NER using the seven contextual LMs (random initialized) for In-Topic and the difference to their pre-trained counterparts in Table 2.

## B.3 The Effect of Removing Random Information

We saw in § 5 that removing topic-specificity has a big impact for some models (like RoBERTa or ELECTRA) but at the same time can even boost the performance of others like BERT. As suggested in Elazar et al. (2021), we apply a sanity check by removing random information from the encodings of LMs. Following the results in Figure 7, removing random information (green bars) performs in between the scenarios with (blue bars) or without (red bars) topic information for cases where we see a clear negative effect when removing topic information. In contrast, removing random information

	DEP		POS		NER	
	<i>Random</i>	$\Delta$	<i>Random</i>	$\Delta$	<i>Random</i>	$\Delta$
ALBERT	1.4	-38.1	6.2	-39.6	3.4	-74.6
BART	1.5	-35.4	5.0	-40.3	2.9	-71.2
BERT	2.1	-23.5	9.6	-32.0	4.5	-63.0
DeBERTa	6.8	-23.1	14.0	-28.4	17.2	-57.4
RoBERTa	2.6	-21.0	10.0	-32.1	5.2	-60.3
ELECTRA	3.0	-30.6	9.8	-31.4	4.1	-71.2
GPT-2	5.8	-18.1	13.6	-25.0	11.0	-50.9

Table 10: Results of evaluating DEP, POS, and NER using the seven contextual LMs (random initialized) for Cross-Topic and the difference to their pre-trained counterparts in Table 2.

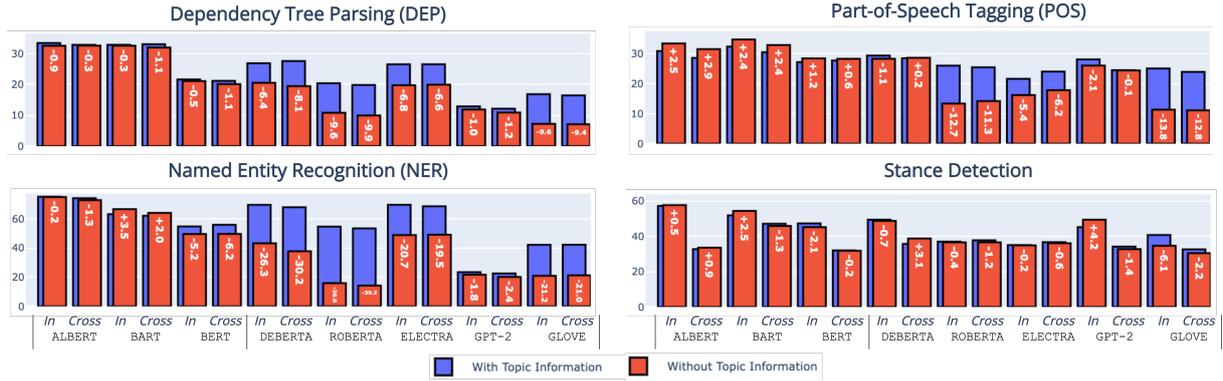

Figure 6: Comparison of the probing results with (blue bars) or without (red bars) topic-specificity for the *will-they-wont-they* dataset (Conforti et al., 2020). The white text indicates the difference between these two scenarios.

can produce a more pronounced effect when we see performance improvements. This observation backs our assumption that removing information can have a regularization effect.

#### B.4 The Effect of Removing Topic Information on *Seen* and *Unseen* Instances

We show in Figure 8 that a performance drop affects *seen* and *unseen* instances for In- and Cross-Topic equally. Exceptionally, we see *unseen* ones are more affected on POS for DeBERTa and RoBERTa. This result indicates that these LMs fall short of generalizing towards rare vocabularies - like *unseen* instances of POS.

#### B.5 Analysis of Per-Class Results for NER

When considering the per-class results of NER in Table 11, we see the classes CARDINAL, MONEY, ORG, and PERSON show the biggest differences between In- and Cross-Topic. For ORG and PERSON, we see their topic-specific terms as the main reason for the performance gap. In contrast, we were surprised about the high difference for CARDINAL. We think this is mainly because this class embodies all numbers belonging to no other class. For MONEY, we see its uneven distribution over topics as the main reason for the performance difference - one topic covers more than 50% of the instances. These entities are highly topic-specific from a statistical point of view.

Despite having almost the same performance for In-Topic, BART and DeBERTa tend to outperform ALBERT on classes with more semantic complexities - like GPE, ORG or PERSON. For Cross-Topic, we see ALBERT performing better in classes unevenly distributed instances over topics

	CARDINAL	DATE	GPE	MONEY	NORP	ORDINAL	ORG	PERCENT	PERSON
In	ALBERT	95.0	95.3	89.4	95.0	91.3	97.8	80.2	99.2
	BART	94.8	94.6	89.7	95.6	91.6	97.3	81.0	99.4
	DeBERTa	95.3	95.6	90.0	96.5	91.5	97.4	81.1	99.2
Cross	ALBERT	91.2	95.0	88.6	55.6	90.8	98.1	78.8	98.9
	BART	90.1	94.2	88.9	35.0	90.7	97.6	79.1	98.8
	DeBERTa	88.3	95.3	88.6	0.0	90.5	97.5	79.8	98.6

Table 11: Per-class results of ALBERT, BART, and DeBERTa on NER for In- and Cross-Topic.

	CARDINAL	DATE	GPE	MONEY	NORP	ORDINAL	ORG	PERCENT	PERSON
In	BART	-0.23	0.04	0.15	0.15	0.02	-0.04	0.08	-0.13
	BERT	1.65	-0.15	-0.04	28.00	-0.14	-0.58	0.06	0.00
	DeBERTa	-1.14	-0.13	-1.48	-7.74	-14.40	-0.30	-0.82	-0.12
	ROBERTa	-6.00	-3.00	-7.82	-24.09	-90.61	-98.06	-2.66	-0.51
Cross	BART	-0.48	0.01	-0.13	2.45	-0.06	-0.52	-0.38	-0.09
	BERT	-0.05	-0.05	1.00	0.00	8.95	-0.60	0.29	0.00
	DeBERTa	-0.07	-0.16	-2.52	0.00	-21.88	-0.35	-0.91	-0.01
	ROBERTa	-9.04	-2.63	-7.45	0.00	-85.23	-98.07	-2.99	-35.97

Table 12: Class-wise effect on the performance when removing topic information of BART, BERT, DeBERTa, and RoBERTa on NER for In- and Cross-Topic.

- like MONEY. Further, it outperforms BART and DeBERTa on less semantical classes (CARDINAL, ORDINAL, PERCENT).

#### B.6 Effect of Removing Token-Level Topic Information of Per-Class Results for NER

Similar to the previous analysis, there are apparent effects of removing topic information when considering NER classes separately. Table 12 shows these results for BART, BERT, DeBERTa, and RoBERTa. Like the overall result, BART, DeBERTa, and RoBERTa perform less when removing topic information. Whereby the effect is the most pronounced for RoBERTa with the highest performance drop for In- and Cross-Topic on classes like NORP or ORDINAL. In addition, these results show that the performance gain from removing topic information within BERT happens on MONEY for In-Topic and NORP for Cross-Topic.

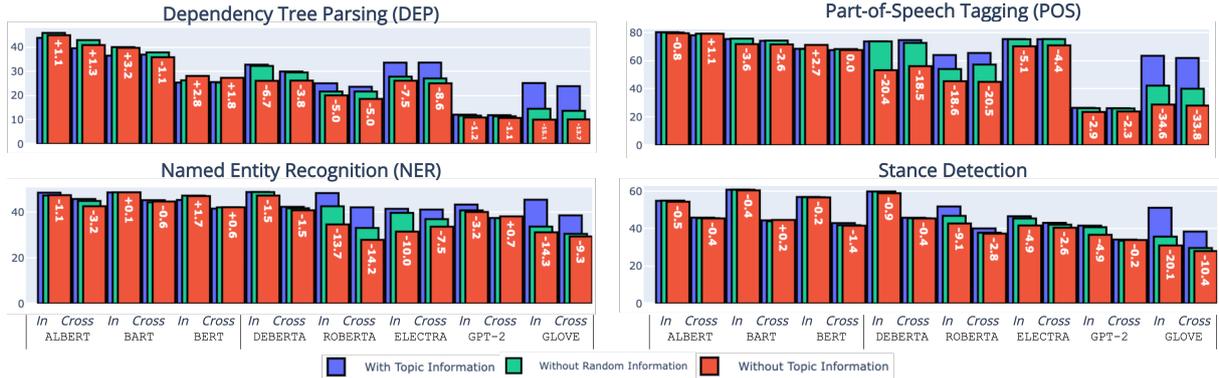

Figure 7: Comparison of the probing results with (blue bars) and without (red bars) topic information, or without random information (green bars). The white text indicates the difference between the blue and red bars.

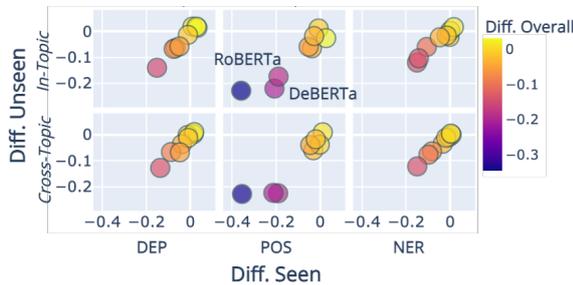

Figure 8: Performance difference for *seen* (x-axis) and *unseen* (y-axis) instances when removing topic information or not. One dot represents one LM.

	CARDINAL	DATE	GPE	MONEY	NORP	ORDINAL	ORG	PERCENT	PERSON
<i>In</i>									
ALBERT	-34.2	-25.4	-26.9	-95.0	-51.9	-60.3	-22.4	-99.2	-21.8
BART	-8.5	-7.2	-7.5	-7.2	-10.4	-36.6	-4.1	-3.8	-2.7
BERT	-1.9	-2.0	-2.0	34.8	-4.4	-17.9	-0.8	-3.9	-1.1
DeBERTa	-15.1	-6.8	-8.7	-19.5	-43.7	-60.8	-8.8	-24.8	-8.3
<i>Cross</i>									
ALBERT	-21.5	-10.4	-19.1	-55.6	-34.4	-13.1	-10.7	-81.0	-9.2
BART	-9.2	-7.4	-7.0	-16.3	-11.2	-24.4	-3.9	-4.5	-2.1
BERT	-2.5	-1.2	-1.2	3.6	-2.2	-9.7	-0.8	-2.6	-0.5
DeBERTa	-18.2	-6.2	-12.7	0.0	-50.6	-76.0	-11.7	-73.5	-6.8

Table 13: Per-class difference before and after fine-tuning on *stance detection* of ALBERT, BART, BERT, and DeBERTa on NER for In- and Cross-Topic.

### B.7 The Effect of Fine-Tuning on NER Classes

Analysing the results (Table B.7) for every NER class gives additional insights into where the fine-tuning had the most significant effect. We generally see the biggest effect on classes with less semantic meaning, like ORDINAL, PERCENT, or MONEY. At the same time, GPE, PERSON, and ORG are less affected as classes with more attached semantics. Regarding the different LMs, ALBERT and DeBERTa show the most performance training, while BERT gains performance for the MONEY class.

	DEP		POS		NER	
	<i>In</i>	<i>Cross</i>	<i>In</i>	<i>Cross</i>	<i>In</i>	<i>Cross</i>
ALBERT	85.2	83.9	93.8	93.6	86.9	85.0
BART	80.9	81.0	92.6	92.0	87.1	84.5
BERT	76.1	76.1	89.2	88.6	85.2	82.9
DeBERTa	81.2	79.9	92.8	93.1	87.5	84.0
RoBERTa	75.9	75.5	89.6	90.1	86.3	83.2
ELECTRA	81.1	80.7	92.3	92.2	82.8	82.2
GPT-2	69.8	69.1	85.8	85.7	84.6	81.1
GloVe	39.5	38.5	46.6	45.9	78.8	77.2
<i>Average</i>	73.7	73.1	85.3	85.2	84.9	82.5

BERT 320k	86.3	85.6	93.7	93.3	-	-
BERT (Tenney et al., 2019c)	93.0	97.0	96.1			
BERT (Tenney et al., 2019a)	95.2	96.5	96.0			
BERT (Hewitt and Liang, 2019b)	89.0	97.2	-			

Table 14: Accuracy results for In- and Cross-Topic probing results for eight LMs, across three random seeds. Further, we report results of gradually increasing the number of consider instance (BERT 80k, BERT 160k, and BERT 320k), as well as reference performance of previous work (Tenney et al., 2019c,a; Hewitt and Liang, 2019b).

### B.8 Annotation Verification

To evaluate probing tasks in the In- and Cross-Topic setup, we rely on data with topic annotations on the instance level - like the *UKP ArgMin* (Stab et al., 2018) or the *wtwt* (Conforti et al., 2020) dataset. Since these datasets do not include linguistic annotations, we make use of spaCy<sup>8</sup> to automatically derive the labels for *dependency tree parsing (DEP)*, *part-of-speech tagging (POS)*, or *named entity recognition (NER)*. We used the `en_core_web_sm` model, which provides reliable labels with a detection performance in terms of accuracy of 97.0 for POS, 90.0-92.0 for DEP, and an F1 score of 85.0 for NER (details available online). Note, this performance referees to iden-

<sup>8</sup><https://spacy.io/>

tify valid candidates (like entities for NER) given a piece of text, and assign the corresponding labels, such as person or organization. In contrast, in probing, we consider only the second step: assigning the right label of a valid candidate. Therefore, we can not directly compare recognition and probing performance.

Considering our results (§ 4), we see these derived labels as reliable and well aligned with previous work (Tenney et al., 2019c,a; Hewitt and Liang, 2019b), even though we mainly report  $F_1$  score. One reason for that is the similar performance ranking (DEP < NER < POS) as in previous work, considering  $F_1$  score as well as the accuracy score reported in Table 14. Another reason is the narrowing accuracy performance gap between our experiments and previous work when we gradually increase the number of consider instance from 40k to 80k, 160k, until 320k.

# LLM-GEm: Large Language Model-Guided Prediction of People’s Empathy Levels towards Newspaper Article

## Abstract

Empathy – encompassing the understanding and supporting others’ emotions and perspectives – strengthens various social interactions, including written communication in healthcare, education and journalism. Detecting empathy using AI models by relying on self-assessed ground truth through crowdsourcing is challenging due to the inherent noise in such annotations. To this end, we propose a novel system, named Large Language Model-Guided Empathy (*LLM-GEm*) prediction system. It rectifies annotation errors based on our defined annotation selection threshold and makes the annotations reliable for conventional empathy prediction models, e.g., BERT-based pre-trained language models (PLMs). Previously, demographic information was often integrated numerically into empathy detection models. In contrast, our *LLM-GEm* leverages GPT-3.5 LLM to convert numerical data into semantically meaningful textual sequences, enabling seamless integration into PLMs. We experiment with three NewsEmpathy datasets involving people’s empathy levels towards newspaper articles and achieve state-of-the-art test performance using a RoBERTa-based PLM. Code and evaluations are publicly available at <https://github.com/hasan-rakibul/LLM-GEm>.

## 1 Introduction

Empathy refers to an inherent ability to understand and convey suitable emotional responses in reaction to the emotions and viewpoints of others (Decety and Jackson, 2004; Olderbak et al., 2014). Seminal work by Batson et al. (1987) proposed the widely-recognised empathy measurement scale by defining empathy as having six aspects: sympathetic, moved, compassionate, tender, warm and softhearted. Empathic capability is key in cultivating interpersonal relationships and mitigating stress and discontent among individuals in our society in various human-to-human interactions.

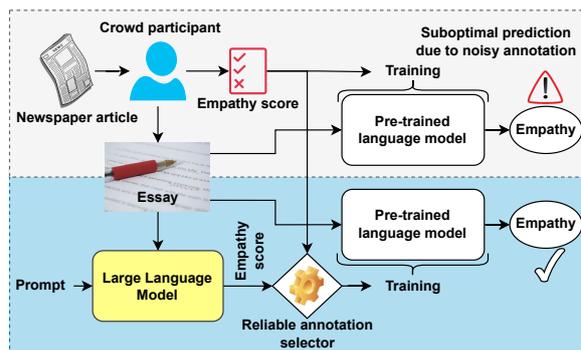

Figure 1: A typical empathy prediction workflow by directly utilising a PLM (Tafreshi et al., 2021; Barriere et al., 2022, 2023) versus our proposed LLM-guided workflow. Because of the noise in crowdsourced data, a typical workflow often results in suboptimal prediction. Our proposed workflow employs LLM to refine or re-define noisy annotations automatically and outperforms the typical approach.

Empathic doctors are better equipped to understand their patients’ concerns, leading to improved communication and patient outcomes (Jani et al., 2012). This empathic connection is not confined to face-to-face interactions but extends to written communication, such as medical reports and informative articles that convey a compassionate understanding of patients’ experiences. In education, especially with the shift towards online learning due to the COVID-19 pandemic, empathy is critical in helping teachers understand their students’ emotional states and create a positive learning environment (Aldrup et al., 2022). In addition to verbal communication, empathy in the education sector also surfaces in written communications, such as emails and feedback on assignments, where the tone and language reflect a genuine concern for students’ well-being. In examining the role of empathy in written journalism, consider the poignant example of a newspaper article detailing a local family’s struggle after a devastating house fire. The

journalist’s empathic narrative goes beyond factual reporting, weaving a story that not only informs but also connects readers emotionally to the human experiences within the news.

Assessment of empathy levels is crucial in determining interaction quality (Bellet and Maloney, 1991). Empathy deficits often lead to conflicts and miscommunications, which can be resolved by measuring empathy levels as the first step, but such measurement is challenging, even for humans (Lawrence et al., 2004). Research endeavours in computational empathy remain limited (Alam et al., 2018) compared to other domains of affective computing, such as emotion (Kaklauskas et al., 2022), primarily due to the lack of high-quality data.

The aphorism, ‘garbage in, garbage out’, signifies how inaccurate data results in inaccurate outputs (Geiger et al., 2020). While crowdsourcing platforms (e.g., Amazon Mechanical Turk, Crowd-Flower and Prolific) offer a simpler and faster way to get a sizeable participant pool, they suffer from false information (Sheehan, 2018). Such erroneous data result from carelessness and multitasking and threaten the validity of findings relying on such data (Jia et al., 2017; Huang et al., 2012). However, such crowdsourcing with self-assessment annotation is a major source of data collection in computational social science and human behaviour studies, such as empathy (Tafreshi et al., 2021) and emotion (Mohammad and Turney, 2010). Computational empathy using crowdsource annotation, therefore, often provides suboptimal performance (Figure 1).

In addition, the subjective nature of empathy necessitates consideration of people’s demographic information, which is normally represented as numbers in the datasets. We, therefore, leverage demographic information into our prediction pipeline and introduce *LLM-GEm*, a Large Language Model (LLM)-guided empathy prediction system. While earlier studies, such as Wang et al. (2021), employed GPT-3 LLM for direct data annotations, to the best of our knowledge, no work has focused on using LLM to refine human annotations. To this end, we leveraged the enhanced capabilities of GPT-3.5 to reduce labelling errors in pre-existing crowdsourced annotations. It will be particularly useful when there is already some noisy crowdsource annotation. We experiment with three publicly available datasets to predict people’s empathy levels toward newspaper articles, where our system results in competitive performance by outperforming prior work.

Our major contributions include (1) application of GPT-3.5 LLM to convert numerical demographic information to semantically meaningful text in order to seamlessly integrate them with a pre-trained language model (PLM), (2) employing GPT-3.5 LLM to reduce annotation errors caused by crowdsourcing, and (3) defining *annotation selection threshold* to systematically select between crowdsource annotation and LLM annotation.

## 2 Related Work

A Workshop on Computational Approaches to Subjectivity, Sentiment & Social Media Analysis (WASSA) has organised a series of competitions on predicting people’s empathy towards newspaper articles. In these challenges from 2021 to 2023, several works (Vasava et al., 2022; Kulkarni et al., 2021; Srinivas et al., 2023; Lu et al., 2023) predicted empathy by fine-tuning RoBERTa PLM followed by some Multi-Layer Perceptron (MLP) layers. Apart from these, some studies (Ghosh et al., 2022; Butala et al., 2021; Hasan et al., 2023a) fine-tuned BERT PLM, and some other studies (Mundra et al., 2021; Lin et al., 2023; Chavan et al., 2023) leveraged an ensemble approach with fine-tuning multiple PLMs. Qian et al. (2022) experimented with multi-task learning and reported that a simple fine-tuning of the RoBERTa base model resulted in better performance (0.480 vs 0.508 Pearson correlation coefficient ( $r$ )). Fine-tuning PLMs, therefore, has become the conventional approach to predict people’s empathy towards newspaper articles. Among different PLMs, RoBERTa has become the most frequently used prediction model in empathy detection studies, as reported in a recent survey covering computation empathy studies from 2013 to 2023 (Hasan et al., 2023b).

Several authors experimented with various approaches to ensure data quality in empathy predictions. As a data augmentation technique, Vasava et al. (2022) translated texts to a random language using Google Translate and then back to English. They combined five demographic features before the final layer of their empathy prediction pipeline. Qian et al. (2022) also harnessed demographic and personality data, which yielded a validation Pearson correlation coefficient ( $r$ ) of 0.53. Notably, this performance surpassed that achieved without incorporating demographic and personality information. Data augmentation and demographic information, therefore, help to predict empathy levels.

As for data annotation employing LLM, Wang et al. (2021) experimented with GPT-3 in annotating data for several natural language processing tasks, including sentiment analysis, question generation and topic classification. They concluded that GPT-3 is a cost-effective way of annotating data but is not as reliable as human annotations. In this paper, we systematically select annotations between GPT-3.5 LLM and crowdsourcing to minimise existing noise in crowdsourcing annotations.

### 3 Method

#### 3.1 Problem Formulation

Consider for the  $i^{\text{th}}$  data sample,  $X = \{x_i^S, x_i^{D_{1,2,\dots,m}}\}$ , where  $x_i^S$  is a text sequence,  $x_i^{D_{1,2,\dots,m}}$  are  $m$  demographic data represented as real numbers. We aim to build a model  $\mathcal{F}$  to predict the degree of empathy  $Y^{\text{crowd}} = \{y_i^{\text{crowd}} \in [u, v]\}$ , where  $y_i^{\text{crowd}}$  represents self-assessed continuous empathy score ranging from  $u$  to  $v$ , collected through crowdsourcing platforms such as Amazon Mechanical Turk. This self-assessed empathy score is referred to as *crowdsourcing annotation* throughout this paper.

We investigate two important aspects of this problem. (1) *Demographics information*: Prior work has experimented with different approaches in integrating numerical demographics information into text-based empathy prediction workflow. For example, Vasava et al. (2022) fused demographic information as numbers in an MLP layer after the PLM. Whereas Chen et al. (2022) used them as fixed sentences and reported a test performance drop from 0.537 to 0.295 Pearson  $r$ . On the other hand, Hasan et al. (2023a) used them as fixed sentences, but in a different style than Chen et al. (2022), and reported a validation performance increase from 0.565 to 0.865 Pearson  $r$ . Given that most text-based empathy prediction systems use PLMs in predicting empathy levels (Tafreshi et al., 2021; Barriere et al., 2022, 2023), it would be straightforward to integrate the demographic numerical information as text into the pipeline. Instead of sentences with a fixed pattern for all samples, naturally varying sentences may improve the performance. Further, the recent rise of LLMs necessitates making these converted texts meaningful so we can use this semantic information in prompt engineering with LLMs.

(2) *Annotation*: Prior work on empathy prediction suffers from suboptimal performance, espe-

cially with crowdsourcing self-annotation. In a series of empathy prediction challenges participated by several researchers for three years (Tafreshi et al., 2021; Barriere et al., 2022, 2023), a maximum Pearson correlation coefficient of only 0.558 is achieved. In contrast, another empathy prediction challenge in its debut (Barriere et al., 2023) got a 0.708 Pearson correlation. Apart from the actual text data to predict empathy, a major difference between these two challenges is the annotation protocol: self-annotation by all participants (0.558) versus controlled annotation of all samples by three external annotators (0.708). Given that crowdsourcing annotation is a faster and simpler way of getting data but suffers from false information (Sheehan, 2018), mitigating the annotation noise is clearly a key problem.

It is important to note that the practice of crowdsourcing annotation for sentiment analysis (Wang et al., 2021) or image analysis (Nowak and Ruger, 2010) differs substantially from annotations in computational social science. Computational social science involves collecting *raw data*, such as people’s reactions to newspaper articles, with or without annotations. Consequently, even if the reliability of self-assessment annotations remains debatable, the underlying raw data can be salvaged by mitigating the noise inherent in the annotations.

#### 3.2 Employing LLM in Empathy Prediction

We employ LLM in three scenarios: (1) processing demographic data, (2) annotation, and (3) data augmentation by rephrasing all essays and demographic sentences.

##### 3.2.1 Numerical Demographics to Text Using LLM

The numerical demographic data  $X^{D_{1,2,\dots,m}}$  can be converted to semantically meaningful text using LLM to effectively integrate them into a text-based empathy prediction pipeline. There can be  $m$  demographic information such as gender, education level, ethnicity, etc. Demographic information for each sample  $i$  can be converted to sentences by first constructing a prompt and feeding it to an LLM:

$$P_i^D = f(x_i^{D_1}, x_i^{D_2}, \dots, x_i^{D_m}) \quad (1)$$

$$x_i^D = \text{LLM}(P_i^D) \quad (2)$$

The actual text sequence where empathy would be predicted, and the demographic sentence for each data sample can then be concatenated as  $x_i =$

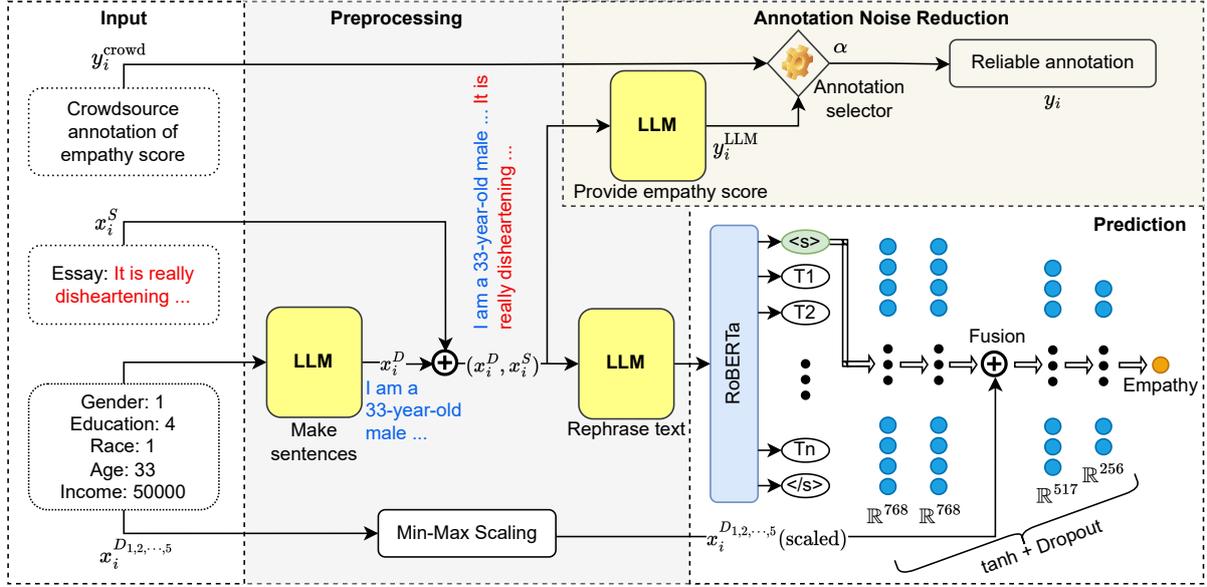

Figure 2: *LLM-GE<sub>m</sub>* system: we first use the LLM to convert demographic data to meaningful text. Essays and demographic sentences are used to annotate the essays using the LLM, and reliable annotations are then selected for each sample. After rephrasing the texts using the LLM, we train a RoBERTa-MLP model to predict empathy levels.

Essay	Crowd.	LLM
“After reading the article, you can’t help but <b>feel really sad</b> and <b>terrible</b> for the people that were affected by the hurricane. It was a situation that <b>they did not deserve</b> and one that they most likely did not cause but mother nature has other plans for us. I <b>feel bad</b> for all the children as well as animals that are there as well with <b>no shelter or food</b> .”	1.00	6.50
“Stories like this always manage to <b>irritate me</b> just a bit. I do not keep up with celebrity news so when some does manage to find it’s way in front of me I’m just like “ <b>who cares</b> ”? I will never see these people in my real life, they will <b>never have an impact on me</b> and will never even cross my mind on their own.”	1.33	1.20

Table 1: Two sample essays and their annotations using crowdsource participants and LLM in a continuous range from 1 to 7, where 1 and 7 refer to the lowest and highest empathy, respectively. Although the first essay is empathic, the self-annotation is the lowest, while the LLM annotation seems reasonable and correct. In the second example, both annotations seem correct. Empathic and non-empathic keywords are marked with blue and red colours, respectively.

$(x_i^S, x_i^D)$ , where the comma (,) symbol represents string concatenation.

### 3.2.2 Reducing Annotation Noise Using LLM

To reduce annotation noise, the best practice is to annotate the data with multiple annotators (Geiger et al., 2020). To this end, essay and demographic text sequences are fed together into an LLM to annotate each sample  $i$ . Some verified and reliable crowdsource annotations, along with their corresponding text sequences, are employed in a few-shot prompt engineering approach to enhance the consistency of the outputs generated by the LLM.

$$P_i^A = f([x_1, y_1^{\text{crowd}}], [x_2, y_2^{\text{crowd}}], \dots, [x_n, y_n^{\text{crowd}}], x_i) \quad (3)$$

$$y_i^{\text{LLM}} = \text{LLM}(P_i^A) \quad (4)$$

where  $[x_1, y_1^{\text{crowd}}], [x_2, y_2^{\text{crowd}}], \dots, [x_n, y_n^{\text{crowd}}]$  are  $n$  verified and reliable crowdsource annotations and corresponding text sequences.

Two sample annotations, by both LLM and crowdsource, are presented in Table 1. Indeed, the annotation by LLM seems reasonable and accurate compared to the crowdsource annotation (Table 1). Even though the crowdsource annotations are noisy, we do not entirely discard the crowdsource annotations, particularly to predict crowdsource ground truth in the test set. In this regard, the annotation selection threshold guides toward more reliable annotations.

Figure 3 illustrates a histogram of differences between LLM and crowdsource annotations. In most cases, there are 0 to 0.5 differences between

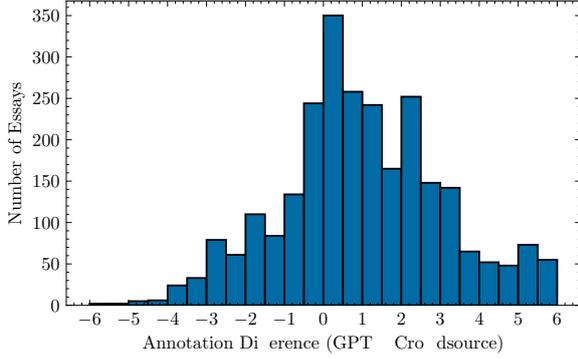

Figure 3: Annotation differences (GPT vs crowdsource).

the annotators. There are, however, cases where LLM and crowdsource annotations differ by larger margins. Refer to Appendix C.2 for more evidence.

An argument could be raised about the necessity of building another AI model guided by LLM, given that LLM, also an AI model, provides reliable empathy scores. LLMs as the prediction model may not be appropriate in some cases. Firstly, dependence solely on LLMs as the prediction model leads to high operating costs and computational demands. Secondly, LLMs may not be appropriate for edge devices such as smartphones and embedded systems. Comparatively smaller models are, therefore, often preferred, which can be optimised to get reasonably good performance compared to LLMs (Wang et al., 2023a). In this paper, we propose a computational empathy model that leverages  $y_i^{\text{LLM}}$  during training but can infer without needing LLMs.

### 3.3 LLM-Gem: LLM-Guided Empathy Prediction

Figure 2 depicts the details of the proposed *LLM-Gem* system. Between LLM annotation  $Y^{\text{LLM}}$  and crowdsource annotations  $Y^{\text{crowd}}$ , we select reliable annotations  $y_i$  for each sample based on annotation selection threshold  $\alpha$ :

$$y_i = \begin{cases} y_i^{\text{LLM}} & \text{if } \Delta > \alpha \\ y_i^{\text{crowd}} & \text{otherwise} \end{cases} \quad (5)$$

where  $\Delta = |y_i^{\text{crowd}} - y_i^{\text{LLM}}|$ , i.e., the absolute difference between two annotations. As an example, if  $y_i^{\text{crowd}} = 1$  and  $y_i^{\text{LLM}} = 6.5$ , the  $\Delta$  becomes 5.5; therefore, the selected annotation  $y_i$  will be 6.5 and 1 for  $0 \leq \alpha < 5.5$  and  $5.5 \leq \alpha \leq 6.0$ , respectively. The thresholds  $\alpha = 0$  and  $\alpha = \Delta$  mean using all LLM and crowdsource annotation, respectively. In the case of  $\alpha \neq \{0, \Delta\}$ , the selected an-

notation pool, concerning the whole training data, will result from both LLM and crowdsource. We, therefore, refer to this case as *mixed* annotation. The threshold  $\alpha$  ranges from 0 (both have the same annotations) to the maximum possible annotation difference:

$$\alpha = \begin{cases} 0 & \text{all LLM annotations} \\ > 0 \ \& \lt; \max(\Delta) & \text{mixed annotations} \\ \max(\Delta) & \text{all crowdsource annotations} \end{cases} \quad (6)$$

A higher  $\Delta$  means a higher probability of annotation anomaly in crowdsource annotation. We train the prediction model using the text sequences, demographic information and the ground truth selected through the annotation selection threshold, and we test our system on the crowdsource annotation. The hidden representation corresponding to the first token ( $\langle s \rangle$ ) from the last layer of the RoBERTa PLM is extracted and fed into an MLP.

Empathy is subjective and, in fact, heavily dependent on people’s demographic information, as proved by earlier studies on computational empathy (Guda et al., 2021; Vasava et al., 2022; Hasan et al., 2023a) and psychology (Borracci et al., 2017). We further leverage numerical demographic data in addition to the textual demographic information. Since the demographic values are in different ranges, we use min-max scaling before fusing the information into the MLP. More details of the architecture are presented in Appendix A.

## 4 Experiments

### 4.1 Experimental Setup

#### 4.1.1 Dataset Setup

To evaluate people’s empathy towards newspaper articles, we experiment with three datasets, consisting of written essays in English, demographic data and ground truth empathy score,  $Y^{\text{crowd}}$ . We manually verify that the demographic data are anonymised with no personal identifying information, such as full name or username. The ground truth is annotated by crowdsource participants based on Batson’s empathy scale involving six aspects of empathy (Batson et al., 1987). The NewsEmpathy v2 *training* dataset consists of whole NewsEmpathy v1 data samples, while the v2 *validation* and *test* sets consist of new samples. The v3 dataset (Omiaomu et al., 2022; Barriere et al., 2023), on the other hand, has no overlapping sam-

ples with its earlier version (v1 and v2). Details of the datasets are presented in Appendix B.

The task in these datasets is to predict continuous empathy level  $Y^{\text{crowd}} \in [1.0, 7.0]$  from input texts  $X = \{\text{Essay, Demographic}\}$ . The essays ( $X^{\text{Essay}}$ ) are text sequences, while the demographic data ( $X^D$ ) are represented as real numbers. As reported by Omiaomu et al. (2022),  $X^{\text{DGender}} \in \{1, 2, 5\}$  corresponds to male, female and others;  $X^{\text{DEducation}} \in \{1, 2, 3, 4, 5, 6, 7\}$  corresponds to different levels of educations;  $X^{\text{DRace}} \in \{1, 2, 3, 4, 5, 6\}$  corresponds to different races;  $X^{\text{DAge}} \in \mathbb{R}$  corresponds to age in years; and  $X^{\text{DIncome}} \in \mathbb{R}$  corresponds to income in USD.

Similar to Barriere et al. (2023), we combine v2 and v3 training datasets and make a single training set, which has 5,268 samples after data augmentation. The model trained on this training set is used for evaluation in v2 and v3 datasets. Evaluation in v1 dataset, however, does not incorporate any external data (no v2, v3 or data augmentation) to maintain consistency with prior work (Buechel et al., 2018). The v1 dataset has 1,670 samples for 10-fold cross-validation.

#### 4.1.2 LLM Setup

To interact with LLM through prompt engineering, we design appropriate prompts based on OpenAI best practices for prompt engineering (Fulford and Ng, 2023). We controlled the degree of randomness of the LLM output by using the *temperature* parameter of OpenAI API. The prompts were mostly sensitive to the presentation of responses, such as responding as ‘6’ or ‘six’ with additional unnecessary sentences, rather than the contents of the response, such as empathy score. We iteratively tested prompts to get responses in the desired format. For numeric demographic data to text conversion, the prompt includes the mapping between numbers and actual information with a typical example sentence. During annotation, we provide three essays and their empathy scores as examples so that the LLM is likely to output the empathy score in a consistent style. Prompts with sample input and output with numerical to textual conversion, annotations, and rephrasing text are presented in Appendix C.1, Appendix C.2, and Appendix C.3, respectively.

#### 4.1.3 Evaluation

We follow the established evaluation protocols by earlier studies on all three datasets. The v1 dataset

comes with no separate validation and test set, and the evaluation protocol reported in Buechel et al. (2018) is 10-fold cross-validation. The v2 and v3 datasets have separate validation and test sets, and prior work (Tafreshi et al., 2021; Barriere et al., 2022, 2023) reported performance on hold-out test sets. The ground truths corresponding to the test sets in the v2 and v3 datasets are not publicly available. Instead, evaluations on test sets are obtainable through the CodaLab (Pavao et al., 2022) challenge websites: v2 dataset at WASSA 2022<sup>1</sup> and v3 dataset at WASSA 2023<sup>2</sup> challenges.

Earlier studies with NewsEmpathy datasets (Hasan et al., 2023a; Mundra et al., 2021) and general fine-tuning of PLMs (Dodge et al., 2020) reported that the initialisation of model parameters and the data orders in training heavily influence the model performance. Thus, we use different initialisation and data ordering in v2 and v3 evaluations through five different seed values (0, 42, 100, 999, 1234). We use Pearson correlation coefficient ( $r$ ) as the evaluation metric, the official metric of WASSA 2021, 2022, and 2023 challenges using NewsEmpathy datasets.

#### 4.1.4 Implementation Details

We utilise gpt-3.5-turbo-0613<sup>3</sup> version of GPT-3.5 LLM for demographic sentences, rephrasing and annotations. Our manual inspection of the annotations supports the correctness of LLM annotations. To check LLM’s consistency in annotation, we annotated 21 samples twice at two different API calls. The annotations are fairly consistent, with a mean variation of 0.3 and a standard deviation of 0.42. On average, the LLM annotation costs us USD 0.94 per 1,000 essays. Of the 5,268 essay samples, GPT-3.5 declined to annotate two samples due to their lack of coherent thoughts or feelings, as they appeared to be a mix of unrelated sentences. Such erroneous samples are indeed challenging to screen out because these samples are textual content in a text dataset; however, GPT-3.5 detects them even without any explicit instructions.

We train and validate the RoBERTa-MLP model, having 125.7M total trainable parameters, utilising Python 3.11 on a single NVIDIA Tesla V100 32GB GPU. The primary software packages in-

<sup>1</sup><https://codalab.lisn.upsaclay.fr/competitions/834>

<sup>2</sup><https://codalab.lisn.upsaclay.fr/competitions/11167>

<sup>3</sup>GPT 3.5 (version: gpt-3.5-turbo-0613) was the latest version at the time of this research.

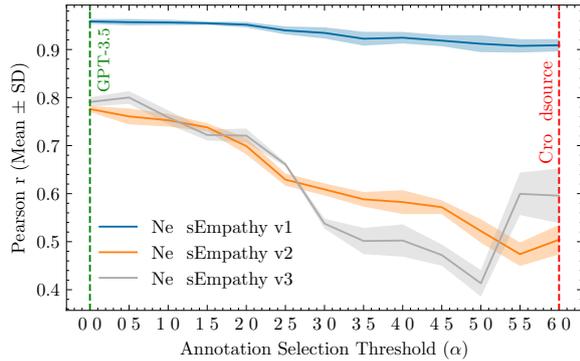

Figure 4: Validation set performance at different annotation selection thresholds, ranging from 0 (all GPT-3.5 LLM annotation) to 6 (all crowdsource annotation).

clude Transformers 4.31.0, Datasets 2.13.0, Pytorch 2.0.1, CUDA 11.7, scikit-learn 1.2.2 and Pandas 2.0.2. We use off-the-shelf roberta-base PLM from Hugging Face (Wolf et al., 2020), which is released under MIT license. To combat overfitting and mitigate catastrophic forgetting, we impose early stopping. Specifically, we stop the training if the validation loss does not significantly decrease (a minimum decrease of 0.01 is considered significant) for three epochs. We train the model for a maximum of 10 epochs with a learning rate of  $1e-5$  in AdamW (Loshchilov and Hutter, 2019) optimiser, a linear learning rate decay scheduler with 6% warmup steps, a batch size of 16 and weight decay of 0.1. We use a fixed seed value of 0 to ensure reproducibility. To get the text embedding from the RoBERTa PLM, we experimented with concatenating the last four hidden states, which did not provide any benefit compared to using only the last hidden state. As the loss function, we experimented with mean-squared-error, Huber loss, and mean-absolute-error and found mean-squared-error more suitable.

#### 4.1.5 Validation Strategy

Seminal work by Liu et al. (2019) introduced RoBERTa and strategies to fine-tune the RoBERTa PLM on downstream tasks. We adhere to the same hyperparameter settings reported in Liu et al. (2019) across our experiments to ensure the performance improvements are solely based on improvement in data quality rather than the choice of common hyperparameters, such as learning rate and batch size.

Annotation selection threshold ( $\alpha$ ) is the primary hyperparameter we introduce for minimising annotation noise. The annotation difference ranges

Data	Annotation	Validation ( $r$ ) (Mean $\pm$ SD)
v1	Crowdsource	$0.909 \pm 0.013$
	LLM-GEm	<b><math>0.958 \pm 0.005</math></b>
v2	Crowdsource	$0.504 \pm 0.031$
	LLM-GEm	<b><math>0.776 \pm 0.006</math></b>
v3	Crowdsource	$0.596 \pm 0.057$
	LLM-GEm	<b><math>0.791 \pm 0.010</math></b>

Table 2: Validation results with 10-fold cross-validation (NewsEmpathy v1) and with five different initialisation and data order (NewsEmpathy v2 and NewsEmpathy v3). The *LLM-GEm* performance is reported at  $\alpha = 0$ .

from zero (both are the same) to six (one annotation is lowest, i.e., one, and the other annotation is highest, i.e., seven). A value of  $\alpha = 0$  and  $\alpha = 6$  denote selecting the entire annotations of LLM and crowdsource, respectively. A value of  $\alpha$  between 0 and 6 means mixed annotations. In addition to tuning the annotations of train data, we experiment with varying the validation annotation. An elevation in the validation score signifies a corresponding enhancement in the quality of the underlying data, given that all other parts of the workflow remain constant. As seen on Figure 4, the validation performance on all three datasets has a clear pattern as the threshold varies. Data quality is, therefore, improved when we use LLM annotations and gradually degraded as we select more crowdsource annotations. The performance on the NewsEmpathy v1 dataset appears relatively modest compared to the other datasets. This discrepancy could potentially be attributed to a smaller number of samples: 1,670 in v1 dataset as opposed to 5,268 in v2 and v3 training sets.

Table 2 reports the validation scores in three datasets with annotations by crowdsource and *LLM-GEm*. Importantly, *LLM-GEm* annotations improve the performance of the validation sets by a large margin in all datasets. The performance is best at the v1 dataset, with a Pearson  $r$  of 0.958.

We also experimented with how newspaper article text contributes towards empathy prediction and how our improved data works on a model reported and implemented by others. These results are presented in Appendix D and Appendix E, respectively.

## 4.2 Benchmarking Results

We compare our system’s performance on similar empathy prediction studies on all three datasets (Ta-

Method	Best Model	Test ( $r$ )

<sup>a</sup> 10-fold cross-validation evaluation as per the prior work on v1 dataset (Buechel et al., 2018)

Table 3: Comparison with similar empathy prediction works on all three datasets. Note that the test sets’ ground truths come from crowdsourcing.

ble 3). Our proposed system, *LLM-GEm*, provides state-of-the-art (SOTA) test results on the v1 and v3 datasets. On the v2 dataset, the performance is 0.053 behind the best result. The major reason behind such suboptimal performance can be the annotation noise in the test set. Given that the test set comes from the same distribution as the training set and we demonstrate how noisy the training set annotation is, it is highly likely that the test set has similar annotation errors. Although prior work (Mundra et al., 2021; Plaza-del Arco et al., 2022; Chen et al., 2022) reported better performance than ours with the same test set, a significant distinction here is the training labels. We train our model with noise-reduced labels, which makes the distribution of training and test labels significantly different. Another reason we anticipate is hyperparameter optimisation. Prior work on NewsEmpathy datasets reported significant changes in performance with hyperparameter optimisation (Hasan et al., 2023a; Mundra et al., 2021). As discussed earlier, we

adhered to the same hyperparameter settings reported in the original RoBERTa paper to ensure the performance improvements are solely based on improvement in data quality. Therefore, SOTA performance on the v2 dataset might be achievable through hyperparameter optimisation.

Several observations are explored from Table 3. (1) Earlier SOTA result (Mundra et al., 2021) on v2 dataset and the second best result (Lin et al., 2023) on v3 dataset leveraged multiple PLMs in ensemble fashion. On the contrary, *LLM-GEm* uses a simple pipeline with a single PLM, followed by some MLP layers and outperforms bulky ensembles.

(2) To use, not to use, or how to use demographic information remains a confounding factor in the literature. For example, Chen et al. (2022) reported decreased performance by using them as fixed sentences, while Hasan et al. (2023a) and Vasava et al. (2022) reported increased performance by using them as fixed sentences and as numbers, respectively. Gruschka et al. (2023), on the other hand, used one-hot encoding, unnecessarily increasing the dimensionality. Our system utilises demographic information both as meaningful varying sentences and as numbers, and the system outperforms earlier work.

(3) There is a decreasing trend of the overall performance of prior work from v2 to v3 dataset, which may be attributed to smaller dataset size (2,655 essays in v2 versus 1,100 essays in v3). Our system provides SOTA results and outperforms all studies by a large margin in v3 dataset.

(4) On the v1 dataset, our work achieves the best improvement of 0.52 Pearson  $r$  as compared to the other two datasets. This notable improvement can be attributed to the reliable annotation and use of demographic sentences – provided by *LLM-GEm* system – utilised on a PLM-based pipeline.

(5) RoBERTa PLM is the most popular in the literature, and several work utilised its fine-tuned versions by emotion-related data (e.g., EmoBERTa and RoBERTa-Twitter (Lin et al., 2023)). We use the RoBERTa base model and achieve SOTA performance.

### 4.3 Ablation Study

#### 4.3.1 Varying Input

Table 4 presents the ablation experiment in two broad categories: (1) discarding LLM annotations and (2) discarding crowdsource annotations. In each category, we vary training data and features.

Annotation	Training Data	Features	Val. ( $r$ )	Test ( $r$ )
Without LLM	v2 + v3	E	0.565	0.433
		$D_t, E$	0.577	0.446
		$D_t, </s> E$	0.560	0.436
		$D_t, D_n, E$	0.626	0.451
Without Crowd.	v3	$D_t, D_n, E$	0.656	0.421
	v2 + v3	$D_t, D_n, E$	0.765	0.468
	v2 + v3 + Augm.	$D_t, D_n, E$	<b>0.792</b>	<b>0.498</b>

$D_t$  – Demographic (text),  $D_n$  – Demographic (number)  
E – Essay, Augm. – Augmentation

Table 4: Ablation study on the most recent v3 dataset by discarding either LLM or crowdsource annotations, varieties in training data samples and features. In the case of features without demographic numbers, no MLP layers are used as they are not required. Experiments are run on the same hyperparameters with a fixed seed value of 0, ensuring the same initialisation and data orders. Note that test set annotations always remain unchanged as crowdsource annotations.

Discarding crowdsource annotation, i.e., including LLM annotation, still improves both validation (0.626 to 0.765) and test (0.451 to 0.468) performance, with the training data and input features remaining unchanged. Verified without LLM annotation, demographic information improves empathy prediction, with an improvement of 0.013 Pearson  $r$  in the test set. This aligns with earlier studies by Hasan et al. (2023a) and Vasava et al. (2022). Using demographic information both as text (with essays) and as number (intermediate fusion) in a single experiment further improves the performance by 0.049 Pearson  $r$  in the validation set. We also experiment with inputting the demographic sentences and essays with a separator token ( $</s>$ ), which slightly lowers the performance compared to simply concatenating. Verified with discarding crowdsource annotations, i.e., including LLM annotations, adding v2 training data and data augmentation improves the performance by 0.109 and 0.027 validation Pearson  $r$ , respectively.

#### 4.3.2 Varying Annotation Selection Threshold

Table 5 presents test performances on v2 and v3 datasets with varying annotation selection threshold  $\alpha$  from zero (all LLM annotations) to six (all crowdsource annotations). On both datasets, the best Pearson  $r$  is achieved in a combination of LLM and crowdsource annotations selected using  $\alpha$  of 5.5 and 4.5, respectively.

$\alpha$	NewsEmpathy v2 ( $r$ )	NewsEmpathy v3 ( $r$ )
0.0 (all LLM)	0.459	0.498
0.5	0.434	0.424
1.0	0.429	0.479
1.5	0.438	0.462
2.0	0.452	0.448
2.5	0.442	0.495
3.0	0.447	0.516
3.5	0.490	0.458
4.0	0.468	0.536
4.5	0.496	<b>0.563</b>
5.0	0.495	0.554
5.5	<b>0.505</b>	0.495
6.0 (all crowd)	0.458	0.481

Table 5: Test performance on v2 and v3 datasets with different annotation selection thresholds  $\alpha$  (defined in Equation (5)) at a fixed seed value of 0.

## 5 Conclusion and Future Work

Empathy plays a crucial role in social dynamics, such as education, health and business. Evaluating people’s empathy levels using computational tools such as AI requires good-quality data. Computational social science often involves collecting data and annotation from crowdsourcing, which often has noise. To this end, our system, *LLM-GE*, aims to minimise annotation noise and ensure data quality. We experiment with three datasets predicting people’s empathy levels towards newspaper articles. We define an annotation selection threshold to systematically select between LLM and crowdsource annotations, which achieves SOTA performance.

Our annotation error mitigation method can be applicable to other self-annotation datasets with necessary adaptations in the prompts (to include/change the details of the problem, range of annotation labels, etc.). For example, Abdul-Mageed et al. (2017) collected self-annotation to detect empathy in social media, where similar error analysis and possible inclusion of LLM may help mitigate annotation noise, if any. Similarly, Hosain and Rahman (2022) used crowdsourcing self-annotated data to detect customers’ empathy behaviour, where our LLM-based annotation noise removal can be helpful. Apart from these, it could be applicable to other similar self-annotated datasets across different computational social science and human behaviour studies. Future work can further investigate better loss functions that closely estimate the Pearson  $r$  evaluation metric. Finally, experimenting with PLMs that are pre-trained on emotion and empathy-related datasets would be another avenue we leave for future work.

## Limitations

The primary limitation is the manual tuning of the annotation selection threshold ( $\alpha$ ). A more principled approach to determining the optimal threshold represents an interesting avenue for further exploration. Second, our LLM-GEM system is slightly behind SOTA in the NewsEmpathy v2 dataset. As discussed in Section 4.2, the major reasons we anticipate are annotation noise in the test set and hyperparameter optimisation. Although few prior works reported better performance than ours with the same test set, a significant distinction here is the training labels. We train our model with noise-reduced labels, which makes the distribution of training and test labels significantly different. With such a distribution shift, model performance degrades, which may require other evaluation approaches (Chen et al., 2021). Even so, our model performance is competitive in the NewsEmpathy v2 dataset and beats the SOTA in the v1 and v3 datasets.

Another limitation is the reliance on the NewsEmpathy v1, v2 and v3 datasets, all of which are based on people reading news articles. Evaluating LLM-GEM on more diverse dataset types would strengthen the generalisability of the results. Finally, we could not train or fine-tune LLM (e.g., GPT-3.5) as the primary empathy prediction model. It would be interesting to examine how such a larger language model performs compared to a smaller language model (e.g., RoBERTa). LLM would likely outperform RoBERTa, but training or fine-tuning LLM may be a suboptimal choice at some scenarios due to increased hardware and overall cost requirements.

## Ethics Statement

Empathy is subjective, and people’s empathy levels depend on demographic factors such as age, gender and ethnicity. This line of research, therefore, should be carefully designed so that the prediction model does not generate biased output by depending more on demographics rather than actual content. Our use of LLM in generating meaningful texts from demographic numbers may not be biased because the LLM here merely constructs sentences according to the pre-defined mapping. Furthermore, rephrasing texts using LLM may not have a significant bias because it is not open-ended text generation (Dhamala et al., 2021). However, LLM outputs may be biased with empathy scores,

capturing gender, race or socioeconomic stereotypes, which warrants future experimentation. With the deployment of our proposed empathy detection system, the privacy of people’s personal and demographic information can be at risk and, therefore, should be addressed as per appropriate ethical guidelines and protocols that come with the datasets.

## Acknowledgements

## A Architecture Details

The *LLM-GE<sub>m</sub>* system (presented in Figure 2) comprises LLM (GPT-3.5) to preprocess data and provide annotation. In preprocessing, we concatenate the essay text sequences with the demographic sentences converted by LLM. Using the selected annotation through annotation selection threshold ( $\alpha$ ), we train a RoBERTa-MLP model. The MLP portion consists of four hidden layers, having tanh activation function, followed by a dropout of 0.2 during training. The first hidden layer has a hidden size of  $768 \times 768$ . The second hidden layer has a hidden size of  $768 \times 512$ . Next, we add the five numerical demographic information; therefore, the next hidden layer’s input size becomes 517. The last layer’s size is  $256 \times 1$ , which provides an empathy score between 1.0 to 7.0. The number of hidden layers, their sizes, activation functions and dropouts are decided through experiments at a fixed seed value of 0.

## B Dataset Details

Table 6 provides the statistics of the datasets. We name these datasets as NewsEmpathy because they involve people’s empathic reactions towards newspaper articles. [Buechel et al. \(2018\)](#) released the first reported dataset of this kind, consisting of 1,860 essays in response to articles involving harm to individuals, organisations or nature. In this NewsEmpathy v1 dataset, 403 participants read five random newspaper articles from a pool of 418 articles and wrote essays reflecting on each news article they read. The raw article varies in length from 101 to 32,058 characters, with an average number of characters of 4,316.

The v1 dataset is further extended by [Tafreshi et al. \(2021\)](#), which includes an additional 161 participants. The extended version (named v2), with 2,655 essays in total, was utilised in WASSA (Workshop on Computational Approaches to Subjectivity, Sentiment & Social Media Analysis) Shared-Task 2022 ([Barriere et al., 2022](#)) and 2021 ([Tafreshi et al., 2021](#)). The NewsEmpathy v3 dataset (1,100 essays) – employed in the WASSA 2023 challenge – utilises 100 selected newspaper articles from the total 418 articles and comprises new essay data.

The v1 dataset is available under the CC BY 4.0 license, and the other two datasets (v2, v3) are available for scientific or research purposes.

Dataset	Train	Validation	Test	Total
v1 (Buechel et al., 2018)				1,860
v2 (Tafreshi et al., 2021)	1,860	270	525	2,655
v3 (Omitaomu et al., 2022)	792	208	100	1,100

Table 6: Datasets with the corresponding number of essays in train, validation and test sets. The NewsEmpathy v1 dataset comes with no train-validation-test splits, and the standard evaluation protocol is 10-fold cross-validation.

## C LLM Prompt and Sample Response

### C.1 Numerical Demographics to Text Using LLM

The following prompt template is used for each participant by providing their demographic information.

#### C.1.1 LLM Prompt

Your task is to format five numerical data (individual’s gender, education level, race, age, and income) into meaningful sentences.

The numerical data are delimited by triple back-ticks.

Write from a first-person point-of-view.

Complete the task with no more than three sentences.

Use the following mapping between the number and the corresponding text:

Gender:

1 = Male

2 = Female

5 = Other

Education level:

1 = Less than a high school diploma

2 = High school diploma

3 = Technical/Vocational school

4 = Some college but no degree

5 = Two-year associate degree

6 = Four-year bachelor’s degree

7 = Postgraduate or professional degree

Race:

1 = White

2 = Hispanic or Latino

3 = Black or African American

4 = Native American or American Indian

5 = Asian/Pacific Islander

6 = Other

Age:

<number> = <number> years

Income:

<number> = <number> USD

For example, if the input numbers are: “Gender: 1, Education level: 5, Race: 1, Age: 25, Income: 40000”

The output can be “I am a 25-year-old male of the White race. I completed a two-year associate degree and earn 40000 USD.”

Input numbers: ``Gender: {gender}, Education level: {education level}, Race: {race}, Age: {age}, Income: {income}``

#### C.1.2 Sample Response

Table 7 illustrates four sample input numerical demographic information and corresponding output (text sequence).

### C.2 Reducing Annotation Noise Using LLM

To annotate, we provide three sample input-output responses as few-shot prompting. In addition to guiding the LLM in annotation, it further facilitates the responses in a consistent style. The following prompt template is used for each essay.

#### C.2.1 LLM Prompt

‘role’: ‘system’, ‘content’: ‘You are an AI model that annotates written essays to provide an empathy score between 1.0 to 7.0 based on the definition of empathy.\n The essays were written by human participants after reading a newspaper article involving harm to individuals, groups of people, nature, etc. The essay is provided to you within triple backticks. Your response must contain one and only empathy score.’,

‘role’: ‘user’, ‘content’: ‘Essay: ``I am a 37-year-old male of the African American race. I have a four-year bachelor’s degree and earn 40000 USD. It breaks my heart to see people living in those conditions. I hope that all the aid that was sent to the island makes it to the people who need it the most. I do not know what I would do it that was my family and I. I would hope that I would do my best, but I can see how depressing and hopeless you could feel having your whole life changed because of a storm and not knowing where your next meal is coming from.``’,

Dataset	Input					LLM Output
	Gender	Edu. level	Race	Age	Income	
v2	1	4	1	33	50000	I am a 33-year-old male of the White race. I have completed some college but have not obtained a degree. Currently, I earn 50000 USD.
	1	6	5	43	50000	I am a 43-year-old male of Asian/Pacific Islander descent. I obtained a four-year bachelor's degree and my income is 50000 USD.
v3	2	6	2	38	24000	I am a 38-year-old female of Hispanic or Latino race. I have a four-year bachelor's degree and earn an income of 24000 USD.
	2	6	1	46	22000	I am a 46-year-old female of the White race. I have a four-year bachelor's degree and earn 22000 USD.

Table 7: Samples of numerical demographic information and corresponding output from LLM.

Dataset	Input essay	Crowd.	LLM Output
v2	"I am a 36-year-old male of Asian/Pacific Islander descent. I have a four-year bachelor's degree and my yearly income is 50000 USD. This <b>doesn't sound too worrisome to me</b> . If you are affected by depression, then <b>you should decide</b> as an individual to find another option. It's just a side effect, I think there are many medicines out there that have depression as a side effect. It is something that individuals should be aware of, but <b>nothing critical</b> ."	1	1.2
	"I am a 28-year-old male of the White race. I completed a two-year associate degree and earn 62000 USD. Some people are just disturbed. Everyone is going to point to mental illness in something like this, but I fear that when <b>things like this happens</b> , it gets easier and easier just to point at people and call them mentally ill. I fear that eventually we are going to get to the point where you can classify someone as mentally ill by the crowd. Just finger pointing. <b>I feel for these victims</b> and the victims of crimes in the future because <b>we spend too much time making excuses and pointing fingers rather than dealing with the problems at hand</b> ."	1	4.5
v3	"I am a 33-year-old male of other gender identity. I have completed some college but no degree and earn 36000 USD. It is terrible that these kids have to starve but it was <b>kind of funny</b> that they were boiling grass I mean think about these africans they <b>always have some sort of crisis even when they are rich</b> in oil they <b>still manage to ruin everything they are like monkeys</b> they resemble apes they <b>behave like animals</b> "	4.33	1
	"I am a 29-year-old male of the White race. I completed a four-year bachelor's degree and my yearly income is 85000 USD. After reading the article, my reaction is that <b>it is very sad</b> that boys that young have to be put behind bars. I think that <b>children should be able to experience their childhood and have fun</b> at that age. They <b>should not be facing hardships</b> at all. <b>They should be playing with friends and be in school</b> at that age and not locked up behind a cell."	1.5	6.5

Table 8: Samples of essay and its annotations using crowdsourcing and LLM in a continuous range between 1 to 7, where 1 and 7 refer to the lowest and highest empathy, respectively. Empathic and non-empathic keywords are marked with blue and red colours, respectively.

'role': 'assistant', 'content': '6.8', should have to endure that and kids are the saddest victims.'''

'role': 'user', 'content': 'Essay: ``I am a 38-year-old female of the White race. I possess a postgraduate or professional degree and earn 42000 USD. It sounds like these boys had a really rough life. I do think we all have personal responsibility for our choices at the end of the day though. Even though you might have it rough, ultimately it is up to you to decide to break the law or use drugs or not. So they had free will too and could have exercised that. Regardless, it is still sad that they went through a rough childhood. Nobody

'role': 'assistant', 'content': '2.0', should have to endure that and kids are the saddest victims.'''

'role': 'user', 'content': 'Essay: ``I am a 29-year-old male of the White race. I have completed some college but do not have a degree. I earn 39,000 USD. I just read an article about how animals in Venezuela are starving to death because of the turmoil that is happening in that country. I feel like there should be some kind of action plan in place for animals in countries that are experiencing hardship so that they can be

Hope / Sadness I am a 37-year-old African American male. I hold a bachelor’s degree and have an annual income of 40000 USD. Witnessing individuals residing in such circumstances deeply saddens me. My fervent wish is that the assistance sent to the island reaches those who require it the most. If I were in their shoes, I cannot fathom the despair and desolation I would feel as my entire life is altered by a storm, uncertain about the source of my next sustenance.

Table 9: Rephrased essays corresponding to input essay text and self-assessed emotion category by participants.

Annotation	Training Data	Model	Features	Validation ( <i>r</i> )	Test ( <i>r</i> )
Crowd.	v2 + v3	RoBERTa	Demog (text) + essay </s> article	0.577	0.442
LLM-GE <sub>m</sub>	v2 + v3 + Augmentation	RoBERTa-MLP	Demog (text, number) + essay </s> article	0.796	0.488
		RoBERTa-similarity	Demog (text, number) + essay </s> article	0.73	0.445

Table 10: Effect of article inclusion with training data samples of NewsEmpathy v2 and NewsEmpathy v3 or with their augmentations, evaluated on NewsEmpathy v3 dataset. All experiments were run on the same hyperparameters with a fixed seed value of 0, ensuring the same initialisation and data orders.

transported to other places in times of crisis. The thought of innocent creatures starving to death in cages really turns my stomach.’’’’,

‘role’: ‘assistant’, ‘content’: ‘5.7’

‘role’: ‘user’, ‘content’: ‘Essay: ’’’{essay}’’’

### C.2.2 Sample Response

Table 8 reports some sample essays and their annotation by LLM. The self-assessed annotations from crowdsourcing are also presented to compare the annotation between LLM and crowdsourcing.

## C.3 Rephrasing Essay for Data Augmentation

We rephrase all essays using LLM prompt engineering as a data augmentation technique. The following prompt template is used for each essay.

### C.3.1 LLM Prompt

In a data collection experiment for empathy detection, the study participant writes essay to describe

their feeling after reading a newspaper article involving harm to individuals, groups or other entities.

The participant’s demographic information are also available within the essay.

As a data augmentation tool for NLP, your task is to paraphrase the demographic and essay information delimited by triple backticks.

Do not add any additional information not contained in the input texts.

Overall, the participant expressed {emotion} emotion. Do not change this overall emotion of the participant’s essay.

Your response must not have any backticks or any additional symbols.

Input demographic and essay: ’’’{essay}’’’

### C.3.2 Sample Response

Table 9 presents some samples of original essays written by participants and corresponding rephrased versions by LLM.

## D Inclusion of Newspaper Article Texts

To accommodate long article sequences in a PLM-based pipeline, we summarise these articles using LLM. The gpt-3.5-turbo-0613 model version could not summarise six articles because this GPT-3.5 model version was limited with a maximum context length of 4,097 tokens. We, therefore, use 16k context length supporting gpt-3.5-turbo-16k version to summarise those six articles. The resulting summarised articles vary from 107 to 2,063 characters, with an average length of 776 characters, although we instruct GPT-3.5 to use at most 1,000 characters. We also rephrase the articles as a data augmentation technique.

### D.1 LLM Prompt to Summarise Articles

Your task is to summarize given text delimited by triple backticks.

Use at most 1000 characters.

Do not add any additional information not contained in the input text.

Input text: ```{article text}```

### D.2 LLM Prompt to Rephrase Articles for Augmentation

As a data augmentation tool for NLP, your task is to paraphrase the newspaper article delimited by triple backticks.

Do not add any additional information not contained in the input texts.

Your response must not have any backticks or any additional symbols.

Input newspaper article: ```{article}```

### D.3 Results with Article Texts

To accommodate newspaper articles, we experiment in two different ways: (1) we combine articles and essays (with demographic sentences) with a separator token ( $\langle /s \rangle$ ) and input them into the empathy prediction pipeline, and (2) we process articles and essays separately on two encoders, calculate their cosine similarity, and input the encoded sequence as well as the similarity score into the prediction pipeline. The idea behind calculating similarity is that for an essay to be empathic, it ideally should have similarities with the articles, with a proportional relationship.

As seen on Table 10, the article texts do not have a meaningful contribution to the overall per-

$\alpha$	Improved data ( $r$ )	Original data ( $r$ )
0.0 (all LLM)	0.746	-
0.5	0.718	-
1.0	0.726	-
1.5	0.721	-
2.0	0.718	-
2.5	0.695	-
3.0	0.656	-
3.5	0.544	-
4.0	0.496	-
4.5	0.472	-
5.0	0.445	-
5.5	0.392	-
6.0 (all crowd)	0.448	0.458

Table 11: Validation set Pearson  $r$  of the model reported by Vasava et al. (2022) on our improved NewsEmpathy v2 datasets and the original v2 dataset (performance on original data is taken from Vasava et al. (2022)). The performance on our data is reported on different annotation selection thresholds  $\alpha$  (defined in Equation (5)) at a fixed seed value of 0.

formance in both crowdsourced and *LLM-GE*m annotations. The inclusion of cosine similarity does not benefit either.

## E Further Validation of Data Improvement

We use our improved NewsEmpathy v2 dataset on the model reported by Vasava et al. (2022) to validate our contribution to data improvement further. We chose this specific work because their implementation and hyperparameter are publicly available<sup>4</sup>. Table 11 compares the validation set Pearson  $r$  using our improved data versus the original data reported in Vasava et al. (2022). As can be seen, our improved data resulted in a significant boost in performance on most annotation selection thresholds, which proves the enhanced quality of the data.

# ICE-Score: Instructing Large Language Models to Evaluate Code

Terry Yue Zhuo

Monash University and CSIRO’s Data61

terry.zhuo@monash.edu

## Abstract

Recent advancements in the field of natural language generation have facilitated the use of large language models to assess the quality of generated text. Although these models have shown promising results in tasks such as machine translation and summarization, their applicability in code intelligence tasks remains limited without human involvement. The complexity of programming concepts required for such tasks makes it difficult to develop evaluation metrics that align with human judgment. Token-matching-based metrics, such as BLEU, have demonstrated weak correlations with human practitioners in code intelligence tasks. Moreover, utilizing human-written test suites to evaluate functional correctness can be challenging in domains with low resources. To overcome these obstacles, we propose ICE-Score, a new evaluation metric via instructing large language models (LLMs) for code assessments. Our metric addresses the limitations of existing approaches by achieving superior correlations with functional correctness and human preferences, without the need for test oracles or references. We evaluate the efficacy of our metric on two different aspects (*human preference* and *execution success*) and four programming languages. Our results demonstrate that our metric surpasses state-of-the-art metrics for code generation, delivering high levels of accuracy and consistency across various programming languages and tasks. We also make our evaluation metric and datasets available to the public<sup>1</sup>, encouraging further research in evaluating code intelligence tasks.

## 1 Introduction

Natural language generation (NLG) systems have seen significant progress in developing large language models (LLMs). These models have shown great promise in generating high-quality and diverse texts that can be difficult to distinguish from

human-written texts (Ouyang et al., 2022). However, evaluating the quality of NLG systems remains a challenging task, primarily due to the limitations of traditional evaluation metrics. Token-matching-based metrics, such as BLEU (Papineni et al., 2002) and ROUGE (Lin, 2004), have been widely used to evaluate NLG systems but have demonstrated poor correlation with human judgment and a lack of ability to capture semantic meanings (Kocmi et al., 2021). Furthermore, these metrics require reference output, which can be challenging to obtain for new tasks and low-resource domains (Liu et al., 2023).

In recent years, the use of LLMs as reference-free evaluators for Natural Language Generation (NLG) tasks has gained attention among researchers. This approach is strongly aligned with human preferences, even when reference texts are unavailable (Liu et al., 2023; Fu et al., 2023). The underlying assumption behind this approach is that LLMs possess a profound understanding of human-generated text and task instructions, enabling them to evaluate various NLG tasks through prompts. The exceptional performance of LLMs in contextual understanding and natural language generation, as evidenced by studies (Brown et al., 2020), further supports this assumption. Moreover, LLMs trained on both textual and code-based data have showcased remarkable capabilities in diverse downstream tasks related to source code, including code generation (OpenAI, 2023; Allal et al., 2023; Li et al., 2023). While a performance gap still exists between LLMs and human developers in code-related tasks, recent research has illustrated that LLMs can be enhanced to handle various source code tasks with appropriate guidance (Chen et al., 2023; Madaan et al., 2023). This indicates the significant potential of LLMs in comprehending and working with source code.

Code evaluation presents unique challenges, requiring a deeper understanding of programming

<sup>1</sup><https://github.com/terryyz/ice-score>

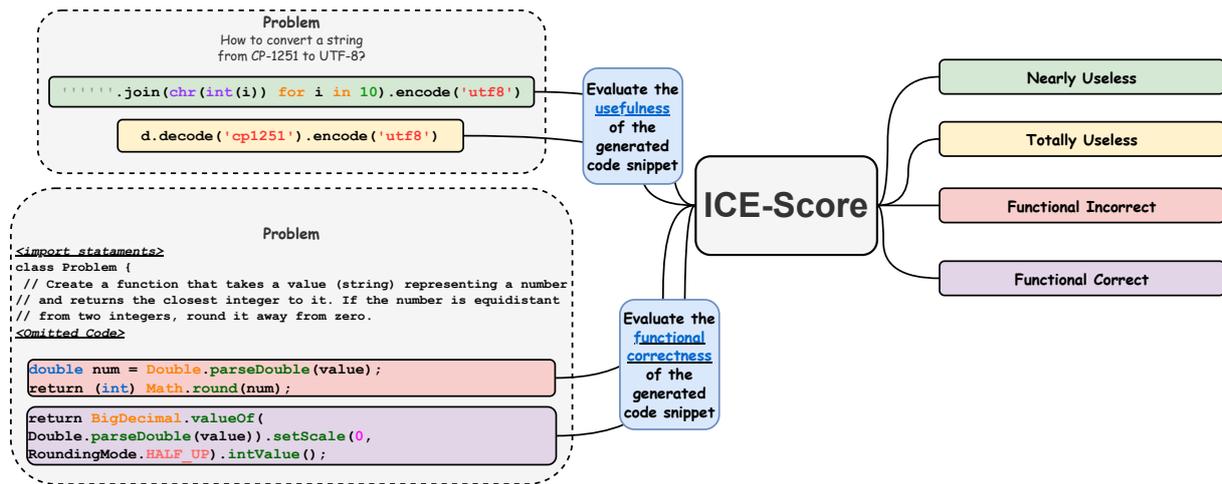

Figure 1: An illustration of ICE-Score. On the left-hand side, we input the task problems and corresponding generated code snippets. On the right-hand side, ICE-Score outputs the corresponding assessments.

concepts and more complex syntax than natural language generation (Hindle et al., 2016). Traditional reference-based evaluation metrics for code generation, such as BLEU (Papineni et al., 2002), ROUGE (Lin, 2004), and chrF (Popović, 2015), rely on token matching to assess performance automatically. However, these metrics have demonstrated poor correlation with human evaluation (Evtikhiev et al., 2023) since they often underestimate the variety of outputs with the same semantic logic. While some studies have incorporated programming features to improve these metrics, they have shown limited gains and poor correlation with functional correctness (Eghbali and Pradel, 2022; Tran et al., 2019). Alternatively, researchers have proposed using well-designed test suites to objectively evaluate code generation performance at the function level (Chen et al., 2021; Zheng et al., 2023; Cassano et al., 2023). However, developing these test suites requires programming expertise, which can be impractical and costly in low-resource scenarios. Additionally, executing model-generated code poses a security risk and must be run in an isolated sandbox, which is technically cumbersome.

More recently, CodeBERTScore (Zhou et al., 2023), a neural-model-based evaluation metric, has been proposed, showing a higher correlation with functional correctness and human preferences by capturing the semantic information of reference code and generated code. However, CodeBERTScore still relies on high-quality references that can be difficult and expensive to obtain. Moreover, the limited performance of the Code-

BERT (Feng et al., 2020) backbone suggests that it has not yet reached a human-level understanding of source code, limiting the effectiveness of CodeBERTScore. Therefore, more advanced evaluation metrics are needed so that they can better capture the complex syntax and semantics of code intelligence tasks.

To address these challenges, we propose a novel evaluation metric based on LLMs trained on both text and code, shown in Figure 1. Specifically, we Instruct LLMs to perform human-like multi-dimensional Code Evaluation, where the metric is denoted as ICE-Score. Our metric leverages the recent NLG metric, G-EVAL (Liu et al., 2023), but achieves superior correlations with subjective human preferences and objective functional correctness, both at the example and corpus levels. Different from G-EVAL, ICE-Score only relies on assessment criteria and evaluation step template, without the need for instruction generation and weighted scoring function.

Based on our extensive evaluation, we have summarized our contributions as follows:

- We designed the first multi-dimensional and reference-free automatic evaluation metric for code intelligence tasks via large language models.
- We conducted extensive experiments to demonstrate the efficacy of ICE-Score on four programming languages (Java, Python, C, C++, and JavaScript) from two aspects (*human-based usefulness* and *execution-based functional correctness*).

- We further discussed several aspects that can improve the performance of ICE-Score, including the backbone model performance and reasoning capability.

## 2 Method

Our evaluation metric ICE-Score, inspired by G-EVAL (Liu et al., 2023), consists of two main components: 1) task definition, evaluation criteria, and detailed evaluation steps, and 2) a given problem and generated code snippet for evaluation. Different from G-EVAL, we only require the input of evaluation criteria and template-based evaluation steps, without the need for generation from LLMs. In addition, As we set the model temperature to 0, our evaluation metric no longer needs a weighted scoring function after iterative score generation. These two differences suggest that ICE-Score is more cost-friendly and efficient.

### 2.1 Instructions for Code Evaluation

The evaluation of code quality involves two main aspects: 1) human judgment of code usefulness and 2) execution-based functional correctness. To provide a comprehensive evaluation, we adopt the design of G-EVAL for the general task instruction, as follows:

*You will be given the code snippet for a problem. Your task is to rate the code snippet only on one metric. Please make sure you read and understand these instructions carefully. Please keep this document open while reviewing, and refer to it as needed.*

Regarding the task-agnostic prompt, we have designed the evaluation criteria for assessing **code usefulness**, as shown in Appendix A.1. These criteria are aligned with previous human evaluations of code quality (Evtikhiev et al., 2023). To evaluate **functional correctness**, we emphasize the importance of considering unit tests during the evaluation process. We present the following criteria for evaluating functional correctness, as provided in Appendix A.2.

For the instruction of evaluation steps, we provide a template-based prompt:

*Evaluation Steps:*

*1. Read the problem carefully and identify the required functionalities of the implementation.*

*2. Read the code snippet and compare it to the problem. Check if the code snippet covers all required functionalities of the problem, and if it aligns with the Evaluation Criteria.*

*3. Assign a score for [Evaluation Aspect] on a scale of 0 to 4, where 0 is the lowest and 4 is the highest based on the Evaluation Criteria.*

Here, we define **[Evaluation Aspect]** as any aspects that are emphasized during the evaluation. In our paper, we consider **code usefulness** and **functional correctness**.

### 2.2 Inputs of Code Evaluation

It is worth noting that most code generative models do not take formatting into account, resulting in unformatted code that requires post-processing of code formatting to be understood, compiled, and executed (Zheng et al., 2023). Additionally, automatic evaluation metrics for code generation, such as CodeBLEU (Ren et al., 2020) and RUBY (Tran et al., 2019), still rely on language-specific program parsers<sup>2</sup>. However, based on prior findings that LLMs can robustly understand input data (Huang et al., 2022; Zhuo et al., 2023; Zhu et al., 2023), we hypothesize that LLMs can also understand programming context without proper formatting. Therefore, for evaluation, we input the problems and generated code (and reference code, if provided). When the reference code is provided, we slightly modify the evaluation steps in the prompt to incorporate it.

## 3 Experiment Setup

We evaluate the effectiveness of ICE-Score using GPT-3.5 (GPT-3.5-turbo<sup>3</sup>) as the backbone across multiple datasets and programming languages. We conduct two experiments to investigate the correlation between ICE-Score and human preference and functional correctness, respectively. We compare the performance of LLM-based evaluations against 7 predominant automatic evaluation metrics, including the state-of-the-art CodeBERTScore (Zhou et al., 2023). To measure the correlation with human preference, we use the

<sup>2</sup><https://tree-sitter.github.io/>

<sup>3</sup><https://platform.openai.com/docs/models/gpt-3-5>

CoNaLa dataset (Yin et al., 2018) and corresponding human annotation on the generated code from various models trained on the dataset (Evtikhiev et al., 2023). To measure the correlation with functional correctness, we use the HumanEval-X dataset (Zheng et al., 2023). We do not consider **distinguishability** as an evaluation option, as prior work (Zhou et al., 2023) has shown it to be an unreliable meta-metric that cannot substitute for execution-based or human-based ratings.

### 3.1 Automatic Evaluation Metric Baselines

The baseline metrics we include can be classified into two groups: **string-based** and **neural-model-based** evaluation.

**String-based Evaluation** Most evaluation metrics in code generation have been adapted from natural language generation (NLG) and rely on comparing the generated code to reference code. The most commonly used metric is BLEU (Papineni et al., 2002), which computes the overlaps of  $n$ -grams in the generated output with those in the reference, where the  $n$ -grams are tokenized using a language-specific tokenizer (Post, 2018). Other metrics include ROUGE-L (Lin, 2004), a recall-oriented metric that looks for the longest common subsequence between the reference and the generated code, and METEOR (Banerjee and Lavie, 2005), which is based on unigram matching between the generated code and the reference. However, studies have shown that BLEU may yield similar results for models with different quality levels from the perspective of human graders in code generation (Evtikhiev et al., 2023), leading to the proposal of new evaluation metrics such as RUBY (Tran et al., 2019). RUBY takes the code structure into account and compares the program dependency graphs (PDG) of the reference and the candidate. If the PDG is impossible to build, the metric falls back to comparing the abstract syntax tree (AST), and if the AST is also impossible to build, it compares the weighted string edit distance between the tokenized reference and candidate sequence. Another recent metric is CodeBLEU (Ren et al., 2020), which is a composite metric that computes a weighted average of four sub-metrics treating code differently: as a data-flow graph, as an abstract syntax tree, and as text. CodeBLEU is designed to evaluate the quality of generated code for code generation, code translation, and code refinement tasks.

Metric	Example			Corpus		
	$\tau$	$r_p$	$r_s$	$\tau$	$r_p$	$r_s$
BLEU	.439	.522	.488	.423	.572	.542
CodeBLEU	.292	.363	.331	.259	.397	.339
chrF	.458	.570	.515	.449	<u>.592</u>	.578
ROUGE-L	.447	.529	.499	.432	.581	.552
METEOR	.410	.507	.462	.415	.557	.534
RUBY	.331	.397	.371	.339	.493	.439
CodeBERTScore-F1	.500	<u>.609</u>	.556	<u>.464</u>	.579	<u>.595</u>
CodeBERTScore-F3	<u>.505</u>	<u>.609</u>	<u>.563</u>	.437	.549	.564
ICE-Score	<b>.556</b>	.613	<b>.594</b>	<b>.546</b>	.649	<b>.635</b>
Ref-ICE-Score	.554	<b>.617</b>	.591	.539	<b>.661</b>	.630

Table 1: Example-level and corpus-level Kendall-Tau ( $\tau$ ), Pearson ( $r_p$ ) and Spearman ( $r_s$ ) correlations with the human preferred usefulness on CoNaLa. ICE-Score: without reference code inputs, or reference-free; Ref-ICE-Score: reference-enhanced. The best performance is **bold**. The second-best performance is underlined.

**Neural-model-based Evaluation** Neural-model-based evaluation is becoming increasingly important for evaluating the quality of code generated by deep learning models. CodeBERTScore (Zhou et al., 2023) is one of the latest approaches that leverages pre-trained code models like CodeBERT (Feng et al., 2020) and best practices from natural language generation evaluation to assess the quality of generated code. CodeBERTScore encodes the generated code and reference code independently and considers the natural language context, contextual information of each token, and implementation diversity. It enables the comparison of code pairs that are lexically different and calculates precision and recall based on the best-matching token vector pairs. This approach provides an effective way to evaluate the effectiveness of deep learning models for code intelligence tasks. Note that the authors of CodeBERTScore provided both F1 and F3 scores, with the optional source input. Therefore, we use these four language-specific variants of CodeBERTScore in our experiments.

### 3.2 Datasets and Evaluation Aspects

**Human-based Usefulness Experiments** Similar to (Zhou et al., 2023), we conduct an evaluation on the CoNaLa benchmark (Yin et al., 2018), which is a widely used dataset for natural language context to Python code generation. To measure the correlation between each evaluation metric and human preference, we utilize the human annotations provided by (Evtikhiev et al., 2023). Specifically, for each example in the dataset, experienced software

Metric	Java		C++		Python		JavaScript		Average	
	$\tau$	$r_s$								
BLEU	.337	.401	.146	.174	.251	.297	.168	.199	.225	.268
CodeBLEU	.355	.421	.157	.187	.272	.323	.226	.267	<u>.253</u>	<u>.299</u>
chrF	.346	.413	.166	.198	.262	.312	.186	.220	.240	.286
ROUGE-L	.327	.389	.143	.171	.240	.284	.151	.179	.215	.256
METEOR	.358	.425	<u>.174</u>	<u>.208</u>	<u>.276</u>	<u>.327</u>	<u>.195</u>	<u>.231</u>	.251	.298
RUBY	.340	.401	.139	.165	.216	.255	.138	.163	.208	.246
CodeBERTScore-F1	.314	.375	.148	.177	.231	.276	.145	.172	.209	.250
CodeBERTScore-F3	.356	.426	.166	.198	.262	.312	.189	.226	.243	.291
ICE-Score	<b>.427</b>	<b>.442</b>	<b>.320</b>	<b>.326</b>	.279	.282	.316	.321	<b>.336</b>	<b>.343</b>
Ref-ICE-Score	.388	.404	.274	.282	<b>.318</b>	<b>.325</b>	<b>.340</b>	<b>.348</b>	.330	.340

Table 2: Example-level Kendall-Tau ( $\tau$ ) and Spearman ( $r_s$ ) correlations with the execution-based functional correctness on HumanEval. ICE-Score: without reference code inputs, or reference-free; Ref-ICE-Score: with reference code inputs, or reference-enhanced. The best performance is **bold**. The second-best performance is underlined.

developers were asked to grade the generated code snippets from five different models. The grading scale ranges from zero to four, with zero indicating that the generated code is irrelevant and unhelpful, and four indicating that the generated code solves the problem accurately. The dataset comprises a total of 2,860 annotated code snippets (5 generations  $\times$  472 examples) with each snippet being graded by 4.5 annotators on average.

**Execution-based Functional Correctness Experiments** We conduct an evaluation of functional correctness using the HumanEval benchmark (Chen et al., 2021), which provides natural language goals, input-output test cases, and reference solutions written by humans for each example. The benchmark originally consists of 164 coding problems in Python, and has been extended by (Cassano et al., 2023) to 18 other programming languages, including Java, C++, Python, and JavaScript. We chose to evaluate our models on these languages, as they are among the most popular programming languages. The translated examples also include the predictions of code-davinci-002 and their corresponding functional correctness scores. Inspired by (Zhou et al., 2023), we obtain them from the HumanEval-X dataset (Zheng et al., 2023). As each problem has nearly 200 generated code samples on average, it would be computationally expensive to evaluate them all using LLMs. Therefore, we randomly select 20 samples from each problem, and collect all samples from problems where no more than 20 versions of code were generated.

**Correlation Metrics** To measure the correlation between each metric’s scores and the references, we follow best practices in natural language evaluation and used Kendall-Tau ( $\tau$ ), Pearson ( $r_p$ ), and Spearman ( $r_s$ ) coefficients.<sup>4</sup> To systematically study the efficacy of each automatic evaluation metric, we compute both example-level and corpus-level correlations. The example-level correlation is the average correlation of each problem example, while the corpus-level correlation is the correlation of all aggregated examples in the task.

## 4 Results

**Human-based Usefulness** Table 1 shows the correlation between different metrics with human preference. We compare two variants of our evaluation approach, reference-free and reference-enhanced evaluations, with 10 baseline metrics and their variants. We find that ICE-Score outperform these metrics by a significant margin, regarding both example- and corpus-level correlations. Our observation is consistent with the work of CodeBERTScore, where the variants of CodeBERTScore mostly outperform the strong baselines like chrF and ROUGE-L. For example, ICE-Score achieves 0.556 and 0.546 measured by Spearman correlation on example level and corpus level, respectively. In contrast, prior evaluation metrics barely reach a score of 0.5. In addition, we find that Ref-ICE-Score does not significantly improve the performance, indicating the reference code may not be optimized. Our further analysis of the human rating of CoNaLa reference code complies

Ref-ICE-Score	<b>.412</b>	<b>.438</b>	<b>.367</b>	<b>.383</b>	<b>.425</b>	<b>.446</b>	<b>.432</b>	<b>.455</b>	<b>.409</b>	<b>.431</b>

Table 3: Corpus-level Kendall-Tau ( $\tau$ ) and Spearman ( $r_s$ ) correlations with the execution-based functional correctness on HumanEval. ICE-Score: without reference code inputs, or reference-free; Ref-ICE-Score: with reference code inputs, or reference-enhanced. The best performance is **bold**. The second-best performance is underlined.

with this implication, where the average score of the reference code only achieves 3.4 out of 4, suggesting that not all human practitioners consider the reference fully useful.

**Execution-based Functional Correctness** Table 2 and Table 3 present the results of example- and corpus-level functional correctness, respectively. From Table 2, we observe that both reference-free and reference-enhanced Ref-ICE-Scores consistently outperform the other baselines across all four programming languages on the example level. ICE-Score even outperforms the reference-enhanced one, suggesting potential bias in some reference code. Additionally, we find that METEOR and CodeBLEU receive better correlations than all variants of CodeBERTScore, indicating that they are still strong baselines compared to the recent neural-model-based evaluators in code generation. In Table 3, we observe that our Ref-ICE-Score achieves state-of-the-art performance among all evaluation metrics. When compared to other baselines, ICE-Score still achieves comparable results to the source-free CodeBERTScore-F3.

## 5 Ablation Study

**Does reasoning help the code evaluation?** Prior work (Wei et al.; Kojima et al.) has demonstrated that the performance of LLMs can be significantly improved via Chain-of-Thought (CoT) and Zero-Shot-Chain-of-Thought (ZS-CoT), where the prompts instruct LLMs to perform the task in a step-by-step manner. Here, we explore the zero-shot reasoning ability of LLMs in evaluating code generation. Specifically, we instruct GPT-3.5 to

Metric	Example			Corpus		
	$\tau$	$r_p$	$r_s$	$\tau$	$r_p$	$r_s$
ICE-Score	.556	.613	.594	.546	.649	.635
CoT-ICE-Score	<b>.561</b>	<b>.628</b>	<b>.600</b>	<b>.579</b>	<b>.703</b>	<b>.665</b>
Ref-ICE-Score	.554	.617	.591	.539	.661	.630
CoT-Ref-ICE-Score	<b>.571</b>	<b>.639</b>	<b>.607</b>	<b>.583</b>	<b>.712</b>	<b>.667</b>

Table 4: Example-level and corpus-level Kendall-Tau ( $\tau$ ), Pearson ( $r_p$ ) and Spearman ( $r_s$ ) correlations with the human preferred usefulness on CoNaLa. ICE-Score: without reference code inputs, or reference-free; Ref-ICE-Score: with reference code inputs, or reference-enhanced. CoT- indicates the use of ZS-CoT. The best performance is **bold**.

perform CoT-evaluation by adding "Step-by-step Evaluation:" at the end of the prompt. An example of the zero-shot-CoT prompt is shown in Figure 2. Instead of using LLMs to extract the evaluation score from the reasoning steps, like the original metric of zero-shot-CoT via multiple queries, we design a rule-based parser to extract scores. Due to limited resources, we only evaluate on CoNaLa in Table 4. Our results show that ZS-CoT can significantly improve the reliability of code evaluation. Additionally, we find that Ref-ICE-Score can achieve better results than reference-free ones via ZS-CoT, even though their performances are similar without CoT processing. This suggests that LLMs can exploit the use of reference code through reasoning.

**Does more-capable backbone LLM yield better performance on code evaluation?** As shown in previous studies (OpenAI, 2023; Bubeck et al., 2023), GPT-4 significantly outperforms GPT-3.5 on various tasks. Therefore, we use GPT-4 as the backbone model for ICE-Score and evalu-

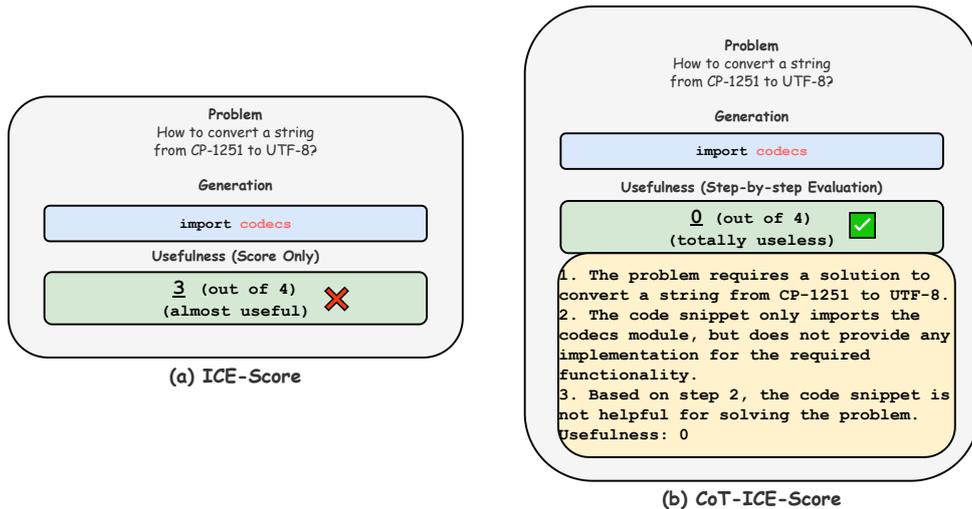

Figure 2: Example inputs and outputs with (a) ICE-Score, (b) ICE-Score with Zero-Shot Chain-of-Thought. With the step-by-step evaluation, the output assessment is more aligned with human preference.

Metric	Example			Corpus		
	$\tau$	$r_p$	$r_s$	$\tau$	$r_p$	$r_s$
ICE-Score-3.5	.556	.613	.594	.546	.649	.635
ICE-Score-4	<b>.612</b>	<b>.658</b>	<b>.611</b>	<b>.592</b>	<b>.720</b>	<b>.688</b>
Ref-ICE-Score-3.5	.554	.617	.591	.539	.661	.630
Ref-ICE-Score-4	<b>.592</b>	<b>.647</b>	<b>.634</b>	<b>.632</b>	<b>.744</b>	<b>.690</b>

Table 5: Example-level and corpus-level Kendall-Tau ( $\tau$ ), Pearson ( $r_p$ ) and Spearman ( $r_s$ ) correlations with the human preferred usefulness on CoNaLa. ICE-Score: without reference code inputs, or reference-free; Ref-ICE-Score: with reference code inputs, or reference-enhanced. -3.5 and -4 suggest the different backbone models. The best performance is **bold**.

ate its performance on CoNaLa. The results in Table 5 indicate that GPT-4 consistently surpasses GPT-3.5-turbo on evaluating code, suggesting it has the superior capability of code comprehension. We also note that using a more capable model like GPT-4 can guarantee even better performance, compared to using ZS-CoT techniques in Table 4.

## 6 Discussion

**Data Contamination** Evaluations on recent closed-source LLMs have been criticized for the possibility of data contamination (Aiyappa et al., 2023), where the model may have already seen the evaluation datasets during training, due to the opaque training details of these models. For instance, Kocmi and Federmann (2023) conducted an empirical study on a few closed-source LLMs, including GPT-3.5, and suggested that LLMs are the state-of-the-art evaluators of translation qual-

ity, based on the evaluation of the WMT22 Metric Shared Task (Freitag et al., 2022). However, as most of the evaluated models were trained on data prior to 2022<sup>5</sup>, it is highly likely that these models have been trained with some human-rated translation quality data. Similarly, G-EVAL (Liu et al., 2023) shows that GPT-3.5 and GPT-4 are the state-of-the-art evaluators of natural language generation (NLG) with the evaluation of three NLG datasets. However, as these human-annotated datasets were released before 2021, it is probable that they were included in the training data of GPT-3.5 and GPT-4. In contrast, our work is minimally impacted by data contamination, as we report the data release year in Table 6. Our analysis suggests that only CoNaLa and HumanEval (Python) datasets may have been contaminated, and it is unlikely that GPT-3.5 has seen any human annotation or generated code during training.

**Human-aligned Evaluation Beyond Code Generation** While our study has shown that LLMs can achieve state-of-the-art performance in evaluating the functional correctness and usefulness of generated source code, the question remains as to whether LLMs can be utilized to evaluate code intelligence tasks beyond code generation. Allamanis et al. (2018) have identified several downstream applications such as code translation, commit message generation, and code summarization. While some studies have investigated the human evaluation of these tasks, none of them have released

<sup>5</sup><https://platform.openai.com/docs/model-index-for-researchers>

Dataset	Release Year	Likely to be contaminated?
CoNaLa	2018	✓
human-annotated CoNaLa w/ generated code	2023	✗
HumanEval (Python)	2021	✓
HumanEval-X (w/o Python)	2023	✗
human-annotated HumanEval-X w/ generated code	2023	✗

Table 6: Dataset, Release Year and the likelihood of data contamination for each dataset used in our study.

the annotation data or fully described the human evaluation criteria. This presents a challenge for analyzing if `ICE-Score` can be adapted to these tasks. For example, [Hu et al. \(2022\)](#) proposed a human evaluation metric for code documentation generation quality, which is specifically designed for code comment generation and commit message generation. Their metric includes three aspects: *Language-related*, *Content-related*, and *Effectiveness-related*, with detailed task descriptions and explanations of assigned scores. We propose that the information provided in their metric can be used to create prompts for LLM-based evaluation and enable human-aligned evaluation of code documentation generation.

## 7 Related Work

**Large Language Models for Code.** LLMs pre-trained on large-scale code data have demonstrated strong capabilities in code intelligence tasks, such as code completion ([Li et al., 2023](#); [Luo et al., 2023](#); [Rozière et al., 2023](#)), code summarization ([Ahmed and Devanbu, 2022](#); [Sun et al., 2023](#)) and program repair ([Surameery and Shakor, 2023](#); [Sobania et al., 2023](#)). However, they remain unreliable, particularly in scenarios that require an understanding of natural language. Recent studies ([Muenighoff et al., 2023b](#); [Ma et al.](#)) show that pre-training on both text and code results in the optimal model performance on natural language and code understanding. Furthermore, in order to make LLMs more human-aligned and more capable of performing complex tasks, instruction tuning is proposed to enhance the capability of following natural language requirements. In this work, we utilize such instruction-tuned LLMs to conduct multi-dimensional code evaluation via various instructions.

**Automatic Evaluation Metrics for Generation.** The quest for reliable and robust automatic evaluation metrics for generated content has been a cornerstone in natural language processing. Tradi-

tionally, string-based metrics such as BLEU ([Papineni et al., 2002](#)), ROUGE ([Lin, 2004](#)), and METEOR ([Banerjee and Lavie, 2005](#)) have dominated the landscape, primarily when assessing machine translation or text summarization outputs. While these metrics provide a quick and cost-effective means of evaluating the quality of the generated text, they often fall short of capturing the nuanced intricacies and semantic richness inherent in natural language. To mitigate such drawbacks, a few neural-based multi-dimensional evaluation metrics have been proposed for text generation, such as UniEval ([Zhong et al., 2022](#)), GPTScore ([Fu et al., 2023](#)) and G-EVAL ([Liu et al., 2023](#)). However, when it comes to code generation, where both syntactical correctness and semantic intent are paramount, there are few attempts to address these challenges. Instead, the most dominant metrics still compute the similarity between generated code and reference code. In this work, we introduce `ICE-Score`, a novel metric that not only addresses the limitations of its predecessors but also harnesses the capabilities of LLMs, setting a new benchmark for the evaluation of code generation tasks.

## 8 Conclusion

In this paper, we propose a novel evaluation metric based on large language models trained on both text and code, which can better capture the complex syntax and semantics of code intelligence tasks. Our metric achieves superior correlations with subjective human preferences and objective functional correctness, both at the example and corpus levels, without reference and test suites. We conduct an extensive evaluation of four programming languages (Java, Python, C, C++, and JavaScript) and demonstrate the effectiveness of our proposed method on human-based usefulness and execution-based functional correctness. We have publicly released our evaluation metrics and datasets to encourage the development of more accurate and effective evaluation metrics for tasks involving source code.

## Acknowledgements

## Limitations

Our proposed evaluation metric is based on the assumption that LLMs can follow the instructions to evaluate the code snippets. The backbone models we investigated are closed-source state-of-the-art LLMs from OpenAI. As we noticed that there is a huge performance gap between current closed-source and open-source LLMs, it is possible that `ICE-Score` can be adapted with an open-source LLM trained on code and text, such as WizardCoder (Luo et al., 2023) and OctoPack (Muenighoff et al., 2023a). Hence, we encourage future investigations on open-source LLMs for code evaluation. In addition, as discussed in Section 6, our experiments only focus on two code generation tasks. There are other code intelligence tasks like program repair and code summarization. However, due to the limited study on human evaluation of these tasks, no open-source dataset is publicly available or documented in detail. Finally, `ICE-Score` assumes that either model weights or model APIs are available, which is costly for some users. We, therefore, suggest future work on proposing low-cost evaluation metrics.

## A Prompts for Code Evaluation

### A.1 Code Usefulness

*Evaluation Criteria:*

*Usefulness (0-4) Usefulness of the code snippet based on the problem description.*

*- A score of 0: Snippet is not at all helpful, it is irrelevant to the problem.*

*- A score of 1: Snippet is slightly helpful, it contains information relevant to the problem, but it is easier to write the*

*solution from scratch.*

*- A score of 2: Snippet is somewhat helpful, it requires significant changes (compared to the size of the snippet), but is still useful.*

*- A score of 3: Snippet is helpful, but needs to be slightly changed to solve the problem.*

*- A score of 4: Snippet is very helpful, it solves the problem.*

### A.2 Functional Correctness

*Evaluation Criteria:*

*Functional Correctness (0-4) - Execution-based quality of the code snippet combined with the problem. The correctness is measured by all possible unit tests and the comparison of the reference code. The combination of the code snippet and the problem should pass all the possible tests based on your understanding of the reference code. The length of the code snippet can not determine the correctness. You need to assess the logic line by line.*

*- A score of 0 (failing all possible tests) means that the code snippet is totally incorrect and meaningless.*

*- A score of 4 (passing all possible tests) means that the code snippet is totally correct and can handle all cases.*

## B Automatic Evaluation Metric Baselines

Our implementations of the automatic evaluation metric baselines except for CodeBERTScore are based on <https://github.com/JetBrains-Research/codegen-metrics>. For CodeBERTScore, we adopt the official release at <https://github.com/neulab/code-bert-score>.

## C Correlation Metrics

For all correlation metrics, we use the implementation from <https://scipy.org/> and call these APIs with the default settings.

# CReSE: Benchmark Dataset and Automatic Evaluation Framework for Recommending Eligibility Criteria from Clinical Trial Information

## Abstract

Eligibility criteria (EC) refer to a set of conditions an individual must meet to participate in a clinical trial, defining the study population and minimizing potential risks to patients. Previous research in clinical trial design has been primarily focused on searching for similar trials and generating EC within manual instructions, employing similarity-based performance metrics, which may not fully reflect human judgment. In this study, we propose a novel task of recommending EC based on clinical trial information, including trial titles, and introduce an automatic evaluation framework to assess the clinical validity of the EC recommendation model. Our new approach, known as **CReSE** (**C**ontrastive learning and **R**e-phrasing-based and **C**linical **R**elevance-preserving **S**entence **E**mbedding), represents EC through contrastive learning and rephrasing via large language models (LLMs). The CReSE model outperforms existing language models pre-trained on the biomedical domain in EC clustering. Additionally, we have curated a benchmark dataset comprising 3.2M high-quality EC-title pairs extracted from 270K clinical trials available on ClinicalTrials.gov. The EC recommendation models achieve commendable performance metrics, with 49.0% precision@1 and 44.2% MAP@5 on our evaluation framework. We expect that our evaluation framework built on the CReSE model will contribute significantly to the development and assessment of the EC recommendation models in terms of clinical validity.

## 1 Introduction

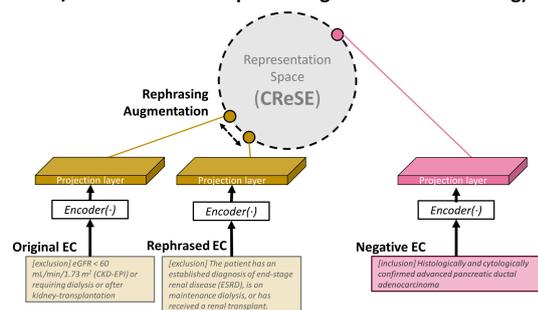

Eligibility criteria (EC) consist of statements that outline the characteristics participants must pos-

sess to be included in a randomized controlled trial (RCT) (FDA, 2020). EC are typically divided into inclusion and exclusion criteria, covering diverse clinical factors such as age, sex, medical history, disease severity, previous treatments, and other physiologic parameters (Duggal et al., 2021). EC are a key design factor of RCTs, along with randomization and blinding, which contribute to the production of causal evidence between intervention and outcome (Akobeng, 2005; Listl et al., 2016). Moreover, EC are an important component of the enrichment strategy and minimize potential risk to study participants (Kim et al., 2017; FDA, 2023).

However, there are concerns that EC are overly restrictive (Breithaupt-Groegler et al., 2017; Osarogiagbon et al., 2021). While restrictive EC ensure homogeneity in the study population (Kim et al., 2021), they may also limit the generalizability of clinical findings and impede the translation of research results into clinical practice. Furthermore, the EC used by previous RCTs are often employed as templates for new trials without appropriate modifications (FDA, 2020). This practice can perpetuate issues such as the under-representation of specific patient subgroups (e.g., children, the elderly, and individuals with infections like HIV infection) (Humphreys et al., 2007; Uldrick et al., 2017).

To overcome these problems, previous studies attempted to automate EC generation or search for similar trials to aid in clinical trial design (Wang et al., 2023b,a; Wang and Sun, 2022). However, these studies relied on similarity-based performance metrics, which do not account for human judgment and clinical semantic similarity (Gehrmann et al., 2023; Moramarco et al., 2022).

**(a) CReSE model (Contrastive learning and Rephrasing-based/Clinical Relevance-preserving Sentence Embedding)**

**(b) EC recommendation from clinical trial information**

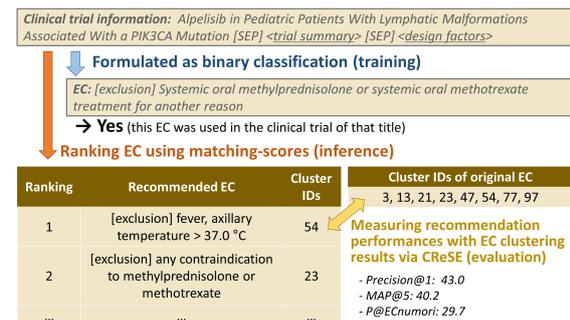

Figure 1: Study overview. a) We develop the CReSE model using contrastive learning and text rephrasing via LLMs to obtain a sentence embedding that preserves clinical relevance between EC. b) We introduce a task of recommending EC from clinical trial information, including trial titles, and provide an automatic evaluation framework to assess the clinical validity of the EC recommendation model using the CReSE model.

Furthermore, certain EC, such as age requirements, are widely employed across studies and are less specific to the purposes and designs of clinical trials (Jin et al., 2017; Magnuson et al., 2021). The presence of these common EC may have led to an overestimation of the model’s performance.

In response, this study aims to recommend EC from clinical trial information, such as titles and summaries, to meet the needs of drug development and clinical evidence generation (Figure 1b). In addition, we propose an automatic evaluation framework to assess the clinical validity of EC recommendation models. To accomplish this, we develop sentence embedding, called **CReSE** (Contrastive learning and **R**ephrasing-based and **C**linical **R**elevance-preserving **S**entence **E**mbedding) (Figures 1a and 2). By employing CReSE, which capture clinical semantic similarities among EC, we assessed the outcomes of the EC recommendation model and leveraged them to enhance the quality of training data. Lastly, we investigate the characteristics that EC recommen-

dation models should possess to be useful in clinical trial design for drug development, as discerned through human evaluation.

To the best of our knowledge, this study is the first attempt to formulate the EC recommendation task. Additionally, in this study, we explored the diverse utility of LLMs in handling biomedical texts in a clinically plausible manner, including rephrasing EC to develop sentence embedding, and streamlining the EC recommendation model into an end-to-end recommendation system.

The main contributions of this paper are as follows:<sup>1</sup>

- We introduce a task and benchmark dataset of recommending EC from clinical trial information without any manual instruction.
- We develop CReSE, a sentence embedding that preserves clinical relevance between EC, to establish an automatic evaluation framework and enhance the quality of training data.
- We assess the feasibility of the EC recommendation model through human evaluation.

## 2 Related Works

Natural language processing research on EC has taken two main paths. The first approach focuses on converting free-text EC into structured criteria or queries using information extraction or context-free grammars (Weng et al., 2011; Kang et al., 2017; Yuan et al., 2019). These studies, known as ‘patient-trial matching’, ultimately aim to estimate the number of patients who match a proposed trial design based on in-hospital electronic medical records (EMRs) before patient enrollment (Zhang et al., 2020). However, a challenge in this approach is the lack of consensus on a universal query grammar for EC (Tu et al., 2009; Boland et al., 2012; Hao et al., 2016).

The second research stream involves studies that generate EC with manual instruction or search for similar trials to aid in clinical trial design (Zhang et al., 2020; Wang and Sun, 2022; Wang et al., 2023b,a; Jin et al., 2023). The AutoTrial study, for instance, proposed a hybrid approach that combines discrete and neural prompting in generating EC (Wang et al., 2023b). Furthermore, the PyTrial study aimed to create a unified Python package that

<sup>1</sup>All data and code used in this study are available at [https://github.com/SiunKim/clinical\\_trial\\_eligibility\\_criteria\\_recommendation](https://github.com/SiunKim/clinical_trial_eligibility_criteria_recommendation).

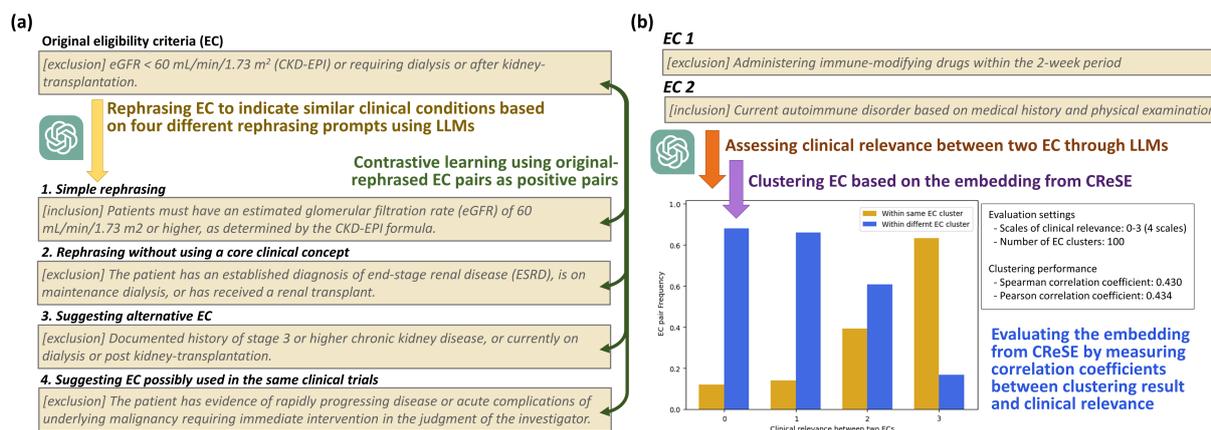

Figure 2: Overview of the development and evaluation of the CReSE model. a) Original EC and their rephrased counterparts generated from four different rephrasing prompts are used as positive pairs in contrastive learning. b) Correlation coefficients between clustering results and clinical relevance assessed by a human expert are employed as the clustering performance measures.

incorporates diverse AI algorithms for tasks related to clinical trials (Wang et al., 2023a).

However, to this date, no study has endeavored to recommend EC exclusively from clinical trial information without manual instructions. Moreover, previous studies have relied on traditional summarization metrics, such as BLEU or ROUGE, and EC parsers in evaluating their models (FAIR, 2022). However, these metrics are still insufficient for measuring clinical semantic similarity between EC, and clinical trial parsers have limited performances on complex EC (Gehrmann et al., 2023; Moramarco et al., 2022).

## 3 Method

### 3.1 Common EC classification

In clinical trials, certain EC, such as “age over 18” or “Patients must provide written, informed consent before any study procedures” are widely used in clinical trials, irrespective of the trial’s objectives or designs. (Duggal et al., 2021). We refer to these commonly used EC as ‘common EC.’ Throughout this study, we exclude common EC to prevent potential overestimation of the EC recommendation model’s performance and to enhance the heterogeneity of the EC dataset for contrastive learning (Appendix B.1, D.1, and E.1).

### 3.2 The CReSE model

#### 3.2.1 Prompts for rephrasing EC

We employed contrastive learning and rephrasing via LLMs as text augmentation to develop the CReSE model. We aimed to extract knowledge

about clinical relevance between EC from LLM through rephrasing and inject this knowledge into the embedding system. In designing the rephrasing prompts, we had two primary goals: 1) to generate diverse natural language expressions for the same patient selection condition, and 2) to obtain EC pairs suitable for selecting similar patient populations in real-world clinical settings or as interchangeable alternatives. Aligned with these design objectives, we devised four different types of rephrasing prompts (Figure 2a):

- **Simple rephrasing** This prompt involves a direct rewording of the input EC. Its purpose is to account for differences in EC description across clinical trials, even when conveying the same content.
- **Rephrasing without core clinical concepts** With this prompt, we aimed to integrate the meaning and context of clinical concepts frequently used in EC into the CReSE model.
- **Suggesting alternative EC** This prompt explores clinical relevance based on the epidemiological co-occurrence among different patient conditions.
- **Suggesting EC possibly used in the same clinical trial** This prompt aids in generating EC variations that might be used within the same clinical trial.

We utilized the ChatGPT model, specifically gpt-3.5-turbo-0301, for EC rephrasing. We obtained a total of 50K original-rephrased EC pairs, which

were used as positive pairs during contrastive learning (Appendix A.2).

### 3.2.2 Contrastive learning

The CReSE model consists of a text encoder and a projection layer. We utilized the embedding of the [CLS] token, which was obtained after passing through both the text encoder and the projection layer, as the EC embedding. The training process of the text encoder was initialized from pre-trained checkpoints of BioLinkBERT (Yasunaga et al., 2022), which exhibited superior performance in classifying common EC among diverse language models (LMs) used in fine-tuning (Appendix B.1).

The CReSE model was trained by maximizing the cosine similarity between embeddings of  $N$  positive pairs and minimizing the cosine similarity of  $N^2 - N$  negative pairs within a batch of  $N$  EC pairs. This training methodology follows the approach used in the CLIP study (Radford et al., 2021). The symmetric cross-entropy loss was used during this training process. Given the notable diversity in the original EC dataset, already achieved through the exclusion of common EC, we chose not to introduce additional techniques for sampling negative pairs.

### 3.3 EC Recommendation Model

We formulated the EC recommendation task as a binary classification, where a pair of individual EC and free-text clinical trial information served as input. The objective is to predict whether a given EC was used in a clinical trial with a specific title and trial information. The positive EC-title pairs consisted of 1.6M non-common EC selected from ClinicalTrials.gov.

The negative EC-title pairs were basically generated by random sampling of EC and trial titles. However, since an identical or similar EC are used in different clinical trials, simply applying random sampling to obtain a negative sample cause a quality issue. Therefore, we took the following two steps to obtain a negative sample: 1) We chose trials where the number of ECs exceeds a predefined threshold (i.e., 8, the average number of EC used in clinical trials) to ensure the quality of EC reporting, and 2) We created an EC-title negative sample by randomly sampling EC whose clusters do not overlap with EC used in a selected trial. Here, EC clustering was conducted using EC embeddings derived from the CReSE model, described in Section 4.2.

Moreover, because relying solely on the title might not provide sufficient information to predict whether an EC was used in a clinical trial, we explored four different types of clinical trial information as input: 1) title only, 2) title + summary, 3) title + key design factors, and 4) title + summary + key design factors (Appendix C.2).

## 4 Experiments

### 4.1 Dataset

In this study, we collected trial information of 445K clinical trials registered on ClinicalTrials.gov from March 2002 to May 2023. From this initial dataset, we selected trials that satisfied several conditions (Appendix B.3) to ensure the quality of reported clinical trial information, resulting in a subset of 270K trials and 3M EC (Table 1). To facilitate comparisons with ChatGPT and GPT-4, we chose 5K trials both before and after September 2019, serving as the knowledge cutoff for these language models. We used this total of 10K trials as the test set.

### 4.2 EC clustering

For EC clustering, we randomly selected a subset of 0.1M EC from the training dataset. To address randomness in the EC selection, we carried out each experiment 20 times using different seed numbers. The results were summarized using the median and the 95% confidence interval of clustering performances. Additionally, due to the significance of the cluster number on performance metrics, we evaluated EC clustering across different numbers of EC clusters (100, 200, and 300).

#### 4.2.1 TF-IDF

To provide a simple baseline, we employed the TF-IDF (Term Frequency-Inverse Document Frequency) approach along with K-means clustering. Stopwords frequently used in EC were excluded before clustering.

#### 4.2.2 Clustering using EC embeddings

For obtaining EC embeddings, we applied mean pooling to the token embeddings of each individual EC. Subsequently, we performed K-means clustering using cosine similarity as the distance measure between EC embeddings. We compared the CReSE model against several LMs pre-trained on the biomedical domain: BioLinkBERT (Yasunaga et al., 2022), BioGPT (Luo et al., 2022), TrialBERT

	<b>Train-Valid</b>	<b>Test</b>
<b>Number of clinical trials</b>	260K	10K
<b>Number of EC (%)</b>		
Total	2.8M (100.0)	176K (100.0)
Common	1.2M (44.4)	78K (44.3)
Non-common	1.6M (55.6)	98K (55.7)
<b>Average number of EC per clinical trial</b>	10.7	17.6
<b>Length of EC in characters (mean <math>\pm</math> SD)</b>	117.8 $\pm$ 70.7	123.7 $\pm$ 73.0

Table 1: Statistics of clinical trials and eligibility criteria (EC) used in this study

(Wang and Sun, 2022), and BioSimCSE (Kanakarajan et al., 2022).

### 4.2.3 BERTopic

To further explore the potential of using text embeddings for clustering, we adopted the BERTopic model, specifically designed for topic clustering based on transformer-based sentence embeddings (Grootendorst, 2022). In the default configuration of BERTopic, text embeddings generated by sentence-transformer (Reimers and Gurevych, 2019) undergo dimensional reduction with UMAP (McInnes et al., 2018) and are subsequently clustered using HDBSCAN (McInnes et al., 2017).

## 4.3 Evaluation Strategy

### 4.3.1 CReSE

To assess EC embeddings from the CReSE model, we measured the correlation coefficients between the clinical relevance scores of EC pairs and whether they were assigned to the same EC cluster (Figure 2b). We utilized two correlation measures, Spearman’s and Pearson’s, with a preference for Spearman’s ranking correlation as the primary performance metric. A physician with over 10 years of experience in designing and executing clinical trial annotated an evaluation data, scoring clinical relevance on a 4-point scale from 0 to 3 for 500 EC pairs (Appendix E.2).

Moreover, we assessed the CReSE model’s proficiency as a semantic embedding beyond the clinical trial domain by evaluating its performance in semantic similarity on the BIOSSES dataset (Soğancıoğlu et al., 2017). This benchmark dataset for biomedical sentence similarity consists of 100 annotated sentence pairs with similarity scores ranging from 0 to 4. Due to the dataset’s limited size, we utilized the correlation between cosine similarity of embeddings and sentence similarity as a performance metric.

### 4.3.2 EC recommendation model

We evaluated the EC recommendation model in two ways. Firstly, we assessed its performance as a binary classifier, using metrics like accuracy, precision, recall, and F1-score. This evaluation aimed to determine the model’s ability to predict whether a given EC was used in a clinical trial of a given title. For comparison, a baseline model is presented using one-shot learning with ChatGPT and GPT-4.

Secondly, we evaluated the model’s recommendation performance based on the EC clustering results. Here, the objective was to determine how accurately the models suggest the most relevant EC cluster from clinical trial information. We reported precision@1, MAP@5 (mean average precision at top 5), and precision@ECno as performance measures. ECno denotes the number of EC originally used in clinical trials. By definition, precision@ECno is equivalent to recall@ECno. In evaluating EC recommendation performances, the true labels are the identifiers of EC clusters that correspond to EC actually used in clinical trials.

### 4.3.3 Human evaluation

We conducted a human evaluation to assess the feasibility of the current EC recommendation model in providing a complete EC set to aid in clinical trial design. Two experienced senior physicians working in a pharmaceutical company, with extensive knowledge in clinical trial design and execution, participated in the assessment. The evaluation encompassed four categories: 1) Protecting patient safety, 2) Clearly defining the study population, 3) Avoiding overly restrictive, 4) Clinically valid and realistic (Appendix E.3). For comparison, we prepared two types of complete EC sets for given trial titles: 1) the original EC set used in clinical trials and 2) the EC set recommended by our model.

Since our EC recommendation model primarily

focuses on non-common EC and ranks candidate EC based on given trial information, there was a limitation in using it to create a complete EC set. To address this issue, we engaged in prompt engineering to propose a complete EC set that would complement the non-common EC recommended by our model (Appendix A.3). The evaluation covered 20 clinical trials uploaded on ClinicalTrials.gov after September 2021, which was the knowledge-cutoff date of ChatGPT.

## 4.4 Results

### 4.4.1 CReSE

Regardless of the clustering method or the number of EC clusters, the CReSE model consistently exhibited superior performance in EC clustering performance compared to other LMs pre-trained in the biomedical domain (Table 2 and Appendix D.3). Moreover, within the BIOSSES dataset, the CReSE model demonstrated the second-highest semantic similarity performance, ranking just below BioSimCSE (Table 3).

In the ablation study, we observed the CReSE model was generally improved when using a more diverse range of rephrasing prompts for the same size of the training dataset (Figure 3). Meanwhile, it was noted that the performance of the CReSE model decreased when using all four rephrasing prompts as the dataset size increased beyond 20K while using three prompts yielded better results than using all four prompts for a dataset size of 40K. In addition, an inverse correlation between validation loss in contrastive learning and clustering performance was observed, although it is not distinctly evident (Appendix D.2).

These findings imply that while rephrasing through LLMs does indeed function as an effective text augmentation method in contrastive learning, aimed at incorporating medical knowledge from LLMs into embedding systems, there remains a need to discover the optimal composition of the dataset containing the original-rephrased text pairs (Appendix D.3). Furthermore, it is clear that there is a difference between the objectives of contrastive learning, where a model predicts whether an EC pair is generated through rephrasing or not, and the assessment of clinical relevance between an EC pair. Thus, when employing rephrasing-via-LLMs as a text augmentation technique, the design of diverse rephrasing prompts becomes crucial.

Clustering methods	Spearman
TF-IDF	32.8 [26.8, 37.9]
<b>Only embeddings</b>	
BioLinkBERT	40.7 [37.5, 46.0]
TrialBERT	39.8 [34.6, 43.2]
BioSimCSE	46.2 [41.0, 50.4]
BioGPT	44.0 [40.6, 48.3]
<b>CReSE (ours)</b>	<b>59.9 [56.3, 63.3]</b>
<b>BERTopic</b>	
BioLinkBERT	46.1 [40.3, 51.4]

Model	Spearman	Pearson
BioSimCSE	86.7	86.7
<b>CReSE (ours)</b>	<b>84.7</b>	<b>80.7</b>
BioSentVec	78.0	81.7
BioGPT	72.1	70.2
BioBART	69.5	67.7
BioClinicalBERT	65.2	65.2
BioBERT	63.8	66.2

Table 3: Results on BIOSSES

### 4.4.2 EC recommendation model

In binary classification, we achieved an accuracy of 81.6% and an F1-score of 82.0% when using only titles as input (Table 4). Moreover, providing additional trial information to trial titles resulted in a significant improvement, pushing the accuracy and F1-score to over 92%. This performance notably surpassed the binary classification results achieved in the one-shot learning setting using ChatGPT and GPT-4.

When evaluating recommendation performances using our evaluation framework, we achieved precision@1, MAP@5, and precision@ECno of 49.0%, 44.2%, and 31.5%, respectively (Table 4). However, it is noteworthy that the performance metrics changed significantly as the overall number of EC clusters used in the evaluation varied (Appendix D.4 and Table 12). Nonetheless, the EC recommendation models consistently outperformed random recommendations by a substantial margin.

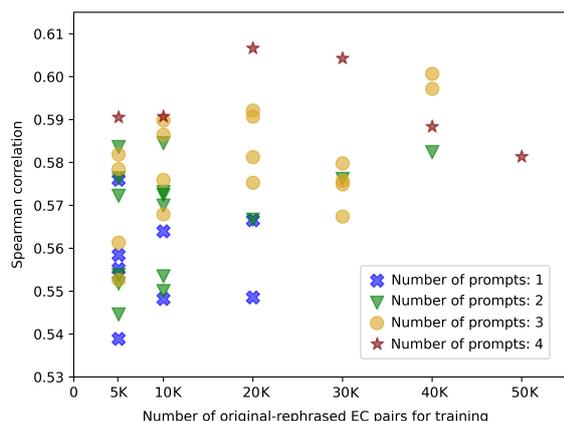

Figure 3: Clustering performance of the CReSE model by the number of rephrasing prompts used to generate a dataset of original-rephrased EC pairs and the size of the dataset

Moreover, when comparing the EC recommendation performance across time periods, we observed that the recommendation model exhibited better results for more recent clinical trials (Table 5). Furthermore, the model performances varied significantly depending on the therapeutic area of trials. These variations are not attributed to the number or distribution of EC within each category, because the performance of random recommendation showed no significant difference within categories. Instead, we attribute these differences to the fact that recent trials provide more specific titles and summaries for guessing EC used in the trials, while EC might be used in a more predictable manner in certain therapeutic areas.

#### 4.4.3 Human evaluation

In the three remaining categories, except the one related to overly restrictive, the EC set proposed by our model demonstrated inadequacy when compared to the original EC set ( $p$ -value  $< 0.05$ , Figure 4). To be specific, the EC set recommended by our model performed poorly in properly protecting patient safety and building a clinically valid EC set, with statistically significant differences of 0.638 and 0.675, respectively. (Appendix D.7)

Furthermore, through consulting with the evaluators, we identified several features that can enhance the practicability of EC recommendation models for clinical trial design in the context of drug development. These proposed features are outlined as follows:

- Incorporating the drug’s mode of action (MoA) and findings from pre-clinical trials

into the recommendation model becomes essential to assist in facilitating clinical trial design for drug development.

- Recognizing the sensitivity of the clinical trial design to regulatory shifts, it would be advantageous for the EC recommendation model to integrate regulatory guidance as one of its inputs.
- Developing a model to propose a suitable standard-of-care (SoC) treatment as a comparator along with suggesting the relevant supporting documents would carry significant value.

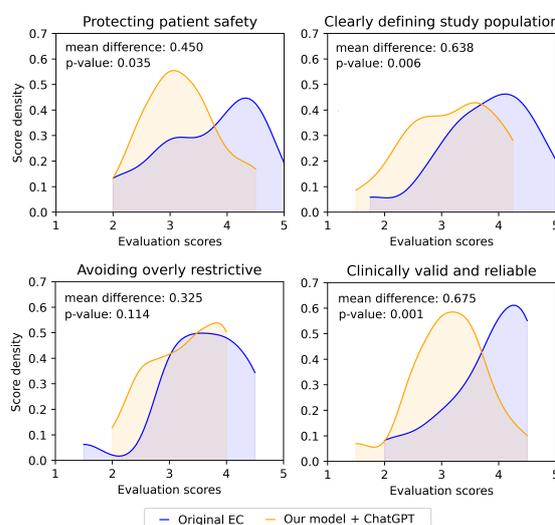

Figure 4: Distribution of human evaluation scores for original EC and EC recommended by our model with ChatGPT in four evaluation categories

## 5 Conclusion

In this study, we introduce the task of recommending EC from clinical trial information and develop the CReSE model, designed to preserve clinical relevance between EC, by employing contrastive learning and using rephrasing via LLMs as text augmentation. We also demonstrate the importance of varied rephrasing prompts for developing the CReSE model through the ablation study. Additionally, we establish the automatic evaluation framework which assesses the clinical validity of the EC recommendation model based on the CReSE model.

In addition, we define common EC and exclude them from the dataset to prevent an overestimation of the EC recommendation model’s performances

Input type	Binary classification				EC recommendation		
	Accuracy	Precision	Recall	F1	P@1	MAP@5	P@ECno
title only	81.6	80.3	83.8	82.0	37.0	29.5	23.7
title + summary	93.1	92.6	93.7	93.1	47.0	41.2	30.0
title + design factors	92.2	91.8	92.7	92.2	46.0	40.4	31.5

random					11.3	11.5	11.6
recommendation	NA	NA	NA	NA	[6.0, 19.0]	[8.3, 15.0]	[10.1, 13.6]

Table 4: Performances of the EC recommendation and baseline models using different input types on binary classification and EC recommendation. The evaluation metrics for EC recommendation were P@1 (precision at 1), MAP@5 (mean average precision at 5), and P@ECno (precision at the number of original EC in trials). We present the median and 95% confidence interval of performances achieved by randomly recommending EC, which helps gauge the task’s difficulty.

and to align the EC recommendation task in accordance with actual needs in trial design. Furthermore, due to inconsistent quality in EC reporting on ClinicalTrials.gov, despite its extensive database, we employ the EC clustering outcomes from the CReSE model to enhance the quality of negative EC-title pairs. Through this refinement, we achieve a high-performance EC recommendation model with precision@1 of 48.0% and MAP@5 of 42.7%, without requiring specialized architecture modeling.

While the primary motivation of this study is to provide an appropriate EC template from limited trial information such as trial titles, we also envision the EC recommendation model as a clinical inference tool for exploring new therapeutic strategies and safety concerns by recommending EC. Although this work does not conclusively determine the potential of LMs as clinical inference tools, we expect that our automatic evaluation framework based on the CReSE model could enhance the development and evaluation of EC recommendation models in terms of clinical validity.

## 6 Limitations

Despite these achievements, we want to underscore several considerations for evaluating the EC recommendation models and applying the automatic evaluation framework in a more clinically valid manner.

First of all, since the evaluation framework heavily relies on EC clustering results, researchers must be aware of the conditions under which clustering

was executed. Our evaluation framework is based on all EC used in clinical trials, irrespective of the trial’s therapeutic area. Thus, for example, exclusion criteria about cancer diagnosis before trial participation were mainly grouped into the same cluster. However, if you plan to employ EC recommendation in designing an oncology trial for an anticancer drug, a more finely-grained clustering result in terms of previous cancer diagnosis might be necessary. In such cases, it would be more fitting to develop EC recommendation and evaluation framework exclusively based on EC used in oncology clinical trials.

Secondly, as the EC recommendation functions as a ‘recommendation’ model, the quality of candidate EC for model inference holds substantial sway over the practical usefulness of the recommendation models. Once again, improving the quality of candidate EC necessitates domain expertise in a specific therapeutic area.

Further, given that EC defining the intervention and study population exhibit greater diversity than those used to protect patient safety, it might be more effective for the EC generation model, rather than the recommendation model, to obtain these defining EC. In such scenarios, the EC recommendation model could serve to filter the generated EC in terms of clinical relevance.

## 7 Ethical Considerations

When incorporating AI into clinical trial design, it is imperative to remain cautious about introducing biases or excessively restricting the patient popu-

Table 5: Performances of the EC recommendation model using title, summary, and design factors as input according to time periods and therapeutic areas of clinical trials. The numbers in parentheses represent the performances when EC topics were randomly recommended.

lation. Indeed, long-standing criticisms have highlighted the overly narrow inclusion criteria in real-world clinical trials, leading to insufficient clinical evidence for specific patient groups, such as pregnant women and individuals living with HIV (Breithaupt-Groegler et al., 2017; Osarogiagbon et al., 2021). The risk of exacerbating this issue arises if EC recommendation models focus solely on increasing statistical power by homogenizing clinical characteristics of patient populations. On the other hand, if leveraging AI models to swiftly access high-quality EC templates for a given trial, the problem of overly restrictive EC derived from the old practice of using EC from previous trials without proper adjustment could be alleviated.

Furthermore, the design and operation of clinical trials for drug development must align with the latest regulatory documents issued by regulatory agencies. Therefore, for the EC recommendation model to find practical utility at the forefront of drug development, the model should be able to incorporate the most recent regulatory modifications.

## A Prompts

In our study, we utilized large language models (LLMs) to handle biomedical free texts in a manner that aligns with clinical validity. Specifically, we rephrased the original eligibility criteria (EC) used in clinical trials using LLMs to develop the CReSE model. Additionally, we assessed the clinical relevance between pairs of EC and streamlined the EC recommendation model through LLMs, transforming it into the end-to-end recommendation system. This section provides an overview of all the prompts that were utilized in our study.

### A.1 Prompts for rephrasing

We developed four different rephrasing prompts in a 2-shot manner for ChatGPT. The aim was to generate an original-rephrased EC dataset for training the CReSE model (Table 6).

Common introduction for rephrasing prompts
You are a world-renowned clinical specialist with expertise in clinical trial design and implementation. <i>{Prompt-specific instructions}</i> The proposed new EC must start with either "[Inclusion]" or "[Exclusion]." Here's an example:
<i>{Examples}</i> Original EC: <i>{EC}</i> Rephrased EC:
Simple rephrasing
<i>Prompt-specific instructions:</i> Please suggest different eligibility criteria (EC) that can identify patients who clinically resemble those already screened using a given EC.
<i>{Examples}:</i> Original EC: "[Exclusion] previous bariatric or gastric surgery" Rephrased EC: "[Inclusion] Eligible patients must have a body mass index (BMI) of 30 or higher." Explanation: A new eligibility criteria for patients with a BMI of 30 or higher has been proposed as an alternative to the original exclusion criteria for bariatric or gastric surgery. This new criterion can help identify patients who are at risk of obesity-related health issues and may benefit from interventions aimed at reducing their BMI. Original EC: '[Exclusion] gastrointestinal disorders affecting absorption' Rephrased EC: "[Inclusion] Eligible patients must not be taking medications that interfere with gastrointestinal absorption." Explanation: A new eligibility criterion has been proposed to replace the old exclusion criterion of gastrointestinal disorders affecting absorption. This new criterion helps to identify patients without significant gastrointestinal problems that could affect the investigational product's absorption.

Table 6: Prompts for rephrasing EC

<p><b>Rephrasing without using a core clinical concept</b></p> <p><i>Prompt-specific instructions:</i> Please rephrased an eligibility criteria (EC) without using any core clinical concept words from the original EC.</p> <p><b>{Examples}:</b>  Original EC: “[Inclusion] International Prostate Symptom Score (IPSS) &lt; 7”  Rephrased EC: “[Inclusion] Participants who report mild or no symptoms related to urination, as assessed by a standardized questionnaire.”  Explanation: The rephrased EC avoids using the specific term "international Prostate Symptom Score (IPSS)" and instead describes the symptoms that would be used to assess the severity of the participant’s urinary issues.  Original EC: “[Exclusion] primary uveal or mucosal melanoma”  Rephrased EC: “[Exclusion] Individuals with a history of melanoma in areas other than the skin.”  Explanation: The rephrased EC avoids using the specific clinical terms "uveal" and "mucosal" melanoma and instead describes the location of the melanoma that would make a participant ineligible for the trial.</p>
<p><b>Suggesting alternative EC</b></p> <p><i>Prompt-specific instructions:</i> Please suggest alternative eligibility criteria (EC) that can serve as substitutes for a given EC when there is not enough patient data to determine whether the current EC is met or not.</p> <p><b>{Examples}:</b>  Original EC: “[Inclusion] hbA1c 7.0% - 10.0%”  Aim of original EC: To determine if the patient has diabetes  Alternative EC: “[Inclusion] Documented history of type 2 diabetes in the past year.”  Original EC: “[Inclusion] platelet count &gt;= 100,000”  Aim of original EC: To ensure the patient has a sufficient platelet count for safe treatment  Alternative EC: “[Inclusion] No history of thrombocytopenia or related conditions in the past year.”</p>
<p><b>Suggesting EC possibly used in the same clinical trial</b></p> <p><i>Prompt-specific instructions:</i> Please suggest an alternative eligibility criteria (EC) that can be utilized in the same clinical trial where a previous EC has already been employed.</p> <p><b>{Examples}:</b>  Original EC: “[Exclusion] cardiac ventricular arrhythmias requiring anti-arrhythmic therapy”  Clinical Trial: "A Phase III Randomized Controlled Trial Evaluating the Efficacy and Safety of Carvedilol in Patients with Chronic Heart Failure"  Suggested EC possibly from the same clinical trial: “[Exclusion] The patient has a history of sustained ventricular tachycardia or ventricular fibrillation, or is at high risk of these conditions as determined by the investigator.”  Original EC: “[Exclusion] history of major organ transplant”  Clinical Trial: "Phase II Study Investigating the Safety and Efficacy of Pembrolizumab in Patients with Advanced Melanoma"  Suggested EC possibly from the same clinical trial: “[Exclusion] The patient is currently on or requires systemic immunosuppressive therapy within two weeks prior to the first dose of study drug.”</p>

Table 6: (continued) Prompts for rephrasing EC

## A.2 Prompts for recommending a complete EC set from the clinical trial title

To provide a baseline system for comparison, we devise a prompt for GPT-4 that request to recommend a complete EC set from the clinical trial titles (Table 7). However, since the EC recommendation model we developed was designed to handle only non-common EC, an additional system to generate a complete EC set from the clinical trial title when using our EC recommendation model was required. To solve this challenge, we integrated ChatGPT into our approach, creating an end-to-end recommendation system, starting from the clinical trial title and effectively suggesting the full set of EC.

## A.3 Prompt for Binary Classification in EC Recommendation

A prompt is designed to cause LLMs to perform a binary classification, given a trial EC and title, to determine whether a given EC is appropriate to be used in a trial with that title or not. (Table 8).

# B Detailed methodology

## B.1 Development of common EC classifier

We employed the BertForSequenceClassification model from Huggingface as the classification model for common EC. In the biomedical domain, we utilized several pre-trained language models (LMs), namely BioClinicalBERT (Alsentzer et al., 2019), BioBERT (Lee et al., 2020), and BioLinkBERT (Yasunaga et al., 2022). Additionally, we adopted BaseBERT (Devlin et al., 2018), ELECTRA (Clark et al., 2020), and XLM-RoBERTa (Conneau et al., 2019) as baseline model for fine-tuning.

## B.2 Original-rephrased EC pairs dataset

After performing the rephrasing, we notice that the two rephrasing prompts, one suggesting alternative EC and one suggesting EC possibly used in the same clinical trial, have a more varied rephrasing pattern than the former two prompts, one about simple rephrasing and one without using a core clinical concept (Table 1). In order to efficiently utilize the ChatGPT API, we rephrased 20K EC using the first two prompts and 5K EC using the second two prompts, thus obtaining a total of 50K original rephrased EC pairs for training the CReSE model. This difference in the total number of rephrased ECs resulted in an imbalance in the composition of training data for the ablation study (Table 9).

## B.3 Selection of clinical trials and evaluation datasets

In this study, we selected trials that satisfied the following five conditions from 445K clinical trials registered on ClinicalTrials.gov from March 2002 to May 2023: 1) the date of information upload was reported, 2) a brief summary and official title were provided, 3) the trials were classified as ‘interventional’ (excluding observational trials), 4) at least two EC were reported, and 5) the intervention investigated in the trial was categorized as ‘Drug’ or ‘Biological’ (excluding ‘Device’ and ‘Behavior’ interventions). Additionally, for EC, we excluded studies where an individual EC was either too short (less than 3 characters) or too long (more than 353 characters).

To ensure a fair comparison with top performing LLMs including ChatGPT and GPT-4, the test dataset consisted of each 5K trials uploaded before and after September 2019, the knowledge cut-off date for ChatGPT and GPT-4. Therefore, the test dataset contains more recent trials than the training dataset, which is why we believe the test dataset has an overall higher number of ECs and longer EC lengths than the training dataset (Table 1).

In addition, we categorized clinical trials into three periods to explore the recommendation performance by the time periods of clinical trials: 1) May 2002 to December 2009, 2) January 2010 to the outbreak of COVID-19 (March 11th, 2020, the declaration of COVID-19 outbreak as a pandemic by WHO), and 3) COVID-19 outbreak to May 2023. Furthermore, recognizing that the EC recommendation performance might vary due to EC compositions and the number of EC used in clinical trials, we also reported the performance measures when EC clusters were randomly recommended. In all the evaluation settings and categories of clinical trials (Tables 4 and 5), we randomly sampled 100 clinical trials for each category and used them as the evaluation dataset.

**Prompt for generating a complete EC set from the clinical trial title and recommend EC by our recommendation model (ChatGPT)**

As an acclaimed specialist in clinical trial design and execution, your task involves drafting an exhaustive list of participant selection guidelines for a specific clinical trial. The details about the trial including its title, summary, and suggested eligibility criteria will be given by the user. Your task is to expand these criteria with a more comprehensive set. When crafting the eligibility criteria, ensure to consider potential risk factors, such as contraindications and possible interactions between the drug and the intervention. Clearly and professionally outline the intervention (as well as any control group treatment) and patient conditions. It's also crucial to confirm that the patient is in a mental and physical state where they can give informed consent. The selection criteria should not unduly narrow the prospective participant pool without medically valid reasoning, such as unjustified exclusion of HIV or HCV patients. Also, verify the patient's clinical and social circumstances to accurately assess the outcome during the follow-up period of the trial, like the presence of a measurable lesion or proximity to the trial location. For inclusion parameters, phrase them as '[inclusion] To be eligible, the patient must ...', and for exclusion parameters, use '[exclusion] To be eligible, the patient must not ...'. An example is provided below for better understanding. Note: the final selection criteria should be provided without duplicating the clinical trial's information or its summary. Also, the explanation for the final selection criteria set should not be included.

Clinical trial title: A Phase 1, Open-Label, Multicenter Study of KYV-101, an Autologous Fully-Human Anti-CD19 Chimeric Antigen Receptor T-Cell (CD19 CAR T) Therapy, in Subjects With Refractory Lupus Nephritis

Recommended eligibility criteria:

[Inclusion] have a confirmed diagnosis of systemic lupus erythematosus (SLE) according to the American College of Rheumatology (ACR) or Systemic Lupus International Collaborating Clinics (SLICC) criteria.

[Inclusion] lupus nephritis, defined by proteinuria, microscopic hematuria, and varying degrees of renal insufficiency.

[Exclusion] not have received prior treatment with any gene therapy medicinal product or any CAR T-cell therapy.

**Complete the eligibility criteria set including the recommended eligibility criteria:**

[Inclusion] To be eligible, the patient must have a confirmed diagnosis of systemic lupus erythematosus (SLE) according to the American College of Rheumatology (ACR) or Systemic Lupus International Collaborating Clinics (SLICC) criteria.

[Inclusion] To be eligible, the patient must have lupus nephritis, defined by proteinuria, microscopic hematuria, and varying degrees of renal insufficiency.

[Exclusion] To be eligible, the patient must not have a concurrent malignancy or history of malignancy within the last 5 years, to prevent potential complications or interactions with the trial treatment.

[Exclusion] To be eligible, the patient must not be pregnant or breastfeeding, due to potential unknown effects of the therapy on a developing fetus or infant.

Clinical trial title: *{Clinical\_trial\_title}*

Recommended eligibility criteria: *{Recommended\_EC}*

Complete the eligibility criteria set including the recommended eligibility criteria:

Table 7: Prompts for generating a complete EC set from the clinical trial title and the recommended non-common EC

<b>Prompt for determining whether a given EC is plausible to be used in a clinical trial of a given title (ChatGPT and GPT-4)</b>
<p>In your role as an esteemed expert in clinical trial design and execution, you are tasked with assessing the suitability of a provided eligibility criterion (EC) for a specific clinical trial based on user-supplied details, including the trial's title and summary. Your responsibility is to offer a credible clinical rationale for the decision, presenting it as either 'Use' or 'Not use.'</p> <p>Clinical Trial Title: A Phase 1, Open-Label, Multicenter Study of KYV-101, an Autologous Fully-Human Anti-CD19 Chimeric Antigen Receptor T-Cell (CD19 CAR T) Therapy, in Subjects With Refractory Lupus Nephritis</p> <p>Suggested Eligibility Criterion: [Inclusion] have a confirmed diagnosis of systemic lupus erythematosus (SLE) according to the American College of Rheumatology (ACR) or Systemic Lupus International Collaborating Clinics (SLICC) criteria.</p> <p>Clinical Explanation for the Decision: The use of the suggested eligibility criterion is deemed appropriate for the specified clinical trial. This criterion mandates that subjects must possess a confirmed diagnosis of systemic lupus erythematosus (SLE) in accordance with the American College of Rheumatology (ACR) or Systemic Lupus International Collaborating Clinics (SLICC) criteria.</p> <p>Final Decision: Use</p> <p>Clinical Trial Title: <i>{Clinical_trial_title}</i></p> <p>Suggested Eligibility Criterion: <i>{Suggested_EC}</i></p> <p>Clinical Explanation for the Decision:</p> <p>Final Decision:</p>

Table 8: Prompt for determining whether a given EC is plausible to be used in a clinical trial of a given title

While evaluating the CReSE model, we constructed the evaluation EC pairs datasets by randomly sampling 200, 300, 300, and 200 EC pairs for clinical relevance scores 0, 1, 2, and 3, respectively, to ensure a balanced distribution of clinical relevance scores.

## C Details on model development

In this section, we provide a comprehensive description of the training conditions for the common EC classifier, the CReSE model, and the EC recommendation model developed as part of this study. All experiments, except for the largest training of the EC recommendation model, were carried out using an RTX 4080 with 16GB of VRAM. For training the EC recommendation model with the entire training dataset, we employed 16 V100 GPUs in parallel.

The maximum token length was restricted to 256, and we ensured reproducibility by fixing all random seeds to 42. During hyper-parameter tuning, we experimented with learning rates of  $5e-5$ ,  $2e-5$ , and  $5e-6$ , and batch sizes of 32 and 64. We employed the AdamW optimizer and linear warmup scheduler with an epsilon value of  $1e-8$  for updating model parameters. The total number of training epochs was set to 25.

### C.1 Development of the CReSE model

In the CReSE model training, we employed BioLinkBERT as the baseline model, which demonstrated superior performance in classifying common EC across various pre-trained LMs. This decision aimed to save time and computation resources. For hyper-parameter tuning, we conducted experiments with the different projection dimensions (256, 512, and 768), batch sizes (16 and 32), learning rates for the text encoder ( $5e-6$  and  $1e-6$ ) and for the projection layer ( $5e-4$ ,  $1e-5$ ,  $5e-6$ , and  $1e-6$ ). The dropout probability of the projection layer was consistently set to 0.1.

During hyper-parameter tuning, we utilized the entire original-rephrased EC dataset comprising 50K examples with the four rephrasing prompts. The model underwent a total of 3 training epochs. We employed the AdamW optimizer with a weight decay of  $1e-4$  and implemented a ReduceLROnPlateau scheduler with patience of 1 and a reduction factor of 0.8. The CReSE model is trained for 10 epochs

For the ablation study, which aimed to investigate the CReSE model's performance variation concerning changes in the composition and size of the training dataset, we kept the hyper-parameters fixed. Specifically, we used a projection dimension of 256, a batch size of 32, and learning rates of  $1e-5$  and  $5e-4$  for the text encoder and projection layer, respectively.

### C.2 Development of the EC recommendation model

In the EC recommendation model, the input text was constructed by combining EC and clinical trial information with the [SEP] token. Among the four types of clinical trial information available for input, we utilized the 'official title' from ClinicalTrials.gov as the title and the 'brief summary' as the summary. The key design factors, written in the free text but in a semi-structured form, encompassed important trial design elements, including the investigated condition, investigational drug or treatment, study phase, number of enrolled patients, and primary outcome measures. When multiple types of trial information were employed as input, each piece of information was concatenated with the [SEP] token.

During the development of the CReSE model, we adopted BioLinkBERT as the baseline LM for the EC recommendation model. For fine-tuning, we added a linear-ReLU stack of two layers with dimensions  $768 \times 2 \times 512$  with a drop-out of 0.1 as the classification layer above the text encoder. Throughout both the main model training and ablation studies, we maintained fixed hyper-parameters values such as a learning rate of 256, a hidden layer dimension of 512, and a dropout probability of 0.1 for the classification layer. Additionally, we applied gradient clipping with a maximum norm of 1.0 during model training. In the main training setting, we set the threshold for the minimum number of EC occurrences in the clinical trials to generate negative EC-title pairs as 8. Moreover, the maximum token length was set to 512 during the main training, while it was set to 256 in the ablation studies to accommodate computation resource limitations. In addition, we increased the batch size to 128, effectively reducing training times. This adjustment resulted in each model training involving 3 epochs taking approximately 3 hours to complete, utilizing 16 V100 GPUs in parallel.

## D Supplementary results

### D.1 Performances of common EC classifiers

After fine-tuning several types of LMs to develop a common EC classifier, we achieved an accuracy of up to 97.99% and an F1-score of 97.78% when using BioLinkBERT (Table 9). In order to minimize the overall computational demands in this study, we used the BioLinkBERT checkpoint in all subsequent experiments as the initial parameter settings of text encoders.

Model name	Binary classification performances (%)			
	Accuracy	Precision	Recall	F1
BERT-base	89.30	83.56	93.85	88.41
BioClinicalBERT	95.99	98.36	92.31	95.24
BioBERT	97.32	95.41	95.38	96.88
BioLinkBERT	97.99	98.51	97.06	97.78
ELECTRA	82.61	86.26	76.88	81.29
XLM-RoBERTa	85.28	79.49	82.30	80.87

Table 9: Performances of common eligibility criteria classifiers

### D.2 Correlation between validation loss for contrastive learning and EC clustering performances

An ablation study trained the CReSE model on training datasets with different configurations and found an inverse relationship between validation loss in contrastive learning and final EC clustering performance (Figure 5). This result suggests that utilizing LLMs for rephrasing indeed serves as an effective method for text augmentation in the context of contrastive learning to integrate medical knowledge from LLMs into embedding systems. However, it's important to note that there is a need to identify the optimal composition of the dataset containing the original-rephrased text pairs. Furthermore, a distinction becomes apparent between the goals of contrastive learning, where the model determines whether an EC pair was made by rephrasing or not, and the evaluation of clinical relevance between EC pairs. Therefore, when employing rephrasing via LLMs as a text augmentation method, the design of diverse rephrasing prompts becomes crucial.

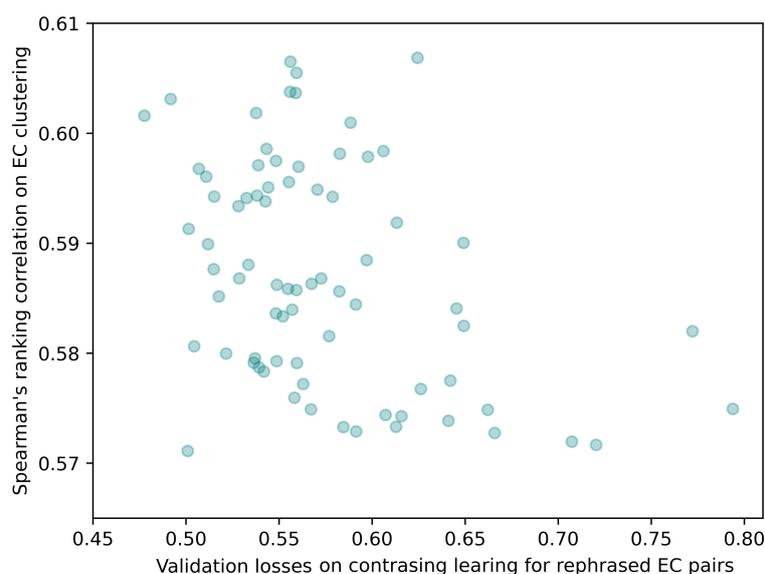

Figure 5: Scatter plot of validation losses and EC clustering performances of the CReSE model trained on diverse compositions of training datasets in the ablation study

### D.3 Performances of the CReSE model

Regardless of the clustering method or the number of EC clusters, the CReSE model consistently exhibited superior performance in EC clustering performance compared to other LMs pre-trained in the biomedical domain (Table 10). Furthermore, when training the EC recommendation model with increasing dataset size, the binary classification performance continues to increase up to 1M positive EC-title pairs, while the recommendation performance stops increasing after 0.2M (Figure 6).

The results of the ablation study revealed that, among the rephrasing prompts, ‘Without a core clinical concept’ was the most effective prompt for training the CReSE model (Table 11). For instance, when only one prompt was employed to construct the Eligibility Criteria (EC) pair data, the clustering performance of the CReSE model reached its peak (57.6) with EC pairs generated using the ‘Without a core clinical concept’ prompt, and reached its lowest point (53.9) when the ‘Suggesting EC possibly used in the same trial’ prompt was utilized. The prompt suggesting EC that might be used together in the same clinical trial, originally introduced to rephrase EC in a more creative way, may indicate a different clinical context than an original EC. Therefore, it does not appear to be an effective method for training the CReSE model when used in isolation. Nevertheless, rephrasing prompts that do not individually achieve optimal CReSE performance seem to contribute to the model’s overall performance when combined with other rephrasing prompts (5K, 4 prompts: 59.1).

Table 10: Comparison of the CReSE model and other biomedical LMs on EC clustering

### D.4 Usage pattern of EC in clinical trials

In this section, we examined the outcomes of EC clustering conducted using the CReSE model to assess the usage pattern of EC in clinical trials. Upon clustering all EC into 300 groups, we observed that the top 35 EC clusters encompassed half of the total EC, while the leading 165 EC clusters represented 90% of the total EC (Figure 7). This suggests a recurring usage pattern of EC describing similar clinical conditions across multiple clinical trials. Consequently, the format of a recommendation task can effectively cover a substantial proportion of EC employed in clinical trials when generating EC templates from trial information.

Total number of original-rephrased EC pairs	Number of prompts	Simple rephrasing	Without a core clinical concept	Suggesting alternative EC	Suggesting EC possibly used in the same trial	Clustering performance

Table 11: Composition of training datasets used in the ablation study for the CReSE model and EC clustering performances on each training dataset settings. EC clustering performances were assessed using Spearman’s ranking correlation.

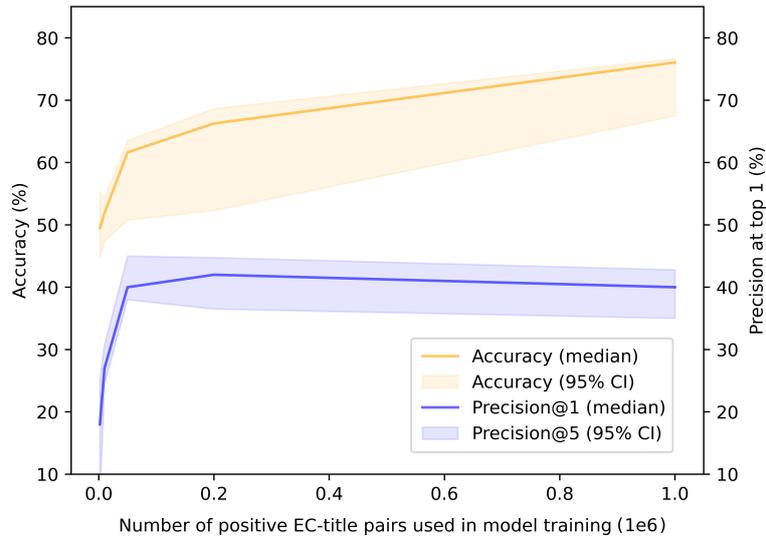

Figure 6: Performances of the EC recommendation models by the size of the training dataset containing EC-title pairs

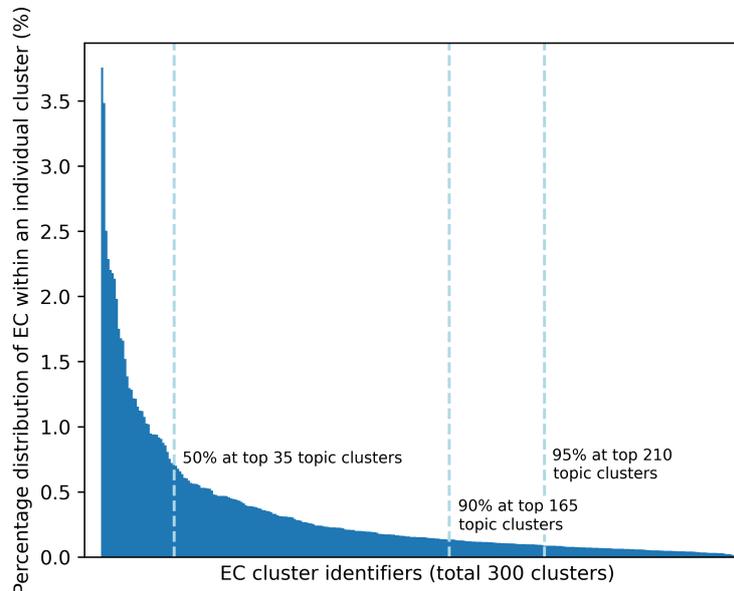

Figure 7: Frequency distribution of EC usage within clinical trials across EC clusters. The total number of clusters is 300.

### D.5 Performances of the EC recommendation models

As the number of EC clusters used for evaluation increases, the overall performance metrics of the EC recommendation model tend to decrease, but the substantial margin over random recommendations is either maintained or even increased (Table 12). While evaluating with 100 EC clusters may offer an intuitive interpretation of the results, it might be more appropriate to assess the recommendation model with a different number of EC clusters, depending on the environment (e.g., therapeutic area) or how the EC recommendation model is utilized.

### D.6 Qualitative review on EC recommendation results

To assess the strengths and weaknesses of our EC recommendation model, we conducted a qualitative comparison between the EC used in actual clinical trials and the set of EC recommended by our model. During this qualitative review, EC recommendations were generated solely based on the titles of the trials.

<b>EC cluster number</b>	<b>P@1</b>	<b>MAP@5</b>	<b>P@ECno</b>
<b>200</b>			
title only	19.0	18.0	14.7
title + summary	32.0	31.4	22.4
title + design factors	36.0	33.2	22.2
title + summary + design factors	37.0	35.2	21.9
random recommendation	7.0 [3.0, 11.0]	6.9 [4.6, 9.5]	6.7 [5.5, 7.9]
<b>300</b>			
title only	15.0	11.7	9.9
title + summary	37.0	29.6	19.4
title + design factors	30.0	27.3	18.9
title + summary + design factors	38.0	30.8	19.5
random recommendation	4.1 [1.0, 7.0]	4.2 [2.3, 6.4]	4.2 [3.1, 5.3]

Table 12: Performances of the EC recommendation model when using different numbers of EC clusters for the evaluation

Given that the EC recommendation model in this study focuses on non-common EC, we excluded EC classified as common among those used in selected clinical trials.

As demonstrated by the provided examples (Table 13), when EC recommendations are derived solely from trial titles, the emphasis tends to be on exclusion criteria. In practice, inclusion criteria are typically used to delineate a patient population that aligns with the specific intervention and patient indication employed in the trial. However, suggesting specific inclusion criteria becomes challenging as study titles usually lack sufficient information. Hence, for precise inclusion criteria recommendations, the brief summary should provide specific details about the targeted intervention or indication in the study. Additionally, when only the trial title serves as the input, the EC recommendation performance is higher for trials with recently updated information, likely because recent trials are more likely to feature titles that clearly articulate the intervention and trial objectives.

Moreover, our EC recommendation model proves valuable in offering an effective EC template when the EC set of an existing trial is inadequately designed, as illustrated in the second case (NCT04380519 in Table 13). For instance, the recommendations can introduce additional screening criteria for diabetic patients, such as that based on C-peptide peak level or metformin prescription history. It can also propose various exclusion criteria to enhance the homogeneity of the patient population, providing trial planners with more options. These EC are particularly beneficial as template suggestions, given their historical usage in numerous previous clinical trials.

<b>Clinial trial title: Study of the Efficacy and Safety of a Single Administration of Olokizumab and RPH-104 With Standard Therapy in Patients With Severe Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2) Infection (COVID-19) [NCT ID: NCT04380519]</b>

Table 13: (continued) Qualitative review on a sample EC recommendation result when using only title as an input text to EC recommendation

## D.7 Human evaluation results

Within the three remaining categories, excluding the one pertaining to overly restrictive recommendations, our model’s proposed EC set exhibited insufficiency in comparison to the original EC set (p-value < 0.05, Table 14). To elaborate, the EC set suggested by our model displayed suboptimal performance in effectively ensuring patient safety and constructing a clinically valid EC set. These differences were statistically significant, measuring 0.638 and 0.675, respectively.

	Original EC	Our model + ChatGPT	Mean difference	P-value
<b>Overall</b>	3.7±0.8	3.2±0.7	0.522	0.010
<b>Protecting patient safety</b>	3.7±0.9	3.2±0.7	0.450	0.035
<b>Defining the study population</b>	3.8±0.8	3.2±0.8	0.638	0.006
<b>Avoiding overly restrictive</b>	3.6±0.7	3.3±0.6	0.325	0.114
<b>Clinically valid and realistic</b>	3.8±0.7	3.2±0.7	0.675	0.001

Table 14: Human evaluation results on four evaluation categories

## E Guideline documents

### E.1 Annotation guideline for classifying common EC

This document serves as an annotation guideline for classifying ‘common EC’ from the entire set of EC. Common EC are defined as EC that have been commonly accepted over time or used as templates across trials, often excluding certain populations from participation without strong clinical or scientific justification (e.g., older adults, those at the extremes of the weight range, those with malignancies or certain infections such as HIV, and children) (FDA, 2020). Additionally, common EC include poorly defined criteria in clinical trials, regardless of the clinical characteristics of investigational drugs and patient conditions. The annotation guideline elaborates on the different types of common EC and provides relevant examples.

#### 1. Common EC universally used in clinical trials

We refer to EC universally used in clinical trials regardless of their purpose and design factors as ‘common EC’ and developed the classifier for common EC. Here are the detailed types of common EC and their definitions and examples (Table 15).

#### 2. EC used to ensure the smooth conduct of the clinical trial

Some common EC were used in clinical trials to ensure the smooth operation of the process, such as assessing the trial location’s accessibility and the communication abilities of enrolled patients (Table 16).

Common EC Type	Definitions and Examples
<b>Used as a template over time</b>	All age restrictions, about patient sex, weight, or BMI range restriction without clinical justification. <i>Ex) “[Inclusion] age 18 years”, “[Inclusion] males and females”, “[Inclusion] Body Mass Index (BMI) 18.5 kg/m2 and 28 kg/m2”</i>
<b>Infant/Child Protection</b>	To protect infant and child from the investigational drug (mostly exclusion criteria): pregnancy, breast-feeding, willing to take contraceptives. <i>Ex) “[Exclusion] pregnancy or breastfeeding”, “[Inclusion] males and females of childbearing potential must agree to utilize highly effective contraception methods from screening”</i>
<b>Drug addiction and alcoholism</b>	To exclude patients with a current or past history of drug addiction. <i>Ex) “[Exclusion] excessive alcohol, opiate, or barbiturate use; history of drug abuse or dependence”</i>
<b>Unapproved Drug/Herbal Supplement</b>	Taking unapproved drugs or herbal supplementary before the trial. <i>Ex) “[Exclusion] use of herbal supplements within 7 days or 5 half-lives (whichever is longer) before the first dose of study intervention”</i>
<b>Hepatic and Renal Function</b>	Excluding patients with reduced hepatic or renal function without adequate clinical and scientific justification - Includes defining hepatic or renal impairment based on a normal range of laboratory values (e.g., AST, ALT, bilirubin, creatinine clearance) <i>Ex) “[Inclusion] there was no previous severe renal dysfunction”, “[Exclusion] if a liver lesion is the site of injection: All AST, ALT and bilirubin greater than 2.5 ULN”</i> *Hormonal and hematological test values such as TSH, PTT, INR, and ANC, as well as cardio tests like QT interval and ECG, are not considered as common EC.
<b>Reduce Patient Risk</b>	Used to reduce the patient risk, but without a clear and appropriate clinical justification: HIV, hepatitis, tuberculosis infection, prior organ transplant, any major infection, any immunodeficiency (not heart disease), active autoimmune disease, no previous malignancy, etc. *Exclusion based on previous surgery is considered as non-common EC <i>Ex) “[Exclusion] any known immunosuppressive condition or immune deficiency disease (including human immunodeficiency virus [HIV] infection), or ongoing receipt of any immunosuppressive therapy”, “[Exclusion] subject positive for hepatitis B virus (HBV) surface antigen, hepatitis B virus core antibody with a negative hepatitis B surface antibody or with detectable serum hepatitis B DNA”</i>

Table 15: Types of common EC and their definitions and examples

<b>Common EC Type</b>	<b>Definitions and Examples</b>
<b>Life expectancy or performance status</b>	Life expectancy or performance status for checking the general health of a patient. <i>Ex) "[Inclusion] life expectancy &gt;= 12 weeks as judged by the Investigator", "[Inclusion] Eastern Cooperative Oncology Group (ECOG) performance status of 0 to 1 at trial entry"</i>
<b>Contraindication</b>	Contraindication, allergy or hypersensitivity to investigational drug, or previous exposure to investigational drug. <i>Ex) "[Exclusion] known allergies, hypersensitivity, or intolerance to monoclonal antibodies or hyaluronidase", "[Exclusion] use any investigational drug within 28 days before the start of trial treatment"</i>
<b>Drug Interaction</b>	Intake of drugs that possibly interact with investigational drugs. <i>Ex) "[Inclusion] maintained on modern therapeutic regimen utilizing non-CYP interacting agents (e.g. excluding ritonavir)"</i>
<b>Conflict of Interest</b>	If there is a conflict of interest through family... <i>Ex) "[Exclusion] family member or household contact who was an employee of the research center or otherwise involved with the conduct of the study"</i>
<b>Mental Illnesses/Informed Consent Form</b>	Broad range of mental illnesses which may harm the ability to make an informed consent or understand a study purpose and protocol by the patient self. <i>Ex) "[Exclusion] mental conditions rendering a subject unable to understand the nature, scope, and possible consequences of the study"</i>
<b>Prior use of (other) investigational drug</b>	If a patient has received any other investigational drug before randomization..  <i>"Ex) [Exclusion] prior treatment with 89Strontium or 153Samarium containing compounds (e.g. Metastron®, Quadramet®)", "[Exclusion] prior thiopurine therapy"</i>  *Prior use of clinically substitutable drugs with the investigational drug is not considered as common-EC. <i>Ex) "Exclusion: Received previous therapy with capecitabine, neratinib, lapatinib, or any other HER2-directed tyrosine kinase inhibitor."</i>
<b>Patient adequate to measure outcome</b>	measurable disease (mainly in oncology trial), Refrain from blood donation, have some contra-indication for measurement. <i>Ex) "[Inclusion] patients must have evaluable disease, either with informative tumor markers or with the measurable disease on imaging, by RECIST (Response Evaluation Criteria in Solid Tumors) criteria (Appendix II)", "[Exclusion] agreement to refrain from blood donation during the course of the study"</i>

Table 15: (continued) Types of common EC and their definitions and examples

<b>Common EC Type</b>	<b>Description and Examples</b>
<b>Area of Residence</b>	To ensure that participants reside in a particular geographical location that allows them easy access to the study site for regular investigations, measurements, or follow-up visits  <i>Ex) “[Inclusion] patients followed in the Rheumatology Department at the hospital of St Etienne”</i>
<b>Limit Language</b>	Limit speaking language to control for language barriers in the study.  <i>Ex) “[Exclusion] speaks a language other than English”</i>
<b>Limit Patient Ethnicity</b>	include or exclude specific ethnic groups.  <i>Ex) “[Exclusion] Limited to individuals of Asian ethnicity”</i>
<b>Informed consent</b>	Informed consent and agree to comply with the protocol: to ensure that potential participants fully understand the study’s purpose, procedures, risks, and benefits before they decide to participate.  <i>Ex) “[Inclusion] study subjects must obtain informed consent to this study and voluntarily sign a written informed consent before screening for enrollment.”</i>
<b>Past or Duplicated Participation</b>	Do not enroll in other studies or previous participation in the same study: to maintain the integrity of the study and avoid potential confounding effects, researchers may exclude individuals who are already participating in other clinical trials or have previously taken part in the same study.  <i>Ex) “[Exclusion] participation in other clinical trials (pharmaceutical trials)”</i>
<b>Commitment of Participant</b>	Confirmation of the patient’s ongoing and good faith participation in the study: to ensure that participants are committed to actively participating in the study and completing all study requirements.  <i>Ex) “[Inclusion] be willing and able to follow study instructions and likely to complete all study requirements”</i>

## E.2 Evaluation guideline for assessing clinical relevance between an EC pair

This document aims to assess the clinical relevance score between an EC pair based on 4-point scales (Table 17).

<b>Instruction for assessing clinical relevance between an EC pair</b>
<p>Please evaluate the clinical relevance of the following two eligibility criteria on a 4-point scale. Below is an example of a clinical situation by clinical relevance score and the corresponding EC pair.</p> <p>Clinical relevance 3: The two eligibility criteria are essentially identical clinically. For example: EC1: “[exclusion] serum albumin is 2.4 g/dL or less” EC2: “[inclusion] serum albumin is 2.4 g/dL or more”</p> <p>Clinical relevance 2: The two eligibility criteria have strong relevance due to factors such as disease progression, or epidemiology. For example: EC1: “[inclusion] 1 focal lesions on MRI (magnetic resonance imaging) studies; Each focal lesion must be 5 mm or more in size” EC2: “[exclusion] kellgren and Lawrence grade <math>\geq 3</math>”</p> <p>Clinical relevance 1: The two eligibility criteria are not directly related, but still have some relevance due to factors such as general treatment plan, disease progression, or epidemiology. For example: EC1: “[inclusion] no concurrent major surgery” EC2: “[inclusion] histologically confirmed transitional cell carcinoma (TCC) of the urothelium”</p> <p>Clinical relevance 0: The eligibility criteria are irrelevant from a clinical perspective. For example: EC1: “[exclusion] history of a severe allergic reaction with generalized urticaria, angioedema, or anaphylaxis in the 2 years prior to enrollment” EC2: “[inclusion] male condoms with spermicide”</p>

Table 17: Instruction for assessing clinical relevance between an EC pair

## E.3 Evaluation guideline for assessing the appropriateness of EC sets

This document aims to evaluate the appropriateness of the eligibility criteria for the given information of clinical trials. The purpose of this evaluation is to assess the extent to which the eligibility criteria adequately address the following points (Table 18): **1) Protecting patient safety, 2) Clearly defining the study population (and study intervention), 3) Avoiding overly restrictive, and 4) Clinically valid and realistic.** Evaluators rated questions from each category on a scale of 1 to 5. By conducting this evaluation, we aim to ensure that the eligibility criteria meet the highest standards of quality and align with the needs of clinical trials. Below is a detailed guideline for each evaluation category and question.

Category	Question	Descriptions/Examples
<b>Protecting patient safety</b>	<p>[1] Do eligibility criteria adequately exclude contraindications of the interventions/drugs being used and minimize potential harm to subjects during the course of the trial?</p> <p>(No 1 - 2 - 3 - 4 - 5 Yes)</p>	<p>This question is to review whether the criteria adequately account for potential risks, contraindications, and precautions that may affect patient safety.</p> <p><i>Ex) Exclusion criteria: History of cancer and/or any known primary immunodeficiency disorder (e.g., HIV)</i></p>
<b>Defining the study population</b>	<p>[2-1] Are the eligibility criteria clearly defining the study population being tested as appropriate to evaluate the given research hypothesis?</p> <p>(No 1 - 2 - 3 - 4 - 5 Yes)</p>	<p>This question is to assess whether the eligibility criteria align with the specific objectives of the study, ensuring that only suitable patients are included, and the study outcomes can be effectively evaluated.</p> <p><i>Ex) Trial title: A Randomised, Double-blind, Placebo-controlled, Phase 3 Trial to Evaluate the Efficacy and Safety of Tralokinumab Monotherapy in Subjects With Moderate to Severe Atopic Dermatitis Who Are Candidates for Systemic Therapy</i></p> <p><i>Inclusion Criteria: Diagnosis of AD as defined by the Hanifin and Rajka (1980) criteria for AD, Diagnosis of AD for 1 year, AD involvement of 10 of body surface area at screening and baseline (visit 3), An EASI score of 12 at screening and 16 at baseline</i></p>
<b>Defining study intervention</b>	<p>[2-2] Are the eligibility criteria clearly define the intervention?</p> <p>(No 1 - 2 - 3 - 4 - 5 Yes)</p>	<p>This question is to assess whether the eligibility criteria for the intervention are explicitly stated and well-defined.</p> <p><i>Ex) Trial title: A Randomised, Double-blind, Placebo-controlled, Phase 3 Trial to Evaluate the Efficacy and Safety of Tralokinumab Monotherapy in Subjects With Moderate to Severe Atopic Dermatitis Who Are Candidates for Systemic Therapy</i></p> <p><i>Inclusion criteria: Subjects with documented systemic treatment for AD in the past year are also considered as inadequate responders to topical treatments and are potentially eligible for treatment with tralokinumab after appropriate washout.</i></p>

Table 18: Evaluation category for assessing the appropriateness of EC sets

Category	Question	Descriptions/Examples
<b>Avioding overly restrictive</b>	<p>[3] Are eligibility criteria based on appropriate clinical evidence and do not unduly limit the study population?</p> <p>(No 1 - 2 - 3 - 4 - 5 Yes)</p>	<p>This question is to evaluate whether the eligibility criteria ensure the patient population is diverse and accurately reflects the target population for the study.</p> <p><i>Ex) ECs that limit the study population</i></p> <p><i>Inclusion criteria: Participants between the ages of 25 and 30.</i></p> <p><i>Exclusion criteria: Participants with any other chronic condition</i></p>
<b>Clinically valid and realistic</b>	<p>[4] Are the eligibility criteria consistent with current medical knowledge and clinical guidelines (standards of care)?</p> <p>(No 1 - 2 - 3 - 4 - 5 Yes)</p>	<p>This question is to evaluate the accuracy, reliability, and consistency of the eligibility criteria against established medical knowledge and accepted clinical guidelines.</p> <p><i>Ex) Trial title: A Phase 3, Multi-Center, Open-Label Study to Assess the Diagnostic Performance and Clinical Impact of 18F-DCFPyL PET/CT Imaging Results in Men With Suspected Recurrence of Prostate Cancer</i></p> <p><i>Suspected recurrence of prostate cancer based on rising PSA after definitive therapy on the basis of: - Post-radical prostatectomy: Detectable or rising PSA that is 0.2 ng/mL with a confirmatory PSA 0.2 ng/mL (American Urological Association)</i></p>

{christoph.leiter, steffen.eger}@uni-mannheim.de

## Abstract

State-of-the-art natural language generation evaluation metrics are based on black-box language models. Hence, recent works consider their explainability with the goals of better understandability for humans and better metric analysis, including failure cases. In contrast, our proposed method BMX: Boosting Natural Language Generation Metrics with explainability explicitly leverages explanations to boost the metrics' performance. In particular, we perceive feature importance explanations as word-level scores, which we convert, via power means, into a segment-level score. We then combine this segment-level score with the original metric to obtain a better metric. Our tests show improvements for multiple metrics across MT and summarization datasets. While improvements in machine translation are small, they are strong for summarization. Notably, BMX with the LIME explainer and preselected parameters achieves an average improvement of 0.087 points in Spearman correlation on the system-level evaluation of SummEval.<sup>1</sup>

## 1 Introduction

Modern language model (LM) based natural language generation (NLG) metrics achieve astonishing results in grading machine generated sentences like humans would (e.g., Bhandari et al., 2020; Freitag et al., 2021b; Specia et al., 2021; Fabbri et al., 2021). As most language models are black-box components, some recent works started to explore the explainability of LM-based metrics (e.g. Fomicheva et al., 2021; Leiter et al., 2022; Sai et al., 2021; Zerva et al., 2022; Chen and Eger, 2023). This exploration, for example, contributes to the foundation of ethical machine learning (e.g. Fort and Couillaud, 2016; European Commission, 2019).

<sup>1</sup>We make our code available at: <https://github.com/Gringham/BMX>

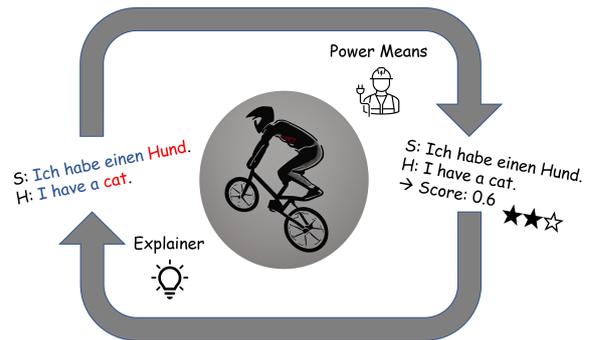

Figure 1: The duality of segment-level natural language generation evaluation metrics (right) and their word-level explanations (left).

Our work is motivated by an intriguing duality that we note between segment-level metrics and their explainability through feature importance techniques, e.g., LIME (Ribeiro et al., 2016):

**Segment-level metrics**<sup>2</sup> return a single score indicating the quality of a generated segment. *Feature importance explanations*<sup>3</sup> increase the granularity of this score, by assigning additional **word-level scores**. These granular scores capture additional information about the generated text and about the metric that processed it, as, e.g., explored by the Eval4NLP21 shared task (Fomicheva et al., 2021) and the WMT22 quality estimation shared task (Zerva et al., 2022). On the other hand, in recent *multidimensional quality metrics* (MQM) datasets, word-level error annotations are converted into segment-level scores using heuristic functions (Freitag et al., 2021a). Likewise, metrics like BERTScore (Zhang et al., 2020) and BARTScore

<sup>2</sup>We use the term *segment-level*, as it includes the option that a metric grades multiple hypothesis sentences. Recent work shows that many sentence-level metrics also perform well on the segment-level (Deutsch et al., 2023).

<sup>3</sup>Also called *relevance scores* or *attribution scores*.

(Yuan et al., 2021) build their segment-level scores upon word-level scores. In other words, we note the duality that feature importance techniques produce word-level scores from segment-level scores and heuristics can aggregate word-level scores into segment-level scores. Figure 1 gives an example of this duality for machine translation (MT), where a German source sentence “Ich habe einen Hund” was wrongly translated into “I have a cat”. On the right side, a segment-level score of 0.6 is assigned by a metric. On the left side, a feature importance explainer is used to explain this score by assigning word-level scores to each input token. Instead of displaying the scores, we use colors to describe the concept. The red words would likely achieve a low importance score, as they are translated incorrectly. The duality arises as the feature importance scores can be recombined into a new segment-level score (here using power-means).

In this work, we explore whether this duality leads to iterative improvements of segment- and word-level scores, with a focus on segment-level scores as these are the main goal of modern metrics. We propose *Boosting natural language generation Metrics with explainability* (BMX), a method that directly leverages word-level explanations to improve the original segment-level score of a metric. Specifically, the approach aggregates word-level feature importance explanations using power means (Rücklé et al., 2018) and combines them with the original score using a linear combination. To obtain the explanations, we leverage model-agnostic explainability techniques, allowing application to any NLG metric. While we consider NLG (especially MT and summarization) as ‘natural use case’, other regression and classification tasks follow similar settings, which makes our approach more generally applicable. For example, in sentiment classification, feature importance techniques might assign high importance scores to tokens with positive sentiment. Hence, aggregating these scores could further inform a classification decision.

We evaluate BMX with several metrics and explainability techniques on 5 MT datasets (3 for exploration + 2 held out for testing), as well as 2 summarization datasets, and discuss conditions for its failure and success. Our work makes the following contributions:

- (i) We highlight the duality of word-level explanations and segment-level scores for NLG metrics.

- (ii) We propose an approach to improve NLG metrics by combining it with model-agnostic explainability techniques.
- (iii) We provide an evaluation that shows that our approach can achieve consistent improvements. For example, after applying BMX, we obtain 0.087 points improvement on SummEval.

## 2 Approach

NLG metrics grade a generated text, also referred to as hypothesis, by comparing it to a ground truth. For MT, the ground truth could be a human written reference translation or the original text in source language. For summarization, the ground truth could be a human written reference summary or the source text that is being summarized. Given a pair of ground truth segment  $\mathbf{g} = \langle g_1, \dots, g_n \rangle$  and hypothesis segment  $\mathbf{h} = \langle h_1, \dots, h_m \rangle$ , a segment-level metric  $\mathcal{S}_0$  generates a single score  $\mathcal{S}_0(\mathbf{g}, \mathbf{h}) = s_0 \in \mathbb{R}$ . This score can be interpreted as, for example, the adequacy/accuracy of the generation of  $\mathbf{h}$  given  $\mathbf{g}$ .

Our algorithm consists of three steps: (1) compute feature importance explanations, (2) aggregate explanation scores, and (3) combine the aggregated explanations with the original score.

### 2.1 Feature importance computation

The input of our algorithm is an arbitrary NLG metric  $\mathcal{S}_0$ , which we aim to improve, and a pair of ground truth and hypothesis segments  $(\mathbf{g}, \mathbf{h})$ . Further, we leverage a feature importance explainer  $\varepsilon$ , e.g., LIME (Ribeiro et al., 2016) or SHAP (Lundberg and Lee, 2017). We use  $\varepsilon$  to compute feature importance scores  $\phi_i$  for each input token of an NLG metric. I.e., we explain  $\mathcal{S}_0$  and its evaluation of  $\mathbf{g}$  and  $\mathbf{h}$  using  $\varepsilon$  and obtain  $\phi \in \mathbb{R}^{m+n}$  as follows:

$$\varepsilon(\mathcal{S}_0, \mathbf{g}, \mathbf{h}) = \langle \phi_1, \dots, \phi_n, \phi_{n+1}, \dots, \phi_{n+m} \rangle$$

The importance scores  $\phi$  specify the contribution of each token in  $\mathbf{g}$  and  $\mathbf{h}$  to  $s_0$ . Note that the metric  $\mathcal{S}_0$  itself is a parameter to  $\varepsilon$  as model-agnostic explainers compare the metrics’ original output with its output for permutations of the input text. For a strong metric, a high feature importance  $\phi_i$  indicates that token  $t_i \in \mathbf{g} \cup \mathbf{h}$  has a positive contribution to the score  $\mathcal{S}_0$  and thus is likely to

be correctly generated<sup>4</sup>. Low feature importance can indicate incorrect translations or summaries. This setup follows the Eval4NLP21 shared task (Fomicheva et al., 2021) for MT. Continuing the example from figure 1, the source sentence “Ich habe einen Hund” is our  $g$  and the hypothesis sentence “I have a cat” is our  $h$ ;  $s_0$  is 0.6 and the output of  $\varepsilon$  are feature importance scores corresponding to the words, e.g.  $\varepsilon(\mathcal{S}_0, g, h) = \phi = \langle 0.5, 0.4, 0.2, 0.0, 0.5, 0.4, 0.2, 0.0 \rangle$ , where the low numbers indicate mistranslations.

In some datasets, multiple references are available for each hypothesis. In these cases, we concatenate the importance scores for each reference segment into  $\phi$ .

## 2.2 Explanation score aggregation

As mentioned above, the feature importance scores of a reasonable metric indicate the generation quality of each token. We combine these values to estimate the quality of the hypothesis at the segment-level. Therefore, we employ an aggregation function  $f : \mathbb{R}^{m+n} \rightarrow \mathbb{R}$  to transform feature importance scores generated from the previous step into a single scalar value. We obtain the aggregated explanation score  $\hat{s}_0$  as follows:

$$f(\varepsilon(\mathcal{S}_0, g, h)) = \hat{s}_0$$

## 2.3 Linear combination

Finally, we linearly combine  $\hat{s}_0$  and  $s_0$  using weight  $w$  to construct a new metric  $\mathcal{S}_1$ :

$$\mathcal{S}_1(g, h) = w \cdot s_0 + (1 - w) \cdot \hat{s}_0 = s_1$$

We note that this three step process (feature importance computation, explanation score aggregation, linear combination) can be applied iteratively by increasing the index of  $\mathcal{S}$  (resp.  $s$ ). I.e., in the next iteration, we can consider  $\mathcal{S}_1$  as the original metric and  $s_1$  as the original score.

## 3 Experiment Setup

In this section, we describe the datasets, metrics, explainers and aggregation methods that we evaluate in §4 and their parameter configurations.

<sup>4</sup>For weak metrics, the segment-level score is incorrect more often, hence the feature importance scores are not as likely to be correlated to correct and incorrect translations.

## 3.1 Datasets

Our configuration of BMX has two parameters  $w$  (see §2.3) and  $p$  (see §3.4) which can either be selected *in-domain* on a labeled subset of the same dataset or *cross-domain* on a different dataset. We mainly evaluate cross-domain selection, as it would allow to apply BMX without additional annotation effort and is, therefore, more desirable. However, cross-domain tasks are generally also more difficult. For summarization, we also test an in-domain stratification approach. We refer to the datasets that we use for parameter search as *calibration datasets* and to those that we evaluate on as *evaluation datasets*.

**MT datasets** We use three *calibration datasets*: the **WMT17** metrics shared task (Bojar et al., 2017) newstest2017 test set in the to-English direction, the 2020 partition of the **MLQE-PE** dataset (Fomicheva et al., 2022) and the **Eval4NLP21** test set (Fomicheva et al., 2021). We evaluate BMX on two further *evaluation datasets*: The **WMT22** Quality Estimation shared task (Zerva et al., 2022) and the **MQM**<sup>5</sup> annotations of newstest21<sup>6</sup> without human written references (Freitag et al., 2021a,b). WMT17, MLQE-PE, Eval4NLP and WMT22 contain *source sentence - hypothesis* pairs and human direct assessment (DA) scores (Graham et al., 2017) that grade the translation quality. For MLQE-PE, Eval4NLP21 and WMT22, human annotators determined these scores based on source and hypothesis sentences; for WMT17 they used reference sentences instead of source sentences. For MQM (Lommel et al., 2014), scores are aggregated from fine-grained human MQM error annotations, and have been shown to be of better quality than crowd-sourced annotations (Freitag et al., 2021a). Table 5 (appendix) shows an overview of the number of samples per language pair and dataset.

**Summarization datasets** We perform *in-domain calibration* on **SummEval** (Fabbri et al., 2021). To do so, we apply cross-validation and split SummEval into eight non-overlapping *configuration* (7 with 208 samples and 1 with 144) and *evaluation* (7 with 1392 samples and 1 with 1456 samples) splits. Also, we make sure that no source text in the configuration set has another hypothesis in the corresponding test set. SummEval contains multiple expert-annotated discrete scores for coherence, consistency, fluency and relevance each and 11 ref-

<sup>5</sup>We further refer to the datasets by these bolded names.

<sup>6</sup><https://github.com/google/wmt-mqm-human-evaluation>

erence summaries per hypothesis. We average the expert annotations for each score.

Further, we use the parameter values obtained on SummEval and perform *cross-domain calibration* on **RealSumm** (Bhandari et al., 2020). SummEval and RealSumm have the same data source, but different annotations and a different selection segments.

### 3.2 Base metrics

We test BMX with the following metrics.

**Reference-based** For summarization, we test BMX with BERTScore (Zhang et al., 2020) and BARTScore (Yuan et al., 2021).

**Reference-free** For MT, we test BMX with XBERTScore (Zhang et al., 2020; Song et al., 2021; Leiter, 2021)<sup>7</sup>, XLMR-SBERT (Reimers and Gurevych, 2020), TransQuest (Ranasinghe et al., 2021) and COMET (Rei et al., 2021).

We report the exact metric configurations in Appendix A.

### 3.3 Explanation techniques

We explore the effectiveness of three model-agnostic explainers: *Erasure* (Li et al., 2016), *LIME* (Ribeiro et al., 2016) and *SHAP* (Lundberg and Lee, 2017) For implementation details refer to appendix D.

**Multiple references:** We handle the computation of the hypothesis and multiple references separately by fixing all but one during each application of the explainers and applying the explainer separately to each of them. E.g., if we have one hypothesis and 11 references and use LIME with 100 permutations, we will apply it 12 times, resulting in 1200 permutations in total.

### 3.4 Aggregation technique

Following Rücklé et al. (2018), we use the power mean (or generalized mean) as a generalization over different means to aggregate token-level feature-importance scores. The power mean of  $n$  positive numbers  $e_1, \dots, e_n$  is computed as:

$$M_p(e_1, \dots, e_n) = \left( \frac{1}{n} \sum_{k=1}^n e_k^p \right)^{\frac{1}{p}}$$

Depending on  $p$ , the power mean takes on the value of specific means, e.g.  $p = -1$  is the harmonic

<sup>7</sup>We refer to BERTScore variants that use multilingual language models as XBERTScore.

mean,  $p = 1$  is the arithmetic mean, and  $p = -\infty$  resp.  $p = +\infty$  is the minimum resp. maximum. We experiment with  $p$ -values between  $[-30, 30]$  in 0.1 steps. The token-level scores resulting from the explanation technique can be negative, which is problematic for power means, as these are defined on positive numbers only<sup>8</sup>. To guarantee positive importance scores, whenever there is a negative importance score for a token, we add a regularization term to all importance scores of the current ground truth/hypothesis pair. This term is the absolute value of the smallest importance score assigned to any token of this pair. Additionally, we generally add a constant  $1e-9$  to each importance score to avoid issues with fluctuations around 0. Future work could explore further methods of aggregation such as different settings of the Kolmogorov mean (de Carvalho, 2016).

### 3.5 Evaluation

To evaluate the BMX metrics, we calculate the correlation on datasets with human annotated scores. E.g., we can compute Pearson correlations per sample as follows:

$$\text{Pearson}(H(LP, D), S_1(LP, D, S_0, \varepsilon, w, p)) \quad (1)$$

Here,  $H$  returns the set of human scores for language pair  $LP$  and dataset  $D$ .  $S_1$  returns the new metric scores, when our method is applied to  $LP$  and  $D$ . Its further parameters are the original metric  $S_0$ , the explainer  $\varepsilon$ , the weight of the linear combination  $w$  and the  $p$  value of the power mean. On WMT22, we evaluate the segment-level Spearman correlation. On the MQM dataset, we evaluate segment- and system-level Kendall correlations. Further, for SummEval we evaluate the system-level Spearman and Kendall correlations. Finally, for RealSumm we report the segment-level Pearson and system-level Kendall correlations. With this setup, we follow the evaluation of the datasets' origin papers. An exception is the system-level evaluation of the MQM dataset, where we report the Kendall correlation per language pair as done by Freitag et al. (2021a).

## 4 Results

In this section, we evaluate the effectiveness of BMX by correlating the results with human judgments of MT and summarization quality annotated

<sup>8</sup>Inserting negative numbers may lead to discontinuities or complex numbers.

in the datasets described in §3.1. To start, we calibrate the parameters  $p$  and  $w$ .

**Calibrating  $p$  and  $w$**  We perform a grid search on the calibration sets (see §3.1) to determine the parameters  $w$  and  $p$  for our evaluation of BMX on the evaluation sets.

For  $p$ , we test 600 equally spaced values in  $[-30, +30]$  and for  $w$ , we test 6 equally spaced values in  $[0, 1]$  (where  $w = 1$  reproduces the original score). This results in 3000 BMX configurations (without  $w = 1$ ) for every metric-explainer combination. Next, we evaluate all  $p$ - $w$ -metric-explainer combinations on the respective calibration set(s). Specifically, for the MT calibration sets we evaluate with segment-level Pearson correlation (see Eq. 1) for each language pair, and for summarization we evaluate with system-level Kendall correlation.

For our evaluation, we select the median of the  $p$  and  $w$  values that led to any increase over the original correlation on the calibration set(s) for each metric-explainer combination.<sup>9</sup>

Our approach of selecting  $p$  and  $w$  is rather simple. Future work might consider more sophisticated ways of optimization, such as considering the areas of highest increase in the grid search or even learning a model to set the parameters based on input segments.

Figure 2 shows exemplary box-plots of  $p$  and  $w$  for XBERTScore, to illustrate the distributions we select from.

**Table structure** In the next paragraphs, we present our results in Tables 1, 2, 3 and 4, using similar structures. The top row shows the metric names. For MT datasets, the left column shows the language-pairs. For SummEval, it describes the aspects graded by human annotators and whether Kendall (KD) or Spearman (SP) correlation is shown. For RealSumm, the left column describes whether segment-level Pearson or system-level Kendall evaluation is shown. Generally, the left-most number indicates the ORIGINAL metric’s correlation for each metric. The other numbers show the correlation of BMX using ERASure, LIME and/or SHAP respectively. Improvements over the original metric are colored in blue. For MT and RealSum, we print results in bold where improvements with BMX are statistically significant ( $p \leq 0.05$ ) with the permute-both test described by

<sup>9</sup>We note that, as a benefit of BMX, not much data is used for the in-domain calibration on SummEval, as the calibration sets have small sizes of  $\sim 200$  samples.

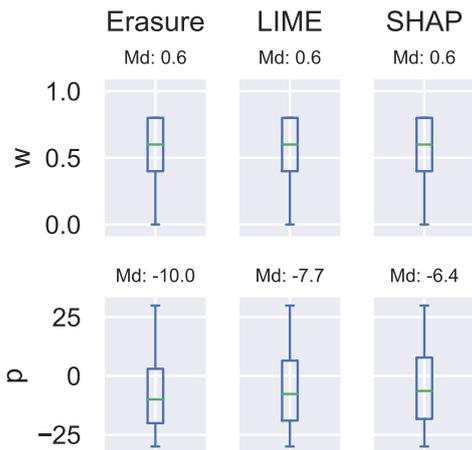

Figure 2: Box-plots of the  $w$  and  $p$  values for XBERTScore leading to improvements with different explainers across all settings of the MT calibration sets. *Md* denotes the Median value.

Deutsch et al. (2021); underscored results remain significant after applying the Bonferroni-correction (per base metric; separately for MT and summarization) (Bonferroni, 1936; Dror et al., 2017).<sup>10</sup> Dror et al. (2018) describe that the statistical significance of cross-validation is underexplored. A simple solution they propose is to check that a predefined number of splits remains significant after applying the Bonferroni-correction. For SummEval, instead of selecting this predefined number, we report the number of significant splits. Each average correlation we report has two superscript numbers. The first indicates the number of significant values before and the second after the Bonferroni correction (per base metric and correlation type). Results are rounded to 3 digits. Therefore, small improvements are indiscernable from the rounded numbers in some cases and can be identified by the coloring.

**Performance on WMT22** Table 1 shows the performance with the preselected  $p$  and  $w$  values from the last section. BMX achieves an improvement in most cases, when running with XBERTScore and XLMR-SBERT, while it only improves TransQuest on two language-pairs. The average improvement with SHAP on XBERTScore and XLMR-SBERT is consistent but rather small with 0.005 points in Spearman correlation. Notably, there are no

<sup>10</sup>We use the permute-both significance test implementation from <https://github.com/danieldeutsch/nlpstats> and the Bonferroni-correction implementation from <https://github.com/danieldeutsch/sacrerouge>.

improvements for the en-yo language pair of the WMT22 QE shared task (Zerva et al., 2022). This language pair was introduced as a low-resource surprise set. The bad performance might be caused by the models not having seen much of Yoruba during training. Potentially BMX does not work here because there is nothing reasonable to explain, as the models do not know the language.

**Performance on MQM** Table 2 shows the performance of BMX enhanced metrics for the MQM test set. On the segment-level, BMX improves all metrics in all language pairs, although only marginally for COMET. The average gain is 0.0075 points in Kendall correlation. In all but two cases, the improvement with BMX is significant. On the system-level BMX decreases the metric correlation for XBERTScore and Transquest. We investigate this in the paragraph *MT failure analysis* in Section 5 and find that better parameter selection can lead to strongly improved scores.

**Performance on SummEval** Table 3 shows the average Kendall and Spearman correlations of BMX (with in-domain calibration on the respective calibration splits) across the 8 test splits that we created from SummEval. In total, there is a strong average gain of 0.074 points in Kendall and 0.087 points in system-level Spearman correlation. Individually, gains are between 6-40%, e.g., BERTScore improves from 0.309 to 0.431 Kendall. These results show that, depending on the setting, BMX can substantially improve existing metrics.

**Performance on RealSumm** Table 4 shows the performance of BMX with BERTScore and BARTScore on the RealSumm dataset. We select the average of  $p$  and  $w$  values of the SummEval calibration splits for this setting as cross-domain calibration. BMX increases the system level correlation of BERTScore by 0.007. However, for BARTScore the performance decreases.

## 5 Analysis

In this section, we compare BMX to a fine-tuned metric on a SummEval split, analyze the failure in RealSumm and explore the stability of the metric when using the LIME explainer.

**Comparison to fine-tuning a metric** We use the out-of-the-box training script of BARTScore to fine-tune BARTScore on the reference-hypothesis pairs of the first calibration split of SummEval.

Then, we evaluate the fine-tuned metric, the original metric and BMX on the first test split and compare the results (see Figure 3). The tuned metric has a better coherence than the original metric and BMX, however, all other aspects are worse than original. BMX has the highest correlation in all other dimensions, which shows that it can use the small-scale training set more efficiently.

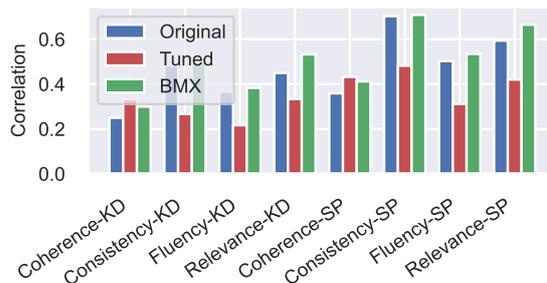

Figure 3: System-level correlation with BARTScore on the first test split of SummEval. Left columns show the original correlation, middle columns show the correlation with BARTScore fine-tuned on the calibration set and right columns show the correlation with BMX.

**MT failure analysis** For some settings, for example with COMET, changes are extremely small. To understand BMX’ internal workings, we plot the human scores and the two factors of the linear combination (the original score and the aggregated feature importance scores) for COMET on WMT22 cs-en (see the figure in Appendix G). The scores are ordered by the human scores from high to low and normalized by z-scoring. We find that many scores that were aggregated from the explanations are uniform, with few outliers. Hence, adding them to the original COMET will hardly change the results. Future work could further explore the causes.

As the system-level correlation decreased for some test setups on the MQM dataset, we further suspect that the transfer of  $p$  and  $w$  from the calibration sets to the evaluation set did not work out well, resulting in decreased correlations. To test this, we perform another grid-search on  $p$  and  $w$  and analyze whether other parameter settings would have performed better. The analysis shows that, even for COMET, the best parameter choice could lead to improvements of over 0.07 Kendall points, with a choice of  $w = 0.2$  and a good selection of  $p$  (see the figure in Appendix 7). For Transquest, the improvements can be over 0.06 Kendall points in en-de with  $w = 0.8$ . Determining  $p$  and  $w$  in an

in-domain setup might lead to better results. However, in real applications, there might not exist a human labeled portion of the dataset the method is applied to. Hence, future work could explore more elaborate mechanisms of selecting  $p$  and  $w$  than using the median of improvements on another dataset.

**RealSumm failure analysis** We suspect that the transfer of  $p$  and  $w$  from SummEval to the domain of RealSumm did not work out well, resulting in decreased correlations. To test this, as for our MT

Dataset	<b>BERTScore</b>	<b>BARTScore</b>
	ORIG/LIME	ORIG/LIME

failure analysis, we perform another grid-search on  $p$  and  $w$  and analyze whether other parameter settings would have performed better. The results of this analysis for BERTScore are visualized in figure 4. A choice of  $w = 0$  could have led to drastic improvements of over 0.3 (over 100% improvement). For BARTScore, the correlation could be improved by over 0.05 with the correct selection (see appendix F). Determining the values in a similar stratification setting as with SummEval might thus have led to better results.

**Stability of LIME** As LIME uses random permutations, we test the stability of the approach for our task. To do so, we select the metric COMET and 3 language pairs of the WMT22 dataset. Then, we compute BMX with LIME using the grid-search configuration of the previous section. We exclude  $w = 1$ , such that we get 3000 scores per language pair. We repeat this process 3 times using 100 per-

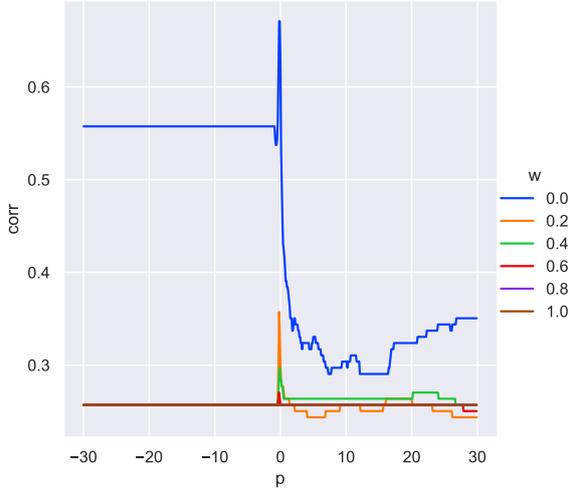

Figure 4: System-level correlation with BERTScore on RealSumm, across  $p$  values from  $-30$  to  $30$  and across  $w$  values from  $0$  to  $1$ , where  $w = 1$  is the original metric (indicated by a black line). BMX is using LIME in this sample.

mutations and 3 times using 1000 permutations. Then we compute the average Pearson correlation among the first 3 runs and the last 3 runs. With 100 permutations, the correlation is 0.9960, indicating very high stability of scores. With 1000 permutations, it is 0.9997. Thus, further runtime can be traded for more stability. Lower  $w$  values are less stable than higher ones (see figure 5). The case of  $w = 0$  does not appear in our experiment calibrations and is therefore not applied on the test sets.

**Influence of WMT2017** In contrast to newer datasets, the WMT17 dataset that we use for calibration is crowdsourced (Bojar et al., 2017). Hence, we investigate its impact on the parameter calibration by removing it and rerunning the experiments. This marginally improves correlation on the test sets (up to 0.002). These results can be seen as a sign of the robustness of our parameter selection method, although it is not optimal performance-wise.

**Segment- and System-level** Generally, we note that the performance increases with BMX tend to be higher on system-level tasks, while they are more stable, but small, on the segment-level. As our analysis shows, the correct parameter selection is very important and can lead to high improvements, but also decreased correlation. Again, we note that future work could explore parameter se-

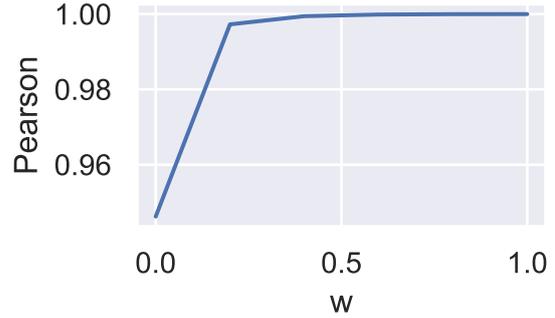

Figure 5: Average Pearson correlation between 3 repeated runs of BMX with LIME and different settings of  $w$  on the x-axis. The tests were computed on 3 language-pairs from WMT22 and the  $p$ -values range from  $-30$  to  $30$  for every  $w$  setting.

lection, such as specifically choosing the parameters for each input, for example, by using a trained model.

## 6 Related Work

Our work is related to the domains of explainability and NLG metrics.

**NLG metrics** While embedding based metrics perform very well, their internal workings have become increasingly complex and cannot be easily understood by humans. The recent shared tasks Eval4NLP (Fomicheva et al., 2021) and WMT22 QE (Zerva et al., 2022) explore the usage of explainability techniques for MT to tackle this issue and provide word-level explanations for segment-level metrics. Motivated by their work, we also use word-level explanations, but additionally aggregate them to improve the original score.

Considering existing metrics, our work is especially related to word-level metrics and metrics that can be considered self-explaining. Word-level metrics like word-level TransQuest (Ranasinghe et al., 2021) (in MT) are designed to assign translation quality scores to each word instead of the whole segment. They can be considered as self-explaining, as they provide the same kind of explanations external explainers would provide (Leiter et al., 2022). Some existing segment-level metrics are self-explaining in this sense as well, as they use segment-level scores that are constructed from other word-level outputs. E.g., BERTScore is based on word-level cosine similarities of contextualized word-embeddings and BARTScore is

based on word-level prediction probabilities of a BART model. We also use word-level scores to construct a new segment-level score. However, to the best of our knowledge, our method is the first to leverage model-agnostic explainability techniques to extract additional word-level information that is incorporated into the final metric. This has the benefit of being applicable to any segment-level NLG metric. BERTScore also has a configuration option to use tf-idf weighting on a token level. This is similar to feature importance explanations in the sense that both techniques assign “importance” scores to words. However, they describe different kinds of importance. Tf-idf weighting considers the general importance of words in a text. So these scores do not relate to “importance of the input to the output score” and potential errors considered by a metric. The Eval4NLP shared task showed that explanations from self-explaining methods tend to be stronger than model agnostic approaches (Fomicheva et al., 2021). Our method can provide another way to incorporate these word-level scores into the final prediction that might be explored by future work. Future work might also explore to use other model-specific explainers, e.g. gradient based or attention based methods (e.g. Treviso et al., 2021).

Another topic related to explainable NLG metrics are fine-grained annotation schemes themselves. For example, the word-level scores annotated in the Eval4NLP shared task (Fomicheva et al., 2021) or fine-grained error annotations like MQM (Lommel et al., 2014) allow for human annotation of explanations that could for example be used to compare the word-level scores in our experiments to.

Further, our approach is conceptually related to recent large language model (LLM) based approaches (released subsequently to our first Arxiv submission), where the LLMs iteratively explain and refine their own textual outputs (e.g. Madaan et al., 2023). Also, further works on metrics have started to employ LLM generated textual error reports in metric heuristics (e.g. Kocmi and Federmann, 2023; Fernandes et al., 2023). We differ from these approaches by not relying on LLMs, and by using external explainers and feature-importance explanations.

**Explainability** We leverage model-agnostic explainability techniques to collect word-level importance scores. There are many works that give an

overview on the topic of explainability, e.g., Lipton (2018); Barredo Arrieta et al. (2020).

Specifically, we want to highlight the similarity of our approach to the concept of simulatability (e.g. Hase and Bansal, 2020). Here, a machine or a human tester tries to reproduce an original model’s output or solve an additional task, using the explanations they receive. We also utilize explanation outputs to accomplish a specific task. However, our focus is not to evaluate the performance of the explainers, but rather to use them to improve metrics for NLG.

## 7 Conclusion

We have presented *BMX: Boosting natural language generation Metrics with eXplainability*, a novel approach that leverages the duality of NLG metrics and feature importance explanations to boost the metrics’ performance. BMX leverages model-agnostic explainability techniques, so that it can be applied to any NLG metric. Additionally, it requires no supervision once the initial parameters for  $p$  and  $w$  are set, which might benefit fully unsupervised or weakly supervised approaches to inducing evaluation metrics (Belouadi and Eger, 2023). Our tests show consistent improvements for multiple configurations on all tested datasets. Notably, we demonstrate strong improvements for summarization with 0.074 points in Kendall correlation on the system-level evaluation of SummEval, being significant on many test splits. On RealSumm, BMX is not as strong, but our analysis shows that a better choice of  $p$  and  $w$  could lead to strong improvements on this dataset as well.

To the best of our knowledge, our approach is the first to leverage the duality of segment-level MTE metrics and their feature-importance explanations directly and we believe that it can lead a step forward towards integrating metrics with explainability. Future work should also consider to which degree BMX can improve the explainability of metrics and apply our framework to other regression and classification tasks, beyond MT and summarization metrics. Future work should also examine how to effectively leverage higher-level iterations.

rics4NLG” and the German Research Foundation (DFG) via the Heisenberg Grant EG 375/5-1.

## Ethical Considerations

Our work might lead to the development of better natural language generation metrics. These metrics could be used to develop better generation systems. For these generation systems there is the risk of malicious usage, e.g., in the generation of hate speech or fake news. We think the benefit of these applications outweighs their misuse and note that our work is only considering their evaluation and hence does not carry a risk itself.

## Limitations

The post-hoc explainers that we use reevaluate permutations of the hypothesis and ground truth segments by calling the original metric. This leads up to a few thousand executions depending on the configurations of LIME and SHAP (for Erasure, the number of executions depends on the input size, thus is much lower). We advise to test the runtime on a few samples and if necessary, adapt the configuration to use less permutations.

Another limitation is that  $p$  and  $w$  need to be calibrated. The most promising approach to do this would be to evaluate a labeled subset of the dataset the metric should be applied on. If this is not feasible, existing datasets with human scores can be used for the calibration. Tuning these two parameters is little effort compared to the billions of parameters of modern LLMs, thus is comparatively efficient and applicable in small data scenarios. Further, due to time constraints, we did not evaluate all metric-explainer combinations. Further analysis might thus show that other settings work even better. In §6, we discuss metrics that produce word-level scores or are self-explaining by default. While not applicable to all metrics, every metric that falls into one of these two groups has another option to compute explanations. As the Eval4NLP shared task showed, these tend to be stronger than model agnostic approaches (Fomicheva et al., 2021). Also, while not explicitly denoted as explanations, they are often already incorporated into the final score, e.g. for BERTScore or BARTScore. Here, we note that our method can provide another way of incorporating these word-level scores into the final prediction that might be explored by future work. Future work might also explore other model-specific explainers, e.g. gradient based or attention based

methods (e.g. Treviso et al., 2021). Lastly, while BMX can potentially be applied to other NLG tasks and other domains in general, we did not test it.

## A Library Configurations

We use the following library and metric versions:

- **LIME**: 0.2.0.1
- **SHAP**: 0.41.0
- **transformers**: 4.20.1, 4.24.0
- **BARTScore, Reference-Based**: bartscore: May 2022, facebook/bart-large-cnn + bart.pth (406,290,432 Parameters). BARTScore (Yuan et al., 2021) returns the average generation probability of a sentence by a fine-tuned BART model as score. We use the *ref*→*hyp* generation direction of BARTScore, while the authors of BARTScore propose to use the *src*→*hyp* generation direction for SummEval (Yuan et al., 2021). We use *ref*→*hyp* as we want to leverage the large number of references in SummEval when applying BMX.
- **BERTScore, Reference-Based**: bertscore: 0.3.11; roberta-large (267,186,176 Parameters), No idf-weighting. BERTScore (Zhang et al., 2020) computes a sentence score from the cosine similarity of contextualized word-embeddings between two input sentences.

- **COMET, Reference-Free**: comet: 1.1.3; wmt21-comet-qe-mqm (569330715 Parameters). We use COMET-QE (Rei et al., 2021), which uses a dual-encoder approach based on XMLR-models fine-tuned on human scores.<sup>11</sup>
- **TransQuest, Reference-Free**: transquest: 1.1.1 TransQuest/monotransquest-da-multilingual; wmt21-comet-qe-mqm (560941057 Parameters). TransQuest (Ranasinghe et al., 2020) is a reference-free trained metric for MT, which employs an XMLR model fine-tuned on human quality estimation scores that grade the hypothesis based on the source sentence. This model directly predicts a segment-level score as the output.
- **XBERTScore, Reference-Free**: bertscore: 0.3.11; joeddav/xlm-roberta-large-xnli (459,120,640 Parameters), No idf-weighting. Leiter (2021) empirically showed that among multiple XLM-RoBERTa (Conneau et al., 2020) model variants, one fine-tuned on a cross-lingual NLI dataset *XNLI*<sup>12</sup> (Conneau et al., 2018) achieves strong results on the Eval4NLP21 (Fomicheva et al., 2021) dataset.
- **XMLR-SBERT**: stsb-xlm-r-multilingual (278,043,648 Parameters). We use XMLR to compute multilingual sentence embeddings (Reimers and Gurevych, 2020). Specifically, we use the cosine similarity of source and target embeddings as another segment-level metric.

For Erasure we use our own implementations.

## B Machine Translation Dataset Overview

See Table 5.

## C Early results: selection of LIME

We performed early experiments on WMT17, Eval4NLP and MLQE-PE, in which we selected the median of the p and w values that lead to the highest improvements per language-pair in a grid search. We only separated the values by explainer and not by metric. These experiments also included a variation of XMoverScore (Zhao et al., 2020) in the reference-free settings, as well as BERTScore and SentenceBLEU (Papineni et al., 2002) in the reference-based settings. XMoverScore is not included in the final experiments due to weak met-

<sup>11</sup>The stronger CometKiwi (Rei et al., 2022) is not yet available at time of writing this paper.

<sup>12</sup>XNLI XMLR-Model: <https://huggingface.co/joeddav/xlm-roberta-large-xnli>

	WMT17	Eval4NLP	MLQE-PE	WMT22	MQM

Total	3871	4000	7000	6000	19133

Table 5: Summary of the MT datasets we are using for exploration. We list the language pairs (LPs) in each set, the number of samples per pair and the total number of samples. The bold LPs occur in multiple datasets. For zh-en some sentences in the dataset could not be loaded, hence this pair has only 501 samples.

ric performance (we use it without target-side language model and cross-lingual mapping). BLEU and BERTScore are not included for machine translation, as only a few of the selected datasets provide reference sentences. It also included Input Marginalization (Kim et al., 2020) as another explainer, which we didn’t include in later experiments due to high runtime. Figure 6 shows a plot with the number of correlation improvements and decreases in each combination of language-pair, dataset and metric per explainer. We can see that LIME performs best, making it the default choice in the rest of our experiments.

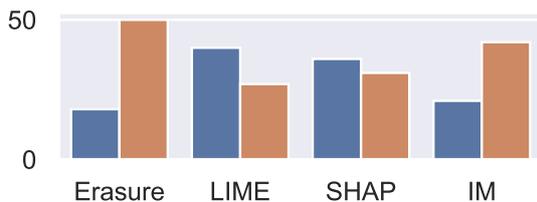

Figure 6: Cases of improvement and decreased performance with  $p$  and  $w$  fixed to the respective explainer’s best median. The blue bars show the number of settings with improved correlation, the orange bars show the number of settings with equal or worse correlation.

## D Implementation details for explainers

- **Erasure:** Li et al. (2016) suggest that model decisions can be investigated by analyzing the effect of feature removal. This is, e.g., used for adversarial attacks by Li et al. (2020). We use Erasure to determine token-level importance scores by analyzing a metric’s prediction with respect to the presence of each

token in the translation. I.e., for each token  $t_i \in \mathbf{g} \cup \mathbf{h}$  we compute the importance  $\phi_i$  as follows:

$$\phi_i = \mathcal{S}(\mathbf{g}, \mathbf{h}) - \mathcal{S}(\mathbf{g}, \mathbf{h})_{/t_i}$$

where  $\mathcal{S}(\mathbf{g}, \mathbf{h})$  is an NLG metric grading the ground truth  $\mathbf{g}$  and hypothesis  $\mathbf{h}$ .  $\mathcal{S}(\mathbf{g}, \mathbf{h})_{/t_i}$  denotes the same input without token  $t_i$ .

- **LIME:** LIME (Ribeiro et al., 2016) is a permutation based method, which trains a linear model that returns similar results as the explained model in a *neighborhood* of inputs. Its weights are assigned to each corresponding word as feature importance explanations. When we explain a metric with LIME, for each ground truth or hypothesis sentence that is explained, LIME trains a linear model that returns similar results as the metric in a *neighborhood* of this sentence. The *dataset* used to fit this model is generated by randomly permuting the input. The labels of this dataset are determined by computing the metric score of this permuted input. Finally, the weights of the linear model are assigned to each token as feature importance explanations. We run LIME with 100 permutations per ground truth and per hypothesis sentence. We use the default replacement token of the LIME library *UNKWORDZ*: <https://github.com/marcotcr/lime>. We use LIME with 100 permutations per hypothesis and ground truth each.
- **SHAP:** SHAP (Lundberg and Lee, 2017) is an explainability technique that either exactly

or approximately computes Shapley values from game theory, which measure the contribution of variables to a result, as feature importance scores. The exact SHAP explanation of a token is calculated using all possible permutations of the target sentence (with a single replacement token). The number of possible permutations grows exponentially with the number of input tokens. Therefore, SHAP is often approximated, e.g. using KernelShap (Lundberg and Lee, 2017). In our experiments, we use the same replacement string as for LIME: *UNKWORDZ*. Also, up to a number of 7 tokens per sentence, we compute the exact SHAP. For more tokens, we use *PermutationSHAP*, which is the default of the SHAP library<sup>13</sup>.

### E MQM with COMET

See Figure 7.

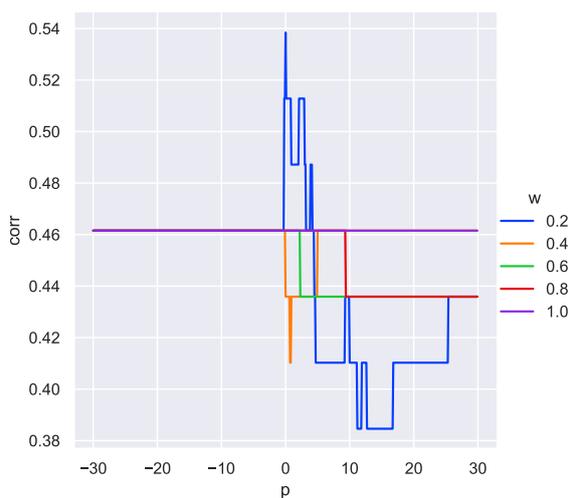

Figure 7: System-level correlation with COMET on the MQM dataset, across  $p$  values from  $-30$  to  $30$  and across  $w$  values from  $0$  to  $1$ , where  $w = 1$  is the original metric (indicated by a black line). BMX is using LIME in this sample.

# Joint Inference of Retrieval and Generation for Passage Re-ranking

Wei Fang and Yung-Sung Chuang and James Glass

Massachusetts Institute of Technology  
{weifang,yungsung,glass}@mit.edu

## Abstract

Passage retrieval is a crucial component of modern open-domain question answering (QA) systems, providing information for downstream QA components to generate accurate and transparent answers. In this study we focus on passage re-ranking, proposing a simple yet effective method, *Joint Passage Re-ranking* (JPR), that optimizes the mutual information between query and passage distributions, integrating both cross-encoders and generative models in the re-ranking process. Experimental results demonstrate that JPR outperforms conventional re-rankers and language model scorers in both open-domain QA retrieval settings and diverse retrieval benchmarks under zero-shot settings.<sup>1</sup>

## 1 Introduction

Passage retrieval is a crucial component in open-domain question answering (QA) (Chen and Yih, 2020), a task that requires answering questions from a wide range of domains and could be applied in systems that fulfill user’s information needs (Voorhees et al., 1999). Retrieval offers downstream QA systems grounding information, which not only improves accuracy in a lot of cases but also provides transparency to how systems generate answers, similar to how articles provide references and citations, such that model hallucinations can be checked with ease. Furthermore, the set of documents to be retrieved from, or knowledge base, can be quickly updated with new documents and knowledge such that models can adapt to temporal changes, and do not need to be continuously re-trained nor require online training paradigms for continual learning.

Early retrieval methods are typically based on term-matching, such as BM25 (Robertson et al., 2009) or TF-IDF (Salton et al., 1975). Such methods, called sparse retrievers, perform keyword

matching efficiently with an inverted index to find relevant contexts. Sparse retrievers often achieve reasonable performance while being computationally efficient and does not require training, but are shown to have limited abilities beyond lexical matching.

Recently, dense retrievers that encode text with continuous embeddings have been heavily studied and utilized in contemporary QA systems, often outperforming their sparse counterparts on high resource evaluation settings (Karpukhin et al., 2020). There are a few drawbacks however, such as higher computational demands during both training and inference, inability to handle large contexts (Luan et al., 2021), and difficulty in generalizing to new domains especially those with limited data (Reddy et al., 2021). Hybrid methods have been explored to get the best of both worlds, generally utilizing an efficient sparse method to retrieve a larger number of possibly relevant contexts, and then perform passage re-ranking with a more computationally-intensive dense model for refined scoring (Nogueira and Cho, 2019).

In this work, we focus on passage re-ranking and explore the use of generative models alongside conventional re-rankers. Previous work have explored pre-trained language models (LM) as the re-ranking scorer (Sachan et al., 2022), however we find that it underperforms conventional re-rankers for both supervised and zero-shot settings. Starting from maximizing mutual information (MI) for inference, which measures how much more queries and passages co-occur compared to appearing independently, we show how a small generative model can be effectively used with conventional cross-encoding re-rankers for improved performance. Experiments on a supervised setting for open-domain QA retrieval and a zero-shot setting across a suite of diverse retrieval benchmarks validate our approach. Our contributions can be summarized as follows:

<sup>1</sup>Source code is available at <https://github.com/wfangtw/jpr>

- We propose *Joint Passage Re-ranking* (JPR), a method utilizing both a cross-encoder and a generative model in the retrieval re-ranking process, optimizing the mutual information between query and passage distributions.
- We demonstrate that JPR outperforms conventional re-rankers and generative scorers in open-domain QA retrieval evaluation and diverse zero-shot retrieval datasets.

## 2 Joint Passage Re-ranking (JPR)

Consider the two distributions  $p(\mathbf{x})$  and  $p(\mathbf{z})$  over all queries  $\mathbf{x} \in \mathcal{X}$  and all passages  $\mathbf{z} \in \mathcal{Z}$ . The conditional distributions  $p(\mathbf{z}|\mathbf{x})$  and  $p(\mathbf{x}|\mathbf{z})$  can be used to infer one domain based on the other. The joint distribution  $p(\mathbf{x}, \mathbf{z})$  characterizes the combined structure of both domains, where  $p(\mathbf{x}, \mathbf{z}) = p(\mathbf{x})p(\mathbf{z}|\mathbf{x}) = p(\mathbf{z})p(\mathbf{x}|\mathbf{z})$ .

Here  $p_\phi(\mathbf{z}|\mathbf{x})$  defines a passage retrieval model, which we parametrize by  $\phi$ , generally trained with maximum likelihood estimation (MLE):  $\mathcal{L}_{\text{retrieval}}(\phi) \triangleq -\mathbb{E}_{\mathbf{x}, \mathbf{z} \sim p(\mathbf{x}, \mathbf{z})} [\log p_\phi(\mathbf{z}|\mathbf{x})]$ . During inference, finding the most probable relevant passage can be written as:

$$\hat{z} = \arg \max_z \log p_\phi(\mathbf{z}|\mathbf{x}). \quad (1)$$

Since we focus on passage re-ranking, we treat  $p_\phi(\mathbf{z}|\mathbf{x})$  in Eq. 1 as re-ranking scores.

### 2.1 Inference by Maximizing Mutual Information

In passage retrieval, documents are commonly chunked into multiple passages of fixed length, some of which containing summaries or general information that are often estimated to have high probabilities by retrieval rankers but do not contain specifics regarding the given query. One of such example is shown in Figure 1. In this work, we approach inference by finding the passage that maximizes the *pointwise mutual information* (PMI) between both domains instead of likelihood:

$$\hat{z} = \arg \max_z \left( \log p(\mathbf{z}|\mathbf{x}) - \log p(\mathbf{z}) \right). \quad (2)$$

We see that maximizing PMI adds a penalizing term compared to MLE in Eq. 1, which discounts such passages that unconditionally have a higher probability, and biases the model towards those that are specific to the given query. A hyperparameter  $\lambda$  is added to control the regularization term. Using

Query ( $x$ )	$\log p(\mathbf{z} \mathbf{x})$	label
who produced the movie i can only imagine	-0.882	0
who played amy grant i i can only imagine	-0.913	0
who wrote the country song i can only imagine	-2.466	1
who wrote and performed i can only imagine	-2.682	1
when was i can only imagine the song released	-3.893	0
when is i can only imagine coming out	-4.507	0

Figure 1: Example showing a passage that is estimated to have high retrieval probabilities for multiple queries by a conventional re-ranker. Each query asks about different specifics of a movie, however the passage contains mostly general information, and could not be used to answer several top-ranked questions. This motivates our use of a penalization term to discount these high probability passages that are not specific to the input query.

Bayes' theorem, we can rewrite Eq. 2 as:

$$\begin{aligned} \hat{z} &= \arg \max_z \left( \log p(\mathbf{z}|\mathbf{x}) - \lambda \log p(\mathbf{z}) \right) \\ &= \arg \max_z \left( (1 - \lambda) \log p(\mathbf{z}|\mathbf{x}) + \lambda \log p(\mathbf{x}|\mathbf{z}) \right). \end{aligned} \quad (3)$$

The PMI objective is equivalent to the convex combination of the terms  $\log p(\mathbf{z}|\mathbf{x})$  and  $\log p(\mathbf{x}|\mathbf{z})$ . Notice that the latter term can be viewed as a conditional generation model that gives the probability of generating a query given a passage. We denote the generative model by  $p_\theta(\mathbf{x}|\mathbf{z})$  with parameters  $\theta$ . This term was previously explored as the sole inference objective in [Sachan et al. \(2022\)](#), in which an LM was used as a question generator for re-scoring. Instead of using either the retrieval model or the generative model only, as explored in prior work, Eq. 3 provides a simple way to use both models jointly for inference, which we refer to as *Joint Passage Re-ranking* (JPR).

### 2.2 Joint Fine-tuning

A straightforward way to obtain the two models that can be used for the aforementioned MI-based inference is to train both models using MLE separately. The retrieval model can be trained with  $\mathcal{L}_{\text{retrieval}}(\phi)$ , while the generative model can be trained with a

Re-ranking Method	Cross-Encoder? $\log p_\phi(z x)$	Generative? $\log p_\theta(x z)$	Natural Questions			TriviaQA		
			Top-1	Top-5	Top-10	Top-1	Top-5	Top-10

BERT-FT	$\checkmark$	$\times$	49.4	66.4	71.4	66.7	77.6	80.2
T5-FT	$\times$	$\checkmark$	34.3	59.6	66.7	56.8	74.1	78.0
UPR (T0-3B)	$\times$	$\checkmark$	36.8	61.6	68.2	57.7	75.4	78.5
JPR	$\checkmark$	$\checkmark$	51.0	<b>68.0</b>	<u>72.3</u>	68.3	78.3	<b>80.5</b>
JPR-FT	$\checkmark$	$\checkmark$	<u>51.4</u>	67.5	71.9	<b>69.2</b>	<b>78.5</b>	<b>80.5</b>
UPR (LLaMA-33B)	$\times$	$\checkmark$	35.0	61.5	69.0	57.2	76.7	79.5
JPR (LLaMA-33B)	$\checkmark$	$\checkmark$	48.2	66.9	71.5	<u>70.1</u>	<u>79.3</u>	<u>80.8</u>

Table 1: Top- $K$  retrieval accuracy (%) on the Natural Questions and TriviaQA test sets. All non-BM25 methods re-rank the top-100 passages retrieved by BM25. Best overall are in **bold** while best non-LLM are underlined.

simple LM loss  $\mathcal{L}_{\text{generation}}(\theta)$ .

However, the terms in Eq. 3 are derived when the distributions are matched, that is, when  $p(x)p_\phi(z|x) = p(z)p_\theta(x|z)$ . When the two models are optimized independently, we cannot ensure that this holds. We therefore attempt to enforce this constraint with joint fine-tuning. Similar to previous work on dual supervised learning, we approach this by adding a regularization term, defined as the symmetric KL divergence between the two distributions:  $\mathcal{L}_{\text{match}}(\phi, \theta) \triangleq D_{\text{sym-KL}}(p_\phi(x, z) || p_\theta(x, z))$ , by enforcing alignment of the marginals multiplied by the conditional probabilities. The joint fine-tuning objective is obtained by combining all three losses:  $\mathcal{L}(\phi, \theta) \triangleq \mathcal{L}_{\text{retrieval}} + \mathcal{L}_{\text{generation}} + \alpha \mathcal{L}_{\text{match}}$ , where  $\alpha$  is a regularization hyperparameter. The additional fine-tuning aligns the two conditional distributions such that the conditions for our derivations hold, thereby enhancing the overall performance.

### 3 Experiments

#### 3.1 Open-Domain QA Retrieval

##### 3.1.1 Data

First, we evaluate on two standard open-domain QA retrieval benchmark datasets: Natural Questions (NQ; Kwiatkowski et al., 2019) and TriviaQA (Joshi et al., 2017). Wikipedia passages used in DPR (Karpukhin et al., 2020) were used in these experiments, which consists of 21M 100-word passages from the English Wikipedia dump of Dec. 20, 2018 (Lee et al., 2019). Additional dataset information can be found in Appx. A.

##### 3.1.2 Setup and Baselines

We adopt the setting from prior work using standard dataset splits, retrieving the top 100 passages for

re-ranking. We use Pyserini (Lin et al., 2021) for BM25 as the initial retriever, with default Lucene parameters of  $k = 0.9$  and  $b = 0.4$ . We report top- $K$  retrieval accuracy, the standard metric.

We compare JPR against several baselines: 1) cross-encoding re-ranker (BERT-FT), a fine-tuned BERT-based (Devlin et al., 2019) re-ranker, running inference with Eq. 1; 2) generative re-ranker (T5-FT), a fine-tuned T5 conditional generation model (Raffel et al., 2020) with the second term of Eq. 3 as inference objective; and 3) UPR (Sachan et al., 2022), a generative re-ranker using the larger pre-trained T0-3B model (Sanh et al., 2022).

For our approach, we report one setting with joint inference (JPR), and another with joint fine-tuning followed by the MI-based inference (JPR-FT). Joint inference uses the separately fine-tuned retrieval re-ranker and generative re-ranker described above directly. For joint fine-tuning, we bootstrap with the two models, and further fine-tune with our proposed objective to match the discriminative and generative distributions.  $\lambda$  and  $\alpha$  are chosen by performance on the development set. Additional details can be found in Appx. B.

Furthermore, we aim to explore the effects of scaling generative re-rankers up. We experiment with a large language model (LLM), the 33B-parameter LLaMA (Touvron et al., 2023), as our generative re-ranker for both UPR and JPR.

##### 3.1.3 Results and Discussion

Open-domain QA retrieval results are shown in Table 1. Using the conventional cross-encoder BERT-FT on initial BM25 results yields decent improvements. UPR, not fine-tuned but being much larger, significantly underperforms BERT-FT. The fine-tuned generative model T5-FT,  $15\times$  smaller than the T0-3B model in UPR, nearly matches the

Dataset	BM25	Re-ranking Method

Table 2: Zero-shot results on BEIR, scores denote **nDCG@10**. All methods re-rank the top-100 passages retrieved by BM25, except for TREC-DL 2019 to compare to prior work. Best overall are in **bold**. Underlined indicate in-domain performance, and *italicized* are based on Pyserini reproductions, differing from those reported in prior work.

performance of UPR. When using JPR, which corresponds to scoring with Eq. 3 using the re-ranker BERT-FT and the generative model T5-FT, surpasses all baselines. The generative model, although used by itself underperforms BERT-FT, boosts performance especially for the top retrieved passages. Matching distributions (JPR-FT) by fine-tuning for a small amount of steps further improves performance, albeit more modestly. For LLM generative re-ranking, despite being multitudes larger, LLaMA-33B surprisingly underperforms against T5-FT and T0-3B on NQ for both UPR and JPR, however on TriviaQA JPR with LLaMA-33B achieves best overall results. Appx. C shows further results for different model pairings.

## 3.2 Zero-Shot Retrieval

### 3.2.1 Data

We further evaluate in a transfer learning setting on BEIR (Thakur et al., 2021), a commonly used benchmark consisting of a suite of information retrieval datasets that span multiple tasks and domains. Datasets in the benchmark contain queries and passages of a variety of styles and lengths, and no training data is provided, making it considerably difficult for models to perform well across all datasets. See Appx. D for more details.

### 3.2.2 Setup and Baselines

We follow BEIR’s zero-shot evaluation on all tasks, using MS MARCO (Nguyen et al., 2017) as training data. Pyserini is used for BM25 to retrieve 100 passages, with default parameters and indexing title and passage as separate fields<sup>23</sup>. The Normalized Cumulative Discount Gain (nDCG@K) (Wang et al., 2013) is used for evaluation, with  $K = 10$ , computed by the official TREC evaluation tool (Van Gysel and de Rijke, 2018).

We compare against the three baselines used previously with slight differences: 1) conventional discriminative re-ranker (BERT-FT), using a BERT-based re-ranker pre-trained on MS MARCO with the same configuration (Reimers and Gurevych, 2019); 2) generative re-ranker (T5-FT), using the same t5-base-lm-adapt but fine-tuned on MS MARCO; and 3) UPR, but re-ranked over 100 instead of 1000. For our proposed approach, we only evaluate the joint inference method (JPR), as the MS MARCO pre-trained re-ranker from SBERT<sup>4</sup> is already at a saddle point, and using it to bootstrap leads to degraded performance. Detailed training hyperparameters can be found in Appx. E.

### 3.2.3 Results and Discussion

Zero-shot results on BEIR are presented in Table 2. JPR attains roughly 2% absolute gain on average simply by utilizing both discriminative and generative models for inference, which is more prominent when compared against in-domain performances in Sec. 3.1 and on TREC-DL 2019. JPR surpasses BERT-FT on 10 out of the 14 tasks and is roughly equal on the other 4, and eclipses T5-FT on 13 of 14. Notably, for two tasks, FEVER and Climate-FEVER, generative re-rankers struggle and exhibit degraded performance, whereas JPR avoids this issue and outperforms BERT-FT. When using the comparatively huge LLaMA, we see that UPR worsens on average, mostly due to major underperformance on tasks such as ArguAna, Touché-2020, FEVER, and Climate-FEVER. On most other tasks it outperforms UPR, suggesting that larger models’ effects may scale both ways, positively on familiar tasks, such as CQADupStack which LLaMA had exposure during LM training, and negatively on a few out-of-domain ones. JPR (LLM) can mitigate the worst cases, however it mostly does not

<sup>2</sup>Pyserini reproductions for BEIR can be found at <https://castorini.github.io/pyserini/2cr/beir.html>.

<sup>3</sup>We follow BEIR and retrieve 100, which is more practical.

<sup>4</sup>[https://www.sbert.net/docs/pretrained\\_cross-encoders.html](https://www.sbert.net/docs/pretrained_cross-encoders.html)

outperform JPR that uses the considerably smaller generative model.

## 4 Related Work

Passage re-ranking seeks to combine the advantages of sparse retrieval methods, such as efficiency, precise matching, and low-resource generalizability (Sciavolino et al., 2021; Reddy et al., 2021), with the superior performance of dense methods in the presence of extensive annotated data (Karpukhin et al., 2020; Guu et al., 2020). Early work by Nogueira and Cho (2019) examined BERT-based supervised re-rankers, while later research proposed reader prediction based re-ranking (Mao et al., 2021) and attempted to use LMs as re-rankers (Sachan et al., 2022), although with limitations. Sequence-to-sequence models have also been investigated to directly generate ranking labels (Nogueira et al., 2020), and further training with explanations can yield improvements under lower-resource scenarios (Ferraretto et al., 2023). More recently, Sun et al. (2023) explored using the proprietary and exceptionally larger ChatGPT models for re-ranking<sup>5</sup>. Departing from existing ensembling techniques for re-ranking such as fusing bi-encoder embeddings (Lu et al., 2021), our method establishes the combination of discriminative and generative re-rankers through PMI maximization.

MI-based objectives, originally introduced in speech recognition to measure input-output dependence (Bahl et al., 1986; Woodland and Povey, 2002), have been applied to different tasks such as dialogue (Li et al., 2016), machine translation (Li and Jurafsky, 2016), and QA (Luo et al., 2022). MI-based joint inference and learning have been explored in question answering and generation (Tang et al., 2017), language understanding and generation (Su et al., 2020), and various vision and language tasks (Xia et al., 2017).

## 5 Conclusion

In this study, we introduce a simple and effective approach to enhance re-ranking for passage retrieval. By jointly utilizing a conventional cross-encoding re-ranker and a conditional query generator for inference, we optimize the pointwise mutual information between the query and passage distributions, achieving improvements in open-domain

<sup>5</sup>Sun et al. (2023) reported results only on a subset of BEIR and uses BM25 “flat” (cf. “multifield”).

QA retrieval, and more significantly in zero-shot information retrieval tasks.

## Acknowledgements

This research was supported by the Centre for Perceptual and Interactive Intelligence (CPII) Ltd. under the Innovation and Technology Commission’s InnoHK Scheme.

## Limitations

First, improvements under the supervised setting for open-domain QA retrieval are diminished as  $K$  increases, and roughly equals out with using conventional re-rankers at  $K = 20$ ; however, there are still many use cases especially for large models with limited context that can benefit from the improvements of our approach. Additionally, in this work we tackle passage re-ranking for retrieval, focusing on the second stage re-ranking scores using dense cross-encoders and generative models. We have not explored approaching the retrieval process without passage re-ranking, that is, directly applying the PMI objective to train a dense retrieval model, which could potentially lead to larger improvements but comes with much higher computational costs. We leave this for future work.

## Ethics Statement

In this work, we used publicly available models and datasets for training and evaluation, and did not collect data or any personal information. The trained models could however potentially be misused and pose ethical risks typical of large language models when deployed in real-world applications, if not thoroughly audited.

## A Open-Domain QA Retrieval Datasets

We show the number of train/dev/test examples in NQ and TriviaQA in Table 3. Please refer to Kwiatkowski et al. (2019) and Joshi et al. (2017) for more details. Note that NQ is licensed under Apache License 2.0, which we follow, and TriviaQA does not provide dataset licenses.

Dataset	Train	Dev	Test
Natural Questions	58,880	8,757	3,610
TriviaQA	60,413	8,837	11,313

Table 3: Dataset splits for NQ and TriviaQA.

## B Open-Domain QA Retrieval Training and Inference Details

### B.1 Training

Generally, conventional cross-encoders are trained to minimize the negative likelihood  $\mathcal{L}_{\text{retrieval}}(\phi) \triangleq -\mathbb{E}_{x,z \sim p(x,z)} [\log p_{\phi}(z|x)]$ , where  $p_{\phi}(z|x)$  is usually calculated from the retrieval score of question-passage pairs, with the partition function approximated by a noise contrastive approach trained either with a classification or a ranking objective (Ma and Collins, 2018). We choose to fine-tune our cross-encoder, BERT-FT, using a 6-layer transformer model (Vaswani et al., 2017), which takes the concatenated input of a query and a passage, with the binary classification objective for noise contrastive learning (Mikolov et al., 2013). The 6-layer SBERT model MiniLM-L-6-v2 we use was previously pre-trained on MS MARCO, which we fine-tune for 2 epochs using the top 32 passages from BM25 on the NQ/TriviaQA training set. We train with a batch size of 128, learning rate of  $5e-5$ , linear warmup and decay with ratio of 0.1.

For training of T5-FT, we fine-tune with  $\mathcal{L}_{\text{generation}}(\theta)$  using the t5-base-lm-adapt model, a 12-layer encoder-decoder configuration with 220M parameters initialized from T5-base v1.1 and trained for an additional 100k steps with an LM objective. It takes a ground truth passage as input with its corresponding query as the decoder target. Ground truth query-passage pairs from the training set was used to fine-tune the model for 2 epochs. We use a batch size of 64, learning rate of  $5e-5$ , and linear warmup and decay ratio of 0.1. Hyperparameters were chosen by performance on the dev set.

UPR uses the pre-trained T0-3B directly without any fine-tuning.

JPR uses BERT-FT and T5-FT, described earlier, directly during inference (see Sec. B.2 below). JPR-FT requires further fine-tuning, which we train for another epoch. Training hyperparameters were searched with the dev set, with one run for each hyperparameter setting, shown in Table 4. We report results for the model with the best-performing run on the dev set.

All models were trained with HuggingFace’s Transformers library (Wolf et al., 2020), using the AdamW optimizer (Loshchilov and Hutter, 2018) with default parameters. The maximum sequence lengths for queries and passages were set to 128 and 512, respectively, for generative models. For

Hyper-parameter	NQ		TriviaQA	
	BERT-FT	T5-FT	BERT-FT	T5-FT
learning rate	1e-5	2e-5	1e-5	1.5e-5
batch size	96	64	64	64
$\alpha$	0.0005	0.0005	0.005	0.005

Table 4: Training hyperparameters for NQ and TriviaQA selected by performance on the dev set.

the cross-encoding BERT-FT, we set the maximum concatenated length to be 512. Training was done with four Nvidia A6000 GPUs, with around 2.5 GPU hours per epoch, equating to around 250 GPU-hours in total.

### B.2 Inference

For the conventional cross-encoding re-ranker (BERT-FT), we re-rank with Eq. 1 by directly ranking the retrieval scores. When using BERT-FT in JPR, we approximate  $\log p_{\phi}(z|x)$  by taking SoftMax over the scores for the 100 retrieved passages. For generative re-rankers T5-FT and UPR, we follow Sachan et al. (2022) and estimate  $\log p_{\theta}(x|z)$  with length-normalized conditional likelihood of the output sequence followed by taking SoftMax over the passages. For JPR, the preceding two terms are weight-averaged according to Eq. 3.

## C Results on Open-Domain QA Retrieval with Different Cross-encoding and Generative Model Pairs

We further show the efficacy of JPR on NQ by conducting additional evaluations on NQ with various model combinations. We experiment with BERT models of different sizes for the cross-encoders, and for generative models we chose T5 models of multiple models sizes. All cross-encoding models were previously pre-trained on MS MARCO, which we fine-tune on NQ, and the T5 models were fine-tuned on NQ, all following training procedures reported in Sec. B. For inference, we use  $\lambda = 0.5$  and follow the inference steps outlined in Sec. B.2. The results are shown in Table 5.

From the results, notice that when T5-small is paired with MiniLM-L-6 for JPR, it aligns with the performance of T5-base paired with MiniLM-L-6. This observation underscores that the additional parameters of T5-base may be superfluous in our application. When comparing JPR (MiniLM-L-6 & T5-small) with the standalone BERT-base, which is in the same parameter ballpark, and the larger BERT-large, it’s evident that the gains from JPR

Cross-encoder	Generative Model	#params	Top-1	Top-5	Top-10
TinyBERT	$\times$	4.4M	37.8	60.3	67.0
MiniLM-L-4	$\times$	19.2M	47.5	65.9	70.9
MiniLM-L-6 (BERT-FT)	$\times$	22.7M	49.4	66.4	71.4
BERT-base	$\times$	109.5M	49.2	66.0	70.8
BERT-large	$\times$	335.1M	49.8	67.5	71.7
$\times$	T5-tiny	15.6M	25.7	51.4	62.0
$\times$	T5-small	77.0M	30.7	57.1	65.2
$\times$	T5-base (T5-FT)	247.6M	34.4	59.7	66.9
MiniLM-L-6	T5-tiny	38.3M	49.6	67.0	71.6
MiniLM-L-6	T5-small	99.7M	50.4	67.3	71.7
MiniLM-L-6	T5-base	270.3M	50.4	67.3	71.8

Table 5: Top- $K$  retrieval accuracy (%) on NQ for different model combinations with the proposed JPR.

are not solely attributable to model size.

tasks are zero-shot and we do not have access to the validation sets.

## D BEIR Benchmark

The BEIR benchmark contains 18 datasets from a variety of text retrieval tasks and domains, 14 of which are publicly available. In this work we evaluate baselines and our approach on the publicly available datasets in BEIR: TREC-COVID (Voorhees et al., 2021), NFCorpus (Boteva et al., 2016), NQ (Kwiatkowski et al., 2019), HotpotQA (Yang et al., 2018), FiQA-2018 (Maia et al., 2018), ArguAna (Wachsmuth et al., 2018), Touché-2020 (Bondarenko et al., 2020), CQADupStack (Hoogeveen et al., 2015), Quora<sup>6</sup>, DBPedia (Hasibi et al., 2017), SCIDOCS (Cohan et al., 2020), FEVER (Thorne et al., 2018), Climate-FEVER (Diggelmann et al., 2020), and SciFact (Wadden et al., 2020). For details on dataset statistics, links, and licenses please refer to BEIR (Thakur et al., 2021). Note that datasets in BEIR that are under copyright were not used in this study, and 4 out of the 14 publicly available datasets do not report dataset licenses. We follow the intended uses for each dataset license.

## E Zero-shot Retrieval Training and Inference Details

For BEIR, since the SBERT model was already pre-trained on MS MARCO, we directly use it for BERT-FT. On the other hand, T5-FT stills requires fine-tuning, which we train for 3 epochs on query-passage pairs in the training set, with batch size of 16 and learning rate of  $5e-5$  with no warmup. The inference process is the same as open-domain QA retrieval, described earlier in Sec. B.2, except for  $\lambda$  which we set to 0.5 for all tasks as the BEIR

## Abstract

Despite advancements in conversational AI, language models encounter challenges to handle diverse conversational tasks, and existing dialogue dataset collections often lack diversity and comprehensiveness. To tackle these issues, we introduce DialogStudio: the largest and most diverse collection of dialogue datasets, unified under a consistent format while preserving their original information. Our collection encompasses data from open-domain dialogues, task-oriented dialogues, natural language understanding, conversational recommendation, dialogue summarization, and knowledge-grounded dialogues, making it an incredibly rich and diverse resource for dialogue research and model training. To further enhance the utility of DialogStudio, we identify the licenses for each dataset, design external knowledge and domain-aware prompts for selected dialogues to facilitate instruction-aware fine-tuning. Furthermore, we develop conversational AI models using the dataset collection, and our experiments in both zero-shot and few-shot learning scenarios demonstrate the superiority of DialogStudio. To improve transparency and support dataset and task-based research, as well as language model pre-training, all datasets, licenses, codes, and models associated with DialogStudio are made publicly accessible<sup>1</sup>.

## 1 Introduction

Recent years have seen remarkable progress in Conversational AI, primarily driven by the advent of approaches and language models (Shuster et al., 2022; Zhang et al., 2023; Longpre et al., 2023; Touvron et al., 2023). Despite the advancements, these models could fall short when handling various tasks in a conversation due to the

lack of comprehensive and diverse training data. Current dialogue datasets (Lin et al., 2021; Asri et al., 2017) are typically limited in size and task-specific, which thus results in suboptimal ability in task-oriented model performance. Additionally, the lack of dataset standardization impedes model generalizability.

A few recent works (Gupta et al., 2022; Longpre et al., 2023; Ding et al., 2023) have introduced a large collection of datasets, which includes diverse tasks based on public datasets. For instance, FlanT5 (Longpre et al., 2023) presents the flan collections with a wide array of datasets and tasks. Despite this breadth, the coverage of dialogue datasets within the Flan collection remains notably sparse, featuring only about ten datasets. Although OPT (Iyer et al., 2022) have incorporated collections with several dialogue datasets, these collections remain inaccessible to the public. In contrast, efforts like InstructDial (Gupta et al., 2022) and ParlAI (Miller et al., 2017) consist of more dialogue datasets, but they lack diversity and comprehensiveness. For instance, ParlAI mainly includes open-domain dialogue datasets, which are exclusively accessible through their platform. Other collections (Gupta et al., 2022; Kim et al., 2022a; Ding et al., 2023; Dubois et al., 2023) often distill single dataset from ChatGPT or process datasets into a sequence-to-sequence format to support language model training, featuring only input-output pairs such as dialogue context and system response. However, previous collections often overlook other crucial dialogue information, constraining their utility for research on individual datasets, tasks, and broader applications.

To overcome the aforementioned challenges, we introduce DialogStudio, the most comprehensive and diverse collection of publicly available dialogue datasets, unified under a consistent format. By aggregating dialogues from various sources, DialogStudio promotes holistic anal-

<sup>\*</sup> Core contributors. Work completed during Kun’s internship at Salesforce. Zhiwei is also a major contributor.

<sup>1</sup><https://github.com/salesforce/DialogStudio>

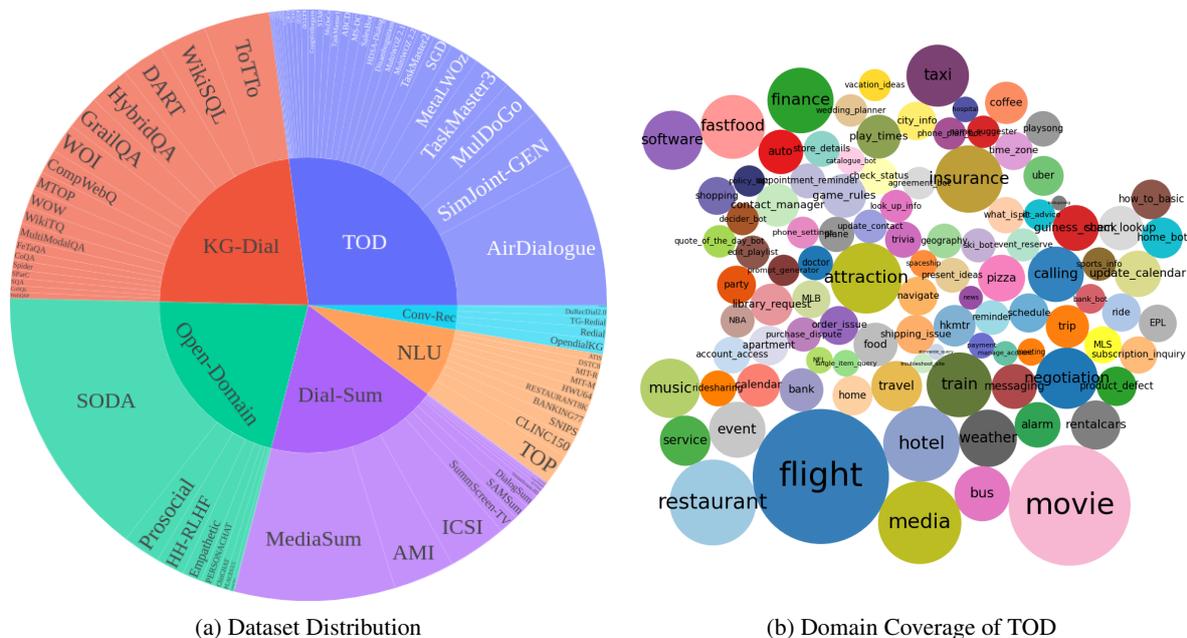

Figure 1: (a) is the distribution of all datasets in DialogStudio. The outer and inner circle list names of datasets and the associated categories, respectively. (b) illustrates covered domains of Task-Oriented Dialogues in DialogStudio.

ysis and the development of models adaptable to a variety of conversational scenarios. The collection spans an extensive range of domains, aspects, and tasks, and it is inclusive of several categories: Open-Domain Dialogues, Task-Oriented Dialogues, Natural Language Understanding, Conversational Recommendation, Dialogue Summarization, and Knowledge-Grounded Dialogues. Thus, it can provide support for research in both individual dialogue tasks and large-scale language pre-training.

DialogStudio stands out not only for its comprehensive coverage but also for its accessibility. It offers easy access with a unified format and documents. A straightforward `load_dataset()` command through HuggingFace allows users to seamlessly interact with the collection, and we have included documentation for each dataset to enhance usability. We anticipate that this collection will enable comprehensive and standardized training and evaluations of dialogue models, fostering fair comparisons and propelling further advancements in Conversational AI.

Furthermore, we identify dialogue domains, design external knowledge for available dialogues and create tailored prompts for selected datasets accordingly. Leveraging these datasets from DialogStudio, we have constructed instruction-aware models, with capacities ranging from 770M to 3B parameters. These models have the ability to

handle various external knowledge and are adept at both response generation and general tasks, demonstrating the benefits of DialogStudio. The main contributions of this paper are as follows:

- We introduce DialogStudio, a meticulously curated collection of more than 80 dialogue datasets. These datasets are unified under a consistent format while retaining their original information. We integrate external knowledge, incorporate domain-aware prompts and identify dataset licenses, making DialogStudio an exceptionally rich and diverse resource for dialogue research and model training.
- We have made our datasets publicly available to enhance transparency and support research efforts. Additionally, we are committed to improving DialogStudio’s usability and will persist in our efforts to refine it, ensuring an optimal user experience.
- We train conversational AI models based on DialogStudio, and these models have demonstrated superior performance over strong baselines in both zero-shot and few-shot learning scenarios.

## 2 Data analysis

### 2.1 Data Visualization

The dialogue datasets are compartmentalized into several categories: *Open-Domain Dialogues*,

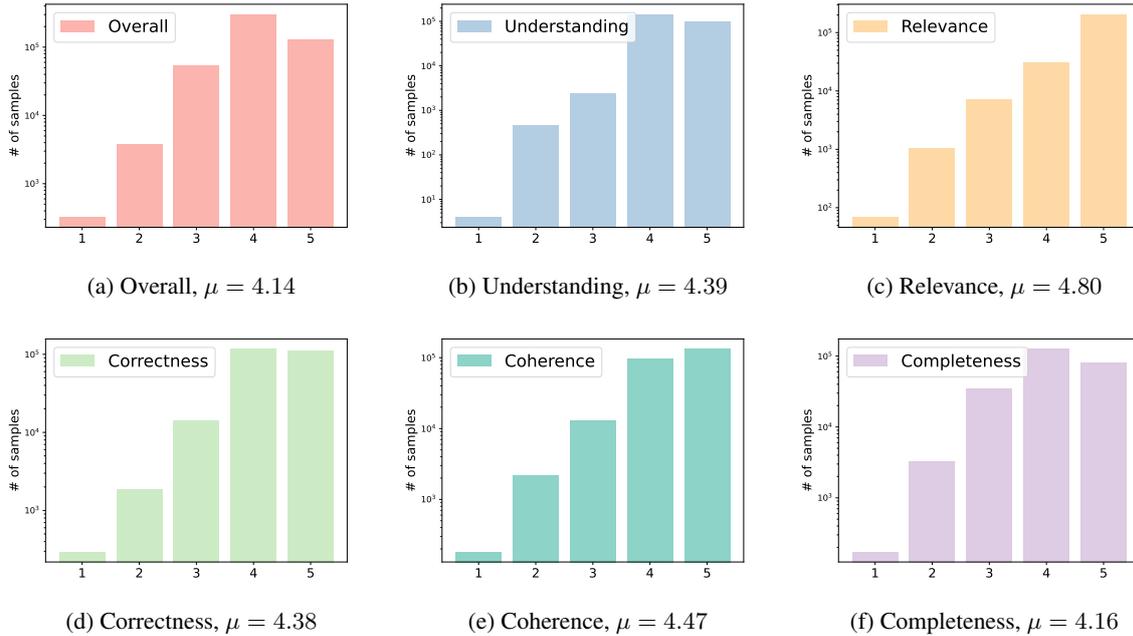

Figure 2: The score distribution for the dialogue quality.

*Task-Oriented Dialogues (TOD)*, *Natural Language Understanding Dialogues (NLU)*, *Conversational Recommendation (Conv-Rec)*, *Dialogue Summarization (Dial-Sum)*, and *Knowledge-Grounded Dialogues (KG-Dial)*. Figure 1a presents an overview of DialogStudio’s dataset categories. Note that the category boundaries are fuzzy as some datasets span multiple categories. For instance, SalesBot (Chiu et al., 2022) contains both casual and task-oriented conversations. Analogously, MultiWOZ (Budzianowski et al., 2018; Zang et al., 2020), a task-oriented dialogue corpus, incorporates knowledge bases and dialogue acts to enhance knowledge-grounded generation. Additionally, DialogStudio demonstrates its diversity by covering a wide range of domains, part of which is shown in Figure 1b.

## 2.2 Data Quality Investigation

Due to the existence of noise in dialogue, we develop a simple yet effective way to verify the quality of the datasets. Specifically, we employ ChatGPT (GPT-3.5-turbo) to evaluate the quality of system responses based on several perspectives (Mehri et al., 2022; Kim et al., 2022a), *i.e.*, Understanding, Relevance, Correctness, Coherence, Completeness and Overall quality. Understanding assesses whether the model’s responses accurately reflect the meaning and intent of the user’s inputs. Relevance demonstrates whether the

generated response should be directly related and appropriate to the preceding user input and the context of the conversation. Coherence measures the logical consistency of the model’s responses within the context of the conversation. Completeness refers to whether the system’s responses fully address the user’s queries or tasks. Overall quality comprehensively rates the quality of dialogue. All scores are in the range of 1-5, and higher scores should only be given to truly exceptional examples. We delicately design the prompt and ask the ChatGPT model to *strictly* rate the score.

Since there are a lot of datasets in DialogStudio, we randomly select 33 multi-turn dialogue datasets and evaluate all the training dialogues of each dataset. To harmonize ChatGPT and human ratings, we take a random sample of 50 training dialogues from each dataset. These were then rated by three expert researchers using the five specified criteria. Post-alignment of ChatGPT and human evaluations, we view dialogues with a score above 3 as being of high quality. Figure 2 illustrates distributions of those scores. We also reveal the average score as the  $\mu$  in each sub-caption. In general, the dialogues show high qualities regarding to the individual criteria and the overall quality.

## 3 Datasets Unification and Access

We collect and process a wide range of datasets, involving different domains, types, and tasks.

Since these datasets originally contain various information and format, we propose a unification strategy to process all the datasets such that they can be loaded in the same data loader.

### 3.1 Unification

Before unifying the format of those datasets, we fixed several issues as follows: 1) we remove those dialogues labeled as multi-turn dialogues, but actually with only one turn and miss either user utterance or system utterance. 2) We manually check the individual dialogues. If one dialogue contains one or more empty user or system utterances, we fill utterances based on corresponding dialogue contexts, dialogue acts, and dialogue information. In total, less than 0.5% of dialogues had these issues. To support research interest on individual datasets, we have flagged and rectified these problematic dialogues.

Additionally, we recognize the success of instruction tuning for dialogue models and thus we manually pre-define five different prompt templates for multi-turn dialogue datasets, such as *This is a bot helping users to {Task\_Domain}. Given the dialogue context and external database, please generate a relevant system response for the user.* The *{Task\_Domain}* is associated with the dialogue domain and we manually create a corresponding description. For example, if a dialogue is of domain *travel*, we set *{Task\_Domain}* as *book a trip*. A concrete example of the prompt is demonstrated in Figure 3. Moreover, many datasets lack a direct mapping between dialogues and their domain information. To address this, we determine the domain of each dialogue using its intent, schema, APIs, and associated databases.

Next, we construct a uniform JSON dictionary format to store all relevant information of each dialogue as illustrated in Figure 3. Compared with existing works, DialogStudio covers more dialogue information and is easier to retrieve the information for arbitrary dialogue-related tasks. Concretely, we include all dialogue-related information, such as the dialogue ID, data split label, domain, task, and content. Additionally, we identify the external knowledge, dialogue state tracking (DST) knowledge, and intent knowledge in the dialogue, which are the most beneficial knowledge for a dialogue.

Regarding external knowledge, we construct it based on information such as databases and dia-

logue acts. Since each dialogue dataset focuses on specific tasks or domains and has a different database and annotation schema, we unify such information into *external knowledge*. For example, if the user is looking for a hotel and asking for its address, the system response should be based on both the search results from the database and the dialogue context. To simulate the realistic situation and avoid directly providing the model with the ground truth resulting hotel, we also randomly sample four other candidate results and mix them with the ground truth result. All information is flattened and converted into a string as external knowledge.

To complete tasks and generate coherent responses, a dialogue system needs to track users' requirements for the task. Those requirements are usually represented as dialogue states. For example, regarding the hotel booking task, a dialogue system needs to extract information such as price range and locations to enable searching hotels in the database. The type of dialogue states varies across different tasks and datasets. As such, it is hard for dialogue systems to predict the values of those dialogue states if unknowing the specific dialogue states the task covers. Therefore, we propose to insert the schema, consisting of pre-defined dialogue state types and values for each task, into the input sequence. For datasets like SGD (Rastogi et al., 2020), which already provides annotation schema, we directly convert the dictionary-structured schema into a string. For the rest datasets that have no such schema file, we iterate over all dialogues and collect potential state annotations to construct a schema. We provide domains, slot types, and slot values in the schema string. For those categorized dialogue slots like "hotel star-ratings", which have a fixed number of candidate values, we provide all possible values. For others that have unlimited possible values, e.g. "stay night", we randomly sample ten values, such that a model can learn what slot values are relevant to these slot types. We put the turn-level ground-truth DST information in "dst", and the general DST information under "dst knowledge", as presented in Figure 3.

Analogously, intent prediction also requires models to know all possible intent types for each task. Therefore, we extract the schema directly from the schema file if it exists. As to datasets without schema, we also iterate over all dialogue

(b) DialogStudio Data

Figure 3: A dialogue format example. Left: original example, right: converted example. Here we only show the first turn and partial information.

in the dataset to collect all potential intents. Then, we put the turn-level ground-truth intent information into "intent", and the general intents under "intent knowledge", as presented in Figure 3. Note that not all datasets provide detailed annotation for dialogue states, intents, or even databases. For dialogue state tracking and intent classification tasks, we only process dialogues with corresponding annotations. Since all data is used for response generation, we leave the external knowledge value for the database blank if there is no related database in the original dataset.

### 3.2 Access and Maintenance

As aforementioned in the format, our DialogStudio data is easy to access via the JSON files. To make DialogStudio more maintainable and accessible, we will publish datasets on both GitHub and HuggingFace. GitHub mainly stores selected dialogue examples and relevant documents. We sample five original dialogues and five converted dialogues for each dataset to facilitate users in

comprehending our format and examining the contents of each dataset. The complete DialogStudio dataset is maintained in our HuggingFace repository, where all the datasets can be directly downloaded or loaded with the HuggingFace `load_dataset(dialogstudio, dataset_name)` API. Given the substantial volume of datasets, optimizing user experience poses a challenge and limitation. We will continuously maintain and update both GitHub and HuggingFace. DialogStudio is built upon public research datasets without individual or private information. We believe it is important to clearly present the license associated with each of these datasets. Consequently, we have included the original licenses for all datasets. All these datasets are supportive of academic research, and some of them also endorse commercial usage. The code that we employ falls under the widely accepted Apache 2.0 license. While we strictly require adherence to the respective dataset licenses for all intended usages on DialogStudio, there remains

a possibility that some works might not fully comply with the licenses.

Regarding the other concerns such as ethical concern, we admit that DialogStudio is collected and maintained by the authors of this work and we did not hire external annotators. Since it contains unified datasets across several categories, it supports various research purposes from individual tasks and datasets to language model pre-training.

## 4 Experiments

In this section, we present the pre-training details, methodologies, and metrics used to assess the performance of our DialogStudio model. The evaluation process aims to measure the model’s ability to both solve task-oriented dialogues and understand general prompt-based instruction.

### 4.1 Model Pre-training

In this section, we introduce more details about how we conduct our pre-training. In regards of training models, we mix several datasets from DialogStudio.

For task-oriented and conversational recommendation datasets, we selected dialogues from a range of sources including KVRET (Eric et al., 2017), AirDialogue (Wei et al., 2018), DSTC2-Clean (Mrkšić et al., 2017), CaSiNo (Chawla et al., 2021), FRAMES (El Asri et al.), WOZ2.0 (Mrkšić et al., 2017), CraigslistBargains (He et al., 2018), Taskmaster1-2 (Byrne et al., 2019), ABCD (Chen et al., 2021a), MulDoGO (Peskov et al., 2019), BiTOD (Lin et al., 2021), SimJoint (Shah et al., 2018), STAR (Mosig et al., 2020), SGD (Rastogi et al., 2020), OpenDialog (Moon et al., 2019) and DuRecDial-2.0 (Liu et al., 2021).

Meanwhile, for knowledge-grounded dialogues, we drew upon dataset from SQA (Iyyer et al., 2017), SParC (Yu et al., 2019b), FeTaQA (Nan et al., 2022), MultiModalQA (Talmor et al., 2021), CompWebQ (Talmor and Berant, 2018), CoSQL (Yu et al., 2019a).

For open-domain dialogues, we sample dialogues from SODA (Kim et al., 2022a), ProsocialDialog (Kim et al., 2022b), Chitchat (Myers et al., 2020).

For each dialogue dataset, we sample at most 11k dialogues. Additionally, we extracted around 11k dialogue turns from question-answering dialogues featured in RACE (Lai et al., 2017), Nar-

rativeQA (Kočíšký et al., 2018), SQUAD (Rajpurkar et al., 2018), MCtest (Richardson et al., 2013), OpenBookQA (Mihaylov et al., 2018), MultiRC (Khashabi et al., 2018). Here, a dialogue turn refers to a pair consisting of a dialogue context and its corresponding system response. The rest datasets in DialogStudio are preserved for future evaluations and downstream fine-tuning.

For each dialogue during the training, we shape the available external knowledge into a string, which is included in dialogue context, and instruct the model to generate a dialogue response based on external knowledge. We use the format *Instruction* \n <USER> user utterance <SYSTEM> system response <USER> ... <USER> user utterance \n <EXTERNAL KNOWLEDGE> supported knowledge to train the model, where <USER>, <SYSTEM> and <EXTERNAL KNOWLEDGE> are special tokens.

We follow the public HuggingFace transformer code (Wolf et al., 2020; Wang et al., 2022) to train the model. For initializing our models, we adopt T5 (Raffel et al., 2020) and Flan-T5 (Longpre et al., 2023) as starting points to respectively establish DialogStudio-T5 and DialogStudio-Flan-T5. For the training of DialogStudio-Flan-T5, we exclude all translation-oriented tasks, limiting the sample size for each Flan task to a maximum of 150 examples. This leads to a cumulative total of 140,000 samples. We train the model up to 3 epochs with bfloat16 precision, a total batch size of 64. We set a constant learning rate 5e-5 and 3e-5 for the large model and the 3B model, respectively. Experiments are conducted using 16 A100 GPUs, each with 40GB of GPU memory.

### 4.2 Evaluation for Response Generation

**Settings.** We evaluate the performance on CoQA (Reddy et al., 2019) and MultiWOZ 2.2 (Zang et al., 2020). CoQA is a multi-turn conversational question answering dataset with 8k conversations about text passages from seven diverse domains. MultiWOZ 2.2 is one of the largest and most widely used multi-domain task-oriented dialogue corpora with more than 10000 dialogues. Each dialogue involves with one or more domains such as *Train, Restaurant, Hotel, Taxi, and Attraction*. The dataset is challenging and complex due to the multi-domain setting and diverse linguistic styles. Note that we exclude both datasets during the pre-training stage to prevent data leakage.

	CoQA		MultiWOZ	
	ROUGE-L	F1	ROUGE-L	F1
Flan-T5-3B (Longpre et al., 2023)	37.1	37.2	7.0	7.4

Tk-INSTRUCT-11B (Wang et al., 2022)	32.3/ <b>62.3</b>	51.1/ <b>69.6</b>	<b>55.0/64.1</b>	46.1/ <b>65.3</b>
Tk-INSTRUCT-3B (Wang et al., 2022)	38.4/51.3	45.7/58.5	48.4/52.8	44.2/54.2
DialogStudio-NIV2-T5-3B	<b>41.3/59.8</b>	57.5/63.7	52.3/55.1	50.4/59.5

Table 2: 0-shot/2-shot/5-shot ROUGE-L testing results on unseen datasets and unseen tasks. Results of baselines are reported by original papers. CR, DAR, and TE, avg. are abbreviations for Coreference Resolution, Dialogue Act Recognition, Textual Entailment, and average results, respectively.

For CoQA, we follow the original paper setting to answer question based on external passage. For MultiWOZ 2.2, we consider the lexicalized dialogue-act-to-response generation task where the model needs to consider both the dialogue context and the dialogue acts during generation. We follow the prompt from (Bang et al., 2023) to instruct models, i.e., *Continue the dialogue as a task-oriented dialogue system called SYSTEM. The answer of SYSTEM should follow the ACTION provided next while answering the USER’s last utterance.*

We focus on zero-shot evaluation and report the ROUGE-L and F1 score (Miller et al., 2017), where ROUGE-L measures the longest common subsequence and F1 measures the Unigram F1 overlap between the prediction and ground-truth response.

**Baselines.** We consider GODEL (Peng et al., 2022) and Flan-T5 (Longpre et al., 2023) as our baselines. GODEL is a T5-based large pre-trained model for goal-oriented dialogues. It is pre-trained with 551M multi-turn Reddit dialogues and 5M knowledge-grounded and question-answering dialogues. Flan-T5 is an instruction-aware model. It is also initialized from T5 and pre-trained on

the Flan collection, which consists of more than 1800 tasks and 400 datasets, including dialogue datasets.

**Results.** Table 1 depicts the results from both zero-shot and few-shot testing. Evidently, our models considerably surpass the baseline models in terms of zero-shot learning, exhibiting a robust generalized ability for response generation in a zero-shot scenario.

Flan-T5-3B, on the other hand, underperforms in the task of generating responses from dialog-acts. This model tends to produce incorrect dialog acts, unnatural utterances, or terminates with an empty end token. One explanation for this is that Flan-T5 models did not receive sufficient dialogue training during the instruction-training phase on the Flan collections. Comparisons between the performances of existing models before and after training on the unified dataset validate DialogStudio’s usefulness.

### 4.3 Evaluation on Super-NaturalInstructions

**Settings.** NIV2 (Wang et al., 2022) introduces an instruction-tuning benchmark with more than 1600 tasks. We select 3 categories with 44 tasks from the held-out test set, which consists of 154

	MMLU		BBH
	0-SHOT	5-SHOT	3-SHOT
TK-INSTRUCT 11B (Wang et al., 2022)	-	41.1	32.9
LLAMA 13B (Touvron et al., 2023)	-	46.2	37.1
Vicuna 13B (Chiang et al., 2023)	-	49.7	37.1
Flan-T5-Large (Longpre et al., 2023)	41.5	41.9	37.1
Flan-T5-XL (Peng et al., 2022)	48.7	49.3	40.2
OPT-IML-Max 30B (Iyer et al., 2022)	46.3	43.2	31.3
DialogStudio-Flan-T5-Large	40.1	40.9	34.2
DialogStudio-Flan-T5-3B	48.3	47.8	40.3

Table 3: Test results on MMLU and BBH. Results come from original papers and InstructEval (Chia et al., 2023).

tasks, i.e., Coreference Resolution, Dialogue Act Recognition, and Textual Entailment. The selected tasks and datasets are unseen in the training stage. Specifically, we strictly follow all settings including metrics in (Wang et al., 2022), i.e., train models with instructions + 2 positive demonstrations and no negative demonstrations. We fine-tune DialogStudio-T5-3B on 756 training tasks.

**Baselines.** OPT (Zhang et al., 2022b) is a set of open decoder-only transformer models pre-trained on 180B tokens. OPT-IML (Iyer et al., 2022) is an instruction meta-learning model based on the OPT-IML bench with more than 1500 tasks. Tk-INSTRUCT (Wang et al., 2022) is initialized from T5 and further pre-trained based on NIV2 collections. Note that we neglect Flan-T5 because it trains with all the downstream datasets and tasks.

**Results.** Table 2 shows the 0-shot and 2-shot results on unseen datasets and unseen tasks. Based on the average performance on 48 tasks, DialogStudio-NIV2-T5-3B outperforms OPT-IML-175B by 5.9% on 2-shot learning with more than 50 times fewer model parameters, and it surpasses Tk-INSTRUCT-11B by 4.3% on 0-shot learning with more than 3 times fewer parameters. The performance demonstrates the strong generalization ability of DialogStudio model. Compared with Tk-INSTRUCT-3B, DialogStudio-NIV2-T5-3B achieves 6.2% and 5.3% improvements on 0-shot and 2-shot learning respectively. Given that both Tk-INSTRUCT and our DialogStudio-NIV2-T5-3B are fine-tuned from the T5 model, this improvement indicates the effectiveness of pre-training with our DialogStudio collection.

#### 4.4 Evaluation on MMLU and BBH

Table 3 presents results on MMLU (Hendrycks et al., 2020) and Big Bench Hard (BBH) (Srivastava et al., 2022).

When comparing the performance of DialogStudio-Flan-T5 with Flan-T5, we observe a minor decrease. However, this is accompanied by a significant improvement in dialogue relevant capabilities.

#### 4.5 Evaluation on Alternative Benchmarks

DialogStudio encompasses not just public realistic dialogue datasets, but also those derived from or shared with ChatGPT, such as SODA (Kim et al., 2022a) and ShareGPT. Due to GPU constraints, we employ techniques like LoRA (Hu et al., 2021) to fine-tune llama (Touvron et al., 2023). When using equivalent datasets from DialogStudio, we observed performance comparable to other models, e.g., Vicuna (Chiang et al., 2023), on benchmarks like AlpacaEval (Dubois et al., 2023) and MT-Bench (Zheng et al., 2023). This demonstrates that DialogStudio caters to research interests in both specific datasets and generalized instruction tuning.

## 5 CONCLUSION

In this study, we have introduced DialogStudio, a comprehensive collection that aggregates more than 80 diverse dialogue datasets while preserving their original information. This aggregation not only represents a significant leap towards consolidating dialogues from varied sources but also offers a rich tapestry of conversational patterns, intents, and structures, capturing the nuances and richness of human interaction. Utilizing DialogStudio, we developed corresponding models, demonstrating superior performance in both zero-shot and few-shot learning scenarios. In the spirit of open research and advancing the field, we are committed to releasing DialogStudio to the broader research community.

## Abstract

Linguistic features have a strong contribution in the context of the automatic assessment of text readability (ARA). They have been one of the anchors between the computational and theoretical models. With the development in the ARA field, the research moved to Deep Learning (DL). In an attempt to reconcile the mixed results reported in this context, we present a systematic comparison of 6 hybrid approaches along with standard Machine Learning and DL approaches, on 4 corpora (different languages and target audiences). The various experiments clearly highlighted two rather simple hybridization methods (soft label and simple concatenation). They also appear to be the most robust on smaller datasets and across various tasks and languages. This study stands out as the first to systematically compare different architectures and approaches to feature hybridization in DL, as well as comparing performance in terms of two languages and two target audiences of the text, which leads to a clearer pattern of results.

## 1 Introduction

A significant proportion of the population suffers from their poor reading skills in their everyday life (Schleicher, 2019, 2022), for example to access medical information (Friedman and Hoffman-Goetz, 2006) or to process administrative tasks (Kimble, 1992). This issue may be tackled with Automatic Readability Assessment (ARA); for example by automating recommendations of texts suited to specific reading levels (Pera and Ng, 2014; Sare et al., 2020).

ARA has leveraged automatic annotation of textual features, and Machine Learning (ML) algorithms. In this context, ARA has largely been modeled using feature engineering (Collins-Thompson, 2014; François, 2015; Vajjala, 2021). Current works rely on distributed representations of texts (i.e. embeddings) (Cha et al., 2017; Filighera et al.,

2019) and Deep Learning (DL) (Nadeem and Ostendorf, 2018; Azpiazu and Pera, 2019; Martinc et al., 2021), yielding improvement over linguistic feature-based systems (e.g., Deutsch et al. (2020); Martinc et al. (2021) for English and Yancey et al. (2021) for French). Consequently, DL has become the new standard in ARA. However, linguistic feature engineering has not been completely discontinued (Imperial, 2021; Weiss and Meurers, 2022). We emphasize two main reasons for that. First, obtaining audience-specific data to produce large corpora, required for DL, is difficult, and vanilla transformers tend to achieve low performance on small readability datasets (Lee et al., 2021). Second, feature-based approaches bring knowledge from cognitive psychology and the modelling of difficulty (Chall and Dale, 1995), offering insights on how textual characteristics affect readers (Javourey-Drevet et al., 2022).

In this work, we focus on hybrid models as a way to combine the accuracy of DL with the grounded interpretability of features, with minimal pre-training costs.<sup>1</sup> We aim to identify an effective architecture for combining linguistic features and transformers for ARA, keeping in mind that there may be an overlap of the information encoded in both representations (Goldberg, 2019; Rosa and Mareček, 2019; Jawahar et al., 2019; Kim et al., 2020). Although this work focuses on ARA, the methodology presented here can be applied to other tasks, particularly those tasks that rely on a restricted data set. The main contributions of this paper are: (1) a systematic analysis of how hybrid architectures compare with traditional ones<sup>2</sup>, (2) recommendations for the best hybrid architecture for ARA, and (3) a study of how those models are impacted by corpora properties (e.g. language, or

<sup>1</sup>Note that other types of hybrid models, such as multi-modal models, are outside the scope of this work.

<sup>2</sup>Developed model is available on [gitlab.com/rswilkens/linguistic-features-in-transformers](https://gitlab.com/rswilkens/linguistic-features-in-transformers).

L1 vs. L2). The paper is structured as follows: we discuss existing work in more details (Section 2), we detail our approach (Section 3) and present the results we obtained (Section 4). We then present an in-depth error analysis (Section 5) before concluding (Section 6).

## 2 Related Work

The inclusion of linguistic features in DL models has been done in various areas of NLP. In some cases, the purpose is to provide additional information that a DL model does not have access to (e.g. information about products (Amplayo et al., 2022)). Additionally, linguistic information can be included to facilitate the learning task, by providing complementary information or information poorly presented in the model. The inclusion of features in DL requires changes in the architecture, which can be done by adding additional layers or modifying the existing ones<sup>3</sup>. In this section, we examine how this modification in architecture is carried out in NLP and particularly in ARA.

### 2.1 Hybrid Models

Feature integration methods can be divided into two categories, depending on whether integration is direct or indirect.

**Direct (or explicit) integration** consists in concatenating feature vectors and embedding vectors. This method is simpler to implement than the indirect method and is the most widely used. It enriches the networks' input with fine-grained linguistic information that may be under-represented or particularly important in the networks' embeddings. Balagopalan and Novikova (2020), for example, connect the last layer of BERT to a vector of 119 lexical and syntactic features to improve an Alzheimer's Disease (AD) detection system. The same method can be found in several other systems: Complex Word Identification (Ortiz-Zambrano et al., 2022); Automatic Essay Scoring (Prabhu et al., 2022); Abusive Language Detection (Koufakou et al., 2020); Natural Language Understanding (Zhang et al., 2020); and assigning a CEFR (Common European Framework of Reference) level to a text<sup>4</sup>(Schmalz and Brutti, 2021).

<sup>3</sup>The modification of existing layers implies the invalidation of pre-trained models, which represents a large training cost and is therefore outside the scope of this work.

<sup>4</sup>Direct integration has also been used with non-linguistic information: Zhang et al. (2021) and Amplayo et al. (2022) integrate extra-textual data (e.g. user or product information) in various classification contexts (mainly sentiment analysis).

Peinelt et al. (2021) proposed an alternative concatenation method by injecting pre-trained (non contextual) embedding into the BERT architecture. To that end, they projected the embedding sequence to BERT's internal dimensions and squashed the output values to a range between -1 and 1.

**Indirect (or implicit) integration** consists in orienting fine tuning by associating one or more auxiliary tasks with the main task. For example, Zhou et al. (2019) propose a multi-task architecture which aims at simultaneously integrating morpho-syntactic (POS-tagging), syntactic (component and dependency parsing) and semantic (span and dependency semantic role labeling) information into the model.

### 2.2 Hybrid Models for ARA

Deutsch et al. (2020) investigated if adding linguistic-based characteristics to deep learning models can increase their performance in ARA. They compared conventional ML (SVMs, Linear Models, and Logistic Regression), CNNs, Transformer, and HANs to do this. They employed the numerical output of a neural model as a feature itself, concatenated with language data, and then fed into one of the non-neural models. Deutsch et al. (2020) identified strong differences in models ranking depending on the corpora.

Imperial (2021) advocated for concatenating raw embeddings with constructed language feature sets and feeding them to typical machine-learning techniques. Li et al. (2022) built a BERT-based model with feature projection and length-balanced loss. They derive a set of topic features by grouping related words with similar difficulty levels. To produce orthogonal features, these features are concatenated and projected (Qin et al., 2020) to the neural network features. According to Li et al. (2022)'s ablation study, the most significant improvement is related to the length-balanced loss they proposed, whereas the features had a minor impact. Lee et al. (2021) employed a soft labeling approach (i.e., the fine-tuned BERT probabilities of the prediction are concatenated with linguistic data), and used the whole to train Random Forest models. Liu and Lee (2023) compared hard labels (the fine-tuned BERT prediction is concatenated with linguistic data), following Deutsch et al. (2020), soft labels, and sentence concatenated with features embeddings, for investigating passage-level ARA. They found that Hard Labels and Soft Labels outperform transformers, but the sentence concatenated model

performed the poorest (similarly to a vanilla transformer model).

In order to give a first indication of the performance of the different strategies for combining features with transformers, Table 1 compiles the performance of the different works presented in this section. Thus, the initial observation points to the use of soft labeling, but the number of features is different between the works and the results using concatenation are based on one corpus only.

### 3 Methodology

In order to find the best approach for combining features and embeddings for ARA, we carried out a systematic comparison of architectures by comparing hybrid and non-hybrid (baselines) architectures. To this end, we selected 4 readability corpora with various characteristics (Section 3.1), on which we computed linguistic features (Section 3.2) before comparing the performance of the 8 architectures described in Section 3.3. To this aim, we split each corpus into train, validation and test sets (60/20/20) using stratified cross validation with groups defined based on target difficulty level and text genre (when available). For comparing performance, we applied the Friedman and Mann-Whitney U tests.

#### 3.1 Corpora

Assessing our architectures requires corpora in which the reading difficulty of each text has been evaluated according to a reference difficulty scale<sup>5</sup>. In this work, we opted for 4 corpora that cover two readability tasks (one targeting native speakers and the other targeting language learners) as well as two languages (English and French)<sup>6</sup>.

**French as Native Language (FLM<sup>7</sup>)** (Wilkins et al., 2022a) is composed of 334 text documents from Belgian school material. They are divided into 9 levels (from grade 4 to grade 12) and three domains (History, Science, and French language). The level of a text is the level of the textbook it was taken from.

**French as Foreign Language (FLE<sup>8</sup>)** (François and Fairon, 2012; Yancey et al., 2021) is composed of 2,734 text documents extracted from French as

a foreign language (FFL) textbooks published between 2001 and 2018. The level of each document ranges across five CEFR levels (Council of Europe, 2001) and is the same as the textbook from which it was taken.

**Cambridge** (Xia et al., 2016) is a collection of 330 reading texts from the Cambridge English Exams, explicitly designed for L2 learners at different proficiency levels. The corpus is divided into five CEFR levels, depending on the proficiency levels.

**Clear** (Crossley et al., 2021) is a set of 4,716 excerpts (written between 1875 and 1922) scored by 1,116 teachers from CommonLit Ease according to their easiness for a student (8 to 17 y/o in the American curriculum), where the final text readability score is the probability of text easiness based on the Bradley-Terry model.

#### 3.2 Linguistic Feature Annotation

Before comparing our different architectures, we needed to identify the relevant features for each corpus. The first challenge is to identify tools that annotate both languages in a similar way. In this sense, the FABRA toolkit (Wilkins et al., 2022a) and its English version (Wilkins et al., 2022b) are suitable options. This toolkit annotates numerous linguistic variables relevant for readability. Since many of these variables are at the word or sentence level, the toolkits use various statistical aggregators (e.g., mean, percentile and skewness) to create the features for each text aiming at a more detailed description of the linguistic variables.<sup>9</sup>

After the 4 corpora were annotated, we had to identify an appropriate set of features to be used in the hybrid models. To this end, we opted for the mRMR (Maximum Relevance Minimum Redundancy) method<sup>10</sup> (Ding and Peng, 2003). More specifically, following Zhao et al. (2019), we used the FCQ variant of mRMR (a combination of Random Forest, Randomized Dependence Coefficient, and Quotient). We explored 10 different sizes of feature sets (10, 20, 30, 40, 50, 100, 200, 300, 400, and 500). Finally, each of these sets was compared using a regression model, and the set of features used in the best performing model for each corpus

<sup>5</sup>All corpora use a discrete scale for difficulty level, except for CLEAR, which uses a continuous scale.

<sup>6</sup>We did not consider corpora where perfect performance has been demonstrated (Lee et al., 2021), as this would limit the models' comparison.

<sup>7</sup>Français Langue Maternelle

<sup>8</sup>Français Langue Étrangère

<sup>9</sup>A list of the variables is available at <https://cental.uclouvain.be/fabra>.

<sup>10</sup>mRMR is a greedy algorithm that chooses the best feature and appends it to the previously selected features on each iteration. The idea is that at each iteration, the algorithm chooses the feature with maximum relevance to classify the target (i.e., univariable classification) and minimum redundancy with the features chosen in previous iterations.

Architecture	WeeBit	OSE	Cambridge
Concatenation BERT, SVM, 54 features (Imperial, 2021)	-	0.704	-
Concatenation BERT, Log. Regression, 54 features (Imperial, 2021)	-	0.732	-
Concatenation + Projection BERT, 255 features (Li et al., 2022)	0.927	0.994	0.877
Soft-Label ROBERTA, Random Forest, 255 features (Lee et al., 2021)	0.902	0.995	0.752
Soft-Label BART, Random Forest, 255 features (Lee et al., 2021)	0.905	0.971	0.727
Soft-Label BERT, SVM, 86 features (Deutsch et al., 2020)	0.877	-	-

Table 1: Summary of F1 measures of readability hybrid models

is chosen.<sup>11</sup>

### 3.3 Models

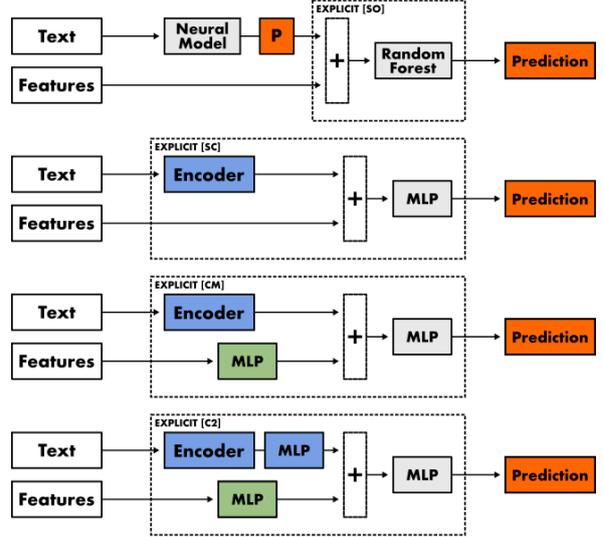

In this work, we explored 8 different architectures<sup>12</sup> (see Figure 1), which may be organized into three groups, based on the features integration method. A key element in the performance of these architectures is the linguistic features to be used. However, considering the different types of corpora explored in this work, it is natural to have different feature sets depending on the language and task. Therefore, the features are considered as a parameter for the architecture.

**Baselines (no integration):** As a basis for comparison with non-hybrid methods, we considered two baselines that do not combine features with deep learning. The first method, based on deep learning exclusively, uses transformers (henceforth **TR**), more specifically the RoBERTa architecture. This choice was based on the decision to use the same architecture for both languages, where there are fewer models available for French. The second method, based on features exclusively, consists in classical statistical methods. In order to remain consistent with the soft label architecture, we chose to use a **Random Forest (RF)**.

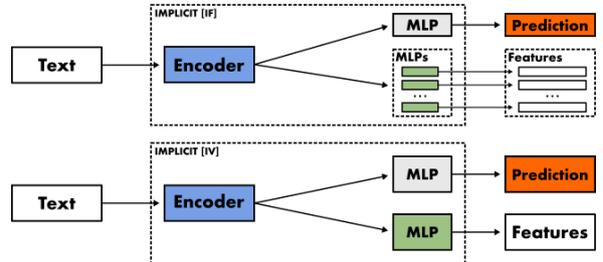

**Direct (or explicit) integration:** We explored two direct integration methods. The first one is soft-labeling. For the **soft-label (SO)**, we followed the architecture employed by Lee et al. (2021) for readability (see Section 2.2). Note that, in the context of a regression task, there is no difference between soft and hard label. The second method consists in feeding the concatenation between the document encoded by the transformer architecture (i.e. CLS) and the features to the MLP, as in various related

<sup>11</sup>We trained the regressor and used its predictions to evaluate the set’s quality. In this assessment, we split each corpus into 80% train and 20% evaluation. This split is the same as the first fold of the cross-validation splits used in the models’ evaluation.

<sup>12</sup>The range of hyperparameters and the selected values for each architecture are described in Appendix A.

(a) Direct (or explicit) integration (architectures, top to bottom *SO*, *SC*, *CM* and *C2*)

(b) Indirect (or implicit) integration (architectures, top to bottom *IF* and *IV*)

Figure 1: The 6 hybrid architectures explored in this work

works (Section 2). We considered the following flavors of implementation (exemplified in Figure 1a). **Simple Concatenation (SC)**, which simply combines the feature vector with the CLS vector and this concatenated vector feeds the output layer (MLP). In this architecture, the MLP is expected to be able to learn the target along with the mapping between the feature and transformer spaces. By adding an MLP between the features and the concatenation, we could simplify the task by allowing the network to separate the mapping between

the spaces and/or even create a richer representation of the features. This architecture, here named **Concatenate MLP (CM)**, allows for greater exploration of the search space by adding a few more parameters to the network ( $5 \times n$ ). In the scope of our work, we used an MLP with a first dense layer of  $4 \times n$  neurons, followed by a dropout layer (10%), followed by a dense layer of  $2 \times n$  neurons that feeds a layer of  $n$  neurons (output), where  $n$  is the number of features. Following the same idea of including MLPs, the latest variant of the concatenation architecture, **Concatenate 2xMLP (C2)**, also adds an MLP between the encoder output and the concatenation. Thus, the concatenation is performed on the output of two MLPs.

**Indirect (or implicit) integration:** Language features can also be imprinted on the network through the use of auxiliary tasks, following a multi-task approach. Here, we tested this idea by exploiting the same features used by the concatenation and RF architectures. Alternatively, we could exploit classic NLP tasks as proposed by Zhou et al. (2019), but this would prevent us from controlling indirect features learned by other tasks, making the comparison between the architectures unfair, as this architecture would have access to different information. The first implicit architecture explored in this work, **Implicit Features (IF)**, learns each feature with an independent regression task using an MLP. Thus, the network has  $n + c$  output layers (where  $c$  is the number of output neurons of the target task; in a regression  $c = 1$ ). Since  $n$  can vary depending on the corpus and can have a value considerably higher than  $c$ , the network could easily overlook the target task. In order to avoid this possible issue, we considered a weight of 0.5 for the loss associated with the target task and 0.5 for the sum of the other losses. *IF* assumes independence between features, which is not always required. We therefore proposed a simple variation of this architecture to exploit this aspect. In this variant, named **Implicit Feature Vector (IV)**, all the features are grouped into a single output vector of size  $n$ . The two implicit models used the same hyperparameter range as the baseline transformers. See Figure 1b for *IF* and *IV* architectures.

## 4 Results

### 4.1 Feature Selection

Among the 10 features sets obtained with mRMR, we selected the top features for each corpus based

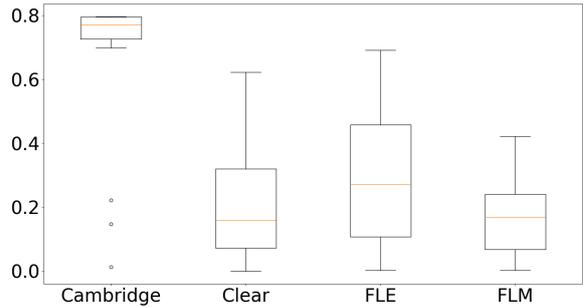

Figure 2: Distribution of the absolute value of correlations between selected features and regression task

on MSE on the development set. We tested regression with MLP and XGBoost by looking at  $R^2$  and RMSE. As the  $R^2$  of the MLP model was very low in all corpora, we discarded it. See Appendix B for the performance of these models for each set of features. As expected, the feature sets are different for each corpus. Therefore, we use 20, 200, 200 and 500 features respectively for Cambridge, FLE, FLM and CLEAR. The distribution of each feature set with the regression target is showed in Figure 3. We also noticed that no feature is shared between the 4 corpora and only 8 are shared between 3 corpora, all of them illustrating lexical phenomena. Metrics of lexical diversity, such as the Corrected Type-Token Ratio (CTTR) of all types of content words, and verb frequency are observable in both English corpora and respectively the FLM and FLE corpus. The remaining 6 features, shared by the two French corpora and CLEAR, illustrate orthographic neighborhood and 5 different flavors of words imageability, varying only in the way the feature distribution was aggregated (80 percentile, average, interquartile range, kurtosis, and 3rd quartile).

### 4.2 Comparing the performance of the 8 architectures

The results (mean and standard deviation) of the 8 architectures trained in a regression task can be seen in Table 2. The first surprising result is the extremely low  $R^2$  value for some models in the FLM corpus (e.g., *C2* and *IV* for FLM), which means that the model is worse than the average of the regression target. Looking at all results directly, we notice that the *Soft Label (SO)* and *Simple Concatenation (SC)* architectures often have the best results. Looking at the statistical significance, the first conclusion is that the differences in architecture do not generate strong differences between the results.

Table 2: Results by model and corpus. Metrics are average RMSE, MAE, R<sup>2</sup> and R (and standard deviation).

For example, the only statistically different models for the Cambridge corpus – for all four measures – are *TR* and *C2*. Similarly, for FLM, the *TR* model is the only one with varying performance in the 4 measures, and the  $R^2$  measure has no discriminating power in the statistical analysis of performance of this corpus; furthermore, we observed no difference between *C2*, *SC* and *SO* for the 4 measures. A more distinct trend can be seen with CLEAR and FLE, where *SO* has the best performance (or no statistical difference from the best score) in both corpora for the 4 measures, and, similarly, *IF* for the CLEAR corpus and, on a smaller scale, *SC* for the FLE corpus (where no difference was observed regarding the MAE and R metrics).

Looking at the results in a nutshell, we compared how many times an architecture obtained the best score (or is not statistically different from the best). By combining this information and the evaluation measure, we can calculate how many times on average an architecture was the best. In addition, this measure allows us to group the averages (through the mean) to obtain a single value per architecture. In this way, we found the following values for each architecture: *SO* 3.8, *SC* 2.5, *IF* 2.3, *CM* 2.0 *RF* 1.8, *IV* 1.5, *C2* 0.8, and *TR* 0.5.

Although these values indicate a general ranking, they do not account for the degree of variability in predictions (in other words, a model with a different rank may or may not produce very different predictions). Aiming to shed light on this, we compared the mean of the absolute difference between the scores of the evaluation metrics for all architectures (corpora and models). The top three architectures obtained the following values of RMSE, MAE,  $R^2$  and R respectively: 0.01, 0.05, 0.00 and 0.00 for *SO*, 0.04, 0.17, 0.03 and 0.03 for *SC*, and 0.22, 0.15, 0.19 and 0.19 for *IF*.

One aspect that needs to be studied for a thorough analysis of the results is the impact of corpus size. Indeed, the different corpora we used vary in their number of samples (from 330 to 4,716 samples). To account for this difference, we created subsamples of the 2 largest corpora (respecting the distribution of level and gender), to reach the same number of samples as the two other corpora. We named these subsamples as  $FLE_{small}$  and  $CLEAR_{small}$ .<sup>13</sup> On these subsamples, we observed that *SO* is the best model in  $FLE_{small}$ , but has no

difference from *SC*, *TR* and *RF* (it kept the same tendency except for *RF*). As for  $CLEAR_{small}$ , we observed a remarkable difference where  $R^2$  scores of *IV* and *SO* are now different from the best score, and we can no longer observe significant differences with the other three scores.

Concerning the average ranking of how many times an architecture obtained the best score (or is not statistically different from the best), we note a difference in ranking order, now becoming *SO* 3.5, *SC* 3.0, *CM* and *RF* 2.8, *IF* 2.0, *C2* 1.5, and *TR* 1.0. Despite those differences, the top two are the same.

Studying the absolute mean difference between the evaluation metrics for all architectures, the top three architectures obtained the following values of RMSE, MAE,  $R^2$  and R respectively 0.01, 0.24, 0.00 and 0.00 for *SO*, 0.05, 0.32, 0.05 and 0.05 for *SC*, 0.04, 0.32, 0.04 and 0.04 for *CM*, and 0.04 0.30 0.03 and 0.03 for *RF*. In this scenario, where all the corpora have a small size, there is an improvement in the RF architecture and a considerable reduction in the TR architecture performance (known for its data hunger), where it obtained an average absolute difference of 0.25 for RMSE, 0.82 for MAE, 0.22 for  $R^2$  and 0.22 for R.

This quantitative evaluation allows us to state that the *SO* architecture has the best overall performance, followed by the *SC* architecture, considering the 8 architectures tested. To the best of our knowledge, there are no other studies in the literature that compare those two architectures. Moreover, the existing work on readability is heavily biased towards using classification algorithms, which limits comparison with our results. However, the regression approach applied here allowed us to make proper use of the CLEAR corpus and to account for the ordinal nature of ARA task. In the end, despite the differences, our results are in line with the initial observations in the literature summarized in Table 1.

In summary, we observe that:

- explicit feature integration models outperform implicit ones and baselines;
- the explicit architecture Soft-label (SO) show higher overall performance and the second-best architecture being Simple Concatenation (SC) on both corpora sizes studied;
- the impact of the differences between the architectures is reduce with small corpora, but

<sup>13</sup>The small samples were generated taking into account the distribution of the regression target and the genres.

the ranking of the two best architectures remained the same; and

- statistical machine learning models perform better than the transformers architecture with small corpora.

## 5 Error analysis

Readability assessment can be strongly influenced by the genre of the documents (Nelson et al., 2012; Dell’Orletta et al., 2014). To investigate this effect in the context of our experiments, we computed the best models’ performance scores on each genre of the FLE Corpus (i.e., informative, narrative, dialogue, mail/e-mail and miscellany) and the CLEAR Corpus (i.e., informational and literature). Results are presented in Table 3. We did not observe a clearly stronger impact of genre on one architecture over the other ones, but we have observed that they perform differently for each genre. We noted that models perform consistently well on the informative genre, with an R of approximately 0.85. They perform worst on the miscellaneous genre in the FLE Corpus (R of 0.75 for *SO* and 0.77 for *SC*), which, despite being the biggest sample with 611 texts, is mostly composed of unusual text formats for readability tasks (e.g., poems, menus, songs, and advertisements). On the other end of the scale, the dialogue and mail/e-mail genres (composed of shorter sentences and numerous personal pronouns) show the highest performance scores, especially for the *SO* model. As for the narrative genre, comparable to the latter two in terms of sample size, it is interesting to note that even though the R and  $R^2$  scores are comparable, their RMSE and MAE scores on this genre reveal a statistically poorer performance. This indicates that the order of the levels was learned, but the range was not properly learned.

We also investigated the effect of the task on model performance to assess whether readability predictions could be influenced by the audience (i.e., L1 vs. L2). To ensure a fair comparison between our corpora of different sizes, we used the  $FLE_{small}$  and  $CLEAR_{small}$  corpora in this study. Models’ performance scores are statistically higher for L2 than for L1 reading (Table 2), which could be explained by several L2 features available in FABRA. Similarly, we compared the performance metrics obtained on English and French corpora and observed that, for the same task (L1 or L2), models perform consistently better on English cor-

pora. The differences observed are striking for the error-based metrics (RMSE and MAE), even though the ranking of architectures remains unaffected for both languages.

Given the large number of features available after the automatic annotation, we investigated the occurrence of features associated with the prediction error of the models. In this study, the feature selection method described in Section 3.2 was used to select the top 100 features associated with error (i.e., statistical residuals). First of all, it is interesting to note that some features used by the models are still correlated with error, hinting that architectures might not have exploited all the information available in the features. The FLM corpus is the most impacted since the intersection between error-related (100 features) and available in the training (200 features) includes 9 features for *SC* and 20 for *SO*. Moreover, we can note that, while lexical features account for roughly half this intersection for both models, discourse features accounts for 30% in *SC*, but for only 17% in *SO*. For each architecture, we then looked at the intersections of these feature lists (error-related and feature set) for the two languages (English and French) and the two tasks (L1 and L2). For the *SC* architecture, the size of the feature intersections for French (10) and English (11) is larger than for L1 (4) and L2 (3). If we compare the two architectures, we observe that the intersections tend to be smaller for *SO* than for the *SC*, suggesting that this model might be able to make better use of the features, which could then be an explanation for his marginal superiority. We also noted that the large proportion of lexical features for French (80% vs. 10% for English) is specific to the *SC* architecture. However, in both models, the intersection for French only includes lexical and syntactic features, and does not include any features related to relationships beyond the sentence level, contrary to English.

## 6 Conclusion

In this paper, seeking to combine the accuracy of DL with the theory-grounded interpretability of features, we carried out a systematic investigation of how to combine transformers and linguistic features. To this end, we compared 8 different architectures (6 hybrid and 2 baselines) on 4 corpora (in different languages and readability tasks). We observed that a Soft Label architecture obtained the best overall performance, followed by Simple Con-

Table 3: Results by genre

catenation. In addition, we explored how language, readability tasks and corpus size impact the performance of these architectures, as well as studying flaws in the use of features by the architectures. The identification of Soft Label as the best architecture is a satisfying result, given that this method is a simple combination of the two proposed baselines, for which several implementations are available. In addition, this result points to an interest for further research into semi-supervised learning in ARA. In addition, our results show several factors associated with the performance of the architectures. Firstly, the size of the corpus can impair the analysis of the difference in performance between the architectures. Second, different types of concatenation may produce better results in specific cases, but overall they perform similarly (overall, Simple Concatenation proved to be the best type of concatenation). Thirdly, implicit architectures have shown some interesting specific results. Given the complexity of these, we suggest that further studies should be carried out in order to explore those approaches. Fourth, traditional ML algorithms, such as RF, are still relevant on small corpora. Finally, transformers, despite being able to maintain some competitive results, are not a silver bullet. As future work, we advocate for further semi-supervised learning studies in ARA and the systematic comparison of hybrid architectures in fields other than ARA.

## Limitations

Despite the results pointing to a straightforward solution, they should be taken with a pinch of salt. Firstly, the work focused on a comparison of the architectures, so all the results are based solely on the regression task (differences might be observed in the classification task) and on the same transformer model. Secondly, we searched for the optimal feature set for each corpus from a large set of features. Although realistic, this creates a positive scenario for the contribution of features. Scenarios where the number of features is reduced may lead to different results (e.g. lower performance of hybrid models). In addition, our results are based on four corpora, but each corpus has its own specificities. Although we believe that using more varied corpora than previous similar research is an asset in arriving at robust general conclusions, it is not impossible that, for the discussion on the effect of task and language in Section 5, other corpora would lead to divergent findings. Finally, since our study focuses on ARA, the results may not hold in different fields.

## A Hyperparameters

In this work, we explored two groups of hyperparameters: (1) random forest hyperparameters and (2) transformer hyperparameters. The hyperparameters explored for the soft-label architecture are a combination of the two groups of hyperparameters, while the other hybrid architectures explore the same hyperparameters as transformers. The following hyperparameters were explored:

- Group 1
  - n\_estimators: 600, 700, 800 and 900;
  - max\_depth: 20, 60, 100 and None;
  - max\_features: sqrt, log2 and None.
- Group 2
  - Learning rate: 1e-2, 1e-3, 1e-4, 1e-5 and 5e-5;
  - Early stop: 1, 3, 5 and 7;
  - Optimizer: adam, sgd;
  - Gradient clipping: no, yes (value of 1)

After exploring the hyperparameters, the following values were chosen for each corpus and architecture:

Corpus	Architecture	n_estimators	max_depth	max_features
Clear	RF	600	60	None
	SO	900	None	None
Cambridge	RF	700	None	None

## Abstract

In the highly constrained context of low-resource language studies, we explore vector representations of speech from a pretrained model to determine their level of abstraction with regard to the audio signal. We propose a new unsupervised method using ABX tests on audio recordings with carefully curated metadata to shed light on the type of information present in the representations. ABX tests determine whether the representations computed by a multilingual speech model encode a given characteristic. Three experiments are devised: one on room acoustics aspects, one on linguistic genre, and one on phonetic aspects. The results confirm that the representations extracted from recordings with different linguistic/extra-linguistic characteristics differ along the same lines. Embedding more audio signal in one vector better discriminates extra-linguistic characteristics, whereas shorter snippets are better to distinguish segmental information. The method is fully unsupervised, potentially opening new research avenues for comparative work on under-documented languages.

## 1 Introduction

In recent improvements in speech processing,<sup>1</sup> the amount of data used at pre-training has been instrumental (Wei et al., 2022), which makes it more challenging – if not impossible – to reach similar levels of performance for endangered languages. Developing new unsupervised approaches, in addition to being cost-effective (Bender et al., 2021), helps us better understand speech models.

Speech is highly multifactorial: a recorded voice tells a message and conveys an intention, and the audio also contains information about the surroundings. This study addresses the topic of the nature of the information encoded in the representations produced by a neural network in an unsupervised

manner. Towards this end, we perform distance measurements over the representations. Our goal is to investigate the level of abstraction encapsulated in these representations.

Our experimental setup relies on tailored datasets to see how specific differences in the input signal are reflected in the output vectors. ABX tests are used on audio data in the Na language (ISO-639-3: nru) and in the Naxi language (nxq). Three series of experiments are devised to assess differences between recordings. (i) The *folk tale series* aims to explore an extra-linguistic dimension by comparing seven versions of the same tale by the same speaker. (ii) The *song styles series* compares different songs interpreted by a single singer. (iii) Finally, the *phonetics series* explores the segmental dimension by comparing sentences (some identical, some different) from different speakers.

The results provide an insight into the nature of the information encoded in the representations of a model such as XLSR-53 (Baevski et al., 2020b; Babu et al., 2021). Our findings suggest that ABX tests can be leveraged to bring out differences in the acoustic setup (room, microphone), in the voice properties, or in the linguistic content. A parametric study shows that processing audio by snippets<sup>2</sup> of 10 s is sufficient to bring out differences in the acoustic setup and in voice properties, while 1 s snippets are better for segmental characteristics.

This study offers an innovative method to detect confounding factors in corpora intended for unsupervised learning, and provides a means to accelerate the classification of recordings (e.g., by noise level or genre) where such metadata are unavailable.

## 2 Method

We propose a method based on two components: (i) ABX tests to determine – via similarity tests –

<sup>1</sup>In ASR, TTS, and even on corpora/languages/tasks not seen at pre-training (Guillaume et al., 2022).

<sup>2</sup>The term ‘snippet’ is preferred over ‘segment’, reserving the latter to refer to phonetic segments.

whether a characteristic of an audio recording is present or not, and (ii) audio corpora with precise metadata. These metadata allow us to build datasets based on one characteristic at a time: language name, speaker ID, room acoustics, microphone type, voice properties or segmental content.

**ABX tests** To find out, in an unsupervised manner, if a multilingual speech model encodes a characteristic  $\mathcal{C}$  of the speech signal, we use the ABX tests introduced by Carlin et al. (2011) and Schatz et al. (2013). The test relies on vector representations built by a pre-trained model for three audio snippets. Let  $A$  and  $X$  denote the snippets that share the characteristic  $\mathcal{C}$ , while  $B$  is the one that does not. The test checks whether the distance  $d(A, X)$  is smaller than  $d(A, B)$ . The metric used in our ABX tests is the cosine distance.

The ABX score corresponds to the proportion of triplets for which the condition  $d(A, X) < d(A, B)$  holds true. An ABX score close to 50 % (or lower) indicates that, on average, the distance between  $A$  and  $X$  is close to the distance between  $A$  and  $B$ , suggesting that  $\mathcal{C}$  is not encoded in the audio representation. Conversely, the closer the score is to 100 %, the more the representation captures the characteristic  $\mathcal{C}$ .

ABX tests are interesting for low-resource scenarios because they require no additional training, so they can be directly applied to the representations (unlike linguistic probes: Belinkov and Glass 2019, 2017; Yin and Neubig 2022).

**Corpora** Our study relies on recordings in Na (ISO-639-3 code: nru) and Naxi (nxq). Na and Naxi are spoken in Southwest China. Na is the mother tongue of approximately 50,000 people. Naxi is more widely spoken, as the mother tongue of approximately 200,000 people. Both languages are gradually replaced by Mandarin, the official language used in schools, administrations and the media (Michaud and Latami, 2011; Zhao, 2022). All recordings come from the Pangloss Collection, an open-access archive of ‘little-documented languages’. Each resource’s DOI is provided in App. E. Three series of recordings selected for their characteristics are considered:

(i) The *folk tale series* consists of seven recording sessions of the same folk tale in Na, told by the same speaker. These experiments focus on the effect of the recording conditions, which are slightly different from one version to another, and

for which ABX tests are performed. For example,  $V_1$  ( $A$ ) is compared to  $V_3$  ( $B$ ), and for that we assume that  $V_1$  is  $X$  and calculate  $d(V_1, V_1)$  vs  $d(V_1, V_3)$ . If  $d(V_1, V_3) > d(V_1, V_1)$  more often than  $d(V_1, V_3) < d(V_1, V_1)$ , then we assume that  $V_1$  and  $V_3$  are distinguished.

The first batch studied comprises three versions:  $V_1$ ,  $V_2$  and  $V_3$ .  $V_1$  was recorded in a room with perceptible reverberation, while  $V_2$  and  $V_3$  were recorded in a damped room.

The second batch is made up of  $V_6$  and  $V_7$ . These two versions were recorded in the same acoustic conditions. The audio was captured simultaneously by two microphones: a headset microphone and a handheld microphone placed on a small stand.

The third batch compares  $V_4$  and  $V_5$  to all the other recordings of the *folk tale series*.  $V_4$  and  $V_5$  have a native listener acting as respondent.

These recordings are particularly interesting because some potential confounding factors (typically the topic and the speaker) are controlled, which makes it possible to focus on the influence of certain specific factors (e.g., room acoustics).

(ii) The *song styles series* consists of five recordings of the same Naxi professional singer. Three only-song recordings are considered, one narrative and one recording with both genres (“Alili”, 50 % text, 50 % song). The aim is to compare these recordings. A trained singer exhibits very different voice properties when singing and talking. Vowel quality and tessitura are affected (Castelengo, 2016, 458). Such differences are perceptible and categorized differently by listeners (Castelengo, 2016, 187). This experiment aims to check if this is reflected in the representations.

(iii) The *phonetics series* is made up of five recordings of phonetic elicitations and one recording of words in a carrier sentence, in the Na language. Three speakers identified as AS, RS and TLT are considered. We included two recording sessions, which allows for intra-speaker comparison.

The five recordings of phonetic elicitations have the same content (apart from the variation inherent to the experimental process in fieldwork conditions: Niebuhr and Michaud 2015) whereas lexical elicitations are a completely different content. Only AS participated in both the phonetic and lexical elicitation sessions.

Tables 1, 2 and 3 in App. A provide a more complete view of the abovementioned metadata.

**Experimental Setting** In all our experiments, we use the XLSR-53<sup>3</sup> model, a wav2vec2 architecture trained on 56 kh of (raw) audio data in 53 languages (Conneau et al., 2020). Na is not present in the pre-training data of this model, but it has been shown that the model can be fine-tuned to do ASR on Na (Guillaume et al., 2022), and therefore the phonetic module is able to handle the diversity of surface realizations of this language. For the comparisons, we consider audio snippets of length 1 s, 5 s, 10 s and 20 s in order to study the effect of snippet length on our ABX test. We use max-pooling to build a single vector representing the snippet. We then build fine-grained heatmaps of ABX scores.

We use the representations from the 21<sup>st</sup> layer, following tests on a validation set. This choice is based on the findings of Pasad et al. (2021, 2023) and Li et al. (2022, 2023), who show that the ability of wav2vec2 representations to capture linguistic information declines in the final three layers.

### 3 Results

Using ABX tests with carefully selected audio recordings, we investigate whether or not the audio representations computed by wav2vec2 capture specific information from the audio signal.

#### 3.1 Study of various versions of the same tale

The aim of this experiment is to determine whether certain extra-linguistic variables (e.g., room acoustics, and type of microphone) are captured in the neural representations. For that, we consider recordings from the *folk tale series* and use ABX tests to distinguish between different versions of the tale: these scores are calculated from triplets consisting of two snippets of 10 s from the same version and one snippet from a different version.<sup>4</sup>

Figure 1 shows that, in most cases, with a 10 s snippet-length it is possible to distinguish between the different recordings, although it is always the same speaker telling the same story: except for a few rare exceptions, which are addressed later, most of the reported scores are well above 50%. What is more, the scores on the diagonals, corresponding to tests where all the excerpts come from the same recording, are all close to 50%. This clearly indicates that the differences found in the

<sup>3</sup>The HuggingFace API was used (model signature: facebook/wav2vec2-large-xlsr-53).

<sup>4</sup>Results for other snippet lengths are reported in App. C.

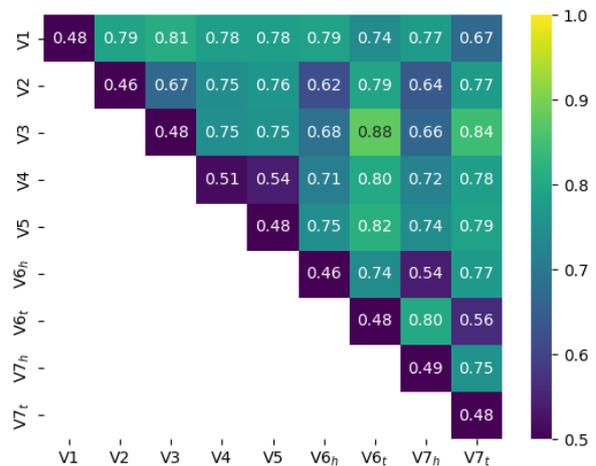

Figure 1: ABX scores when distinguishing different versions of the *folk tale series*. Snippet length = 10 s.

other ABX tests are not due to linguistic content (the words spoken), but rather to acoustic configuration. It suggests that neural representations capture much more than the linguistic information needed to understand speech, and it seems possible to use them to retrieve information related to the recording conditions.

A more precise analysis of the scores between two recording conditions provides a better understanding of the information that is or is not captured by the representations.

The first batch is a comparison between  $V_1$ ,  $V_2$  and  $V_3$  (NW corner of Figure 1): the ABX scores show that the representation of  $V_2$  and  $V_3$  are indistinguishable when compared to the representations of  $V_1$  (0.79 vs 0.81). We know from Section 2 that the main difference between these three recordings is related to the recording venue:  $V_2$  and  $V_3$  were recorded in the same place, less reverberating than the place where  $V_1$  was recorded. To confirm the influence of this parameter, we carried out a complementary experiment by artificially adding *reverb*<sup>5</sup> to the  $V_2$  recordings and measuring the ABX score between the  $V_1$  and modified  $V_2$  recordings. Figure 2 shows the evolution of the ABX score as a function of the amount of reverb added. One interesting observation is that when gradually increasing the amount of reverb in  $V_2$ , the ABX score decreases first before increasing again. It means that  $V_1$  is closer to  $V_2$  with 5% reverb, which suggests a relation of causality between the amount of reverberation and the degree of closeness between the recordings of this batch.

<sup>5</sup>We use Audacity to add 5, 10, 15 or 20% reverb.

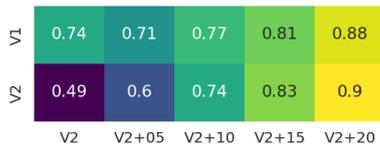

Figure 2: Reproducing  $V_1$  room tone with artificial room tone applied on  $V_2$ . Snippet length = 5 s.

In the second batch, the sub-versions of  $V_6$  and  $V_7$  are labeled as  $h$  for *headset* and  $t$  for *table* (remember that the two types of microphone used are (i) headset microphone and (ii) handheld microphone placed on a small stand, on a table). Figure 1 shows that the XLSR-53 representations can effectively distinguish between microphone types with high precision. For instance, the ABX scores between  $V_{6,h}$  and  $V_{6,t}$  are some of the highest in our experiment. However, when it comes to distinguishing between two different recordings made with the same microphone (i.e.  $V_{6,h}$ - $V_{7,h}$  and  $V_{6,t}$ - $V_{7,t}$ ), the ABX scores are only slightly better than scores for the same recording. This suggests that the representations, extracted in 10 s long snippets, strongly depend on the microphone used: two vectors representing the same audio signal but recorded by different microphones come out as more dissimilar than those representing two different audio signals recorded by the same microphone.

Figure 1 also brings out uncanny similarity between recordings  $V_4$  and  $V_5$ . The ABX score between these is only 54 %, whereas it is no lower than 71 % for all other pairs. Now,  $V_4$  and  $V_5$  are the only recordings at which a listener from the language community was present: the others were produced with just the investigator – who has low fluency in Na – as audience. This looks like a case of linguistic adaptation (Piazza et al., 2022). It suggests possibilities for automatically generating hypotheses about the communicative setting of a recording.

In this experiment series, all our observations are most visible with 10 s snippets, which seems to be the proper setting to reveal differences at a broad acoustic level. It also seems to be a suitable snippet size to reveal differences at the prosodic level. Further experiments are necessary to confirm our conclusions.

### 3.2 Study of different song styles

The aim of this experiment is to explore whether or not the extraction settings devised in the preceding experiment allow us to explore the representations

with regard to the voice properties of the speaker. Several recordings of a professional Naxi singer are compared to one another : one song in the “Alili” style, two in the “Guqi” style, one in the “Wo Menda” style, and one narrative. The songs originally contained a non-sung introduction which has been removed for the comparisons, except for the “Alili”-style song, which is half-text and half-song.

Figure 3 shows that all the songs are strongly distinguished from the narrative, except for the “Alili” recording, which is half-text half-song. Interestingly, the “Alili” recording patterns neither with the songs nor with the narrative: it stands halfway between. As for the two songs in the “Guqi” style, they exhibit the lowest ABX score (0.57), which suggests that song style may be detectable.

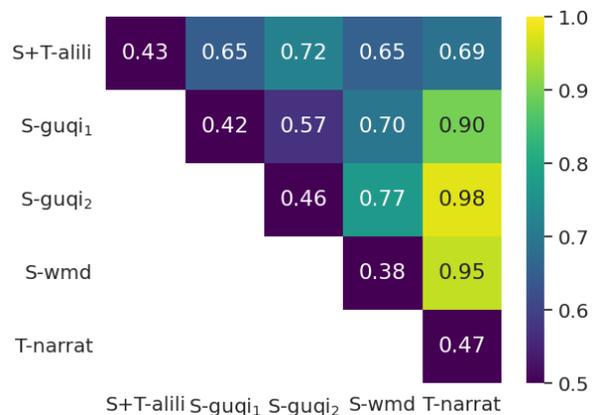

Figure 3: ABX scores for the comparisons between different genres (T=text (narrative), S=song). Songs in three different styles and narratives are performed by a professional Naxi singer. Snippet length = 10 s.

These results suggest that voice properties are present in the representations, since we can distinguish between a narrative and various song styles for the same speaker, and even regroup by song style. These results are very encouraging for future studies that aim at using neural models to perform prosodic studies.

### 3.3 Study of a phonetics corpus

While it is quite obvious that two sentences with a different linguistic content in perfectly controlled conditions will come out as different when submitted to an ABX test, the answer is not immediate when it comes to a whole recording. It is also not obvious that two different sentences uttered by two different speakers are distinguished solely due to a difference in the linguistic content: speaker ID acts

as a confounding factor.

The aim of this experiment is to perform ABX tests on data with differences on the phonetic segments. To do this, we rely on a phonetics corpus recorded in a controlled manner, where each speaker received similar instructions. Some recordings have the same content ( $AS_{1,2}$ ,  $RS_{1,2}$ ,  $TLT$ ), and one recording has a different content ( $AS_{Lex}$ ). The scores are calculated from triplets consisting of two snippets of 1 s from the same recording and one snippet from a different recording.<sup>6</sup>

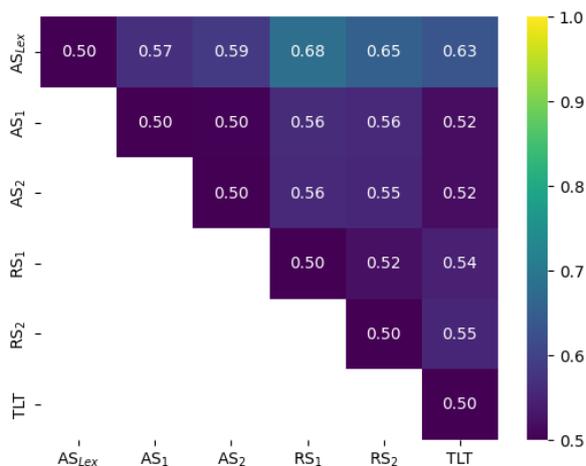

Figure 4: ABX scores for comparisons within the *phonetics series*. Speaker AS has three recordings ( $AS_1$ ,  $AS_2$ ,  $AS_{Lex}$ ), RS has two ( $RS_1$ ,  $RS_2$ ) and TLT has one. Snippet length = 1 s.

First, Figure 4 shows that with a 1 s snippet-length it is nearly not possible to distinguish between the different recordings of the same sentences, even when the speakers differ. It suggests that neural representations, in this configuration, effectively ‘centrifugate’ the extra-linguistic information. This observation is not surprising given how the models are pre-trained (Baevski et al., 2020a), and it is a convenient springboard for the second part of the analysis, which consists in comparing these recordings of identical sentences to another one with different sentences.

The results in the first row of Figure 4 indeed suggest that the ABX tests reveal differences in linguistic content. The magnitude of the discrepancy (between row 1 and the others) depends on whether or not the speaker is different. The fixed-speaker discrepancy is around 0.07, while the cross-speaker discrepancy is around 0.11. It suggests that even with 1 s snippets, speaker ID is still reflected in

<sup>6</sup>Results for other snippet lengths are reported in App. D.

some way in the representations.

In this study, ABX scores are averaged over an entire recording. For phonetic differences, it would be interesting to be able to perform comparisons on a per-sentence basis, but it would constitute a departure from a fully unsupervised approach.

## 4 Discussion and conclusion

When one undertakes the task of comparing vector representations of audio, differences are expected, too many of them rather than too few. We adopted an experimental method to submit a given model to different experiments with test variables.

In the first two series, the recordings are distinguished according to (i) technical acoustic properties in the *folk tale series*, or (ii) voice properties in batch  $V_4$ ,  $V_5$  of the *folk tale series* or in the *song styles series*. A 10 s snippet length seems to best reveal differences in characteristics such as (i) room acoustics or microphone type or (ii) speech rate or genre. Our aim in these two series was to explore to what degree extra-linguistic information is present in the representations. Being able to detect acoustic differences such as the amount of reverb in a room, or the fact that we are not only capable of measuring differences between narratives and songs but also to distinguish between song styles, gives us reasons to think that our method should be useful to automatically classify recordings based on room acoustics, interview setup, or genre. The prosodic characteristics of a recording also seem to be encoded, which is encouraging for future research on tone using unsupervised methods on audio recordings.

In the *phonetics series*, we focused on 1 s snippet lengths. The recordings of three speakers who participated in a phonetics experiment, quasi-identical to one another, are distinguished from a recording with a different content, but the distinction is not very strong. The snippets from this series are shorter and result in smaller differences on the ABX score. This observation suggests that differences are only detected when the segmental content changes, and shows the consistency of our method. Using this method on cross-speaker, or cross-linguistic snippets however requires additional investigations to devise a method more suited to phonetic segments. Among possible improvements, using segmented corpora would be an interesting avenue of research.

## Limitations

As is often the case for endangered languages (Liu et al., 2022), our corpora rely on a few speakers of the same gender. In our case, we exploit a resource with rich metadata to build experiments with minimal differences and observe sets that differ by one characteristic only. The conclusions drawn on the speaker-independent setting in Section 3 may need to be reanalyzed when we run the experiment on cross-gender data.

Our study does not perform comparisons with other methods for identifying characteristics, because other methods require more data than the amount treated here (typically linguistic probes using classifiers).

We have not investigated how the model reacts to a superposition of variables sensitive to a given snippet length. Therefore, we would need to extend our experiments further, e.g., to check how a 10 s snippet length is handled when assessing a discrepancy in speaker and room acoustics.

We plan to extend this study by adding data from experimental phonetics experiments related to second language acquisition, as they often include productions from the same speaker in multiple languages. Experimental phonetics corpora are devised under highly controlled conditions, which is beneficial for our study as it removes potential confounding factors.

## Ethics Statement

The study presented here relies on small-sized corpora because the methods are meant for low-resource languages, i.e., without a significant amount of data available. This limitation is offset by the wealth of metadata available for each recording in the Pangloss Collection. Pangloss is a world language open-access archive developed in a Dublin-core compliant framework (Weibel et al., 1998).

The data used in this study are first-hand, collected by researchers working with the communities to document and describe their language. They are the result of months of collaborative work in the field to transcribe and translate the data with native speakers (typically the speaker himself/herself). The speakers all consented to the use of these data for scientific purposes and were compensated for their work as linguistic consultants.

All data and models in this study are open-access under a Creative Commons license stated on the

consultation page for each resource (which is also the landing page of its DOI listed in Table 4). The information needed for reproducibility is present in the text (model information) or the appendices (data). The metadata collected were directly collected via questionnaires during the fieldwork. Gender, for example, corresponds to the gender the speaker provided in the questionnaire.

## Acknowledgments

We are grateful for constant support from the Na and Naxi communities. We would like to especially thank Mrs. Wang Sada and Mrs. Latami Dashilame of the Na community for their sharing of their expertise, their generosity with their time, and their confidence and encouragement.

This research was partially funded by the DIAGNOSTIC project supported by the *Agence d'Innovation de Défense* (grant n° 2022 65 007) and the DEEPTIPO project supported by the *Agence Nationale de la Recherche* (ANR-23-CE38-0003-01).

We are grateful to the sponsors of the field trips that made data collection on Naxi and Na possible (from 2002 to 2019). Specifically, we wish to acknowledge the Grenoble UGA IDEX international mobility program's support for fieldwork on Lataddi (Shekua) Na in 2019.

## B M and SD values showing that ABX tests can be used to measure differences between our corpora

Figure 5 shows mean and standard deviation values for a comparison between inter-recordings scores (*phonetics series* and *folk tale series* barplots) and intra-recording scores (*same-recording*), for different snippet lengths. For all snippet lengths, the

average inter-recording ABX score is always significantly higher than the average intra-recording score, even for 1 s snippet-length. This shows that ABX tests can be used to measure differences in our experiments.

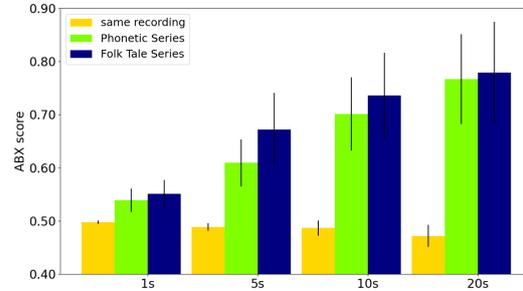

Figure 5: Average ABX scores for 1, 5, 10, 20 s snippets.

## C ABX scores when distinguishing different versions of the folk tale series by the same speaker.

The 20 s value for snippet length has been investigated, and it does not bring out much more than the 10 s snippet length. In addition a 20 s snippet length with max-pooling tackles the limits of the max-pooling method. Indeed, we believe there is a limit to the amount of audio we can have in an embedding. Indeed, with the max pooling extraction method, each of the 980 vectors before pooling the 20 s of audio will only occupy, on average, 1.04 cells per final vector since it only has 1,024 components. The results can be seen in Figure 6 for 20 s snippets, Figure 7 for 10 s snippets, Figure 8 for 5 s snippets, Figure 9 for 1 s snippets.

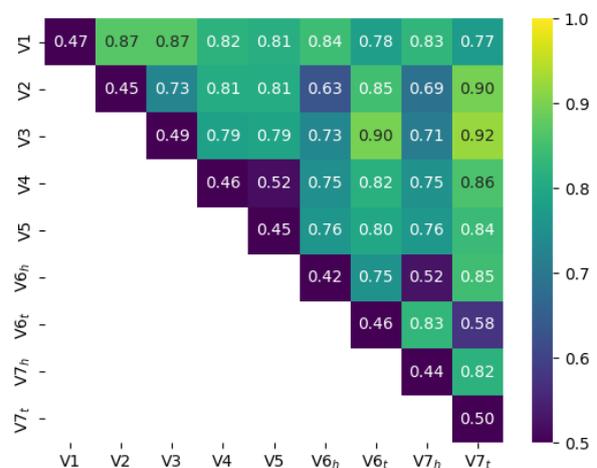

Figure 6: ABX scores for the *folk tale series*. (snippet length = 20 s).

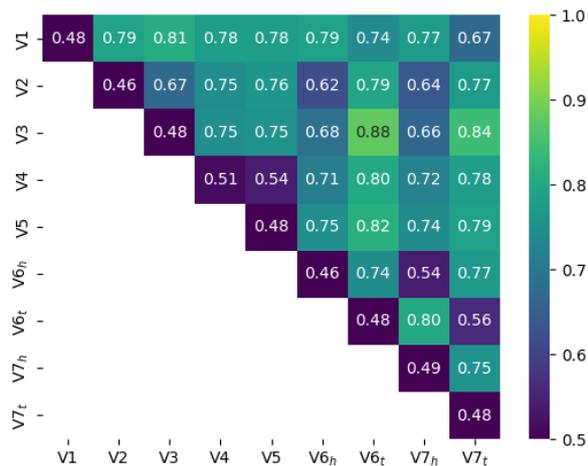

Figure 7: ABX scores for the *folk tale series* (snippet length = 10 s).

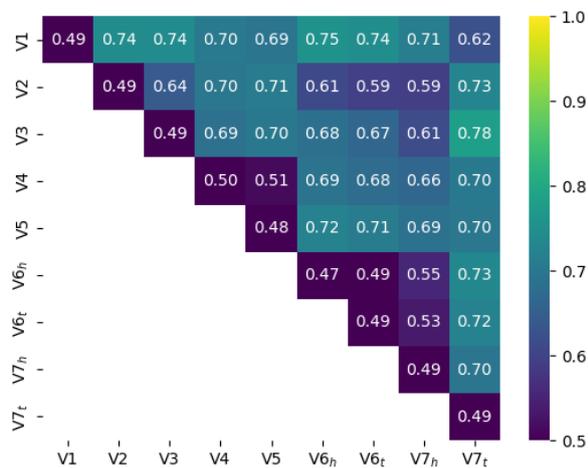

Figure 8: ABX scores for the *folk tale series* (snippet length = 5 s).

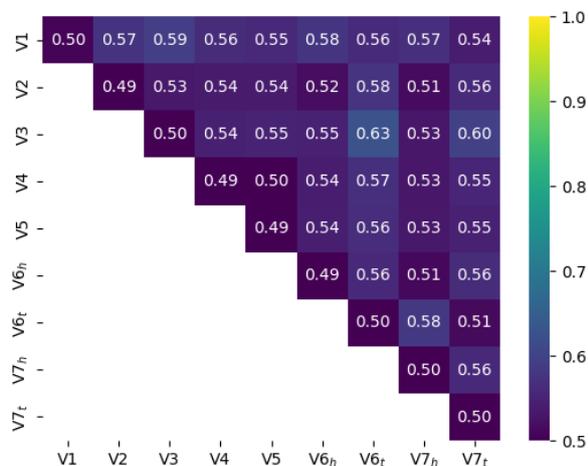

Figure 9: ABX scores for the *folk tale series* (snippet length = 1 s).

### D ABX scores when distinguishing between elements of the *phonetics series*

The results can be seen in Figure 10 for 20 s snippets, Figure 11 for 10 s snippets, Figure 12 for 5 s snippets, Figure 13 for 1 s snippets.

Figure 10: ABX scores for the comparisons between elements of the *phonetics series* (snippet length = 20 s).

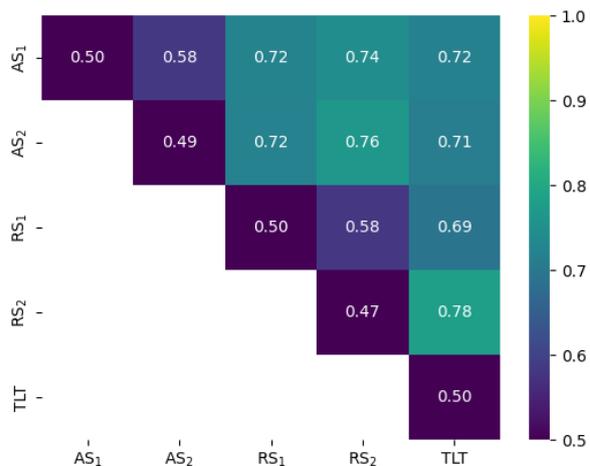

Figure 11: ABX scores for the comparisons between elements of the *phonetics series* (snippet length = 10 s).

# The Queen of England is not England’s Queen: On the Lack of Factual Coherency in PLMs

Paul Youssef<sup>†</sup> Jörg Schlötterer<sup>†‡</sup> Christin Seifert<sup>†</sup>

<sup>†</sup>University of Marburg, <sup>‡</sup>University of Mannheim

{paul.youssef, joerg.schloetterer, christin.seifert}@uni-marburg.de

## Abstract

Factual knowledge encoded in Pre-trained Language Models (PLMs) enriches their representations and justifies their use as knowledge bases. Previous work has focused on probing PLMs for factual knowledge by measuring how often they can correctly predict an *object* entity given a subject and a relation, and improving fact retrieval by optimizing the prompts used for querying PLMs. In this work, we consider a complementary aspect, namely the coherency of factual knowledge in PLMs, i.e., how often can PLMs predict the *subject* entity given its initial prediction of the object entity. This goes beyond evaluating how much PLMs know, and focuses on the internal state of knowledge inside them. Our results indicate that PLMs have low coherency using manually written, optimized and paraphrased prompts, but including an evidence paragraph leads to substantial improvement. This shows that PLMs fail to model inverse relations and need further enhancements to be able to handle retrieving facts from their parameters in a coherent manner, and to be considered as knowledge bases.

## 1 Introduction

Pre-trained Language Models (PLMs) are probed for factual knowledge to investigate their usage as knowledge bases, and gain a better understanding of the rich representations they provide (Petroni et al., 2019). Previous extensions have focused on extracting more facts (Zhong et al., 2021; Li et al., 2022b), increasing the consistency of PLMs to paraphrased prompts (Elazar et al., 2021), identifying the parts of PLMs that are responsible for storing knowledge (Dai et al., 2022) and updating facts in them (Meng et al., 2022, 2023).

More recently, Berglund et al. (2023) study the generalization abilities of PLMs from “A is B” to “B is A”, and show that if a PLM is trained on “The capital of Malta is Valetta” it will not be able to correctly answer the question: “Which country has

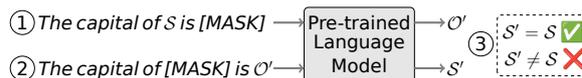

Figure 1: Probing coherency in PLMs. 1) The PLM makes a prediction based on an entity  $S$  and a relation. 2) The PLM makes a second prediction based on the same relation and its first prediction  $O'$ . 3) If the PLM predicts  $S$  in the second step it shows coherent behavior.

Valetta as its capital?”. In this work, we introduce an intrinsic and complementary aspect, namely the *coherency* of PLMs with respect to factual knowledge. Coherency is not concerned with correctness of the PLMs’ predictions, but with the internal state of knowledge in PLMs and its consistency. More concretely, we first ask a PLM to answer the question: “What is the capital of Malta?”, and if it answers “Berlin”, we ask it to answer the question: “Which country has Berlin as its capital?”, and if it answers “Malta”, then we say that the PLM has answered coherently (even though the answer is factually wrong). Note that in practice we use Cloze prompts instead of questions to make the task closer to language modeling (see Figure 1). Intuitively, if a human can tell the capital of a country given that country’s name, then she is also able to tell the country given its capital’s name. Given that PLMs are queried with a subject and a relation to extract a object, we define coherency as the ability of the PLM to infer the subject given its initial prediction for the object entity and vice versa.

Our contributions are the following: (1) we introduce coherency to investigate the internal state of factual knowledge in PLMs; (2) we evaluate different PLMs, showing that they have low coherency; (3) we show that optimized and paraphrased prompts do not improve coherency, but the use of evidence paragraphs substantially improves coherency. We make our code available.<sup>1</sup>

<sup>1</sup><https://github.com/paulyoussef/coherency>

## 2 Coherency

PLMs are known to capture vast amount of facts from their pre-training corpora. This has encouraged the community to consider using them as knowledge bases (KBs) (Petroni et al., 2019; Sung et al., 2021), which can be constructed without expensive annotations, and which can easily be queried using natural language. However, the use of PLMs as KBs has many limitations (AlKhamissi et al., 2022). For example, PLMs are quite sensitive to their prompts, and cannot be easily updated with new facts. Factual knowledge in PLMs is estimated by evaluating how often PLMs can correctly predict an object entity  $\mathcal{O}$ , given a subject entity  $\mathcal{S}$  and a relation  $\mathcal{R}$ , when provided with a prompt which contains the subject and the relation:  $t(\mathcal{S}, \mathcal{R})$ , where  $t$  is a function that maps a subject entity and a relation to a prompt in natural language that contains the given entity and expresses the relation in natural language, e.g., (Malta, capital-of)  $\rightarrow$  “The capital of Malta is [MASK]”. In this work, we focus on evaluating the coherency of PLMs with respect to the factual knowledge stored in their parameters, i.e., how often can PLMs predict  $\mathcal{S}$  using  $t(\mathcal{O}', \mathcal{R})$ , given that it predicted  $\mathcal{O}'$  using  $t(\mathcal{S}, \mathcal{R})$ . For example, “The capital of [MASK] is Berlin”  $\rightarrow$  Malta is coherent with “The capital of Malta is [MASK]”  $\rightarrow$  “Berlin”. We do not evaluate if the predictions are factually correct, because we are interested in the coherency of the PLMs’ world view, regardless of its correctness. We show and discuss correctness scores in Appendix A.

Coherency can be easily calculated for 1-1 relations, but is more challenging, if we consider N-1 or N-M relations, since multiple entities could be correct when trying to predict the subject entity. To address this, we exclude all correct entities except the ground truth subject  $\mathcal{S}$  in the second inference step, following Bordes et al. (2013) and Petroni et al. (2019). Since PLMs are known to have certain biases and are sensitive to the prompts, we start with predicting the object given the subject in a first round. In a second round, we start by predicting the subject given the object. The complete algorithm for estimating coherency in PLMs for all types of relations is shown in Algorithm 1. After estimating coherency for each relation, we macro-average over all relations, because we are interested in the average performance for the use case of PLMs-as-KBs, which involves storing facts

from different types of relations.

---

**Algorithm 1:** Coherency in PLMs

---

```
Input: PLM, dataset with  $n$  relations
Output: coherency
scores_per_relation = []
// iterate over relations
for  $i \leftarrow 1$  to  $n$  do

    else
      | scores.append(0)
  scores_per_relation.append(mean(scores))
return  $mean(scores\_per\_relation)$ 
```

---

## 3 Experimental Setup

Here, we describe the data and PLMs, which we use, and our experiments in detail.

### 3.1 Data

In our experiments, we use the T-REx (Elsahar et al., 2018) subset of LAMA (Petroni et al., 2019), which is often used to estimate factual knowledge in PLMs. T-REx consists of 41 relations with their corresponding templates, and subject-object pairs, for which the relations hold in English. For each of the relations, a manually-written template is provided, which we use to construct the prompts. Some statistics and an example from the T-REx subset are shown in Table 10 in Appendix D.

### 3.2 How coherent are PLMs?

In this experiment, we aim to find out how coherent are PLMs. We mostly focus on PLMs which are

trained to fill in the blanks based on context, since these make use of a bidirectional context, and we expect them to perform better than autoregressive PLMs on this task. More specifically, we consider BERT (Devlin et al., 2019), InformBERT (Sadeq et al., 2022), T5 (Raffel et al., 2020), and T5-SSM (Guu et al., 2020; Roberts et al., 2020). InformBERT adapts the masking strategy of BERT to focus on more informative tokens. T5-SSM models are additionally trained with Salient Span Masking objective (SSM), which masks only named entities in the pre-training phase. More information about the models are provided in Appendix C. If available, we consider several sizes of the same model in order to investigate the effect of scaling PLMs on coherency. For BERT-based models, we only consider entities that correspond to one token, in order to adhere to the task format from pre-training. We evaluate all models in a zero-shot setting with no finetuning, since we are interested in the coherency of factual knowledge in PLMs after the pre-training phase. For BERT-based models, we choose the token with the highest probability. For T5-models, we use beam search with 10 beams. We use partial match, which returns true if one of the two predictions is contained in the other after converting both to lower case, when comparing the predictions against the ground truth entities.

For completeness, we also evaluate on autoregressive PLMs. More specifically, we consider GPT-2 (Radford et al., 2019) and GPT-Neo (Gao et al., 2020; Black et al., 2021). For autoregressive PLMs, we use typed querying (Kassner et al., 2021), i.e., we extract a probability distribution over a pre-defined set of entities from the model, and choose the most probable entity as the final prediction. Typed querying makes it easy to extract valid answers (entities) from the PLMs’ outputs, but also makes the task easier for PLMs since it restricts the output space. We extend the templates from LAMA such that the subject/object entities appear at the very end. We consider autoregressive PLMs only in this experiment.

### 3.3 Do optimized prompts improve coherency?

Optimizing prompts leads to better fact retrieval (Zhong et al., 2021). In this experiment, we investigate whether optimized prompts lead to higher coherency as well. We utilize Shin et al. (2020)’ optimized prompts for T-REx. These prompts differ from one model to another, and from

the models we consider, optimized prompts are only available for BERT models.

### 3.4 Does providing an evidence paragraph increase coherency?

PLMs can fill in the blanks based on the knowledge they have stored in their parameters (parametric knowledge), or based on information that is provided in their inputs (contextual knowledge). The latter boils down to extracting the right information from the input. Previous work has shown that providing evidence paragraphs as additional inputs makes PLMs’ predictions more factual (Petroni et al., 2020). Here, we investigate how these evidence paragraphs affect the coherency of factual knowledge in PLMs. The provided evidence paragraphs from LAMA contain a Wikipedia paragraph that expresses the facts. We append the evidence paragraphs to the inputs from the first experiment.

### 3.5 Is Coherency stable across paraphrased prompts?

PLMs are known to be sensitive to the provided prompts, i.e., small insignificant changes, that preserve the meaning cause the PLMs to change their predictions (Elazar et al., 2021). As a result, retrieving facts from PLMs is highly affected by the prompts used. In this experiment, we consider the effect of using paraphrased prompts on coherency. Does coherency stay the same across different prompts or is it highly variant? We evaluate whether coherency varies with paraphrased prompts from Elazar et al. (2021)’s ParaRel dataset. ParaRel provides paraphrases for 38 of the 41 relations in T-Rex. For each one of the 38 relations, we randomly select a template from ParaRel, and measure how coherency is changed over 10 runs. We consider bert-base and t5-base for this experiment.

## 4 Results and Discussion

The results for the first three experiments are shown in Table 1. We show the results for autoregressive PLMs separately in Table 2, because we probe autoregressive PLMs with typed querying. We do not evaluate if the predictions are factually correct. For correctness scores see Table 4 in Appendix A. Since we considered only one-token entities from T-REx for BERT models, we show a normalized version of the results on this subset for better comparability in Table 6, and the results with the total number of instances in Table 7 in Appendix A.

**PLMs show poor coherency.** We notice that all PLMs have poor coherency. Autoregressive PLMs perform even worse than masked PLMs, even though the task is made easier for them through typed querying (cf. Section 3.2). The poor performance of autoregressive PLMs might be due to their unidirectional training objective, whereas masked PLMs make use of a bidirectional context. Increasing the number of parameters in T5 models leads to consistent improvements in performance. However, this does not generalize to the BERT models (bert-base performs better than bert-large), and to the T5 models that are trained with SSM (t5-large-ssm performs better than t5-3b-ssm). The SSM objective is beneficial for the large variant of T5 (t5-large-ssm improves by 6.5 percentage points over t5-large, and even outperforms t5-3b, which has 4 times as many parameters). Contrarily, this improvement does not generalize to the 3b variant (t5-3b outperforms its SSM counterpart). InformBERT falls short of normal BERT, even though it was shown to outperform BERT, when it comes to facts retrieval (Sadeq et al., 2022). Hence, better facts retrieval does not necessarily affect coherency positively. In general, scaling and entity-centric training objectives have to some extent a positive effect on coherency. We also notice that in most cases models perform worse in the first round. Round 1 can be more difficult, since it may involve predicting a specific subject based on a generic object in the second step (e.g., “[MASK] is located in Bern”), whereas the second round goes into opposite and easier direction (“University of Bern is located in [MASK]”). PLMs are known to not provide specific answers (Huang et al., 2023).

We show the results per relation type in Table 5 in Appendix A. The evaluation dataset contains 2 **1-1** relations, 23 **N-1** relations and 16 **N-M** relations with 3 of the 16 **N-M** relations being symmetric. Most PLMs have high coherency on **1-1** relations, but the number of instances for these relations is limited (747 at most), on **N-1**, **N-M** and symmetric relations the performance drops significantly. This shows that **N-1** and **N-M** relations are challenging for PLMs not just with respect to facts retrieval (Petroni et al., 2019), but also with respect to developing a coherent knowledge state.

We also show and categorize examples from different PLMs in Table 8 in Appendix B. In general, one can notice that incoherent predictions are due to: 1) The answer being incorrect in the first step, making it more difficult to predict the answer in the

second step (rows 6-7); 2) The templates being not specific enough allowing for non-factual completions (row 8); 3) missing context to retrieve correct relation for non 1-1 relations (row 3).

**Optimizing prompts does not help.** Optimized prompts lead to a drop in coherency in the second experiment (see results under optimized prompts in Table 1) 1. This shows that prompts that better retrieve object entities does not help retrieve the corresponding subject entities. Previous work showed that optimized prompts overfit the facts distribution of objects (Cao et al., 2021), which might negatively affect their ability to retrieve the subject entities. This is also evident by the difference in scores between the two rounds.

**Evidence paragraphs improve coherency.** Including evidence paragraphs in the inputs substantially improves performance (see results under evidence paragraphs in Table 1). This shows that PLMs are better at extracting answers from their inputs than recalling them from their parameters. In fact, adding an evidence paragraph reduces the performance gaps among models of different sizes and pre-training objectives. This suggests that retrieval-based approaches are indeed a promising alternative to scaling language models (Kandpal et al., 2023). Still, coherency is not high under this setting as well. We believe this is due to the PLMs failing to extract the correct entities or to the conflicts between contextual and parametric knowledge in PLMs (Neeman et al., 2023).

**Coherency varies across paraphrases.** Table 3 shows the minimum, average and maximum coherency scores with paraphrased prompts. A breakdown in relations is available in Appendix A (Fig. 2).<sup>2</sup> As with fact retrieval, the results indicate that prompts have a significant effect on the performance. For example, there are more than 25 percentage points difference in coherency between the min and max scores for t5-base. Still, even when considering the best prompts, the overall coherency score is low.

In general, our analysis shows that PLMs do not possess a coherent knowledge state. The low coherency might be due: 1) The fact that PLMs make predictions based on shallow surface level features (Poerner et al., 2020; Li et al., 2022a), which makes PLMs output relevant but incoherent

<sup>2</sup>Note that, for this experiment, we use only 38 of the 41 relations in T-Rex – The ones for which paraphrases exist.

and non-factual predictions (for an example see row 6 in Table 8). This is inherent to all PLMs, and requires further architectural improvements; 2) The training data for PLMs, which might be biased towards certain entities (the more frequent ones); 3) The uni-directional training in the case of autoregressive PLMs that makes PLMs sensitive to the order in which the entities are observed.

Model	Round 1	Round 2	Avg.
bert-base-uncased	9.74	11.81	10.78
bert-large-uncased	9.83	10.29	10.06

## 5 Related Work

**Reversal curse.** Berglund et al. (2023) investigate the generalization abilities of autoregressive PLMs from one data form, that is encountered during training (A is B), to another (B is A), showing a generalization failure. Berglund et al. (2023) refer to this generalization inability in autoregressive PLMs as the *reversal curse*. Our work is close

Model	Round 1	Round 2	Avg.
gpt2	0.24	3.98	2.11
gpt-neo-1.3B	0.44	<b>12.85</b>	<b>6.65</b>
gpt-neo-2.7B	<b>0.56</b>	11.82	6.19

Table 2: Coherency score per round and on average for autoregressive PLMs using manually-written prompts. The highest performance is in **bold**. Autoregressive PLMs are probed using typed querying.

Model	Min.	Avg.	Max.	#Instances
bert-base-uncased	3.74	11.16	19.25	2852
t5-base	6.51	16.88	31.69	27788

Table 3: Coherency scores with different paraphrases. We show the results with the worst/average/best performing prompts per relation.

but complementary to theirs. We focus on the coherency of the internal state of factual knowledge in autoregressive *and* masked PLMs, *regardless* of how correct the PLMs’ predictions are.

**Factual knowledge in PLMs.** PLMs contain vast amounts of linguistic (Tenney et al., 2019; Jawahar et al., 2019), commonsense (Davison et al., 2019) and factual knowledge (Roberts et al., 2020) that is captured during pre-training. Many works focus on factual knowledge in PLMs (Youssef et al., 2023), since factual knowledge is said to contribute to the rich presentations produced by PLMs, and potentially justifies the use of PLMs as KBs (Petroni et al., 2019; Ye et al., 2022). For example, Shin et al. (2020); Zhong et al. (2021) optimize prompts to extract more facts from PLMs, Elazar et al. (2021); Fierro and Søgaard (2022) investigate the sensitivity of PLMs to paraphrased prompts, (Malkin et al., 2022; Wang et al., 2023) debias the outputs of PLMs for better facts extraction, Meng et al. (2022, 2023) address editing facts in PLMs to make it possible to correct and update facts. However, these works collectively focus on extrinsic aspects. We focus on a more intrinsic aspect, i.e., the coherency of factual knowledge inside PLMs. This complements aspects addressed in previous work.

## 6 Conclusion

In this work, we focused on evaluating the coherency of factual knowledge in PLMs. We considered the use of manually-written, optimized, and paraphrased prompts. Our results indicate poor coherency. The inclusion of an evidence paragraph leads to substantial improvements. This shows that PLMs can leverage contextual knowledge better than parametric knowledge and highlights the importance of retrieval-augmented PLMs. We believe that further improvements are needed to improve coherency in PLMs, and to consider them as alternatives to KBs. We believe that future work should focus on further improving PLMs on the architectural level, the data level, and the interface between them (pre-training objectives).

## 7 Limitations

Coherency can be easily determined using 1-1 relations. For N-1 or N-M relations, some potential answers should be excluded. However, it is quite difficult to exclude every possible answer for certain relations (e.g., everyone who is an English native speaker) from the model’s vocabulary. We only excluded answers that are present in LAMA, following previous work (Bordes et al., 2013) and (Petroni et al., 2019). This might have had a negative effect on the results (cf. Section 4, discussion of lower scores in round 1).

## A Additional Results

**Correctness.** We investigate how correct the PLMs’ predictions are. For each instance, we count how often the first prediction in the first round (**c1**), and in the second round (**c2**) were correct. We only consider the first predictions in each round, since having the incorrect answer in the first inference step of each round makes it more difficult for the model to answer correctly in the second inference step. We also report how often are all predictions correct (**all correct**). We calculate each score for all relations, and average over all relations. Results are shown in Table 4. We notice that for all models the **c1** scores are higher than the **c2** scores. We believe this is because in the first inference step in round 1, models predict *object* entities, whereas in the first step of round 2 they predict *subject* entities. Predicting subject entities is more difficult, since their corresponding mask tokens are placed at the beginning of the templates. This allows for valid completions that do not contain any entities. For example, if the template is “[MASK] is the capital of Malta”, then “It” is also a valid completion with no entities. Additionally, predicting the subject entity based on the object entity might be ambiguous (see discussion in Section 4).

**Coherency scores per relation type.** Coherency scores per relation type are shown in Table 5.

**Coherency on a subset.** Table 6 shows a normalized version of the coherency scores using manually-written prompts.

**Coherency over relations with different paraphrases.** Figure 2 shows the average coherency scores with standard deviation over different relations when using paraphrased prompts. Note that bert-base-uncased has less relations than t5-base (36 vs. 38), since some relations ended up with no instances after excluding multi-token entities. In general, we notice high standard deviation for most relations.

**Coherency scores with the number of instances.** Table 7 shows the coherency scores with the size of the test set in instances.

## B Examples

We show examples of several failures from different prompts and categorize these in Table 8.

## C Additional Details on Masked Language Models

Masked PLMs are trained to predict one or several tokens given a context. This is considered a generalization of the conventional language modeling objective that predicts the next token based on its left context. BERT (Devlin et al., 2019), an encoder-only model, was trained using the Masked Language Modeling (MLM) objective. T5, an encoder-decoder model, was also trained using a variant of the MLM objective in addition to a mixture of supervised tasks. In the Salient Span Masking (SSM) versions of T5, the models are additionally trained by masking only entities to push the model to focus more on these (Guu et al., 2020; Roberts et al., 2020). Similarly, Sadeq et al. (2022) leverage pointwise mutual information to mask salient tokens in an unsupervised manner. Table 9 provides an overview of the architecture and the number of parameters for each model.

## D Choice of Datasets

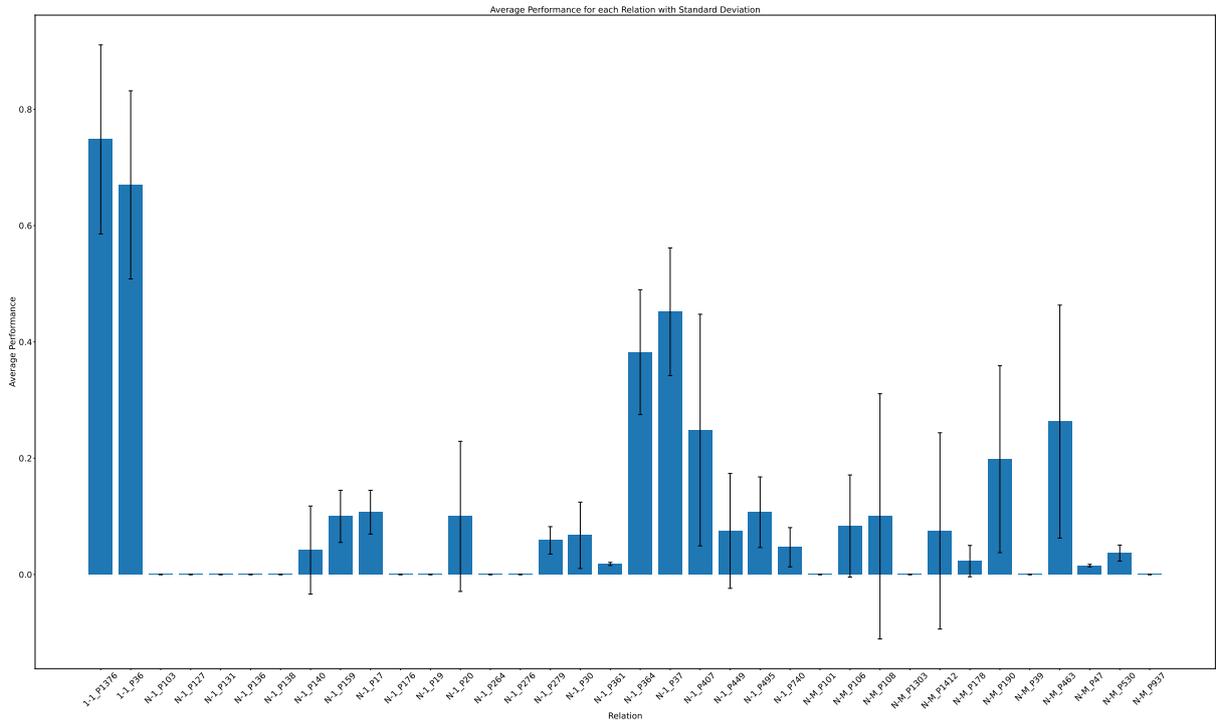

The LAMA probe (Petroni et al., 2019) has been proposed to assess how much factual knowledge is contained in PLMs. We believe it is suitable for the experiments we conduct, since it consists of (subject, relation, object) triples. This allows

Model	c1	c2	All correct	#relations	#Instances
bert-base-uncased	30.77	8.55	4.27	39	2919
bert-large-uncased	25.96	8.39	4.22	39	2919
InformBERT	22.33	5.97	4.34	39	2926

us to evaluate, how often PLMs can predict one entity (either the subject or object) given the other entity and the relation. Additionally, LAMA covers 41 relations of different types, which helps us provide a coherency estimate based on all of these relations. See Table 10 for an overview. We also used the ParaRel dataset (Elazar et al., 2021). This dataset has been proposed to measure the sensitivity of PLMs to paraphrased prompts with respect to factual knowledge. Similarly, we use ParaRel to investigate how the coherency score is affected by paraphrased prompts. All the datasets we used are in English. Additionally, we used the prompts obtained by Autoprompt (Shin et al., 2020) to investigate the effect of having optimized prompts on the performance. We manually create prompts for autoregressive PLMs. These templates are included with our code.<sup>3</sup>

## E Computational Resources

In all of our experiments, we use a NVIDIA A100 GPU with 80GB of memory. Our experiments took roughly 25 GPU days.

## Abstract

Code representation is important to machine learning models in the code-related applications. Existing code summarization approaches primarily leverage Abstract Syntax Trees (ASTs) and sequential information from source code to generate code summaries while often overlooking the critical consideration of the interplay of dependencies among code elements and code hierarchy. However, effective summarization necessitates a holistic analysis of code snippets from three distinct aspects: lexical, syntactic, and semantic information. In this paper, we propose a novel code summarization approach utilizing Heterogeneous Code Representations (HCRs) and our specially designed HIERARCHYNET. HCRs adeptly capture essential code features at lexical, syntactic, and semantic levels within a hierarchical structure. HIERARCHYNET processes each layer of the HCR separately, employing a Heterogeneous Graph Transformer, a Tree-based CNN, and a Transformer Encoder. In addition, HIERARCHYNET demonstrates superior performance compared to fine-tuned pre-trained models, including CodeT5, and CodeBERT, as well as large language models that employ zero/few-shot settings, such as CodeLlama, StarCoder, and CodeGen. Implementation details can be found at <https://github.com/FSoft-AI4Code/HierarchyNet>.

## 1 Introduction

Summarizing code is crucial for aiding developers in comprehending and maintaining source code. Yet, manual documentation is a laborious process. An automated method is required to craft comments efficiently. To generate precise summaries, a model should grasp lexical, syntax, and semantic

aspects within the code. It's imperative to capture relationships such as data and control dependencies among program elements to enhance code representation learning for code summarization.

Early sequence-based techniques (Iyer et al., 2016; Ahmad et al., 2020) treated code as a sequence of texts, but they did not take into account the complex interdependence of program elements in syntax or semantics. Structured-based approaches (Alon et al., 2019a; LeClair et al., 2019; Shi et al., 2021; Chai and Li, 2022) were later proposed to better capture the syntactic information. The state-of-the-art approaches, such as CAST (Shi et al., 2021) and PA-Former (Chai and Li, 2022), leverage the idea of *hierarchically* splitting the AST into smaller parts based on its structure. CAST hierarchically splits the AST's code blocks based on certain attributes, while PA-Former works by treating statements as spans and splitting them into (sub)-tokens. These code-hierarchy approaches bring the benefits in terms of effective and affordable training of neural models. However, a common drawback is that they ignore the program dependencies in code representations. There are other lines of work leveraging graphs (LeClair et al., 2020; Fernandes et al., 2019; Hellendoorn et al., 2020a) that model program dependencies by adding edges to the AST, in which the edges are the dependencies derived from static analysis. However, these approaches do not take into account the code hierarchy as the previous line of work.

We propose a novel approach called *Heterogeneous Code Representation* (HCR) to overcome these limitations by combining the strengths of both methodologies. HCR excels in encapsulating crucial code attributes across lexical, syntactic, and semantic dimensions within a hierarchical structure. This structure organizes program elements based on their features: sequences for code tokens, AST subtrees for syntax, and graphs for dependencies. Significantly, we adeptly capture program depen-

\*Equal contribution. Listing order is based on the alphabetical ordering of author surnames.

Emails: minhnh46@fpt.com.vn, dqnbui.2016@smu.edu.-sg, truongson.hy@indstate.edu, long.tran-thanh@warwick.ac.uk, tien.n.nguyen@utdallas.edu

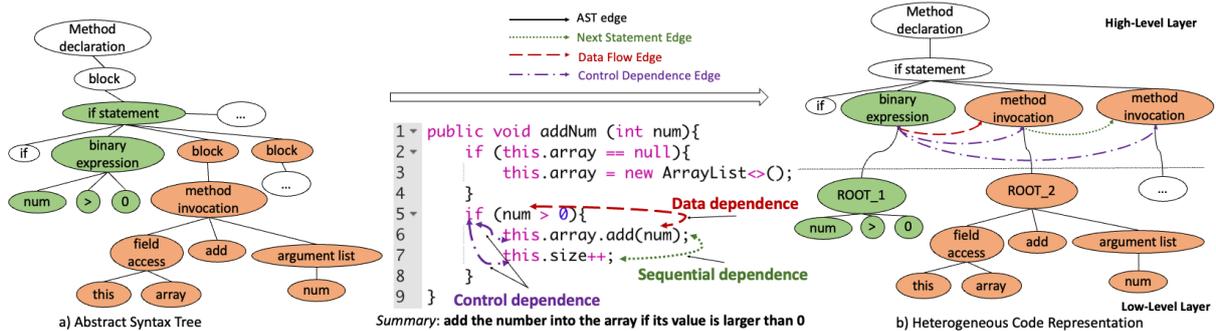

Figure 1: Motivating Example on Heterogeneous Code Representation

dependencies by abstracting coarse-grained nodes into a higher-level layer and fine-grained nodes into a lower-level layer. This strategy enhances the generation of summaries as our model gains a more comprehensive understanding of the source code.

To process our representations, we introduce a heterogeneous architecture, called HIERARCHYNET, which comprises a Transformer Encoder for processing lexical information, a Tree-based Encoder for processing syntactic information, and a Graph-based Encoder for capturing program dependencies. These layers do not operate individually but hierarchically, which intuitively captures the relationships between program elements even better. Our comprehensive evaluation across diverse scenarios shows the effectiveness of our model in code summarization compared to state-of-the-art (SOTA) methods. Our model surpasses these methods in three distinct settings: (1) hierarchical neural networks (NNs) of code akin to us, such as PA-former and CAST; (2) fine-tuned SOTA pretrained language models of code, such as CodeT5 and CodeBERT; and (3) in-context learning of Large Code Language Models using zero-shot and few-shot settings, such as StarCoder and CodeGen.

To summarize, our key contributions include:

(1) *Heterogeneous Code Representation*: a novel code representation that incorporates sequences, trees, and graphs to effectively capture the lexical, syntactic, and semantic aspects of source code.

(2) HIERARCHYNET: a novel *hierarchical neural network architecture*, designed in a modular manner, where each module in the architecture is responsible for processing each layer in the *Heterogeneous Code Representation*. The key modules include the Transformer Encoder, Tree-based CNN, and Heterogeneous Graph Transformer, as well as a novel Hierarchy-Aware Cross Attention module for attending to information across layers.

(3) In our comprehensive evaluation on various established datasets for code summarization, including TL-CodeSum (Hu et al., 2018), DeepCom (Hu et al., 2020a), and FunCom (LeClair et al., 2019), HIERARCHYNET shows significantly superior performance compared to the baselines. In a variety of settings, HIERARCHYNET outperforms a wide range of models: (1) similar hierarchical NNs of code, such as PA-former and CAST; (2) fine-tuned SOTAs that are pretrained language models of code, such as CodeT5 and CodeBERT; and (3) in-context learning of Large Code Language Models using zero-shot and few-shot settings, such as CodeLlama, StarCoder, and CodeGen.

(4) We make our source code and implementation easy to reproduce via an anonymous link, allowing for future improvements for the research community: <https://github.com/FSoft-AI4Code/HierarchyNet>.

## 2 Related Work

**Code Summarization** Research in generating the descriptions for source code has evolved through various techniques. Initially, sequence-based methods treated code as text (Iyer et al., 2016; Ahmad et al., 2020; Wei et al., 2019), disregarding syntactic or semantic dependencies among program elements. For example, NeuralCodeSum (Ahmad et al., 2020) is a purely transformer-based approach that receives code tokens and generates summaries. Structure-based and tree-based approaches were also proposed to capture the syntax of source code (Tai et al., 2015; Mou et al., 2016a; Bui et al., 2021b; LeClair et al., 2019; Hu et al., 2020a; Peng et al., 2021b; Shi et al., 2021; Chai and Li, 2022). For instance, TreeLSTM (Tai et al., 2015) employs bottom-up node accumulation, while TPTrans (Peng et al., 2021b) integrates AST path information into the transformer.

CAST (Shi et al., 2021) and PA-former (Chai and Li, 2022) are currently the state-of-the-art methods with the same key idea of breaking the code into a structural hierarchy. Finally, graph-based techniques were used to capture code semantics by adding inductive bias into the AST through semantic edges, turning it into a graph (LeClair et al., 2020; Fernandes et al., 2019; Hellendoorn et al., 2020a). However, they still encounter challenges in representing code hierarchy and program dependencies, as well as neural networks to handle them.

### Pretrained Language Models for Source Code

Besides code summarization, language models of code generally support various code understanding tasks, such as code generation (Feng et al., 2020a; Wang et al., 2021b; Elnaggar et al., 2021), code completion (Feng et al., 2020a; Wang et al., 2021b; Peng et al., 2021a), program repair (Xia et al., 2022), etc. A large body of recent work employs language models from natural language processing for code (Feng et al., 2020a; Wang et al., 2021b; Guo et al., 2020; Ahmad et al., 2021; Bui et al., 2021a; Elnaggar et al., 2021; Peng et al., 2021a; Kanade et al., 2020; Chakraborty et al., 2022; Ahmed and Devanbu, 2022; Niu et al., 2022), applying similar pretraining strategies as used for natural languages. Despite their promising performance, these pretrained models have not been empirically demonstrated to effectively capture semantics in source code, such as data, control flows, and other program dependencies among code elements. In contrast, incorporating code-specific features into representations as inductive biases has been shown to increase the model’s knowledge (Al-lamanis et al., 2018a; Hellendoorn et al., 2020b).

## 3 Motivation

Let us use an example to motivate and illustrate the key ideas of our solution. Figure 1 shows a code snippet and its corresponding summarization. The task is to collect the positive numbers into an array. To generate an accurate summary, a model needs to capture code features at the lexical, syntactic, and semantic levels. For example, at the lexical level, the sub-tokens `add`, `num`, and `array` should resemble words in the summary. The tokens `>` and `0` correspond to the texts ‘larger than’ and ‘0’ in the summary. At the syntactic level, the model should recognize code structures, such as the `if` statement at line 5 indicating a conditional sentence in the summary.

Importantly, the control and data dependencies among the statements could provide valuable insights into the intended execution order. Ignoring control dependencies hinders the model’s ability to capture such intentions because the sequential order in the code may not reflect the execution order. For example, despite their sequential order, the execution of the statement at line 6 is not guaranteed to follow the statement at line 5, as it is dependent on the outcome of the *if condition* at line 5. Moreover, the data dependency via the variable `num` at line 5 and line 6 is also crucial for summarization as it indicates that only positive numbers are collected.

Previous approaches, such as those outlined in LeClair et al. (2020), Fernandes et al. (2019), and Hellendoorn et al. (2020a), utilize heuristics from static analysis to connect nodes in the AST to represent dependencies. However, the large size of the AST can pose challenges for a model to effectively capture dependencies among distant nodes (Alon and Yahav, 2021). In contrast, state-of-the-art approaches such as CAST (Shi et al., 2021) and PA-Former (Chai and Li, 2022) create a hierarchy among code elements by splitting the AST into smaller parts. However, these methods do not maintain program dependencies among the elements.

We propose the *Heterogeneous Code Representation* (Figure 1b) to restructure code into **hierarchical layers**, abstracting meaningful entities such as statements or expressions into single nodes in a higher layer. Importantly, HCR also enables the representation of **dependencies**, including data, control, sequential, and syntactic dependencies. We introduce a heterogeneous neural network utilizing an appropriate neural network at each level: a transformer encoder for code tokens, a tree-based encoder for AST subtrees, and a graph neural network for the coarse-grained dependencies. This approach reduces the computational workload and improves capturing the dependencies between distant nodes in an AST (an issue with the prior works).

## 4 Heterogeneous Code Representation

This section presents the Heterogeneous Code Representation (HCR) that integrates both hierarchical structure of source code as well as program dependencies among program elements. Figure 2 (left-side) displays the three layers of Heterogeneous Code Representation (HCR). The first layer, denoted by the "Linearized AST Sequence," is a sequence of nodes  $L$  from the serialization process

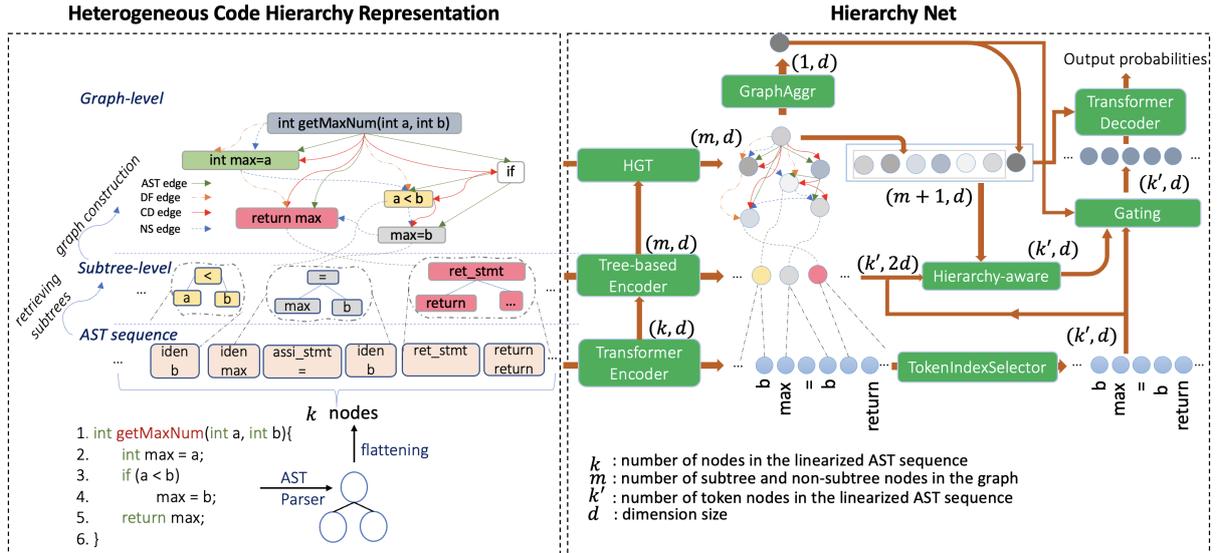

Figure 2: HIERARCHYNET Architecture

of the Abstract Syntax Tree (AST) of the given program. The second layer, the "Subtree-level," represents the statement and expression-level program elements, each represented by a significantly smaller subtree  $T'$  consisting of nodes from the original AST  $T$ . Finally, the last one is the highest-level and coarsest-grained layer, the "Graph level", which is represented by a graph  $G$  consisting of nodes from  $T'$ , enriched by semantic edges such as control and data dependencies. Such dependencies are built from static program analysis. Next, we will present in details each layer in our model.

#### 4.1 Serialized AST Sequence

We begin by parsing a program into an Abstract Syntax Tree (AST)  $T$ . Each token node contains a non-empty token, which is often made up of multiple sub-tokens. To incorporate these sub-tokens, we insert new sub-token nodes as children of the corresponding token node. The AST is then serialized to create a sequence of nodes  $L$ . Specifically, we convert the AST into a sequence of nodes by a traversal such that the original token order is maintained (Figure 2). Formally, the linearized AST sequence  $L = [l_1, l_2, \dots, l_k]$  (where  $k$  is the size of  $T$ ) represents the lowest level of HCRs.

#### 4.2 Syntactic Level

A function is usually a combination of many statements and expressions, each of which often represents a sufficient amount of information to understand how/what it does. We extract the AST subtrees corresponding to statements and expres-

sions. These subtrees are then abstracted by replacing them with placeholder nodes in  $T'$ , resulting in a smaller tree  $T'$ . This process is done through a depth-first traversal of the AST, where subtrees are replaced and further traversal is halted at the subtree's root node. This results in a new tree  $T'$  and a set of subtrees  $ST$ , with some nodes in  $T'$  pointing to elements in  $ST$ , which forms the second level in our HCRs. Note: some nodes in  $L$  do not belong to any subtrees (non-subtree nodes).

#### 4.3 Semantic Level

We use the reduced AST  $T'$  and incorporate semantic edges among the nodes to create graph  $G$  (as depicted in Figure 2). Our graph includes four distinct edge types: AST edges, Data-flow (DF) edges, Control-dependence (CD) edges, and Next-subtree (NS) edges. These edges represent various forms of connections between program elements, such as code structures, data and control dependencies, and sibling statements in the source code.

### 5 Neural Network Architecture

This section explains the neural network architecture for our HIERARCHYNET method (Figure 2). Each node  $l_i$  in a sequence of nodes  $L$  has two attributes: *token* and *type*. The initial representation of each node  $l_i$  is computed by concatenating the embeddings of its *token* and its *type*. These embeddings can be looked up from two learnable embedding matrices (token and type). We denote  $s_i$  be the initial embedding of the node  $l_i$ ,  $i \in \mathbb{N}$ ,  $0 < i \leq k$  where  $k$  is the length of  $L$ .

The neural network architecture, HIERARCHYNET, consists of the following components.

### 5.1 Transformer Encoder

The Transformer Encoder encodes the linearized AST sequence  $L$  to capture lexical values. It takes initial embeddings  $[s_1, s_2, \dots, s_k]$  as input and produces the output  $[h_1, h_2, \dots, h_k]$ .

### 5.2 Tree-based Encoder

This layer’s primary role is to process the subtrees in the Subtree layer. Additionally, it also embeds non-subtree nodes in the  $L$  by applying a non-linear transformation. To model local patterns and hierarchical relations among nodes within the same subtree, all subtrees are passed through a Tree-based CNN (Mou et al., 2016b). An attention aggregation method (Alon et al., 2019b) is then employed to encode each subtree as an embedding vector, using a global attention vector  $\alpha$ . The output of this layer are denoted as  $\{\hat{t}_i\}_{i=1}^m$  where  $m$  is the number of subtrees and non-subtree nodes.

### 5.3 Heterogeneous Graph Transformer

After obtaining the embeddings of all the subtrees, we further encode the dependencies among the nodes in the heterogeneous graph  $G$ . We adapt the Heterogeneous Graph Transformer (HGT) (Hu et al., 2020b) to process the graph effectively. The outputs are the vectors  $\{n_i\}_{i=1}^m$  that not only bring textual information (by Transformer Encoder and next-subtree edges) but also are contextualized by the locally hierarchical structures of the subtrees and dependence information that are unique characteristics in source code.

### 5.4 Graph Aggregation (GraphAggr)

Upon completion of the HGT processing, it is essential to aggregate the individual nodes within the graph into a vector that represents the graph. Similar to the tree aggregation technique employed in the Tree-based Encoder, an attention mechanism is utilized to aggregate the nodes and generate a graph embedding, denoted as  $g$ , by using the global attention vector  $\beta$ . This graph embedding  $g$  encapsulates the overall semantic meaning of the code.

### 5.5 Token Index Selector

The TokenIndexSelector layer utilizes the output of the Transformer Encoder as input and serves to retain the embeddings of nodes  $l_i$  that possess non-empty token attributes while discarding those

that do not. The rationale is that the Transformer Encoder effectively encodes textual meaning but is inadequate in encoding syntax (as represented by the type attribute), which could potentially introduce noise to subsequent layers (such as the Gating Layer and Transformer Decoder). It is worth noting that the Subtree layer effectively encodes syntax information using Tree-based CNN. Formally, let  $H'$  be the sequence of the elements  $h_i$  such that  $l_i$  is a token node, for all  $0 < i \leq k$ . We denote the members of  $H'$  by  $h'_1, h'_2, \dots, h'_{k'}$  where  $k'$  is the number of token nodes in the  $L$ .

### 5.6 Hierarchy-Aware Cross Attention

Although information is gathered in a bottom-up manner, there may still be missing connections between layers. To address this issue, we introduce the Hierarchy-aware Cross Attention (HACA) layer, which enables the TokenIndexSelector layer to focus on the information from the HGT layer. This layer, depicted in Figure 2, calculates the attention of each token toward nodes in the structure (tree + graph). Keys  $K$  and values  $V$  are derived from the combination of the nodes’ embeddings  $\{n_i\}_{i=1}^m$  and the graph embedding  $g$ . Additionally, a token can occur multiple times in a code snippet, even with the use of positional encoding, the vectors of these tokens may be similar. To differentiate these occurrences, we concatenate their corresponding subtrees. For example, by examining the subtrees, we can discern the different roles of the variable  $a$  at lines 1 and 2. We enhance the distinctions by concatenating  $h'_i$  and  $\hat{t}_i$  to create the vector query  $q_i$ ; formally,  $q_i = f_{ca}([h'_i, \hat{t}_i])$  where  $f_{ca}$  is a projection from  $\mathbb{R}^{2d}$  to  $\mathbb{R}^d$ . Then the cross-attention is computed as usual, that is  $\text{softmax}\left(\frac{QK^T}{\sqrt{d_k}}\right)V$  where  $d_k$  is the inner dimension size of each attention layer. This layer produces  $\{c_i\}_{i=1}^{k'}$  where  $c_i$  is the fused hierarchical context dedicated to the token node corresponding to  $h'_i$ , for all  $0 < i \leq k'$ .

### 5.7 Gating Layer

The HACA layer is responsible for calculating attention scores across different layers, but it does not perform information integration. We introduce the Gating layer to combine the information across different layers in the hierarchy, serving as the input for the Transformer Decoder. The goal is to combine the outputs  $\{c_i\}_{i=1}^{k'}$  of HACA with the lex-

Table 1: Comparative Code Summarization Performance on TL-CodeSum and FunCom Datasets (RQ1).

ical information of  $\{h_i^l\}_{i=1}^{k^l}$ . To balance the two sources of information, we propose to add a sufficient amount of context from  $c_i$  to  $h_i^l$ . We take inspiration from the gating layer in Cho et al. (2014), and modify it to achieve this goal. Specifically, the ratio between the two sources is controlled by the graph embedding, as  $g$  is the highest level of abstraction and contains a global understanding of the code. Formally, the computation can be summarized as:  $\lambda = \text{sigmoid}(Wg + b)$ , where  $W \in \mathbb{R}^{d \times d}$ ,  $b \in \mathbb{R}^d$  or  $W \in \mathbb{R}^d$ ,  $b \in \mathbb{R}$  are learnable parameters, and  $d$  is the dimension of the vector  $g$ . We then apply a non-linear projection  $f_c$  to map  $c_i$  onto the space of  $h_i^l$  and form the hierarchy-aware hidden state by:  $e_i = \lambda f_c(c_i) + (1 - \lambda)h_i^l$ . Finally,  $\{e_i\}_{i=1}^{k^l}$  are final encoder hidden states.

## 5.8 Transformer Decoder

Unlike the vanilla Transformer Decoder (Vaswani et al., 2017), we need to combine the two sources, including hierarchy-aware textual information (the output of Gating layer) and the structural/semantic meaning (the output of HGT and GraphAggr).

Therefore, in HIERARCHYNET, we leverage the serial strategy (Libovický et al., 2018) in computing the encoder-decoder attention one by one for each input encoder. The key and value sets of the first cross-attention come from the output of HGT and GraphAggr. Those sets of the other cross-attention are from the output of Gating layer.

## 6 Empirical Evaluation

We have conducted several experiments to evaluate HIERARCHYNET. We seek to answer the following research questions:

1. RQ1. **[Automated Evaluation]**. How well does HIERARCHYNET perform in code summarization compared with the SOTA approaches?
2. RQ2. **[Human Evaluation]**. How well does HIERARCHYNET perform in code summarization in a human study with human evaluation?
3. RQ3. **[Ablation Study]**. How well do different components in HIERARCHYNET contribute to its overall code summarization performance?

### 6.1 Automated Evaluation (RQ1)

**Datasets.** To ensure a comprehensive comparison with several SOTA baselines, we considered multiple well-established datasets for code summarization, namely TL-CodeSum (Hu et al., 2018), DeepCom (Hu et al., 2020a), FunCom (LeClair et al., 2019), and FunCom-50 (Chai and Li, 2022). Note that different baselines use distinct datasets and achieve SOTA results. The FunCom-50 dataset was used by PA-Former (Chai and Li, 2022), but with a number of samples filtered out from FunCom, approximately 50% of the data. We followed the original dataset’s partition in FunCom (LeClair et al., 2019) for training, testing, and validation.

Table 2: Comparative Code Summarization Performance on DeepCom and FunCom-50 Datasets (RQ1).

**Baselines.** We compared HIERARCHYNET against three categories of baselines. The first category includes the baselines trained from scratch without utilizing pretrained checkpoints. Examples include CAST (Shi et al., 2021) and PA-Former (Chai and Li, 2022), which are consciously designed to incorporate code structures. Additional baselines in this category, grouped by code representation and neural architecture, including *sequence-based models* (NCS (Ahmad et al., 2020)), *structure-based and tree-based models* (ASTAttGru (LeClair et al., 2019), HDeepCom (Hu et al., 2020a), TPTrans (Peng et al., 2021b), TreeLSTM (Tai et al., 2015), CodeASTNN (Shi et al., 2021), SiT (Hongqiu et al., 2021)), and *graph-based models* (GREAT (Hellendoorn et al., 2020a)).

The second category comprises fine-tuned baselines for code summarization from well-known pretrained models. For representative models, we fine-tune CodeT5-base (Wang et al., 2021a) and CodeBERT-base (Feng et al., 2020b), considering CodeT5 as the state-of-the-art for code summarization and CodeBERT as a widely-used model.

The third category encompasses large language models that can perform in-context learning for code understanding tasks using zero-shot, one-shot, or few-shot learning approaches. For this category,

we used CodeLlama 13B (Roziere et al., 2023), StarCoder (Li et al., 2023) and CodeGen-Multi 2B (Nijkamp et al., 2023).

**Metrics.** We employ BLEU (Papineni et al., 2002), Meteor (Banerjee and Lavie, 2005), Rouge-L (Lin, 2004), Cider (Vedantam et al., 2015) and F1-score, which are commonly used as the evaluation metrics for code summarization.

**Results.** The results shown in Table 1 and 2 indicate that HIERARCHYNET exhibits superior performance compared to the CAST and PA-former methods by a significant margin on the four datasets. Specifically, HIERARCHYNET achieves an average improvement of 4.46 and 3.48 BLEU scores over CAST and PA-former, respectively. Notably, PA-Former, which is currently considered the state-of-the-art baseline, only outperforms CAST by an average of 1 BLEU score. Furthermore, HIERARCHYNET also consistently surpasses CodeT5-base and CodeBERT-base and outperforms Large Language Models for code such as CodeLlama, StarCoder and CodeGen-Multi 2B in all three prompting scenarios (zero/one/two-shot) on the datasets.

In conclusion, the results show that HIERARCHYNET, which utilizes a hierarchical-based architecture and dependencies information, significantly improves code summarization performance.

Table 3: Results of Ablation Study on Heterogeneous Code Representation (RQ3)

## 6.2 Human Evaluation (RQ2)

In line with prior work on code summarization (Iyer et al., 2016; Shi et al., 2021; Chai and Li, 2022), we conducted a user study with the participation of five software development experts to examine the efficacy of our method in practice. We presented each participant with 100 random examples from the testing segment of the FunCom dataset, along with three respective summaries produced by HIERARCHYNET, PA-former, and CAST. In order to avoid potential biases, we do not provide the ground truth, and summaries of different methods are randomly tagged with placeholder names. Following Shi et al. (2021); Chai and Li (2022), we adopt two human evaluation criteria: 1) *naturalness*: grammar, fluency, and readability of generated summaries. 2) *usefulness*: to what extent generated summaries are useful to comprehend the code. Each aspect is divided into three standards rating from 1 to 3, with higher scores indicating better performance. The final score for each criterion is the average of all samples. As shown in Table 4, HIERARCHYNET outperforms both CAST and PA-former in terms of naturalness and usefulness.

## 7 Model Analysis (RQ3)

### 7.1 Study on Heterogeneous Code Representation (HCR)

We investigated the influence of the HCR components on code summarization performance using the TL-CodeSum dataset, as shown in Table 3. Starting with only the AST-sequence layer resulted in suboptimal performance. Incorporating Subtree and Graph layers incrementally improved results. Our AST-edge-focused experiment at the Graph

Methods	Naturalness	Usefulness
CAST	2.76	2.48
PA-former	2.77	2.50
HIERARCHYNET	<b>2.81</b>	<b>2.52</b>

Table 4: Results of User Study (RQ2)

level surpassed CAST’s performance (Table 1), suggesting our hierarchy’s superiority. While the CD and DF edges notably impact performance, NS edges are less crucial. Still, excluding any edges reduces performance, indicating that the dependencies positively contributed to the performance.

### 7.2 Study on HierarchyNet

Method	BLEU	Meteor	Rouge-L	Cider
HIERARCHYNET	<b>48.01</b>	<b>30.30</b>	<b>57.90</b>	<b>4.20</b>
<i>w/o Hierarchy-aware</i>	46.63	29.49	56.63	4.03
<i>w/o TokenIndexSelector</i>	45.70	28.39	55.06	3.93

Table 5: Ablation Study of HIERARCHYNET (RQ3)

Decoding strategy	BLEU	Meteor	Rouge-L	Cider
serial decoding	<b>48.01</b>	<b>30.30</b>	<b>57.90</b>	<b>4.20</b>
only Gating layer’s output	45.34	28.28	55.33	3.89
concat	47.22	29.41	56.45	4.10

Table 6: Ablation Study on Decoding Strategy (RQ3)

In addition, we aim to demonstrate the significance of our proposed layers in Hierarchy Net, including Hierarchy-Aware Cross-Attention (abbreviated as Hierarchy-Aware) and TokenIndexSelector, on the TL-CodeSum dataset. The result (Table 5) shows that the removal of any of these com-

ponents significantly degrades performance. This confirms that the Transformer architecture alone is not sufficient to encode both textual and structural/semantic meanings of code, thus highlighting the importance of explicitly integrating semantic and structural information using Hierarchy-Aware Attention. Additionally, we found that removing TokenIndexSelector has a negative impact on performance, which is likely due to the redundant information in the sequence fed to the Decoder.

To show the effectiveness of the serial decoding with the two consecutive cross attention in the Decoder, we compare to two alternatives that just use a cross attention in the Decoder. Specifically, the first option calls for utilizing the Gating layer’s output. The other way is concatenating the TokenIndexSelector’s output, HGT’s output and GraphAggr’s output into single extended sequences, which are then fed to the Decoder. As shown in Table 6, more information employed in the Decoder in the latter strategy leads to the better performance compared to only Gating layer’s output. However, combining our proposed code hierarchy representation with the serial decoding achieves the highest results.

### 7.3 Comparison with LLMs

Model	Average word count
StarCoder (zero-shot)	10.64
StarCoder (one-shot)	7.59
StarCoder (two-shot)	8.12
CodeGen 2B (zero-shot)	4.95
CodeGen 2B (one-shot)	8.46
CodeGen 2B (two-shot)	8.49
References	9.97

Table 7: Comparative Results with LLMs regarding the Average Word Count of Summaries

Given that LLMs may potentially generate responses longer and more detailed than the ground truth, our objective is to thoroughly analyze and ensure the fairness of our evaluation. We present the average word count of summaries generated by LLMs compared to references on DeepCom in Table 7. Notably, LLMs like StarCoder and CodeGen 2B tend to produce shorter summaries than the ground truth. Although, in the zero-shot setting, StarCoder can generate slightly longer summaries, this difference is negligible. As a result, summaries generated by LLMs are considered to be of similar length to the references in the ground truth.

Moreover, the experimental results reveal a substantial performance disparity between our proposed method and large language models across all metrics. Specifically, in terms of Rouge-L, the gaps amount to approximately 10, 30, and 30 when compared to StarCoder on FunCom, DeepCom, and FunCom-50, respectively. Regarding Meteor, these are 5, 13, and 15, respectively. The study (Roy et al., 2021) shows that there is a statistically significant difference in performance between models whose performance difference is greater than 10 points. Furthermore, it finds that for the gaps exceeding 10 points, the metrics, like Rouge-L and Meteor, strongly agree with human assessment.

## 8 Conclusion

We introduce an innovative framework for code summarization that combines Heterogeneous Code Representations (HCRs) with HIERARCHYNET, a neural architecture tailored for processing HCRs. Our HCRs capture critical code attributes across lexical, syntactic, and semantic levels by organizing coarse-grained code elements into a higher-level layer while integrating fine-grained program elements into a lower-level layer. HIERARCHYNET is engineered to handle each layer of the HCR independently, enabling the representation of information gathered at the fine-grained level as input at the coarse-grained level. The core concept of HIERARCHYNET lies in integrating multi-level code representations and program dependencies. Our empirical evaluations demonstrate that our approach surpasses various state-of-the-art techniques across diverse settings, including structure-based models (CAST, PA-Former), fine-tuned pretrained models (CodeT5, CodeBERT), and in-context learning (CodeLlama, StarCoder, CodeGen). Our ablation study shows that all of the components in HIERARCHYNET contribute positively to its high performance. We also conducted a human study to evaluate the code summarization results produced by HIERARCHYNET. The results show that human subjects highly regarded the code summarization results from our model.

## Acknowledgments

## Limitations

Our approach presents opportunities for improvement.

1. First, our Heterogeneous Code Representations (HCRs) with coarse-grained semantic edges have proven effective for code summarization. However, there may be potential for further enhancement by exploring alternative options for cross-layer semantic edges, such as connecting nodes at the fine-grained level with nodes at the coarse-grained level. This could be beneficial for other code representation learning tasks, such as variable name prediction (Allamanis et al., 2018b) and data flow analysis using neural models (Gu et al., 2021). Our next step is to conduct further research on extending HCRs to include these alternative options and evaluate their performance on other code representation learning tasks.
2. Second, while HIERARCHYNET effectively processes the HCRs, there is room for further optimization. We chose the layers in the HIERARCHYNET based on heuristics, resulting in the HGT being the best option for processing graphs. At the subtree-level, we chose the TBCNN as it is more computationally efficient compared to other state-of-the-art methods for processing ASTs, such as TreeCaps (Bui et al., 2021b). However, our approach can be considered a framework rather than a single neural model, so other advancements in tree- or graph-based models or sequence-based models can easily be incorporated to improve performance.
3. Finally, we did not provide any analysis on the explainability of our model. Explainability is an important aspect of code learning models (Bui et al., 2019; Bielik and Vechev, 2020; Zhang et al., 2020; Rabin et al., 2021), and is crucial for the real-world usage of practitioners in code summarization. Our current model design has the potential to support explainability in the future, as the inputs of the high-level layer are computed based on the attention aggregation mechanism, with each input being assigned an attention score. These attention scores can be used to visualize and explain the importance of code elements in a hierarchical way. We will explore this extension as a future work.

## Ethics Statement

Our framework aims to revolutionize the way software is modeled by taking a new approach with a broader impact in the field. While language models for code have shown impressive performance and have the potential to boost developer productivity, they still face challenges with computational cost and memory consumption. For example, when modeling code and software at the repository level, such as on Github, the AI framework must consider the context of the current code being edited, as well as additional contexts from other files or API calls from external libraries. This is a dependency on a larger scale level in the context of software modeling. Currently, language models typically only model code within the scope of a function or within a single file for tasks such as code summarization or generation. However, this limitation may not be due to the language model itself, but rather the infrastructure of supported IDEs and the software modeling approach. We propose a more realistic way to represent programs as "repository=>file=>class=>function=>statement=>token." The simplest way to model such a hierarchy is to treat them all as a very large sequence and use Large Language Models to model it, but this results in large memory consumption and expensive computational costs. A more affordable approach is to represent large software as modules, where each module can be represented differently at each level. Each layer may require dependency analysis or not, depending on its characteristics. For example, the semantic edges used to connect components clearly differ at each level, requiring careful design of them. Existing approaches to representing the entire program as a graph will fail in this case because the set of semantic edges are designed the same for all nodes without treating them differently. Also, each of the modules can be preprocessed separately on different computing units and aggregated later to achieve efficient computation cost and save memory. We have already demonstrated efficacy when modeling the program at three levels: "function=>statement=>token" and plan to extend this further. Our natural way of structuring the source code hierarchically is also aligned well with the advances in programming language and software engineering research in program representations. We believe our solution can be viewed as a framework and opens up a new research direction for representing software.

lonneke.vanderplas@idiap.ch

## Abstract

We study the effect of one type of imbalance often present in real-life multilingual classification datasets: an uneven distribution of labels across languages. We show evidence that fine-tuning a transformer-based Large Language Model (LLM) on a dataset with this imbalance leads to worse performance, a more pronounced separation of languages in the latent space, and the promotion of uninformative features. We modify the traditional class weighing approach to imbalance by calculating class weights separately for each language and show that this helps mitigate those detrimental effects. These results create awareness of the negative effects of language-specific class imbalance in multilingual fine-tuning and the way in which the model learns to rely on the separation of languages to perform the task.

## 1 Introduction

Transformer-based Large Language Models (LLMs) lend themselves well to automatic classification tasks due to their superior performance, ability to be pre-trained on large amounts of data, and easy fine-tuning on downstream tasks. Recently, methods like LoRA (Hu et al., 2021) and Adapters (Houlsby et al., 2019) have been developed to fine-tune LLMs using fewer resources, making automation of classification tasks using LLMs more accessible than ever. Multilingual versions of large language models, such as mBERT are readily available. They are pre-trained on large multilingual corpora and build latent spaces that have both language-agnostic and language-specific components (Pires et al., 2019).

Previous works have studied the effect of fine-tuning on monolingual data on the representation of the multilingual space and cross-lingual transfer performance (Conneau et al., 2020; Lample and Conneau, 2019) and showed that fine-tuning on a specific task with monolingual data reduces

language-specificity (Tanti et al., 2021). What is relatively understudied is the effect of multilingual fine-tuning on the multilingual space, which is especially interesting because it is not guaranteed that labels are similarly distributed across languages which could create an incentive for the model to rely on language for predictions. Oftentimes, curated multilingual datasets will have the same distribution of labels across languages, and it is pointed out as a desirable property (Schwenk and Li, 2018). However, in real-world datasets, data is often heterogeneous and class label distributions can vary significantly between languages. An example of this is the SemEval 2018 Task 1 dataset (Mohammad et al., 2018). Class imbalance in the monolingual setting has been the focus of many previous works (Henning et al., 2023), some work addresses class imbalance in the multilingual setting (Yilmaz et al., 2021), but to the best of our knowledge, language-specific class imbalance has not been studied in detail.

In this paper, we analyse the effect of class imbalance<sup>1</sup> on the model with a number of experiments of multilingual classification on two different datasets. We chose to work with balanced dataset which we artificially imbalance to allow for controlled experiments. More specifically, we create two subsets of the data, one with a uniform joint distribution of language and labels and one with a skewed one. We want to create a better understanding of the influence of imbalance in multilingual fine-tuning. We first show that imbalance has a negative influence on performance and leads to the latent space becoming more separated by language. Then, using SHAP values, we show evidence that the model learns to encode the imbalance even in non-informative tokens, thus effectively learning

---

<sup>1</sup>In this paper, we refer to the non-uniform joint distribution of language and label as "imbalance", even though in the traditional sense imbalance mainly refers to the marginal distribution of labels.

to classify based on language identity to an extent. We modify the traditional class weighing method to weigh datapoints of different languages separately and show that this mitigates the negative effects of the imbalance.

In summary, our main contributions are:

- We show the detrimental effects of language-specific class imbalance, namely worse performance and a greater separation of languages in the latent space.
- Using SHAP values, we show that the model pays more attention to uninformative features when fine-tuned on a dataset with this imbalance, in effect acting more like a language identifier.
- We provide a simple method for mitigation by adapting the traditional class weighing method to multilingual fine-tuning.

## 2 Methods

### 2.1 Text classification

We use a large language model followed by a classifier head to perform the text classification. For each dataset, we create two subsets of the same size to be used for fine-tuning. One of them, which we will refer to as "**imbalanced**", is sampled in a way such that the joint distribution of language and labels is skewed, but the marginal distributions of language and of labels are uniform. The other subset is referred to as "**balanced**" because the joint distribution of labels and languages is uniform. We sample these subsets such as to maximize the overlap of datapoints between the two to control for the quality of the training data. The test sets for both tasks are balanced. The classifier head is one feed-forward layer followed by a SoftMax layer.

### 2.2 Language identification

To analyze the language-specificity of the latent space of the models, we train a logistic regression classifier on the task of identifying the language of text from an external dataset. We use the last CLS token as feature vector. We use sklearn’s default parameters, and we report 5-fold cross-validation scores. This is meant to measure how identifiable the languages are in the latent space. We use 1000 articles per language, and we only include the languages the model has seen during fine-tuning. We also report the language identification accuracy on the test sets of the dataset used for fine-tuning.

### 2.3 Cumulative difference in SHAP values

We use SHAP values (Lundberg and Lee, 2017) to investigate how the model makes predictions and how this changes between the balanced and imbalanced cases. SHAP values estimate the marginal contributions of each input token by iteratively masking them and observing the changes in the predicted probability. For a given datapoint  $\{T, y\}$  where  $T$  is a sequence of tokens  $\{t_i\}_{i=0}^{|T|-1}$  and  $y$  is a class label, a fine-tuned LLM attributes probability  $p(T, y)$  to the event " $T$  belongs to class  $y$ ". SHAP values  $S(t)$  explain the contribution of each token  $t$  to that probability according to:

$$p(T, y) = \sum_{t \in T} S(t) + b \quad (1)$$

$b$  is the value that the model attributes to  $p(T_{mask}, y)$  where  $T_{mask} = \{mask\}_{i=0}^{|T|-1}$ , i.e. the probability of label  $y$  that the model gives to an input of mask tokens of the same length as  $T$ . We name  $S_{bal}(t)$  and  $S_{imbal}(t)$  the SHAP values calculated from the models trained on the balanced and imbalanced datasets respectively. We create three subsets of the tokens:

$$T_{pos} = \{t_i \in T \mid S_{bal}(t_i) > 0.01\}$$

$$T_{neg} = \{t_i \in T \mid S_{bal}(t_i) < -0.01\}$$

$$T_{neutral} = \{t_i \in T \mid -0.01 \leq S_{bal}(t_i) \leq 0.01\}$$

We calculate the cumulative difference in SHAP value for each set  $T_{pos}, T_{neg}$  and  $T_{neutral}$  as  $\sum_{t \in T} S_{imbal}(t) - S_{bal}(t)$ . We calculate this metric for each datapoint in the test set, group them by language and average them.

### 2.4 Per-language class weighing

The traditional class weighing method to address label imbalance in machine learning consists in weighing under- and over-represented labels in the loss such that they count more or less in the gradient calculation<sup>2</sup>. We modify it by applying different class weights for each language and label pair. Let  $n_l$  be the number of samples in language  $l$ ,  $n_{c,l}$  the number of samples in language  $l$  with label  $c$ ,  $C$  the total number of classes and  $w_{c,l}$  the weight applied to a sample of class  $c$  and of language  $l$ . The weights are calculated according to:

$$w_{c,l} = \frac{n_l}{C \cdot n_{c,l}} \quad (2)$$

<sup>2</sup>We attempted other methods for mitigation, namely entropy maximisation and gradient reversal of a language identification head. These methods prevented the model from learning.

### 3 Experimental setup

The language model that we use is Multilingual BERT (Devlin et al., 2019). Specifically, we use the "bert-base-multilingual-cased" model from Huggingface. We use a batch size of 16 with a gradient accumulation step of 8. We select the best model according to the validation loss. We use a linearly decreasing learning rate starting at  $5e - 5$  for the language model and  $5e - 4$  for the classifier head. They both reach 0 at the end of training<sup>3</sup>. We also perform the same experiments with XLM-R (Conneau et al., 2020) and report the results in the annex A.2.

We use the Amazon reviews dataset (Keung et al., 2020) in French, German, Spanish, English, Japanese and Chinese, as those are all the available languages in the dataset, and XNLI (Conneau et al., 2018) in French and English, since we wanted to test a bilingual setup. XNLI is a text entailment task. For the Amazon dataset, we train our models to predict the number of stars given (from 1 to 5). For the language identification experiments, we use the Wiki dataset (Foundation), specifically the pre-processed Wikipedia dataset found on huggingface. The distribution of labels per language for the imbalanced datasets can be seen in Tables 1a and 1b. The test sets for both XNLI and the Amazon reviews dataset are balanced in both marginal and joint distributions of language and labels.

## 4 Results and discussion

In this section, we discuss results with respect to task performance first, after which we will shed light on the effect on language specificity of the multilingual space by showing results from experiments on language identification. We will show in detail what happens to different sets of features when confronted with class imbalance using SHAP

<sup>3</sup>We make our code available [here](#).

values. Lastly, we show that per-language class weighing mitigates the effects of the imbalance.

#### 4.1 The imbalance worsens performance

In Table 3, we report the test set accuracy for models trained on the balanced and imbalanced datasets. Unsurprisingly, we see that the models trained on the balanced datasets perform better than the ones trained on the imbalanced datasets. To understand how the imbalance causes the model to perform worse, we check the distribution of predicted classes by the imbalanced model on the test set in Table 2a. We see that English, German, and Chinese texts are more likely to have lower reviews, whereas French, Spanish, and Japanese texts are more likely to have higher reviews, thereby following the class distribution in the imbalanced datasets. This seems to indicate that the model learns to make predictions based on language. In Table 2b, we see the same effect with the XNLI labels: English is more likely to be labeled as contradiction, whereas French is more likely to be labeled as en-

tailment.

## 4.2 The languages are more identifiable in the latent space

Ideally, the aim of multilingual fine-tuning is to allow the model to discover patterns across different languages that help it do the task well in a given language. However, if the model learns to rely on language identification rather than patterns that generalize across languages, we expect the latent space to have clearer separation of the languages. In Table 4, we can see that for both XNLI and the Amazon reviews dataset, the language identification accuracy is higher for the model trained on the imbalanced dataset compared with the balanced one. This is further evidence that the model focuses more on the language of the input in the presence of imbalance.

## 4.3 The model learns to rely on non-informative tokens

Knowing that the languages become more distinct in the latent space in the presence of imbalance, we want to use SHAP values to analyze how the model makes predictions at the token level.

### 4.3.1 Amazon reviews

In Figure 1a, on the left side, the average cumulative difference in SHAP value for label 1 of the Amazon reviews dataset is shown. French, Spanish

and Japanese positive tokens contribute more negatively in the imbalanced case, and negative tokens contribute more positively. Thus, tokens that had a high absolute SHAP value in the balanced case now have a lower absolute value in the imbalanced case for these under-represented languages. The model relies less on features that were informative in the balanced case for these languages. For the over-represented languages, the main effect is that neutral tokens now contribute positively to the prediction. The model thus sees non-informative tokens in the over-represented language as an indication of that label.

On the right side, we see the same plot for label 5. There is a significant difference in base value which we attribute to model artifacts. This means that the SHAP values in the imbalanced case will have a negative bias since the base value is much higher for that model. Thus, the difference in SHAP value between that model and the balanced one will also have a negative bias<sup>4</sup>. However, we can still see that the under- and over-represented language groups are treated differently: positive and neutral tokens for the over-represented languages become less negative than for the under-represented ones, and neutral token become more positive for the over-represented and more negative for the under-represented.

<sup>4</sup>We discuss this issue further in Annex A.3 and introduce a way to mitigate it.

### 4.3.2 XNLI

Figure 1c shows the same plots for the XNLI dataset. French is over-represented for the "entailment" label, and English is over-represented for the "contradiction" label. For both labels, the neutral tokens contribute more positively for the over-represented language and more negatively for the under-represented. The model again learns to rely on non-informative tokens from the over-represented language. For the under-represented language, the positive tokens contribute more negatively, and the negative ones more positively. Their absolute SHAP values are thus lower and the model again learns to rely less on informative tokens for this language. It is actually also the case for the over-represented language but to a lesser extent. This simply points to the fact that the model is paying less attention to informative features overall and more attention to the language of the input.

The overall trend in both XNLI and the Amazon reviews dataset is that positive tokens contribute more negatively and negative tokens contribute more positively. Neutral tokens contribute either positively if they are of the over-represented languages or negatively if they are of the under-represented languages. Thus, the model puts less importance on features that were relevant in the balanced case and treats the simple presence of non-informative tokens of a certain language as indication of a certain label, in effect acting more like a language identifier.

### 4.4 Per-language class weighing mitigates the effect of the imbalance

First, Table 3 shows that overall performance on the tasks improves with class weighing on imbalanced data. Also, in Table 4, we see that language identification scores are lower with the class weighing method than without, being almost on-par with the balanced case.

Figure 1b and 1d show that while the cumulative difference in SHAP value is not null, it is on average smaller than without the weighing. We still see that positive tokens are less positive, and negative tokens are more positive, i.e. SHAP values of relevant features are smaller in this case than in the balanced case, but we do not see a clear separation between over- and under-represented languages like we do in the imbalanced case. More-

over, the difference in SHAP values for neutral tokens is minimal, which means that uninformative tokens stay irrelevant for the model.

Overall, we see that the per-language class weighing method mitigates the effects of the language-specific class imbalance: the latent space is less separated by language and the model does not learn to treat tokens from under- and over-represented languages differently.

## 5 Conclusion

In this paper, we showed that a language model trained on a seemingly balanced multilingual dataset, with uniform marginal distributions of languages and of labels, but skewed joint distribution of language and label, will learn this skew. We first showed that the model performs worse in the presence of this imbalance. Based on the distribution of the test set predictions, we show that it learns to make predictions based on language, which can negatively impact its out-of-distribution performance. We also showed that the imbalance leads to the latent space being more separated by language. We then analyzed SHAP values to better understand how the way the model makes predictions changes. SHAP values showed that features that the model used when trained on balanced data became less important when trained on imbalanced data, and that features that were "neutral", i.e. didn't contribute to the prediction of a given label, became more important. We modify the traditional method of class weighing by calculating class weights separately for each language and train a model on the imbalanced dataset with a weighted loss. We show that this simple method is effective at mitigating the negative effects of the imbalance.

This is of high stakes, as training on multiple languages is often done in real-life cases, and preventing the perpetuation of biases is often desirable. It is a reminder that large language models and deep learning architectures in general do not necessarily follow human intuition and will make predictions based on what is available in the data. Training a model to build robust features requires careful consideration of not just the marginal distribution of the dataset features but also of their joint distribution.

## 6 Limitations

A main limitation of our study is the artificial nature of our datasets. These datasets have equal repre-

sentation of languages and labels, which allowed us to isolate the issue of language-label imbalance. However, in real-life datasets, one will often face imbalances both in the marginal and joint distributions.

Another limitation is the sole use of SHAP values for our explainability method. We used Layer Integrated Gradients but we would not be able to show cumulative values which show an overall picture of the effects. However, according to (Atanasova et al., 2020), occlusion methods like SHAP are only worse than gradient-based methods in terms of their computational efficiency.

Our method for per-language class weighing simply modifies the traditional class weighing method. However, as seen in (Henning et al., 2023), newer weighing methods exist which could also have been adapted and led to improved performance.

	Imbal.+CW	0.605	0.607

Table 7: Language identification average accuracy for XLM-R

the mBERT results also apply to XLM-R: imbalance makes the latent space more distinct, it promotes uninformative features and demotes relevant ones, and per-language class weighing can help mitigate those effects. The XLM-R models have been trained with an added loss to minimize their difference in base value to make the results more interpretable, which is explained in A.3.

### A.3 SHAP value bias due to difference in base values

One of the main issues we faced using SHAP values is that they are not easily comparable across models due to the difference in base values. In the current implementation of SHAP values, the base values are calculated by replacing every token in the input by the mask token and taking the output probabilities. Ideally, we want those probabilities to be the same across models. To achieve this, we added the entropy of the output distribution of a fully masked input multiplied by -1 to the loss at every gradient step, so as to incentivise the model to output a uniform distribution. Let  $M(T) : \mathbb{R}^{L \times d} \rightarrow \mathbb{R}^C$  be the model we use for prediction, where  $T$  is the input of token embeddings of length  $L$ ,  $d$  is the dimension of the embedding and  $C$  is the number of classes and  $\mathbb{C}$  the set of classes. Let  $m$  be an input of mask tokens of length between 1 and  $L$ . We add the following loss to the total loss:

$$l = \sum_{c \in \mathbb{C}} M(m)[c] \cdot \log(M(m)[c]) \quad (3)$$

We refer to it as the masked input entropy loss. We find that this does not hinder downstream task

performance, but makes differences in base values much smaller, making the cumulative difference in SHAP values much easier to interpret. We show the same plots as in Figure 1 with models trained with this added loss in Figure 3. We also only show the XLM-R results with this added loss in Figure 2.

#### **A.4 Justification for threshold**

We set our threshold at a SHAP value of 0.01 for what we consider neutral and positive/negative tokens as this resulted in an approximate 20/60/20 (neg./neut./pos.) split. We experimented with a threshold of 0.001 and 0.05. The first one did not include enough tokens in the neutral token groups for the cumulative difference in SHAP value to make sense. The second one showed similar results in the cumulative difference in SHAP values, just with slightly different magnitudes. Our analysis most likely still holds with higher thresholds, up to a point. We had considered regression-type analysis between the SHAP values of models trained on balanced and imbalanced data because they would not have required the addition of a threshold. However, they would not have allowed us to capture the cumulative effect of the change in SHAP values.

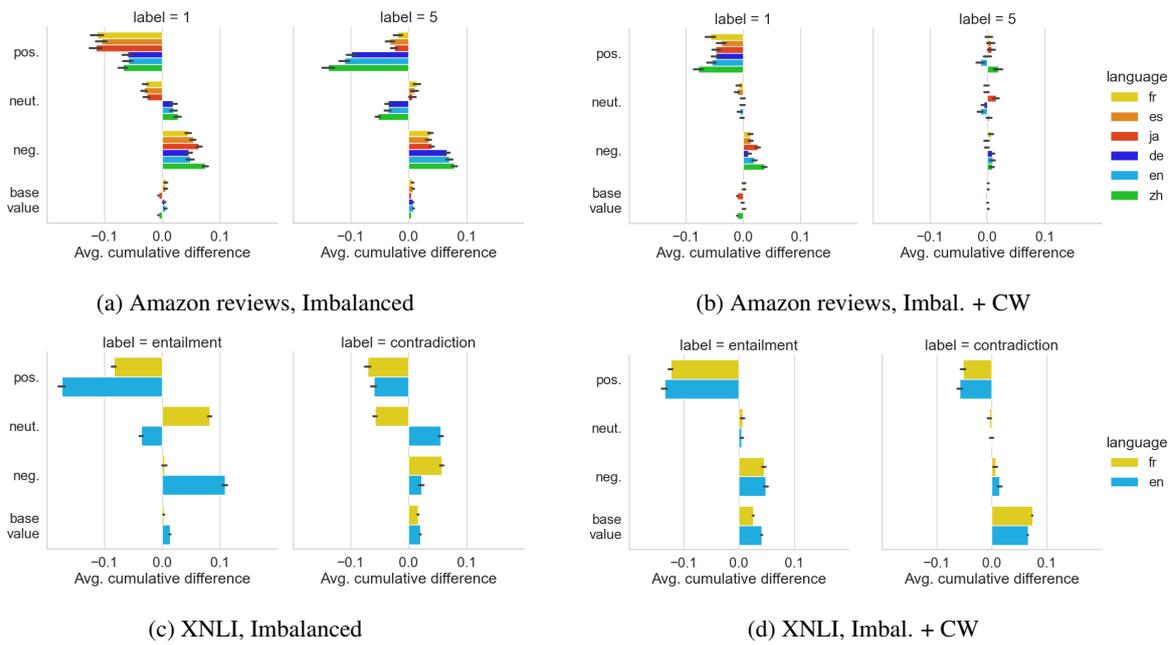

Figure 2: Average cumulative difference in SHAP value by token category for XLM-R with the added masked input entropy maximisation loss.

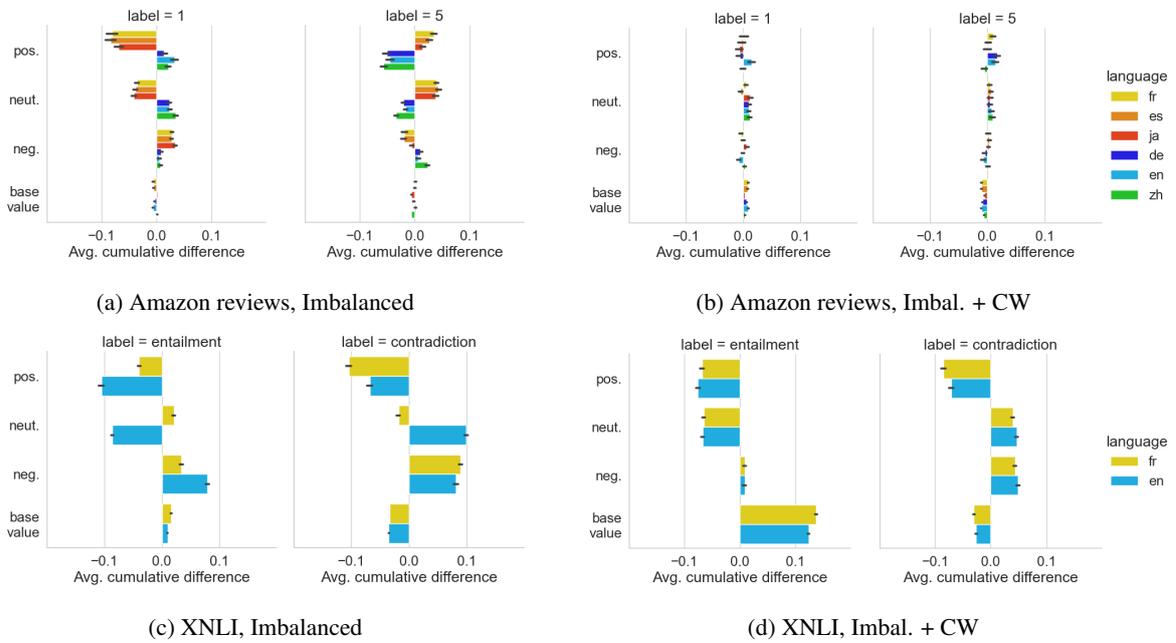

Figure 3: Average cumulative difference in SHAP value by token category for mBERT with the added masked input entropy maximisation loss.

# NL2FORMULA: Generating Spreadsheet Formulas from Natural Language Queries

## Abstract

Writing formulas on spreadsheets, such as Microsoft Excel and Google Sheets, is a widespread practice among users performing data analysis. However, crafting formulas on spreadsheets remains a tedious and error-prone task for many end-users, particularly when dealing with complex operations. To alleviate the burden associated with writing spreadsheet formulas, this paper introduces a novel benchmark task called NL2FORMULA, with the aim to generate executable formulas that are grounded on a spreadsheet table, given a Natural Language (NL) query as input. To accomplish this, we construct a comprehensive dataset consisting of 70,799 paired NL queries and corresponding spreadsheet formulas, covering 21,670 tables and 37 types of formula functions. We realize the NL2FORMULA task by providing a sequence-to-sequence baseline implementation called *f*CODER. Experimental results validate the effectiveness of *f*CODER, demonstrating its superior performance compared to the baseline models. Furthermore, we also compare *f*CODER with an initial GPT-3.5 model (i.e., *text-davinci-003*). Lastly, through in-depth error analysis, we identify potential challenges in the NL2FORMULA task and advocate for further investigation.<sup>1</sup>

## 1 Introduction

It is a widespread practice among users to engage in data analysis by composing formulas within spreadsheet applications such as Microsoft Excel and Google Sheets. While spreadsheet formula languages (e.g., Microsoft Excel Formula) are relatively simpler than general-purpose programming

languages for data analysis, formulating these formulas on spreadsheets remains burdensome and error-prone for end-users (Gulwani, 2011; Cheung et al., 2016). To address this challenge, numerous approaches and tools (e.g., FlashFill (Gulwani, 2011) and SPREADSHEETCODER (Chen et al., 2021)) have been proposed to automatically generate spreadsheet formulas.

Building upon substantial progress in spreadsheet formula generation, this paper goes beyond the existing efforts by introducing a novel Natural Language (NL) interface capable of generating spreadsheet formulas from a user’s NL query (short for NL2FORMULA). We believe that, for the majority of end-users, expressing their intentions in NL is more accessible than working with formulas when performing data analytics on spreadsheets.

Figure 1 presents two representative running examples to illustrate the task of NL2FORMULA. This task involves generating the corresponding spreadsheet formula automatically, given a spreadsheet table and an NL query input from an end-user. The resulting formula is intended for execution in spreadsheet applications, such as Microsoft Excel. In this paper, we focus the spreadsheet application only on Microsoft Excel, where spreadsheet formulas can take on various forms, offering a wide range of possibilities for exploration. Specifically, we present two primary categories of spreadsheet formulas. The first category is the Analysis Query (Figure 1 (a)), typically comprising Excel formula functions utilized for data analysis. The second category is the Calculation (Figure 1 (b)), consisting of basic numerical operations used for straightforward calculations.

It is important to note that NL2FORMULA shares similarities with the well-studied task of TEXT2SQL, which involves translating an NL description into a SQL query grounded on a database table (Yaghmazadeh et al., 2017; Yu et al., 2018; Zhong et al., 2017). However, it differs in two

\* Work was done while Wei Zhao was pursuing a master degree at Huazhong University of Science and Technology, and during an internship at Microsoft.

† Yao Wan is the corresponding author.

<sup>1</sup>All the experimental data and source code used in this paper are available at <https://github.com/timetub/NL2Formula>.

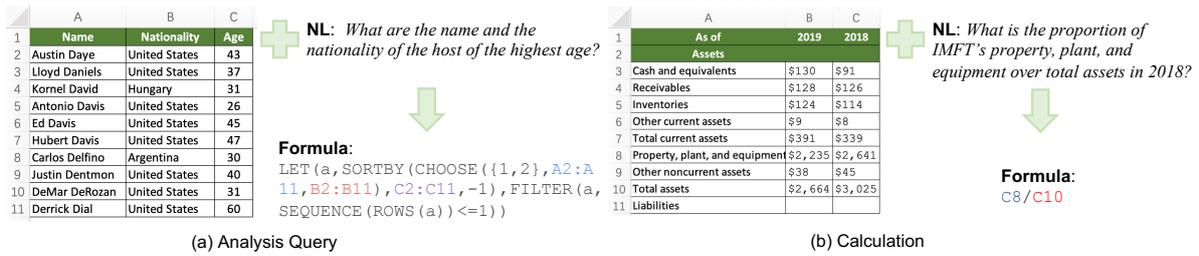

Figure 1: Two running examples from our created dataset for NL2FORMULA.

fundamental aspects. (1) *The structure of a spreadsheet table is more flexible than that of a database table.* Unlike fixed patterns in databases, the meta-data (e.g., headers and orientation) of tables in a spreadsheet is optional, and the placement of the table in the layout is highly flexible. This flexibility presents significant challenges when it comes to representing the data. (2) *The formula is typically expressed by the index of data location.* In the process of generating formulas, it becomes crucial not only to determine which columns in the table should be selected but also to identify the exact position of the cell containing these values. Additionally, the expression of formulas can change with the placement of the table in the layout.

In this paper, we pioneer the effort to formulate and benchmark the task of NL2FORMULA. One main challenge lies in the lack of well-labeled data for training. To tackle this issue, we construct a novel dataset comprising paired NL queries and their corresponding formulas, grounded on specific spreadsheet tables. As manual labeling would require extensive human effort and time, we opt for an indirect transformation approach using an existing dataset of TEXT2SQL (i.e., Spider (Yu et al., 2018)), which is composed of 10,181 NL descriptions along with their corresponding SQL queries. We devise a set of conversion rules by analyzing the grammar of SQL and Excel formulas. By applying the formulated conversion rules, we convert SQL queries from the established TEXT2SQL datasets into formulas suitable for NL2FORMULA. Additionally, to augment the dataset, we engage in the manual collection of labeled data following a set of predefined rules. As a result, we produce a comprehensive dataset comprising 70,799 paired NL queries and formulas, associated with a total of 21,670 tables.

Furthermore, we establish a benchmark for NL2FORMULA. In this benchmark, we also present *f*CODER, a sequence-to-sequence frame-

work based on the pre-trained language model T5 (Raffel et al., 2020). As a baseline model, we adapt FORTAP (Cheng et al., 2021), originally designed for synthesizing spreadsheet formulas, for comparison. We conduct comprehensive experiments and analysis to assess the effectiveness of our proposed *f*CODER. The experimental results demonstrate that *f*CODER achieves the highest performance with 70.6% *Exact Matching Accuracy* and 77.1% *Accuracy* based on the results of running formulas on a specific engine (i.e., Microsoft Excel). After conducting a comprehensive analysis of the experimental results, we have identified potential areas for improvement and future directions that warrant further exploration.

In summary, the key contributions of this paper are three-fold. (1) We are the first to formulate a new task of NL2FORMULA, that can serve as an interface allowing users to effortlessly translate input NL queries into spreadsheet formulas. (2) We introduce a novel dataset that comprises 70,799 paired NL queries and their corresponding formulas, associated with 21,670 tables. (3) We benchmark several models for the task of NL2FORMULA, including our designed *f*CODER that is based on pre-trained T5, as well as FORTAP (Cheng et al., 2021) that is adapted from TUTA (Wang et al., 2021).

## 2 Background and The Problem

**Spreadsheet Formula.** Spreadsheets, which are formulated as a two-dimensional grid of cells, play a vital role in our daily lives, especially for data analysis. Typically in a spreadsheet, rows are numbered sequentially from top to bottom, beginning at 1, while columns are designated alphabetically from left to right using the base-26 system, with ‘A’ to ‘Z’ as the digits.

We can perform various computing, data processing, and operational tasks using pre-defined formulas within the spreadsheet. In a formula, we can refer to a cell by combining its column and row

numbers, as shown by the notation (e.g., B2). Additionally, we have the option to use a range operator “:” to create a rectangular range between two cells, with the top-left and bottom-right corners specified. For instance, the formula =SUM (A1 : B5) encompasses all cells in columns A and B, ranging from row 1 to row 5. In general, a formula is composed of constant values, arithmetic operations, function calls, and references to cells. Formally, the Microsoft Excel formula studied in this paper can be defined by the extended BNF grammar, referred to Appendix A. Figure 2 shows a detailed example of the Excel formula.

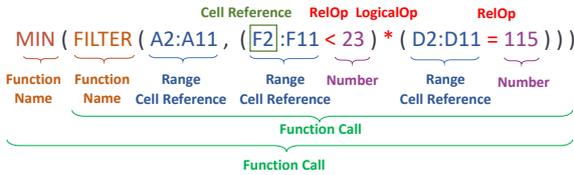

Figure 2: An example of the Excel formula.

**Problem Statement.** Let  $N$  denote the NL query composed of a sequence of tokens  $\{q_1, q_2, \dots, q_L\}$ , and  $T$  denote the corresponding tabular context composed of a collection of cells  $\{c_1, c_2, \dots, c_M\}$ . Let  $F$  denote the corresponding formula to predict that is denoted a sequence of tokens  $\{y_1, y_2, \dots, y_K\}$ . Inspired by previous semantic parsing tasks, we formulate the task of NL2FORMULA as a sequence-to-sequence problem, where the source sequence is the NL query and its tabular contexts, while the target sequence is the formula. More specifically, the NL2FORMULA problem is expressed as follows: given a source NL sequence  $N$ , as well as the tabular context  $T$ , the goal is to learn a mapping function  $f$  to map the input  $\{N, T\}$  into a formula  $F$ , i.e.,  $F = f_\theta(N; T)$ , where  $\theta$  is the parameters of model  $f$ .

### 3 NL2FORMULA: The Dataset

#### 3.1 Dataset Construction

Constructing a paired dataset of NL queries and spreadsheet formulas poses considerable challenges. One approach to tackle this is by inviting experts to generate corresponding NL queries and spreadsheet formulas based on the tabular content. However, this method is time-consuming and labor-intensive, demanding significant human effort. Hence, it drives us to explore alternative ways of indirectly creating the NL2FORMULA dataset.

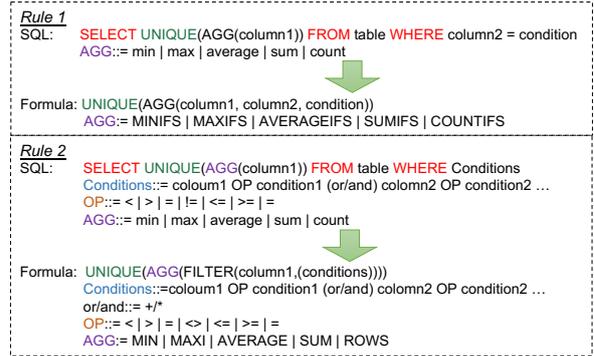

Figure 3: Two simple examples of conversion rules to translate SQL queries into formulas.

Fortunately, we discovered a related task called TEXT2SQL, which has already undergone extensive study. Leveraging this, we develop a converter from the TEXT2SQL dataset to the NL2FORMULA dataset. The underlying intuition is that both SQL queries and spreadsheet formulas specify the required data in a similar fashion.

**Rule-Based SQL to Formula.** By analyzing SQL grammar and Excel formula grammar, we manually define several conversion rules to convert the SQL queries into Excel formulas. For example, in certain conditions that necessitate single operations (e.g., MAX) in SQL, we can utilize the corresponding MAXIFS function in a spreadsheet formula. In more intricate scenarios involving multiple conditions and operators in SQL (e.g., MIN and AND), we can replace them with equivalent Excel formulas (e.g., MIN and FILTER). In situations requiring sorting and combination operations, we need to employ a combination of various Excel formula functions (e.g., HSTACK, UNIQUE, and SORT). We present two straightforward examples of conversion rules in Figure 3.

In practice, we primarily utilize two TEXT2SQL datasets: WikiSQL (Zhong et al., 2017) and Spider (Yu et al., 2018). WikiSQL is an extensive dataset consisting of 80,654 instances of paired NL queries and SQL queries, derived from 24,241 tables sourced from Wikipedia. This dataset exclusively comprises single tables and simple SQL queries. However, our objective is to create a more challenging dataset that encompasses a wider range of formula functions and categories. To achieve this, we integrate the Spider dataset, with the potential to enhance the diversity of formulas. Spider is a complex and cross-domain TEXT2SQL dataset annotated by 11 graduate students. It comprises

10,181 NL queries and 5,693 unique complex SQL queries derived from 200 databases containing multiple tables across 138 different domains. Due to the constraints posed by existing models regarding input data length, we select tables with 3 to 20 rows and 3 to 10 columns. As a result, we obtain approximately 19,789 candidate tables.

**Data Augmentation.** Based on our investigation, all the formulas converted from TEXT2SQL are analysis-oriented, commonly referred to as *Analysis Query*. In other words, these formulas predominantly consist of formula functions such as `AVERAGE` and `MAXIFS`. Notably, simple numerical operations such as addition (+), subtraction (-), multiplication ( $\times$ ), and division ( $\div$ ) (also referred to as *Calculation*) are excluded from the converted formulas. To complement this, we manually augment the data by incorporating a question-answering benchmark named TATQA (Zhu et al., 2021), which includes numerous numerical operation formulas.

### 3.2 Data Statistics and Analysis

We finally obtain 70,799 pairs of NL queries and spreadsheet formulas, covering 21,670 tables. The tables are randomly split into a training set (75%), validation set (10%), and test set (15%). The basic statistics of each split are shown in Table 1. The length of a formula is defined by the number of its keywords. We can observe that the average formula length is about 10, indicating the difficulty in predicting these formulas.

To better comprehend the performance of models on various formulas, we categorize the formulas into two groups: *Analysis Query* and *Calculation*. In particular, *Analysis Query* formulas encompass 37 types of formula functions, while *Calculation* formulas consist of addition, subtraction, division, and composition. Moreover, for *Analysis Query*, we have tailored the division standards of hardness levels, which are classified into 3 categories: *Simple*, *Medium*, and *Complex*. Specifically, the division standard is based on the number of formula components, selections, and conditions. For instance, we define a formula as *Simple* if it typically represents a short-length query with 1-2 functions, *Medium* for 3-4 functions, and any formula with more than 4 functions is considered *Complex* and falls into the long-length category.

Figure 4 depicts the hardness distribution of the

Table 1: Statistics of the NL2FORMULA dataset.

Statistics	Train	Val.	Test
# of tabular contexts	16,791	1,743	3,136
# of NL queries	55,165	5,523	10,111
Avg. # of table rows	10.8	10.8	10.8
Avg. # of table columns	6.0	6.0	5.9
Avg. length of NL	11.2	11.6	11.4
Avg. length of formula	10.2	10.1	10.0

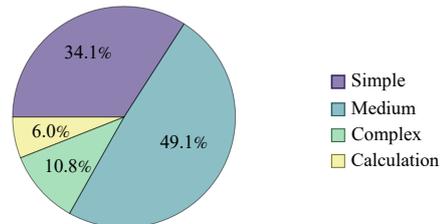

Figure 4: Distribution of formulas in NL2FORMULA dataset, including *Analysis Query* of three hardness levels (*Simple*, *Medium*, *Complex*), and *Calculation*.

dataset. It is evident that the majority of formulas consist of medium-level analysis queries, accounting for 49.1%.

### 3.3 Data Quality Assessment

To ensure the quality of our NL2FORMULA dataset, we follow a rigorous process. Initially, we randomly sample 5% of the original data and convert it from SQL queries to formula queries. Subsequently, we input these queries into a spreadsheet to assess their smooth execution. Based on the execution results, we make necessary adjustments to the conversion rules for formula queries that fail to execute successfully. To guarantee accuracy and reliability, we engage five verifiers with extensive experience in NLP and familiarity with spreadsheet formulas. Each verifier is tasked with checking and approving 500 pairs of NL queries and formula queries, randomly selected from the dataset. Their expertise ensures meticulous scrutiny of the data. Finally, in cases where we identify faulty formulas, we verify their formula patterns and search the dataset for all instances of such patterns, making the necessary modifications to rectify the situation.

## 4 fCODER : A Reference Framework

For the task of NL2FORMULA, we adopt the encoder-decoder paradigm as the baseline approach. In this paradigm, an encoder network embeds the NL queries and tabular contexts into an

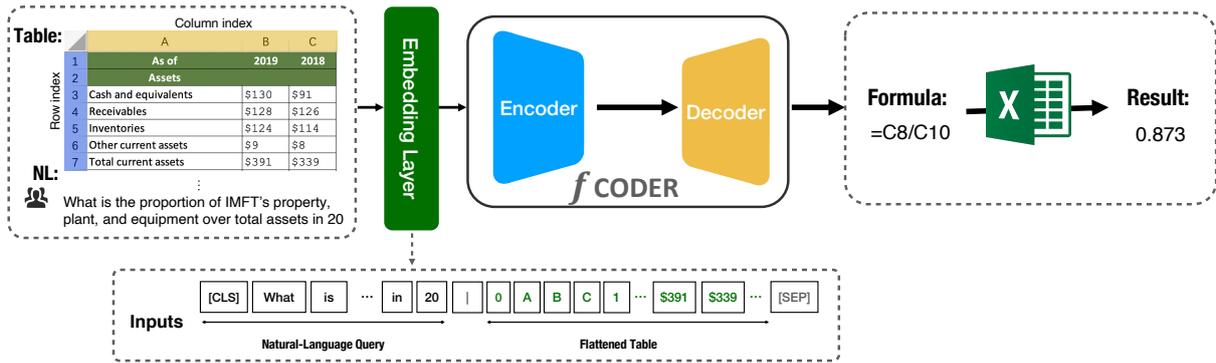

Figure 5: An overview of the  $f$ CODER, which is a reference framework for NL2FORMULA.

embedding vector, while a decoder network generates the formula based on the encoded vector. Figure 5 illustrates the overview of the encoder-decoder framework for NL2FORMULA.

**Input Preparation.** We represent each table using its column index, row index, and the corresponding content. Specifically, we work with two types of inputs: an NL query and tabular content. Each input is transformed into a sequence, and subsequently, the two sequences are concatenated. We employ a unique symbol  $|$  to differentiate between the sequence of NL queries and tabular content. Furthermore, we utilize a specific token  $[CLS]$  to mark the inception of the concatenated sequence, resulting in a hybrid representation of the two elements, as follows:

$$X = [CLS], q_1, q_2, \dots, q_L, |, c_1, c_2, \dots, c_M.$$

For each token  $x_i$  in  $X$ , we begin by encoding it using a word embedding layer, resulting in the token embedding  $\mathbf{x}_i^{token}$ . Next, we incorporate a positional embedding to account for the position of each token, represented as  $\mathbf{x}_i^{position}$ . The ultimate embedding of each token for an input sample  $X$  is determined as follows:

$$\mathbf{x}_i = \text{Emb}(x_i) = \mathbf{x}_i^{token} + \mathbf{x}_i^{position}. \quad (1)$$

After processing each token as discussed above, the output sequence is represented by  $\mathbf{X} = \text{Emb}(X)$ , which serves as the input to the encoder network.

**Encoder.** We input the embedding matrix  $\mathbf{X}$  into the encoder network, yielding the corresponding output  $\mathbf{O}^e$  as follows:

$$\mathbf{O}^e = \text{Encoder}(\mathbf{X}). \quad (2)$$

Finally, these output embeddings are passed as input to the decoders.

**Decoder.** At the  $t$ -th time step in the decoding process, the operations of the decoder network can be formulated as follows:

$$\mathbf{O}_t^d = \text{Decoder}(\mathbf{O}^e, \text{Emb}(ctx)), \quad (3)$$

where  $\mathbf{O}_t^d$  is the output of the decoder network,  $ctx$  denotes the current partial sequence of the generated formula, i.e.,  $y_0, \dots, y_{t-1}$ , which is also mapped into vector forms via an embedding layer.

We feed the output of the decoder into a Softmax layer, to map the output vector into a probability vector over the whole vocabulary, as follows:

$$p(y_t|ctx, \mathbf{X}) = \text{Softmax}(\mathbf{W}^d \mathbf{O}_t^d + \mathbf{b}^d), \quad (4)$$

where  $\mathbf{W}^d$  and  $\mathbf{b}^d$  are the linear layer parameters.

**Model Learning.** To train the  $f$ CODER model, we employ the cross-entropy loss function, as follows:

$$\mathcal{L} = - \sum_{t=1}^T \log p_\theta(y_t|ctx, \mathbf{X}), \quad (5)$$

where  $\theta$  denotes all the model parameters, and  $T$  is the maximum step of formula generation.

## 5 Experimental Evaluation

### 5.1 Benchmarked Models

▷ **FORTAP (Cheng et al., 2021).** FORTAP, building on TUTA (Wang et al., 2021), extends table pre-training to include spreadsheet formulas for enhanced formula prediction, question answering, and cell type classification. We introduce an adaptation of FORTAP to NL2FORMULA, where the task is to predict formulas for a specified cell within a table. We embed the NL query into the table and designate the following row as the target cell. A two-stage LSTM (Hochreiter and Schmidhuber,

Table 2: Overall performance of the *f*CODER and baselines on the validation and test datasets, in terms of the EM and ERA metrics.

Models	Exact Match				Execution Result Assessment	
	Validation		Test		Validation	Test
	Sketch	Formula	Sketch	Formula	Formula	Formula
FOR TAP	-	-	58.4	24.2	-	-
GPT3.5 (10-Shot)	-	-	-	21.4	-	25.2
<i>f</i> CODER-Small	97.0	65.6	96.9	65.5	71.2	70.4
<i>f</i> CODER-Base	97.4	70.5	97.2	69.4	73.3	75.0
<i>f</i> CODER-Large	97.5	71.5	97.6	70.6	76.8	77.1

1997) decoder then processes this integrated data to produce formula sketches and pinpoint reference cells, yielding the target formula.

▷ **GPT-3.5 (Brown et al., 2020).** With recent advancements in the domain of Large Language Models (LLMs), remarkable breakthroughs have been achieved in the field of NLP (Zhao et al., 2023; Kaddour et al., 2023). In this study, we compare the performance of our proposed methodology with GPT-3.5 on the NL2FORMULA dataset, utilizing the open-sourced `text-davinci-003` model. The prompt template used by GPT-3.5 is referred to Appendix B

▷ ***f*CODER.** We adopt the T5 model (Raffel et al., 2020) as the initial implementation of the *f*CODER framework. T5 converts all text-based language problems into a text-to-text format and serves as a typical sequence-to-sequence model. Some variants of the model are also included in this paper, namely *f*CODER-Small, *f*CODER-Base, and *f*CODER-Large, with parameter sizes of 60M, 220M, and 770M, respectively.

Additionally, we also perform a preliminary comparison between *f*CODER and ChatGPT (OpenAI) in the Appendix C.

## 5.2 Evaluation Metrics

Inspired by the evaluations in TEXT2SQL, we also employ two similar metrics: *Exact Match (EM)* and *Execution Results Assessment (ERA)*. Furthermore, we categorize the formulas into two main groups: *Analysis Query* and *Calculation*. Additionally, within the *Analysis Query* category, we further differentiate formulas into three levels, namely, *Simple*, *Medium*, and *Complex*, based on the number of functions they incorporate.

**Exact Match (EM).** The *Exact Match* is a widely recognized metric used to evaluate the performance

of models. It demands a flawless match between the model’s output formulas and standard formulas, encompassing all its components and table ranges. To provide a fine-grained analysis of the model’s performance on different granularities of formulas, we present both the *Sketch EM* score and the *Formula EM* score across all models.

**Execution Result Assessment (ERA).** To assess the semantic equivalence of predicted formulas, we also compare their execution results in Microsoft Excel. To streamline this evaluation process, we have developed an automated Python script for large-scale batch execution.

## 5.3 Results and Analysis

**Overall Performance** We begin by analyzing and discussing the overall performance of various models, which includes the baseline FOR TAP, GPT-3.5, and our proposed *f*CODER, on the NL2FORMULA task. Table 2 presents a comprehensive evaluation of these models on both the validation and test datasets, in terms of the EM (including *Sketch EM* and *Formula EM*) and ERA metrics.

From this table, we can observe a notable performance disparity between the baseline model FOR TAP and our proposed *f*CODER models. The former achieves an EM accuracy of 24.2 on the test set, indicating its struggle to precisely match the ground truth answers. One possible reason is that FOR TAP is not specifically designed for this task; instead, it focuses on the context of individual cells, neglecting to capture the connections between the entire table and the question. In contrast, the *f*CODER-Small model, despite having the smallest number of parameters, significantly outperforms FOR TAP, achieving an impressive EM accuracy of 65.5 on the test dataset. These results demonstrate the ef-

Table 3: Experimental results of *f*CODER models across different types of formulas, with varying levels of difficulty on the test dataset.

Models	Exact Match				Execution Result Assessment			
	Simple	Medium	Complex	Calculation	Simple	Medium	Complex	Calculation
GPT3.5 (10-Shot)	8.5	25.8	0.3	55.8	17.4	26.6	0.6	59.5
<i>f</i> CODER-Small	39.9	73.9	54.5	62.2	58.6	82.7	56.3	64.8
<i>f</i> CODER-Base	44.5	76.9	53.4	71.8	63.0	87.4	56.0	74.5
<i>f</i> CODER-Large	45.4	76.0	58.4	76.5	64.5	88.7	61.6	79.5

fectiveness of *f*CODER in generating accurate formulas from tabular data.

Furthermore, we can observe that the GPT-3.5 model with a 10-shot in-context learning approach achieves an EM accuracy of 21.4 and an execution results accuracy of 25.2. GPT-3.5 model also falls short of matching the performance of the *f*CODER series models. This discrepancy could be attributed to the relative simplicity of the current prompt design. Due to the constraints of length of input tokens, we can only provide a prompt consisting of 10 examples at a time, which seems to be insufficient in quantity.

**Performance on Varying Hardness** We also evaluate the performance of models across both types of formulas, namely, *Analysis Query* and *Calculation*, encompassing varying levels of difficulty, as shown in Table 3. From this table, it is interesting to see that our *f*CODER models demonstrate lower performance in the *Simple* level compared to the *Medium* level, in terms of EM accuracy. Through our human inspection, we have determined that this phenomenon can be ascribed to the fact that the model has a tendency to generate diverse formula queries, primarily stemming from the ambiguity introduced by NL queries. Furthermore, it is evident that *f*CODER attains high performance in the ERA metric. This is attributed to the *f*CODER’s ability to generate diverse expressions while consistently yielding the correct result.

In comparing the performance of our model with GPT-3.5 utilizing a 10-shot context, it is evident that the GPT-3.5 model exhibits poor performance in generating formulas within the *Analysis Query* category, highlighting a considerable need for further enhancements. Nonetheless, it is intriguing to observe that the GPT-3.5 model demonstrates a comparable level of proficiency in generating formulas within the *Calculation* category.

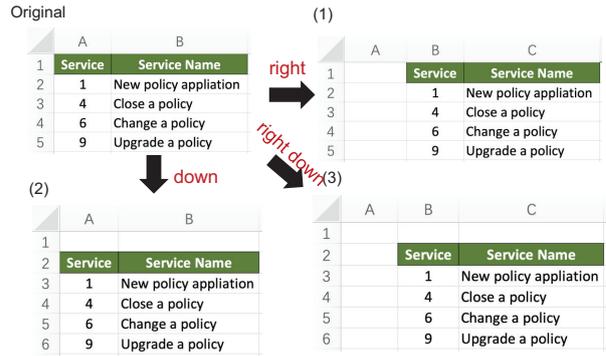

Figure 6: An example of a table as well as its three variants of movement in three different directions.

**The Impact of Table Position.** As previously mentioned, the spreadsheet table is flexible. Therefore, we further explore the performance of the model in generating formulas under different table placements. Specifically, the position of the original tables in our dataset starts from the first row and the column “A”. We empirically move these tables in the following three ways, as shown in Figure 6: (1) Moving one column to the right, i.e., the starting position of tables is changed to “B1”. (2) Moving one row down, i.e., the starting position of tables is changed to “A2”. (3) Moving down and right, i.e., the starting position of tables is changed to “B2”. In this scenario, the formulas will also be changed. For example, a formula in the original scenario, `SORTBY(B2:B5, B2:B5, 1)`, would be transformed to `SORTBY(C3:C6, C3:C6, 1)` in scenario (3). Initially, we use the *f*CODER-Base trained in the original position to verify the three scenarios. We explore whether the model can adapt to different table placements in spreadsheets, which were not seen during training. However, the performance of the model is poor, achieving only an average EM accuracy of 6.7%. We find that most of the errors are caused by the fact that our model fails to infer the cell index accurately.

## 5.4 Case Study and Error Analysis

Figure 7 presents an illustrative example of the prediction formula, which differs from the golden formula, yet yields identical results when executed in the spreadsheet. The table in A1:J6 contains the NL description “What is the lowest number of laps in the 5th position?” provided in the 8th row. The given golden formula is `MINIFS(G2:G6, J2:J6, “5th”)`, and the resulting value after executing this formula in Excel is “3”, displayed in cell A9. On the other hand, the model prediction formula, `MIN(FILTER(G2:G6, J2:J6=“5th”))`, produces the same result, which is demonstrated in cell C9.

Season	Series	Team	Races	Wins	Poles	F/Laps	Podiums	Points	Position
2006	Renault 2	Time Rac	13	1	1	3	2	123	5th
2007	Three Sudac	esário F3	14	2	2	1	10	85	2nd
2008	Renault 3	illon Eusk	13	0	0	2	0	3	29th
2009	Indy Light	andersen	15	2	1	1	4	392	6th
2010	dyCar Seri	quest Rac	11	0	0	5	0	149	24th

8 What is the lowest number of f/laps in the 5th position?

9 =3

9 =MIN(FILTER(G2:G6, J2:J6="5th"))

9 =3

Figure 7: An example of the prediction formula, which is different from the ground-truth formula but the execution results in the spreadsheet are the same.

To gain a comprehensive insight into the effectiveness of our constructed model on NL2FORMULA, we conduct a detailed examination of the *f*CODER-Large, specifically focusing on instances where errors occur. We randomly sample 200 error instances from the test dataset (50 per level). We classify them into four categories, as shown in Figure 8: (1) Wrong Evidence: The model obtains incorrect supporting evidence or infers the wrong cell index from the table. Additionally, the example of the formula demonstrates the model’s failure to identify the correct evidence from the NL query. (2) Missing Evidence: The model fails to extract complete supporting evidence from the table to arrive at the correct answer. (3) Wrong Intent Inference: The model is unsuccessful in understanding the intent expressed by the NL query. (4) Wrong Calculation: The model correctly infers the intention from the NL query and accurately locates the cell index in the table. However, the model fails to compute the answer using the correct evidence. We find that most of these errors stem from the model’s inability to accurately infer or extract the correct evidence from the tables and NL queries.

## 6 Related Work

**Semantic Parsing.** Semantic parsing is a task to transform NL queries into structured representations that can be understood and processed by machines. So far, many datasets for semantic parsing have been built with different query formats, such as ATIS (Price, 1990), Geo-Query (Zelle and Mooney, 1996), and JOBS (Tang and Mooney, 2001). Their output format is logic forms and has been studied extensively (Dong and Lapata, 2016; Berant and Liang, 2014; Reddy et al., 2014; Zettlemoyer and Collins, 2012; Wong and Mooney, 2007). In recent years, using SQL queries as programs in semantic parsing is more popular, and many datasets have been built, including Restaurants (Popescu et al., 2003), Academic (Li and Jagadish, 2014), Yelp and IMDB (Yaghmazadeh et al., 2017), Scholar (Iyer et al., 2017), WikisQL (Zhong et al., 2017), Spider (Yu et al., 2018), and CoSQL (Yu et al., 2019).

**Formula Synthesis.** Formula synthesis is a branch of program synthesis that has been studied in many works. FlashFill (Gulwani, 2011; Gulwani et al., 2012) utilizes input-output examples to help end-users automatically synthesize string transformation tasks in spreadsheets. Recent studies have explored various neural architectures for learning programs from examples (Kalyan et al., 2018; Parisotto et al., 2017), but they do not consider context-specific information from spreadsheet tables. FORTAP (Cheng et al., 2021) and SPREEDSHEETCODER (Chen et al., 2021) are the prior approaches for synthesizing spreadsheet formulas from tabular context. Our work provides a standardized benchmark for evaluating and comparing future formula generation work, fostering advancement and understanding of the field.

**Tabular Data Processing.** Several studies have pretrained Transformers on tables. TableBERT (Chen et al., 2020) linearized tables as sentences so that tables can be directly processed by the pre-trained BERT model. TUTA (Wang et al., 2021) is the first effort to pre-train Transformers on variously structured tables. FORTAP (Cheng et al., 2021) use formulas for numerical-reasoning-aware table pre-training. To improve the representation of utterances and tables for neural semantic parsing, several works joined contextual representations of utterances and tables, such as TAPAS (Herzig et al., 2020) and TABERT (Yin

et al., 2020). Furthermore, Chen et al. (2021) introduced SPREADSHEETCODER, which leverages machine learning to assist in formula prediction in spreadsheets.

## 7 Conclusion

In this paper, we have presented a novel and challenging research problem, NL2FORMULA, and develop an accompanying dataset that includes spreadsheet tables, NL queries, and formulas. We construct a comprehensive dataset consisting of 70,799 paired NL queries and corresponding spreadsheet formulas, covering 21,670 tables and 37 types of formula functions. We also realize the NL2FORMULA task by providing a sequence-to-sequence baseline implementation called *f*CODER. Through in-depth error analysis, we identify potential challenges in the NL2FORMULA task and advocate for further investigation. We believe that the benchmark developed in this paper can promote the related research in NL2FORMULA.

## 8 Limitations

There are several limitations of our research. One is that the formula queries in our NL2FORMULA dataset are converted from several TEXT2SQL datasets, resulting in a relatively fixed table structure. Additionally, while we made efforts to include as many formula functions and combinations as possible in our experiments, we have not yet fully covered all types of formula functions, such as the “FIND” function used for string queries. In our future work, we aim to expand the range of formula queries by incorporating additional formula

functions, specifically targeting a broader array of scenarios. This expansion will include incorporating diverse data samples that utilize functions like “CONCATENATE”, “LEN”, and “REPLACE”. These particular functions are essential for tasks related to data cleaning, preparation, and textual data manipulation. Moreover, we intend to explore the capabilities of models under multi-type tables, including horizontal and vertical tables, to simulate more realistic application scenarios. Furthermore, we aim to investigate situations involving multiple tables under the same spreadsheet.

Another limitation is the maximum length of model input, which is generally 512 characters. Despite controlling the length of rows and columns in the tables in this paper, we observed some errors caused by the model not fully encoding the table.

An additional potential limitation of our approach is the inability to directly execute custom-defined lambda functions in the current Excel environment. The DAX library, with its different grammar from Excel formulas, is used to build formulas and expressions in Excel data models like Power BI, Analysis Services, and Power Pivot. Consequently, we cannot use our execution result metric to measure the performance of custom-defined lambda functions. This limitation may impact the accuracy and comprehensiveness of our evaluation for this specific functionality.

## A BNF Grammar of Formula

The extended BNF grammar of the Microsoft Excel formula studied in this paper is defined as follows:

```

$$\begin{aligned} \langle Formula \rangle & ::= = \langle Expr \rangle \\ \langle Expr \rangle & ::= \langle Term \rangle \{ \langle AddOp \rangle \langle Term \rangle \} \\ \langle Term \rangle & ::= \langle Factor \rangle \{ \langle MulOp \rangle \langle Factor \rangle \} \\ \langle Factor \rangle & ::= \langle Number \rangle \mid \langle CellReference \rangle \mid \langle FunctionCall \rangle \mid \langle Expr \rangle \\ \langle CellReference \rangle & ::= \langle ColumnName \rangle \langle RowNumber \rangle \\ \langle ColumnName \rangle & ::= \langle Letter \rangle \{ \langle Letter \rangle \} \\ \langle RowNumber \rangle & ::= \langle Digit \rangle \{ \langle Digit \rangle \} \\ \langle FunctionCall \rangle & ::= \langle FunctionName \rangle ( [ \langle ArgumentList \rangle ] ) \\ \langle ArgumentList \rangle & ::= \langle Expr \rangle \{ , \langle Expr \rangle \} \\ \langle AddOp \rangle & ::= + \mid - \\ \langle MulOp \rangle & ::= * \mid / \\ \langle RelOp \rangle & ::= < \mid > \mid <= \mid >= \mid ! = \\ \langle LogicalOp \rangle & ::= + \mid * \\ \langle FunctionName \rangle & ::= [a-zA-Z]+ \\ \langle Number \rangle & ::= \langle Integer \rangle \mid \langle Decimal \rangle \\ \langle Integer \rangle & ::= \langle Digit \rangle \{ \langle Digit \rangle \} \\ \langle Decimal \rangle & ::= \langle Integer \rangle . \langle Digit \rangle \mid . \langle Digit \rangle \\ \langle Letter \rangle & ::= [a-zA-Z] \\ \langle Digit \rangle & ::= [0-9] \end{aligned}$$

```

## B Prompt Template Used by GPT-3.5

We utilize a 10-shot in-context learning strategy, where for each new question and table, we dynamically select the Top-10 most similar NL-Formula pair examples from our training set. The similarity is determined based on their BLEU scores (Papineni et al., 2002). These selected examples, comprising 10 pairs of NL queries and formulas, are then integrated into a prompt to guide the model in generating its result. We use the following prompt template:

```
NL: [NL description]
Formula: [Excel Formula]
...(*10)
NL: [NL description]
Formula: [Excel Formula]
NL: [NL description]
Formula: [to be generated]
```

Table 4: Execution results of *f*CODER and ChatGPT, at different levels of hardness.

	Simple	Medium	Complex	Calculation	Overall
ChatGPT3.5-DirectQA	11.5	38.9	21.1	0.8	27.7
ChatGPT3.5-Agent	22.4	67.9	44.7	3.6	49.4
<i>f</i> CODER -Large	87.0	91.6	71.1	80.5	89.1

## C Preliminary Comparison to ChatGPT

We explore the capabilities of ChatGPT for the task of NL2FORMULA. In addition to prompting LLMs to generate formulas (see Sect. 5), we also explore alternative approaches utilizing LLMs for the processing of tabular data. We leverage Langchain (Chase, 2022), a framework purposefully crafted to harness the potential of LLMs in the realm of application development. We investigate ChatGPT through two distinct approaches: (1) Direct Question-Answering (Direct-QA): We input the complete flattened table directly into the LLMs, prompting it to provide a direct answer to the NL query without any intermediate processing. (2) Langchain-Agent (Agent): We employ the Langchain CSVAgent workflow, which entails the transformation of the original spreadsheet into a Pandas data frame and the generation of Python code to extract or manipulate data to respond to the NL query.

We comprehensively evaluate ChatGPT’s ability to handle tabular information and respond to NL queries. We randomly select 3,000 samples from the test dataset, which exclusively feature built-in Excel functions and exclude custom-defined lambda functions. Table 4 shows the evaluation results on the NL2FORMULA dataset. From this table, we can observe that ChatGPT exhibits moderate proficiency in processing spreadsheet data. They also unveil limitations in performing basic numerical operations within the Calculation subset, due to their constrained arithmetic and complex reasoning capabilities. Interestingly, the utilization of ChatGPT with Langchain CSVAgents exhibits notably superior performance when compared to the Direct-QA method. This is because the Langchain agent generates Python code for manipulating Dataframes, which closely aligns with the current *Code Interpreter* in handling tabular data.
