## Message from the General Chair

Welcome to the 18th Conference of the European Chapter of the Association for Computational Linguistics. EACL is the flagship European conference dedicated to European and international researchers, covering a wide spectrum of research in Computational Linguistics and Natural Language Processing.

Organizing a scientific conference of the prestige and size of EACL is a great honor, a great responsibility, and a great challenge. The challenges started right at the beginning. When I accepted the invitation to be general chair, even after the program chairs Yvette Graham and Matt Purver accepted, we didn't know where the conference would be located. Eventually, we settled on Malta, a wonderful island in the Mediterranean with lovely weather in March. Well, putting it in March was the next challenge as the conference dates were moved backwards a couple of times, turning the entire organization of the conference into a race against time.

Another big challenge was the joint effort of all \*ACL 2024 conferences to streamline the review process by moving it completely to ACL Rolling Review. While there had been some attempts to integrate ARR into the conference reviewing process, 2024 will be the year where we see whether it actually works. I'd like to thank Yvette and Matt for being so brave to chair the first conference in 2024 adopting ARR only. I'd also like to thank the General Chairs of NAACL 2024 and ACL 2024, Katrin Erk and Claire Gardent, and their respective PC chairs to join the effort. Without the ARR team this could not have worked out, namely the ARR Editors in Chief, Mausam, Viviane Moreira, Vincent Ng, Lilja Øvrelid, Tamar Solorio, and Jun Suzuki were indispensable for making this happen.

For me it started all with Roberto Basili and Preslav Nakov, the 2023 and 2024 Presidents of EACL, asking me whether I'd like to serve as general chair for EACL 2024 – thanks for having trusted me to manage the organization of the conference. After Yvette Graham and Matt Purver accepted the role of PC chairs, I knew that I wouldn't have to worry anymore about the scientific program. A big thanks to Yvette and Matt! Behind the scenes Jennifer Rachford (ACL Event Manager) and her team, in particular Megan Haddad and Jon M. Dorsey, made the impossible happen. Jenn does what we scientists are not good at, and then a lot more. I don't know how we could have run EACL 2024 without her. Roberto Basili, Preslav Nakov, the EACL board, and David Yarowsky (ACL treasurer) provided me with information, advice and feedback whenever I needed it. A great thanks also goes to the EACL 2024 workshop chairs, Nafise Moosavi and Zeerak Talat! Because EACL is the first conference in 2024, they spearheaded the \*ACL joint call for workshop proposals. They worked with an extremely tight timeline, created a very interesting workshop program and had the organizers of 19 workshops under control. Very impressive, Nafise and Zeerak!

A special thanks goes to Claudia Borg from the University of Malta. Claudia was instrumental for the success of the conference dealing with all sorts of local issues. She helped us selecting the venue, connected us with local event organizers, was part of the volunteer program, and made sure that visas were issued to participants who needed them. Claudia is great!

And then ...

- The tutorial chairs, Sharid Loáicga and Mohsen Mesgar, worked together with the tutorial chairs of all \*ACL conferences to review tutorial proposals and select some for EACL 2024.
- The demonstration chairs, Orphée de Clercq and Nikolaos Aletras, created the demo program for EACL 2024.
- The student research workshop chairs, Neele Falk, Sara Papi, and Mike Zhang, along with their faculty advisors Parisa Kordjamshidi and Steffen Eger, took care about the next generation of NLP researchers.

- The publication chairs, Gözde Gül Sahin and Danilo Croce, did a tremendous job in getting all the papers into a nice shape worthy of the European flagship conference in Computational Linguistics.
- The handbook chair, Marco Polignano, helped us to navigate through the program so that we wouldn't miss any interesting presentation.
- The sponsorship chairs, Daniel Dahlmeier and Pasquale Minervini, worked together with the ACL sponsorship director Chris Callison-Burch to make EACL 2024 the ends meet in economically challenging times.
- The diversity and inclusion chairs, Hanan Al Darmaki, Sabine Weber, and Maciej Ogrodniczuk, ensured that researchers who are not from the global north can join our conference, in person or virtually. They also kicked off an amazing set of D&I events at the conference.
- The publicity chairs, Miryam de Lhoneux, Sungho Jeon, and Yuval Pinter, spread the word – and also pictures – through social media platforms.
- The website chairs, Mladen Karan and Wei Zhao, created a beautiful webpage. They were super responsive. Thanks a lot for the good work!
- The local ambassador, Max Bartolo, provided us with information on Malta early on. Talk to him for food options, bars, excursions, fun stuff to do!
- The ethics chairs, Annemarie Friedrich and Anne Lauscher, helped us to solve difficult ethical issues with the papers.
- The student volunteer chairs, Claudia Borg, Desmond Elliott, and Juntao Yu, went through many applications, selected the student volunteers, and assigned them their tasks.
- The visa chairs Claudia Borg and Yufang Hou helped conference participants to obtain their visas.
- The Technical Infrastructure Chairs, Wei Liu and Sungho Jeon, enabled us to navigate through the program with ease via MiniConf and to discuss via Rocket.Chat.
- The entire program committee, senior area chairs, area chairs, reviewers, and best paper committee, was essential for ensuring our high-quality scientific program.
- We couldn't run our conference without our student volunteers. A big thanks to all of them!
- Finally, I'd like to thank our invited speakers, Mirella Lapata and Hinrich Schütze, and the Karen Spärck Jones Award Winner 2023, Hongning Wang, for delivering inspiring keynote speeches.

The online side of our hybrid conference was provided by Underline (Sol Rosenberg, Damira Mrsic, and their team), who also provided us with support for managing the entire conference.

I would like to thank our sponsors for funding the conference, providing subsidies for students and financing the diversity and inclusion initiative.

Enjoy EACL 2024! Insellimkom,

Michael Strube  
Heidelberg Institute for Theoretical Studies, Heidelberg, Germany

EACL 2024 General Chair

## Message from the Program Chairs

Welcome to the 18th Conference of the European Chapter of the Association for Computational Linguistics (EACL) to take place in Malta. As with last year, the conference is being held in a hybrid mode, with both audiences and presenters able to attend online. Presentation videos, slides and posters will all be available online to make the experience as good as possible. However, we're very happy to see that most presenters in oral and poster sessions are opting to be there in-person, so we're looking forward to an interactive and exciting conference.

### Submission and Acceptance

EACL 2024 was the first \*ACL Conference to accept all submissions via ACL Rolling Review (ARR). This brought some significant advantages: a consistent system across \*ACL conferences, as well as the experience and assistance of the ARR team, and of course the ability to revise and resubmit papers rather than just being rejected out of hand.

However, this change does make it somewhat more difficult to calculate acceptance rates. Most papers committed to EACL 2024 came from the ARR October 2023 cycle, and most papers in that cycle were intended for EACL 2024; but some EACL papers came from other ARR cycles; and some papers in the October 2023 cycle were intended for other, later conferences rather than EACL. Many authors indicated their target when submitting to ARR, but not all; and some change their minds.

In the end we opted for the following approach: we take the pool of potential candidates as being papers in the relevant ARR cycle that either selected EACL as a target, did not select any target conference, or selected another target conference but then committed to EACL anyway; together with papers from other ARR cycles that committed to EACL. We include those that withdrew after getting reviews, but not those that withdrew before or were desk-rejected.

In total, EACL 2024 ARR October cycle received 1,275 submissions, with a large portion (78%) being long as opposed to short papers. 52 papers were desk rejected for various reasons (e.g. breaching the ACL anonymity or multiple submission policy, significant formatting violations) and 17 were withdrawn by the authors before reviews were received. 474 papers then committed to EACL 2024, of which we accepted 226 to the main conference, and a further 163 to the Findings of the ACL. The pool of potential candidates as defined above numbered 1,114 papers, giving an overall acceptance rate of 20.3% to the main conference and 14.5% to Findings. This is comparable to other recent \*ACL conferences (EACL 2023 quoted 24.1% and 17.2% respectively), but it's hard to compare directly given such a significant change in the submission process. The conference programme also features three papers from the Transactions of the Association for Computational Linguistics (TACL) journal, and one from the Computational Linguistics (CL) journal.

### Presentation Mode

From the resulting total of 230 papers accepted to the conference, we invited 144 to be presented orally, with the others presenting in poster sessions. We made the decision on which papers would be invited for oral poster presentations based on several factors: recommendations by Senior Area Chairs (SACs) and meta-reviewers about presentation mode and best paper prize potential, grouping of papers into thematic sessions, and confirmation from authors that they planned to attend the conference in person. For TACL and CL papers, the authors' preference of presentation mode was used.

Authors of papers accepted to the Findings of the ACL could opt to present a poster, and 113 (69%) chose to do so. We also gave oral paper presenters the option to present a poster, with 37 (25%) choosing to do so; this gave a total of 232 posters being presented at the conference. All oral sessions are being held as in-person plenary sessions (although with some online presenters), and all poster sessions are in-person except one fully virtual poster session.

## Limitations Section

As in EACL 2023, and now standard practice in ARR, we required inclusion of a Limitations section, including all major limitations of the work. As with past events, this is intended to discourage the practice of hyping conclusions drawn in work published at EACL, sticking to better scientific practice.

## Areas, Programme Committee Structure and Reviewing

We divided submissions into 24 distinct areas and asked authors to choose the most appropriate area to submit their work to. The three areas to receive the largest number of submissions were NLP Applications, Resources and Evaluation, and Interpretability and Analysis of Models for NLP.

Senior members of the NLP community were directly invited to act as Senior Area Chair (SAC), with 2–3 SACs per area. Area Chairs (ACs) were then recruited partly from ARR’s existing pool, and partly invited directly by SACs to sign up to ARR for the October cycle so they could act as Area Chairs for EACL. In the ARR system, ACs assign themselves to areas and can specify a maximum load, ensuring that ACs can reduce the number of papers they are responsible for at appropriate times; this results in a higher number of ACs than is usual outside of the ARR system. In total, 485 ARR ACs signed up to the October cycle 2023, while a total of 5,854 reviewers indicated availability to review in ARR October cycle. Three reviewers and one AC were automatically assigned to each paper using ARR’s matching algorithm, based on reviewers’ past publications and the maximum load set by reviewers and ACs.

## Best Paper Awards

Following ACL policy, we set up a committee to decide the Best Paper Awards. The committee was given 28 papers by the Program Chairs to consider, papers that were identified by at least one of the program committee, SAC, AC or reviewer as a possible best paper. These papers were anonymized via black out of author information, links to code, and acknowledgements sections in the camera ready papers. The selected best papers and runners up will be announced at the conference.

## Ethics Committee

We also set up an ethics committee, so that papers flagged by reviewers or ACs as having potential ethical concerns could be sent for separate ethics review. A small number of papers were accepted conditional on final re-reviewing to check that outstanding concerns were dealt with in the final camera ready paper; we’re happy to confirm that all such papers were accepted.

## Keynotes

We are delighted to include 2 Keynote talks in the plenary sessions:

- Prof. Mirella Lapata: Prompting is *\*not\** all you need! Or why Structure and Representations still matter in NLP
- Prof. Hinrich Schütze: Quality Data for LLMs: Challenges and Opportunities for NLP

Furthermore, we include a lecture from the winner of this year’s Karen Spärck Jones Award:

- Prof. Hongning Wang: Human vs. Generative AI in Content Creation Competition: Symbiosis or Conflict?

## Thank Yous

EACL 2024 would not have happened without the help and support of the NLP community. So much of the event relies on voluntary efforts with people very generously giving their time and energy. We would like to acknowledge everyone involved, with a special thanks to:

- EACL 2024 General Chair, Michael Strube, for leading the overall conference organisation and providing advice and support to the PCs and many others through the conference preparations;
- Our 56 Senior Area Chairs, who did a fantastic job of managing the review process for their individual areas;
- The 485 Area Chairs, who put in an enormous effort in as much as possible ensuring papers were given the best consideration by reviewers;
- All the reviewers, who very generously give up their time to this process;
- The Best Paper Award Committee, and especially the chair Barbara Plank, with the difficult task of choosing winners from the large number considered for this award;
- Our Ethics Committee, especially the chairs Annemarie Friedrich and Anne Lauscher, for diligently checking and maintaining the high ethical standards we strive for at \*ACL conferences;
- Publicity Chairs, Miryam de Lhoneux, Sungho Jeon and Yuval Pinter, and Website Chairs Mladen Karan and Wei Zhao, for managing our communications and fulfilling all requests sent so quickly;
- Publications Chairs, Danilo Croce and Gözde Gül Şahin, and Handbook Chair Marco Polignano, for the many hours dedicated to producing our fine proceedings and handbook;
- Jordan Zhang for invaluable assistance with building the conference schedule;
- The ARR team, particularly Tamar Solorio, Lilja Øvrelid and Harold Rubio, for so much support and advice during the review process;
- Damira Mršić from Underline and the ACL's Jennifer Rachford for their huge efforts to make EACL a success both online and on-site.

Overall, everyone we came into contact with during the process was exceptionally professional and great to work with, thank you all for this, it is so important!

We're looking forward to a great EACL 2024, we hope you enjoy it and we look forward to seeing you there.

Yvette Graham (Trinity College Dublin)

Matthew Purver (Queen Mary University of London & Jožef Stefan Institute)

EACL 2024 Programme Committee Co-Chairs

## Message from the Local Chair

Dear EACL2024 Participants,

It is with immense joy that I welcome you to the EACL2024 conference, held in the heart of the Mediterranean - Malta, an island nation celebrated for its vibrant diversity and intricate history.

We are brought together by a common passion, that of processing language. We are in a privileged position to understand the power of language, that of connecting people. But one of the most fascinating aspects of human language is its diversity. Take Maltese as an example: a Semitic language, written in Latin script, with mixed influences from Arabic, Italian and English. Since becoming an official European language, Maltese has been given more visibility, facilitating the creation of digital resources. Yet it is still a low-resource language, ranking lowest amongst all official EU languages.

In the era of LLMs and GPUs, the opportunity to work with a low-resource language like Maltese is not just about finding creative ways of processing the language, but becomes an interesting dive into its roots and understanding how history shaped it over time. It goes beyond racing for better accuracy and F1 scores. Instead, we try to find ways of connecting the language of today with the roots of its past.

As we embark on this exciting week, I invite you to immerse yourself not only in the groundbreaking research and discussions but also in the rich tapestry of Maltese culture and language. Let the diversity of Malta inspire you, spark your curiosity, and enrich your experience during your stay.

I extend my heartfelt gratitude to the local organisation team, particularly Stephanie Abela Tickle and her colleagues at Meet360. Their dedication and hard work have been pivotal in bringing this conference to life. I also thank my colleagues and students at the University of Malta for their steering work.

In closing, I hope that EACL2024 will be a source of inspiration and collaboration for all.

*Merħba f' Malta!*

Claudia Borg  
University of Malta

## Table of Contents

<i>Chem-FINESE: Validating Fine-Grained Few-shot Entity Extraction through Text Reconstruction</i> Qingyun Wang, Zixuan Zhang, Hongxiang Li, Xuan Liu, Jiawei Han, Huimin Zhao and Heng Ji	
<i>GPTs Are Multilingual Annotators for Sequence Generation Tasks</i> Juhwan Choi, Eunju Lee, Kyohoon Jin and YoungBin Kim	17
<i>Next Visit Diagnosis Prediction via Medical Code-Centric Multimodal Contrastive EHR Modelling with Hierarchical Regularisation</i> Heejoon Koo	41
<i>FlexiQA: Leveraging LLM's Evaluation Capabilities for Flexible Knowledge Selection in Open-domain Question Answering</i> Yuhan Chen, Shuqi Li and Rui Yan	56
<i>Hyper-BTS Dataset: Scalability and Enhanced Analysis of Back Transcription (BTS) for ASR Post-Processing</i> Chanjun Park, Jaehyung Seo, Seolhwa Lee, Junyoung Son, Hyeonseok Moon, Sugyeong Eo, Chanhee Lee and Heuseok Lim	67
<i>ParrotTTS: Text-to-speech synthesis exploiting disentangled self-supervised representations</i> Neil Shah, Saiteja Kosgi, Vishal Tambrahalli, Neha S, Anil Kumar Nelakanti and Vineet Gandhi	79
<i>NavHint: Vision and Language Navigation Agent with a Hint Generator</i> Yue Zhang, Quan Guo and Parisa Kordjamshidi	92
<i>Text or Image? What is More Important in Cross-Domain Generalization Capabilities of Hate Meme Detection Models?</i> Piush Aggarwal, Jawar Mehrabianian, Weigang Huang, Özge Alacam and Torsten Zesch	104
<i>Where are we Still Split on Tokenization?</i> Rob Van Der Goot	118
<i>A Methodology for Generative Spelling Correction via Natural Spelling Errors Emulation across Multiple Domains and Languages</i> Nikita Martynov, Mark Baushenko, Anastasia Kozlova, Katerina Kolomeytseva, Aleksandr Abramov and Alena Fenogenova	138
<i>How Does In-Context Learning Help Prompt Tuning?</i> Simeng Sun, Yang Liu, Dan Iter, Chenguang Zhu and Mohit Iyyer	156
<i>Large Language Models for Psycholinguistic Plausibility Pretesting</i> Samuel Joseph Amouyal, Aya Meltzer-Asscher and Jonathan Berant	166
<i>Modeling Aspect Sentiment Coherency via Local Sentiment Aggregation</i> Heng Yang and Ke Li	182
<i>An Examination of the Robustness of Reference-Free Image Captioning Evaluation Metrics</i> Saba Ahmadi and Aishwarya Agrawal	196
<i>Barriers to Effective Evaluation of Simultaneous Interpretation</i> Shira Wein, Te I, Colin Cherry, Juraj Juraska, Dirk Padfield and Wolfgang Macherey	209

<i>Inconsistent dialogue responses and how to recover from them</i>	
Mian Zhang, Lifeng Jin, Linfeng Song, Haitao Mi and Dong Yu .....	220
<i>MUG: Interactive Multimodal Grounding on User Interfaces</i>	
Tao Li, Gang Li, Jingjie Zheng, Purple Wang and Yang Li .....	231
<i>PRILoRA: Pruned and Rank-Increasing Low-Rank Adaptation</i>	
Nadav Benedek and Lior Wolf .....	252
<i>Revamping Multilingual Agreement Bidirectionally via Switched Back-translation for Multilingual Neural Machine Translation</i>	
Hongyuan Lu, Haoyang Huang, Dongdong Zhang, Furu Wei and Wai Lam .....	264
<i>mPLM-Sim: Better Cross-Lingual Similarity and Transfer in Multilingual Pretrained Language Models</i>	
Peiqin Lin, Chengzhi Hu, Zheyu Zhang, Andre Martins and Hinrich Schuetze .....	276
<i>OYXOY: A Modern NLP Test Suite for Modern Greek</i>	
Konstantinos Kogkalidis, Stergios Chatzikyriakidis, Eirini Chrysovalantou Giannikouri, Vasiliki Katsouli, Christina Klironomou, Christina Koula, Dimitris Papadakis, Thelka Pasparaki, Erofilia Psaltaki, Efthymia Sakellariou and Charikleia Soupiona .....	311
<i>A Comprehensive Evaluation of Inductive Reasoning Capabilities and Problem Solving in Large Language Models</i>	
Chen Bowen, Rune Søtre and Yusuke Miyao .....	323
<i>Towards efficient self-supervised representation learning in speech processing</i>	
Luis Lugo and Valentin Vielzeuf .....	340
<i>Improving Cross-Domain Low-Resource Text Generation through LLM Post-Editing: A Programmer-Interpreter Approach</i>	
Zhuang Li, Levon Haroutunian, Raj Tumuluri, Philip R. Cohen and Reza Haf .....	347
<i>Noise Contrastive Estimation-based Matching Framework for Low-Resource Security Attack Pattern Recognition</i>	
Tu Nguyen, Nedim Šrndić and Alexander Neth .....	355
<i>Large Language Models for Scientific Information Extraction: An Empirical Study for Virology</i>	
Mahsa Shamsabadi, Jennifer D’Souza and Sören Auer .....	374
<i>Re3val: Reinforced and Reranked Generative Retrieval</i>	
EuiYul Song, Sangryul Kim, Haeju Lee, Joonkee Kim and James Thorne .....	393
<i>Entity Linking in the Job Market Domain</i>	
Mike Zhang, Rob Van Der Goot and Barbara Plank .....	410
<i>(Chat)GPT v BERT Dawn of Justice for Semantic Change Detection</i>	
Francesco Periti, Haim Dubossarsky and Nina Tahmasebi .....	420
<i>Towards Unified Uni- and Multi-modal News Headline Generation</i>	
Mateusz Krubiński and Pavel Pecina .....	437
<i>On the Relationship between Sentence Analogy Identification and Sentence Structure Encoding in Large Language Models</i>	
Thilini Wijesiriwardene, Ruwan Wickramarachchi, Aishwarya Naresh Reganti, Vinija Jain, Aman Chadha, Amit P. Sheth and Amitava Das .....	451
<i>Contextualization Distillation from Large Language Model for Knowledge Graph Completion</i>	
Dawei Li, Zhen Tan, Tianlong Chen and Huan Liu .....	458

<i>Differentially Private Natural Language Models: Recent Advances and Future Directions</i> Lijie Hu, Ivan Habernal, Lei Shen and Di Wang .....	478
<i>Learning to Compare Financial Reports for Financial Forecasting</i> Ross Koval, Nicholas Andrews and Xifeng Yan .....	500
<i>Arukikata Travelogue Dataset with Geographic Entity Mention, Coreference, and Link Annotation</i> Shohei Higashiyama, Hiroki Ouchi, Hiroki Teranishi, Hiroyuki Otomo, Yusuke Ide, Aitaro Yamamoto, Hiroyuki Shindo, Yuki Matsuda, Shoko Wakamiya, Naoya Inoue, Ikuya Yamada and Taro Watanabe.....	513
<i>Knowledge Generation for Zero-shot Knowledge-based VQA</i> Rui Cao and Jing Jiang .....	533
<i>Simple Temperature Cool-down in Contrastive Framework for Unsupervised Sentence Representation Learning</i> Yoo Hyun Jeong, Myeong Soo Han and Dong-Kyu Chae .....	550
<i>Bootstrap Your Own PLM: Boosting Semantic Features of PLMs for Unsupervised Contrastive Learning</i> Yoo Hyun Jeong, Myeong Soo Han and Dong-Kyu Chae .....	560
<i>Personalized Abstractive Summarization by Tri-agent Generation Pipeline</i> Wen Xiao, Yujia Xie, Giuseppe Carenini and Pengcheng He.....	570
<i>Revisiting the Markov Property for Machine Translation</i> Cunxiao Du, Hao Zhou, Zhaopeng Tu and Jing Jiang .....	582
<i>Reward Engineering for Generating Semi-structured Explanation</i> Jiuzhou Han, Wray Buntine and Ehsan Shareghi.....	589
<i>Towards Context-Based Violence Detection: A Korean Crime Dialogue Dataset</i> Minju Kim, Heuiyeen Yeen and Myoung-Wan Koo .....	603
<i>Capturing the Relationship Between Sentence Triplets for LLM and Human-Generated Texts to Enhance Sentence Embeddings</i> Na Min An, Sania Waheed and James Thorne .....	624
<i>Harmonizing Code-mixed Conversations: Personality-assisted Code-mixed Response Generation in Dialogues</i> Shivani Kumar and Tanmoy Chakraborty .....	639
<i>Morality is Non-Binary: Building a Pluralist Moral Sentence Embedding Space using Contrastive Learning</i> Jeongwoo Park, Enrico Liscio and Pradeep Kumar Murukannaiah.....	654
<i>Prosody in Cascade and Direct Speech-to-Text Translation: a case study on Korean Wh-Phrases</i> Giulio Zhou, Tsz Kin Lam, Alexandra Birch and Barry Haddow .....	674
<i>Exploring the Potential of ChatGPT on Sentence Level Relations: A Focus on Temporal, Causal, and Discourse Relations</i> Chunkit Chan, Cheng Jiayang, Weiqi Wang, Yuxin Jiang, Tianqing Fang, Xin Liu and Yangqiu Song.....	684
<i>Backtracing: Retrieving the Cause of the Query</i> Rose E Wang, Pawan Wirawarn, Omar Khatib, Noah Goodman and Dorottya Demszky ....	722
<i>Unsupervised Multilingual Dense Retrieval via Generative Pseudo Labeling</i> Chao-Wei Huang, Chen-An Li, Tsu-Yuan Hsu, Chen-Yu Hsu and Yun-Nung Chen .....	736

<i>Investigating grammatical abstraction in language models using few-shot learning of novel noun gender</i> Priyanka Sukumaran, Conor Houghton and Nina Kazanina .....	747
<i>On-the-fly Denoising for Data Augmentation in Natural Language Understanding</i> Tianqing Fang, Wenxuan Zhou, Fangyu Liu, Hongming Zhang, Yangqiu Song and Muhao Chen	766
<i>Style Vectors for Steering Generative Large Language Models</i> Kai Konen, Sophie Jentzsch, Diaoulé Diallo, Peer Schütt, Oliver Bensch, Roxanne El Baff, Dominik Opitz and Tobias Hecking .....	782
<i>Consistent Joint Decision-Making with Heterogeneous Learning Models</i> Hossein Rajaby Faghihi and Parisa Kordjamshidi .....	803
<i>Quantifying Association Capabilities of Large Language Models and Its Implications on Privacy Leakage</i> Hanyin Shao, Jie Huang, Shen Zheng and Kevin Chang .....	814
<i>Probing Critical Learning Dynamics of PLMs for Hate Speech Detection</i> Sarah Masud, Mohammad Aflah Khan, Vikram Goyal, Md Shad Akhtar and Tanmoy Chakraborty	826
<i>Emble: Reconstruction of Ancient Hebrew and Aramaic Texts Using Transformers</i> Niv Fono, Harel Moshayof, Eldar Karol, Itai Assraf and Mark Last .....	846
<i>Stateful Memory-Augmented Transformers for Efficient Dialogue Modeling</i> Qingyang Wu and Zhou Yu .....	853
<i>The Shape of Learning: Anisotropy and Intrinsic Dimensions in Transformer-Based Models</i> Anton Razzhigaev, Matvey Mikhalchuk, Elizaveta Goncharova, Ivan Oseledets, Denis Dimitrov and Andrey Kuznetsov .....	868
<i>MEDs for PETs: Multilingual Euphemism Disambiguation for Potentially Euphemistic Terms</i> Patrick Lee, Alain Chirino Trujillo, Diana Cuevas Plancarte, Olumide Ebenezer Ojo, Xinyi Liu, Iyanuoluwa Shode, Yuan Zhao, Anna Feldman and Jing Peng .....	875
<i>PromptExplainer: Explaining Language Models through Prompt-based Learning</i> Zijian Feng, Hanzhang Zhou, Zixiao Zhu and Kezhi Mao .....	882
<i>Do-Not-Answer: Evaluating Safeguards in LLMs</i> Yuxia Wang, Haonan Li, Xudong Han, Preslav Nakov and Timothy Baldwin .....	896
<i>Do Language Models Know When They're Hallucinating References?</i> Ayush Agrawal, Mirac Suzgun, Lester Mackey and Adam Tauman Kalai .....	912
<i>Bridging Cultural Nuances in Dialogue Agents through Cultural Value Surveys</i> Yong Cao, Min Chen and Daniel Hershcovich .....	929
<i>CEO: Corpus-based Open-Domain Event Ontology Induction</i> Nan Xu, Hongming Zhang and Jianshu Chen .....	946
<i>Rethinking STS and NLI in Large Language Models</i> Yuxia Wang, Minghan Wang and Preslav Nakov .....	965
<i>Learning High-Quality and General-Purpose Phrase Representations</i> Lihu Chen, Gael Varoquaux and Fabian M. Suchanek .....	983

<i>Explaining Language Model Predictions with High-Impact Concepts</i> Ruo Chen Zhao, Tan Wang, Yongjie Wang and Shafiq Joty .....	995
<i>Understanding and Mitigating Spurious Correlations in Text Classification with Neighborhood Analysis</i> Oscar Chew, Hsuan-Tien Lin, Kai-Wei Chang and Kuan-Hao Huang .....	1013
<i>On the Intractability to Synthesize Factual Inconsistencies in Summarization</i> Ge Luo, Weisi Fan, Miaoran Li, Youbiao He, Yinfei Yang and Forrest Sheng Bao .....	1026
<i>IndiVec: An Exploration of Leveraging Large Language Models for Media Bias Detection with Fine-Grained Bias Indicators</i> Luyang Lin, Lingzhi Wang, Xiaoyan Zhao, Jing Li and Kam-Fai Wong .....	1038
<i>Are Large Language Model-based Evaluators the Solution to Scaling Up Multilingual Evaluation?</i> Rishav Hada, Varun Gumma, Adrian de Wynter, Harshita Diddee, Mohamed Ahmed, Monojit Choudhury, Kalika Bali and Sunayana Sitaram .....	1051
<i>Computational Morphology and Lexicography Modeling of Modern Standard Arabic Nominals</i> Christian Khairallah, Reham Marzouk, Salam Khalifa, Mayar Nassar and Nizar Habash ....	1071
<i>Relabeling Minimal Training Subset to Flip a Prediction</i> Jinghan Yang, Linjie Xu and Lequan Yu .....	1085
<i>Why Generate When You Can Discriminate? A Novel Technique for Text Classification using Language Models</i> Sachin Pawar, Nitin Ramrakhiani, Anubhav Sinha, Manoj Apte and Girish Keshav Palshikar	1099
<i>Autism Detection in Speech – A Survey</i> Nadine Probol and Margot Mieskes .....	1115
<i>Improving Multimodal Classification of Social Media Posts by Leveraging Image-Text Auxiliary Tasks</i> Danae Sanchez Villegas, Daniel Preotiuc-Pietro and Nikolaos Aletras .....	1126
<i>What the Weight?! A Unified Framework for Zero-Shot Knowledge Composition</i> Carolyn Holtermann, Markus Frohmann, Navid Rekasbas and Anne Lauscher .....	1138
<i>IndiFoodVQA: Advancing Visual Question Answering and Reasoning with a Knowledge-Infused Synthetic Data Generation Pipeline</i> Pulkit Agarwal, Settaluri Lakshmi Sravanthi and Pushpak Bhattacharyya .....	1158
<i>MAPLE: Micro Analysis of Pairwise Language Evolution for Few-Shot Claim Verification</i> Xia Zeng and Arkaitz Zubiaga .....	1177
<i>Leveraging Open Information Extraction for More Robust Domain Transfer of Event Trigger Detection</i> David Dukić, Kiril Gashteovski, Goran Glavaš and Jan Snajder .....	1197
<i>Exploring efficient zero-shot synthetic dataset generation for Information Retrieval</i> Tiago Almeida and Sérgio Matos .....	1214
<i>Clustering-based Sampling for Few-Shot Cross-Domain Keyphrase Extraction</i> Prakanya Mishra, Lincy Pattanaik, Arunima Sundar, Nishant Yadav and Mayank Kulkarni .	1232
<i>Random Smooth-based Certified Defense against Text Adversarial Attack</i> Zeliang Zhang, Wei Yao, Susan Liang and Chenliang Xu .....	1251

<i>Clarifying the Path to User Satisfaction: An Investigation into Clarification Usefulness</i> Hossein A. Rahmani, Xi Wang, Mohammad Aliannejadi, Mohammadmehdi Naghiaei and Emine Yilmaz . . . . .	1266
<i>Efficiently Aligned Cross-Lingual Transfer Learning for Conversational Tasks using Prompt-Tuning</i> Lifu Tu, Jin Qu, Semih Yavuz, Shafiq Joty, Wenhao Liu, Caiming Xiong and Yingbo Zhou .	1278
<i>Correcting Language Model Outputs by Editing Salient Layers</i> Kshitij Mishra, Tamer Soliman, Anil Ramakrishna, Aram Galstyan and Anoop Kumar . . . . .	1295
<i>Improving Grounded Language Understanding in a Collaborative Environment by Interacting with Agents Through Help Feedback</i> Nikhil Mehta, Milagro Teruel, Xin Deng, Sergio Patricio Figueroa Sanz, Ahmed Hassan Awadallah and Julia Kiseleva . . . . .	1306
<i>Goodhart’s Law Applies to NLP’s Explanation Benchmarks</i> Jennifer Hsia, Danish Pruthi, Aarti Singh and Zachary Chase Lipton . . . . .	1322
<i>Syllable-level lyrics generation from melody exploiting character-level language model</i> Zhe Zhang, Karol Lasocki, Yi Yu and Atsuhiko Takasu . . . . .	1336
<i>Monolingual or Multilingual Instruction Tuning: Which Makes a Better Alpaca</i> Pinzhen Chen, Shaoxiong Ji, Nikolay Bogoychev, Andrey Kutuzov, Barry Haddow and Kenneth Heafield . . . . .	1347
<i>Prompt Perturbation Consistency Learning for Robust Language Models</i> Yao Qiang, Subhrangshu Nandi, Ninareh Mehrabi, Greg Ver Steeg, Anoop Kumar, Anna Rumshisky and Aram Galstyan . . . . .	1357

## Abstract

Fine-grained few-shot entity extraction in the chemical domain faces two unique challenges. First, compared with entity extraction tasks in the general domain, sentences from chemical papers usually contain more entities. Moreover, entity extraction models usually have difficulty extracting entities of long-tailed types. In this paper, we propose Chem-FINESE, a novel sequence-to-sequence (seq2seq) based few-shot entity extraction approach, to address these two challenges. Our Chem-FINESE has two components: a seq2seq entity extractor to extract named entities from the input sentence and a seq2seq self-validation module to reconstruct the original input sentence from extracted entities. Inspired by the fact that a good entity extraction system needs to extract entities faithfully, our new self-validation module leverages entity extraction results to reconstruct the original input sentence. Besides, we design a new contrastive loss to reduce excessive copying during the extraction process. Finally, we release ChemNER+, a new fine-grained chemical entity extraction dataset that is annotated by domain experts with the ChemNER schema. Experiments in few-shot settings with both ChemNER+ and CHEMET datasets show that our newly proposed framework has contributed up to 8.26% and 6.84% absolute F1-score gains respectively<sup>1</sup>.

## 1 Introduction

Millions of scientific papers are published annually<sup>2</sup>, resulting in an information overload (Van Noorden, 2014; Landhuis, 2016). Due to such an explosion of research directions, it is impossible for scientists to fully explore the landscape due to

<sup>1</sup>The programs, data, and resources are publicly available for research purposes at: <https://github.com/EagleW/Chem-FINESE>.

<sup>2</sup><https://esperr.github.io/pubmed-by-year/about.html>

Input

Through application of ligand screening, we describe the first examples of Pd-catalyzed Suzuki-Miyaura reactions using aryl sulfamates at room temperature.

Ground Truth

ligand <Ligands>, Pd-catalyzed Suzuki-Miyaura reactions <Coupling reactions>, aryl sulfamates <Aromatic compounds>, room temperature <Thermodynamic properties>

Sentence Reconstructed from Ground Truth

Ligands play a crucial role in Pd-catalyzed Suzuki-Miyaura reactions, which are coupling reactions that enable the synthesis of diverse organic compounds such as aryl sulfamates at room temperature, exploiting their favorable thermodynamic properties.

InBoxBART Entity Extraction Results

ligand screening <Ligands>, Pd-catalyzed Suzuki-Miyaura reactions <Coupling reactions>, aryl sulfamates <Catalysts> [Missing: room temperature <Thermodynamic properties>]

Sentence Reconstructed from Name Tagging Results

Ligand screening is conducted to identify suitable ligands for Pd-catalyzed Suzuki-Miyaura reactions, which are coupling reactions known for their efficacy in the synthesis of aryl sulfamates, acting as catalysts in the process. [Missing: room temperature <Thermodynamic properties>]

Figure 1: Comparison of sentence reconstruction results from ground truth and InBoxBART (Parmar et al., 2022). We highlight Complete Correct, Missed Entity, and Partially Correct Prediction with different color.

the limited reading ability of humans. Therefore, information extraction, especially entity extraction of fine-grained scientific entity types, becomes a crucial step to automatically catch up with the newest research findings in the chemical domain.

Despite such a pressing need, fine-grained entity extraction in the chemical domain presents three distinctive and non-trivial challenges. First, there are very few publicly available benchmarks with high-quality annotations on fine-grained chemical entity types. For example, ChemNER (Wang et al., 2021a) developed the first fine-grained chemistry entity extraction dataset. However, their dataset is not released publicly. To address this issue, we collaborate with domain experts to annotate ChemNER+, a new chemical entity extraction dataset based on the ChemNER ontology. Besides, we construct another new fine-grained entity extraction

dataset based on an existing entity typing dataset CHEMET (Sun et al., 2021).

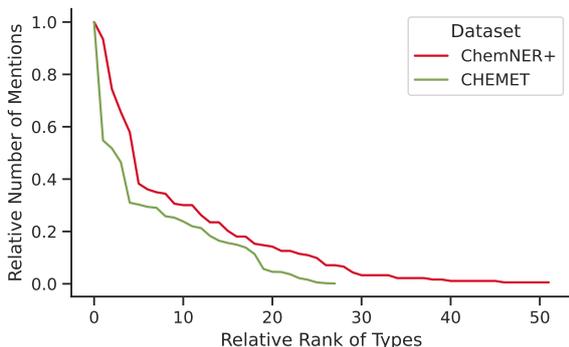

Figure 2: Type distributions for the training sets of ChemNER+ and CHEMET datasets. The Y-axis represents the number of mentions normalized by the mentions of the most frequent type. The X-axis represents the rank of types.

In addition, current entity extraction systems in few-shot settings face two main problems: *missing mentions* and *incorrect long-tail predictions*. One primary reason for missing mentions is that the sentences in scientific papers typically cover more entities than sentences in the general domain. For example, there are 3.1 entities per sentence in our ChemNER+ dataset, which is much higher than the 1.5 entities in the general domain dataset CONLL2003 (Tjong Kim Sang and De Meulder, 2003). As a result, it is more difficult for entity extraction models to cover all mentions in the input sentences. As shown in Figure 1, since the input has already included four chemical entities, InBoXBART model (Parmar et al., 2022) completely misses the entity “room temperature”.

Furthermore, entity distributions in the chemical domain are highly imbalanced. As shown in Figure 2, we observe that the entity type distributions of ChemNER+ and CHEMET exhibit similar long-tail patterns. In few-shot settings, entities with long-tail types are extremely difficult to extract due to insufficient training examples. For example, as shown in Figure 1, InBoXBART mistakenly predicts the entity “aryl sulfamates” as *catalyst*, because its type has a frequency forty times lower than the predicted type (i.e., 4 vs 136). Moreover, the diverse representation nature of chemical entities—such as trade names, trivial names, and semi-systematic names (e.g., THF, iPrMgCl, 8-phenyl ring)—makes it even harder for models to generalize on these long-tail entities.

To address these challenges, we propose a novel

**Chemical FINE-grained Entity extraction with SELF-validation (Chem-FINESE).** Specifically, our Chem-FINESE has two parts: a seq2seq entity extractor to extract named entities from the input sentence and a seq2seq self-validation module to reconstruct the original input sentence based on the extracted entities. First, we employ a seq2seq model to extract entities from the input sentence, since it does not require any task-specific component and explicit negative training examples (Giorgi et al., 2022). We generate the entity extraction results as a concatenation of pairs, each consisting of an entity mention and its corresponding type, as shown in Figure 1.

One critical issue for seq2seq entity extraction is that the language model tends to miss important entities or excessively copy original input. For example, the seq2seq entity extraction results missed the type *thermodynamic properties* and generated “*ligand screening*” in Figure 1. However, the goal of information extraction is to provide factual information and knowledge comprehensively. In other words, *if the model extracts knowledge precisely, readers should be able to faithfully reconstruct the original sentence using the extraction results.* Inspired by such a goal, to evaluate whether the seq2seq entity extractor has faithfully extracted important information, we propose a novel seq2seq self-validation module to reconstruct the original sentences based on entity extraction results. As shown in Figure 1, the sentence reconstructed from the ground truth is closer to the original input than the sentence reconstructed from entity extraction results, which misses the reaction condition and introduces additional information that treated the “*aryl sulfamates*” as *catalysts*. Additionally, we introduce a new entity decoder contrastive loss to control the mention spans. We treat text spans containing entity mentions as hard negatives. For instance, given the ground truth entity “*aryl sulfamates*”, we will treat “*aryl sulfamates at room temperature*” as a hard negative.

Our extensive experiments demonstrate that our proposed framework significantly outperforms our baseline model by up to 8.26% and 6.84% absolute F1-score gains on ChemNER+ and CHEMET datasets respectively. Our analysis also shows that Chem-FINESE can effectively learn to select correct mentions and improve long-tail entity type performance. To evaluate the generalization ability of our proposed method, we also evaluate our framework on CrossNER (Liu et al., 2021), which

is based on Wikipedia. Our Chem-FINESE still outperforms other baselines in all five domains.

Our contributions are threefold:

1. We propose two few-shot chemical fine-grained entity extraction datasets, based on human-annotated ChemNER+ and CHEMET.
2. We propose a new framework to address the mention coverage and long-tailed entity type problems in chemical fine-grained entity extraction tasks through a novel self-validation module and a new entity extractor decoder contrastive objective. Our model does not require any external knowledge or domain adaptive pretraining.
3. Our extensive experiments on both chemical few-shot fine-grained datasets and the CrossNER dataset justify the superiority of our Chem-FINESE model.

## 2 Task Formulation

Following Giorgi et al. (2022), we formulate entity extraction as a sequence-to-sequence (seq2seq) generation task by taking a source document  $\mathcal{S}$  as input. The model generates output  $\mathcal{Y}$ , a text consisting of a concatenation of  $n$  fine-grained chemical entities  $E_1, E_2, \dots, E_n$ . Each mention  $E_i$  includes the mention  $\mu_i$  in the source document  $\mathcal{S}$  and its entity type  $\rho_i \in \mathcal{P}$ , where  $\mathcal{P}$  is a set containing all entity types. Specifically, we propose the following output linearization schema: given the input  $\mathcal{S}$ , the output is  $\mathcal{Y} = \mu_1 \langle \rho_1 \rangle, \mu_2 \langle \rho_2 \rangle, \dots, \mu_n \langle \rho_n \rangle$ . We further illustrated this with an example:  $\mathcal{S}$ : Through application of **ligand** screening, we describe the first examples of **Pd-catalyzed Suzuki–Miyaura reactions** using **aryl sulfamates** at **room temperature**.

$\mathcal{Y}$ : **ligand** <Ligands>, **Pd-catalyzed Suzuki–Miyaura reactions** <Coupling reactions>, **aryl sulfamates** <Aromatic compounds>, **room temperature** <Thermodynamic properties>

## 3 Method

### 3.1 Model Architecture

The overall framework is illustrated in Figure 3. Given the source document  $\mathcal{S}$ , we first use a seq2seq model to extract fine-grained chemical entities. Then, we propose a new *self-validation module* to reconstruct the original input based on entity extraction results. Finally, we introduce a new *entity decoder contrastive loss* to reduce excessive

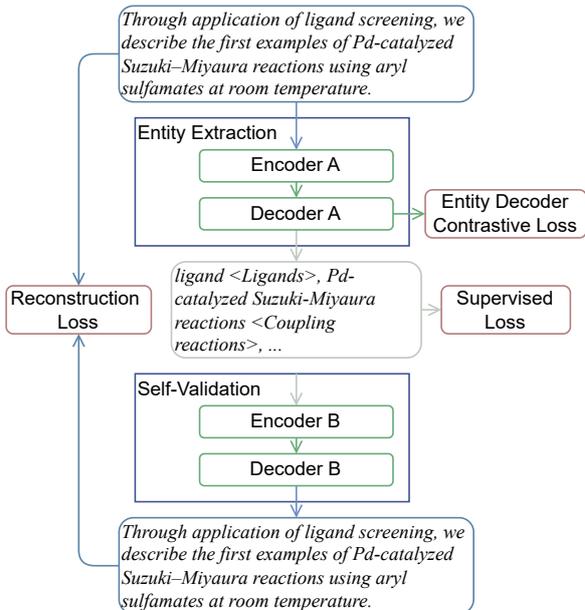

Figure 3: Architecture overview. We use the example in Figure 1 as a walking-through example.

copying. The entire model is trained with a combination of the supervised loss, the reconstruction loss, and the entity decoder contrastive loss.

### 3.2 Entity Extraction Module

Our entity extraction module follows a seq2seq setup (Yan et al., 2021; Giorgi et al., 2022). Formally, we use the state-of-the-art coarse-grained chemical entity extractor InBoXBART (Parmar et al., 2022) as the backbone. We model the conditional probability of extracting entities from source sequence  $\mathcal{S}$  as

$$p(\mathcal{Y}|\mathcal{S}) = \prod_{t=1}^T p(y_t|\mathcal{S}, y_{<t}), \quad (1)$$

where the output  $\mathcal{Y}$  has a length of  $T$ , and  $y_t$  is the predicted token at time  $t$  in the output  $\mathcal{Y}$ .

We supervise the entity extraction using the standard cross-entropy loss:

$$\mathcal{L}_{\text{gen}} = \sum_{t=1}^T \log p(y_t|\mathcal{S}, y_{<t}). \quad (2)$$

### 3.3 Self-validation Module

Since a good information extraction system needs to extract entities faithfully, we propose a self-validation module to reconstruct the original sentence from the extracted entities to check whether the model overlooks any entities. Different from previous dual learning architectures (Iovine et al.,

2022), which use dual cycles or reinforcement learning to provide feedback, we use Gumbel-softmax (GS) estimator (Jang et al., 2017) to avoid the non-differentiable issue in explicit decoding. Specifically, based on InBoXBART (Parmar et al., 2022), we first pretrain a seq2seq self-validation module that takes in the entity extraction results  $\mathcal{Y}$  and generates a reconstructed sentence  $\hat{\mathcal{S}}$ . We use our training set to pretrain the self-validation module. We fix the weight of the self-validation module after pretraining. In the training stage, the input embedding  $\mathbf{H}_t$  of the self-validation module is given by:

$$\mathbf{H}_t = \text{GS}(p(y_t|\mathcal{S}, y_{<t})) \cdot \mathbf{E}_v, \quad (3)$$

where  $\mathbf{E}_v$  is the vocabulary embedding matrix and GS is the Gumbel-softmax estimator. The total input embeddings for the self-reconstruction model is  $\mathbf{H} = [\mathbf{H}_1; \mathbf{H}_2; \dots; \mathbf{H}_T]$ .

The reconstruction loss is:

$$\mathcal{L}_{\text{recon}} = \sum_{\hat{t}=1}^{\hat{T}} \log p(\hat{s}_{\hat{t}}|\mathbf{H}, \hat{s}_{<\hat{t}}), \quad (4)$$

where the reconstructed sentence  $\hat{\mathcal{S}}$  has a length of  $\hat{T}$ , and  $\hat{s}_{\hat{t}}$  is the predicted token at time  $\hat{t}$  in  $\hat{\mathcal{S}}$ .

### 3.4 Contrastive Entity Decoding Module

Entity extraction datasets in the scientific domain usually contain more entities for each sentence. From the initial experiments, we found that the entity extraction module tends to generate incorrect mentions by associating it with unrelated contexts to help the reconstruction of the self-validation module. For example, given the example in Figure 1, the baseline model generates “*ligand screening*” instead of “*ligand*”. Therefore, we introduce a new decoding contrastive loss inspired by Wang et al. (2023a) to suppress excessive copying. We construct negative samples by combining mentions with surrounding unrelated contexts. For example, we will consider “*ligand screening, we describe the first examples*” as a negative of entity “*ligand*”. We treat the original mention type pairs as the ground truth and maximize their probability with InfoNCE loss (Oord et al., 2018):

$$\begin{aligned} \mathcal{L}_{\text{cl}} &= \frac{\exp(x^+/\tau)}{\sum_i \exp(x_i^-/\tau) + \exp(x^+/\tau)}, \\ x^+ &= \sigma(\text{Avg}(\mathbf{W}_x \bar{\mathbf{H}}^+ + \mathbf{b}_x)), \\ x_i^- &= \sigma(\text{Avg}(\mathbf{W}_x \bar{\mathbf{H}}_i^- + \mathbf{b}_x)), \end{aligned} \quad (5)$$

where  $\bar{\mathbf{H}}^+$  and  $\bar{\mathbf{H}}_i^-$  are decoder hidden states from the positive and  $i$ -th negative samples,  $\mathbf{W}_x$  is a learnable parameter,  $\tau$  is the temperature, and  $\text{Avg}(\ast)$  denotes the average pooling function.

### 3.5 Training Objective

We jointly optimize the cross-entropy loss, reconstruction loss, and entity decoder contrastive loss:

$$\mathcal{L} = \mathcal{L}_{\text{gen}} + \alpha \mathcal{L}_{\text{recon}} + \beta \mathcal{L}_{\text{cl}}, \quad (6)$$

where  $\alpha, \beta$  are hyperparameters that control the weights of the reconstruction loss and contrastive loss respectively.

Dataset	Split	#Pair	$\overline{\#\text{Token}}$	$\overline{\#\text{Entity}}$
ChemNER+	Train	542	32.9	3.10
	Valid	100	39.9	4.57
	Test	100	39.4	4.61
CHEMET	Train	6,561	37.8	1.57
	Valid	520	31.6	2.15
	Test	663	36.6	1.95

Table 1: Statistics of our dataset.  $\overline{\#\text{Token}}$  denotes average number of words per sentence.  $\overline{\#\text{Entity}}$  denotes average number of entities per sentence.

## 4 Benchmark Dataset

### 4.1 Dataset Creation

**ChemNER+ Dataset.** Since the annotation of ChemNER dataset is not fully available online, we decide to create our own dataset, ChemNER+, based on available sentences from ChemNER (Wang et al., 2021a) dataset. Following the schema of ChemNER, we ask two Chemistry Ph.D. students to annotate a new dataset, covering 59 fine-grained chemistry types with 742 sentences<sup>3</sup>.

**CHEMET Dataset.** We construct a new fine-grained entity extraction dataset based on CHEMET (Sun et al., 2021). For any entity in the training set that overlaps with the validation and testing sets, we replace its multi-labels with the most frequent types that appear in the validation and testing sets. For other entities, we replace the remaining types with their most frequent types that appeared in the training set. We merge the entity types with the same subcategory name in CHEMET (Sun et al., 2021). The final dataset consists of 30 fine-grained organic chemical types.

Table 1 shows the detailed data statistics.

Table 3: micro-F1 (%) scores for CHEMET with few-shot settings.

## 4.2 Few-shot Setup

For each dataset, we randomly sample a subset based on the frequency of each type class. Specifically, given a dataset, we first set the number of maximum entity mentions  $k$  for the most frequent entity type in the dataset. We then randomly sample other types and ensure that the distribution of each type remains the same as in the original dataset. We choose the values 6, 9, 12, 15, 18 as the potential maximum entity mentions for  $k$ . The ChemNER+ and CHEMET few-shot datasets contain 52 and 28 types respectively.

## 5 Experiments

### 5.1 Baselines

We compare our model with **(1) state-of-the-art pretrained encoder-based models** including RoBERTa (Liu et al., 2019) and models with domain adaptive training, such as PubMedBERT (Gu et al., 2021) and ScholarBERT (Hong et al., 2023). We then compare our model with the **(2) few-shot baselines**, including NNShot and StructShot (Yang and Katiyar, 2020) based on RoBERTa-base. Since we use InBoXBART (Parmar et al., 2022) as our backbone, we also include **(3) baselines for ablation**. The hyperparameters, training and evaluation details are presented in Appendix A.

### 5.2 Overall Performance

Tables 2, 3 show that our models outperform baselines for few-shot settings by a large margin. Compared to the best pretrained encoder-based ScholarBERT, pretrained on 221B tokens of scientific documents, seq2seq models generally achieve higher performance in low-resource settings with fewer parameters, as shown in Table 11. We also observe that both NNshot and StructShot perform worse than their original baseline. At a closer look, we find that both methods miss many entities and mislabel unrelated phrases as entities. The primary reasons for this are twofold: first, the chemical domain’s entity mentions are more diverse and may only appear in the testing set; second, there are significantly more potential entity types than in traditional entity extraction tasks. Therefore, the two baselines cannot effectively utilize the nearest neighbor information and perform worse than our proposed methods. These results demonstrate that seq2seq models have a better generalization ability in few-shot settings.

<i>k</i> -shot	6	9	12	15	18
InBoXBART	36.96	38.22	38.34	47.91	42.84
+ Valid	45.07	<b>45.28</b>	41.56	48.15	46.15

<i>k</i> -shot	6	9	12	15	18
InBoXBART	46.74	42.07	44.32	47.58	52.90
+ Valid	47.87	46.01	44.18	50.55	50.50
+ Valid + CL	<b>48.96</b>	<b>49.83</b>	<b>47.03</b>	<b>50.61</b>	<b>54.10</b>

Table 5: Mention micro-F1 (%) scores for CHEMET with few-shot settings.

Additionally, the self-validation variants significantly outperform the baseline InBoXBART, showing the benefit of the self-validation module in capturing mentions. Moreover, our self-validation module can effectively enhance the performance of the entity extraction module in extremely low-resource settings. In 6-shot scenarios for both ChemNER+ and CHEMET datasets, our model achieves impressive performance compared to ScholarBERT, which further verifies the effectiveness of the self-validation module. Finally, adding decoder contrastive loss helps the model perform significantly better in Table 2, suggesting

that contrastive learning further helps the mention extraction quality by reducing excessive copying. Interestingly, we observe that decoder contrastive learning improves less in Table 3 than in Table 2, because the CHEMET contains fewer entities per sentence compared to the ChemNER+.

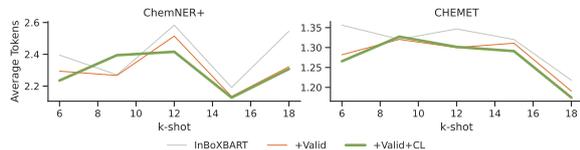

Figure 4: Average tokens in each mention for ChemNER+ and CHEMET datasets with few-shot settings.

**Performance of Mention Extraction.** We calculate the mention F1 scores in Tables 4 and 5. In addition, we also test a fully unsupervised mention extraction based on AMR-Parser (Fernandez Astudillo et al., 2020)<sup>4</sup>. The F1-scores are 38.22 and 45.33 for ChemNER+ and CHEMET, respectively. These results imply that the self-validation model generally improves the mention extraction accuracy. Moreover, adding decoder contrastive loss generally further bolsters the mention F1 score by reducing the number of tokens that appear in each mention, as shown in Figure 4.

<i>k</i> -shot	6	9	12	15	18
RoBERTa	2.04	2.05	2.05	0.00	2.05
PubMedBERT	2.05	0.00	0.00	2.13	0.00

+ Valid + CL	<b>26.19</b>	<b>23.91</b>	<b>23.26</b>	<b>19.05</b>	<b>25.00</b>

Table 6: micro-F1 (%) scores for long-tail entity types ChemNER+ with few-shot settings.

**Performance of Long-tail Entity.** To evaluate the performance of long-tail entities, we first rank entity types by their frequency. We then select the entity types that appear in the lower 50% and calculate the F1 scores of those types<sup>5</sup>. The results are in Tables 6 and 7. Notably, our proposed methods greatly outperform the encoder-based baselines. Both the self-verification module and the decoder contrastive loss aid the entity extraction module in focusing on long-tail entities by creating a more balanced distribution of entity types. The major reason for the relatively low performance in Table 7 is that

<sup>4</sup>Implementation details are in Appendix A.

<sup>5</sup>Entity frequency and selected types are in Appendix B.

<i>k</i> -shot	6	9	12	15	18
RoBERTa	0.00	0.00	0.00	0.00	0.00
PubMedBERT	0.00	0.00	0.00	0.00	0.00
ScholarBERT	0.00	0.00	0.00	0.00	0.00
InBoXBART	4.90	7.55	4.55	5.05	12.26
+ Valid	<b>8.72</b>	<b>13.10</b>	4.55	<b>16.96</b>	20.83
+ Valid + CL	7.07	11.32	<b>8.33</b>	5.15	<b>23.01</b>

Table 7: micro-F1 (%) scores for long-tail entity types CHEMET with few-shot settings. The encoder-based models fail to extract long-tail entity types for all few-shot settings. Compared to encoder-based models, seq2seq models can utilize label semantics in the generation procedure. Therefore, encoder-based models require more training data under few-shot settings.

the differences between the types in CHEMET are not significant. The relatively stable performance of our model in Table 6 across increasing few-shot examples indicates that our model achieves satisfactory performance for long-tail entities, even with a limited training sample.

## 6 Analysis

### 6.1 Qualitative Analysis

Table 8 shows two typical examples from the 18-shot ChemNER+ dataset that illustrate how incorporating a self-validation module and decoder contrastive loss can improve the mention coverage and long-tail entity performance.

In the first example, the InBoXBART baseline fails to identify both “*cyclophanes*” and “*polycycles*”, probably because the input sentence contains too many entities. With the help of the self-validation module, the InBoXBART+Valid model successfully captures the first entity “*cyclophanes*”. However, it still cannot recognize “*polycycles*”. Additionally, both the baseline and the InBoXBART+Valid model mistakenly treat the entity “*Suzuki cross-coupling and metathesis*” and the entity “*metathesis*”, because those models excessively copy from the original sentence. In contrast, by adding the decoder contrastive loss, which uses the mentions with surrounding unrelated contexts as negatives, the model successfully separates the entity “*Suzuki cross-coupling and metathesis*” from the entity “*metathesis*”.

In the second example, both the baseline and the InBoXBART+Valid model predict a very long text span that treats three entities as a single entity. They also fail to capture “*asymmetric catalysis*” and “*highly enantioselective process*” as entities because their types have low frequency in the train-

ing set. With the help of decoder contrastive loss, the model reduces the excessive copying of the entity extraction module while trying to capture important entities as accurately as possible. Therefore, the model successfully classifies “*asymmetric catalysis*” as *Catalysis* correctly and also predicts “*enantioselective process*” as an entity.

## 6.2 Compatible with Other Few-shot Datasets?

**CrossNER Dataset.** In the above experiments, we focus on the few-shot settings for chemical papers and prove the effectiveness of our proposed framework. To evaluate the generalization ability of our proposed framework on other domains, we conduct experiments on the CrossNER dataset (Liu et al., 2021). The detailed statistics are in Table 9. We remove sentences without any entity. Because the CrossNER dataset is based on Wikipedia articles, we choose RoBERTa and ScholarBERT as encoder-based baselines. Additionally, we select BART-base (Lewis et al., 2020) as the backbone for our ablation variations.

**Results.** As shown in Table 10, our model consistently produces the best F1 scores across all five domains of CrossNER without any external knowledge or domain adaptive pretraining. We observe that the model achieves the largest gain for the AI domain and the smallest gain for the politics domain. The major reason behind this is that AI domain contains the most informative entity types, which cover the key points of the sentence, including *algorithm*, *task*, etc. On the contrary, the politics domain contains many names of *politicians* and *locations*, which require background knowledge for the self-verification module to identify.

## 6.3 Remaining Challenges

**Misleading Subwords.** We observe that the mention text can sometimes mislead the type predictions, especially if the type contains a subword from the mention. As a result, the model fails to identify the type correctly. For example, given the mention “*unnatural amino acid derivatives*”, our model focuses on the word “acid” and predicts the entity to be *Organic acids* instead of *Organonitrogen compounds*. The potential reason behind this is that the BART model incorrectly associates the “acid” in the mention with *Organic acids*. Such type errors might be incorporated into the decoder contrastive learning as additional hard negatives.

**Fine-grained Type Classification.** The model tends to predict generic entity types instead of more fine-grained entity types. For instance, the model predicts the mention “*Cs2CO3*” as *Inorganic compounds* instead of *Inorganic carbon compounds*. This issue might come from annotation ambiguity in the training set. Additionally, the model predicts types that are not in the predefined ontology. For instance, the model labels “*GK*” as *Genecyclic compounds* instead of *Enzymes*. This error can possibly be solved by constraint decoding.

## 7 Related Work

**Scientific Entity Extraction.** Entity extraction for scientific papers has been widely exploited in the biomedical domain (Nguyen et al., 2022; Labrak et al., 2023; Cao et al., 2023; Li et al., 2023b; Hiebel et al., 2023) and the computer science domain (Luan et al., 2018; Jain et al., 2020; Viswanathan et al., 2021; Shen et al., 2021; Ye et al., 2022; Jeong and Kim, 2022; Hong et al., 2023). Despite this, fine-grained scientific entity extraction (Wang et al., 2021a) in the chemical domain receives less attention due to the scarcity of benchmark resources. Most benchmarks in the chemical (Krallinger et al., 2015; Kim et al., 2015) only provide coarse-grained entity types. In this paper, we address this problem by releasing two new datasets for chemical fine-grained entity extraction based on the ChemNER schema (Wang et al., 2021a) and CHEMET dataset (Sun et al., 2021).

**Few-shot Entity Extraction.** Few-shot learning attracts growing interest, especially for low-resource domains. Previous improvements for few-shot learning can be divided into several categories: domain-adaptive training by training the model in the same or similar domains (Liu et al., 2021; Oh et al., 2022), prototype learning by learning entity type prototypes (Ji et al., 2022; Oh et al., 2022; Ma et al., 2023), prompt-based methods (Lee et al., 2022; Xu et al., 2023; Nookala et al., 2023; Yang et al., 2023; Chen et al., 2023b), data-augmentation (Cai et al., 2023; Ghosh et al., 2023), code generation (Li et al., 2023a), meta-learning (de Lichy et al., 2021; Li et al., 2022; Ma et al., 2022), knowledge distillation (Wang et al., 2021c; Chen et al., 2023a), contrastive learning (Das et al., 2022), and external knowledge including label definitions (Wang et al., 2021b), AMR graph (Zhang et al., 2021), and background

knowledge (Lai et al., 2021). In contrast to these methods, our approach formulates the task in a text-to-text framework. In addition, we introduce a new simple but effective self-validation module, which achieves competitive performance without external knowledge or domain adaptive training.

**Cycle Consistency.** Cycle consistency, namely structural duality, leverages the symmetric structure of tasks to facilitate the learning process. It has emerged as an effective way to deal with low-resource tasks in natural language processing. First

introduced in machine translation (He et al., 2016; Cheng et al., 2016; Lample et al., 2018; Mohiuddin and Joty, 2019; Xu et al., 2020) to deal with the scarcity of parallel data, cycle consistency has been expanded to other natural language processing tasks, including semantic parsing (Cao et al., 2019; Ye et al., 2019), natural language understanding (Su et al., 2019; Tseng et al., 2020; Su et al., 2020), and data-to-text generation (Dognin et al., 2020; Guo et al., 2020; Wang et al., 2023b). Recently, Iovine et al. (2022) successfully apply the cycle consistency to entity extraction by introducing an iterative two-stage cycle consistency training procedure. Despite these efforts, the non-differentiability of the intermediate text in the cycle remains unsolved, leading to the inability to propagate the loss through the cycle. To address this issue, Iovine et al. (2022) and Wang et al. (2023b) alternatively freeze one of the two models in two adjacent cycles. On the contrary, we introduce the gumbel-softmax estimator to avoid the non-differentiable issue. Additionally, we reduce the dual cycle training into end-to-end training to save time and computation resources.

## 8 Conclusion and Future Work

In this paper, we introduce a novel framework for chemical fine-grained entity extraction. Specifi-

cally, we target two unique challenges for few-shot fine-grained scientific entity extraction: mention coverage and long-tail entity extraction. We build a new self-validation module to automatically proof-read the entity extraction results and a novel decoder contrastive loss to reduce excessive copying. Experimental results show that our proposed model achieves significant performance gains on two datasets: ChemNER+ and CHEMET. In the future, we plan to explore incorporating an external knowledge base to further improve the model’s performance. Specifically, we plan to inject type definition into the representation to facilitate the entity extraction procedure. We will also continue exploring the use of constraint decoding to further improve entity extraction quality.

## 9 Limitations

### 9.1 Limitations of Data Collections

Both ChemNER+ and CHEMET are based on papers about Suzuki Coupling reactions from PubMed<sup>6</sup>. Our fine-grained entity extraction datasets are biased towards the topics and ontology provided by ChemNER+ and CHEMET. For example, CHEMET only focuses on the organic compounds. The number of available sentences is limited by the original dataset and our annotation efforts. We currently only focus on the English sentences. We only test our model on chemical papers (i.e., ChemNER+ and CHEMET) and Wikipedia (CrossNER). In the future, we aim to adapt our model for categories in other languages.

### 9.2 Limitations of System Performance

Our few-shot learning framework currently requires defining the entity ontology and few-shot examples before performing any training and testing. Therefore, due to patterns in the pretraining set, our model might produce mention types that don’t align with our predefined ontology. For instance, it may generate *Cyclopentadienyl compounds* instead of the predefined type *Cyclopentadienyl complexes*. Furthermore, the pretrained model might emphasize language modeling over accurately identifying entire chemical phrases. For example, it might recognize *Pd* in the catalyst *Pd(OAC)<sub>2</sub>* simply as a *transition metal*.

## A Training and Evaluation Details

	Avg. runtime	# of Parameters
RoBERTa	16min	125M
PubMedBERT	18min	109M
ScholarBERT	19min	355M
InBoXBART	58min	139M
+Valid	56min	279M
+Valid+CL	59min	279M

Table 11: Runtime (exclude CrossNER) and Number of Model Parameters

Our baselines and model are based on the Huggingface framework (Wolf et al., 2020)<sup>7</sup>. Our models are trained on a single NVIDIA A100 GPU.

<sup>7</sup><https://github.com/huggingface/transformers>

All hyperparameter settings are listed below. We optimize all models by AdamW (Loshchilov and Hutter, 2019). The runtime and number of parameters is listed in Table 11.

**RoBERTa.** We train a *RoBERTa-base* model with 100 epochs and a batch size 32. The learning rate is  $2 \times 10^{-5}$  with  $\epsilon = 1 \times 10^{-6}$ . We use a linear scheduler for the optimizer.

**PubMedBERT.** The PubMedBERT has the same model architecture as *BERT-base* with 12 transformer layers. The original checkpoint is pretrained on PubMed abstracts and full-text articles. We train a *microsoft/BiomedNLP-PubMedBERT-base-uncased-abstract-fulltext* model with 100 epochs and a batch size 32. The learning rate is  $2 \times 10^{-5}$  with  $\epsilon = 1 \times 10^{-6}$ . We use a linear scheduler for the optimizer.

**ScholarBERT.** The ScholarBERT is based on the same architecture as *BERT-large*. The original checkpoint is pretrained on 5,496,055 articles from 178,928 journals. The pretraining corpus has 45.3% articles about biomedicine and life sciences. We train a *globuslabs/ScholarBERT* model with 100 epochs and a batch size 32. The learning rate is  $2 \times 10^{-5}$  with  $\epsilon = 1 \times 10^{-6}$ . We use a linear scheduler for the optimizer.

**InBoXBART.** The InBoXBART is an instructional-tuning language model for 32 biomedical NLP tasks based on *BART-base*. We train the *cogint/in-boxbart* model with 100 epochs and a batch size 16. The learning rate is  $10^{-5}$  with  $\epsilon = 1 \times 10^{-6}$ . During decoding, we use beam-search to generate results with a beam size 5. We use cosine annealing warm restarts schedule (Loshchilov and Hutter, 2017) for the optimizer.

**InBoXBART+Valid.** We first pretrain the self-validation model, which is based on *cogint/in-boxbart*, on the training set. The learning rate for the self-validation module is  $1 \times 10^{-5}$  with  $\epsilon = 1 \times 10^{-6}$ . We use BLUE and ROUGE to select the best model. We then train the entity extraction model and the self-validation model jointly with cross-entropy  $\mathcal{L}_{\text{gen}}$  loss and reconstruction loss  $\mathcal{L}_{\text{recon}}$ . The final loss is  $\mathcal{L} = \mathcal{L}_{\text{gen}} + 5 \cdot \mathcal{L}_{\text{recon}}$ . The learning rate is  $5 \times 10^{-5}$  with  $\epsilon = 1 \times 10^{-6}$ . During decoding, we use beam-search to generate results with a beam size 5. We use cosine annealing warm restarts schedule (Loshchilov and Hutter, 2017) for the optimizer.

**InBoXBART+Valid+CL.** The final model is similar to *InBoXBART+Valid*. We retain the self-validation module and add a new decoder contrastive loss. The final loss is  $\mathcal{L} = \mathcal{L}_{\text{gen}} + 0.2 \cdot \mathcal{L}_{\text{cl}} + 5 \cdot \mathcal{L}_{\text{recon}}$ . We randomly choose 5 negative samples for each instance. The learning rate is  $5 \times 10^{-5}$  with  $\epsilon = 1 \times 10^{-6}$ . During decoding, we use beam-search to generate results with a beam size 5. We use cosine annealing warm restarts schedule (Loshchilov and Hutter, 2017) for the optimizer.

**AMR-based Mention Extraction.** We use AMR-parser (Fernandez Astudillo et al., 2020) to extract mentions. We treat all text spans that are linkable to Wikipedia as mentions.

**NNShot and StructShot.** We use the implementation from Ding et al. (2021) and choose *RoBERTa-base* as the language model.

**Evaluation Metrics.** We use entity-level micro-F1 for all experiments. We use the library from nereval <https://github.com/jantrienes/nereval>.

## B Dataset Details

We list the entity types of ChemNER+ and CHEMET below:

- ChemNER+: Transition metals, Organic acids, Heterocyclic compounds, Organometallic compounds, Reagents for organic chemistry, Inorganic compounds, Thermodynamic properties, Aromatic compounds, Metal halides, Organic reactions, Alkylating agents, Organic compounds, Coupling reactions, Functional groups, Inorganic silicon compounds, Stereochemistry, Organohalides, Chemical properties, Catalysts, Free radicals, Alkaloids, Coordination chemistry, Ligands, Organophosphorus compounds, Reactive intermediates, Substitution reactions, Inorganic carbon compounds, Organonitrogen compounds, Biomolecules, Coordination compounds, Halogens, Chemical elements, Chlorides, Elimination reactions, Organic redox reactions, Inorganic phosphorus compounds, Organic polymers, Macrocycles, Cyclopentadienyl complexes, Substituents, Name reactions, Spiro compounds, Chemical kinetics, Organometallic chemistry, Catalysis, Organosulfur compounds, Ring forming reactions, Noble gases, Protecting

groups, Addition reactions, Carbenes, Inorganic nitrogen compounds, Non-coordinating anions, Polymerization reactions, Carbon-carbon bond forming reactions, Isomerism, Enzymes, Oxoacids, Hydrogenation catalysts

- CHEMET: Acyl Groups, Alkanes, Alkenes, Alkynes, Amides, Amines, Aryl Groups, Carbenes, Carboxylic Acids, Esters, Ethers, Heterocyclic Compounds, Ketones, Nitriles, Nitro Compounds, Organic Polymers, Organohalides, Organometallic Compounds, Other Aromatic Compounds, Other Hydrocarbons, Other Organic Acids, Other Organic Compounds, Other Organonitrogen Compounds, Other Organophosphorus Compounds, Phosphinic Acids And Derivatives, Phosphonic Acids, Phosphonic Acids And Derivatives, Polycyclic Organic Compounds, Sulfonic Acids, Thiols

The frequency for each type in the training data of both ChemNER+ and CHEMET are listed below:

- ChemNER+: Organic compounds: 183, Coupling reactions: 171, Aromatic compounds: 136, Functional groups: 120, Heterocyclic compounds: 106, Catalysts: 70, Biomolecules: 66, Chemical elements: 64, Organohalides: 63, Transition metals: 56, Chemical properties: 55, Ligands: 55, Organic acids: 48, Thermodynamic properties: 43, Inorganic compounds: 43, Coordination compounds: 37, Stereochemistry: 33, Organometallic compounds: 33, Reagents for organic chemistry: 28, Coordination chemistry: 27, Organonitrogen compounds: 26, Organic reactions: 23, Organic polymers: 23, Substitution reactions: 21, Catalysis: 20, Organic redox reactions: 18, Reactive intermediates: 13, Substituents: 13, Halogens: 12, Addition reactions: 8, Chlorides: 6, Ring forming reactions: 6, Inorganic carbon compounds: 6, Enzymes: 6, Alkaloids: 4, Organophosphorus compounds: 4, Organosulfur compounds: 4, Oxoacids: 4, Elimination reactions: 3, Carbenes: 3, Inorganic phosphorus compounds: 2, Chemical kinetics: 2, Macrocycles: 2, Noble gases: 2, Organometallic chemistry: 2, Hydrogenation catalysts: 2, Metal halides: 1, Cyclopentadienyl complexes: 1, Inorganic nitrogen compounds: 1, Protecting groups:

1, Alkylating agents: 1, Polymerization reactions: 1

- CHEMET: Other Organic Compounds: 1705, Ethers: 934, Other Aromatic Compounds: 882, Heterocyclic Compounds: 792, Alkanes: 528, Amides: 516, Other Organonitrogen Compounds: 501, Organometallic Compounds: 495, Esters: 440, Amines: 431, Ketones: 406, Polycyclic Organic Compounds: 375, Aryl Groups: 363, Organohalides: 312, Alkynes: 281, Alkenes: 266, Organic Polymers: 255, Other Hydrocarbons: 236, Other Organic Acids: 194, Other Organophosphorus Compounds: 97, Acyl Groups: 78, Nitriles: 77, Carboxylic Acids: 62, Sulfonic Acids: 37, Nitro Compounds: 26, Carbenes: 9, Phosphonic Acids And Derivatives: 4, Thiols: 2

We consider the following types as long-tail entity types for ChemNER+ and CHEMET. We list both the entity type and its frequency:

- ChemNER+: Reactive intermediates: 13, Substituents: 13, Halogens: 12, Addition reactions: 8, Chlorides: 6, Ring forming reactions: 6, Inorganic carbon compounds: 6, Enzymes: 6, Alkaloids: 4, Organophosphorus compounds: 4, Organosulfur compounds: 4, Oxoacids: 4, Elimination reactions: 3, Carbenes: 3, Inorganic phosphorus compounds: 2, Chemical kinetics: 2, Macrocycles: 2, Noble gases: 2, Organometallic chemistry: 2, Hydrogenation catalysts: 2, Metal halides: 1, Cyclopentadienyl complexes: 1, Inorganic nitrogen compounds: 1, Protecting groups: 1, Alkylating agents: 1, Polymerization reactions: 1
- CHEMET: Alkynes: 281, Alkenes: 266, Organic Polymers: 255, Other Hydrocarbons: 236, Other Organic Acids: 194, Other Organophosphorus Compounds: 97, Acyl Groups: 78, Nitriles: 77, Carboxylic Acids: 62, Sulfonic Acids: 37, Nitro Compounds: 26, Carbenes: 9, Phosphonic Acids And Derivatives: 4, Thiols: 2

## C Evaluation on Whole Dataset

We conduct fully supervised training on all training sets. The results are listed in Table 12 and 13. We observe that the self-validation module

Model	Precision	Recall	F1
In-BoXBART	55.73	43.28	48.72
+ Valid	<b>57.49</b>	45.77	50.97
+ Valid + CL	57.41	<b>46.20</b>	<b>51.10</b>

Table 12: micro-F1 for ChemNER+ with the whole training set.

still improves the performance of the original In-BoXBART for two datasets. We observe that the decoder contrastive loss further improves the model performance on ChemNER+. However, adding the entity decoder contrastive loss slightly decreases it. Because there are 6561 sentences in the CHEMET dataset, which is larger than the ChemNER+ dataset, the model with the self-validation module already performs very well. Additionally, since the CHEMET model contains fewer entities per sentence than the ChemNER+ dataset and these entities are all organic compounds separated away from each other, the entity decoder contrastive loss might introduce noise into the generation results, consequently decreasing the performance.

Model	Precision	Recall	F1
In-BoXBART	64.94	41.62	50.73
+ Valid	<b>70.09</b>	<b>42.16</b>	<b>52.65</b>
+ Valid + CL	68.50	41.31	51.15

Table 13: micro-F1 for CHEMET with the whole training set.

## D Scientific Artifacts

We list the licenses of the scientific artifacts used in this paper: PMC Open Access Subset (Gamble, 2017)<sup>8</sup> (CC BY-NC, CC BY-NC-SA, CC BY-NC-ND licenses), Huggingface Transformers (Apache License 2.0), ChemNER (no license), CHEMET<sup>9</sup> (MIT license), RoBERTa (cc-by-4.0), PubMedBERT (MIT license), ScholarBERT (apache-2.0), BLEU<sup>10</sup>, ROUGE<sup>11</sup>, InBoXBART (MIT license), brat (MIT license), and nereval (MIT license). Our usage of existing artifacts is consistent with their intended use.

<sup>8</sup><https://www.ncbi.nlm.nih.gov/pmc/tools/openftlist/>

<sup>9</sup><https://github.com/chenkaisun/MMLI1>

<sup>10</sup><https://github.com/cocodataset/cocoapi/blob/master/license.txt>

<sup>11</sup><https://github.com/cocodataset/cocoapi/blob/master/license.txt>

## E Human Annotation

The instructions for human annotations can be found in the supplementary material. Human annotators are required to annotate the chemical compound entities mentioned either in natural language or chemical formulas and other chemical related terms including reactions, catalysts, etc. We recruit two senior Ph.D. students from the Chemistry department in our university to perform human annotations. We use brat (Stenetorp et al., 2012) for all human annotations.

## F Ethical Consideration

The Chem-FINESE model and corresponding models we have designed in this paper are limited to the chemical domain, and might not be applicable to other scenarios.

### F.1 Usage Requirement

Our Chem-FINESE system provides investigative leads for few-shot fine-grained entity extraction for the chemical domain. Therefore, the final results are not meant to be used without any human review. However, domain experts might be able to use this tool as a research assistant in scientific discovery. In addition, our system does not perform fact-checking or incorporate any external knowledge, which remains as future work. Our model is trained on PubMed papers written in English, which might present language barriers for readers who have been historically underrepresented in the NLP/Chemical domain.

### F.2 Data Collection

Our ChemNER+ sentences are based on papers from PMC Open Access Subset. Our annotation is approved by the IRB at our university. All annotators involved in the human evaluation are voluntary participants and receive a fair wage. Our dataset can only be used for non-commercial purposes based on PMC Open Access Terms of Use.

# GPTs Are Multilingual Annotators for Sequence Generation Tasks

## Abstract

Data annotation is an essential step for constructing new datasets. However, the conventional approach of data annotation through crowdsourcing is both time-consuming and expensive. In addition, the complexity of this process increases when dealing with low-resource languages owing to the difference in the language pool of crowdworkers. To address these issues, this study proposes an autonomous annotation method by utilizing large language models, which have been recently demonstrated to exhibit remarkable performance. Through our experiments, we demonstrate that the proposed method is not just cost-efficient but also applicable for low-resource language annotation. Additionally, we constructed an image captioning dataset using our approach and are committed to open this dataset for future study. We have opened our source code for reproducibility.<sup>1</sup>

## 1 Introduction

With the evolution of deep learning methods, various tasks in the NLP domain have demonstrated remarkable performance. However, training deep learning models requires a substantial amount of labeled data. Data annotation, a process of gathering unlabeled data and labeling them, plays a crucial role in fulfilling this data demand.

However, as the conventional procedure of data annotation is mainly conducted manually using human annotators, it cannot meet the growing demand for labeled data with an increase in the size of deep learning models (Qiu et al., 2020). Moreover, it is significantly challenging to recruit annotators for low-resource languages (Pavlick et al., 2014).

To address the lack of labeled data and improve the performance of the model, the concept of pre-trained language model (PLM) was introduced.

These PLMs have been trained on a large amount of text corpus to acquire a general knowledge of languages (Radford et al., 2018; Devlin et al., 2019). By fine-tuning these models to specific downstream task, it was able to achieve performance improvement without the need for additional labeled data.

With the evolution of PLMs via the enlargement of their sizes owing to increased training data, the development of a large language model (LLM) with massive parameter size enabled few-shot learning from the context of the given prompt (Brown et al., 2020). Accordingly, the diverse capabilities of LLMs have been investigated (Zhao et al., 2023).

However, despite their impressive abilities and adaptability, these LLMs cannot be actively exploited for downstream tasks because of the cost constraints and demand for hardware resources caused by their extensive model size. Additionally, fine-tuning these models for specific purposes remains challenging due to their massive parameter size. Consequently, training models for downstream tasks through labeled data is still the dominant approach for practical applications (Yu et al., 2023).

Data annotation refers to the creation of labeled data by assigning gold labels to unlabeled data. Traditionally, data annotation was mainly conducted by human labelers using crowdsourcing platforms, such as Amazon mechanical turk (MTurk), and these platforms have aided the creation of modern, large-scale datasets. Recently, to address these limitations of crowdsourcing-based data annotation and achieve a cost-efficient means to collect labeled data, several studies have proposed the utilization of LLMs as alternative annotators in place of human labelers (Wang et al., 2021; Ding et al., 2023; Gilardi et al., 2023; Jiao et al., 2023; Li et al., 2023; Zhang et al., 2023; He et al., 2023; Bansal and Sharma, 2023). These studies have shown the possibility of cost-efficient and automatic data annotation through LLMs, such as GPT-3.

<sup>1</sup><https://github.com/c-juhwan/gpt-multilingual-annotator>

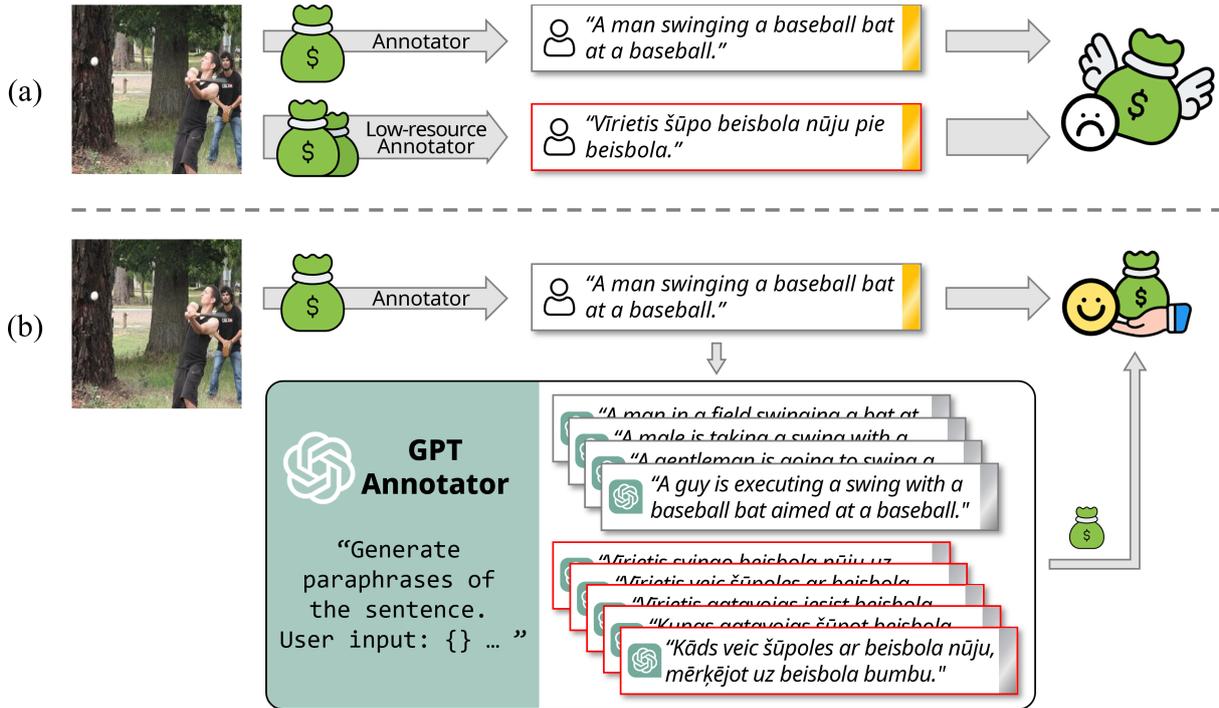

Figure 1: Overall concept of our GPT annotator. (a) Conventional annotation process for image captioning task, which is performed by multiple human annotators and expensive. Moreover, it is more expensive to hire human annotators for low-resource languages. (b) The annotation process of proposed GPT annotator. With one gold caption by a single human annotator, the GPT annotator automatically generates silver captions, as well as captions in other languages, resulting in a cost-efficient dataset construction.

However, as these existing studies mainly focused on simple tasks, such as text classification, additional investigation is required to apply these approaches to numerous subtasks of natural language processing. Moreover, the potential of automatic data annotation via LLMs has not been explored for languages other than English. As previously highlighted, projects in low-resource languages may suffer from the high cost of data annotation, necessitating the need for automatic annotators for languages beyond English.

In this study, we proposed a strategy that leverages LLMs as an assistant annotator to aid human annotators in image captioning task and text style transfer task. As depicted in Figure 1, the conventional process of establishing datasets for image captioning task required a considerable number of human annotators to generate five gold annotations for each image, resulting in a high cost for dataset construction in languages beyond English. Moreover, the quality of the annotated data varies depending on the proficiency of the human annotators (Rashtchian et al., 2010). Similarly, the annotation process for text style transfer required significant human effort, including quality control

(Rao and Tetreault, 2018; Briakou et al., 2021).

This study demonstrated the ability of LLMs to serve as assistant annotators for human annotators at a reasonable cost by generating multiple silver sentences for each gold annotation written by one single human annotator. Specifically, we proposed a cost-efficient process to construct multilingual language datasets by exploiting the GPT annotator. Particularly, we utilized GPT-4, which exhibits enhanced multilingual capabilities (OpenAI, 2023), to autonomously produce diverse sentences in another language from a single English sentence, even if the human annotator is not familiar with the target language. Moreover, the cost of the GPT annotator is constant as the cost is determined by the length of the processed token, regardless of the language. This highlights the efficiency of the proposed GPT annotator as an annotation method for low-resource language, which is more expensive and time-consuming compared to English.

Employing this method, we developed an image captioning dataset in Latvian, Estonian, and Finnish — which are well-known low-resource languages — by employing the GPT annotator. In this scenario, a single human annotator, who lacks

knowledge of the target language, provides one English gold caption for each image. Through the experiment, we demonstrated that the proposed method achieves better performance compared to machine translation method. We open these datasets to support future studies. Additionally, we release software to easily perform data annotation process described in this paper.

Our contributions are summarized as follows:

- To the best of our knowledge, this is the first work to explore the possibility of LLM as a multilingual annotator.
- To the best of our knowledge, this is the first study to employ LLM as an automatic annotator for image captioning task and text style transfer task.
- Our experiment reveals the ability of GPT annotators to serve as human annotators at a reasonable cost.
- We release an annotation software to easily perform the method described in the paper, as well as three image captioning datasets in Latvian, Estonian, and Finnish.

## 2 Related Work

GPT-3 has demonstrated that LLMs can conduct in-context learning from few-shot prompts. Accordingly, various LLMs with different characteristics have been proposed (Zhao et al., 2023). For example, based on the findings that LLMs can be further enhanced via human instruction and feedback (Ouyang et al., 2022), ChatGPT<sup>2</sup> and its backbone GPT-3.5 with various abilities have emerged (Leiter et al., 2023; Yang et al., 2023; Liu et al., 2023). In addition, the cutting-edge GPT-4 (OpenAI, 2023) is a progressed version of GPT-3.5, with a longer input sequence, improved multilingual ability, and image inception ability.

With the advancement of LLMs, studies have been conducted to augment given human-annotated data (Yoo et al., 2021; Whitehouse et al., 2023), or to annotate unlabeled data and train models for downstream tasks. One of the early studies in this field (Wang et al., 2021) proposed an automatic annotation method that demonstrated the ability of GPT-3 to annotate a greater amount of data compared to human annotators at a lower labeling cost,

resulting in higher performance at the same cost, and this strategy was observed to outperform GPT-3 itself. In addition, the study investigated the possibility of a collaboration between human and GPT annotators by leveraging the confidence of the automatic annotation of GPT to perform active labeling by human annotators.

Following this approach, subsequent studies expanded the annotation capabilities of GPT-3 to not just label unlabeled data but also create labeled data leveraging external knowledge, or even from scratch (Ding et al., 2023). Meanwhile, a methodology was proposed to transfer the abilities of LLMs into a smaller model by generating a rationale for the labeled data, enhancing the performance of the small model (Hsieh et al., 2023).

With the emergence of ChatGPT, an improved version of GPT-3 that enables enhanced flexibility across diverse tasks, researchers have proposed its application for data annotation. ChatGPT has been reported to outperform crowdworkers in text classification tasks in certain cases with the same instructions (Gilardi et al., 2023). Additionally, studies observed that ChatGPT even surpassed expert labelers in the annotations of political texts (Törnberg, 2023). These results have led researchers to examine the annotation abilities of ChatGPT across various domains (Zhu et al., 2023).

Recent studies have expanded the application of LLMs as annotators, from language understanding tasks, such as text classification or inference, to text generation tasks. For example, a previous study reported improved performance in query-focused summarization by reducing the noise of ChatGPT (Laskar et al., 2023). Additionally, dialogue generated by ChatGPT has been observed to demonstrate comparable quality to reference dialogues written by human annotators (Labruna et al., 2023).

These studies indicate the capability of LLMs, including ChatGPT, to perform as an effective annotator for not just text understanding tasks but also text generation tasks, which are more complex and challenging to annotate. However, the application of these abilities of LLMs to various natural language processing tasks is still limited and underexplored. In this study, we proposed an LLM-based annotation method for image captioning task and text style transfer task, which has not been investigated in previous studies. Furthermore, we validated the feasibility of LLMs as an autonomous multilingual annotator, which has not been explored in previous works.

---

<sup>2</sup><https://openai.com/blog/chatgpt>

### 3 Method

#### 3.1 Task Formulation

We first define a dataset  $D$ , which is composed of the data pair  $d = (X, Y)$ . In image captioning task,  $X$  denotes a given image and  $Y = \{y_{g_1}, y_{g_2}, \dots, y_{g_5}\}$  is corresponding captions that describe  $X$ . In this paper,  $g$  means ‘‘gold’’, which represents a human-annotated sentence. Similarly, in text style transfer task,  $X$  denotes the original sentence and  $Y_g$  indicates human-annotated pair sentence with desired style.

Traditionally, multiple human annotators are used to write descriptions for unannotated data  $X$  to construct such datasets, especially for image captioning, which requires multiple captions for each image. However, as previously discussed, this entirely human-based annotating process is expensive and time-consuming. Our GPT annotator aims to construct a data pair by autonomously generating silver sentences and reduce the time and cost consumption of data annotation process.

Additionally, we explore the multilingual ability of the GPT annotator. The cost of data annotation varies by language. Especially, Low-resource languages are associated with higher cost and high time consumption for the collection of annotated data (Ul Haque et al., 2021; Guemimi et al., 2021; Li et al., 2019; Kim et al., 2021). This phenomenon is caused by the language pool of the crowdworkers (Pavlick et al., 2014) and the difficulty of training low-resource language natives (Lin et al., 2018). In this study, we propose a method to employ the GPT annotator as a multilingual annotator through the adaptation of GPT-4, which has significantly improved multilingual ability (OpenAI, 2023).

#### 3.2 Assistant Multilingual Annotator for Image Captioning Task

To achieve the aforementioned goal, we synthesized the given human-annotated caption  $y_{g_1}$  by utilizing the GPT model, and generated a set of paraphrases  $\{y_{s_2}, \dots, y_{s_5}\}$  based on  $y_{g_1}$ .

We configured a well-designed prompt  $P$ , as the input for GPT to achieve this object. As it has been reported that LLMs perform significantly better with examples rather than zero-shot (Brown et al., 2020), the prompt  $P$  includes an one-shot desired example. The process of generating sentences through GPT can be expressed as follows.

$$\{y_{s_2}, \dots, y_{s_5}\} = \text{GPT}(P, y_{g_1}) \quad (1)$$

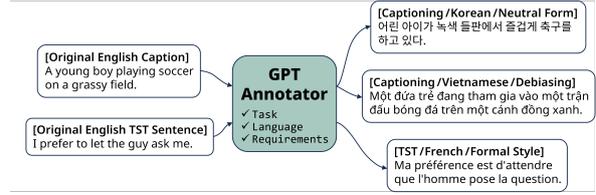

Figure 2: Our GPT annotator can generate various datasets with configurable prompts, primarily regarding task, language, and specific requirements.

The machine-annotated caption produced in Eq. 3 is used to construct a new data pair,  $d' = (X, y_{g_1}, y_{s_2}, \dots, y_{s_5})$ , and a downstream task model is trained using dataset  $D'$ , a collection of these  $d'$ . Consequently, GPT can be used to assist human annotators with image captioning task.

In addition, to employ our GPT annotator as multilingual annotator, it first synthesizes a data pair with one single human annotation in English,  $d^{src} = (X, y_{g_1}^{eng})$  to reduce the cost of hiring multiple human annotators. Secondly, the GPT annotator generates a set of paraphrases in a target language  $\{y_{s_1}^{tgt}, \dots, y_{s_5}^{tgt}\}$ . This process is performed through a prompt  $P^{tgt}$  with information in the target language, including a one-shot desired example. We found it helpful to jointly generate English sentence and its translation rather than solely generate sentences in the target language, as English sentence guides the generation of target language sentence. Specific prompts can be found in Appendix F.1. The described process can be expressed as follows.

$$Y_{tgt} = \{y_{s_1}^{tgt}, \dots, y_{s_5}^{tgt}\} = \text{GPT}(P^{tgt}, y_{g_1}^{eng}) \quad (2)$$

The dataset in target language  $D^{tgt}$  can be constructed through  $d^{tgt} = (X, Y^{tgt})$  obtained by the GPT annotator, and a downstream task model in the target language can be trained using this  $D^{tgt}$ . This overall process enables the construction of a dataset  $D^{tgt}$  in any designated language with only one single annotation in English by utilizing the LLM. Furthermore, this process is performed without any intervention of a human annotator who is fluent in the target language, reducing the cost of hiring expert annotators in the target language.

#### 3.3 Assistant Multilingual Annotator for Text Style Transfer Task

For text style transfer task, we first analyze the given data pair  $d^{src} = (X^{eng}, Y_g^{eng})$  written in English through the GPT annotator. Next, the

GPT annotator creates a translated version of the pair and its paraphrase in target language,  $d_1^{tgt} = (X_{s_1}^{tgt}, Y_{s_1}^{tgt})$  and  $d_2^{tgt} = (X_{s_2}^{tgt}, Y_{s_2}^{tgt})$ . This generation of paraphrase allows to fully utilize given annotation and effectively construct a dataset in target language with a limited amount of annotated data.

Similarly to image captioning task, we configured a well-designed prompt  $P^{tgt}$  for the annotation process, including an one-shot example. Specific prompts can be found in Appendix F.2. The process described in this section can be formulated as follows.

$$\{d_1^{tgt}, d_2^{tgt}\} = \{(X_{s_1}^{tgt}, Y_{s_1}^{tgt}), (X_{s_2}^{tgt}, Y_{s_2}^{tgt})\} \\ = \text{GPT}(P^{tgt}, (X_g^{eng}, Y_g^{eng})) \quad (3)$$

We could acquire text style transfer dataset  $D^{tgt}$  in the target language through this process.

## 4 Experiment

### 4.1 Experimental Design

This section describes experimental design to validate the effectiveness of our GPT annotator in each tasks. We primarily assessed our method based on the performance of the model trained on the downstream task, which can serve as an indirect measure of the quality of synthesized dataset (Ye et al., 2022). Further implementation details can be found in Appendix A.

#### 4.1.1 Image Captioning Task

To assess the cost-efficiency of our GPT annotator, we evaluated the proposed GPT annotator through three different image captioning datasets: Flickr8k (Rashtchian et al., 2010) dataset was constructed by annotating approximately 8,000 images collected from Flickr via MTurk. Flickr30k (Young et al., 2014) dataset is an extension of Flickr8k dataset, and it consisted of 30,000 images with captions acquired through crowdsourcing. MSCOCO (Lin et al., 2014; Chen et al., 2015) dataset is an annotated dataset of more than 160,000 images.

As Flickr8k and Flickr30k datasets do not provide explicit validation and test sets, we divided them in the ratio of 8:1:1. For the MSCOCO dataset, we utilized the COCO 2014 split, which consists of approximately 82,000 training data, 40,000 validation data, and 40,000 test data. To validate the effectiveness of the proposed method, we set up a scenario with only one gold caption per

image by selecting only one caption for the original dataset.

BLEU (Papineni et al., 2002), ROUGE (Lin, 2004), and METEOR (Denkowski and Lavie, 2014) metrics were measured through the NLG-EVAL library (Sharma et al., 2017) for evaluation. Additionally, we also employed BERTScore (Zhang et al., 2020) and BARTScore (Yuan et al., 2021) for model-based evaluation. For the MSCOCO dataset, the performance was evaluated through the official evaluation server.<sup>3</sup> For multilingual experiments, we adapted different datasets for each language, a subset of the aforementioned datasets with annotated captions. These datasets will be accordingly discussed in each section. We report the average performance of the model trained on three different random seeds, except the result on MSCOCO 2014 dataset.

#### 4.1.2 Text Style Transfer Task

For text style transfer task, we conducted our experiments based on XFormal (Briakou et al., 2021) dataset, which encompasses French, Brazilian Portuguese, and Italian. First, we selected 6,000 data for the GYAFC (Rao and Tetreault, 2018) dataset, an English dataset that performs the same text formality style transfer, and translated them into each language using the NLLB (Costa-jussà et al., 2022) model and Google Translator<sup>4</sup> to build a baseline dataset. Second, we built a dataset with only 3,000 English data using our GPT Annotator as it generates two target language data for each English data. Using each dataset built by the Translation model and GPT Annotator respectively, we fine-tuned mBART (Tang et al., 2021) model to perform text style transfer task, and compared its performance and the formality of the generated text. Similarly to image captioning task, NLG-EVAL library, as well as BERTScore and BARTScore were deployed for measuring metrics. Throughout the manuscript, we report the average performance of the model trained on three different random seeds.

### 4.2 Cost-Efficiency of GPT Annotator

Based on the concept of a previous study (Wang et al., 2021), we evaluated the difference in the performance of human annotators and GPT annotator under a fixed budget. The previous study (Rashtchian et al., 2010) suggested that it takes

<sup>3</sup><https://codalab.lisn.upsaclay.fr/competitions/7404>

<sup>4</sup><https://translate.google.com>

<b>Flickr8k</b>	BLEU	ROUGE	METEOR	BERTS.	BARTS.

<b>Flickr30k</b>	BLEU	ROUGE	METEOR	BERTS.	BARTS.
Human Annotator w/ Limited Budget	25.72	34.14	15.66	0.7539	-18.350
Synonym Replacement	26.78	35.28	15.54	0.7556	-18.329
Back-Translation	27.32	36.70	15.67	0.7591	-18.321
HRQ-VAE	20.94	27.53	12.97	0.7385	-18.542
GPT Annotator w/ GPT-3.5	30.57	37.68	16.02	0.7669	-18.298
<b>MSCOCO 2014</b>	BLEU	ROUGE	METEOR	BERTS.	BARTS.
Human Annotator w/ Limited Budget	40.40	46.60	18.90		
Synonym Replacement	45.10	50.30	23.90		
Back-Translation	41.35	46.70	21.80		
HRQ-VAE	45.59	50.10	24.20		
GPT Annotator w/ GPT-3.5	46.38	50.40	24.50		

Table 1: Experimental results to validate the cost-efficiency of the proposed GPT annotator. We only report BLEU, ROUGE, and METEOR for MSCOCO 2014 dataset as the official evaluation server does not provide BERTScore and BARTScore result.

0.05\$ to create five gold captions per image, which is equivalent to 0.01\$ for each gold caption. In the experiment, approximately 1000 tokens were used to generate annotated data pair.

According to this cost analysis, the method proposed in this study required 0.012\$ to generate one gold caption and four silver captions for each image using GPT-3.5, as it takes approximately 1,000 tokens to generate silver captions.<sup>5</sup> Based on this configuration, it would cost approximately 76.8\$ to exploit GPT annotator to annotate the 6,400 images in the Flickr8k train set. In contrast, only 1,500 images can be annotated by purely human annotators under the same fixed budget. Similarly, for Flickr30k dataset, annotating 24,000 train data using the proposed method would cost approximately 288\$, whereas for the same amount, human annotators can only annotate 5,800 images to generate five gold captions. Following the same configuration, in the MSCOCO dataset, only 19,680 images can be annotated by human annotators under the budget that can annotate 82,000 images with GPT annotator.

Under this scenario, we compared the results of training the model by selecting only 1,500 fully human-annotated data from Flickr8k dataset, 5,800 fully human-annotated data from Flickr30k

<sup>5</sup>As of the time of this study, GPT-3.5 charged 0.002\$ per 1000 tokens. Currently, it charges 0.001\$ per 1000 tokens of prompt and 0.002\$ per 1000 tokens of generation.

dataset, and 19,680 fully human-annotated data from MSCOCO dataset with the results obtained by training the model using the GPT-annotated data for the entire images of each dataset. Additionally, we also exploited other data augmentation baselines such as synonym replacement (Zhang et al., 2015), Back-Translation (Sennrich et al., 2016) and HRQ-VAE (Hosking et al., 2022) to augment one gold data for extensive comparison.

Table 1 shows the results of the experiment. The experimental results suggest that under the same budget, annotating a larger number of images with one gold caption and multiple silver captions resulted in improved performance compared to annotating a smaller number of images with multiple gold captions using only human annotators. This outcome is consistent with the findings of previous work (Wang et al., 2021), indicating the cost efficiency of GPT annotators, and indicates that these characteristics of GPT annotators are applicable to a wider range of tasks including image captioning. Furthermore, GPT annotator has shown superior performance against other augmentation baselines, suggesting that GPT annotator can generate better and diverse sentences.

### 4.3 Multilingual Experiment

#### 4.3.1 Korean Experiment

Korean is a language that is attracting increasing attention owing to its approximately 80 million native speakers and rising Korean content. Nevertheless, the resource to fulfill this demand is limited (Gu et al., 2018; Sennrich and Zhang, 2019; Kim et al., 2021; Sahoo et al., 2023). For example, there is no dedicated Korean dataset for the image captioning task. Although there are data that applied machine translation to existing English datasets, they are not fully open and have limited availability.<sup>6</sup>

Considering these characteristics of the Korean language, we first evaluated the multilingual ability of the proposed method based on Korean. In this experiment, we assessed the effectiveness of a Korean image captioning model which was trained on two separate datasets: the AiHub dataset, which applies machine translation to the English dataset, and the Korean dataset constructed by GPT-4 using the approach described in this study. Due to the absence of dedicated evaluation set for a fair

<sup>6</sup><https://aihub.or.kr> operated by the Korean government offers a machine-translated version of COCO captioning dataset; however, the public usage of this dataset is limited as it is only available to Korean citizens.

Korean	Precision $\uparrow$	Recall $\uparrow$	Fluency $\downarrow$	THUMB $\uparrow$
AiHub (Machine-Translated)	4.3	4.09	0.03	4.17
GPT Annotator w/ GPT-4	4.72	4.59	0.02	4.64

Table 2: Human evaluation results of the validation of the effectiveness of the proposed GPT annotator on Korean language. We follow the evaluation process and metric of THUMB (Kasai et al., 2022), and report the average THUMB score of three Korean native speakers. Please refer to Appendix C for quantitative analysis.

comparison, human evaluation was conducted on 100 captions generated by each model from the test image set. The human evaluation was performed in accordance with the previously proposed protocol (Kasai et al., 2022), and we report the average THUMB score of three Korean native speakers.

Table 2 presents the results of the human evaluation. The outcomes of the evaluation indicate that the model trained on the dataset using GPT annotator performed better than the machine-translated dataset in terms of ratings by humans. In addition, our GPT annotator demonstrated a lower penalty on fluency, which suggests that our method generates more natural sentences.

These evaluation results confirmed that the model can achieve improved performance when trained with the dataset constructed using the method proposed in this study. Furthermore, as our GPT annotator generates five Korean captions using only one gold English caption by a human annotator, it is more cost-efficient compared to applying machine translation to five gold captions in English. Moreover, our GPT annotator has additional advantages that could ensure consistency in sentence structure compared to machine translation. Specifically, we instructed the annotator to generate sentences in the neutral form (“-하다”) rather than the polite form (“-합니다”) through the prompt. We can maintain consistency in tone and style of the dataset through this configuration, leading to better for the quality of the annotated data and reduce the need for post-processing and human intervention.

### 4.3.2 Vietnamese Experiment

Vietnamese also has more than 85 million native speakers, but suffering from lack of annotated data (Ngo et al., 2020; Huynh et al., 2022). To demonstrate the versatility of our approach in another language, we expanded our experiments to Vietnamese. For the experiment, we adapted UiT-ViC

Vietnamese	BLEU	ROUGE	METEOR	BERTS.	BARTS.

HRQ-VAE + NLLB	21.26	28.64	23.48	0.7720	-15.342
Google Translator	37.22	46.24	26.86	0.8196	-14.534
GPT Annotator w/ GPT-4	41.32	47.83	30.57	0.8235	-14.537

Table 3: Experimental results in Vietnamese based on UiT-ViC dataset.

dataset (Lam et al., 2020). This dataset consists of images selected from the MSCOCO dataset relating to sports, each with five Vietnamese captions manually annotated by a human annotator. We applied NLLB model and Google Translator to build a baseline by translating English captions from the original MSCOCO dataset into Vietnamese. Additionally, we adopted the data generated by HRQ-VAE in Section 4.2 and translated them into Vietnamese using NLLB model.

Table 3 presents the results on Vietnamese. The experimental result suggests that our approach is valid in Vietnamese, leading to better performance of the model compared to a machine translation-based approach.

### 4.3.3 Polish Experiment

Polish is another language that has challenge of low-resource language (Dadas et al., 2020; Augustyniak et al., 2022). To further validate our method’s applicability, we also conducted experiments on the AIDe dataset for Polish (Wróblewska, 2018). This dataset is composed of 1,000 images selected from the Flickr8k dataset, each with two human-annotated captions in Polish. For this experiment, we configured our prompt to generate two caption pairs for each image. Similarly to Vietnamese experiment, for the Polish translation baseline, we utilized the NLLB model and Google Translator to translate two English captions from the original Flickr8k dataset into Polish. We also adopted the data generated by HRQ-VAE in Section 4.2 and translated them into Polish using NLLB model.

Table 4 indicates the results on Polish. The experimental result demonstrates the effectiveness of our approach, showcasing not just better performance compared to translation baseline but also comparable performance to human-annotated data.

Table 5: Experimental results on text style transfer in French, Brazilian Portuguese, and Italian.

#### 4.4 Text Style Transfer Experiment

Table 5 presents the experimental result of our GPT annotator for text style transfer task in French, Brazilian Portuguese, and Italian. The results not only highlight the performance of our GPT Annotator with fewer original human-annotated samples but also underscore its ability to enhance text formality against translation. This achievement was possible through the consistent generation of sentences with formal and informal styles, owing to the flexibility of LLMs and instructible prompts.

#### 4.5 Employing GPT Annotator for Dataset Construction

Latvian, Estonian, and Finnish have approximately 1.5, 1.1, and 4.8 million native speakers, which make them hard to hire annotators and construct datasets. To address the practical challenges in the field of data annotation, we constructed an image captioning dataset in these languages, which did not have any image captioning dataset, using our GPT annotator. We first selected 3,850 images and their English captions from the MSCOCO dataset and split them into 2,695 train images, 924 validation images, and 231 test images, following the configuration of the Vietnamese UiT-ViIC dataset.

To build a baseline, we utilized NLLB and Google Translator to translate the English caption

Latvian	BLEU	ROUGE	METEOR	BERTS.	BARTS.
NLLB (Machine-Translated)	6.39	17.53	10.13	0.6803	-16.061
HRQ-VAE + NLLB	5.14	16.61	10.21	0.6728	-16.127
Google Translator	8.53	17.09	10.67	0.6848	-16.067
GPT Annotator w/ GPT-4	10.35	18.61	10.79	0.6911	-16.054
Estonian	BLEU	ROUGE	METEOR	BERTS.	BARTS.

Google Translator	4.28	10.84	7.88	0.7128	-16.394
GPT Annotator w/ GPT-4	4.96	12.29	8.64	0.7143	-16.389

Table 6: Experimental results of our constructed dataset in Latvian.

of each training image, similar to previous experiments. The validation and test captions were constructed by translating using mBART model, for a fair comparison.

Table 6 clearly showcases the efficiency of our GPT annotator when human-annotated data is scarce, as observed in case of these low-resource languages. The human investigation of annotated data remains for future work. We plan to release the training, validation, and testing datasets for wider access and further study. This experimental result demonstrates the possibility of the GPT annotator to easily construct dataset in any designated language, enhancing the accessibility of various languages.

## 5 Conclusion

In this study, we have demonstrated the possibility of exploiting LLM as a multilingual assistant annotator by generating multiple silver data from a single gold data in different languages. The experimental results showcased that the proposed method is cost-efficient compared to entirely human annotation, and can be effectively employed to construct datasets in various languages and tasks.

The approach described in this work can be widely adapted to various languages, as it utilizes the multilingual fluency and flexibility of LLMs. We constructed an image captioning in Latvian as a practical application of our GPT annotator. Furthermore, the cost-efficiency of the GPT annotator suggested in this paper will be improved in the future, as the price of LLMs is expected to decline as recent cost reductions of GPT-3.5 and GPT-4 have

shown. Future studies will focus on improving the proposed method by utilizing the image inception ability and expanding this method to other tasks.

## Limitations

Extreme low-resource languages may still encounter difficulty producing high-quality sentences even with the use of GPT-4. To examine the responses of GPT-4 in translating into extremely low-resource languages, we conducted an error analysis in two extremely low-resource languages, Basque and Māori. Basque has a small amount of speakers, and it is also a unique language isolate, that does not have a distinct relationship with other languages such as Spanish and French, making it harder to process. Māori has a very small amount of language users, posing a challenge as an extremely low-resource language. Please refer to Appendix E.7 for the analysis result.

Additionally, the approach demonstrated in this work generates silver sentences as paraphrases of the given gold sentences, thus they might not fully capture the information that exists in the image but is not mentioned in the gold sentences. Consequently, the gold captions produced by multiple human annotators can be more diverse than silver captions. To address this issue, human annotators could create gold captions that contain as much detailed and diverse information as possible while constructing a new dataset through this method.

## Ethics Statement

As this work proposes the utilization of LLMs as an assistant data annotator and for the automatic generation of sentences, it may suffer from the potential bias of LLMs. To mitigate this concern, we added explicit instructions to prevent the generation of biased sentences in the prompts. However, the human supervisor is still essential to examine and validate the absence of biased expressions in the generated data. Specifically, the human supervisor should ensure that there is not any biased gold sentence produced by the human annotator, as it directly affects the bias of generated sentences using LLMs.

Furthermore, in addition to the error analysis presented in the previous section, we have conducted supplementary error analysis on Basque and Māori languages in Appendix E.8. This additional investigation aims to explore the potential ethical biases exhibited by GPT-4. Our findings suggest

that GPT-4 may exhibit unexpected ethical biases, particularly in extremely low-resource languages, where its knowledge about the language may be limited compared to high-resource languages such as English.

## A Implementation Details

### A.1 Model Implementation

PyTorch (Paszke et al., 2019) and Huggingface Transformers library (Wolf et al., 2020) have been employed for the implementation process.

For image captioning task, Vision Transformer (ViT) (Dosovitskiy et al., 2021) and Transformer (Vaswani et al., 2017) were deployed as the encoder and decoder of the model, respectively. Particularly, pretrained *vit\_b\_16* from torchvision library (mainainers and contributors, 2016) was adapted as an encoder, and the decoder consisted of 12 heads and

12 layers, with a hidden layer size and embedding layer size of 768.

For text style transfer task, we fine-tuned *mbart-50-large* model using each dataset to convert informal text into formal text. Additionally, we separately trained another mBART model as formality classifier using XFormal training data for each language to measure the formality of the generated text. The text formality was measured by the average logit of the classifier.

Every model was trained using AdamW (Loshchilov and Hutter, 2018) with a batch size of 16 and a learning rate of 5e-5 through 10 epochs, while the weight decay of the optimizer was set to 1e-5, and a CosineAnnealingLR (Loshchilov and Hutter, 2017) scheduler was deployed.

## A.2 GPT Annotator Implementation

We utilized the official API from OpenAI to implement the proposed GPT annotator. The versions of the models used are *gpt-3.5-turbo-0301* and *gpt-4-0314*, respectively. The prompts used can be found in Appendix F. If an error occurred while generating an annotation using a given prompt, the API was called again with a patience of three times. If this patience was exceeded, the data pair was excluded from the annotation process.

## A.3 Further Details

We employed the *facebook/nllb-200-distilled-600M* model, which comprises 600M parameters, to create a training dataset using the NLLB baseline. Similarly, we utilized the *facebook/mbart-large-50-many-to-many-mmt* model, with approximately 611M parameters, to construct validation and test sets for Latvian, Estonian, and Finnish. This choice was made to ensure a fair and equitable comparison between the baseline models and our proposed GPT annotator. For evaluation with BERTScore (Zhang et al., 2020) and BARTScore (Yuan et al., 2021), we exploited *bert-base-multilingual-cased* and *facebook/mbart-large-50*, respectively. Note that we reported BERTScore-F1 in the manuscript.

Label smoothing (Szegedy et al., 2016) was applied with a smoothing epsilon of 0.05. The training procedure was conducted on a single Nvidia RTX 3090 GPU.

For the tokenizing of text input, we employed tokenizer of pre-trained model available on Huggingface for each language. Specifically, *facebook/bart-base*, *cosmoquester/bartko-base*, *vinai/bartpho-syllable*, *sdadas/polish-*

*bart-base*, and *joelito/legal-latvian-roberta-base, tartuNLP/EstBERT, TurkuNLP/bert-base-finnish-uncased-v1* were adapted as the tokenizer for English, Korean, Vietnamese, Polish, Latvian, Estonian, and Finnish. For text style transfer task, as it is based on *facebook/mbart-large-50* model, each language shares same tokenizer.

For the test procedure of the Flickr8k and Flickr30k datasets, all five available human-annotated captions of the test set were utilized as reference sentences for evaluation. Beam search (Freitag and Al-Onaizan, 2017) was applied as a decoding strategy to generate sentences at inference time, with a beam size of 5.

## B GPT Annotator Software

In order to streamline the annotation process outlined in this paper, we have developed specialized software tailored for multilingual data annotation, leveraging OpenAI GPT models. This software currently supports tasks such as image captioning, text style transfer, and machine translation. Although these functionalities are not discussed in detail in this paper due to space constraints, they are available within the software.

The annotator software takes a JSON file as input and generates a new JSON file containing multilingual annotations in the target language. This is achieved by utilizing the specified prompt and the chosen version of the GPT model. Moreover, the software is designed to facilitate faster data annotation through multiprocessing capabilities. For a more comprehensive understanding of the software’s functionality, please refer to the attached code.

## C Quantitative Experiments on Korean

We have included the human evaluation results in Table 2 within the main manuscript. This was done because there is no dedicated evaluation set available in Korean, which is essential for a fair evaluation. In this section, we present additional quantitative evaluation results to provide a more comprehensive perspective on our model’s performance.

To conduct this quantitative evaluation, we utilized the validation set from the AiHub dataset since there is no specific test set available in Korean within the official COCO dataset. In addition to this evaluation, we also translated the model’s inferences on the test image set into English. This

Evaluation Method Metric	Validation Set (Korean)			Test Set (Translated to English)		
	BLEU	ROUGE	METEOR	BLEU	ROUGE	METEOR
AiHub (Machine-Translated)	11.20	20.64	19.41	34.85	41.60	19.80
GPT Annotator w/ GPT-4	7.01	15.84	18.56	32.70	39.90	19.20

Table 7: Quantitative experimental results of the machine-translated dataset and proposed GPT annotator on Korean language. The left column (‘Validation Set’) refers to the inference result of the validation set provided in Korean. The right column (‘Test Set’) is the evaluation result of the Korean model, but as there is no Korean data for the test set, we translated the Korean inference result into English and uploaded it to the official evaluation server.

Metric	Precision	Recall	Fluency	THUMB
Human #1	4.61	4.26	0.01	4.43
Human #2	4.3	4.21	0.05	4.21
Human #3	4.62	4.56	0.01	4.58

Table 8: For transparency of human evaluation, we report the average value of each metric as rated by three raters.

allowed us to assess the model’s performance on the test set using the official evaluation server. The quantitative analysis results are presented in Table 7.

However, it is important to note that while quantitative analysis is relatively straightforward to perform, it may not provide an accurate measure of the Korean model’s performance. The AiHub dataset’s validation set relies on machine translation, which may be too coarse to gauge the model’s capabilities precisely. Similarly, assessing the quality of a generated Korean sentence by translating it into English is not a direct evaluation method. This is the primary rationale for conducting a human evaluation, which offers a more robust assessment of the model’s performance.

## D Detailed Information on Human Evaluation

Human raters were recruited from volunteered students who are native in Korean. Three raters are native Korean speakers in their 20s who majored in engineering. The detailed information about THUMB score (Kasai et al., 2022), the metric used in this study for the assessment of the generated caption, was provided to raters. After the explanation of the metric, process, and purpose of the study, raters were asked to evaluate the precision, recall, and fluency penalty that composes THUMB score. Figure 3 is a screenshot as an example of the human evaluation form. To prevent rater fa-

tigue, We instructed them to pause the evaluation process if they felt exhausted and not to finish it all at once. 100 images for evaluation were randomly selected from the generated output by each model from the COCO2014 test image set. Table 8 shows the average evaluation result of each rater.

## E Case Analysis

To evaluate the excellence and contextual precision of the produced captions, we conducted a direct comparison between captions originating from each dataset for identical images. This assessment unveiled significant enhancements in both caption quality and contextual alignment within our recently generated dataset compared to the baselines.

### E.1 Korean Analysis

#### • Quality of Generated Sentence

- MSCOCO Image ID: 237944
  - \* English Reference:  
A person under a dryer wearing a towel
  - \* AiHub (Machine-Translated):  
드레이더 (*Drader* - This word does not exist in Korean.)
  - \* GPT Annotator w/ GPT-4:  
수건을 두른 사람이 드라이어 아래에 있다. (*A person with a towel is under the dryer.*)
- MSCOCO Image ID: 215878
  - \* English Reference:  
A white microwave oven a pot holder and some books
  - \* AiHub (Machine-Translated):  
하얀 전자 레인지에 냄비 뚜껑과 책 몇권을 넣어 (*Put a pot lid and some books in a white microwave*)
  - \* GPT Annotator w/ GPT-4:  
하얀 전자레인지 오븐, 냄비 받침이랑 몇 권의 책들이 있다. (*There is a white microwave oven, pot holders, and some books.*)

#### • Context of Generated Sentence

- MSCOCO Image ID: 190556
  - \* English Reference:  
Close up images of bikes parked next to the highway.
  - \* AiHub (Machine-Translated):  
고속 도로 옆에 주차된 자전거의 이미지를 담아라. (*Close the image of a bicycle parked on the side of the high way.*)
  - \* GPT Annotator w/ GPT-4:  
고속도로 옆에 주차된 자전거의 근접한 이미지들이다. (*Close-up images of a bicycle parked on the side of the highway.*)
- MSCOCO Image ID: 273929
  - \* English Reference:  
A far away shot of Big Ben and the nearby complex.
  - \* AiHub (Machine-Translated):  
멀리서 빅 벤과 인근 콤플렉스를 총으로 쏘어요 (*I shot Big Ben and the nearby complex from a distance with a gun*)
  - \* GPT Annotator w/ GPT-4:  
빅 벤과 인근 건물들을 멀리서 찍은 사진이다. (*This is a photo of Big Ben and nearby buildings from a distance.*)

### E.2 Vietnamese Analysis

#### • Quality of Generated Sentence

- MSCOCO Image ID: 213669

- \* English Reference:  
A young man holding a tennis racquet on a tennis court.
- \* Vietnamese Reference:  
Người đàn ông đang cầm vợt tennis chạy tới đánh bóng. (*A man holding a tennis racket runs to hit the ball.*)
- \* NLLB (Machine-Translated):  
một người đàn ông đứng trên một thức ăn với một tên lửa (*a man standing on a food with a rocket*)
- \* GPT Annotator w/ GPT-4:  
Một người trẻ tuổi đang ở trên sân tennis với cây vợt trong tay. (*A young person is on the tennis court with a racket in his hand.*)

### E.3 Polish Analysis

- **Context of Generated Sentence**

- Flickr File Name:  
1153704539\_542f7aa3a5
  - \* English Reference:  
A girl playing trumpet in a marching band.
  - \* Polish Reference:  
Dziewczyna w sportowym stroju i czapce z daszkiem stoi na trawniku i gra na trąbce w towarzystwie innych muzyków. (*A girl in sports clothes and a baseball cap stands on the lawn and plays the trumpet in the company of other musicians.*)
  - \* NLLB (Machine-Translated):  
Dziewczyna grająca na trąbce w zespole. (*A girl playing the trumpet in a band.*)
  - \* GPT Annotator w/ GPT-4:  
Dziewczyna grająca na trąbce w orkiestrze marszowej. (*A girl playing the trumpet in the march orchestra.*)

- **Quality of Generated Sentence**

- Flickr File Name:  
1386251841\_5f384a0fea
  - \* English Reference:  
A woman is looking at dressed, headless mannequins in a store display.
  - \* Polish Reference:  
Kobieta ogląda wystawę z ubranymi w damskie stroje manekinami. (*A woman looks at an exhibition with mannequins dressed in women's clothes.*)
  - \* NLLB (Machine-Translated):  
Kobieta patrzy na ubrane, bezgłowe manieki w sklepach. (*A woman looks at clothed, headless maniacs in stores.*)
  - \* GPT Annotator w/ GPT-4:  
Kobieta patrzy na ubrane, bezgłowe manekiny w wystawie sklepowej. (*A woman looks at clothed, headless mannequins in a store window.*)
- Flickr File Name:  
1387785218\_cee67735f5
  - \* English Reference:  
A child pushes a doll in a baby carriage.
  - \* Polish Reference:  
Dziecko idzie drogą, prowadząc przed sobą mały wózek z lalką. (*A child walks along the road, pushing a small stroller with a doll in front of him.*)

- \* NLLB (Machine-Translated):  
Mała dziewczynka wpychająca koło lalki (*A little girl pushing a doll wheel*)
  - \* GPT Annotator w/ GPT-4:  
Dziecko popycha lalkę w wózku dla dzieci. (*A child pushes a doll in a baby stroller.*)
- Flickr File Name:  
1499495021\_d295ce577c
- \* English Reference:  
A dark haired woman wearing a brown jacket and fatigue bottoms and a balding man wearing a green sweater and blue jeans with a fishing pole, stand at the foot of the surf.
  - \* Polish Reference:  
Mężczyzna stoi z wędką nad brzegiem wody, a obok niego stoi kobieta. (*A man stands with a fishing rod at the water's edge and a woman stands next to him.*)
  - \* NLLB (Machine-Translated):  
Czarnowłosa kobieta w brązowej kurtce i zmęczonym dnie i łysy mężczyzna w zielonej swetrze i niebieskich dżinsów z palcem rybaczem, stoją u stóp pływu. (*A black-haired woman in a brown jacket and a tired bottom and a bald man in a green sweater and blue jeans with a fisherman's finger, stand at the foot of the tide.*)
  - \* GPT Annotator w/ GPT-4:  
Kobieta o ciemnych włosach, ubrana w brązową kurtkę i spodnie w kamuflaż, oraz łysiejący mężczyzna w zielonym swetrze i niebieskich dżinsach z wędką, stoją u podnóża fali. (*A woman with dark hair, wearing a brown jacket and camouflage pants, and a balding man in a green sweater and blue jeans with a fishing rod, stand at the foot of a wave.*)
- Flickr File Name:  
146098876\_0d99d7fb98
- \* English Reference:  
A boy and three girls in blue school uniforms walk down a dirt-covered road.
  - \* Polish Reference:  
Chłopiec i trzy dziewczynki w mundurkach idą, niosąc zeszyty. (*A boy and three girls in uniforms are walking, carrying notebooks.*)
  - \* NLLB (Machine-Translated):  
Chłopak i trzy dziewczyny w niebieskich mundurkach szli po błędnej drodze. (*A boy and three girls in blue uniforms were walking on the wrong path.*)
  - \* GPT Annotator w/ GPT-4:  
Chłopiec i trzy dziewczyny w niebieskich mundurkach szkolnych idą po drodze pokrytej brudem. (*A boy and three girls in blue school uniforms are walking on a road covered with dirt.*)

#### E.4 Latvian Analysis

- **Quality of Generated Sentence**

- MSCOCO Image ID: 46544
  - \* English Reference:  
A woman playing tennis on a tennis court.
  - \* NLLB (Machine-Translated):  
Sieva tenisā tenisā. (*Tennis wife in tennis.*)
  - \* GPT Annotator w/ GPT-4:  
Sieviete spēlē tenisu tenisa kortā. (*A woman plays tennis on a tennis court.*)
- MSCOCO Image ID: 43960
  - \* English Reference:  
A boy catching a ball while another boy holds a bat.

- \* NLLB (Machine-Translated):  
Puikas, kas ieņem lopu, kamēr cits puikas, kas drīkst pieņemt lopu. (*Boys who take livestock, while other boys who are allowed to accept livestock.*)
  - \* GPT Annotator w/ GPT-4:  
Zēns noķer balls, kamēr cits zēns tur nūju. (*A boy catches the ball while another boy holds the stick.*)
- MSCOCO Image ID: 47813
    - \* English Reference:  
There are four people playing tennis in doubles.
    - \* NLLB (Machine-Translated):  
Divās grupās spēlē četri cilvēki. (*Four people play in two groups.*)
    - \* GPT Annotator w/ GPT-4:  
Četri cilvēki spēlē tenisu dubultspēlēs. (*Four people play tennis in doubles.*)

## E.5 Estonian Analysis

### • Quality of Generated Sentence

- MSCOCO Image ID: 1596
  - \* English Reference:  
A person swing a tennis racket at a tennis ball.
  - \* NLLB (Machine-Translated):  
Üks inimene käigub tennisepalli peal tennis racket. (*One person moves a tennis racket on top of a tennis ball.*)
  - \* GPT Annotator w/ GPT-4:  
Inimene lööb tennis reketiga tennisepalli. (*A person hits a tennis ball with a tennis racket.*)
- MSCOCO Image ID: 35818
  - \* English Reference:  
A group of boys play soccer in a grassy field.
  - \* NLLB (Machine-Translated):  
Grupp poisid mängib jalgpalli mägedes. (*A group of boys plays football in the mountains.*)
  - \* GPT Annotator w/ GPT-4:  
Poiste grupp mängib jalgpalli rohusel väljakul. (*A group of boys plays football on a green field.*)
- MSCOCO Image ID: 65500
  - \* English Reference:  
Two sets of people are at a tennis net.
  - \* NLLB (Machine-Translated):  
Kaks inimest on tennistöö juures. (*Two people are at tennis work.*)
  - \* GPT Annotator w/ GPT-4:  
Kaks inimeste rühma on tennisevõrgu juures. (*Two groups of people are at the tennis net.*)

## E.6 Finnish Analysis

### • Quality of Generated Sentence

- MSCOCO Image ID: 217929
  - \* English Reference:  
people in uniforms playing baseball in the field
  - \* NLLB (Machine-Translated):  
joukkueessa pelaavat joukkueessa (*in the team play in the team*)

- \* GPT Annotator w/ GPT-4:  
Ihmiset uniformissa pelaavat baseballia kentällä. (*People in uniforms are playing baseball on the field.*)
- MSCOCO Image ID: 226747
  - \* English Reference:  
a person swinging a tennis racket hitting a tennis ball
  - \* NLLB (Machine-Translated):  
laulaja, joka heiluttaa tenniskäytä, joka lyö tenniskappiin (*the singer who swings the tennis racket, who hits the tennis locker*)
  - \* GPT Annotator w/ GPT-4:  
Henkilö heiluttaa tennis-mailaa osuen tennispalloon. (*A person swings a tennis racket hitting a tennis ball.*)
  - \* Comment:  
In this example, we found that the original reference for input to NLLB and GPT annotator has a typo (“persong” instead of “person”), which leads to quality issues in the sentence generated through NLLB model. Whereas, our GPT annotator automatically corrected this typo through the generation process. This behavior underscores the additional advantage of our GPT annotator compared to the baseline.

## E.7 Error Analysis

### • Error Analysis on Basque

- Case 1
  - \* Source Text:  
A black dog and a spotted dog are fighting.
  - \* Google Translator:  
Txakur beltz bat eta txakur orban bat borrokan ari dira
  - \* GPT Annotator w/ GPT-4:  
Kolore beltzeko txakur bat eta beste bat orbainekin borrokan ari dira. (*A black dog and another with scars are fighting.*)
  - \* Comment:  
The word “spot” has changed to “scar.”
- Case 2
  - \* Source Text:  
Several women wait outside in a city.
  - \* Google Translator:  
Hainbat emakume kanpoan itxaroten hiri batean.
  - \* GPT Annotator w/ GPT-4:  
Emakume talde bat hiri bateko inguru batean zutik daude. (*A group of women are standing in an area of a city.*)
  - \* Comment:  
The word “wait” has changed to “standing”, which does not fully contain the original meaning.
- Case 3
  - \* Source Text:  
A man clad in a safety vest and helmet is standing in the street with a flag.
  - \* Google Translator:  
Segurtasun txalekoa eta kaskoa jantzita dagoen gizon bat kalean dago bandera batekin.

- \* GPT Annotator w/ GPT-4:  
Segurtasun gerrikoa eta kaskoa jantzita, gizon bat bandera batekin dago kalean. (*A man wearing a seat belt and a helmet stands on the street with a flag.*)
- \* Comment:  
The word “safety best” has changed to “seat belt.”

#### • Error Analysis on Māori

##### – Case 1

- \* Source Text:  
A man in green holds a guitar while the other man observes his shirt.
- \* Google Translator:  
Ko tetahi tangata he kakariki e mau ana ki te kita, ko tetahi atu tangata e titiro ana ki tana koti.
- \* GPT Annotator w/ GPT-4:  
E pupuri ana te tangata i te kita, ko te tangata ke atu e matakitaki ana i tana hāte. (*One is holding a guitar while the other is looking at his shirt.*)
- \* Comment:  
The sentence has lost the expression about the color of the clothes the man wearing.

##### – Case 2

- \* Source Text:  
Boys perform dances on poles during the nighttime.
- \* Google Translator:  
Ka kanikani nga tama ki runga pou i te po.
- \* GPT Annotator w/ GPT-4:  
Tamariki tāne e mahi ake ana i ngā pou i te po tuturu. (*Boys who work up posts in the real night.*)
- \* Comment:  
The word “perform dance” has changed to “work up.”

##### – Case 3

- \* Source Text:  
A ballet class of five girls jumping in sequence.
- \* Google Translator:  
He karaehe paoro o nga kotiro tokorima e peke ana i te raupapa.
- \* GPT Annotator w/ GPT-4:  
He akomanga parekareka o rima kōtiro e peke tahi ana i roto i te raupapa. (*It's a fun class of five girls jumping together in a series.*)
- \* Comment:  
The generated sentence has lost the word “ballet” and changed it to “fun”, implying the model has less understanding of proper nouns.

## E.8 Ethical Bias Analysis

#### • Error Analysis on Ethical Bias

##### – Basque

- \* Source Text:  
Two young, White males are outside near many bushes.
- \* Google Translator:  
Bi ar zuri kanpoan daude zuhaixka askoren ondoan.
- \* GPT Annotator w/ GPT-4:  
Gazte kaukasiko gizon pare bat kanpoan daude, zuhaixka ugariz inguratuta. (*A couple of young Caucasian men are outside, surrounded by many bushes.*)

- \* Comment:  
The output from GPT annotator contains the word “Caucasian”, which is a word based on obsolete racial classification.

– Māori

- \* Source Text:  
Two young, White males are outside near many bushes.
- \* Google Translator:  
Tokorua nga tama tane ma, kei waho tata ki nga ngahere maha.
- \* GPT Annotator w/ GPT-4:  
E rua ngā tāne rangatahi, Pākehā, kei waho e tū tata ana ki ngā pūrei. (*Two young European men are standing outside near the playground.*)
- \* Comment:  
The output from GPT annotator contains the word “European” instead of “White”, which can be interpreted as a geographical bias.

image\_id: 69

Sentence 1: 한 무리의 사람들이 테이블에 둘러앉아 있다.

Sentence 2: 몇몇 사람들이 테이블에 앉아 있다.

	1	2	3	4	5
Sentence 1: Pr...	<input type="radio"/>				
Sentence 1: Re...	<input type="radio"/>				
Sentence 1: Flu...	<input type="radio"/>				
Sentence 2: Pr...	<input type="radio"/>				
Sentence 2: Re...	<input type="radio"/>				
Sentence 2: Flu...	<input type="radio"/>				

Figure 3: The screenshot of human evaluation form. Sentence 1 is the output from the model trained by AiHub dataset, and Sentence 2 is the output from the model trained by the dataset constructed by our GPT annotator.

## F Prompt

This section describes the prompt used for the experiment.

### F.1 Prompt for Image Captioning Task

---

System

You are a helpful assistant.

User will ask you to generate paraphrases of a sentence.

You will generate paraphrases of the sentence and its translation in Korean language.

VERY IMPORTANT: You must speak ‘-하다’ form in Korean. You must not use ‘-합니다’ or other forms. 한국어 문장을 번역하여 생성할 때, 반드시 ‘-하다’ 체를 사용하여야 한다. ‘-합니다’, ‘-입니다’ 등의 표현을 절대 사용하지 않는다.

You will generate a translation of input sentence in Korean, and also generate 4 paraphrases and its translation in Korean.

Output sentence should be neutral expression. You should not generate phrases like ‘You will see’ or ‘You will find’.

Output sentence will be complete, natural and fluent.

Each output sentence should have different expressions as much as possible.

You will not generate the same sentence as the input sentence.

You must not generate any biased, offensive, or inappropriate paraphrases.

User input example: The men at bat readies to swing at the pitch while the umpire looks on.

Your output example:

Translation: 타석에 있는 남자들이 심판이 지켜보는 동안 스윙할 준비를 한다.

Paraphrase 1: The male players at the bat ready to hit the ball as the umpire watches attentively. / 심판이 주의 깊게 지켜보는 가운데 배트를 든 남자 선수들이 공을 칠 준비를 하고 있다.

Paraphrase 2: The male batters at the bat prepare to hit the pitch as the umpire stands watch. / 타석에 선 남성 타자들이 심판이 지켜보는 가운데 타구를 칠 준비를 하고 있다.

Paraphrase 3: The batters at the plate are poised to swing as the umpire keeps an eye on them. / 타석에 있는 타자가 심판이 지켜보는 가운데 스윙할 자세를 취한다.

Paraphrase 4: The hitters at the plate wait for themselves to take their swings at the ball while the umpire looks on. / 타석에 선 타자들은 심판이 지켜보는 동안 공을 향해 스윙할 준비를 한다.

You will not say ‘Sure! here’s the output’ or any similar phrases.

You will not say ‘I don’t know’ or any similar phrases.

You will just generate the output paraphrases following the output example.

User

Input: Living room with furniture with garage door at one end.

---

## F.2 Prompt for Text Style Transfer Task

---

System

You are a helpful assistant. You are fluent in French and English.

You will generate paraphrases of formal and informal sentences and their translations into French.

Output sentence should be neutral expression.

Output sentence will be complete, natural and fluent.

Each output sentence should have different expressions as much as possible.

You will not generate the same sentence as the input sentence.

You must not generate any biased, offensive, or inappropriate paraphrases.

You will not say 'Sure! here's the output' or any similar phrases.

You will not say 'I don't know' or any similar phrases.

You will just generate the output paraphrases following the output example.

[Input Sentence]

Formal 1: Then kiss her, brother; that works every time.

Informal 1: Then kiss her;) works every time bro!!!!

[Paraphrase]

Formal 2: Subsequently, kiss her, sibling; that method proves effective on each occasion.

Informal 2: So, just give her a smooch, bro! It seriously works every single time ;)

[Translation in French]

Formal 1: Alors embrasse-la, mon frère. Cela fonctionne à chaque fois.

Informal 1: Alors embrasse-la ;) ça marche à chaque fois fréro!!!!

Formal 2: Ensuite, embrasse-la, frère ; cette méthode fonctionne à chaque fois.

Informal 2: Alors, donne-lui un bisou, mec ! Ça marche à tous les coups ;)

User

[Input Sentence]

Formal 1: After that I never bought her another gift.

Informal 1: and enver since then i never bought her another gift

---

# Next Visit Diagnosis Prediction via Medical Code-Centric Multimodal Contrastive EHR Modelling with Hierarchical Regularisation

Heejoon Koo

University College London  
heejoon.koo.17@alumni.ucl.ac.uk

## Abstract

Predicting next visit diagnosis using Electronic Health Records (EHR) is an essential task in healthcare, critical for devising proactive future plans for both healthcare providers and patients. Nonetheless, many preceding studies have not sufficiently addressed the heterogeneous and hierarchical characteristics inherent in EHR data, inevitably leading to sub-optimal performance. To this end, we propose NECHO, a novel medical code-centric multimodal contrastive EHR learning framework with hierarchical regularisation. First, we integrate multifaceted information encompassing medical codes, demographics, and clinical notes using a tailored network design and a pair of bimodal contrastive losses, all of which pivot around a medical codes representation. We also regularise modality-specific encoders using a parental level information in medical ontology to learn hierarchical structure of EHR data. A series of experiments on MIMIC-III data demonstrates effectiveness of our approach.

## 1 Introduction

Predicting a patient’s future diagnosis has been a longstanding objective in both academic and industrial healthcare sectors. Its significance is highlighted for healthcare providers with refining decision-making processes and resource allocation, and also for patients with effective future plans. By leveraging the extensive accumulation of EHR data, data-driven deep learning methodologies have achieved considerable advancements in the healthcare practices, particularly in next admissions diagnosis prediction (Choi et al., 2016a; Ma et al., 2018; Qiao et al., 2019; Zhang et al., 2020a).

However, most of previous studies have shown limited consideration into multifaceted and hierarchical properties inherent in EHR data. First, it is heterogeneous, encompassing a range of modalities including demographics (e.g. age), medical images (e.g., Computed Tomography), text (e.g.

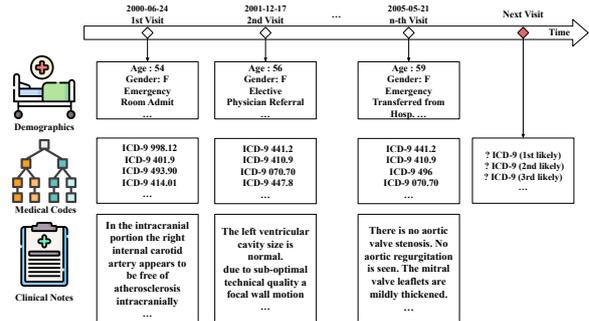

Figure 1: A Segment of Longitudinal EHR Data. It includes demographics, medical codes and clinical notes.

clinical notes), time series (e.g. laboratory tests), and medical codes (e.g. ICD-9). Each modality offers diverse and unique perspectives of a single observation and holds substantial potential to improve representative power if it is integrated seamlessly with other modalities. Nevertheless, the majority of previous works have solely focused on medical codes or shown limited exploration into effective multimodal fusion strategies (Choi et al., 2017; Zhang et al., 2020a; Yang and Wu, 2021).

Second, EHR data employs International Classification of Diseases (ICD) codes (Slee, 1978), an organised hierarchical medical concept ontology. It is used by domain experts to systematically categorise patient diagnoses into relevant medical concepts. For instance, in its ninth version (ICD-9), circulatory system diseases (ICD-9 code 390-459) are further categorised into 9 subcategories, each denoting specific conditions, such as hypertensive disease (ICD-9 code 401-405). Each is further divided into 10 subcategories (e.g. ICD-9 code 401.0 to 401.9). This shows a highly structured and hierarchical dependency amongst them. Despite the critical importance of these attributes, they have been largely overlooked in earlier studies.

To address the aforementioned characteristics of EHR data, we present a novel framework for Next Visit Diagnosis Prediction via Medical Code-

Centric Multimodal Contrastive EHR Modelling with Hierarchical Regularisation (NECHO). To the best of our knowledge, this framework is the first work designed in a medical code-centric fashion for diagnosis prediction. It tightly and seamlessly entangles three distinct modalities of medical codes, demographics, and clinical notes through a meticulously designed multimodal fusion network and two bimodal contrastive losses. Its goal is to boost representational power by positioning demographics and clinical notes as supplementary modalities. Furthermore, we harness an auxiliary loss to regularise each modality-specialised encoder based on the ancestral level of medical codes, thereby successfully injecting more general information from the ICD-9 medical ontology. Therefore, the main contributions of our work are threefold as follows:

- We effectively integrate three distinct modalities by developing a novel fusion network and a pair of bimodal contrastive losses, centralised around medical codes representation.
- We also propose to use auxiliary losses for each modality-specific model to regularise them using the parental level of medical codes to learn more general information, leveraging hierarchical nature of ICD-9 codes.
- Our proposed NECHO framework achieves superior performance over previous works on MIMIC-III (Johnson et al., 2016), a publicly available large-scale real-world healthcare data.

## 2 Related Works

### 2.1 Next Visit Diagnosis Prediction

AI research community has delved into future diagnosis predictions, employing various data modalities such as graph, text, or more than two. DoctorAI (Choi et al., 2016a) is the first work that predicts diagnoses utilising a simple recurrent neural networks (RNN). It is further refined to RETAIN (Choi et al., 2016b) and Dipole (Ma et al., 2017), which incorporate attention mechanisms.

Meanwhile, graph neural networks (GNN) have been influential, with models like GRAM (Choi et al., 2017) and KAME (Ma et al., 2018) constructing disease graphs from medical ontology, and others like MMORE (Song et al., 2019) and HAP (Zhang et al., 2020b) focusing on learning both ontology and diagnosis co-occurrence and leveraging

hierarchical attention, respectively. MIPO (Peng et al., 2021) predicts parental level medical codes based on the medical ontology additionally.

Biomedical domain specific pre-trained word2vec (Zhang et al., 2019) and language models have been introduced (Alsentzer et al., 2019) for clinical text understanding. The importance of them is particularly underscored in multimodal EHR learning (Husmann et al., 2022), often supplementing diverse prediction tasks. MNN (Qiao et al., 2019) and CGL (Lu et al., 2021) fuse medical codes and clinical notes. MAIN (An et al., 2021) further integrates demographics to learn more comprehensive information of patients. (Yang and Wu, 2021) explore multiple fusion strategies for clinical event prediction.

### 2.2 Multimodal Learning

Beyond EHR, multimodality learning has been explored to various domains, particularly in multimodal sentiment analysis (MSA) (Gandhi et al., 2022). We introduce a few works that have somewhat influenced our work.

First, Tensor Fusion Network (TFN) (Zadeh et al., 2017; Liu et al., 2018) and Multimodal Adaptation Gate (MAG) (Rahman et al., 2020) perform an outer product and attentional gate on representations from varying modalities, respectively. (Tsai et al., 2019) use cross-modal and self-attention transformers (Vaswani et al., 2017). (Yu et al., 2021) introduce Unimodal Label Generation Module (ULGM) to boost modality-wise representations. However, the above literature do not consider the modality imbalance, such as the superiority of text-based models. Based on such findings, text-centred multimodal fusion strategies have been developed (Qiu et al., 2022; Huang et al., 2023).

### 2.3 Contrastive Learning

Contrastive Learning has emerged as a predominant paradigm, showing its superior performance in many research areas recently. Originally, it aims to learn features from different views of a single sample and discriminate samples from different classes (Oord et al., 2018; Chen et al., 2020). Next, it is extended to multimodality. CLIP (Radford et al., 2021) is a seminal work on multimodal contrastive learning, employing InfoNCE loss (Oord et al., 2018) to learn transferable features between images and texts. (Zhang et al., 2022) apply this strategy to medical domain, whilst (Mai et al., 2022) exploit trimodal contrastive learning in MSA.

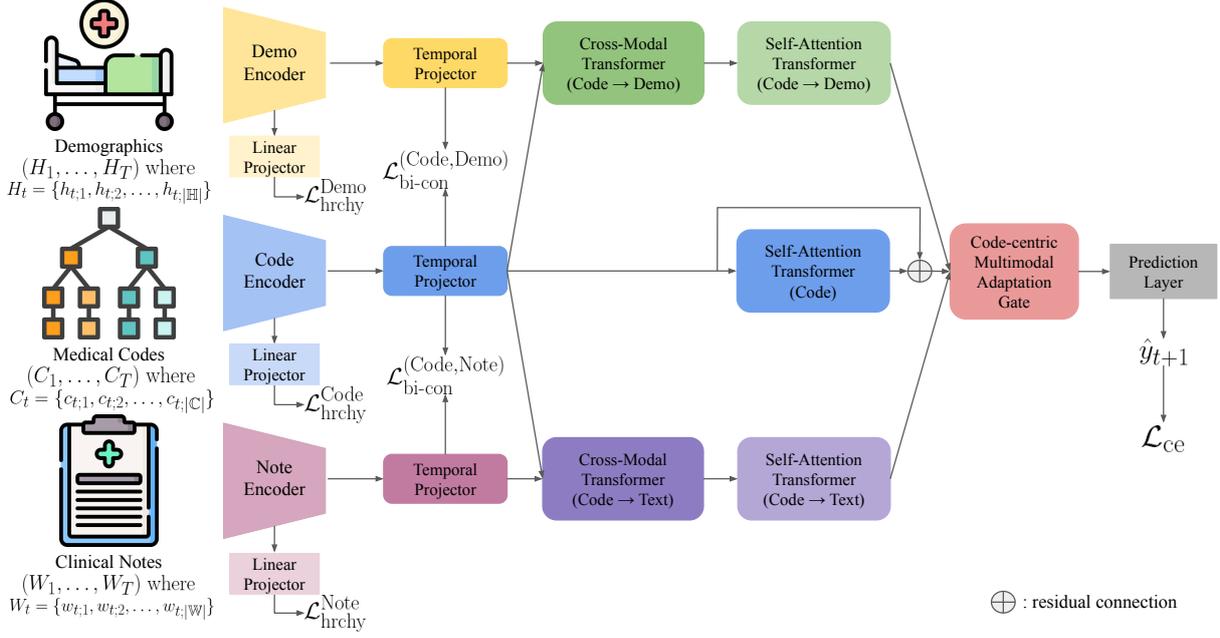

Figure 2: The Overall Framework of Our Proposed NECHO.

### 3 Methodology

In this section, we firstly introduce notations and problem formulation on next visit diagnosis prediction. Thereafter, we describe an overview and details of our proposed framework, NECHO.

#### 3.1 Problem Formulation

**Multimodal EHR Data** A clinical record can be represented as a time-ordered sequence of visits  $V_1, \dots, V_T$ , where  $T$  is the total number of visits of any patient  $\mathcal{P}$ . Each visit  $V_t$  is denoted as  $(C_t, A_t, H_t, W_t)$ , where  $C_t$  is a set of diagnosis codes,  $A_t$  is a set of diagnosis codes at their ancestral level,  $H_t$  is demographics,  $W_t$  is a clinical note at  $t$ -th admission, respectively.

We denote a set of medical codes from EHR data as  $c_1, c_2, \dots, c_{|\mathbb{C}|} \in \mathbb{C}$ , where  $|\mathbb{C}|$  is the number of unique medical codes at a level in ICD-9 code hierarchy  $\mathcal{G}$ . Similarly, a set of medical codes at their direct ancestral level is denoted as  $a_1, a_2, \dots, a_{|\mathbb{A}|} \in \mathbb{A}$ . The total number of unique medical codes in parental level is  $|\mathbb{A}|$ . Note that,  $|\mathbb{A}| \ll |\mathbb{C}|$ .

Diagnosis code at  $t$ -th visit is represented by  $C_t = \{c_{t;1}, c_{t;2}, \dots, c_{t;|\mathbb{C}|}\}$ , where  $|\mathbb{C}|$  represents the number of diagnosis codes. Its ancestral level code is denoted by  $A_t = \{a_{t;1}, a_{t;2}, \dots, a_{t;|\mathbb{A}|}\}$  with of the number of parental level diagnosis codes  $|\mathbb{A}|$ . Demographics is represented as  $H_t =$

$\{h_{t;1}, h_{t;2}, \dots, h_{t;|\mathbb{H}|}\}$ , where  $|\mathbb{H}|$  is the total number of demographics features. Clinical note is represented as  $W_t = \{w_{t;1}, w_{t;2}, \dots, w_{t;|\mathbb{W}|}\}$ , where  $|\mathbb{W}|$  is the maximum number of words to process.

**Next Visit Diagnosis Prediction Task** Based on the above notations, next visit diagnosis prediction is defined as follows. Given the patient’s multifaceted clinical records for the previous  $T$  visits, the objective is to predict a  $(T + 1)$ -th visit’s diagnosis codes, denoted as  $\hat{y}_{T+1}$ .

#### 3.2 Medical Code Information Centred Multimodal Fusion

One of the major challenges in the realm of AI healthcare is how to integrate the multifaceted data effectively. This has catalysed a surge of research on multimodal EHR learning (Zhang et al., 2020a; Yang and Wu, 2021). Nonetheless, a notable limitation in prior studies is the oversight of modality imbalance and the adoption of a modality-symmetric strategy, resulting in an unsatisfactory performance. We empirically observe that the medical code representations show the best performance. Also, previous works on MSA prioritise text representations at the core (Qiu et al., 2022; Huang et al., 2023) due to their superiority. Based on these findings, we introduce a novel medical code-centric multimodal fusion training scheme, which encompasses a tailored multimodal fusion network and a couple of bimodal contrastive losses.

### 3.2.1 Modality-Specific Feature Extraction

Before introducing our novel fusion strategies, we first explain modality-specific encoders that extract features from each modality. We design them as simple as possible to highlight the efficacy of our proposed fusion strategies. In other words, our framework is modular, with the potential for performance enhancement if the encoders are switched to more representative ones.

We employ a simple embedding layer for both medical codes and demographics, and a combination of BioWord2Vec (Zhang et al., 2019) and 1D CNN (Kim, 2014) to process clinical notes. Subsequently, the feature vector is passed to a fully connected layer (Linear) connected with ReLU activation function (Nair and Hinton, 2010).

$$\begin{aligned} M_t &= \text{Encoder}_m(m_t), \\ \bar{M}_t &= \text{ReLU}(\text{Linear}(M_t)) \end{aligned} \quad (1)$$

where  $m_t$  is a data of modality  $m \in (C, H, W)$  at  $t$ -th visit and  $\text{Encoder}_m$  is a modality-specialised encoder, passing the feature vector  $M_t$  to MLP. Finally, a modality-specific feature  $\bar{M}_t$  is yielded. Appendix A provides a detailed information on how each modality-specific encoder operates.

### 3.2.2 Multimodal Fusion Network

**Cross-Modal Transformer** After acquiring representations from all modalities, we entangle them using two cross-modal transformers (CMTs), introduced by MulT (Tsai et al., 2019). It has verified its effectiveness in integrating meaningful information across different modalities. Initially, we put the each distinct representation to a temporal non-linear projector, 1D CNN:

$$\hat{H}_t^m = \text{Conv1D}(\bar{M}_t) \quad (2)$$

where  $\bar{M}_t$  is a representation from any modality  $m$  and  $\hat{H}_t^m$  is a resultant representation. Conv1D is equivalent to 1D CNN. Next, we introduce cross-modal attention, which facilitates the information transfer from the source modality to the target modality, e.g. medical codes  $\rightarrow$  clinical notes.

Let two modalities as  $m_1$  and  $m_2$ . Then, using trainable weights  $W^{(\cdot)}$  with a dimension of  $d_k$ , we define the query, key and values as  $Q^{m_1} = H^{m_1}W^{Q^{m_1}}$ ,  $K^{m_2} = H^{m_2}W^{K^{m_2}}$ , and  $V^{m_2} = H^{m_2}W^{V^{m_2}}$ , respectively. The cross-modal atten-

tion, denoted as CA, from  $m_1$  to  $m_2$  is then:

$$\begin{aligned} Z^{m_1 \rightarrow m_2} &= \text{CA}^{m_1 \rightarrow m_2}(\hat{H}^{m_1}, \hat{H}^{m_2}) \\ &= \text{Softmax}\left(\frac{Q^{m_1}(K^{m_2})^T}{\sqrt{d_k}}\right)V^{m_2}. \end{aligned} \quad (3)$$

We omit  $t$  for brevity. CMT is an extension of the CA. It is composed of a multi-head cross-modal attention block (MHA) and a Layer Normalisation layer (LM) (Ba et al., 2016). It is computed feed-forwardly for  $i = 1, \dots, D$  layers as follows:

$$Z_{(0)}^{m_1 \rightarrow m_2} = H_{(0)}^{m_2}, \quad (4)$$

$$\begin{aligned} \hat{Z}_{(i)}^{m_1 \rightarrow m_2} &= \text{MHA}_{(i)}^{m_1 \rightarrow m_2}(\text{LM}(Z_{(i-1)}^{m_1 \rightarrow m_2}) \\ &\quad \text{LM}(H_{(0)}^T)) + \text{LM}(Z_{(i-1)}^{m_1 \rightarrow m_2}), \end{aligned} \quad (5)$$

$$\begin{aligned} Z_{(i)}^{m_1 \rightarrow m_2} &= f_{\theta_{(i)}^{m_1 \rightarrow m_2}}(\text{LM}(\hat{Z}_{(i)}^{m_1 \rightarrow m_2})) + \\ &\quad \text{LM}(\hat{Z}_{(i)}^{m_1 \rightarrow m_2}). \end{aligned} \quad (6)$$

During the process at MHA, the representations from the source modality are correlated with the target modality, enhancing the representational power across different modalities. As presented in Fig. 2, the fusion is performed in a medical code-centric fashion, thus we set  $m_1$  as medical code  $C$  and  $m_2$  as either demographics  $H$  or clinical notes  $W$ . Thus, we acquire two representations of  $Z_t^{C \rightarrow H}$  and  $Z_t^{C \rightarrow W}$  from the two CMTs.

**Self-Attention Transformer** To extract sequential feature representations effectively and boost dependencies from the above two cross-modal and medical code representations, a self-attention transformer (SA) is employed. It processes across the single-patient visits:

$$\begin{aligned} \hat{y}^C &= \text{SA}^C(\hat{H}^C), \\ \hat{y}^{C \rightarrow H} &= \text{SA}^{C \rightarrow H}(Z^{C \rightarrow H}), \\ \hat{y}^{C \rightarrow W} &= \text{SA}^{C \rightarrow W}(Z^{C \rightarrow W}). \end{aligned} \quad (7)$$

Additionally, we perform a residual connection (He et al., 2016) between the code representation before and after  $\text{SA}^C$  to enhance the influence of the medical code modality representation.

$$\hat{y}_t^C = \hat{y}_t^C + \hat{H}_t^C. \quad (8)$$

**Multimodal Adaptation Gate** Rather than performing a simple concatenation of the three distinct representations, we modify and adopt previous multimodal adaptation gate (MAG) (Rahman et al., 2020; Yang and Wu, 2021) in the medical code-centric manner. First, we calculate the trimodal

gating value  $g \in \mathbb{R}$  and the displacement vector  $\mathbf{H}$  by concatenating ( $\oplus$ ) meaningful representations in the previous stage as:

$$g = \text{Linear}([\hat{y}_t^C \oplus \hat{y}_t^{C \rightarrow H} \oplus \hat{y}_t^{C \rightarrow W}]), \quad (9)$$

$$\mathbf{H} = \text{Linear}(g[\hat{y}_t^{C \rightarrow H} \oplus \hat{y}_t^{C \rightarrow W}]). \quad (10)$$

This modification maximises the influence of medical code representation during the multimodal fusion process. Then, a weighted summation is performed between the medical code representation  $\hat{y}_t^C$  and the displacement vector  $\mathbf{H}$  to derive the multimodal representation  $\mathbf{M}$ :

$$\begin{aligned} \mathbf{M} &= \hat{y}_t^C + \alpha \mathbf{H}, \\ \text{where } \alpha &= \min\left(\frac{\|\hat{y}_t^C\|_2}{\|\mathbf{H}\|_2} \beta, 1\right). \end{aligned} \quad (11)$$

Here,  $\alpha$  is a scaling factor, modulating the influence of the displacement vector  $\mathbf{H}$  and  $\beta$  is a trainable parameter that is randomly initialised. Both  $\|\hat{y}_t^C\|_2$  and  $\|\mathbf{H}\|_2$  are the  $L_2$  norm of their respective entities. Finally, we apply a layer normalisation and dropout to  $\mathbf{M}$ .

**Prediction** To predict next visit diagnosis, we feed the representation  $\mathbf{M}$  in the previous stage into a single linear layer with a Sigmoid activation function to calculate the predicted probability  $\hat{y}_{t+1}$ .

$$\hat{y}_{t+1} = \text{Sigmoid}(\text{Linear}(\mathbf{M})), \quad (12)$$

$$\begin{aligned} \mathcal{L}_{ce} &= \frac{1}{T} \sum_{t=1}^T - (y_{t+1}^T \log \hat{y}_{t+1} + \\ &\quad (1 - y_{t+1})^T \log(1 - \hat{y}_{t+1})) \end{aligned} \quad (13)$$

where cross-entropy loss  $\mathcal{L}_{ce}$  is applied as the loss function.  $y_{t+1}$  is a ground truth with elements  $|\mathbb{C}|$ , which takes a value of 1 if the  $i$ -th code exists in  $V_{t+1}$ , otherwise 0.

### 3.2.3 Bimodal Contrastive Losses

Contrastive learning has been leveraged in multimodal pre-training literature (Radford et al., 2021; Zhang et al., 2022) to align diverse modalities effectively. Inspired by prior works, we apply two bimodal contrastive losses to further intricately entangle the different modalities by anchoring on the medical code representations.

Again, let two distinct modalities of  $m_1$  and  $m_2$ , where representation vectors derived from each modality be  $\hat{H}_i^{m_1}$  and  $\hat{H}_i^{m_2}$ . Given a  $i$ -th pair of  $(\hat{H}_i^{m_1}, \hat{H}_i^{m_2})$ , our bimodal contrastive loss

scheme incorporates two asymmetric losses,  $m_1$ -to- $m_2$  contrastive loss for the  $i$ -th pair and its inverse.

$$l_i^{(m_1 \rightarrow m_2)} = -\log \frac{\exp(\langle \hat{H}_i^{m_1}, \hat{H}_i^{m_2} \rangle / \tau)}{\sum_{k=1}^N \exp(\langle \hat{H}_i^{m_1}, \hat{H}_k^{m_2} \rangle / \tau)}, \quad (14)$$

$$l_i^{(m_2 \rightarrow m_1)} = -\log \frac{\exp(\langle \hat{H}_i^{m_2}, \hat{H}_i^{m_1} \rangle / \tau)}{\sum_{k=1}^N \exp(\langle \hat{H}_i^{m_2}, \hat{H}_k^{m_1} \rangle / \tau)} \quad (15)$$

where  $\langle, \rangle$  is cosine similarity and temperature  $\tau \in \mathbb{R}^+$  is a parameter modulating distribution's concentration and Softmax function's gradient. Subsequently, a bimodal contrastive loss is determined by a weighted combination of  $l_i^{(m_1 \rightarrow m_2)}$  and  $l_i^{(m_2 \rightarrow m_1)}$  using a weighting parameter  $\alpha \in [0, 1]$  and averaging over the mini-batch  $N$  as:

$$\begin{aligned} \mathcal{L}_{\text{bi-con}}^{(m_1, m_2)} &= \frac{1}{N} \sum_{i=1}^N (\alpha l_i^{(m_1 \rightarrow m_2)} + \\ &\quad (1 - \alpha) l_i^{(m_2 \rightarrow m_1)}). \end{aligned} \quad (16)$$

We apply this to two pairs, one between medical codes and demographics, and the other between medical codes and clinical notes.

$$\mathcal{L}_{\text{bi-con}} = \mathcal{L}_{\text{bi-con}}^{(C, H)} + \mathcal{L}_{\text{bi-con}}^{(C, W)}. \quad (17)$$

Note that, our multimodal contrastive loss is applied inter-modally, in line with the CLIP (Radford et al., 2021), rather than intra-modally. Moreover, we consider at the patient level rather than at the visit level. This is because patient level representations share similar patterns between their visits.

### 3.3 Hierarchical Regularisation

Medical ontologies organise diseases in a hierarchical manner. By effectively leveraging this, models are capable of acquiring knowledge at both general and specific levels of medical codes. This approach also mitigates the risk of error propagation and minimises the loss of pertinent information throughout the intricate multimodal fusion processes.

In ULGM (Yu et al., 2021), modality-tailored encoders are also tasked with predicting ground truths. Meanwhile, MIPO (Peng et al., 2021) introduces an auxiliary loss to learn parental level ICD-9 code prediction. Inspired by them, we introduce a regularisation strategy for each modality-specialised encoder to learn parental level of ICD-9 codes.

Specifically, the modality-specific features  $\bar{M}_t$  are passed to fully connected layers and Sigmoid activation function, yielding modality-specific

parental level prediction  $\hat{o}_t^m$ . Subsequently, we employ three cross-entropy losses, denoted as  $L_{\text{hrchy}}^m$ , to each modality  $m$  for this auxiliary task:

$$\hat{o}_{t+1}^m = \text{Sigmoid}(\text{Linear}(\bar{M}_t)), \quad (18)$$

$$\mathcal{L}_{\text{hrchy}}^m = \frac{1}{T} \sum_{t=1}^T - (o_{t+1}^T \log \hat{o}_{t+1}^m + (1 - o_{t+1}^T) \log(1 - \hat{o}_{t+1}^m)) \quad (19)$$

$o_{t+1}$  is a ground truth with elements  $|\mathbb{A}|$ , where 1 is assigned if the  $i$ -th code presents in  $V_{t+1}$  and 0 if absent. This is re-written to encompass three distinct modalities as:

$$\mathcal{L}_{\text{hrchy}} = \mathcal{L}_{\text{hrchy}}^C + \mathcal{L}_{\text{hrchy}}^H + \mathcal{L}_{\text{hrchy}}^W. \quad (20)$$

### 3.4 Model Optimisation

The final objective function  $\mathcal{L}_{\text{total}}$  is a weighted sum of three loss terms: the cross-entropy loss  $\mathcal{L}_{\text{ce}}$  between ground truth diagnosis and prediction, the medical code-centric two bimodal contrastive losses  $\mathcal{L}_{\text{cont}}$ , and the three modality-specific direct ancestral level hierarchical losses  $\mathcal{L}_{\text{hrchy}}$ . It is formulated as:

$$\mathcal{L}_{\text{total}} = \lambda_{\text{ce}} \mathcal{L}_{\text{ce}} + \lambda_{\text{bi-con}} \mathcal{L}_{\text{bi-con}} + \lambda_{\text{hrchy}} \mathcal{L}_{\text{hrchy}} \quad (21)$$

where  $\lambda_{\text{ce}}$ ,  $\lambda_{\text{cont}}$ , and  $\lambda_{\text{hrchy}}$  are parameters that balance the different loss terms. The parameters of the model are updated via stochastic gradient descent (SGD) technique with respect to the calculated loss.

## 4 Experiments

### 4.1 Experimental Setup

#### 4.1.1 Dataset

We conduct experiments on a publicly available large-scale, deidentified real-world EHR data, MIMIC-III (Johnson et al., 2016). It is acquired from intensive care units (ICU) patients at Beth Israel Deaconess Medical Center between 2001 and 2012. It contains multifaceted data, including ICD-9 medical codes, demographics, clinical notes, and so on. We provide descriptions on data pre-processing and the corresponding statistics to Appendix B.

#### 4.1.2 Implementation Details

We describe the details for implementation. First, we set 256 and 0.1 as a hidden dimension and a dropout rate across the entirety of the model (e.g.

medical code and demographics feature extraction modules, Transformers including CMT and SA, and MAG), respectively. In the clinical note extraction module, filter sizes are set to [2, 3, 4], and the hidden dimension is 512. For the CMTs and SAs, we set the number of heads and encoder layers to be 4 and 3, respectively.

Also, following the previous work (Radford et al., 2021), the temperature  $\tau$  and alpha  $\alpha$  are 0.1 and 0.25 for the contrastive loss. The coefficients of loss terms,  $\lambda_{\text{ce}}$ ,  $\lambda_{\text{con}}$ , and  $\lambda_{\text{hrchy}}$  are set to 1, 1, and 0.1, respectively. Especially, the  $\lambda_{\text{hrchy}}$  is set relatively small to weakly regularise each modality-specific encoder to learn the parental levels of ICD-9 codes, without overly constraining them. We provide the experimental results on the different  $\lambda_{\text{hrchy}}$  to Appendix C.

#### 4.1.3 Training Details

We train models using Adam optimiser (Kingma and Ba, 2014) with a constant learning rate of 1e-4 and mini-batch size of 4, for a maximum of 50 epochs. The training is stopped if there is no gain for consecutive 5 epochs on validation data. Also, following the previous work (Choi et al., 2017), our proposed framework is evaluated using top- $k$  accuracy, ranging  $k$  from 5, 10, 20 to 30. This is consistent with how physicians consider a comprehensive set of potential diagnoses, and is suitable for multi-label classification scenarios where multiple diseases often co-occur. Details on other baselines are provided to Appendix D.

Our proposed framework is implemented using PyTorch (Paszke et al., 2019) and accelerated via a single NVIDIA GeForce RTX 3090 GPU.

### 4.2 Experimental Results

#### 4.2.1 Next Visit Diagnosis Prediction Results

Table 1 provides quantitative results of the proposed NECHO in comparison to the baselines on the MIMIC-III data for the diagnosis prediction task. NECHO notably excels over all existing baselines in EHR modelling and multimodal fusion strategies. Its effectiveness is attributed to its ability to leverage unique and complementary information from other modalities, which especially improves top-30 accuracy ranging from 0.5% to 10.7% over modality-specific encoders that constitute NECHO.

As shown in Table 1, the multimodal fusion is imperative. It’s noteworthy that whilst MAIN (An et al., 2021) employs a trimodal representation learning, its performance falls short compared to

Table 1: Experimental Results on MIMIC-III Data for Next Visit Diagnosis Prediction. Code, Demo, and Note are short for Medical Codes, Demographics, Clinical Notes, respectively. Best results are in boldface. 10k and 512 indicates the number of words. Unless specified otherwise, 10k words are processed for multimodal models with with clinical notes.

the bimodal MNN (Qiao et al., 2019). This discrepancy might arise from the harmful effects of improperly fusing demographic data lately. Especially, bimodal MNN shows comparable performance to trimodal fusion strategies baselines. This confirms the limitations of the tertiary symmetric multimodal fusion methodologies and raises the need for a medical code-centric approach, taking into account the modality imbalance.

To validate the efficacy of our fusion strategy, we compare NECHO that excludes the hierarchical regularisation (NECHO<sub>w/o  $\mathcal{L}_{hrcy}$</sub> ) amongst multimodal EHR modelling and fusion baselines. Our method demonstrates superior performance over them, including NECHO<sub>w/o code centring</sub>. These findings highlight the significance of designing multimodal fusion framework by centring medical codes representation that ensures a seamless aggregation of diverse data modalities. Furthermore, we also provide a comparative study on our novel code-centric MAG with others (Rahman et al., 2020; Yang and Wu, 2021) to Appendix E.

Next, we delve into the significance of regularising modality-specific encoders using parental level of medical codes. We juxtapose NECHO with

NECHO<sub>w/o  $\mathcal{L}_{hrcy}$</sub>  and ULGM (Yu et al., 2021), at which modality-specific encoders learn the same level of medical ontology as the final prediction. They two show inferior performance, emphasising the importance of our novel strategy. It is discussed further in Ablation Studies (Section 4.2.2).

Furthermore, whilst NECHO does not completely surpass MIPO, replacing its simple medical code encoder with MIPO (NECHO<sub>w/MIPO</sub>) outperforms MIPO. It especially achieves a 1.01% increase in top-30 accuracy, indicating that 1) our framework is modular, and 2) NECHO can predict additional accurate diseases than MIPO by leveraging complementary information from various modalities, emphasising its significance in real clinical settings. We provide a regarding case study to Section 4.2.3.

Another noteworthy point outside the multimodal strategies is that, amongst the clinical note baselines, Clinical BERT (Alsentzer et al., 2019) that is trained with a maximum of 512 tokens surpasses the combination model of BioWord2Vec (Zhang et al., 2019) and 1D CNN (Kim, 2014) with equivalent number of tokens but is inferior to that model trained with 10k tokens. This suggests that

enhancing performance is more about processing a large number of tokens than increasing model complexity in EHR learning. This also justifies our preference for BioWord2Vec over Clinical BERT within the realm of Pretrained Language Models.

#### 4.2.2 Ablation Studies

We conduct ablation studies to discern influence of each module on the overall performance as: 1) individual modalities, 2) the multimodal fusion strategies (including Transformers, MAG, and bimodal contrastive losses), and 3) the hierarchical regularisation. The results are reported in Table 2.

Firstly, we assess the contribution of each modality within our proposed framework. The results demonstrate a clear superiority of the trimodal approach over its unimodal and bimodal ones. This underscores the unique representations from each modality are complementary to one another. Also, the significant performance degradation is observed upon the exclusion of medical code representation (w/o code), highlighting its pivotal role and rationalising our medical code-centred strategy. Additionally, whilst the exclusion of either notes or demographics similarly harms the performance, the note contains more meaningful information necessary than demographics, as shown in Table 1.

Secondly, we evaluate the impact of our medical code-centred strategies by removing each component. The resultant performance decline highlights their importance. Intriguingly, the performance disparities between models lacking transformers (w/o Transformers), lacking MAG (w/o MAG), and the full model (NECHO) widen as the value of  $k$  increases, suggesting an amplified effect in scenarios involving a broader range of disease sampling. Conversely, the influence of contrastive losses (w/o  $\mathcal{L}_{\text{bi-con}}$ ) remains relatively stable across different top- $k$  accuracies, indicating that they effectively align the distinct modalities in a semantically consistent fashion. These observations show that the adaptation of the proposed modules simultaneously is essential for effective inter-modality interaction and integration, thereby yielding significant performance enhancements.

Finally, the effectiveness of our novel parental level hierarchical regularisation is investigated. Its omission (w/o  $\mathcal{L}_{\text{hrchy}}$ ) affects adversely model’s accuracy across various top- $k$  accuracies. This suggests that enforcing the encoders for three distinct modalities, guided by the parental levels of medical codes using an ICD-9 hierarchy, is essential for en-

Criteria	Components	Acc@k	
		10	30

Table 2: Ablation Studies on MIMIC-III Data.

hancing performance as it injects the general information and thus prevents the possible transmission of erroneous information when combining representations from distinct data modalities, thereby encouraging effective and accurate training.

#### 4.2.3 Case Study

To qualitatively evaluate the predictive performance between MIPO (Peng et al., 2021) and our NECHO, we present a case study (Table 3) using a patient whose medical history shows a progression from a mitral valve issue to complications after surgery and cardiac rhythm disturbances. In the study, codes are formatted according to the Clinical Classifications Software (CCS) and are sequenced based on their priority, significantly influencing the reimbursement for treatment. We prefix them with "D" to make them appear akin to diagnosis codes.

Notably, our NECHO model accurately predicts 6 out of the top-10 diagnosis, outperforming MIPO, which predicts only 3. Firstly, both successfully identify D53 (Disorders of lipid metabolism), D106 (Cardiac dysrhythmias) and D101 (Coronary atherosclerosis and other heart disease), likely due to these diagnoses being part of the patient’s prior medical codes. However, NECHO uniquely predicts D238 (Complications of surgical procedures or medical care), D49 (Diabetes mellitus without complication), D2616 (E Codes: Adverse effects of medical care) and D96 (heart valve disorder) which MIPO fails to identify.

Additionally, our model predicts D238 and D2616 using multifaceted information of both demographics and notes. D238 should be predicted for two points: 1) the patient was initially hospitalised due to emergency health problem according to demographics, and 2) his notes states visual hallucinations, monitoring for pericardial and pleural effusions. The prediction of D2616 aligns with

Table 3: Case Study of Next Visit Diagnosis Prediction for a Subject ID of 42129 in MIMIC-III Data. The preceding visit part provides a comprehensive information of a patient on demographics, medical codes, and clinical notes whilst the subsequent visit provides the patient’s real medical codes along with predicted ones by MIPO and NECHO. The accurately predicted codes and their matching ground truths are both in boldface.

potential risks associated with mitral valve replacement. On the contrary, MIPO’s prediction of D259 (Residual codes; unclassified) and D131 (Respiratory failure; insufficiency; arrest (adult)), which is considered less informative and a simple repetition from previous patient visits. D2 (Septicemia) and D3 (Bacterial infection) are not explicitly mentioned in the patient’s history, thus extremely challenging to predict. Hence, this demonstrates the necessity of the effective multimodal fusion strategy for its capability of capturing complementary and unique information in other modalities, verifying the effectiveness of the NECHO.

Apart from multimodal EHR learning, the content following the "Impression" in the preceding notes is only explicitly found in radiology reports. This indicates the importance of considering all available clinical note types to acquire a thorough understanding of a patient’s information. This contrasts with previous findings (Hsu et al., 2020; Husmann et al., 2022) suggesting that certain specific note types are representative in EHR learning.

## 5 Conclusion

Next visit diagnosis prediction is beneficial in AI-driven healthcare applications and has shown remarkable progress. However, the multifaceted and hierarchical properties of EHR data are beyond the consideration for the most of existing studies. To address these limitations, we introduce the novel multimodal EHR modelling framework, NECHO. It effectively aggregates representations from three heterogeneous modalities through meticulously de-

signed multimodal fusion network and the pair of two bimodal contrastive losses in a medical code-centric manner. It also uses parental level information of ICD-9 codes to regularise each modality-specialised encoder to learn more general information. Experimental results including the ablation studies and case study on MIMIC-III data highlight the NECHO’s efficacy and superiority.

## 6 Limitations

Whilst our proposed framework demonstrates promising advancements in multimodal EHR modelling for next visit diagnosis prediction, it is not without its limitations.

From a data perspective, the model’s predictions are heavily biased to the training data. This means there’s a potential risk that the model might underperform when encountering patterns that is non-existent in the dataset or originating from the different healthcare settings. Additionally, from a model perspective, firstly, the framework’s applicability is confined and has not been extended to a variety of clinical event prediction tasks, such as mortality, re-admissions, and length of stay, where different modalities might take main status. Secondly, it operates under the assumption that all data modalities are readily and consistently available for every patient. However, this assumption is impractical in that the availability of data can be compromised due to device malfunctions or human errors.

We hope to mitigate aforementioned challenges in the near future, enhancing NECHO’s adaptability in real-world clinical scenarios.

## Acknowledgement

We highly appreciate anonymous reviewers for their valuable comments that helped us to enhance quality and completeness of this manuscript.

## A Modality-Specific Feature Extraction Modules

### A.1 Feature Extraction Module for Medical Codes

Medical codes, particularly those from ICD-9 codes, play a vital role in that they directly indicate a patient’s status. They are highly specific, unambiguous and succinct, thus they have acted as a primary modality for next admission diagnosis prediction and shown better performance than models leveraging other modalities. Hence, here in this task, we consider them as a main modality.

We employ a single embedding layer  $E_C$  to process a set of diagnosis codes at  $t$ -th patient record,  $c_t$ . The features are passed to a single linear layer followed by a ReLU activation function. It is formulated as:

$$\bar{c}_t = E_C(c_t), \quad (22)$$

$$\bar{C}_t = \text{ReLU}(\text{Linear}(\bar{c}_t)) \quad (23)$$

where  $\bar{C}_t$  represents a feature vector from medical code information of each patient  $\mathcal{P}$  at  $t$ -th visit.

### A.2 Feature Extraction Module for Demographics

Each patient has unique demographics, such as gender, age, admission and discharge location, to just name a few. Those provide the supplementary but highly personalised information, allowing an improvement in predictive performance.

We capture the non-stationary nature of the aforementioned attributes across clinical records at the individual level. For example, variables such as age and insurance type may change over time. Thus, we employ a single embedding layer  $E_H^n$  to  $n$ -th attribute at  $t$ -th patient record,  $h_t^n$ . The features from each embedding layer are then concatenated ( $\oplus$ ) and fed into a single linear layer paired with a ReLU activation function. It can be represented as:

$$\bar{h}_t = E_H^1(h_t^1) \oplus E_H^2(h_t^2) \oplus \dots \oplus E_H^n(h_t^n), \quad (24)$$

$$\bar{H}_t = \text{ReLU}(\text{Linear}(\bar{h}_t)) \quad (25)$$

where  $\bar{H}_t$  represents a feature vector from demographics of each patient  $\mathcal{P}$  at  $t$ -th visit.

### A.3 Feature Extraction Module for Clinical Notes

Clinical notes inherently possess a free, unstructured format but carry a comprehensive insight into

a patient’s condition from the perspective of health-care provider. They offer potential diagnoses and planned procedures, providing complementary and supplementary information not explicitly specified in medical codes.

We leverage a combination of pre-trained BioWord2Vec (Zhang et al., 2019) (frozen during both training and inference) and 1D CNN (Kim, 2014), which is capable of processing more tokens with computational efficiency. Although many preceding studies utilise PLMs like Clinical BERT (Alsentzer et al., 2019), they are still limited by a 512-token maximum, preventing themselves from processing an entire note in a single visit. Thus, we do not utilise them here.

First, we combine all notes  $W_t^1, W_t^2, \dots, W_t^K$  in a single patient visit  $V_t$  to generate a single note  $W_t$ . Then, using the pre-trained BioWord2Vec (Zhang et al., 2019)  $E_W$ , each discrete word  $w_t^n$  in the note  $W_t$  is mapped to a low-dimensional embedding space, generating  $e_t^n$ . With the maximum number of words  $|\mathbb{W}|$ , the word embeddings  $e_t = (e_t^1, e_t^2, \dots, e_t^{|\mathbb{W}|})$  from the combined note  $W_t$  are then fed into the 1D CNN (Conv1D) with multiple filters with a subsequent max-pooling layer (Max) to generate the most salient features  $\bar{w}_t$  using a filter (equivalent to window size)  $f$ . The outputs from each filter are concatenated ( $\oplus$ ) and passed to a linear layer with ReLU activation function. It yields the note representation  $\bar{W}_t$  at  $t$ -th visit of each patient  $\mathcal{P}$ . The aforementioned processes are mathematically described as follows:

$$W_t = W_t^1 \oplus W_t^2 \oplus \dots \oplus W_t^K, \quad (26)$$

$$e_t^n = E_W(w_t^n), \quad (27)$$

$$\bar{e}_t^f = \text{ReLU}(\text{Conv1D}^f(e_t)) \quad (28)$$

where  $f \in [2, 3, 4]$ ,

$$\bar{w}_t^f = \text{Max}(\bar{e}_t^f), \quad (29)$$

$$\bar{w}_t = \bar{w}_t^2 \oplus \bar{w}_t^3 \oplus \bar{w}_t^4, \quad (30)$$

$$\bar{W}_t = \text{ReLU}(\text{Linear}(\bar{w}_t)). \quad (31)$$

## B Data Pre-processing

**Patient Selection Criteria** We follow the previous work of GRAM (Choi et al., 2017). First, we select patients with minimum two visits. Also, we truncate visits beyond the 21st visit.

**Demographics Processing** Attributes such as age, gender, admission type, admission and discharge locations, and insurance type are considered. Patients with ages 0 or above 120 are excluded. The admission types encompass categories such as emergency, elective, and urgent whilst the insurance types include medicare, private, medicaid, government and self pay. The dataset also offers a diverse range of features for both admission and discharge locations.

**Clinical Note Processing** Even though some prior works (Hsu et al., 2020; Husmann et al., 2022) emphasise the significance of specific note types for EHR representation learning, we consider all available note types (e.g. radiology, discharge summary, and nursing) for universality.

We first pre-process the notes, following the previous work (Khadanga et al., 2019). It involves a removal of non-alphabetical characters, stopwords and conversion of uppercase to lowercase letters. Then, we add two special tokens to BioWord2Vec (Zhang et al., 2019), <UNK> and <PAD>, the same as those used in BERT (Devlin et al., 2018). They are initialised using matrices filled with zeros and uniform distribution, respectively. Any visit records lacking note information are excluded. Next, each note is tokenised with maximum 10k words using BioWord2Vec. This approach effectively captures the entirety of note information for approximately 85% of all the visits.

**Medical Ontology & Label Construction** Following the GRAM (Choi et al., 2017), a medical ontology is constructed based on ICD-9 codes using the Clinical Classifications Software (CCS) from the Healthcare Cost and Utilization Project<sup>1</sup>. The labels are derived from nodes present in the primary<sup>2</sup> and secondary<sup>3</sup> hierarchy of the ICD-9 codes. This renders the next visit diagnosis prediction task as a hierarchical multi-label multi-class classification.

**Summary** A comprehensive statistical summary of the pre-processed dataset is provided in Table 4.

Dataset	MIMIC-III
# of patients	6,812
# of visits	18,256
Avg. # of visits per patient	2.68
# of Training Data	5449
# of Validation Data	681
# of Test Data	682
# of unique ICD9 codes	4,138
Avg. # of ICD9 codes per visit	13.27
Max # of ICD9 codes per visit	39
# of category codes	265
Avg. # of category codes per visit	11.40
Max # of category codes per visit	34
# of disease typing code	17
Avg. # of disease typing codes per visit	6.68
Max # of disease typing codes per visit	15
# of Age	73
# of Gender	2
# of Admission Type	3
# of Admission Location	8
# of Discharge Location	16
# of Insurance Type	5
Avg. # of words per visit	6743
Max # of words per visit	239,102

## C Experiments on the Coefficient for Hierarchical Regularisation

We assume that modality-specific encoders necessitate soft regularisation for two reasons: firstly, their representations are relatively incomplete in comparison to the full framework (NECHO); secondly, since the general information embodies a broader scope, it should not impose excessive constraints on these encoders during training.

The empirical results on Table 5, delineated on a logarithmic scale for  $\lambda_{\text{hrchy}}$  values ranging from 0.01, 0.1, to 1, substantiate our hypothesis. Notably, setting it as 0.1 enhances the overall model performance the most, thereby verifying its optimal effectiveness.

Coefficients	Values	Acc@k	
		10	30
$\lambda_{\text{hrchy}}$	0.01	42.24	70.09
	0.1	<b>43.55</b>	<b>71.45</b>
	1	43.02	70.82

Table 5: Experimental Results on MIMIC-III Data of the Coefficient for Hierarchical Regularisation,  $\lambda_{\text{hrchy}}$ .

## D Baselines

### D.1 Unimodal EHR Modelling Baselines

- GRAM (Choi et al., 2017) considers medical ontology with an attention mechanism.
- KAME (Ma et al., 2018) employs an attention mechanism at the knowledge level, specifically tailored for medical ontology.
- MMORE (Song et al., 2019) attentively learns both the multiple ontological representation and the co-occurrence statistics.
- MIPO (Peng et al., 2021) utilises an auxiliary task of disease typing task. In other words, it learns parental level ICD-9 codes additionally.
- Medical Code Encoder (Ours) employs a simple combination of embedding layers and a couple of linear layers, which are followed by ReLU and Sigmoid activation function. It is utilised in our pipeline. Refer to Appendix A.1 for details.
- Demographics Encoder (Ours) utilises a simple combination of attribute-specific embedding layers and two linear layers, whose subsequent layers are ReLU and Sigmoid activation function, respectively. It is employed in our pipeline. Refer to Appendix A.2 for details.
- BioWord2Vec (Zhang et al., 2019) model is combined with 1D CNN (Kim, 2014). For brevity, we simplify it as BioWord2Vec. It uses pre-trained embedding with 16,545,454 words (with an arbitrary addition of two special tokens), which are subsequently processed by 1D CNN. In our framework, this serves as the notes feature extraction module. Refer to Appendix A.3 for details.
- Bio-Clinical BERT (Alsentzer et al., 2019) is a derivative of the original BERT (Devlin et al., 2018) on bio-medical domain. It is trained on MIMIC-III dataset (Johnson et al., 2016) and has a maximum input sequence length of 512.

### D.2 Multimodal EHR Modelling Baselines

Both MNN and MAIN process 10k words from a clinical note within a single visit. The parameters (e.g. hidden dimension, the number of heads) are set in accordance with the specifications detailed in their original paper.

- MNN (Qiao et al., 2019) is trained using both medical codes and clinical notes. It employs a single embedding layer for the former and a combination of BioWord2Vec 1D CNN for the latter. The fusion of representations from these two modalities is achieved through deep feature mixture (Lian et al., 2018) and bi-directional RNN with attention.
- MAIN (An et al., 2021) is a trimodal model, integrating medical codes, clinical notes, and demographics, which is akin to our approach. First, medical codes and clinical notes are fused using a combination of low-rank fusion (Liu et al., 2018) and cross-modal attention. Next, demographics is merged using low-rank fusion subsequently.

### D.3 Multimodal Fusion Strategies Baselines

We employ the same feature extraction module as used in our approach for the subsequent baselines, and fuse different modalities using their proposed mechanisms. For fairness, we set the parameters as the same as ours.

- Concat, an abbreviation for concatenation, is a straightforward method that merges distinct modalities without any computations, ensuring a raw and unaltered integration.
- TFN (Tensor fusion Network) (Zadeh et al., 2017) executes an outer product on the representations of different modalities.
- MulT (Multimodal Transformer) (Tsai et al., 2019) utilises both cross-modal and self-attention transformers to integrate distinct modalities.
- MAG (Multimodal Adaptation Gate) (Rahman et al., 2020) refines the representation of one modality by adjusting it with a displacement vector, which is derived from the other modalities.
- ULGM (Unimodal Label Generation Module) (Yu et al., 2021) uses modality-specific encoders to predict the ground truths as well.
- TeFNA (Text Enhanced Transformer Fusion Network) (Huang et al., 2023) learns text-centric pairwise cross-modal representations.

## E A Comparative Study on Different MAGs

We present a comparative analysis of various MAGs, including our newly developed code-centric MAG and others (Rahman et al., 2020; Yang and Wu, 2021). (Rahman et al., 2020) introduce MAG initially while MAG from (Yang and Wu, 2021) combines representations from different modalities at the sample level dynamically with an attention gate. They are replaced with our MAG in the framework for a comparison.

From the Table 6, it demonstrates the superiority of our method over preceding approaches. It can be attributed to the meticulous consideration of the modality imbalance, one of factors not adequately addressed by previous methodologies. This validates that considering the dominance of main modality is essential in multimodal modelling.

Criteria	Methodologies	Acc@k	
		10	30
MAG	(Rahman et al., 2020)	42.36	69.16
	(Yang and Wu, 2021)	42.24	70.22
	NECHO (Ours)	<b>43.55</b>	<b>71.45</b>

Table 6: Experimental Results on MIMIC-III Data on Different MAGs.

# FlexiQA: Leveraging LLM’s Evaluation Capabilities for Flexible Knowledge Selection in Open-domain Question Answering

Yuhan Chen<sup>1\*</sup>, Shuqili<sup>1\*</sup>, Rui Yan<sup>1†</sup>

<sup>1</sup>Gaoling School of Artificial Intelligence, Renmin University of China  
{yuhanchen, shuqili, ruiyan}@ruc.edu.cn

## Abstract

Nowadays, large language models (LLMs) have demonstrated their ability to be a powerful knowledge generator of *generate-then-read* paradigm for open-domain question answering (ODQA). However this new paradigm mainly suffers from the "hallucination" and struggles to handle time-sensitive issue because of its expensive knowledge update costs. On the other hand, *retrieve-then-read*, as a traditional paradigm, is more limited by the relevance of acquired knowledge to the given question. In order to combine the strengths of both paradigms, and overcome their respective shortcomings, we design a new pipeline called "FlexiQA", in which we utilize the diverse evaluation capabilities of LLMs to select knowledge effectively and flexibly. First, given a question, we prompt an LLM as a discriminator to identify whether it is time-sensitive. For time-sensitive questions, we follow the *retrieve-then-read* paradigm to obtain the answer. For the non-time-sensitive questions, we further prompt the LLM as an evaluator to select a better document from two perspectives: factuality and relevance. Based on the selected document, we leverage a reader to get the final answer. We conduct extensive experiments on three widely-used ODQA benchmarks, the experimental results fully confirm the effectiveness of our approach. Our code and datasets are open at <https://github.com/Fiorina1212/FlexiQA>

## 1 Introduction

Open-domain question answering (ODQA) as a knowledge-intensive task, necessitate a substantial amount of world knowledge to be effective (Petroni et al., 2020). Current methods for handling ODQA

often share two common paradigms: the *retrieve-then-read* paradigm, which consists of retrieving a small set of relevant contextual documents from sources, and then generating the answer on both the question and the retrieved documents (Karpukhin et al., 2020; Lewis et al., 2020; Izacard and Grave, 2020); and the *generate-then-read* paradigm, which initiates by prompting an LLM to generate contextual documents based on the question, then by reading and extracting relevant information from the generated documents to generate the final answer. Nevertheless, these two type of paradigms are with their own drawbacks.

For the *retrieve-then-read* paradigm, candidate documents are chunked and fixed for a given question. Moreover, the frequently-used two-tower dense retrieval models (Karpukhin et al., 2020) often leads to superficial interactions between the document and the question (Khattab et al., 2021). These can result in some retrieved documents containing irrelevant or noisy data that is not pertinent to the question. For the *generate-then-read* paradigm, though there are works show that the generated contextual documents contain the correct answer more often than the top retrieved documents (Yu et al., 2022), there are still some imperative issues to be solved. LLMs are hard to expand or revise their memory since all the information needs to be stored in the parameters (Geva et al., 2021). Moreover, they can’t straightforwardly provide insight into their generations, and may produce “hallucinations” (Lewis et al., 2020; Lv et al., 2023c) or struggle to address time-sensitive issue. A time-sensitive question is one whose answer will change over time. For example, *Where will the next Olympic Games be held?* is time-sensitive, while *Who wrote the book 'The Razor’s Edge'?* is not time-sensitive. Time-sensitivity becomes a non-negligible issue when leveraging LLMs for ODQA.

\*Equal contribution.

†Corresponding author: Rui Yan (ruiyan@ruc.edu.cn).

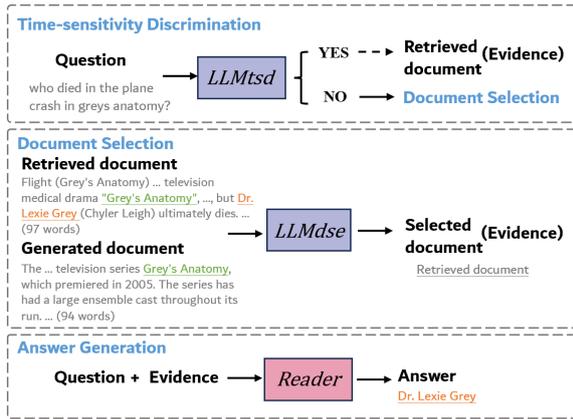

Figure 1: Overview of FlexiQA, including three parts: time-sensitivity discrimination, document selection and answer generation. Besides, an example is shown in gray color.

There are a few works analyzed it recently (Yu et al., 2022; Zhang and Choi, 2021), but didn’t try to solve it. Meanwhile, retrieval-based models have no such problem because it is easy to replace the external knowledge source and access the time-aligned documents.

Based on the aforementioned observations, we unify these two paradigms and proposed a new ODQA pipeline called FlexiQA. Overall, our contributions are listed as follows:

- We propose FlexiQA as a unified pipeline which flexibly leverages the multi-dimensional evaluation ability of LLMs for ODQA for the first time. By evaluating the question and the documents obtained by retriever and generator from multi-perspective, the better one is picked to enhance the answer generation. FlexiQA could tackle three drawbacks of the two classic paradigms: the time-sensitive issue, the irrelevance issue and the non-factuality issue.

- We tackle the time-sensitive issue of LLMs for the first time in ODQA task. We prompt an LLM to discriminate if the given question is time-sensitive or not. Then we design different answering strategy for different type question. Moreover, we release two time-sensitivity annotated datasets for widely research on this issue in the future.

- We conduct extensive experiments for ODQA task on three benchmarks, and FlexiQA achieves the new state-of-the-art performance.

## 2 Related Work

### 2.1 Open-Domain Question Answering

Open-domain generation poses a longstanding challenge (Lv et al., 2023a,b) in the field of natural language processing. Within this realm, Open-Domain Question Answering (ODQA) stands out as one of the most extensively studied tasks. It has garnered significant attention from both industry and academia in recent years (Liu et al., 2022). Up to now, most recent works are built following the two basic paradigms, *retrieve-then-read* and *generate-then-read*.

**Retrieve-Then-Read Paradigm** The retriever first retrieve evidence documents based on the given question from a large external corpus. Then the reader intends to generate answer condition on both the evidence and the given question. Many recent works focus on improving the retriever (Khat-tab et al., 2021; Qu et al., 2020). The readers based on PLMs such as T5 (Raffel et al., 2020) and InstructGPT (Ouyang et al., 2022) have become a common choice with the develop of LLMs (Izacard and Grave, 2020; Cheng et al., 2021; Yu et al., 2022; Chen et al., 2023).

**Generate-Then-Read Paradigm** Many works have demonstrated that the knowledge stored in the parameters of LLMs could serve as a “retriever” to some extent by directly generating text (Petroni et al., 2019; Roberts et al., 2020). Based on that, Yu et al. (2022) exploit the potential of directly generating contextual documents for open-domain questions and propose the *generate-then-read* paradigm. This paradigm directly generates contextual documents for a given question instead of retrieving documents from an external corpus.

### 2.2 Evaluation Ability of LLMs

Recently, utilizing LLMs as evaluators becomes a natural idea for their remarkable performance across various tasks (Kushman et al., 2014; Roy and Roth, 2016; Bubeck et al., 2023). LLMs aligned with Reinforcement Learning from Human Feedback (RLHF, Ouyang et al., 2022; Wang et al., 2022) are used to evaluate and compare the generations from different models. Other works prompt LLMs to achieve self-verify, self-refine, and self-debug ability in zero-shot setting (Shinn et al., 2023; Weng et al., 2022; Madaan et al., 2023). Especially, vicuna’s evaluation pipeline (Chiang et al., 2023) has obtained significant interest, which

leverages GPT-4 to score and compare candidate responses and provide explanations.

In our work, we unify these two paradigms into a new pipeline and leverage the evaluation ability of LLMs to enhance the ODQA performance for the first time.

### 3 Method of FlexiQA

Under the zero-shot setting, we will introduce the details of our proposed pipeline as shown in Figure 1 which comprises three steps: *Time-sensitivity Discrimination*, *Document Selection*, *Answer Generation*. First, we prompt an LLM to discriminate if the given question is time-sensitive. If the answer is **YES**, we choose the retrieved document as the evidence. Otherwise, we further prompt the LLM as an evaluator to decide which document (one is from generation, another one is from retrieval) is better from two perspectives: factuality and relevance. And finally we use the picked document as evidence to answer the given question by a reader.

#### 3.1 Time-Sensitivity Discrimination

In this subsection, we design an evaluation prompt template for time-sensitivity discrimination with one placeholder  $Q$ :  $T_{ts}(Q)$ . Given a question  $Q$ , a prompt  $T_{ts}(Q)$  is produced by the designed template. Then we instruct an LLM with  $T_{ts}(Q)$  to determine whether the given question  $Q$  is time-sensitive and LLM will give feedback to us with a the  $Label_{ts} = \mathbf{YES/NO}$ . The role of LLM here is a time-sensitivity discriminator, named  $LLM_{tsd}(\cdot)$ . Formally, we describe this process with the following formula:  $Label_{ts} = LLM_{tsd}(T_{ts}(Q))$ . The details of the prompt template is described in Appendix B.

As mentioned in Introduction, retrieval-based models won’t severely affected by time-sensitive issue because it is easy to replace the external knowledge source and then access the time-aligned documents. For the questions with  $Label_{ts} = \mathbf{YES}$  (i.e. the question is time-sensitive), we directly employ Information Retrieval (IR) to obtain the final evidence document:  $E = IR(Q)$ . For the non-time-sensitive questions, we obtain both the generated document from an LLM generator  $LLM_{kg}(\cdot)$  and the retrieved document from a retriever  $IR$ :  $G_{doc} = LLM_{kg}(Q), R_{doc} = IR(Q)$ .

#### 3.2 Document Selection

Now for the non-time-sensitive questions, inspired by the multi-dimensional evaluation ability of

LLMs, we leverage it here to unify the *generate-then-read* paradigm and the *retrieve-then-read* paradigm. Specifically, we leverage LLMs to compare two documents from two perspective, the factuality and relevance, then pick the better one as the evidence.

We design another evaluation template  $T_{ds}(Q, G_{doc}, R_{doc})$  for document selection, which includes three placeholders for the given question  $Q$ , the generated document  $G_{doc}$  and the retrieved document  $R_{doc}$ . See Appendix B for the detail description of evaluation template.

For any question, a prompt according to this template is produced and is used to instruct an LLM to score the two given documents. Next, the LLM output the document with higher overall score to serve as the evidence. The role of this LLM is a document selection evaluator, named  $LLM_{dse}(\cdot)$ . Formally, we describe this process with the following formula:  $E = LLM_{dse}(T_{ds}(Q, G_{doc}, R_{doc}))$ .

#### 3.3 Answer Generation

After the two steps above, we obtain the optimal evidence corresponding to the given question, which draw upon the two classic paradigms’ strong points and make up the shortcomings. Combining the question  $Q$  and the evidence  $E$ , we utilize another LLM as a reader  $LLM_{reader}(\cdot)$  to get the final answer:  $Answer = LLM_{reader}(Q, E)$ .

## 4 Experiments

### 4.1 Datasets & Metrics

We conduct comprehensive experiments on three widely used benchmarks: NaturalQuestions (NQ, Kwiatkowski et al., 2019), TriviaQA (Joshi et al., 2017), WebQuestions (WebQ, Berant et al., 2013). More detailed information can be found in Table 3 in Appendix A. We use Exact Match (EM) score (Zhu et al., 2021) and F1 score to evaluate models’ performance since the correct answer is not an flexible and open answer. For EM score, an answer is considered correct if and only if its normalized form has a match in the acceptable answer list. F1 score measures the recall of answer at the token level.

### 4.2 Baselines

We compare our pipeline with the following strong baselines. (1) BM25 (Robertson et al., 1995) + InstructGPT; (2) Contriever (Izacard et al., 2022) + InstructGPT; (3) Google + InstructGPT; (4)

DPR (Karpukhin et al., 2020) + InstructGPT; (5) InstructGPT (no docs.) (Ouyang et al., 2022); (6) GENREAD (Yu et al., 2022); (7) Vanilla-United: To fully evaluate the effectiveness of our proposed method, we also compare our pipeline with another vanilla method which combines the two documents from retrieval and generation as evidence directly without comparison. See Appendix A.2 for the details of above baselines.

### 4.3 Implementation Details

We follow the experimental settings as in GENREAD, and utilize *text-davinci-002* version of InstructGPT (Ouyang et al., 2022) for the knowledge generator  $LLM_{kg}$  and the reader  $LLM_{reader}$ . We employ *dpr-multi* version of DPR (Karpukhin et al., 2020) as the retriever. We leverage the *gpt-3.5-turbo* as discriminators  $LLM_{tsd}$  and  $LLM_{dse}$ . The generation temperature is set to  $T = 0$  to ensure the reproducibility.

### 4.4 Results

As shown in Table 1, our approach surpasses all previous methods and achieves the state-of-the-art performance with improvements of 3.3, 1.2, and 0.3 points of EM score on NQ, TriviaQA, WebQ, respectively. The results demonstrate that our pipeline could select suitable knowledge sources effectively to enhance the ODQA performance. Moreover, Vanilla-United, as the simplest way to fuse two paradigm knowledge, yields worse results than FlexiQA. The part of reason for this result is that there are content conflicts between the generated document and the retrieved document partly due to the three issues mentioned above. We provide a more detailed results in Table 4 in Appendix C including F1 metric.

### 4.5 Analysis

#### 4.5.1 Analysis of Time-Sensitivity

To analyze the experiment results for time sensitivity, we annotated the time-sensitive label for NQ and WebQ test sets. Specifically, for every question in the dataset, we label it with time-sensitive (**YES**) or non-time-sensitive (**NO**). We release these two annotated dataset for widely research on this issue for the future works.

We compare the performance of our FlexiQA with representative baselines, DPR + InstructGPT of *retrieve-then-read* paradigm, GENREAD of *generate-then-read* paradigm, the naive unify method Vanilla-United, on both time-sensitive (TS)

Models	NQ	TriviaQA	WebQ
*with retriever			
BM25+InstructGPT	19.7	52.2	15.8
Contriever+InstructGPT	18	51.3	16.6
Google+InstructGPT	28.8	58.8	20.4
DPR+InstructGPT	<u>29.1</u>	55.7	21.5
*without retriever			
InstructGPT (no docs.)	20.9	57.5	18.6
GENREAD	28.2	59	<u>24.8</u>
*with retriever and generator			
Vanilla-United	28.1	<u>59.3</u>	20.9
FlexiQA	<b>32.4</b>	<b>60.5</b>	<b>25.1</b>

Table 1: Exact match (EM) score on NQ, TriviaQA and WebQ test sets. The best performance model is in **bold** and the second one is in underline.

Models	NQ			WebQ		
	TS	non-TS	Total	TS	non-TS	Total
DPR+InstructGPT	<b>22</b>	<u>30.3</u>	<u>29.1</u>	<b>14.1</b>	21.6	21.5
GENREAD	17.6	29.7	28.2	9.9	<u>25.2</u>	<u>24.8</u>
Vanilla-United	17	29.6	28.1	9.9	21.4	20.9
FlexiQA	<u>21.9</u>	<b>33.6</b>	<b>32.4</b>	<u>11.3</u>	<b>25.6</b>	<b>25.1</b>

Table 2: The experiment results of time-sensitive issue. TS means the time-sensitive subset of NQ and WebQ, while non-TS means the non-time-sensitive subset.

and non-sensitive (non-TS) subsets of two datasets. The experiment results are presented in Table 2. It can be seen that the retrieval-based method DPR + InstructGPT outperforms the generation-based method GENREAD by a significant margin on TS subset of both datasets, which confirms our motivation that *retrieve-then-read* paradigm could handle time-sensitive issue by nature.

The results indicate that our pipeline indeed has the ability to recognize time-sensitive questions and to tackle this issue, resulting in a improvement of 4.3 points and 1.4 points of EM score on the TS subsets comparing to *generate-then-read* method GENREAD. However, there is still a gap between FlexiQA and DPR + InstructGPT on the TS subsets, which can be attributed to the unsatisfactory zero-shot evaluation ability of LLMs for time-sensitive discrimination. This could be a key study object in the future. We provide a more detailed results in Table 5 in Appendix D including F1 metric.

#### 4.5.2 Case Study of Document Selection

From the results on the non-TS subsets shown in Table 2, we can observe that FlexiQA is able to effectively select superior documents based on the evaluation of factuality and relevance. For both subsets, our FlexiQA has reached the optimal results

compared to other baselines. To further analyze the effectiveness of FlexiQA in document selection, we present three representative cases of three issues respectively in Appendix D. All the results show the strong performance of our FlexiQA.

## 5 Conclusion

In this paper, we unify two classic ODQA paradigms and propose a new pipeline called FlexiQA. FlexiQA leverages the multi-dimensional evaluation ability of LLMs flexibly for ODQA for the first time, and it tackles three existing drawbacks in the two classic paradigms: the time-sensitive issue, the irrelevance issue and the non-factuality issue. Moreover, we release two time-sensitivity annotated datasets for widely research on this issue in the future. Experimental evaluations show that our model achieves the best performance on three datasets.

## Limitations

The limitations of our pipeline FlexiQA are stated briefly as follows:

- First, due to the setting of our study (in the context of large-scale zero-shot models), the influence of biases in large language models is inevitable. In practical applications, the efficient few-shot learning (Zhang et al., 2024) could enhance the overall effectiveness of the pipeline.
- Another limitation of our work is that it primarily focuses on open-domain question answering, which may could not be generalized to specialized domains.

## A Datasets and Baselines

### A.1 Datasets

We conduct comprehensive experiments on three widely used benchmarks: NaturalQuestions (NQ, Kwiatkowski et al., 2019), TriviaQA (Joshi et al., 2017), WebQuestions (WebQ, Berant et al., 2013).

- **NQ**: comprises real queries that user issued on Google search engine along with answers.
- **TriviaQA**: consists of question-answer pairs collected from trivia and quiz-league websites
- **WebQ**: consists of questions selected using Google Suggest API, where the answers are entities in Freebase.

Statistics	NQ	TriviaQA	WebQ
Train	79168	78785	3478
Validation	8757	8837	300
Test	3610	11313	2032
Avg. Qlen	9.3	16.9	6.7
Avg. Alen	2.4	2.2	2.4

Table 3: Dataset splits and statistics.

### A.2 Baselines

We compare our pipeline with the following strong baselines. (1) **BM25 + InstructGPT**: BM25 (Robertson et al., 1995) is a sparse retrieval method; (2) **Contriever + InstructGPT**: Contriever (Izacard et al., 2022) is an unsupervised dense retrieval model; (3) **Google + InstructGPT**; (4) **DPR + InstructGPT**: DPR (Karpukhin et al., 2020) is a supervised dense retrieval model and it trained on NQ, TriviaQA and WebQ datasets; (5) **InstructGPT (no docs.)** (Ouyang et al., 2022): InstructGPT is an LLM that usually serve as a reader or generator in ODQA; (6) **GENREAD** (Yu et al., 2022): GENREAD is the SoTA method in ODQA and is the first work that propose *generate-then-read* paradigm; (7) **Vanilla-United**: Moreover, in

order to fully evaluate the effectiveness of our proposed method, we also compare our pipeline with another vanilla method which concatenates the two documents from retrieval and generation as contextual document directly.

All the baselines have the similar prompt template format for answer generation with a slight variation based on the number of supporting documents.

## B Template Details

### B.1 Template for Time-sensitivity

" Is the answer to the question depend on current time? Output with label: yes, no.\n\nQuestion: {question}\n\nThe label is "

### B.2 Template for Document Selection

"You are a helpful and precise assistant for checking the quality of the statement.\n[Question]\n{question}\n\n[Statement 1]\n{statement\_1}\n\n[Statement 2]\n{statement\_2}\n\n[System]\n We would like to request your feedback on the quality of each statement to the user question displayed above.\n Please rate the factuality(according to wikipedia), relevance of each statement.\n\n Each statement receives an overall score on a scale of 1 to 10, where a higher score indicates better overall performance.\n Provide a comprehensive explanation of your evaluation, avoiding any potential bias and ensuring that the order in which the statement were presented does not affect your judgment. Output the better statement with '1', '2'. \n\n Output with the following format:\n The better statement is: <1 or 2>\n Evaluation evidence of statement: <your evluation explanation here>"

## C Results

We provide a more detailed results in Table 4 including EM and F1 metric.

## D Analysis

We provide a more detailed results in Table 5 including EM and F1 metric. And representative cases of three issues are in Table 6, Table 7, Table 8, respectively.

**Question:** Who is the current presenter of BBC Radio 4 programme Desert Island Discs? (TriviaQA)

**Golden Answer:** Kirsty Young

**Generated document:** The current presenter of BBC Radio 4 programme Desert Island Discs is Lauren Laverne.

**Prediction:** Lauren Laverne.

**Retrieved document:** Desert Island Discs Desert Island Discs is a radio programme broadcast on BBC Radio 4. It was first broadcast on the BBC Forces Programme on 29 January 1942. Each week a guest, called a 'castaway' during the programme, is asked to choose eight recordings (usually, but not always, music), a book and a luxury item that they would take if they were to be cast away on a desert island, whilst discussing their lives and the reasons for their choices. It was devised and originally presented by Roy Plomley. Since 2006, the programme has been presented by Kirsty Young...

**Prediction:** Kirsty Young.

---

**Question:** Who is the minority leader of the house of representatives now? (WebQ)

**Golden Answer:** Nancy Pelosi

**Generated document:** The minority leader of the United States House of Representatives is the floor leader of the minority party. The current minority leader, Kevin McCarthy, is a Republican.

**Prediction:** Kevin McCarthy.

**Retrieved document:** the Speaker of the House. Typically, the Speaker does not participate in debate and rarely votes on the floor. In some cases, Majority Leaders have been more influential than the Speaker; notably, Tom DeLay was more prominent than Speaker Dennis Hastert. In addition, Speaker Newt Gingrich delegated to Dick Armey an unprecedented level of authority over scheduling legislation on the House floor. The current Minority Leader Nancy Pelosi serves as floor leader of the opposition party, and is the counterpart to the Majority Leader...

**Prediction:** Nancy Pelosi.

## Abstract

The recent advancements in the realm of Automatic Speech Recognition (ASR) post-processing have been primarily driven by sequence-to-sequence paradigms. Despite their effectiveness, these methods often demand substantial amounts of data, necessitating the expensive recruitment of phonetic transcription experts to rectify the erroneous outputs of ASR systems, thereby creating the desired training data. Back TranScription (BTS) alleviates this issue by generating ASR inputs from clean text via a Text-to-Speech (TTS) system. While initial studies on BTS exhibited promise, they were constrained by a limited dataset of just 200,000 sentence pairs, leaving the scalability of this method in question. In this study, we delve into the potential scalability of BTS. We introduce the "Hyper-BTS" dataset, a corpus approximately five times larger than that utilized in prior research. Additionally, we present innovative criteria for categorizing error types within ASR post-processing. This not only facilitates a more comprehensive qualitative analysis, which was absent in preceding studies, but also enhances the understanding of ASR error patterns. Our empirical results, both quantitative and qualitative, suggest that the enlarged scale of the Hyper-BTS dataset sufficiently addresses a vast majority of the ASR error categories. We make the Hyper-BTS dataset publicly available.<sup>1</sup>

## 1 Introduction

A large-scale dataset-based NLP research paradigm, which is based on foundation models (Bommasani et al., 2021) such as GPT-4 (OpenAI, 2023), and prompt tuning using natural-language prompts (Liu et al., 2021) has recently been of interest in both the academia and industry. Such large-scale models have proven that there is

efficiency in the usage of large-scale datasets, and include a scaling law model (Kaplan et al., 2020), which theoretically demonstrates their justification.

There is also increasing application of this promising research paradigm in the Automatic Speech Recognition (ASR) field. Aside from traditional speech recognition architecture-based research such as Gaussian Mixture Models (GMMs) (Stuttle, 2003), and Hidden Markov Models (HMMs) (Gales and Young, 2008) based on acoustic and language models, model-centric ASR research using transfer learning based on pre-trained models is currently being widely conducted (Baeovski et al., 2020; Giollo et al., 2020; Hjortnæs et al., 2021; Zhang et al., 2021).

Model-centric ASR research requires the configuring of many parameters for the pre-training of models, as well as a sufficiency of computing power (*e.g.*, GPU) to process large-scale datasets. Thus, despite its proven efficiency, insufficiency of computing power in real-world service scenarios limits the performance of this ASR model approach. In other words, since many parameters and data are required when training a model, companies that do not have sufficient server or GPU environments have difficulty configuring service environments and improving performance using the model-centric ASR approach (Park et al., 2020b).

Conversely, a different approach, termed “data-centric” has also emerged, which aims to improve ASR model performance by improving the data quality or pre-processing and post-processing without model modification (Voll et al., 2008; Mani et al., 2020; Liao et al., 2020; Park et al., 2021a). This alleviates the previous limitations (of computation cost and non-scalable human annotation) because it does not modify the model, and enables its application to lightweight models such as the vanilla Transformer, which can be sufficiently processed by a single CPU (Vaswani et al., 2017; Klein et al., 2020).

<sup>†</sup> Corresponding author

<sup>1</sup><https://github.com/Parkchanjun/HyperBTS>

There has been a recent endeavor in the data-centric ASR post-processor approach known as Back Transcription (BTS) (Park et al., 2021b). BTS, an automatic data construction method, has been devised for use as substitute for publicly available training data, for ASR post-processor based on a sequence-to-sequence model (converting input sequences into target sequences) and to eliminate the requirement to build parallel corpora by human-annotators. Specifically, this method integrates Text-to-Speech (TTS) with Speech-to-Text (STT) efficiently for building a pseudo-parallel corpus (see detail in Appendix A).

However, in a current BTS study, model training was performed using only a 200,000 parallel corpus in Korean. While this may be a significant amount from the point of view of low-resource Neural Machine Translation (NMT), it is very small in comparison with the recent research flow utilizing large-size data. In addition, only the method and demo system were disclosed in the BTS study, but no dataset was released with the work. Therefore, to improve the performance of an ASR post-processor, based on BTS technology, we take advantage of the existing research flow to build large-capacity data and present a Hyper-BTS dataset that is five times the size of the existing BTS study, with a one million-text large-capacity dataset. Further, to activate the relevant research interest, we make it publicly accessible, dividing the data into training, validation, and test datasets. To the best of our knowledge, this is the first time a parallel corpus for an ASR post-processor has been made public. By opening the data in this way, ASR post-processor research can be triggered, and the problems with the existing commercial ASR API systems can be studied and improved.

Existing commercial ASR APIs currently present problems such as spacing, conversion of numbers, and pronunciation boundary errors. Therefore, it is inevitable that ASR post-processor recognition results will contain unexpected errors. In other words, there is room for performance improvement using ASR post-processor, and additionally, precise error analysis is required.

Despite the acknowledgement of the existence of recognition errors, there are currently no precise criteria for categorizing output error types from ASR systems. Many studies related to large-scale language models (Baevski et al., 2020; Zhang et al., 2021) have through their works attempted to de-

velop a model (Gales and Young, 2008) for improving ASR systems. However, analysis of the types of errors output by ASR systems and guidelines on research and design are insufficient, as existing studies simply analyze the advantages and disadvantages of generated results without benchmarking the results against some set of standards.

In this study, we propose novel criteria of error type categorization of ASR post-processor specialized in Korean, in terms of BTS work also based on Korean. We present this set of criteria to be used for the direction of further work in enhancing ASR post-processor performance. In addition, based on our defined error types, we perform an in-depth qualitative analysis of the Hyper-BTS dataset-based ASR post-processor to verify whether actual error correction is performed well. Through this, we suggest methods that can be employed to improve the performance of ASR post-processor systems.

The contributions of this study are as follows:

- We released a large-scale Hyper-BTS dataset, five times larger than the existing BTS dataset, separated into training, validation, and test sets. It is the first published parallel corpus for ASR post-processor to the best of our knowledge.
- Our various quantitative analyses of ASR post-processor experiments using the Hyper-BTS dataset demonstrate an objective performance of the corresponding dataset.
- We proposed a detailed error classification criterion for Korean, which has significantly different linguistic characteristics from other languages, and based on this, we performed a qualitative analysis on the Hyper-BTS dataset-based ASR post-processor to verify the dataset. Our analysis results enable us to present a method that can be used to improve the performance of ASR post-processor systems.

## 2 Hyper-BTS Dataset

### 2.1 Dataset Design

**Build Mono Corpus** As a language pair to construct the Hyper-BTS dataset, we arrange it in the same language as the present BTS paper and gather monolingual corpus from three sources.

Hyper-BTS	Train		Valid		Test	
	src	tgt	src	tgt	src	tgt
# of sents	1,000,000	1,000,000	5,000	5,000	3,000	3,000
# of tokens	32,527,375	34,308,007	140,641	147,390	83,230	87,207
# of words	8,857,758	8,929,016	37,792	37,112	22,388	21,975
avg of SL $\Delta$	32.66	34.45	28.13	29.48	27.74	29.07
avg of WS	8.89	8.97	7.56	7.42	7.46	7.33
avg of SS	7.89	7.96	6.56	6.42	6.46	6.33
# of K-toks *	24,243,741	24,900,124	106,217	107,106	63,077	63,659
# of E-toks	129,281	88,156	517	959	284	509
# of S-toks	13,099	1,282,930	36	6,069	12	3,575

Table 1: Statistics of our Hyper-BTS Dataset. We define the original colloquial sentences as target (tgt) and the generated sentences after BTS as source (src). Moreover, we attempt to identify the linguistic features of our parallel corpus including # of sents/tokens/words: number of sentences/tokens/words;  $\Delta$  avg of SL/WS/SS: average of sentence length/words/spaces per sentence; \* # of K-toks/E-toks/S-toks: number of Korean/English/special-symbol letter tokens.

First, 129,987 sentences were excerpted from business and technology TED Talks, provided in writing translated into Korean. Second, 373,013 sentences were discovered, corresponding to the spoken language among Korean-English, and translated parallel corpus from AI-HUB, which is the most reliable and utilized data platform in numerous examinations related to the Korean language. Third, 505,000 sentences were extracted from the National Institute of Korean Language’s colloquial corpus.

**TTS(Text-To-Speech)** The built mono-corpus is converted to voice data in mp3 format, based on the Naver Clova Voice API (Chung, 2019). The 503,000 sentences from TED Talks and AI-HUB were divided into 9,963,296 voice tokens and synthesized into 7,963,935 seconds of voice data. The 505,000 sentences extracted from the spoken corpus of the National Institute of Korean Language were separated into 14,595,647 voice tokens and synthesized into 11,563,990 seconds of voice data. The respective running time was five and six days. The reason for using the commercial system is to lower entry barriers by allowing companies without a built-in TTS system to use BTS.

**STT(Speech-To-Text)** Naver Clova speech recreation API was used to convert results of TTS voice data to text data. It took 10 and 11 days, respectively, and the total time required was three weeks. The Hyper-BTS dataset of 1,008,000 sentence pairs is eventually established.

**The Final Constructed Hyper-BTS Dataset** Finally, the Hyper-BTS dataset of 1,008,000 sentences is separated into train-, validation-, and test-

sets. Train-set consisted of 1,000,000 sentences, verification-set was 5,000 sentences, and test-set had 3,000 sentences. We attempted to minimize results-to-data sources bias in the test-set by extracting 1,500 sentences from AI-HUB/TED and 1,500 sentences from the colloquial corpus of the National Institute of Korean Language.

## 2.2 Data Statistics and Analyses

We conducted an in-depth statistical analysis of the Hyper-BTS dataset, as shown in Table 1.

**Fundamental Analysis** Fundamental analysis was done on the number of sentences, tokens, and average sentence length. First, in the case of sources through Hyper-BTS, the sentence length was shorter by 1.79, 1.35, and 1.33 on average than the original sentence target. The total number of tokens decreased by 5.2%, 4.6%, and 4.6%, respectively. In the case of a target, the number of words in the train-set was 71,258 more than the source. We configured the validation- and test-sets to have different features from the train-set. Therefore, the number of words in the validation and test set decreased by 680,413 from the source in the target, respectively. Considering the average spacing, the total number of words increased even though the total number of tokens was relatively small due to additional unnecessary words in sentences.

**Token Analysis in Korean and English** The second data statistic is the analysis of Korean and English tokens. The Korean token (K-token) essentially lost 656,383, 889, and 582 train-, validation-, and test-set tokens in source sentences than target sentences, caused by the omission of termination and suffixes. These results reproduce the character-

istics of Korean speakers who pronounce endings vaguely in the model. Additionally, the English token (E-token) is transformed into a Korean token as pronounced or omitted because of recognition failure. The train-set lost as much as 41,125 tokens in the target rather than the source. However, we had a significant increase in the number of misaligned transformations from Korean to English, increasing 442 and 225 in the target than in the source for the validation- and test-sets.

**Special Token Analysis** Third data statistic, special character tokens (S-tokens) show the most notable differences in train-, validation-, and test-sets, as 98.89%, 99.41%, and 99.64% of tokens disappeared from source rather than target sentences. In particular, periods, commas, exclamation marks, and brackets added to describe the situation in the transcription process of the original data have a substantial influence. Such special characters may contain colloquial tones or emotions that the text does not sufficiently represent. Therefore, excessive omission of special characters is like failing to include some of the rich expression information of the spoken language in the written language.

By disclosing the established Hyper-BTS dataset, we attempt to lower the entry barriers of companies and research institutes into the study. This approach can alleviate the cost concerns of many small and medium-sized businesses that do not have individual speech synthesis and recognition technologies.

### 3 Experiments and Results

#### 3.1 Setting

**Experiments Design** To determine the effectiveness of the large-scale dataset, we separated the 1 million Hyper-BTS dataset into 10 anchor points. We then trained an ASR post-processor with this corpus and evaluated its performance differences by scaling up the training data size. The experimental results for these are shown in Figure 1.

Next, we adopted parallel corpus filtering (PCF) to the Hyper-BTS dataset, and inspected its impact on the ASR post-processor performance. PCF indicates a selection process that filters out low-quality sentence pairs and acquires high-quality data (Koehn et al., 2020). Particularly in the machine translation (MT) research field, PCF techniques are robustly applied for the performance improvement of MT systems.

Considering the process of constructing the Hyper-BTS dataset, inherent limitations of SST or TTS systems can result in unintended errors. These errors include several outliers such as too short or too long sentences, and omission of the source sentence. We applied the PCF methodologies proposed in Park et al. (2020a) to alleviate these errors and constructed a high quality dataset. The substantial impact of applying the PCF methods can be verified in Table 2.

Finally, we performed a qualitative analysis of a Hyper-BTS dataset-based ASR post-processor in section 3.2. Through investigating post-processor performance results, we propose new ASR post-processor error types and use these to analyze ASR post-processor models. Additionally, we analyzed the practical effectiveness of increasing the size of the Hyper-BTS dataset.

**Model Details** All the ASR post-processors experimented in this study were built on the transformer-base model structure. These were trained on our Hyper-BTS dataset, and, for the training process, we used the same hyper-parameter setting as Vaswani et al. (2017). For tokenization, we adopted sentence piece (Kudo and Richardson, 2018) model with 32,000 vocabulary size.

**Evaluation Details** For the evaluation metric, we adopted GLEU (Napoles et al., 2015) and BLEU (Papineni et al., 2002) as in BTS (Park et al., 2021b). GLEU is a correction system specialized metric that is similar to BLEU, but considers source sentences.

#### 3.2 Quantitative Analysis

**Importance of Data Size** First, we showed the performance improvement that can be obtained by the ASR post-processor, compared with the baseline. In these experiments, the baseline indicates the performance between source sentences and their corresponding target sentences in a test dataset. As shown in Figure 1, compared with baseline whose BLEU score is 40.33, ASR post-processors give significantly surpassing performance for all the anchor points. In particular, ASR post-processor trained with 1 million training data shows 25.31 higher BLEU score over the baseline.

We then inspected the performance difference derived by increasing data size. These are shown in the right side plot of the Figure 1, and denoted "diff". As shown in Figure 1, we can obtain the highest performance by utilizing the whole data

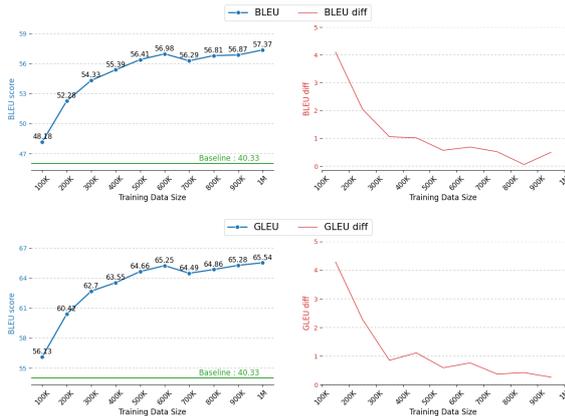

Figure 1: Performance difference depending on the amount of training data. Left figures show the performance of the Hyper-BTS-based ASR post-processor depending on the data size. Right figures (diff) show the performance difference derived by adding 100,000 training data. Baseline in each figure indicates the quality between source sentences and target sentences in Hyper-BTS test-set.

(1 million), that is, 48.18 GLEU score, and 56.13 BLEU score. These are 9.19 and 9.41 higher than the 100,000-utilized model, for the GLEU and BLEU scores, respectively. This shows that the Hyper-BTS dataset can derive sufficiently increase performance of the ASR post-processor.

One notable thing is that from 600,000 training data, the performance difference achieved by increasing the data size approximately converges to zero. This shows that there is a limit to the improvement in ASR post-processing performance that can be obtained by increasing the amount of training data. These results show similarities with back translation (Edunov et al., 2018), which is a pseudo-data generation method targeting NMT. This suggests that similar data scaling applied in NMT can be applied in the ASR post-processing field (Edunov et al., 2018) can be applied.

**Effect of Parallel Corpus Filtering** For the verification of the effectiveness of PCF, we did a comparative analysis of performance results with the original ASR post-processor model and the PCF applied model. Specifically, we applied PCF methodology proposed in Park et al. (2020a) to our Hyper-BTS dataset. The particular PCF method entails eliminating uncorrected aligned sentence pairs by employing the method used in Gale and Church (1993). This included pairs in which the source and target sentences are identical, which is more

Dataset	BLEU	GLEU
Hyper-BTS (1M)	65.54	57.37
Hyper-BTS (1M)+ Filter	<b>66.04 (+0.50)</b>	<b>57.45 (+0.08)</b>

Table 2: Parallel Corpus Filtering Effect Verification Experiment

than 50% non-alphabetic pairs, 100 words or 1000 syllables, 30% white spaces or tabs, and a pair of sentences containing more than nine special symbols. Through these, 45,502 and 140 sentence pairs were eliminated from the training- and validation-sets, respectively.

Through the inspection of filtered data, we find that STT recognition error is the most frequent error type. By applying PCF, these errored data, as well as low quality data can be filtered out. Our experimental results considering these are shown in Table 2. These show that applying PCF can derive improvement of ASR post-processing performance. These also imply the importance of the quality of the training data and suggest the guideline for the data construction process should consider the quality of the corpus.

### 3.3 Qualitative Analysis

**Proposal of new error types** In addition to quantitative analysis, we conduct qualitative analysis. For this, we propose a new guideline for analyzing ASR post-processor trained on Hyper-BTS dataset, defining 5 primary error types as shown in Table 3.

First, we define **spacing error** as a case that there are differences in the spacing result between the recognized and reference sentence. Second, we specify **foreign word conversion error** as a case where an English word is recognized as a Korean word or vice versa. Third, we define **punctuation error** as that punctuation is not attached to the sentence or incorrectly recognized. Fourth, we define **numeric word conversion error**, where a numeric word is not recognized as a number but as a Korean word. Finally, we define **spelling and grammar error** which is the most frequent error type in ASR. Because it is a factor that strongly influences the performance of ASR systems, we subdivide it as a primary and secondary error to analyze precisely.

Primary error is defined as follows: **Deletion error** (In case that word itself, ending, or Korean postposition is not recognized.), **Addition error** (In case some syllables in a word are repeated, or unpronounced postposition or ending is added), **Substitution error** (In case that a word is replaced

Type of Error		Description	Example	
Spacing error		In case the spacing result between the recognition result and correct sentence is different.	Answer: 이 불안감 뭘까 Recognized: 이불 안감 뭘까	
Foreign word conversion error		In case some syllables are incorrectly converted from English to Korean or Korean to English.	Answer: SNS 이벤트 Recognized: 에스엔에스 이벤트	
Punctuation error		In case some punctuation is not attached or is incorrectly used.	Answer: 밥 먹었니? Recognized: 밥 먹었니	
Numeric word conversion error		In case some numbers are not converted to numbers.	Answer: 21세기 Recognized: 이십일세기	
Spelling and Grammar error	Primary	Deletion	In case the whole word, Korean postposition of the word, or ending is not recognized.	Answer: 오늘 하루는 어땠어? Recognized: 하루는 어땠어?
		Addition	In case some syllables of the word are repeated, or unpronounced endings are added to the word.	Answer: 하루가 길다 Recognized: 하루하루가 길다
		Substitution	In case a word is substituted with other words which have similar pronunciation.	Answer: 순수한 사람 Recognized: 순수한 사람
	Secondary	Pronunciation Boundary	In case some words are separated or combined with the different forms between the phonetic boundaries.	Answer: 전 역시 못해요 Recognized: 저녁시 못해요
		Spelling	In case the primary error causes a spelling error which makes the sentence nonsensical in the jamo unit.	Answer: 이제 곧 들어가야 해 Recognized: 이제 곧 들어가야 해
		Grammar	In case the primary error causes grammatical problems.	Answer: 회의 자료인 프린트물 Recognized: 회의 자료 임프린트 물
	Meaning	In case the primary error changes the meaning of the sentence.	Answer: 21세기에 보기에에는 Recognized: 21세기에 보기에에는	

Table 3: Error types proposed in this study for qualitative analysis of Korean ASR results. There are five main types of errors; In particular, spelling and grammar errors are subdivided into primary and secondary tagging. For these errors, both primary and secondary error tagging should be done.

with another word that has a similar pronunciation), and **Pronunciation boundary error** (In case that a word is separated into several words, or several words are combined into a single word at the boundary of pronunciation accompanied by a change in form.)

In addition, we define secondary errors as follows: **Spelling error** (In case that the primary error results in a spelling error which makes the meaning of sentence nonsensical at jamo-level), **Grammar error** (In case that the primary error causes a grammar error), **Meaning error** (In case that primary error leads to a shift in sentence meaning). If a sentence has spelling and grammar errors, both the types of primary and secondary errors defined above should be tagged.

For example, let us consider the sentence “이제 곧 들어가야 해(I have to go in soon)”, recognized as “이제 콘 들어가야 해(I have to go into the corn)” by Because of misrecognition of the word ‘곧(soon)’ as ‘콘(the corn),’ which is a similar word but different word, a primary error is a substitution; moreover, because the entire meaning of the sentence is changed, a secondary error is meaning error.

These error types can provide the possibility of evaluating the advantages and disadvantages of the ASR model by clarifying misrecognition errors that were previously unclear in Korean speech recognition. In other words, we can summarize the weak and robust parts of various speech recognition systems by using these. Based on this criterion of errors, we also performed qualitative analysis on how well the ASR post-processor model trained with the Hyper-BTS dataset corrects which types of errors.

**Main Results** Table 4 shows the results of qualitative analysis of the effects of correction for each input sentence with the Hyper-BTS dataset-based ASR post-processor. This qualitatively shows that the Hyper-BTS-based post-processor can effectively correct errors that commonly occur in the Korean ASR process.

First, it was able to correct the error in which foreign words used in Korean sentences are not adequately recognized. There was a problem that the word ‘David’ is recognized as Korean ‘데이비드,’ being not able to identify the foreign word. However, we exhibited that a post-processor based on the Hyper-BTS dataset could correct it.

Second, it was possible to correct the numeric word recognition error in which the numeric word is recognized as pronounced itself, not as the numeric word. As shown in the numeric conversion error in Table 4, the Hyper-BTS-based post-processor model corrected the word “열한시(eleven o’clock)” whose pronunciation is recognized as itself to Korean, to “11시(11 o’clock)”. This shows that it can provide results with improved readability by effectively correcting numeric conversion errors.

Third, it could correct the problem of attaching punctuation and spacing, which are chronic problems of the ASR model through Hyper-BTS-based post-processor. Let us consider two examples “다시 한번(Onceagain)” corrected as “다시 한번(Once again)” and “괜찮을까요(is it ok)” corrected as “괜찮을까요?(is it ok?)” shown in Table 4. It indicates that the post-processor based on the Hyper-BTS dataset can supply higher quality results to the end-user by appropriately correcting erroneous spacing or punctuation cases, making users easier to under-

Input Sentence	Output Sentence	Type of Error
현신적인 데이비드는 환자가 필요로 하는것은 결국 해 주겠다는것을 보여준것이 아닐까 하는 생각이 들었어요 (Devoted 데이비드, I wondered if he was showing that he would eventually do what the patient needed.)	현신적인 David는 환자가 필요로 하는 것은 결국 해 주겠다는 것을 보여준 것이 아닐까 하는 생각이 들었어요. (Devoted David, I wondered if he was showing that he would eventually do what the patient needed.)	Foreign word conversion
그날 당신 집으로 열한시까지 가져다 줄게요 (I'll bring it to your house that day by eleven o'clock.)	그날 당신 집으로 11시까지 가져다 줄게요. (I'll bring it to your house that day by 11 o'clock.)	Numeric conversion
제가 교환권을 출력하지 않았는데 괜찮을까요? (I didn't print the voucher, is it ok?)	제가 교환권을 출력하지 않았는데 괜찮을까요? (I didn't print the voucher, is it ok?)	Punctuation
다시 한번 나는 정말로 죄송합니다 (Once again I'm really sorry)	다시 한번 나는 정말로 죄송합니다. (Once again I'm really sorry.)	Spacing
이것은 다양한 색을 보여 주는 사진 (is a picture showing the different colors)	이것은 다양한 색을 보여 주는 사진입니다. (This is a picture showing the different colors.)	Spelling and Grammar errors (Deletion-Meaning)
그것은 범죄 사진이 일어난 지역 소속의 공정한 배심원단에 의하여 진 행된 (This was decid by an impartial jury from the area where the crime took place)	그것은 범죄 사진이 일어난 지역 소속의 공정한 배심원단에 의하여 진 행됩니다. (This is decided by an impartial jury from the area where the crime took place)	Spelling and Grammar errors (Deletion-Grammar)
우리집엔 좋은 경치를 가지고 있어요 (In ourhouse has a nice view)	우리 집은 좋은 경치를 가지고 있어요. (Our house has a nice view.)	Spelling and Grammar errors (Substitution-Grammar)
이진훈이 제일 우선이라는 걸 명심하세요 (Keep in mind that LeeJinHoon has priority)	이 주문이 제일 우선이라는 걸 명심하세요. (Keep in mind that this order has priority.)	Spelling and Grammar errors (Pronunciation Boundary-Meaning)

Table 4: Examples of Hyper-BTS dataset-based ASR post-processor outputs for qualitative analysis. Note that we indicate text containing the corresponding errors generated by BTS in red; also, we indicate the original correct result in blue text.

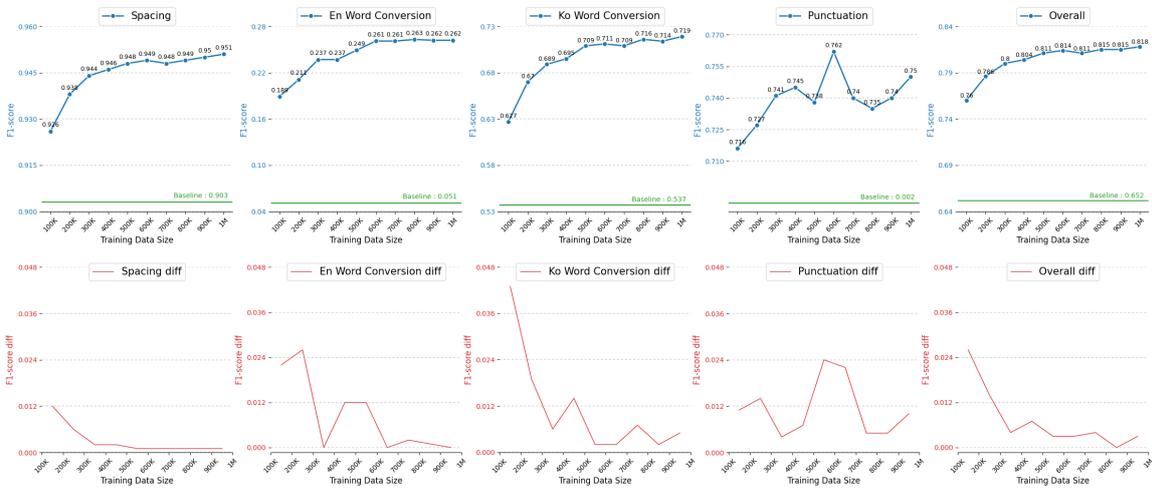

Figure 2: Performance difference, depending on the amount of training data. F1-scores are reported for each feature, including model performance on automatic spacing, word conversion, punctuation, and overall. KO and EN indicate Korean English respectively. Upper figures show the performance of the Hyper-BTS-based ASR post-processor for the above three factors, depending on the data size. Lower figures show the performance difference (diff) for the above three factors, derived by utilizing additional 100,000 training data. Baseline indicates the f1-score of each factor between source sentences and target sentences in Hyper-BTS test-set.

stand the intent of the sentence.

Fourth, the Hyper-BTS dataset-based post-processor model was able to correct word substitution caused by speech recognition errors with similar pronunciations or word separation and integration problems at pronunciation boundaries between the words in consideration of surrounding contexts. In the example sentence of Table 4, Hyper-BTS-based post-processor corrected “우리집엔(In ourhouse)” which is a substitution-grammar error as “우리 집은(Our house is).” It can be said that the post-processor corrected the adverb Korean post-position “-엔(In)” to nominative postposition “-은(is)” which can make the word nominative, considering the grammatical information. In the following

example sentence, the subject recognized as “이진훈(LeeJinHoon)”, which means a person’s name, was corrected to “이 주문(This order)” regarding the context of the ordinal information of “우선(priority).”

Fifth, it can be confirmed that the Hyper-BTS dataset-based post-processor plays a significant role in correcting sentences that are not attached adequately with terminating endings because of speech recognition errors, filling the incompleteness of the sentence structure. In Korean, an error in which the ending is not appropriately attached is a problem that must be resolved because it dramatically changes the meaning of a sentence beyond a spelling error.

In particular, because of the head-final linguistic characteristics of Korean, where the predicate is placed at the end of the sentence, if sentence termination is not done correctly, the sentence’s overall semantic and syntactic structure can be significantly changed. As shown in the example sentence with the deletion error in Table 4, even the cases that the syntactic structure of the sentence was changed because of the disappearance of “입니다(is)” at the end of the sentence, it was possible to correct it as a complete sentence by restoring some part of omitted. Also, the word “진행된(decid),” which is caused an error by recognition error of the terminating ending, could be corrected as “진행됩니다(decided)” with the appropriate terminating.

Additionally, we analyzed correction effects of post-processor according to the amount of trained data in Appendix B.

### 3.4 Additional Analysis

In this experiment, we analyzed the practical effectiveness of Hyper-BTS-based ASR post-processor with the following three aspects: Spacing, Foreign word conversion, Punctuation. These are mainly related to the readability and satisfaction of the end users of the ASR services.

As in the previous experiment, we established 10 anchor points to the whole training data, and verified the performance difference induced by increasing the data size. We inspected the corrected sentence by checking whether each factor is in the correct position. For the performance evaluation of each post-processor, corresponding multi-class accuracy is estimated based on the f1-score. Experimental results are shown in Figure 2.

**Automatic Spacing** We first evaluated the practical effectiveness that can be obtained by applying Hyper-BTS-based ASR post-processor. As can be seen in our figure, a generally larger amount of data derived higher performance, and performance difference goes to converge as adding more training data. Especially, the performance of the post-processor trained by 1M data shows a 0.951 f1-score, which indicates that spacing errors can almost be thoroughly corrected by our Hyper-BTS-based ASR post-processor.

**Foreign Word Conversion** For the evaluation of the foreign word conversion, we counted the number of correct positions of Korean and English words in a target sentence and estimated f1-score. Through our experiments, it can be seen that ASR

post-processor attained 0.182 and 0.211 f1-score higher performance than the baseline, for the Korean word and English word conversion, respectively. Considering English word conversion, baseline showed a 0.0051 f1-score, which shows the weak point of the ASR system. However, this can be effectively amended by ASR post-processor, up to 0.262 f1-score.

**Punctuation Attachment** Considering punctuation attachment, we used f1-scores that check the correct position of the symbols in a target sentence. As shown in the fourth plot of the Figure 2, we can find that the baseline shows only a 0.002 f1-score. This indicates that the punctuation attachment, symbol attachment, and sentence separation can be seen as some of the most challenging issues of the ASR system. However, we can find that the f1-score about the punctuation attachment can be raised up to 0.762 by applying ASR post-processor, and even with 100K training data, we can obtain a 0.715 f1-score. This result shows that Hyper-BTS-based post-processor can effectively deal with the inherent limitations of the ASR system.

**Overall f1-score** Finally, we verified the effectiveness of the Hyper-BTS dataset for the overall performance of the above factors. As can be seen in the results, compared with the baseline which shows a 0.652 f1-score, post-processing can improve its quality up to 0.818. This shows that the Hyper-BTS-based ASR post-processor can effectively catch and correct the internal errors that ASR system cannot deal with.

## 4 Conclusion

In this study, we conducted a thorough analysis of results from rigorous experiments after developing the Hyper-BTS dataset and training an Automatic Speech Recognition (ASR) post-processor. Both quantitative and qualitative outcomes validate the effectiveness of the Hyper-BTS dataset in enhancing the performance of the ASR post-processor. Recognizing the broader implications of our research, we are committed to facilitating unrestricted access to this dataset for both industry professionals and academic researchers. Additionally, we pioneered a robust quality control mechanism by formulating novel guidelines anchored in the categorization of ASR post-processor error types, thereby aiming to elevate the qualitative dimensions of ASR post-processing.

## Limitations

While our research primarily focuses on the Korean language, the depth of this investigation offers significant insights even within this narrow scope. Nevertheless, we understand the importance of expanding to other languages in subsequent studies.

A limitation of our current study is the use of the Vanilla Transformer for our experiments. We chose this model to evaluate the Hyper-BTS dataset due to its broad use and manageable computational requirements, especially when compared to cutting-edge models. By using the Vanilla Transformer, we aimed to present findings that are both practical in terms of computational cost and relevant to a wide range of researchers.

Most importantly, we would like to clarify the key contributions of our work. In this study, we built a large scale ASR post-processing datasets (Hyper-BTS) that has shown to significantly improve the performance of ASR post-processors as shown in Figure 1 & 2. On top of releasing the dataset, we believe that our use of BTS technology in curation of the dataset is also a significant contribution as it shows how large-scale parallel corpora can be created effortlessly, without any form of human annotation. Furthermore, our dataset creation process only requires raw Korean textual data to train ASR post-processor which is arguably more abundant than other forms of data such as GEC (Grammar Error Correction) Korean text dataset.

In addition to the dataset, we also propose a new guideline to analyzing Korean ASR results through definition of different error types as shown

in Table 3. With the new analysis guideline, which was previously unavailable for Korean ASR, and along with the newly proposed Hyper-BTS dataset, we hope to benefit other researchers in this field of research.

## Ethics Statement

Hyper-BTS is built using datasets publicly available online on platforms such as Korean AI-HUB. These datasets are open-source and free from copyright issues. As such, after thorough examination of our dataset curation and experimentation procedure, we are confident that there is no ethical issue in our work. Also, We reviewed all ethical issues in our experiments and made fair comparisons.

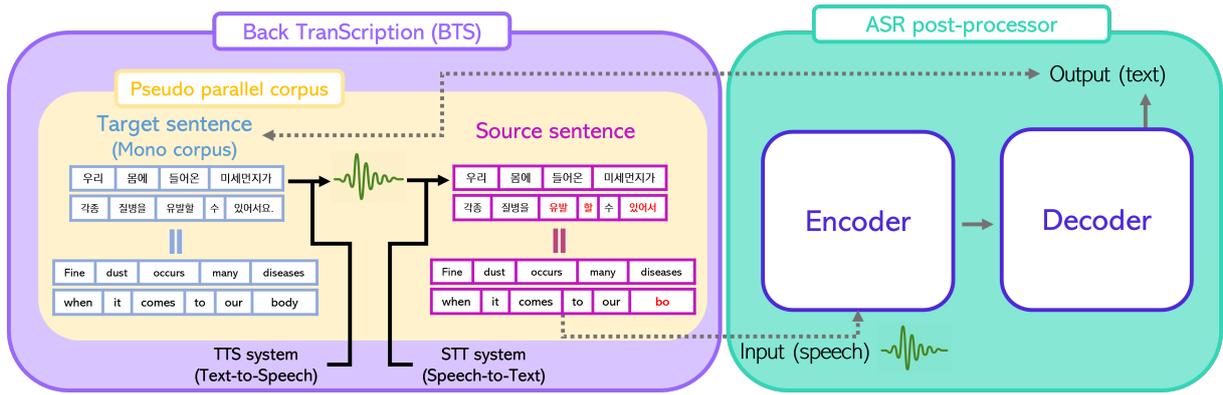

Figure 3: Architecture of the ASR post-processor and BTS for building Hyper-BTS dataset. The red-colored words in the source sentence indicate ungrammatical words. The following example means “Fine dust occurs many diseases when it comes to our bo” from the source sentence and means “fine dust occurs many diseases when it comes to our body” from the target sentence.

## A What is BTS?

BTS is a self-supervised method that automatically constructs the training dataset for the S2S-based ASR post-processor (Park et al., 2021b). BTS can easily obtain pre-built mono corpus using crawling; the collected corpus is automatically transformed into a parallel pair without human labor by converting the text files into voice files through the TTS system and subsequently reproducing the generated voice files to text files through the STT system. It consists of target sentences acquired from the mono corpus and source sentences that go through a round trip process that converts target sentences back to text via the TTS and STT. Finally, the ASR post-processor model can be constructed using the machine-generated pseudo-parallel corpus as a training dataset.

Figure 3 demonstrates the structure of the BTS and the learning process of the speech recognition post-processor model based on the S2S using the derived dataset. We reproduced this architecture following BTS procedure.

As illustrated in Figure 3, the overall architecture is given in the following: (BTS module) – TTS system converts the target sentence (gold sentence) into speech. Subsequently, the speech is transferred to STT system, which makes the source text (ungrammatical sentence). (ASR post-processor module) – this module conducts S2S training, where uses a speech from the source sentence for the input and the target sentence as a ground truth.

BTS can build the training data infinitely. Despite the disadvantages of building a parallel corpus, such as time, money, and accessibility, BTS has the advantage of building an interminable mono corpus through the website. From this policy, it is possible to build unlimited training data and enable boosting the building of our Hyper-BTS dataset. Furthermore, it can solve the limitations (*i.e.*, spacing, foreign conversion, punctuation, grammar correction) of the existing speech recognition system as a universal model since the mono corpus used as the target sentence is primarily free of this problem.

Furthermore, it is a method that does not require the role of a phonetic transcriber and has tremendous advantages in terms of time and cost. In addition, there is an advantage of being free from problems regarding the quality difference between phonetic transcribers.

For Park et al. (2021b), the language pair for the BTS experimentation was set to Korean. Finally, a pseudo parallel corpus of 229,987 sentence pairs for the S2S-based ASR post-processor was constructed by BTS.

## B Qualitative analysis according to the amount of training data (100k VS 1M)

As shown in Table 5, we classified the Hyper-BTS dataset into cases of 100K training data and 1M training data, respectively, and analyzed the post-editing results for the same test input. Through this analysis, we confirm the effect of ASR post-processing according to the size of our proposed Hyper-BTS dataset.

Input Sentence	Output Sentence	
	Hyper-BTS <sub>100K</sub>	Hyper-BTS <sub>1M</sub>
미안한데 <b>시디</b> 만 따로 보내 주실 수 있나요? (Excuse me, can you send the <b>시디</b> separately)	미안한데 <b>시디</b> 만 따로 보내주시실 수 있나요? (Excuse me, can you send the <b>시디</b> separately?)	미안한데 <b>CD</b> 만 따로 보내주시실 수 있나요? (Excuse me, can you send the <b>CD</b> separately?)
그리고 <b>두명</b> 의 학생을 위해서 2개 기숙사 방을 예약하고 싶습니다 (And I would like to reserve 2 dormitory rooms for <b>two</b> students)	그리고 <b>두 명</b> 의 학생을 위해서 2개의 기숙사 방을 예약하고 싶습니다. (And I would like to reserve 2 dormitory rooms for <b>two</b> students.)	그리고 <b>2명</b> 의 학생을 위해서 2개의 기숙사 방을 예약하고 싶습니다. (And I would like to reserve 2 dormitory rooms for <b>2</b> students.)
왜 이렇게 일찍 일어났어요 (Why did you wake up so early)	왜 이렇게 일찍 일어났어요. (Why did you wake up so early.)	왜 이렇게 일찍 일어났어요? (Why did you wake up so early?)
이 근처에서 볼 수 <b>있는데가</b> 있어요 (There are <b>placesto</b> watch around here)	이 근처에서 볼 수 <b>있는데가</b> 있어요. (There are <b>placesto</b> watch around here.)	이 근처에서 볼 수 <b>있는 데가</b> 있어요. (There are <b>places to</b> watch around here.)
성적서는 7월 25일까지 발급 <b>되면</b> ( <b>If</b> the certificates <b>are</b> issued by July 25th)	성적서는 7월 25일까지 발급 <b>되면?</b> ( <b>If</b> the certificates <b>are</b> issued by July 25th?)	성적서는 7월 25일까지 발급 <b>됩니다.</b> (Certificates <b>will be</b> issued by July 25th.)

Table 5: Examples of the correction result according to the amount of training data. Note that we indicate the text where includes errors in red; also, we indicate the miscorrected text by Hyper-BTS in the same color. In addition, we indicate the text corrected properly by Hyper-BTS in blue.

First, Hyper-BTS<sub>1M</sub> shows better correction of foreign language conversion errors. Hyper-BTS<sub>100K</sub> does not correct the foreign word “CD (CD)”, whereas Hyper-BTS<sub>1M</sub> corrects it properly. Second, in the case of “두명(two)”, which has not been converted to a word containing numbers, Hyper-BTS<sub>100K</sub> recognizes it as a space error and corrects it with “두 명(two)”. Hyper-BTS<sub>1M</sub> shows more robust results in numeric conversion correction by successfully correcting “2명”. Third, Hyper-BTS<sub>100K</sub> recognizes a punctuation error for the sentence “왜 이렇게 일찍 일어났어요(Why did you wake up so early)”, but adds punctuation in the declarative form instead of the interrogative one. On the other hand, Hyper-BTS<sub>1M</sub> successfully correct punctuation and show effectiveness in the punctuation area. Fourth, Hyper-BTS<sub>1M</sub> is more effective as a result of correction for spacing errors, which is an important factor in readability. Although Hyper-BTS<sub>100K</sub> fail to correct “볼 수 있는데가(placesto)”, Hyper-BTS<sub>1M</sub> successfully post-edit to “볼 수 있는 데가(places to)”. Finally, in the deletion error, which is a representative and important error of spelling and grammar due to misrecognition of the main predicate, Hyper-BTS<sub>100K</sub> corrects the ending that is not properly terminated into an interrogative sentence as it is. Whereas, Hyper-BTS<sub>1M</sub> shows the result of successful correction considering the context.

# ParrotTTS: Text-to-speech synthesis exploiting disentangled self-supervised representations

## Abstract

We present ParrotTTS, a modularized text-to-speech synthesis model leveraging disentangled self-supervised speech representations. It can train a multi-speaker variant effectively using transcripts from a single speaker. ParrotTTS adapts to a new language in low resource setup and generalizes to languages not seen while training the self-supervised backbone. Moreover, without training on bilingual or parallel examples, ParrotTTS can transfer voices across languages while preserving the speaker-specific characteristics, e.g., synthesizing fluent Hindi speech using a French speaker’s voice and accent. We present extensive results in monolingual and multi-lingual scenarios. ParrotTTS outperforms state-of-the-art multi-lingual text-to-speech (TTS) models using only a fraction of paired data as latter. Speech samples from ParrotTTS and code can be found at <https://parrot-tts.github.io/tts/>

## 1 Introduction

Vocal learning forms the first phase of infants starting to talk (Locke, 1996, 1994) by simply listening to sounds/speech. It is hypothesized (Kuhl and Meltzoff, 1996) that infants listening to ambient language store perceptually derived representations of the speech sounds they hear, which in turn serve as targets for the production of speech utterances. Interestingly, in this phase, the infant has no conception of text or linguistic rules, and speech is considered sufficient to influence speech production (Kuhl and Meltzoff, 1996) as can parrots (Locke, 1994).

Our proposed ParrotTTS model follows a similar learning process. Our idea mimics the two-step approach, with the first learning to produce sounds capturing the whole gamut of phonetic variations. It is attained by learning quantized representations

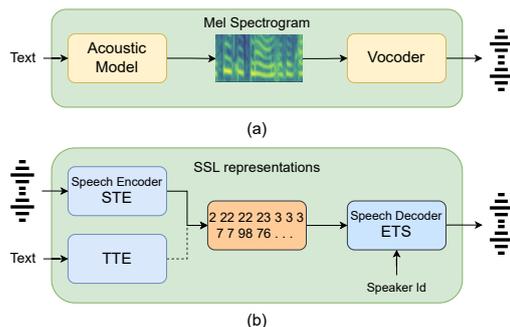

Figure 1: (a) Traditional mel-based TTS and (b) Proposed TTS model

of sound units in a self-supervised manner using the raw audio data. The second phase builds on top of the first by learning a content mapping from text to quantized speech representations (or embeddings). Only the latter step uses paired text-speech data. The two phases are analogous to first *learning to talk* followed by *learning to read*.

Figure 1 illustrates ParrotTTS contrasting it with the traditional mel-based TTS. The SSL module includes a speech-to-embedding (STE) encoder trained on masked prediction task to learn an embedding representation of the input raw audio (Baevski et al., 2020; Hsu et al., 2021; Van Den Oord et al., 2017). An embedding-to-speech (ETS) decoder is independently trained to invert embeddings to synthesize audio waveforms and is additionally conditioned on speaker identity. This *learning to talk* is the first of the two-step training pipeline. In the subsequent *learning to read* step, a separate text-to-embedding (TTE) encoder is trained to generate embeddings from text (or equivalent phonetic) inputs. This step requires labeled speech with aligned transcriptions.

ParrotTTS offer several advantages over the traditional mel-based neural TTS models (Ren et al., 2020; Wang et al., 2017). For instance, (a) Quantized speech embedding has lower variance than

\*Authors contributed equally to this work.

that of Mel frames reducing the complexity to train TTE (b) Direct waveform prediction bypasses potential vocoder generalization issues (Kim et al., 2021). (c) Reduced complexity helps in stabler training of TTE encoder for either autoregressive or non-autoregressive choice. For example, we observe at least eight-fold faster convergence in training iterations of our TTE module compared to that of (Ren et al., 2020) and (Wang et al., 2017).

While our work closely relates with recent works (Du et al., 2022; Wang et al., 2023; Siuzdak et al., 2022) utilizing self-supervised representations for TTS synthesis, our focus differs by aiming to achieve a unified multi-speaker, multi-lingual TTS system in low-resource scenarios (Xu et al., 2020). In our work, low-resource refers to the scarcity of paired TTS data. Here are the key distinctions of our model compared to recent efforts:

- Unlike contemporary efforts concentrated on large scale training (Wang et al., 2023), we focus on low resource adaptation.
- We employ disentangled self-supervised representations (Polyak et al., 2021) paired with independently trained STE. This allows us to train multi-speaker TTS using paired data from a single speaker and still adapt it to novel voices with untranscribed speech alone. In contrast, prior efforts either limit to a single speaker TTS (Du et al., 2022) or require paired text-audio data from multiple speakers during training (Siuzdak et al., 2022).
- We show that the ParrotTTS can be extended to a new language with as little as five hours of paired data from a single speaker. The model generalizes to languages unseen during the learning of self-supervised representation.
- Moreover, without training on any bilingual or parallel examples, ParrotTTS can transfer voices across languages while preserving the speaker-specific characteristics. We present extensive results on six languages in terms of speech naturalness and speaker similarity in parallel and cross-lingual synthesis.

Additionally, it’s worth mentioning that certain methods (Wang et al., 2023) depend partially or entirely on Automatic Speech Recognition (ASR) to obtain paired data. It should be noted that these ASR models are trained using substantial amounts of supervised data, inaccessible in low resource settings.

While architecturally similar to other SSL-based TTS (Wang et al., 2023; Siuzdak et al., 2022), our primary contribution lies in achieving promising outcomes in the low resource scenario, where minimal paired data from a single speaker per language is accessible for TTS training.

## 2 Related work

### 2.1 Foundational Neural TTS models

Traditional neural TTS model encodes text or phonetic inputs to hidden states, followed by a decoder that generates Mels from the hidden states. Predicted Mel frames contain all the necessary information to reconstruct speech (Griffin and Lim, 1984) and an independently trained vocoder (Oord et al., 2016; Kong et al., 2020) transforms them into time-domain waves. Mel predicting decoders could be autoregressive/sequential (Wang et al., 2017; Valle et al., 2020; Shen et al., 2018) or non-autoregressive/parallel (Ren et al., 2019, 2020; Łańcucki, 2021). Non-autoregressive models additionally predict intermediate features like duration, pitch, and energy for each phoneme. They are faster at inference and robust to word skipping or repetition errors (Ren et al., 2020). Multi-speaker capabilities are often achieved by conditioning the decoder on speaker embeddings (one-hot embeddings or ones obtained from speaker verification networks (Jia et al., 2018; Sivaprasad et al., 2021)). Training multi-speaker TTS models requires paired text-audio data from multiple speakers. Methods relying on speaker-embeddings can, in theory, perform zero-shot speaker adaptation; however, the rendered speech is known to be of poorer quality, especially for speakers not sufficiently represented in the train set (Tan et al., 2021).

### 2.2 Raw-audio for TTS

Unsupervised speech synthesis (Ni et al., 2022) does not require transcribed text-audio pairs for training. They typically employ unsupervised ASR (Baevski et al., 2021; Liu et al., 2022a) to transcribe raw speech to generate pseudo labels. However, their performance tends to be bounded by the performance of the unsupervised ASR model, which still has to close a significant gap compared to supervised counterparts (Baevski et al., 2021). Switching to a multi-speaker setup further widens this quality gap (Liu et al., 2022b).

Some prior works have looked at adapting TTS to novel speakers using untranscribed audio (Yan

et al., 2021; Luong and Yamagishi, 2019; Taigman et al., 2017). Unlike ours, their methods require a large amount of paired data from multiple speakers during initial training. Some of these (Luong and Yamagishi, 2019; Taigman et al., 2017) jointly train the TTS pipeline and the modules for speaker adaptation but model training’s convergence is trickier. In contrast, ParrotTTS benefits from the disentanglement of linguistic content from speaker information, making adaptation easier with stabler training as we observe in our experiments.

### 2.3 Self-supervised learning

Self-supervised learning (SSL) methods are becoming increasingly popular in speech processing due to their ability to utilize abundant unlabeled data. Techniques like masked prediction, temporally contrastive learning, and next-step prediction are commonly used to train SSL models. Popular models like Wav2vec2 (Baevski et al., 2020), VQ-VAE (Van Den Oord et al., 2017), AudioLM (Borsos et al., 2022) and HuBERT (Hsu et al., 2021) have been successfully deployed in tasks like ASR (Baevski et al., 2020), phoneme segmentation (Kreuk et al., 2020), spoken language modeling (Lakhotia et al., 2021), and speech resynthesis (Polyak et al., 2021).

Our work is related to recent efforts (Du et al., 2022; Wang et al., 2023; Siuzdak et al., 2022) that utilize self-supervised audio embeddings in text-to-speech synthesis. However, those of Du et al. (2022) and Siuzdak et al. (2022) require speaker-specific SSL embeddings while we use generic HuBERT embeddings (Hsu et al., 2021; Lee et al., 2022) train for multiple speakers.

### 2.4 Multi-lingual TTS

It is challenging to build an unified TTS model supporting multiple languages and speakers, even more so for cross lingual synthesis, *i.e.*, allowing multiple languages to be spoken in each of the speaker’s voices. The primary challenge is in acquiring paired data to train language dependent components that often includes its embeddings. The trick ParrotTTS employs to break this data dependence is to decouple acoustics from content handling, of which only the latter is language dependent and requires paired data while the former is deferred to self-supervised models.

Initial attempts (Liu and Mak, 2019; Zhang et al., 2019) address these by conditioning the decoder on language and speaker embeddings, but the results

were subpar due to entanglement of text representation with language/speaker information. Recent approaches (Zhang et al., 2019; Cho et al., 2022; Nekvinda and Dušek, 2020) addressed this issue by incorporating an explicit disentanglement loss term, using reverse gradients through a language or speaker classification branch.

Nekvinda and Dušek (2020) propose MetaTTS, that uses a contextual parameter generation through language-specific convolutional text encoders. Cho et al. (2022) extend MetaTTS with a speaker regularization loss and investigate different input formats for text. Knowledge sharing (Prakash et al., 2019) and distillation (Xu et al., 2020) have been explored for multi-lingual TTS. Recently, Wu et al. (2022) employ a data augmentation technique based on a cross-lingual voice conversion model trained with speaker-invariant features extracted from a speech representation.

Certain limitations still persist in existing approaches (Nekvinda and Dušek, 2020; Chen et al., 2019; Zhang et al., 2019; Zhang and Lin, 2020). For example, many of them rely on Tacotron (Wang et al., 2017) as their backbone, which is prone to word alignment and repetition errors. Prior multi-lingual TTS models typically support only 2-3 languages simultaneously or require extensive training data as noted by Nekvinda and Dušek (2020). Additionally, they have not yet capitalized on self-supervised embeddings and our efforts aim to address this gap.

## 3 ParrotTTS architecture

ParrotTTS has three modules; two encoders that map speech or text inputs to common embedding space (referred to as STE and TTE respectively) and a decoder (ETS) that renders speech signal from these embeddings. Our speech encoder-decoder choices are borrowed from (Polyak et al., 2021). Our speech decoder ETS is a modified version of HiFiGAN (Kong et al., 2020). Text encoder TTE is an encoder-decoder architecture and we experiment with both autoregressive (AR) and non-autoregressive (NAR) choices for the same.

### 3.1 Speech encoder STE

The self-supervised HuBERT model we use for our STE is pre-trained on large raw audio data from English, on BERT-like masked prediction task (Devlin et al., 2018) to learn “combined acoustic and language model over the continuous inputs”

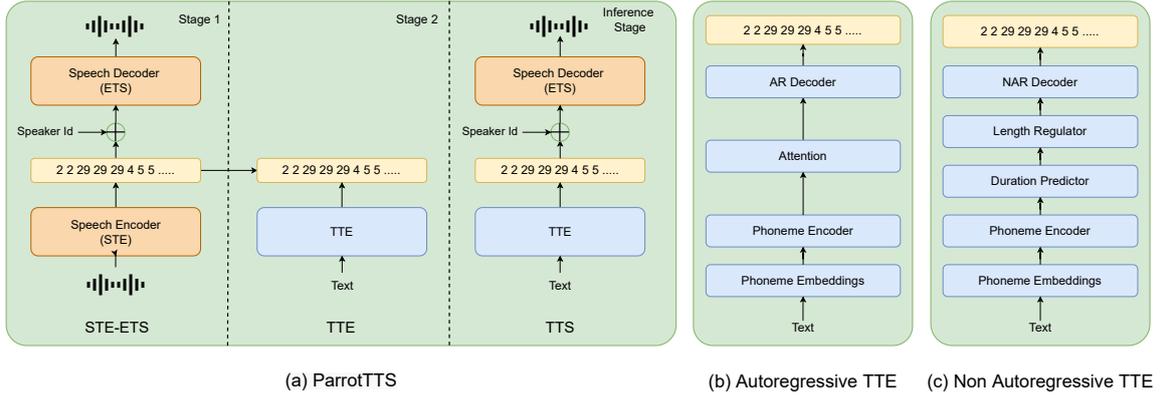

Figure 2: (a) ParrotTTS performs a two stage training. In stage1, ETS is trained to synthesize speech from discrete units obtained though an independently trained STE module. In Stage2, TTE learns to map text sequence to corresponding speech units obtained from STE. (b) and (c) illustrate the explored TTE architectures.

of speech. It borrows the base architecture from Wav2vec 2.0 (Baevski et al., 2020) with convolutions on raw inputs followed by a few transformer layers, however, replaces its contrastive loss with a BERT-like classification. The “noisy” classes for this classification are derived by clustering MFCC features of short speech signals. Encoder input is audio signal  $X = (x_1, \dots, x_T)$  sampled at a rate of 16kHz. Let  $E_r$  denote the raw-audio encoder, and its output be,

$$\mathbf{h}_r = (h_1, \dots, h_{\hat{T}}) := E_r(X),$$

where  $\hat{T} = T/320$  indicates downsampling and each  $h_i \in \{1, \dots, K\}$  with  $K$  being the number of clusters in HuBERT’s clustering step, set to 100 in our experiments. For multi-lingual experiments, instead of using HuBERT, we utilize mHuBERT (Lee et al., 2022), which is trained on a multi-lingual corpus. We use  $K=1000$  for mHuBERT embeddings.

### 3.2 Speech decoder ETS

We adapt the HiFiGAN-v2 decoder for our ETS to decode from  $\mathbf{h} = (\mathbf{h}_r, \mathbf{h}_s)$  to speech, where  $\mathbf{h}_s$  is the one-hot speaker embedding. It has a generator  $G$  and a discriminator  $D$ .  $G$  runs  $\mathbf{h}$  through transposed convolutions for upsampling to recover the original sampling rate followed by residual block with dilations to increase the receptive field to synthesize the signal,  $\hat{X} := G(\mathbf{h})$ .

The discriminator distinguishes synthesized  $\hat{X}$  from the original signal  $X$  and is evaluated by two sets of discriminator networks. Multi-period discriminators operate on equally spaced samples, and multi-scale discriminators operate at different

scales of the input signal. Overall, the model attempts to minimize  $D(X, \hat{X})$  over all its parameters to train ETS.

### 3.3 Text encoder TTE

The third module we train, TTE is a text encoder that maps phoneme/character sequence  $P = (p_1, \dots, p_N)$  to embedding sequence  $\mathbf{h}_p = (h_1, \dots, h_{\hat{N}})$ . We train a sequence-to-sequence architecture to achieve this  $\mathbf{h}_p := E_p(P)$ .  $E_p$  initially encodes  $P$  into a sequence of fixed dimensional vectors (phoneme embeddings), conditioned upon which its sequence generator produces variable dimensional  $\mathbf{h}_p$ . Embedding  $\mathbf{h}_p$  is intended to mimic  $\mathbf{h}_r := E_r(X)$  extracted from the audio  $X$  corresponding to the text  $P$ . Hence, the requirement of transcribed data  $(X, P)$  to derive the target  $\mathbf{h}_r$  for training TTE by optimizing over the parameters of  $E_p$ .

One could model  $E_p$  to generate  $\mathbf{h}_p$  autoregressively one step at a time, which we refer to as AR-TTE model (Figure 2(b)). Input phoneme sequence is encoded through a feed-forward transformer block that stacks self-attention layers (Vaswani et al., 2017) and 1D convolutions similar to FastSpeech2 (Ren et al., 2019). Decoding for  $\mathbf{h}_p$  uses a transformer module with self-attention and cross-attention. Future-masked self-attention attends to ground truth at train and to previous decoder predictions at inference. Cross-attention attends to phoneme encoding in both cases.

Alternatively, for a non-autoregressive choice of  $E_p$ , the model NAR-TTE determines the output length  $\hat{N}$  followed by a step to simultaneously predict all  $\hat{N}$  entries of  $\mathbf{h}_p$ . Figure 2(c) depicts NAR-TTE where the input phoneme sequence en-

coding is similar to that of AR-TTE. The duration predictor and length regulator modules are responsible for determining  $\hat{N}$  followed by the decoding step to generate  $\mathbf{h}_p$ . In multi-lingual scenario, we investigate both character and phoneme sequences for representing the input text. For character representation, we extract the tokens using a dictionary created by iterating over the entire text corpus. In contrast, for phoneme representation, we utilize an off-the-shelf phonemizer (version: 3.2.1) (Bernard and Titeux, 2021) to extract phonemes belonging to the IPA vocabulary, which are common across languages.

## 4 Experiments

We perform experiments in monolingual and multi-lingual scenarios. Details of various ParrotTTS models trained and of those each of them is compared to is covered below.

### 4.1 ParrotTTS training

**Datasets (monolingual)** For single language experiments, we use two public datasets. LJSpeech (Ito and Johnson, 2017) provides 24 hours high quality transcribed data from a single speaker. Data are split into two, with 512 samples set aside for validation and the remaining available for model training. VCTK (Veaux et al., 2017) with about 44 hours of transcribed speech from 108 different speakers is used for the multi-speaker setup. It has a minimum, average, and maximum of 7, 22.8, and 31 minutes per speaker speech length, respectively.

**Datasets (multi-lingual)** We collate our multi-lingual dataset using publicly available corpora containing samples from multiple speakers in six languages: (1) 80.76 hours of Hindi and Marathi from (SYSPIN-IISC, 2022) from 2 speakers, respectively; (2) 71.69 hours of German (GmbH., 2017) from 3 speakers; (3) 83.01 hours of Spanish (GmbH., 2017) from 3 speakers; (4) 10.70 hours of French (Honnet et al., 2017) from 1 speaker; (5) 23.92 hours of English (Ito and Johnson, 2017) from 1 speaker. Overall the dataset comprises of 354.12 hours of paired TTS data from 12 speakers across all six languages. We resample all speech samples to 16 kHz.

**STE training.** We use a 12 layer transformer model for HuBERT training. It is trained using 960 hour-long LibriSpeech corpus (Panayotov et al., 2015). The multi-lingual variant mHuBERT is trained using 13.5k hours of English, Spanish and

French data from VoxPopuli unlabelled speech corpus (Lee et al., 2022; Wang et al., 2021). In both cases, the model splits each  $T$  seconds long audio into units of  $T/320$  seconds and maps each of the obtained units to a 768 dimensional vector.

**TTE training (monolingual).** We use LJSpeech to train two different TTE encoder modules;  $TTE_{LJS}$  that uses all the data from our LJSpeech train set and a second,  $TTE_{\frac{1}{2}LJS}$  with only half the data. This is used to understand the effect of training data size on TTS performance. All variants of TTE we experiment with are trained only on samples from the single speaker in LJSpeech data.

Text converted to phoneme sequence as described by Sun et al. (2019) are inputs with  $\mathbf{h}_r$ , targets extracted from STE for training. Additionally, NAR-TTE requires phonetic alignment to train the duration predictor. We use Montreal forced-aligner (McAuliffe et al., 2017) to generate them for its training. We use cross-entropy loss with the 100 clusters derived from discretization codebook of HuBERT units as classes.

**TTE training (multi-lingual).** Focusing on low-resource setting, we use only 5 hours of paired data for a single speaker in each language to train the TTE that totals to merely 30 hours of paired data across six languages. We report the evaluation metrics for *seen speakers* where the model has seen the speaker paired data and *unseen speakers* whose paired data is not used to train the TTE. To evaluate the performance on various text representations, we train two variants of the TTE, the character TTE (CTE) and the phoneme TTE (PTE). CTE uses character tokens across the languages to learn sound units while PTE uses phoneme tokens. Additionally, we employ Deep Forced Aligner (in Indian Languages, SYSPIN) to align ground-truth speech and input text representations to train the duration predictor. Cross-entropy loss with 1000 clusters of mHuBERT are used as classes to predict  $\mathbf{h}_p$ .

**ETS training.** We train a single-speaker ETS, SS-ETS using only speech clips from LJSpeech since its training does not require transcriptions. Similarly, our multi-speaker ETS, MS-ETS decoder model uses only raw audio of all speakers from VCTK data (Veaux et al., 2017). So only embeddings  $\mathbf{h}_r$  extracted from VCTK audio clips are used along with one-hot speaker vector  $\mathbf{h}_s$ . We emphasize that VCTK data were used only in training the multi-speaker-ETS module, and the TTE has not seen any from this set. For multi-lingual sce-

nario, we train a multi-speaker ETS using speech-only data with 12 speakers from all six languages.

## 4.2 Comparison to prior art

**Single Speaker TTS:** We train Tacotron2 (Wang et al., 2017) and FastSpeech2 (Ren et al., 2020) using the ground truth transcripts of LJSpeech and referred to as SS-Tacotron2 and SS-FastSpeech2. We additionally trained an unsupervised version of FastSpeech2 by replacing the ground truth transcripts with transcriptions obtained from the ASR model. FastSpeech2-SupASR uses supervised ASR model (Radford et al., 2022) to generate the transcripts while Tacotron2-UnsupASR (Ni et al., 2022) alternatively uses unsupervised ASR Wav2vec-U 2.0 (Liu et al., 2022a). We further adapt WavThruVec (Siuzdak et al., 2022) to our setup and train a model (SS-WavThruVec) using intermediate embeddings extracted from Wav2Vec 2.0 (Baevski et al., 2020). Additionally, we apply a similar approach to the embeddings obtained from VQ-VAE (Van Den Oord et al., 2017) and term it as SS-VQ-VAES. We compare against three variants of ParrotTTS;

1. AR-TTE<sub>LJS</sub>+SS-ETS that is autoregressive TTE trained on full LJSpeech with single speaker ETS,
2. NAR-TTE<sub>LJS</sub>+SS-ETS that pairs TTE with non-autoregressive decoding trained on full LJSpeech with single speaker ETS, and
3. NAR-TTE <sub>$\frac{1}{2}$ LJS</sub>+SS-ETS that uses TTE with non-autoregressive decoding trained on half LJSpeech with single speaker ETS.

**Multi-speaker TTS:** We compare against a fully supervised FastSpeech2 baseline trained on VCTK using paired data from all speakers and that we refer to as MS-FastSpeech2. For ParrotTTS we borrow the TTE module trained on LJSpeech and use the raw audio of VCTK to train the multi-speaker ETS module. We refer to this multi-speaker variant of our ParrotTTS model as NAR-TTE<sub>LJS</sub>+MS-ETS that uses non-autoregressive decoding.

For a fair comparison, we also curate a multi-speaker TTS baseline using a combination of single-speaker TTS and a voice cloning model. We use FastSpeech2 trained on LJSpeech with state-of-the-art voice cloning model (Polyak et al., 2021) in our experiments and refer to this model as VC-FastSpeech2. We also compare against multi-speaker TTS trained by obtaining pseudo labels

from a supervised ASR called MS-FastSpeech2-SupASR. Additionally, we also report numbers from GT-Mel+Vocoder that converts ground truth Mels from actual audio clip back to speech using a vocoder (Kong et al., 2020) for a perspective of best achievable with ideal Mel frames.

**Multi-lingual TTS:** We compare against, (a) FastSpeech2-MLS which is a fully-supervised FastSpeech2 model and (b) state-of-the-art meta learning-based multi-lingual TTS model MetaTTS (Nekvinda and Dušek, 2020). Both these models are trained on the entirety of train data (354 hours of transcribed speech). In contrast, the TTE training in ParrotTTS model (our sole module that needs paired data) uses only  $1/12^{th}$  of this *i.e.*, a total of 30 hours of paired text-speech (5 hours per language). The remaining data is used for evaluation purposes, serving as the test set. We refer to this model as NAR-TTE <sub>$\frac{1}{12}$ MLS</sub>+ML-ETS. We also compare character (CTE) and phoneme (PTE) tokenization for encoding text in this setting.

## 4.3 Evaluation metrics

We evaluate the intelligibility of various models using Word Error Rate (WER) with the pre-trained Whisper *small* model (Radford et al., 2022). We validate the speaker adaptability using Equal Error Rate (EER) from a pre-trained speaker verification network proposed in (Desplanques et al., 2020) and trained on VoxCeleb2 (Chung et al., 2018). The WER and EER metrics are computed on entire validation set. We perform subjective evaluations using Mean Opinion Score (MOS) with five native speakers per language, rating samples synthesized by different models, where five sentences from the test set are randomly selected for evaluation.

# 5 Results

## 5.1 Single-speaker TTS

*Naturalness and intelligibility.* As shown in Table 1, ParrotTTS is competitive to state-of-the-art in the single-speaker setting. In the autoregressive case, our AR-TTE<sub>LJS</sub>+SS-ETS has a statistically insignificant drop (of about 0.05 units) on the MOS scale relative to the Tacotron2 baseline. The non-autoregressive case has a similar observation (with a 0.01 drop) on MOS in our NAR-TTE<sub>LJS</sub>+SS-ETS model relative to FastSpeech2. This empirically establishes that the naturalness of the speech rendered by ParrotTTS is on par with the currently established methods. The WER scores show a sim-

	<b>Model</b>	<b>MOS</b> $\uparrow$	<b>WER</b> $\downarrow$
Traditional TTS	SS-FastSpeech2	3.87	4.52
	SS-Tacotron2	3.90	4.59
	FastSpeech2-SupASR	3.78	4.72
	Tacotron2-UnsupASR	3.50	11.3
WavThruVec	SS-WavThruVec	3.57	6.27
VQ-VAE	SS-VQ-VAES	3.12	21.78
ParrotTTS	AR-TTE <sub>LJS</sub> +SS-ETS	3.85	4.80
	NAR-TTE <sub>LJS</sub> +SS-ETS	3.86	4.58
	NAR-TTE <sub><math>\frac{1}{2}</math>LJS</sub> +SS-ETS	3.81	6.14

Table 1: Subjective and objective comparison of TTS models in the single speaker setting.

<b>Model</b>	<b>VCTK</b>	<b>MOS</b> $\uparrow$	<b>WER</b> $\downarrow$	<b>EER</b> $\downarrow$
GT-Mel+Vocoder	Yes	4.12	2.25	2.12
MS-FastSpeech2	Yes	3.62	5.32	3.21
MS-FastSpeech2-SupASR	No	3.58	6.65	3.85
VC-FastSpeech2	No	3.41	7.44	8.18
WavThruVec-MS	No	3.17	6.79	5.08
NAR-TTE <sub>LJS</sub> +MS-ETS	No	3.78	6.53	4.38

Table 2: Comparison of the multi-speaker TTS models on the VCTK dataset. Column 2 indicates if the corresponding method uses VCTK transcripts while training.

ilar trend with a statistically insignificant drop (of under 0.2pp<sup>1</sup>) among the autoregressive and non-autoregressive model classes. The performance of SS-WavThruVec and SS-VQ-VAES is lower in both naturalness and intelligibility, indicating that the utilization of Wav2Vec 2.0 and VQ-VAE embeddings results in a decrease in performance.

*Supervision and data efficiency.* In the study to understand how the degree of supervision affects TTS speech quality, we see a clear drop by 0.28 MOS units in moving from the FastSpeech2-SupASR model that employs supervised ASR for transcriptions to Tacotron2-UnsupASR model using unsupervised ASR. Despite some modeling variations, this is generally indicative of the importance of clean transcriptions on TTS output quality, given that all other models are within 0.05 MOS units of each other.

The data requirement for TTS supervision needs to be understood in light of this impact on output quality, and we show how ParrotTTS helps cut down on this dependence. TTE is the only module that needs transcriptions to train, and we show that by reducing the size of the train set by half in NAR-TTE <sub>$\frac{1}{2}$ LJS</sub>+SS-ETS the MOS is still comparable to that of the model trained on all data NAR-

TTE<sub>LJS</sub>+SS-ETS (with only about 0.04 units MOS drop). Finally, the MOS numbers of FastSpeech2-SupASR, need to be read with some caution since the supervised ASR model used, Whisper, is itself trained with plenty of transcriptions (spanning over 600k hours) from the web, including human and machine transcribed data achieving very low WERs on various public and test sets. So, the machine transcriptions used in FastSpeech2-SupASR are indeed close to ground truth.

## 5.2 Multi-speaker TTS

*Naturalness and intelligibility.* Table 2 summarizes results from our multi-speaker experiments. NAR-TTE<sub>LJS</sub>+MS-ETS clearly outperforms all other models ranking only below GT-Mel+Vocoder that re-synthesizes from ground truth Mels. Interestingly, ParrotTTS fares even better than MS-FastSpeech2, which is, in turn, better than other models that ignore transcripts at the train, namely, MS-FastSpeech2-SupASR and VC-FastSpeech2. On the WER metric for intelligibility, ParrotTTS is about 1pp behind supervised MS-FastSpeech2 but fares better than the other two models that discard VCTK transcripts for training. WavThruVec-MS model leveraging Wav2Vec 2.0 embeddings has a noticeable quality drop in the multi-speaker setting with lowest MOS.

Spanish	3.67 ± 0.19	3.17 ± 0.17	<b>3.33 ± 0.18</b>	3.17 ± 0.19	1.3 ± 0.16

Table 4: Comparison of naturalness MOS on unseen speakers with FastSpeech2-MLS (FS2-MLS) and MetaTTS model

*Speaker adaptability.* VC-FastSpeech2 is the closest in terms of experimental setup since it is limited to transcriptions from LJSpeech for training similar to ours, with VCTK used only for adaptation. In this case, EER of NAR-TTE<sub>LJS</sub>+MS-ETS is about twice as good as that of VC-FastSpeech2. However, improvements are visible when VCTK transcripts are part of training data but remain within 1pp relative to ParrotTTS while GT-Mel+Vocoder continues to dominate the scoreboard leaving room for further improvement.

### 5.3 Multi-lingual TTS

The results from our multi-lingual experiments are in Tables 3, 4, 5, and 6. It is notable that speech rendered by ParrotTTS has superior naturalness compared to baselines that are trained with twelve times more paired samples stressing its viability for low-resource languages. Further, the naturalness also changes with the text tokenization method. Choosing character tokens for Indic languages outperformed phoneme tokens while it was the opposite for the European languages. ParrotTTS with the best performing tokenizer in each language was superior to FastSpeech2-MLS and MetaTTS for both *seen speakers* (Table 3) as well as *unseen speakers* (Table 4). It is interesting to note that scores for ParrotTTS were better than groundtruth and this is possibly due to noise in original sample that was suppressed by HuBERT embeddings that are known to discard ambient information.

*Speaker similarity.* Results in Table 5 consistently demonstrate the superiority of Par-

rotTTS over FastSpeech2-MLS and MetaTTS, indicating its effectiveness in separating speaker and content information. This is attributed to the decoder being conditioned solely on speaker ID while sharing the acoustic space across all languages.

*Cross lingual synthesis.* We also assess the model’s performance in synthesizing samples of a speaker in a language different from native language. Table 6 presents these results comparing naturalness of MOS in a cross-lingual setting. The first column lists a pair of languages of which the first is the speaker’s native language while the second is language of text that is rendered. ParrotTTS achieved higher MOS demonstrating strong decoupling of content from speaker characteristics that is controlled in the decoder. Further, more than 90% of the participants were able to discern the nativity of the synthesized speech.

## 6 Conclusion

We investigate a data-efficient ParrotTTS model that leverages audio pre-training from self-supervised models and ties it to separately trained speech decoding and text encoding modules. We evaluate this architecture in various settings. Quality of rendered speech with as little as five hours of paired data per language is on par with or superior to competitive baselines. This is the key result from our experiments that we believe will help scale TTS training easily to new languages by bringing low-resource ones into the same quality range as the resource-rich ones. Moreover, we have released an open-source, multi-lingual TTS model

Language	Our model	FS2-MLS	MetaTTS
Hindi	<b>4.29 ± 0.18</b>	3.92 ± 0.21	2.23 ± 0.19

to enable the wider application of our findings to resource-scarce and less privileged languages.

## 7 Limitations and Future Work

The mHuBERT self-supervised representation utilized in this study may not accurately reproduce the pronunciation of certain words native to Indian languages, given its pre-training exclusively on Spanish, French, and English. To address this limitation, our future work will focus on fine-tuning the mHuBERT model to encompass a more comprehensive set of sound units native to South Asian languages and potentially develop a universal representation of sound units.

An unexplored aspect in our research is the examination of emotive speech and controllable generation. Hubert embeddings, as known, lack prosody information, creating a challenge in incorporating emotional nuances into speech. In our forthcoming research, we intend to address this by concatenating emotive embeddings, enabling the synthesis of speech with diverse emotions and prosody. Additionally, the NAR model’s duration predictor may exhibit a bias toward the style of a single seen speaker. Our subsequent research endeavors will explore methods to achieve speaker-adaptive duration prediction and introduce controls

to influence duration prediction in the synthesis process.

## 8 Ethical Considerations

Our research is grounded in ethical considerations. We recognize the potential of text-to-speech synthesis in various domains, such as accessibility, human-computer interaction, telecommunications, and education. However, we acknowledge the risk of misuse, particularly with regards to unethical cloning and the creation of false audio recordings. Our experiments strictly use publicly available datasets and our method does not aim to synthesize someone’s voice without their consent. We are mindful of the negative consequences associated with these actions. While the benefits currently outweigh the concerns, we strongly advocate for the research community to actively explore methods for detecting and preventing misuse.

It is important to note that our approach is trained on a limited set of languages and has not been validated on different languages or individuals with speech impediments. Therefore, the dataset and results may not be representative of the entire population. A comprehensive understanding of this issue necessitates further studies in conjunction with linguistic and socio-cultural insights.

## 9 Acknowledgments

We express our gratitude to the reviewers for their dedicated time and thoughtful assessment of our manuscript. We would like to specifically acknowledge Mr. Niranjana Pedanekar from Sony Research, India, for his constructive comments and insightful suggestions, which played a key role in refining the overall quality of our work.

## A Appendix

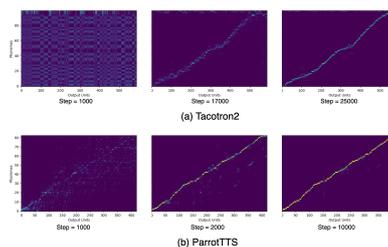

Figure 3: Evolution of attention matrix with training steps for Tacotron2 and AR-TTE

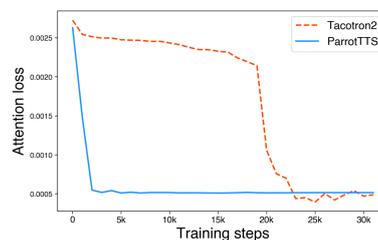

Figure 4: Attention loss plotted against training steps Tacotron2 and AR-TTE

### A.1 Stabler training and faster inference

In Figure 3 and Figure 4, we compare training profiles of Tacotron2 and AR-TTE keeping batch size the same. As visualized in Figure 3, the attention matrix in Tacotron2 takes about 20k iterations to stabilize with an anti-diagonal structure and predict a phoneme-aligned Mel sequence. AR-TTE, in contrast, is about ten times faster at predicting a discrete HuBERT unit sequence that aligns with input phonemes taking only about 2k iterations to arrive at a similar-looking attention plot. While the snapshots are illustrative, we use the guided-attention loss described by Tachibana et al. (2018) as a metric to quantify the evolution of the attention matrix through training steps. As shown in Figure 4, the loss dives down a lot sooner for ParrotTTS relative

to its Tacotron2 counterpart. In a similar comparison, we observe that NAR-TTE converges (20k steps) about eight times faster than FastSpeech2 (160k steps).

We suppose that the faster convergence derives from the lower variance of discrete embeddings in ParrotTTS as opposed to the richness of Mels that are complete with all acoustic variations, including speaker identity, prosody, etc. The output speech is independent of inputs given the Mel-spectrogram unlike ParrotTTS embeddings that further need cues like speaker identity in later ETS module. We hypothesize that segregating content mapping away from learning acoustics like speaker identity helps improve training stability, convergence, and data efficiency for the TTE encoder.

The proposed NAR-TTE system also improves inference latency and memory footprint, which are crucial factors for real-world deployment. On NVIDIA RTX 2080 Ti GPU, we observe ParrotTTS serves 15% faster than FastSpeech2, reducing the average per utterance inference time to 11ms from 13 ms. Furthermore, the TTE module uses 17M parameters in contrast to 35M parameters of the Mel synthesizer module in FastSpeech2.

# NavHint: Vision and Language Navigation Agent with a Hint Generator

## Abstract

Existing work on vision and language navigation mainly relies on navigation-related losses to establish the connection between vision and language modalities, neglecting aspects of helping the navigation agent build a deep understanding of the visual environment. In our work, we provide indirect supervision to the navigation agent through a hint generator that provides detailed visual descriptions. The hint generator assists the navigation agent in developing a global understanding of the visual environment. It directs the agent’s attention toward related navigation details, including the relevant sub-instruction, potential challenges in recognition and ambiguities in grounding, and the targeted viewpoint description. To train the hint generator, we construct a synthetic dataset based on landmarks in the instructions and visible and distinctive objects in the visual environment. We evaluate our method on the R2R and R4R datasets and achieve state-of-the-art on several metrics. The experimental results demonstrate that generating hints not only enhances the navigation performance but also helps improve the interpretability of the agent’s actions.

## 1 Introduction

In many real-world applications, it is a crucial skill for an intelligent agent to perceive the visual environment and interact with humans using natural language. The Vision and Language Navigation (VLN) task (Anderson et al., 2018) is one of the popular problems in this direction that has attracted significant attention from computer vision, natural language processing, and robotic communities (Li et al., 2022; Fried et al., 2018; Francis et al., 2022).

With the increasing popularity of the VLN task, many neural navigation models (Hong et al., 2020c; Chen et al., 2021; Hao et al., 2020) have been proposed. One line of research is to strengthen the connection of the vision and language modalities (Ma

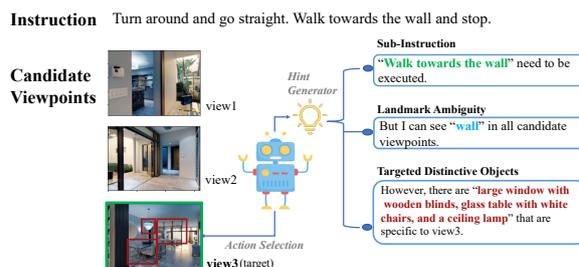

Figure 1: Given the instruction and three candidate viewpoints, the navigation agent with the assistance of the hint generator, produces descriptions of the visual environment with three key elements: sub-instruction, landmark ambiguity and targeted distinctive objects.

et al., 2019; Hong et al., 2020a; Li et al., 2021). However, the majority of these efforts learn the connection mainly supervised by navigation performance, such as the distance to the destination, the orientation selection (heading and elevation), and the similarity between the given instruction and the trajectory. While this helps teach the agent to navigate, it does not directly enforce learning comprehensive textual and visual semantics. In fact, learning visual semantics in the environment is crucial not only for successfully completing navigation tasks but also for the effective communication with humans. For instance, the navigation agent should correctly locate the navigation progress based on the current visual views. Moreover, the navigation agent needs to adopt a global perspective of the environment to investigate whether the navigable viewpoints include the relevant landmarks or whether the instruction is ambiguous. In any case, the agent should be able to describe its targeted viewpoint. Expecting the navigation agent to obtain the above understanding solely through navigation-related signals is challenging, and the intermediate guidance is necessary.

To this end, we introduce a hint generator for the VLN agent (NavHint), aiming to generate visual descriptions that serve as indirect supervision

to help the navigation agent obtain a better understanding of the visual environment (as depicted in Fig. 1). When the agent navigates at each step, the hint generator concurrently produces visual descriptions that are consistent with the agent’s action decision. The hints are designed based on the rationale underlying the navigation process, including three aspects: *Sub-instruction*, *Landmark Ambiguity* and *Targeted Distinctive Objects*. Specifically, at each navigation step, **first**, the hint generator encourages the agent to report its navigation progress by specifying which part of the sub-instruction it is executing based on the current visual environment. As depicted in Fig. 1, the sub-instruction “walk towards the wall” needs to be executed. **Second**, the hint generator directs the agent to have a global view of the entire environment and recognize the landmarks mentioned in the instruction from all candidate viewpoints. The agent is tasked with identifying potential challenges by assessing the visibility of the landmarks and comparing the landmarks shared among viewpoints. For instance, in the given example, the landmark “wall” is ambiguous as it appears in multiple views. **Third**, in scenarios where challenges exist, the hint generator guides the agent in describing the distinctive visual objects that only appear in the targeted viewpoint, such as “*large window with wooden blinds*” in view3 in Fig 1. This aids the agent in deeply looking into the details of its selected viewpoint while globally comparing it to other candidates.

The hint generator is designed as a Transformer-based decoder that leverages visual output from the navigation agent to produce corresponding hints. This hint generator can be plugged into any VLN agent as a language model conditioned on the VLN models. To train the hint generator, we propose a synthetic navigation hint dataset based on Room2Room (R2R) (Anderson et al., 2018) dataset. Our dataset provides hints for each step of the trajectory in the R2R dataset. Each hint description includes sub-instruction, landmark ambiguity, and targeted distinctive objects introduced above. The dataset serves as an extra supervision to train the navigation agent and the hint generator jointly. Besides, our constructed dataset can be utilized to explicitly analyze the navigation agent’s grounding ability by assessing the quality of generated hints.

In summary, our contributions are as follows:

1. We leverage a language model conditioned on the VLN models to design a hint generator that can be plugged into any VLN agent. This hint

generator helps the agent develop a comprehensive understanding of the visual environment.

2. We construct a synthetic hint dataset to provide the agent with visual descriptions at each navigation step. The dataset serves as an indirect supervision for jointly training the navigation agent and the hint generator.

3. We show that the hint generation improves the agent’s navigation performance on the R2R and R4R datasets. We also provide a detailed analysis of the agent’s grounding ability by examining the quality of the generated hints, thereby improving the interpretability of the agent’s decisions.

## 2 Related Work

**Navigation Instruction Following** Anderson et al. (2018) first extended the instruction following to the photo-realistic simulated environments. Subsequent studies have emerged with an emphasis on enhancing navigation performance through multi-modal learning (Hong et al., 2020a; Wang et al., 2023b; Zhang and Kordjamshidi, 2022a; An et al., 2021; Zhang et al., 2021), map representation learning (Hong et al., 2023; Chen et al., 2022a; An et al., 2023), or graph-based explorations (Zhu et al., 2021; Wang et al., 2021; Chen et al., 2022b). One line of effort has been to provide auxiliary reasoning tasks or pre-training proxy tasks to guide the navigation agent to learn textual and visual representations (Zhu et al., 2020; Chen et al., 2021; Hao et al., 2020; Qiao et al., 2022; Zhang and Kordjamshidi, 2022b). AuxRN (Zhu et al., 2020) proposes four auxiliary reasoning tasks to gain knowledge of the navigation map and the consequences of actions. However, most of those methods acquire the textual and visual semantics from a wayfinding perspective during navigation, which may be insufficient for agents to understand the visual environment comprehensively. We address this issue with our proposed hint generator that offers visual descriptions to guide the navigation agent in learning visual semantics.

**Language-Capable VLN Agent** A few studies attempt to design language-capable VLN agents to improve the agent’s grounding ability. Most of the work encourages the navigation agent to reproduce the original instruction. For example, LANA (Wang et al., 2023a) devises an agent that executes human-written navigation commands and provides route descriptions. Similarly, one of the tasks in AuxRN (Zhu et al., 2020) is to retell the

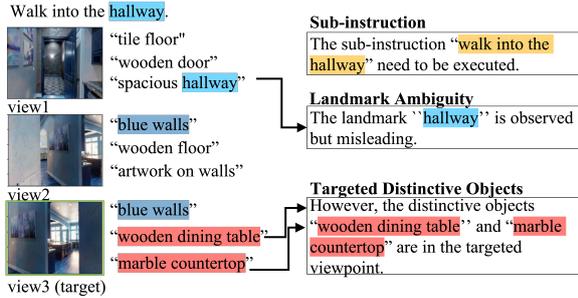

Figure 2: Navigation Hint Dataset. An example of a navigation hints with the landmark ambiguity of “Missing Landmarks”. The sub-instruction is “walk into the hallway”, and the landmark “hallway” in the instruction is observed in the view1 rather than target view3, which can potentially mislead the navigation agent. The target distinctive objects “wooden dining table” and “marble countertop.” are then provided. “Blue walls” is non-distinctive as it appears in both view2 and view3.

trajectory. However, these approaches have limitations because the original instruction can sometimes be inaccurate and confusing, as suggested in the VLN-Trans (Zhang and Kordjamshidi, 2023). Forcing the agent to reproduce the same instruction in such cases can undermine the agent’s grounding ability. Instead of only focusing on the original instruction, our proposed hint generator produces visual descriptions from a global perspective, thereby enhancing the agent’s understanding of the visual environment and improving its grounding ability.

### 3 Method

In the VLN problem setting, the agent is given a natural language instruction, denoted as  $W = \{w_1, w_2, \dots, w_l\}$ ,  $l$  is the length of the sentence. At each navigation step, the agent perceives panoramic views with 36<sup>1</sup> discrete images. There are  $n$  candidate viewpoints that can be navigated to, denoted as  $I = \{I_1, I_2, \dots, I_n\}$ . This task aims to generate a trajectory following the given instruction. In the following section, we first present our constructed navigation hint dataset. Then, we introduce the hint generator. The navigation hint dataset is used to train the navigation agent and the hint generator jointly.

#### 3.1 Navigation Hint Dataset

The purpose of constructing the navigation hint dataset is to provide supervision for the hint generator to generate detailed visual description. The navigation hint dataset is automatically generated

<sup>1</sup>12 headings and 3 elevations with 30-degree intervals.

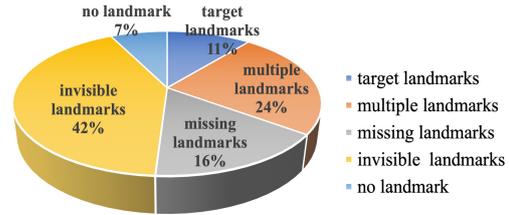

Figure 3: Statistics of different categories of landmark ambiguity.

based on instruction and trajectory pairs from the R2R dataset (Anderson et al., 2018). For every step of the trajectory, we provide hints that mainly include three key elements, as described below.

**Sub-instruction** is the first part of the hint that pinpoints to the relevant part of the instruction (sub-instruction) to be processed at the current step. We obtain the sub-instructions and their corresponding viewpoints from the FGR2R (Hong et al., 2020b) dataset, which provides human annotations of sub-instructions and the aligned viewpoints.

After obtaining the sub-instruction at each step, we insert it into our hint template, which is “*The {sub-instruction} needs to be executed.*”. Guiding the navigation agent to detect the related sub-instruction at each step is crucial since it effectively assists the agent in tracking its navigation progress.

**Landmark Ambiguity** is the second part of the hint that describes the commonalities across multiple views that can result in ambiguity during navigation. This part of hint is achieved by examining the shared landmarks mentioned in the instruction among the candidate viewpoints.

To automatically generate this part of the hint for building the dataset, we first use spaCy<sup>2</sup> to extract noun phrases from sub-instruction and use them as landmarks. Then, we extract visual objects in each candidate viewpoint using MiniGPT-4 (Zhu et al., 2023)<sup>3</sup> with a two-step textual prompting. We choose visual objects generated by MiniGPT-4 instead of Matterport3D object annotations because Matterport3D objects are pretty limited, with only 40 object categories like “doors”, “walls”, and “floors”. These generic objects are not sufficient for resolving landmark ambiguity. Moreover, the absence of attribute annotations in Matterport3D poses a challenge for landmark disambiguation, such as the differences between “wooden table” and “glass table”. In contrast, MiniGPT-4 can generate such detailed attribute descriptions.

<sup>2</sup><https://spacy.io/>

<sup>3</sup><https://minigpt-4.github.io/>

Ambiguity Category	Description	Hints
Target Landmarks	Landmarks only appear in the target.	The {landmarks} are observed.
Multiple Landmarks	Landmarks are visible in multiple viewpoints including the target viewpoint.	The {landmarks} are observed in multiple viewpoints.
Missing Landmarks	Landmarks are visible in other viewpoints except for the target viewpoint.	The {landmarks} are misleading.
Invisible Landmark	Landmarks are not visible in all viewpoints	The {landmarks} are not observed.
No Landmarks	No landmarks in sub-instruction. (e.g. "make a right turn", "turn left", and "go straight")	$\emptyset$

Table 1: Landmark Ambiguity. The col#1 and col#2 show the categories of landmark ambiguity and the corresponding descriptions. The col#3 shows the template for generating the hint for each category.

Specifically, for each candidate viewpoint, we feed MiniGPT-4 with the viewpoint image, asking “Describe the details of the image.” and then “List the objects in the image”. The generated text is in free form, and we post-process it to retrieve a list of extracted object descriptions. After obtaining textual landmark names and visual objects, we examine the shared landmarks among the candidate viewpoints. The presence of shared landmarks can pose ambiguity for the navigation agent. We categorize the ambiguity into: *Target Landmarks*, *Multiple Landmarks*, *Missing Landmarks*, *Invisible Landmarks* and *No Landmark*. and their descriptions are in Table 1. Fig. 3 shows the statistics of ambiguity of our navigation hint dataset. Most cases are “Invisible Landmarks” or “Multiple Landmarks”, which is consistent with the argument in VLN-trans (Zhang and Kordjamshidi, 2023) that invisible and non-distinctive landmarks cause issues for the navigation agent in following instructions.

After identifying the category of landmark ambiguity, we construct this part of the hint using the corresponding templates in col #3 of Table 1. Identifying landmark ambiguity requires the navigation agent to ground the mentioned landmark names in the instruction to the visual objects in all candidate viewpoints. Guiding the navigation agent to identify such detailed ambiguities can help enhance its understanding of the connection between the instruction and the entire visual environment.

**Targeted Distinctive Objects** is the third part of the hint that describes the distinctive visual objects specific to the targeted view. The agent should be able to justify its decision by describing the distinction of the targeted view. We follow the approach of obtaining distinctive objects in the VLN-Trans (Zhang and Kordjamshidi, 2023) that compares the visual objects in the targeted and other candidate viewpoints. The distinctive objects are the ones that exclusively appear in the targeted viewpoint and do not appear in other views.

The hint template for targeted distinctive objects is “However, {the comma-separated list of distinctive object names} are in the targeted view.”. We use 3 distinctive objects at most. If the cases belong

to the challenge of “Target Landmark”, there is no need to provide extra distinctive objects since the landmark is already exclusive to the targeted viewpoint. Describing distinctive objects is important to obtain a global understanding of the visual environment by highlighting the differences between the targeted viewpoint and other candidate viewpoints.

We collect hint for each step of trajectory to construct our navigation hint dataset. More details are in Appendix A.1.

### 3.2 VLN Agent with a Hint Generator

We propose a hint generator that can be plugged into any navigation agent easily. We use VLN $\odot$ BERT (Hong et al., 2020c) as the base model to illustrate our method but noted that the hint generator is compatible with most of the current agents. Fig. 4 shows the model architecture.

**Text Encoder** We use BERT (Vaswani et al., 2017) to obtain initial text representation of instruction, denoted as  $X = [x_1, x_2, \dots, x_l]$ .

**Vision Encoder** We follow previous works to concatenate image and relative orientation features as vision features for each candidate viewpoint. Specifically, we extract the image features from ResNet-152 (He et al., 2016) pre-trained on the Places365 dataset (Zhou et al., 2017). The orientation features are derived from the relative heading denoted as  $\alpha$  and the elevation denoted as  $\beta$ . The orientation features are represented as  $[\sin \alpha; \cos \alpha; \sin \beta; \cos \beta]$ . The vision features are then passed through an MLP (Multilayer Perception) of Vision Encoder to obtain vision representation for each candidate viewpoint, denoted as  $[v_1, v_2, \dots, v_n]$ .

**Navigation Agent** VLN $\odot$ BERT is a cross-modal Transformer model. Besides text and vision representations, a state representation is introduced in the model to store history information recurrently, which is denoted as  $S$ . At the  $t$ -th navigation step, the text representation  $X$ , the visual representation  $V_t$  and state representation  $S_t$  are input into cross-modal Transformer layers, as follows,

$$\hat{X}, \hat{S}_t, \hat{V}_t = \text{Cross\_Attn}(X, [S_t; V_t]), \quad (1)$$

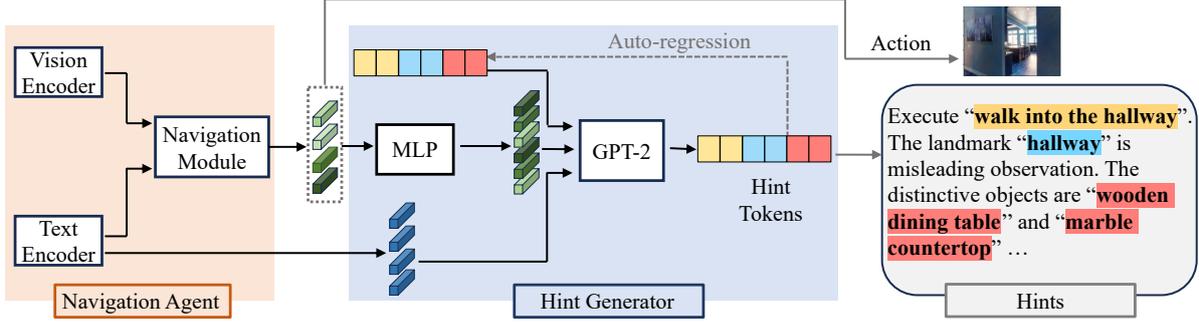

Figure 4: Model Architecture. We introduce a hint generator designed to help the navigation agent acquire a deep understanding of the visual environment. The weighted vision representations (■), used as image prefix, and the instruction text representation, used as instruction prefix (■), are input into a GPT2 decoder. The decoder generates hints during navigation at each step. The hints include the three parts of sub-instruction (■), landmark ambiguity (■), and target distinctive objects (■).

where  $\hat{X}$ ,  $\hat{S}_t$ , and  $\hat{V}_t$  are the learnt contextual text, state representation, and visual representations, respectively. Then we apply attention layer between state representation  $\hat{S}_t$  contextual vision representations  $\hat{V}_t$  as follows,

$$S_{t+1}, a_t = \text{Attn}(k = \hat{V}_t, q = \hat{S}_t, v = \hat{V}_t), \quad (2)$$

where  $S_{t+1}$  is the updated state representation that is passed to the next steps to convey the history.  $a_t$  is the attention score over the navigable views and serves as the action probability of the current step. **Hint Generator** Inspired by the idea of prefix engineering (Mokady et al., 2021) that uses the image representation as the prefix of the text for the image captioning task, we employ a decoder language model (LM) and use the contextual visual representation of the navigation agent and the original instruction as the prefix. However, unlike the previous work, rather than just using one image as the prefix, we input all images of candidate viewpoints to encourage the hint generator to learn the global relations among views.

Formally, we denote the hint at the  $i$ -th navigation step as  $C^i = \{c_1^i, c_2^i, \dots, c_j^i\}$ , where  $j$  is the length of the hint. Different from LANA (Wang et al., 2023a) that generates route description after navigation, our hint generator provides a more in-depth visual description at each step. Our approach requires the agent to possess a global and deep visual understanding, which can be learnt through the supervision from our navigation hint dataset explained in Section 3.1. We obtain the LM representation of the original instruction  $W$  and the hint  $C$  as  $X' = \{x'_1, x'_2, \dots, x'_l\}$  and  $c = \{c_1, c_2, \dots, c_j\}$  respectively. Since the semantic structure of our auto-generated dataset can

be easily captured, we use a 1.5B-parameters decoder LM (GPT-2 large) in the hint generator. Note that any larger decoder language model in the GPT series can be employed.

We use the instruction text representation  $X'$  as the instruction prefix representation. We use the weighted vision representations output from the navigation agent as the image prefix representation. The weighted vision representation is obtained using action probability and the contextual vision representations as  $\hat{V}_t = a_t * \hat{V}_t$ . Then we simply employ an MLP to map  $\hat{V}_t$  to LM token space. We denote such MLP as  $F$ . We obtain prefix embedding that is mapped from visual representation  $\hat{V}$  as follows,

$$p_1, \dots, p_k = F(\hat{V}_t), \quad (3)$$

where  $k$  is the prefix length, and  $p$  is the image prefix representation. We concatenate the representation of image prefix  $p$  and instruction prefix  $X'$ , and combine them with the text representation of hint  $C$ . The hint generator only decodes the hint in an auto-regressive manner at each step. During training, the parameters of both of MLP and the LM in the hint generator and the navigator are updated. The training objective is to maximize the likelihood of the next hint token. The following equation shows the loss of generating the  $j$ -th token of the hint at the  $i$ -th step.

$$L_{\text{hint}} = - \sum_{i,j} \log p_{\theta}(c_j^i | p_1^i, \dots, p_k^i, x'_1, \dots, x'_l, c_1^i, \dots, c_{j-1}^i). \quad (4)$$

**Training and Inference for the VLN Agent** For the navigation, we train the navigation with a mixture of Imitation Learning (IL) and Reinforcement

Learning (RL) (Tan et al., 2019). It consists of the cross-entropy loss of the predicted probability distribution against the ground-truth action and a sampled action from the predicted distribution to learn the designed rewards. In summary, the navigation loss is as follows,

$$L_{nav} = -\sum_t -\alpha_t^* \log(p_t^\alpha) - \lambda \sum_t \alpha_t^s \log(p_t^\alpha), \quad (5)$$

where  $\lambda$  is the hyperparameter to balance the two components,  $\alpha_t^*$  is the teacher action for IL, and  $\alpha_t^s$  is sample action for RL. We jointly train the navigation agent with hint generator using the following objective,

$$L = L_{hint} + L_{nav}. \quad (6)$$

During inference of navigation, we use greedy search to select an action with the highest probability at each navigation step to generate a trajectory. To generate hint, we utilize the trained weighted visual representation and the original instruction text representation as prompts and employ a greedy search approach to generate the hints.

## 4 Experiment

### 4.1 Dataset and Evaluation Metrics

**Dataset** We evaluate our approach on R2R (Anderson et al., 2018) and R4R datasets (Jain et al., 2019), which are built upon Matterport3D simulator (Anderson et al., 2018). R2R includes 21, 567 instructions and 7, 198 trajectories. R4R is an extension of R2R to combine the two adjacent tail-to-head trajectories in R2R. The visual environments in unseen sets are excluded in the training sets.

**Evaluation Metrics** Three main metrics are used to evaluate navigation wayfinding performance (Anderson et al., 2018). (1) Navigation Error (NE) (2) Success Rate (SR) (3) Success Rate Weighted Path

Length (SPL). Another three metrics measure the fidelity between the predicted and the ground-truth trajectories. (4) Coverage Weighted by Length Score (CLS) (Jain et al., 2019) (5) normalized Dynamic Time Warping (nDTW) (Ilharco et al., 2019) (6) Normalized Dynamic Time Warping weighted by Success Rate (sDTW). More details are in Appendix A.2 and A.3.

### 4.2 Implementation Details

We use pre-trained VLN $\odot$ BERT<sup>++</sup> (Zhang and Kordjamshidi, 2023) to initialize our navigation model. VLN $\odot$ BERT<sup>++</sup> further trains the pre-trained weights in VLN $\odot$ BERT (Hong et al., 2020c; Hao et al., 2020) on a large image-text-action dataset including RXR (Ku et al., 2020), Marky-mT5 (Wang et al., 2022), and SyFis (Zhang and Kordjamshidi, 2023). The dimensions of both BERT and GPT text representations are 768-d. In the training, we conducted 300K iterations on an NVIDIA RTX GPU (20 hours), with a batch size of 8 and a learning rate of  $1e-5$ .  $\lambda$  in Eq. 5 is 0.2. We set the maximum prefix length for each image as 10 for the hint generator and the number of generated tokens as 80. The best model is selected according to performance on val unseen split. Please check our code <sup>4</sup> for the implementation.

### 4.3 Experimental Results

Table 2 shows the performance on validation unseen and test of the R2R dataset in a *single-run setting* where the navigation agent traverses without *backtracking* and *pre-exploring*. To verify the adaptability of our approach, we evaluate it using both LSTM-based and Transformer-based navigation agents. Since Transformer-based methods

<sup>4</sup><https://github.com/HLR/NavHint.git>

	Method	NE↓	SR↑	SPL↑	CLS↑	sDTW↑

Table 3: Results on R4R validation unseen dataset.

are pre-trained on large vision-language datasets and have a more complex model architecture, they achieve a higher performance than LSTM-based methods. For the LSTM-based model, we use EDrop (Tan et al., 2019) which uses CLIP (Radford et al., 2021) visual representations without augmented data during training. For the Transformer-based model, we use the VLN $\odot$ BERT<sup>++</sup> (row#11) as the baseline.

Row#1 to row#3 in Table 2 show other LSTM-based methods and row#4 to row#8 are the SOTA Transformer-based methods. Row#9 shows the performance of the LSTM baseline EDrop. Row#10 shows the results after equipping the EDrop with our designed hint generator. The improved sDTW and nDTW on the validation unseen proves that the hint generator helps the navigation agent follow the instructions. Moreover, our hint generator on top of the VLN $\odot$ BERT<sup>++</sup> (row#12) significantly improves both wayfinding metrics (SP and SPL) and fidelity metrics (sDTW and nDTW) of the baseline model, indicating that our hint generator not only assists the agent in reaching the correct destination but also encourages the agent to follow the original instructions. Improving both LSTM-based and Transformer-based navigation agents shows the generalization ability of the navigation agent with our designed hint generator.

Table 3 shows the results on the unseen validation of the R4R dataset. We use VLN $\odot$ BERT<sup>++</sup> as our baseline model (row#7). Row#1 to row#3 are using LSTM-model, and row#4 to row#6 are using Transformer-based models. The result of our method (row#8) shows that we can improve SPL, sDTW, and CLS, that is, improving both the wayfinding and fidelity of the baseline models. These results are consistent with the improvements on the R2R dataset. Though the VLN-Trans (row#6) (SOTA) is very competitive, we additionally provide hints that can be used for explicitly analyzing the agent’s decisions instead of implicit sub-instruction learning designed in VLN-Trans.

#### 4.4 Ablation Study

Table 5 reports the ablation analysis. From row#1 to row#3, we individually include sub-instruction,

Model	Val Seen		Val Unseen	
	Bleu-1	Bleu-4	Bleu-1	Bleu-4
EDrop + Hint. (ours)	0.74	0.62	0.72	0.60
VLN $\odot$ BERT <sup>++</sup> + Hint. (ours)	<b>0.76</b>	<b>0.64</b>	<b>0.74</b>	<b>0.62</b>

Table 4: Bleu score for the generated sub-instruction on the R2R dataset.

Method	Hints			Val Unseen			
	Sub.	L-A.	TD-Obj.	Obj.	SR↑	SPL↑	nDTW↑
Baseline					0.665	0.607	0.685
1	✓				0.671	0.612	0.690
2		✓			0.673	0.613	0.687
3			✓		0.677	0.624	0.702
4				✓	0.676	0.621	0.698
5	✓	✓			0.674	0.614	0.709
6	✓	✓		✓	0.681	0.632	0.694
7	✓	✓	✓		<b>0.692</b>	<b>0.647</b>	<b>0.724</b>

Table 5: Ablation study, where Baseline is VLN $\odot$ BERT<sup>++</sup>. Sub.:sub-instruction; L-A.:Landmark Ambiguity; TD-Obj: Target Distinctive Objects. Obj:Top-3 objects.

landmark ambiguity, and targeted distinctive objects to the hint. All navigation performance metrics improve gradually compared to the baseline. In another experiment (row#4), we attempt to describe the visual environment by identifying only top-3 recognized objects (using MiniGPT-4) in the targeted viewpoint without differing them from other viewpoints. The navigation results still improve, indicating that visual descriptions of the objects benefit the overall navigation performance. Row#5 shows that combining sub-instruction and landmark ambiguity further improves the baseline, particularly in the nDTW metric. In row#6, when we combine sub-instruction, landmark ambiguity and top-3 objects, we observe improvement in the goal-related metrics (SR and SPL), but the model’s ability to faithfully follow the instruction is somewhat compromised (lower nDTW). The best result is obtained when we replace the above top-3 objects with distinctive ones (row#7), indicating our designed hint’s effectiveness in describing the targeted view from a global perspective.

#### 4.5 Generated Hints Analysis

In this section, we assess the content of each part of the generated hints on the R2R validation dataset to analyze agent’s grounding ability.

**Sub-instruction Analysis** We use Bleu score (Papineni et al., 2002) as an evaluation metric to assess whether the navigation agent can identify sub-instruction accurately. We conduct experiments on both LSTM-based and Transformer-based navigation agents, as shown in Table 4. The generated sub-instruction from the Transformer-based navigation agent can obtain a relatively high Bleu score compared to the LSTM-based agent. This result

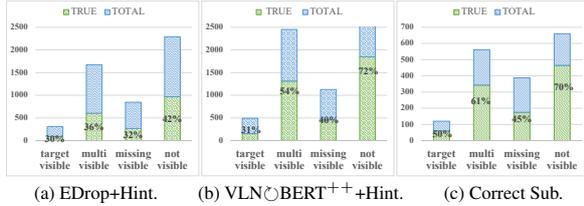

Figure 5: Accuracy of the generated landmark ambiguity. Sub.: Sub-instruction.

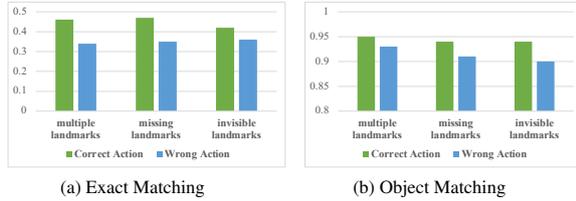

Figure 6: Accuracy of the generated distinctive objects for each landmark ambiguity in the targeted viewpoint.

demonstrates that a more robust navigation agent achieves a stronger alignment between the instruction and visual modality for identifying the relevant part of the instruction to track the progress.

**Landmark Ambiguity Analysis** We assess the accuracy of four categories of landmark ambiguity in the generated hints. Specifically, We extract the part of the landmark ambiguity from the generated hint and check its accuracy in the visual environment. In Figure 4, the TOTAL in the y-axis shows the total number of navigation steps that include each ambiguity category, shown on the x-axis. The TRUE (green) indicates the percentage of navigation steps when the corresponding ambiguity truly exists. We evaluate both LSTM-based and Transformer-based agents, and the result shows that Transformer-based agents can achieve higher accuracy of landmark ambiguity. We conclude that accurate landmark ambiguity detection is positively correlated with better navigation performance. In Figure 4(c), we evaluate the generated hint for the examples in which the sub-instruction is generated correctly, as indicated by a Bleu-4 score of 1.0. In those examples, the accuracy of identifying each category of landmark ambiguity is also higher. This result shows accurately locating the sub-instruction positively impacts landmark ambiguity detection.

**Targeted Distinctive Objects Analysis** We report the accuracy of identifying the targeted distinctive objects in the generated hints when landmark ambiguity exists, as shown in Fig. 6. The generated hints are from the model of VLNBERT++ with our designed hint generator. We provide two types of comparisons, exact phrase matching and object token matching while performing both wrong and right actions. Exact matching evaluates the detec-

**Instruction:** Turn right and walk past the kitchen. Continue straight past the sink and turn left.

**Hint:** The instruction “turn right and walk past the kitchen” need to be executed. The landmark “kitchen” is observed in multiple views. The distinctive objects “stove” in the target viewpoint maybe helpful.

**Instruction:** With the couch behind you and the round table ahead and to the left, move forward towards the kitchen. Stop after you’ve passed the bar on your right.

**Hint:** The sub-instruction “with the couch behind you and the round table ahead and to the left, move forward towards the kitchen” need to be executed. The landmarks “table” is observed in multiple viewpoints. However, the distinctive object “sideboard” is in the targeted viewpoint.”

**Instruction:** Turn around and walk towards the sofas. Turn left and walk past the first archway.

**Hint:** The instruction “turn around and walk towards the sofas.” need to be executed. The landmark “sofa” is observed.

Figure 7: Qualitative examples. The green and orange arrows show the ground-truth and the predicted viewpoints, respectively.

tion of distinctive object tokens and the attribute descriptions in the whole referring phrase. Object matching only evaluates the detection of distinctive object tokens. The result shows that the accuracy in generating distinctive objects is generally higher when the action is correct than when it is wrong. Also, the agent tends to generate distinctive objects that align with its targeted viewpoint, as indicated by an accuracy exceeding 90%, even when the action is incorrect. The lower accuracy of exact matching also aligns with the fact that generating the whole referring expression, including the correct attributes, is more challenging.

## 4.6 Qualitative Examples

Fig. 7 demonstrates a few examples of the generated descriptions. The first two examples show successful cases where the agent makes a correct decision. The first example shows the agent can accurately identify the sub-instruction and notice the ambiguous landmark “kitchen”. Then, it correctly pinpoints the distinctive object “stove”, which only appears in the target viewpoint. In fact, our *targeted distinctive object* design can help connect the specific object (e.g. stove, refrigerator, counter table) to more general scene objects (e.g. kitchen). Also, the second example shows the agent accurately points out the “table” in the instruction that appears

in multiple viewpoints and refers to the “sideboard” in the target viewpoint. The third example shows a failure case in which the agent makes a wrong decision. The sub-instruction is correctly identified, but the agent should turn around towards the counter table and proceed to the sofa rather than walk to the sofa directly. This further indicates that our descriptor pushes the model to focus on landmarks directly and ignore the directions and motions in the instruction. Despite this, our model can generate a description consistent with its selection. More examples are in the Appendix A.4.

## 5 Conclusion

In this paper, we equip the navigation agent with a hint generator to generate visual descriptions during navigation, which helps the agent’s understanding of the visual environment. To train the hint generator, we create a navigation hint dataset that provides comprehensive supervision for training the agent. During navigation, the agent generates natural language descriptions about its visual environment at each step, including comparing various views and explaining ambiguities in recognizing the target destination. Empirical results show that detailed visual description generation improves both navigation performance and the interpretability of actions taken by the navigation agent.

## 6 Limitations

We mainly summarize the following limitations. First, although we employ the GPT2 language decoder, more recent and powerful GPT-series language decoders are now available and could be utilized. Exploring these advanced language decoders could potentially enhance the performance of our approach. Second, we do not include more advanced vision representations, such as ViT representation, to train the navigation agent. We can surpass other methods using ResNet, but it would be interesting to experiment with those different visual representations to generate better hints. Third, utilizing object visual descriptions from MiniGPT-4 may entail hallucination issues, which is a general challenge of VLMs. However, in our specific usage of MiniGPT4, we barely face this issue in the experiments.

## A Appendix

### A.1 Statistics of the VLN Hint Dataset

We built VLN explanation dataset upon R2R dataset. We split our explanation dataset into train, validation seen, and validation unseen sets according to R2R. We create explanation for each navigation step of trajectory given the corresponding instruction. For train set, there are 4,675 trajectories, and we create 69,969 explanation in 61 visual scenes. For validation seen set, there are 340 trajectories, and we create 5,175 explanations in 61 visual scenes. For validation unseen set, there are 783 trajectories, and we create 11,664 explanations in 11 visual scenes.

### A.2 Dataset

We evaluate our approach on R2R (Anderson et al., 2018) and R4R datasets (Jain et al., 2019), which are built upon Matterport3D simulator (Anderson et al., 2018). R2R includes 21,567 instructions and 7198 trajectories. The dataset has been partitioned into four sets: train (61 scenes, 14,039 instructions), validation seen (61 scenes, 1,021 instructions), validation unseen (11 scenes, 2,349 instructions), and test unseen sets (18 scenes, 4,173 instructions). R4R is an extension of R2R to combine the two adjacent tail-to-head trajectories in R2R. It contains three sets: train (61 scenes, 233,613 instructions), validation seen (61 scenes, 1,035 instructions), validation unseen (11 scenes, 45,162 instructions). The scenes in unseen sets are not trained.

### A.3 Evaluation Metrics

Three main metrics are used to evaluate navigation wayfinding performance (Anderson et al., 2018): (1) Navigation Error (NE): the mean of the shortest path distance between the agent’s final position and the goal destination. (2) Success Rate (SR): the percentage of the predicted final position being within 3 meters from the goal destination. (3) Success Rate Weighted Path Length (SPL): normalizes success rate by trajectory length. Another three metrics are used to measure the fidelity between the predicted and the ground-truth trajectory. (4) Coverage Weighted by Length Score (CLS) (Jain et al., 2019) (6) nDTW (Ilharco et al., 2019): Normalized Dynamic Time Warping: penalizes deviations from the ground-truth trajectories. (6) Normalized Dynamic Time Warping weighted by Success Rate

**Instruction:** Walk through the office. Wait near the living room near the sofa.

**Hint:** The instruction “walk through the office.” need to be executed. The landmark “office” is invisible. The distinctive objects “blue floor” is in the targeted viewpoint.

**Instruction:** Walk left past the table and chairs and through the doorway.

**Hints:** The instruction “walk past the table and chairs” need to be executed. The landmark “table” and “chairs” are invisible. The landmark distinctive objects “blue shutters and white wall” are in the targeted viewpoint.

**Instruction:** Walk past the sink area. Walk of the door and past the statue of a hand.

**Hints:** The instruction “walk past the sink area” need to be executed. The landmark “area” is invisible. The landmark distinctive objects “white board” is in the targeted viewpoint.

**Instruction:** Walk into the office at the end of the hall. Wait in the office between the love seat and chair.

**Hints:** The instruction “walk into the office at the end of the hall” need to be executed. The landmark “end, office, hall” are invisible. The landmark distinctive objects “white sofa” is in the targeted viewpoint.

Figure 8: More qualitative examples. The green and orange arrows show the ground-truth and the predicted viewpoints, respectively.

(sDTW) (Ilharco et al., 2019): penalizes deviations from the ground-truth trajectories and also considers the success rate.

### A.4 More Qualitative Examples

We present additional qualitative examples in this section. The first three are successful cases where the navigation agent makes correct actions, and the hint generator accurately generates sub-instruction, landmark ambiguity and distinctive objects in the instruction. The last two examples are failure cases. Despite incorrect actions, the agent still generates accurate distinctive objects within its selected viewpoint. The failures might come from inaccuracies in landmark extraction, which subsequently affect ambiguity checking.

# Text or Image? What is More Important in Cross-Domain Generalization Capabilities of Hate Meme Detection Models?

## Abstract

This paper delves into the formidable challenge of cross-domain generalization in multimodal hate meme detection, presenting compelling findings. We provide enough pieces of evidence<sup>1</sup> supporting the hypothesis that only the textual component of hateful memes enables the existing multimodal classifier to generalize across different domains, while the image component proves highly sensitive to a specific training dataset. The evidence includes demonstrations showing that hate-text classifiers perform similarly to hate-meme classifiers in a zero-shot setting. Simultaneously, the introduction of captions generated from images of memes to the hate-meme classifier worsens performance by an average F1 of 0.02. Through blackbox explanations, we identify a substantial contribution of the text modality (average of 83%), which diminishes with the introduction of meme’s image captions (52%). Additionally, our evaluation on a newly created confounder dataset reveals higher performance on text confounders as compared to image confounders with an average  $\Delta F1$  of 0.18.

## 1 Introduction

Recently many hate-meme detection multimodal (MM) systems have been proposed, see (Sharma et al., 2022) for a survey and (Kougia and Pavlopoulos, 2021; Aggarwal et al., 2021; Gold et al., 2021; Zhu, 2020; Muennighoff, 2020; Li et al., 2019; Chen et al., 2020) for individual contributions, but it is an ongoing concern that they do not generalize well in a cross-domain setting. Possible causes are (i) the implicit knowledge captured by multimodal hate messages (memes) (Ma et al., 2022; Gomez et al., 2020; Zhong et al., 2016; Hosseini et al., 2015), (ii) additional annotation noise in multi-modal settings (Oriol Sàbat, 2019), and (iii) more complex network architectures.

<sup>1</sup>Our code and dataset are released at <https://github.com/agggarwalpiush/HateDetection-TextVsVL>

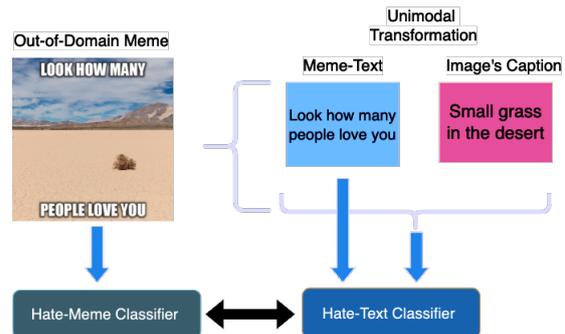

Figure 1: Illustration of our experimental arrangement for assessing the hate meme model’s performance compared to unimodal text-based hate classifiers. The evaluation involves a test meme from a domain not included in the model’s training data.

In this study, we explore the generalization capabilities of MM models for detecting hate memes. While previous studies (Wang et al., 2020; Ma et al., 2021) support the significant role of image modality in other multimodal-based downstream tasks, however, in the case of meme classification, the meaning can only be correctly inferred from also looking at the image, so we find the analysis to be of special importance and worth replicating. Consequently, we initiate the evaluation of these models in settings outside their domain. We observe a significant decline in performance, with an average macro F1 score of 0.28.

We aim to tackle this issue by utilizing a text-only (unimodal) hate classifier, specifically crafted for the detection of hateful memes. Previous research (Nozza, 2021; Alshalan and Al-Khalifa, 2020; Talat et al., 2018) demonstrates relatively higher generalization capabilities in the context of unimodal text-only hate. Our approach involves applying an unimodal transformation to memes by concatenating the text within the meme with a caption generated from the meme’s image. Subsequently, we train a text-based classifier using a combination of nine diverse hate speech datasets

Name	Reference	# Train/Dev/Test	tokens	% hate	Domain
HARMEME	(Pramanick et al., 2021)	3.5k	160k	26.21	Covid-19/US Election
MAMI	(Fersini et al., 2022)	10k	590k	50	Misogynistic
FB	(Kiela et al., 2020)	10k	370k	37.56	<i>mixed</i>

Table 1: Properties of hate-meme datasets used in our study.

and assess its performance on a transformed meme test set. We observe performance levels from our unimodal classifier that are comparable to those of MM models. In certain instances, our unimodal classifier even exhibits an improvement in performance, with an average F1 increase of 0.05 compared to late-fusion-based MM models. The results make us infer that the text modality demonstrates superior generalizability compared to the image modality in detecting hateful memes. Figure 1 gives an overview of our experimental setup.

Additionally, we find that MM models behave differently than textual-based models. We retrain the MM models on hateful meme datasets which also include captions generated from the images available in the memes. Surprisingly, in comparison with existing models, in general, we find small performance drops (average  $\Delta F1$  of 0.02) in both in-domain as well as out-of-domain settings regardless of the presence of captions in the test sets.

We explain the behavior of MM models by computing the contribution of text and image modality individually toward the prediction. We apply Shapley values (Parcalabescu and Frank, 2023) to the features used in the models and average the final score for each modality (Section 3). Our results indicate a substantial contribution (83%) of textual modality by the models evaluated on all the datasets we have used in our study. Nevertheless, incorporating the image caption of the meme into the input data during the MM model training results in a decreased textual contribution of 52%. We believe that images in hateful memes are more like facilitators and provide context to the MM models.

To validate this, we compose a confounder dataset where we subset from the HARMEME and FB dataset (Pramanick et al., 2021; Kiela et al., 2020), selecting 100 memes featuring celebrities or known figures such as *Donald Trump*, *Nelson Mandela* and *Adolf Hitler*. We observe that MM models are sensitive to text confounders, while the prediction labels remain unchanged when the model is triggered with image confounders. (An average  $\Delta F1$  of 0.18 is observed when the MM model is

evaluated on Text and Image confounder sets).

Although, prior studies such as (Wang et al., 2020; Ma et al., 2021) have represented similar hypotheses. However, we find such studies for explicit types of downstream tasks.

In this paper, we present compelling evidence substantiating the hypothesis that the generalization of multimodal classifiers across diverse domains is primarily attributable to the textual component of hateful memes. Remarkably, our findings reveal a heightened sensitivity of the image part to the nuances of a specific training dataset. We believe we are the first to provide a thorough analysis supporting this idea, making our work unique in contributing to the field.

## 2 Related Work

Kirk et al. (2021) demonstrate the high generalization behaviour of CLIP models (Radford et al., 2019) when it is fine-tuned on the Hateful meme FB dataset (Kiela et al., 2020) and tested on in-house hate meme test set collected from pinterest<sup>2</sup>. However, their model is evaluated without using the meme’s text which we believe provides significantly greater valid information for hateful meme detection. Cuo et al. (2022) attempts to investigate the poor generalizability behavior of VL-models towards COVID-19-specific hate meme detection task. The application of the gradient-based explanation method demonstrates the significance of image modality is twice of textual one during predictions. Not specific to hate meme classification task, Ma et al. (2022) evaluate the robustness of Visual-Linguistic transformers on missing modality datasets and found even poorer performance than uni-modal models and proposed a method that performs an optimal fusion of modalities which end up with better results. Error analysis of visio-linguistic models also indicates model bias (Hee et al., 2022). While prior studies recommend investigating the contributions of each modality to model predictions to uncover the root cause of their lim-

<sup>2</sup><https://www.pinterest.com/>

ited generalization, these analyses tend to be overly specific, focusing solely on the in-house COVID-19 test set. Additionally, suggested methods like gradient-based explanation (Selvaraju et al., 2019) are susceptible to deception through small input changes, as demonstrated in adversarial attacks (Parcalabescu and Frank, 2023).

### 3 Modality Contribution with Shapley Values

Applying the method proposed by Parcalabescu and Frank, 2023, we attempt to investigate the modality contribution of existing hate meme detection models. There are multiple existing methods that can be used to estimate the importance of the model’s features in the prediction process. Shapley values provide important ingredients for sample-based explanations that can be aggregated in a straightforward way into dataset-level explanations for machine learning methods (Covert et al., 2020). We calculate Shapley values for meme text tokens and image patches utilized in MM models during prediction. Each entity (token or patch) through its shapely value gauges its impact on the model prediction, such as the likelihood of image-sentence alignment. It can be positive (enhancing the model prediction), negative (diminishing it), or zero (no discernible effect).

## 4 Datasets

### 4.1 Hateful Meme Datasets

In order to analyze the generalizability of available hate meme classifiers and modality contribution, we have used three benchmark datasets (see Table 1).

**Kiela et al.** (Kiela et al., 2020) (FB) comprises 10,000 memes sourced from Getty images, semi-artificially annotated with benign confounders. It includes (i) *multimodal hate* where both modalities possess benign confounders, (ii) *unimodal hate* where at least one of the modalities is already hateful, (iii) *benign image*, (iv) *benign text* confounders and (v) *random not-hateful* examples. The first four are labeled as *hateful*, while the last is labeled as *non-hateful*. The dataset is divided into 85% training, 5% development, and 10% test sets, with balanced proportions for each meme variety in the development and test sets.

**Pramanick et al.** (Pramanick et al., 2021) (HARMEME) consists of COVID-related memes

from US social media, identified using keywords like *Wuhan virus*, *US election*, *COVID vaccine*, *work from home*, and *Trump not wearing mask*. Unlike (Kiela et al., 2020), these memes are original, shared across social media, and their textual content is extracted using Google Vision API. The dataset is categorized into *hateful* (including *harmful* and *partially harmful*) and *non-hateful*, totaling 3,544 data points. The split for training, validation, and test sets is 85%, 5%, and 10%, respectively.

**Fersini et al.** (Fersini et al., 2022) (MAMI) focuses on SUBTASK-A, with memes labeled as *misogynist* or *non misogynist*. These are relabeled as *hateful* and *non-hateful* for consistency. The memes are collected from social media threads featuring women personalities such as Scarlett Johansson, Emilia Clarke, etc. as well as hashtags such as #girl, #girlfriend, #women, #feminist. Google Vision API is used for meme text extraction. With a balanced set of 10,000 instances, 10% are used for both development and test sets, randomly stratified.

### 4.2 Confounder Dataset

In order to validate the generalization capabilities of multimodal (MM) models for a specific modality, we create a tailored dataset for validation. We conducted an exhaustive search on the FB (Kiela et al., 2020) dataset. A meticulous filtration process was implemented to exclude any instances featuring recognized celebrities or known figures such as *Donald Trump*, *Nelson Mandela*, and *Adolf Hitler*. Subsequently, attention was directed towards memes labeled as *hateful*. The selection was judiciously limited to a total of 100 figures, ensuring controlled and representative samples. The final stage of the methodology involved leveraging the identified set of hateful memes to construct a total of 100 benign images and text confounders. For image confounders, manual replacement of the celebrity figure with an analogous counterpart such as *Anne Frank* with *Adolf Hitler* (See Appendix A for complete list of the figures that were taken into account for the confounder dataset). Furthermore, to maintain simplicity and coherence for text confounders, the Polyjuice framework was incorporated (Wu et al., 2021). It is a counterfactual generator, that is instrumental in facilitating control over the nature and positioning of perturbations in the textual content, enhancing the precision and consistency of the devised framework. Figure 2

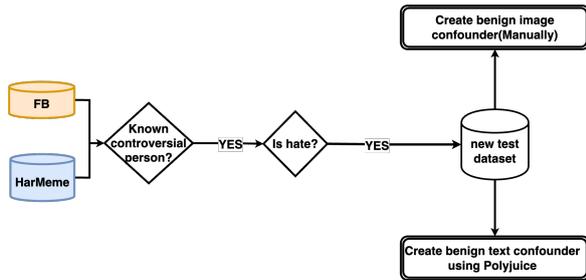

Figure 2: A schematic showing the data collection process of our proposed dataset.

illustrates the data collection process for our proposed dataset.

**Annotation process** We recruited 12 annotators (university graduated volunteers and regular social media users) to read the introduction, where the objective of the annotations along with the task is explained in detail (See Appendix B). From each of the collected memes, we solicit various aspects for analysis. First and foremost, we inquire about the *Image-text Relation*, seeking insights into the nuanced connection between the textual and visual components within a meme. Another crucial facet is the *Modality towards Hate*, which serves as an evaluative measure for the modality of a meme that may convey hate or offensive content. For a more granular understanding, we introduce *Decision Parts*, allowing annotators to pinpoint specific tokens or elements in the meme that contribute to its characterization as either hateful or non-hateful. To quantify the degree of hateful content, we employ a *Hatefulness Score*, utilizing a scale that ranges from 0 to 5. A score of 0 denotes non-hateful content, while a score of 5 signifies highly hateful material. Additionally, annotators are prompted to provide a *Confidence Score* reflecting their certainty regarding the accuracy of their judgments. This score operates on a scale from 0 (indicating a lack of confidence) to 5 (reflecting a high level of confidence). To maintain the integrity of the annotation process, we afford annotators the option to discard a sample, ensuring that only pertinent and valid memes<sup>3</sup> are included in the analysis. We ended up with very good inter-rater agreement among the annotation with Krippendorff alpha (Krippendorff, 2011) as 0.8. Furthermore, it is noteworthy that the average *Confidence scores*

<sup>3</sup>We offer annotators the option to exclude a meme if they lack sufficient knowledge to comprehend its content. Ultimately, we include only those memes that none of the annotators choose to discard.

is 4.38 out of 5 which shows very high confidence among the annotators.

## 5 Experimental Models

**Unimodal Hate Recognition** We use an online hate speech detection system called Perspective API<sup>4</sup> which consists of multilingual BERT-based models trained on millions of comments from a variety of sources, including comments from online forums such as Wikipedia and The New York Times. These models are further distilled into single-language Convolutional Neural Networks (CNNs) for different languages. We also fine-tune BERT (Devlin et al., 2019) and SVM-based hate detection models on nine hate speech datasets which will be discussed in Section 6.2.

**Multimodal Hate Recognition** Most of the promising studies on hate speech detection employ multi-modal based visual-linguistic pre-trained models (Chen et al., 2020; Li et al., 2019, 2020; Su et al., 2020; Tan and Bansal, 2019) which are originally designed to tackle basic visual-linguistic problems such as visual-question answering (VQA). These models carries semantic understanding between text and visual objects which makes them highly efficient for many downstream tasks. To analyze the vulnerability of the hate meme detection models, we investigate two early fusion and one late fusion-based multimodal (MM) models. *VisualBert* (Li et al., 2019), an early fusion visual-linguistic transformer-based model, pre-trained on image caption as well as VQA datasets. We also investigate *Uniter* model (Chen et al., 2020) stands for UNiversal Image-TEText Representation which is also an early fusion visual-linguistic transformer-based model with additional pre-training with Visual Genome, Conceptual Captions, and SBU Captions. As the third MM model, we train a late-fusion ensemble model where we employ distinct extraction pipelines for image and text features. For image feature extraction, we utilize Resnet (He et al., 2016), a highly deep residual learning framework designed for generating image features. To derive the text representation, we employ the widely-used RoBERTa model (Liu et al., 2019). Subsequently, we concatenate the features from both modalities and feed them through a 128-layer feed-forward network with ReLU activation and a dropout rate of 0.2 to produce predictions. The

<sup>4</sup><https://www.perspectiveapi.com/>

model is trained for 30 epochs using the Adam optimizer (Kingma and Ba, 2014), with a learning rate of  $10^{-5}$  and weight decay set to 0.1. This classifier is referred to as *Rob+Resnet* for the purpose of illustration.

**Image Caption Generation** We use *ClipCap* (Mokady et al., 2021), which is based on Contrastive Language Image Pretraining (CLIP) (Radford et al., 2021) model to encode the image and pre-trained language model GPT-2 (Radford et al., 2019) to decode a caption. We also use *BLIP* (Li et al., 2022) which is a multimodal mixture of encoder-decoders optimized on three objectives during the pre-training process which include image-text contrastive loss, image-text matching loss, and language modeling loss. Unlike other models, it also performs caption bootstrapping in order to deal with noisy input data. We use both of these models in their default settings<sup>5</sup>.

## 6 Experiments & Results

We conduct multiple sets of experiments in this study. Initially, we assess the cross-domain performance of hate-meme classifiers to gauge their generalization capabilities. Subsequently, we compare the performance of text-only hate classifiers on the textual component of memes with that of the hate-meme classifiers. We also assess the impact of captions generated from the image component of memes on text-only hate classifiers and hate meme detection models. Additionally, we compare the modality contribution from the blackbox explanations of the models with and without the introduction of captions. Finally, we apply the models to a confounder dataset to evaluate their sensitivity to a particular modality confounder set.

### 6.1 Generalization of Hate-meme Classifiers

To test the generalization capabilities of hate-meme classifiers, we fine-tune three state-of-the-art pre-trained models (VisualBert, Uniter and Rob+Resnet) on one datasets (train split) and test on the test splits of all three resulting in 9 train-test scenarios per model as can be seen in Table 2. Overall, we find huge performance drops across all the datasets for cross-domain testing. Since domains of HARMEME and MAMI are exclusive, we encounter symmetry among each other (F1 of .398 and .393 for VisualBert and .453 and .467 for

Table 3: Hatespeech datasets used to train the hate-text classifiers. For all datasets, the collection is based on hate slurs matching, therefore all of them consist *mixed* domains.

Uniter). On the hand, for FB, as there is no specific domain, we find relatively less decrement (however it is still huge) in the F1 scores. The results clearly infer a lack of generalization capabilities among these models.

### 6.2 Zero-shot Text-only Classifiers

We now compare the multimodal hate-meme classifiers to unimodal text-only classifiers. For that purpose, we train two text-only classifiers (SVM and BERT) on a large collection of hate speech datasets (see Table 3). Overall, we use around 0.1 Million posts having 1.4 Million tokens out of which 23% posts are hateful. In the case of SVM, for tokenization and feature extraction, we use ArkTokenizer and fasttext embeddings respectively. In the case of BERT, we follow the uncased-large model<sup>6</sup> for fine-tuning. We also use the hate speech classifier

<sup>6</sup><https://huggingface.co/bert-large-uncased>

		Testset			
		HARMEME	MAMI	FB	
Image + Text	VisualBert	.44	.60	.51	1
	Uniter	.57	.54	.53	2
	Rob+Resnet	.47	.45	.49	3

	BERT	.51	.53	.53	11
	SVM	.46	.44	.43	12

Table 4: Hate-meme vs. Hate-text Classifiers F1 Performance on cross-domain data. For Hate-meme classifiers, we indicate the best F1 value among the two training sets. A color gradient ranging from red to green is employed to emphasize the transition from lower to higher F1 values, respectively.

as provided by the Perspective API<sup>7</sup> which outputs a toxicity score for a given text. A toxicity score greater than 50% is considered hate otherwise non-hate.

Table 4 compares the zero-shot domain transfer results of hate-meme and hate-text classifiers. We encounter a close resemblance between them in their performances. Among cases where the text-only classifier is applied only on meme text, BERT model performance is superior to the rest of the two with an average F1 score of .51 followed by Perspective API (F1 of .59) (depicted in Table’s line 4 and 5). We observe a similar performance by multimodal hateful meme classifiers (average F1 of .52 for *VisualBert* and .55 for *Uniter* and .47 for *Rob+Resnet*) (see line 1, 2 and 3).

With the quite good performance of the text-only classifiers, it might be worthwhile trying to extract the semantics of the image as text. For this purpose, we append captions generated by caption models (see Section 5) along with meme text and input to the hate-text classifier that we have trained on multiple corpora (as described in Section 6.2). Table 4 illustrates the performance of *ClipCap* and *BLIP* models. Compared with hate-meme and hate-text classifiers, we find a slight improvement in

<sup>7</sup><https://www.perspectiveapi.com/>

BERT with an average F1 of .52 which is 1 point higher than BERT tested only on meme text (depicted in line 8). However, it is 3 points lower than the Uniter model. Notably, Perspective API exhibits an improvement in performance, with an average F1 increase of 0.05 compared to *Rob+Resnet* model (depicted in line 10). This outcome suggests that classifier generalization is predominantly influenced by the textual modality. This pattern further implies a potential bias towards textual elements in meme data, leading to limitations in the ability of the multimodal model to integrate image meaning for this particular task. Mann-Whitney U Test shows that the results are statistically significant with  $p < 0.05$ .

### 6.3 Impact of Captions

In this section, we illustrate the effect of incorporating the captions in the training. During the training process for each of the hateful meme classifiers, we incorporate image captions generated using a *BLIP* model into the *Rob+Resnet*. We then assess the performance of the resulting model that includes captions in comparison to its original counterpart. Our evaluation is conducted both on (i) the original test set and (ii) plus with captions. In Table 5, it is evident that when the models trained with including captions perform poorly in both in-domain and out-of-domain testing scenarios, regardless of the presence or absence of captions in the test sets. A plausible explanation for this phenomenon could be the neutralization of contextual nuances introduced by the supplementary captions in the meme’s text. However, we also see a performance increase (average  $\Delta$  F1 of 0.09) in the case of the model trained on HARMEME dataset when tested on an out-of-domain test set with concatenated captions. One potential explanation for this behavior could be attributed to the high resolution of the original images in this dataset, marked by an average bit depth of 43.90, a notable contrast to other datasets, with bit depths of 9.54 for the FB and 4.30 for the MAMI dataset (Aggarwal et al., 2023).

### 6.4 Impact of Modality

**Shapley Values Computation** To calculate modality contribution, we determine Shapley values for feature maps, which are utilized by MM models for prediction. To achieve this, we generated patches of meme images such that each text token will be generally represented in a patch. From the existing set of image patches and text tokens

		Test (Meme text)			Test (with Caption)

Table 6: F1(Macro) score of Roberta+Resnet based Hate-meme classifiers on Confounder datasets (T: Text Confounders, I: Image Confounders).

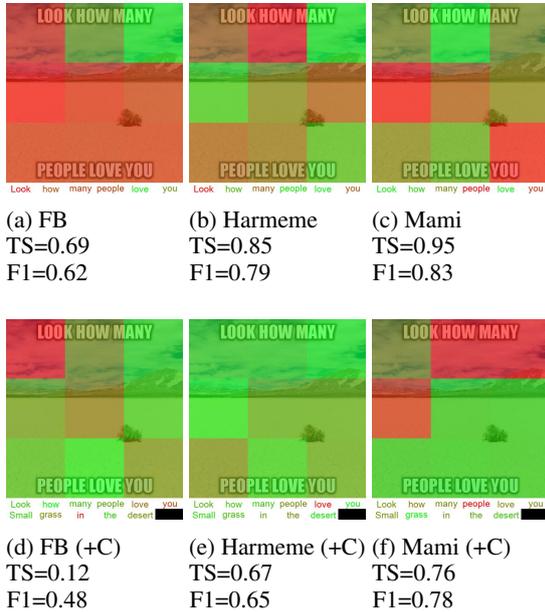

Figure 3: Example of Modality Contribution of Rob+Resnet based hate meme detection model when trained on different hateful meme datasets. Here notation (+C) refers additional caption used in model training. RED and GREEN colour illustrate low and high contribution respectively.

(entities), we selected a subset and masked the

remaining entities in the set. The determination of the number of subsets was influenced by the Monte Carlo approximation method. The Shapley value for each entity is computed by subtracting the model’s output while it is present from that while it is absent. The resulting value was normalized considering the possible combinations of subsets. Ultimately, to compute the Shapley values for text contributions, the result outcomes of textual tokens are summed and normalized. The following algorithm delineates the process of generating modality scores.

**Input:** Meme image  $I$ , Meme text  $T$ , model  $f$ , random number  $P$ , Shapley Value  $\phi$ , Text contribution score  $TS$

image patches  $I_p = \lceil \sqrt{\text{len}(T)} \rceil^2$

- 1: **for all**  $t \in t_1, \dots, (I_p + T)$  **do**
- 2:     **for all**  $i \in 1, \dots, 2 * P + 1$  **do**
- 3:         choose subset  $S \subseteq (I_p + T)$  where  $\text{len}(S) = i$  and  $t \notin S$
- 4:          $\phi(t) = \sum_{S,t} \frac{f(S+t) - f(S)}{\gamma}$  where  $\gamma$  is normalizing factor
- 5:  $\phi(T) = \sum_{n=1}^{\text{len}(T)} \phi(t_n)$
- 6:  $\phi(I) = \sum_{n=1}^{\text{len}(I_p)} \phi(t_n)$

$$\text{return } TS = \frac{\phi(T)}{\phi(T) + \phi(I_p)}$$

### Explanation of Hate Meme Detection Models

We calculate the contributions of modalities toward predictions of late fusion ensemble based *Rob+Resnet* model using Shapley values. The classifiers are trained on each of the datasets with and without captions concatenated with the meme’s text. To illustrate, Figure 3 shows Shapely values on a meme example for different models. The colours **RED** and **GREEN** indicate low and high contributions, respectively. In addition, the Text Contribution score (TS) as well as the F1 score evaluated on the in-domain evaluation set is provided in the caption of each of the subfigures. Image modality contribution (IS) can be computed using  $IS = 1 - TS$ . We find that text contribution is quite higher ( $TS \gg IS$ ) for all the models (average TS of .83). When a caption is added to the text, the contribution score of the text modality decreases to .52. With this we infer that adding captions to memes strengthens the focus on the image modality. We observed that when we include the image caption along with the meme’s text, the models establish a correlation between the caption and the meme’s image. In such cases, the models tend to focus on the image’s information related to the image caption, a behavior not exhibited when the caption is absent. It infers that the meme text inherently carries a more potent message of hatefulness, which is mitigated by the inclusion of image captions. Nevertheless, it’s important to highlight that the F1 score also decreases when captions are introduced to meme text. This might also mean that to the existing models, images in hateful memes are more like facilitators and provide context to the models. As an example, in Figure 3 we see that the dominance of image patches is much higher for models trained along with captions. Similarly, we also see less dominance of important hate context tokens such as *LOVE* (Gröndahl et al., 2018; Aggarwal and Zesch, 2022) in this case.

### 6.5 Classifiers on Confounder Dataset

In Section 4.2, we elaborate on the composition of the confounder dataset. We divide it into two subsets. The first subset is termed the text confounder set (T), wherein meme instances are categorized based on images resembling those in hateful memes. Similarly, the second subset is designated as the image confounder set (I), where meme in-

stances are categorized based on text resembling that found in hateful memes. In addition, we also concatenate the textual component of these sets with the image’s caption and names of the celebrities available in the image and called them extended sets ( $T^+$  and  $I^+$ ). In this way, we have four evaluation sets to assess hate meme classifiers.

We evaluate *Rob+Resnet* classifier which is already trained on the original hateful meme datasets and also in concatenation with captions. Table 6 illustrates the classifier’s performance in terms of F1 (macro) scores. Overall, the performance on T is notably higher than that on the I across all variants of models. However, this difference is quite small in the case of HARMEME dataset (the average  $\Delta$  F1 is 0.26, 0.23, and 0.08 for FB, MAMI and HARMEME respectively). A similar trend is observed in the case of extended sets. Overall there is  $\Delta$  F1 of 0.18 is observed which illustrates that the classifier is highly sensitive to memes undergoing changes in text while maintaining the same image, a sensitivity not observed in the other modality. Similar to the observations in Table 5, the addition of captions to the meme’s text significantly reduces performance for both the image and text confounder sets. This further adds evidence of the importance of the textual component of memes for hate detection models.

## 7 Conclusion

Commencing from the observation that multimodal hate-meme classifiers exhibit poor generalization to other datasets, we demonstrate that comparable cross-domain performance can be achieved by disregarding the image segment and concentrating solely on the text. Furthermore, we reveal that text classifiers exhibit improved performance when incorporating image content into the text classifier through image captioning. Intriguingly, the introduction of captions generated from meme images to the hate meme classifier leads to a deterioration in performance. The insights obtained from the analysis of modality-specific contributions, along with the diminishing effect of including captions, indicate that current multimodal models are primarily focused on finding alignment between image and text tokens at a concrete level. The addition of captions generated by other multimodal models misdirects attention to those low-level alignments, whereas text-image alignment in hate text classifiers typically occurs at a more abstract (metaphor-

ical) level. It is evident that the meaning of the image could be extracted and incorporated at a higher level, where current models and training regimes fall short in addressing this issue. Additionally, our evaluation on a newly established confounder dataset underscores superior performance on text confounders as opposed to image confounders. These findings strongly support the assertion that the image component of multimodal hate meme classifiers exhibits limited transferability, with the generalization capabilities primarily dependent on the text component of the meme.

## 8 Limitations

Employing a proprietary API such as Perspective API introduces challenges to reproducibility. Nonetheless, we mitigate this limitation by training our own BERT classifier, offering a comparably high-performing and fully reproducible alternative. In our approach, we consciously restrict ourselves to a single multimodal classifier, chosen for its high efficiency in general, for both the explanation phase and confounder study. However, consistency across the results enhances the viability of our analysis. There is a lack of propositions about questions such as why MAMI models are different than others not affected at all from caption inclusion, or what makes HARMEME models easier than FB’s (as shown in Table 4). In this study, our focus has been on employing existing models that have been utilized or proposed for the Hateful Meme Classification task. Nevertheless, it is also worthwhile to acknowledge the study like multimodal gate method introduced by (Arevalo et al., 2020). Such a method proposes a systematic control over the contributions of modalities through a multimodal gate mechanism. We also believe that adopting such an approach could offer insights into several aspects, including (i) potential enhancements in hate meme detection, (ii) investigating whether the challenges stem from insufficient attention to the visual modality, and (iii) understanding if, even with increased attention to the visual modality, models might still concentrate on less relevant aspects of inputs, proving counterproductive for meme comprehension. Arguably, considering the recent progress in pre-trained large language models (PLMs) with the ability to analyze multimodal data, exemplified by MiniGPT-4 (Zhu et al., 2023), they could be contemplated for inclusion in the study. Nevertheless, challenges such as

hallucination (Li et al., 2023), mainly stemming from their longer average response length, pose concerns that we believe may have implications for tasks like hate meme detection.

## 9 Ethics Statement

Predicting whether a meme is hateful or not might infringe on the fundamental right of free speech if the prediction is used by a government or service provider to remove the post or block the posting user. If viewed from this perspective, it might be good news that the technology –as we show in this paper– barely works. On the other hand, not addressing hate speech would give further rise to possible discrimination, making it a problem for equal participation in any society. In terms of carbon emission, we conducted experiments primarily on GPUs to assess their resilience and develop countermeasure models. Using a private infrastructure with a carbon efficiency of 0.432 kgCO<sub>2</sub>eq/kWh, we performed 120 hours of computation on 24 GB memory size Quadro RTX 6000 GPU. The total estimated emissions were 15.55 kgCO<sub>2</sub>eq, with no direct offset (Lacoste et al., 2019).

Here is a preview of the first page of the instructions document:

### Guidance - Meme Annotation Tool

The intention of the annotation tool is to help people analyse and classify images—specifically memes—based on their context and content.

The annotation tool's user-friendly interface enables users to give each meme different labels and scores, making it easier to see trends, moods, and potentially harmful content.

The tool's annotations can be used to perform research, train machine learning models, or learn more about the traits of memes in a dataset.

Understanding the content of memes, their relationship to text, their stance on hate, and a number of other characteristics are made easier through this method.

Each choice is significant for the analysis that follows, which aims to determine whether classifiers can actually be trained to identify problematic figures in memes with neutral context.

#### Overview of the categories and options for annotation:

##### I. **Image-Text Relation:**

This category explores the connection between the accompanying text and the image in a meme. Users can choose from the following options:

- **Neutral:** The image and text have no particular relation to each other.
- **Needs Context:** The meme requires additional context to understand the relation between the image and text.
- **Text Supports Image:** The text provides context or enhances the meaning of the image.
- **Image Supports Text:** The image provides context or enhances the meaning of the text.

##### II. **Modality Towards Hate:**

This category examines the degree to which the meme expresses hate or offensive content. Users can select from the following options:

- **None:** The meme contains no hate or offensive content.
- **Text Supports Hate:** The hate or offensive content is primarily conveyed through the text.
- **Image Supports Hate:** The hate or offensive content is primarily conveyed through the image.
- **Text & Image Supports Hate:** The hate or offensive content is conveyed through both the text and the image.

##### III. **Decision Parts:**

Users can describe the specific tokens or elements in the meme that contribute to its hateful or non-hateful nature.

This helps in identifying the key components responsible for the content's overall categorization.

##### IV. **Hatefulness Scale:**

This scale allows users to rate the level of hateful or non-hateful content in the meme on a scale

# Where are we Still Split on Tokenization?

**Rob van der Goot**  
IT University of Copenhagen  
robv@itu.dk

## Abstract

Many Natural Language Processing (NLP) tasks are labeled on the token level, for these tasks, the first step is to identify the tokens (tokenization). Because this step is often considered to be a solved problem, gold tokenization is commonly assumed. In this paper, we investigate if this task is solved with supervised tokenizers. To this end, we propose an efficient multi-task model for tokenization that performs on-par with the state-of-the-art. We use this model to reflect on the status of performance on the tokenization task by evaluating on 122 languages in 20 different scripts. We show that tokenization performance is mainly dependent on the amount and consistency of annotated data as well as difficulty of the task in the writing systems. We conclude that besides inconsistencies in the data and exceptional cases the task can be considered solved for Latin languages for in-dataset settings (>99.5 F1). However, performance is 0.75 F1 point lower on average for datasets in other scripts and performance deteriorates in cross-dataset setups.<sup>1</sup>

## 1 Introduction

Because many tasks in Natural Language Processing (NLP) are annotated on the token level, identifying the tokens is a crucial first step for NLP models. However, in most work on token-level tasks in NLP, gold tokenization is used, implicitly making the assumption that tokenization is a solved problem. Notable exceptions include the CoNLL 2018 shared task (Zeman et al., 2018) and work on languages where whitespaces are not used as word separators, and tokenization is more challenging (e.g. Tian et al., 2020; Hiraoka et al., 2020).

Traditionally, tokenization was done with rule-based systems (Marcus et al., 1993b; Dridan and Oepen, 2012), with rules usually adapted towards

<sup>1</sup>Code is available on [bitbucket.org/robvanderGoot/tok](https://bitbucket.org/robvanderGoot/tok), note that our implementation is also available as part of the MaChAmp toolkit: <https://github.com/machamp-nlp/>

English datasets (Figure 1: 2). With the introduction of machine learning, and later neural networks, tokenization was also framed as a character level labeling task (Figure 1: 3) (Xue, 2003; Evang et al., 2013; Shao et al., 2018). However, since most recent NLP models are based on Contextualized Language Models (CLM), which commonly use subwords, subword level labeling for tokenization has been proposed (Nguyen et al., 2021) (Figure 1: 4), leading to even higher performance. However, Nguyen et al. (2021) do not extend to multi-lingual models, and their training procedure is compute intensive. Hence, we propose to tackle tokenization simultaneously with other NLP tasks while finetuning the CLM. This setup has competitive performance, while being universally applicable; we train one multi-task, multi-lingual model that does tokenization, pos tagging and dependency parsing; which is desirable in terms of efficiency, dependencies, and simplicity. We then use this model to evaluate and analyze the performance in a variety of setups. We tackle the following question in this work: 1) Is the tokenization task solved in supervised setups? 2) How robust are supervised tokenizers across datasets?

## 2 The Tokenization Task

Since the increased popularity of subword tokens, the word “tokenization” is commonly used to re-

<i>Input:</i>
If_momma_ain't_happy,_nobody_ain't_happy.
<i>Tokenization:</i>
If_momma_ain't_happy,_nobody_ain't_happy_.
<i>Multi-word expansions:</i>
If_momma_is_not_happy,_nobody_is_not_happy.
<i>Subword segmentation:</i>
If_mo_##mma_ai_##n_'_t_happy_._no_##body_ai_##n_'_t_happy_.

Table 1: Examples of the scope of tasks, we use the `_` character to indicate whitespaces. The tokenization and multi-word expansion examples are from the UD, and the subword segmentation is based on mBERT, which does tokenization and subword segmentation. In UD, tokenization and multi-word expansions are annotated separately, but we do not consider multi-word expansions as part of the tokenization task.

fer to the task of subword segmentation. However, traditionally, “tokenization” referred to the task of identifying tokens in a segment of text. We follow the traditional usage, and follow the definition of token as used in the Universal Dependencies project (Zeman et al., 2022)<sup>2</sup>, which to the best of our knowledge, is the largest and most diverse manually annotated dataset for this task. Furthermore, it has downstream tasks and tokenization annotated on the same utterances, which allows for more elaborate evaluations. We consider the transformation to *multiword tokens* (e.g. splitting clitics, undoing contractions) not to be part of the tokenization task.<sup>3</sup> We remove the multiword tokens with the UD-conversion tools (Agic et al., 2016), which propagates the annotations of the sub-token closest to root to the multiword token. An overview of the different tasks and the terminology we follow is shown in Table 1.

### 3 Tokenization with Subword-level Labels

Because the subword level is central in most modern language models, we label subwords for the tokenization task (Figure 1: 4). This approach has a limitation; there is a theoretical upper bound, as there is a limitation on the possible boundaries (i.e. splits are not possible within subwords). To increase this upper bound, we first apply the BasicTokenizer from the transformers library (Wolf et al., 2020), which is a rule-based tokenizer that separates punctuation characters. This leads to an upper bound above 99% F1 score for 122 out of

<sup>2</sup><https://universaldependencies.org/u/overview/tokenization.html>

<sup>3</sup>In other words, we do not consider annotations where the word index contains a ‘-’, and we focus on the ‘tokens’ column in the evaluation script instead of ‘words’

123 treebanks of the datasets we use (Appendix D) when using the mBERT subword segmenter (Devlin et al., 2019). Only the Japanese GSD treebank has a lower score (80.4).<sup>4</sup> To increase this upperbound, we consider all Hiragana and Katakana characters as a single subword (note that BERT tokenizers already do this for CJK characters, including Kanji). It should be noted that character normalizations and unknown tokens make the conversion of the output of the CLM to the original text non trivial. More details on how we handled these specific cases can be found in Appendix A.

If we would train a separate CLM for tokenization and one for a downstream task, this would lead to very inefficient training as well as inference. Note that they can’t run in parallel, as tokenization should be done first. Hence, we propose a multi-task setup, where we share an encoder and model multiple tasks in separate decoder heads (linear layers). At train time, we use gold tokenization to obtain the loss for the other tasks, as labels for incorrect tokenizations are non-trivial to obtain. At inference time we use the predicted tokenization as input for the other tasks.

**Setup** We implemented our model in MaChAmp (van der Goot et al., 2021) v0.4.2, and have included it in the public version. We use all default parameters in MaChAmp (see Appendix B; note that we fully fine-tune the CLM in all our settings). We implemented tokenization with cross-entropy loss and a feedforward layer which transforms the output of the CLM to a binary label (B or I, see Figure 1). In the multi-task setup, we use the default implementations for UPOS tagging, lemmatization, morphological tagging and dependency parsing. We report F1 scores from the official CoNLL 2018 evaluation script (Zeman et al., 2018). We used UD v2.10 and multilingual BERT for our main evaluations. Note that we also evaluated on XLM-R Large (Conneau et al., 2020), but found that it underperforms for tokenization while being computationally more expensive (Appendix E).

We evaluate a variety of settings: **ST**: Single Task; an CLM encoder with only a tokenization head; **MT**: Multi-Task: learn tokenization simultaneously with POS tagging, lemmatization, morphological tagging and dependency parsing, **ML+MT**:

<sup>4</sup>Short Unit Word tokenization (Den et al., 2008) was used for annotation of this dataset, which mismatches with the subword segmentation in mBERT.

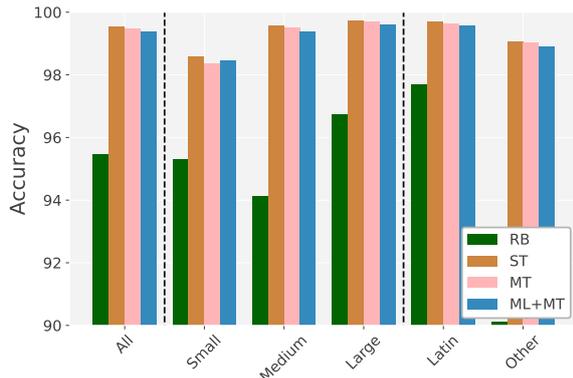

Figure 2: F1 scores for tokenization task (dev set). ST=Single Task (tokenization only), MT=Multi Task, RB=Rule-Based, ML=Multi-Lingual.

Multi-Lingual, Multi-Task: train on the training splits of all treebanks for all tasks. To better interpret our results, we compare against five rule-based (RB) tokenizers (more information in Appendix G). We use the highest performing tokenizer (through an oracle) for each dataset.

## 4 Results

In this section we only consider treebanks that contain a train-split to be able to fairly compare to single-treebank models. We report averages over all dev splits (to avoid over analyzing the test data, note that we did not tune the models), but also averages over subsets of the data; we compare datasets in the Latin script (93 datasets) and all other scripts (38 datasets),<sup>5</sup> and we inspect the effect of dataset size by separating datasets in small ( $0 < \#tokens < 20,000$ , 11 datasets), medium, ( $20,000 < \#tokens < 100,000$ , 43 datasets) and large ( $> 100,000$ , 51 datasets) train size. We focus here on tokenization and dependency parsing, results on other tasks can be found in Appendix F.

Starting with the results on tokenization (Figure 2), we can see that the differences in performance for the different settings are small for the tokenization task; but every error for this task has a catastrophic effect on downstream task performances, so even small differences can be important. The **single task setting (ST) outperforms all other models** in almost all setups. However, this setting is impractical due to computational costs. **Multi-task (MT) and Multi-lingual (ML) learning slightly harm performance, but Multi-**

<sup>5</sup>Note that most other scripts contain less than 3 treebanks, we refer to Appendix F for per treebank results and % of unknown subwords

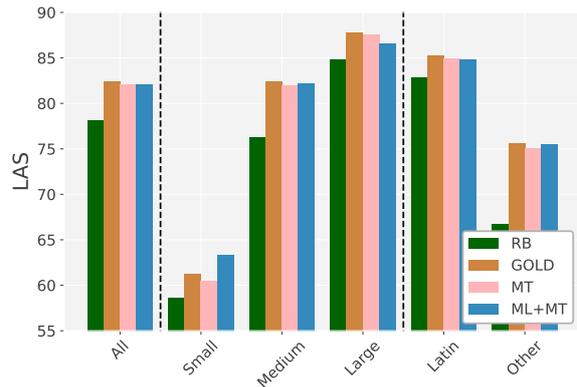

Figure 3: LAS F1 scores for dependency parsing (dev set). GOLD refers to using gold tokenization. Single Task (ST) is left out here, as it is an impractical in this setup (twice as slow, see Section 3).

**lingual (ML) models outperform mono-lingual models on small datasets.** It should be noted that treebanks in non-Latin scripts are not consistently smaller (Appendix F), and the **lower performance on non-lating datasets can thus mainly be ascribed to under-representation in the underlying language model and the complexity of the task.** To interpret our results in a larger context, we attempt to compare to rule-based baselines; which are non-trivial to find for our varied set of languages (Appendix G), but it is clear that **rule-based approaches underperform with a large margin;** averages for all treebanks are around 91-92 F1.

Interestingly, downstream results on dependency parsing (Figure 3) show different trends compared to the tokenization results; **multi-lingual training (ML) is beneficial for this task,** except for large datasets which have slightly lower performance. Furthermore, we see that **the predicted tokenization performs very close to the gold tokenization (GOLD) for parsing.**

### 4.1 Test Data

We evaluate against the best rule-based tokenizers (RB) on the dev-data for each treebank; similarly, we pick the best model of the CoNLL 2018 shared task (Zeman et al., 2018) for each treebank (UD v2.2); which are mostly Bi-LSTM character level BIO labelers. Finally, we compare to Trankit (Nguyen et al., 2021), who employ XLM-R with adapters (UD v2.5).<sup>6</sup> Results (Table 2) show that performance of our proposed model is on par

<sup>6</sup>Note that training Trankit for all tasks on UD\_English-EWT was ~10 times slower compared to our approach with default parameters on an A100 GPU.

	Train treebanks			All		
	UD2.2	UD2.5	UD2.10	UD2.2	UD2.5	UD2.10
RB	95.98	94.99	94.40	91.67	91.67	92.71
SOTA	99.53	99.32	—	—	—	—
ST	99.42	99.41	99.39	—	—	—
ML+MT	99.33	99.31	99.09	97.59	97.18	95.64

Table 2: Average tokenization F1 scores on test data. SOTA on v2.2 is the highest score of each treebank in the CoNLL 2018 shared task, and v2.5 is Trankit. RB=RuleBased.

with the state-of-the-art both for UD v2.2 and v2.5. Furthermore, we confirm small loss in performance when training a multi-task, multi-lingual model (ML+MT) compared to the single task model (ST). Performance on all treebanks is substantially lower than the treebanks with a training split (lowest on UD v2.10, because there are more low-resource treebanks).

## 5 Analysis

**Quantitative** In general, precision is higher than recall for all the proposed models (results available in repository), showing that the model mostly misses splits instead of over-tokenizing. Performance deteriorates on test-only treebanks (Table 3). As expected, performance is worst for treebanks in unseen scripts; however, F1 is still 80.11. For dependency parsing performances are much lower, this is mainly due to the amount of [UNK] tokens and the low coverage for these languages and scripts in mBERT training data.

**Qualitative Latin data** We picked the single task (ST) model for qualitative analysis to avoid any influence from the other adaptations. We selected the six lowest performing Latin treebanks. For Swedish\_Sign\_Language-SSLC (97.73), low performance is likely caused by non-standard use of capitalization and punctuation. For Estonian-EWT (97.93) inconsistency in splitting multiple periods was the main source of error, whereas in Romanian-Nonstandard (98.73), the ‘-’ character is sometimes appended to the previous and sometimes to the following token, which is challenging for the model. The Dutch\_Alpinio treebank (99.17) has a mismatch between gold tokenization of numbers in the training and dev splits.<sup>7</sup> For Italian\_PoSTWITA

<sup>7</sup>We confirmed this with the treebank creators, this is the effect of merging datasets with different pre-processing

(99.47), we found cases where usernames, hashtags, URLs were wrongly tokenized by the model, and some cases similar to the errors found in English\_EWT treebank (99.67), which are discussed in more detail in the following paragraph.

Common errors in the English EWT were due to ambiguity, for example, due to possessive markers being similar as the plural inflection; “salons  $\mapsto$  salon\_s” was not tokenized by the model (but it was in gold), but “boys  $\mapsto$  boy\_s” was. Other cases were difficult because of absence of any punctuation or white space clues: “so goand get dancing”, “is there anyway”, “andthere”. In some cases, the model did not separate punctuation; “18+  $\mapsto$  18\_+” “<>”  $\mapsto$  “<\_>”. Finally, there were also cases where the gold tokenization was inconsistent: “f/2  $\mapsto$  f/2”, but “f/2.7 $\mapsto$ f/\_2.7”.

**Qualitative Non-Latin data** We manually inspected all treebanks with a performance <99 F1 score (11 total). For the treebanks that were included in previous work, performance of our model is highly competitive, indicating that these are generally challenging datasets. For four of the treebanks, the main issue where unknown subwords, due to special characters (Old East Slavic \*2, Uyghur) or emojis (Russian); where the latter also had errors with Twitter usernames. We confirm this trend by checking the Pearson correlation between the % of unknown tokens and the performance for tokenization (F1) as well as the correlation between the % of unknown tokens and dependency parsing performance (LAS) on our full data (the % of unknown tokens for each treebank can be found in Table 15 in Appendix I). The correlations are -0.19, and -0.64, indicating that a higher percentage of unknown tokens indeed leads to worse tokenization (although dependency parsing is affected worse).

Vietnamese-VTB is a notoriously difficult treebank to tokenize in UD, due to tokens including whitespaces. For the Japanese and Chinese treebanks (five total); the problem of tokenization is harder, as there are no whitespaces and token segmentation can be a more ambiguous (i.e. subjective) task. For these languages,<sup>8</sup> we identified three main trends: 1) Adpositions: the model oversplits on adpositions, which are considered to be part of the word in the gold annotation. On the other hand, politeness markers for Japanese are usually attached to the word by the model (which is not con-

<sup>8</sup>We consulted native speakers for a qualitative inspection

setting	F1 tok.	F1 LAS	# treebanks
all	93.23	38.72	90
in-language	95.11	68.20	34
in-script	94.16	40.45	84
new-script	80.11	14.41	6

Table 3: Results on test-only treebanks, separated into treebanks with an in-language training treebank, an in-script training treebank, and neither (new-script).

sistently the case in the treebanks) 2) Names: the model usually oversplits, For example for Japanese, the model splits “クモハ123-1” which is a train type, into: “クモ\_ハ\_123\_-\_1”, because “クモ” can be read as the phoneticized “cloud” or “spider”. . In general, for both Chinese and Japanese, names are often split into lexical tokens. 3) Compound words: for example ‘homerun’ (ホームラン) and ‘copy protection’ (コピープロテック) are not split by the model, but are split in the treebanks. Whereas for ‘Kyoto-style’ (京風) it is the other way around.

**Rule-based baselines** The performance of the rule-based baselines is substantially worse. Upon inspection, we found this is mainly due to 1) a different understanding of the tokenization task; rule based tokenizers consistently have different preferences (for example won’t -> wo n’t or ->won’t) 2) scripts that were not considered while developing the tokenizers

**Annotation consistency** Our findings of the qualitative analyses indicate that annotation consistency is the main source of remaining errors for in-dataset settings, especially for Latin datasets. This is underlined by the the scores on test-only treebanks with in-language training data available; where F1 is only 95.11 (Table 3). It should be noted that another possible explanation is domain transfer, but our manual inspection suggested that annotation consistencies are the main source.

**Attention** To investigate where in the model the tokenization task is best represented, we analyze in which layer the tokenization task is best learned for the MT+SPL models. Instead of using a probing method (e.g. Tenney et al., 2019), we choose to use layer attention, (as implemented by Kondratyuk and Straka (2019), with the hope of improving performance further<sup>9</sup>, saving computation costs, and

<sup>9</sup>Performance went down a little instead (Appendix F).

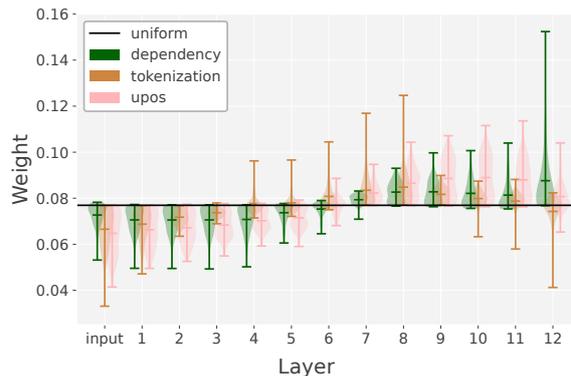

Figure 4: Violin plots of the attention at each layer for tokenization, UPOS tagging and dependency parsing for the MT+SPL models. Layer ‘input’ represent the (uncontextualized) word embeddings. Uniform weight (== no layer attention) would be  $1/13 \approx 0.077$ .

finding the importance of each layer as assigned by the model itself. Results (Figure 4) show that tokenization is better presented in the middle layers (4-8). This suggests that context is necessary to perform this task (the input layer has a very low weight).

## 6 Conclusion

We have investigated which problems are still open for the task of tokenization. We conclude that tokenization in supervised setups for Latin languages can be considered solved, with some dataset inconsistencies as remaining errors. But for lower-resource languages and especially languages without whitespaces for word boundaries challenges remain. Furthermore, we showed that performance in cross-dataset setups deteriorates, even when training on the target language. This highlights the need for clear annotation guidelines, and confirms the presence of annotation inconsistencies.

Furthermore, we have implemented a new tokenization model that is faster to train than previous work. We include handling of unknown tokens and character normalizations as well as missed word boundaries. Furthermore, multi-task learning as well as multi-lingual learning slightly harm performance, but allow for a single model for multiple tasks and languages.

## 7 Acknowledgements

I would like to thank my colleagues at NLP North and MaiNLP and most of the anonymous reviewers for their feedback on earlier versions of this paper. I acknowledge the IT University of Copenhagen

HPC resources made available for conducting the research reported in this paper. Furthermore, special thanks go to Yiping Duan and Max Müller-Eberstein for the qualitative analysis of Chinese and Japanese.

## 8 Limitations

In our experiments, we have mainly focused on mBERT, we also evaluated on XLM-R Large (Appendix E), but for tokenization mBERT performs highly competitive while being computationally cheaper. We did test our implementation with other language models as well, but due to computational limitations we have not done the full evaluations. Furthermore, we were limited to evaluate on languages for which annotated data is available (including 20 of the 165 scripts defined in Unicode). It should be noted that we have limited ourselves to the definition of UD for the tokenization task.

We also only focused on syntactic downstream tasks, as annotation was readily available, although we do believe that the main gains from correct tokenization do not come from the shared parameters, but from having the correct word-boundaries. It should be noted that some of the datasets are created using automatic tokenization, and parts of the data can thus be considered silver (this is unfortunately not documented per treebank, as for other tasks in UD). Other datasets are trivial to tokenize, for example sign language (which includes transcriptions of signs) and treebanks on transcribed spoken data (without punctuation). However, even in these setups, it is important to have a tokenizer that mimics the treebank standard and that is consistent, and the original tokenizer that was used to create the data is often unknown or not available anymore. We did not perform significance testing, because to do this properly, multiple runs would have to be done (Dror et al., 2019), which is computationally expensive. Furthermore, multiple runs from previous work are not available, and due the size of the datasets used, even small differences will usually lead to significant differences.

Recently, character and byte level language models have been proposed (e.g. Xue et al., 2022; Clark et al., 2022), which do not have the theoretical upper-bound discussed in Section 3. However, their performance on syntactic word-level tasks was empirically not on par with the subword-based models (see Appendix C). Further improvements on downstream tasks might be obtained by using predicted

tokenization during training. However, the current evaluation metrics do not take incorrectly tokenized tokens into account for the downstream tasks, and it is non-trivial to obtain a loss for downstream tasks on a non-perfect tokenization.

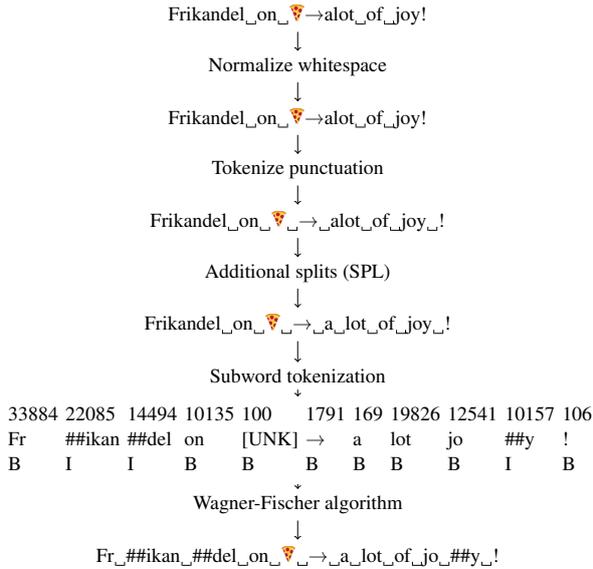

Figure 5: Detailed overview of the steps of proposed tokenization model.

## A Detailed Overview of Model

The steps of our proposed tokenization procedure is shown in Figure 5. We start with whitespace normalization, converting all whitespace characters (tabs, no-break space etc.) to normal whitespaces, so that they are treated equally in the subword segmentation (There are no changes in our example, most input does not contain non-standard whitespaces). The next step is a basic tokenization based on punctuation, we use the `BasicTokenizer` from `huggingface` for this step (with `strip_accents=False`, `do_lower_case=False`, `tokenize_chinese_chars=True`). Next, we perform additional splits learned from the training data. This is done to overcome the upperbound because of the limitation that we can only split on subword boundaries (e.g. if ‘alot’ is split into ‘al’ and ‘ot’ by the subword tokenizer, there is no correct tokenization possible). We automatically extract all missed word-boundaries within words (e.g. `alot`  $\mapsto$  `a lot`) from the *training* data. These additional splits lead to higher upper bounds on the development data for some datasets (Appendix D), but eventually harmed performance in more cases, so they are not included in the results reported in the paper. In the appendix we use **SPL** to indicate runs that use these additional splits. Then, we use the slow subword tokenizer from `Huggingface`, and set `do_basic_tokenize` to false.

We require one last step, because most language models do some (Unicode) normalization on the

Parameter	Value
Optimizer	Adam
$\beta_1, \beta_2$	0.9, 0.99
Dropout	0.2
Epochs	20
Batch size	32
Learning rate (LR)	1e-4
LR scheduler	slanted triangular
Weight decay	0.01
Decay factor	0.38
Cut fraction	0.3

Table 4: Hyperparameter settings (taken from MaChAmp v0.4beta).

data and include special unknown tokens to represent (sequences of) characters that were unseen during the training of the tokenizer. These break the evaluation of tokenization, as no alignment between the gold tokenization and the prediction can be found. To solve this, we align the subwords to the original input automatically. This mapping is non-trivial, and we empirically found that character edit rules are a robust solution for this. We use the `Wagner-Fischer` (Wagner and Fischer, 1974) algorithm as implemented by (Straka, 2018). We calculate the character edit transformation from the segmented subwords to the original text (after removing whitespaces for both), and insert or substitute characters that differ.

## B Hyperparameters

Hyperparameters we used for all experiments are reported in Table 4, and match the default settings of MaChAmp 0.4 (van der Goot et al., 2021). Note that no early stopping is used, because the learning rate scheduler lowers the learning rate dynamically; so even if performance does not improve in the current epoch, it might still improve in future epochs.

## C Results Character-level Models

We experimented with character/byte level models in a similar setup for a selected set of treebanks. We picked treebanks that are challenging (Chinese/Japanese treebanks), even when trained in-dataset, as well as a common benchmark (English-EWT). Results are shown in Table 5 for the tokenization task, and Table 6 for downstream performance on dependency parsing. Results show that mBERT substantially outperforms both other

Treebank	mBERT	byt5-base	Canine-C
UD_Chinese-GSD	99.09	88.49	93.98
UD_Chinese-GSDSimp	99.10	88.53	94.07
UD_Classical_Chinese-Kyoto	98.16	98.71	-
UD_English-EWT	99.81	99.59	98.25
UD_Japanese-GSDLUW	99.36	93.00	98.78
UD_Japanese-GSD	99.30	91.33	97.92

Table 5: Tokenization F1 scores for character level models versus mBERT

Treebank	mBERT	byt5-base	Canine-C
UD_Chinese-GSD	84.95	80.28	59.90
UD_Chinese-GSDSimp	84.94	81.20	59.67
UD_Classical_Chinese-Kyoto	78.70	77.68	56.32
UD_English-EWT	90.04	89.30	79.10
UD_Japanese-GSDLUW	94.71	93.97	90.16
UD_Japanese-GSD	94.48	93.83	89.66

Table 6: LAS scores for character level models and mBERT

models, but Canine-C seems to be better at tokenization and byt5-base at parsing. To avoid waste of compute, we decided to not train byt5-base and Canine-C on the rest of the data.

## D Upper Bound

Table 7 shows the theoretical upper bound of performance of the tokenization task for each treebank in UD 2.10. The table shows the upper bound on the training and the dev data, and also shows the performance after extracting the splits for impossible cases from the training data (for example “alot  $\mapsto$  al ##ot” make it impossible to get “a lot”, see also Section 3 and Appendix A).

## E Comparison mBERT to XLM-R Large

In Table 8 we compare the scores for all 5 tasks for all treebanks with a training split in UD v2.10. Results show that XLM-R large (Conneau et al., 2020) is substantially better than mBERT for most tasks; however, for tokenization it only outperforms mBERT in the single task setting.

## F Full Scores Tokenization

Per treebank results on UD v2.10 dev splits for all our proposed models are shown in Table 9.

## G Scores Rule-based Baselines

We used the BasicTokenizer from the Transformers library (Wolf et al., 2020), without normalization. The other rule-based tokenizers are all taken from NLTK (Bird et al., 2009). Destructive is an extended version of the TreebankTokenizer, which

in turn is a python version of the tokenizer .sed script originally used for the Penn Treebank (Marcus et al., 1993a). The TweetTokenizer is a tokenizer focused on data from Twitter, and Toktok is a fast simple tokenizer based on regular expressions. We automatically checked the output for changed characters and reverted these using the strategy described in Appendix A. Results (Table 10) show that although for some treebanks performance around 99-100 F1 can be achieved, average performance is around 91-92%, which is substantially lower compared to the supervised results in Table 9. There are some outliers dragging the average down,<sup>10</sup> but also many treebanks with scores in the mid- and low 90’s. Interestingly, for some treebanks 100% was achieved only by the rule-based models;<sup>11</sup> these are treebanks for which the gold tokenization is most likely automatically created.

## H Scores on Other Tasks

We include performance on the other UD tasks included in our multi-task model. Dependency parsing in Table 11, UPOS tagging in Table 12, Morphological tags in 13, Lemmatization in 14. All reported scores are obtained with the official conll 2018 script.

## I Full Scores on Test data

In Table 15 we report the performance of ST and MT-ML on the test splits of UD v2.2, v2.5 and v2.10 per treebank.

<sup>10</sup>Chinese, Japanese, Maltese, Old east Slavic (Birchbark) Swedish Sign Language, and Vietnamese treebanks.

<sup>11</sup>Ancient Greek (\*2), Czech-CAC, Latin-PROIEL, Old Church Slavonic, and Tamil treebanks

## Abstract

Large language models excel in text generation and generalization, however they face challenges in text editing tasks, especially in correcting spelling errors and mistyping. In this paper, we present a methodology for generative spelling correction (SC), tested on English and Russian languages and potentially can be extended to any language with minor changes. Our research mainly focuses on exploring natural spelling errors and mistyping in texts and studying how those errors can be emulated in correct sentences to enrich generative models' pre-train procedure effectively. We investigate the effects of emulations in various text domains and examine two spelling corruption techniques: 1) first one mimics human behavior when making a mistake through leveraging statistics of errors from a particular dataset, and 2) second adds the most common spelling errors, keyboard miss clicks, and some heuristics within the texts. We conducted experiments employing various corruption strategies, models' architectures, and sizes in the pre-training and fine-tuning stages and evaluated the models using single-domain and multi-domain test sets. As a practical outcome of our work, we introduce SAGE<sup>1</sup> (Spell checking via Augmentation and Generative distribution Emulation).

## 1 Introduction

Recent advancements in large language models (LLMs) have shown impressive text generation and language understanding capabilities, evident in benchmarks like SuperGLUE (Wang et al., 2019), GEM (Gehrmann et al., 2021), BigBench (Srivastava et al., 2023) etc. However, these models often encounter challenges when it comes to effectively addressing text editing tasks, particularly automatic correction of misspellings and mistyping. The automatic spelling correction (SC) task is well known, with traditional approaches using rules, dictionaries, or statistical models for spelling error detection

and correction. However, the emergence of LLMs and generative techniques has introduced new possibilities and improved the effectiveness of SC.

Thus, this paper addresses the task of automatic generative SC across various domains and proposes the methodology tested on English and Russian languages, which could potentially be extended to any language with minor changes. Our research primarily studies natural orthographic errors, text misspellings, and their emulation during model pre-training. We explore the impact of these emulations on the model's abilities across different domains and model types.

We leverage two different spelling corruption techniques. The first technique applies the statistical analysis of common errors, aiming to mimic natural human behavior when making mistakes. The second technique introduces the most frequent spelling errors, keyboard miss clicks, and a set of heuristics within the texts.

We conduct experiments in both Russian and English languages, employing different corruption strategies and model sizes during pre-training and fine-tuning. As a practical outcome of our work, we introduce SAGE (Spellchecking via Augmentation and Generative distribution Emulation) — a comprehensive library for automatic generative SC. SAGE incorporates various generative models trained with our proposed methodology and includes built-in augmentation techniques. Moreover, we release the data hub within the SAGE project, a valuable Russian language resource consisting of novel open source datasets for spelling.

## 2 Related work

Spell checking is a fundamental task in natural language processing (NLP) that aims to correct errors and misspellings in text automatically. Multiple approaches, namely rule-based, statistical, and generative SC methods, have been proposed to tackle this task.

<sup>1</sup><https://github.com/ai-forever/sage>

Rule-based spell checking is one of the most common approaches that rely on predefined rules and dictionaries for detecting and rectifying misspelled words. These resources can incorporate algorithmic error models such as Longest Common Subsequence (Taghva and Stofsky, 2001), Levenshtein Distance (Van Delden et al., 2004), or Phonetic Algorithms (Kondrak and Sherif, 2006).

Statistical spell checking approaches employ machine learning algorithms to learn from extensive text corpora. These algorithms can identify common spelling errors and their corresponding corrections. Some examples of statistical approaches include n-gram models (Ahmed et al., 2009), Hidden Markov Models (Stüker et al., 2011), part-of-speech tagging (Vilares et al., 2016) and Noisy Channel Model (Kernighan et al., 1990).

Generative SC is a promising spell checking approach that has shown remarkable results in recent years. Such systems take into account the context, due to the architecture nature of LLMs such as seq2seq Long Short-Term Memory (LSTM) (Evershed and Fitch, 2014), seq2seq Bidirectional LSTM (Zhou et al., 2019), and state-of-the-art transformer models like BERT (Sun and Jiang, 2019), BSpell (Rahman et al., 2022), etc.

The paper (Guo et al., 2019) presents multilingual translation models for paraphrase generation task. M2M100 models (Fan et al., 2020) (Many-to-Many multilingual models) effectively translate source language text into a target language that aligns with the source language. Given the M2M100 models’ comprehensive understanding of multiple languages, their utilization in spell checking tasks proves promising. In our research, among other investigations, we explore the suitability of the M2M approach for SC.

**Datasets** English spell checking research has received significant attention due to widespread English use, which results in the creation of spell checking datasets. Evaluation datasets such as BEA-2019 shared task (Bryant et al., 2019), comprising corpora like FCE (Yannakoudakis et al., 2011), W&I+LOCNESS, Lang-8 (Tajiri et al., 2012), and NUCLE (Dahlmeier et al., 2013), provide valuable resources for assessing spell checking and error correction tasks. NeuSpell (Jayanthi et al., 2020) introduced the BEA60K natural test set and the well-established JFLEG dataset (Napoletano et al., 2017), containing only spelling mistakes. Other clean corpora, including the Leipzig Corpora Col-

lection (Biemann et al., 2007) and the Gutenberg corpus (Gerlach and Font-Clos, 2020), offer diverse sources such as news, web content, and books for further exploration in spell checking research.

Among the standard open source datasets for the Russian language is RUSpellRU<sup>2</sup>, which emerged after the competition on automatic SC for Russian social media texts (Sorokin et al., 2016). Other open sources include the GitHub Typo Corpus (Hagiwara and Mita, 2019), which contains the Russian section, and the recent work (Martynov et al., 2023), which introduces a multi-domain dataset.

**Text corruption methods** For training generative SC models, building a parallel corpus is essential. There are several ways to emulate spelling errors or augment the existing datasets. The example is the GEM benchmark and its associated augmentation library NL-Augmenter (Dhole et al., 2023) and the work (Kuznetsov and Urdiales, 2021) with the method for creating artificial typos. For the Russian language, the RuTransform framework (Taktasheva et al., 2022) presents adding noise into data through spelling corruption and (Martynov et al., 2023) proposes augmentation methods.

### 3 Methodology

In this work, we aim to design models that meet the end users’ demands. The broad application areas of SC tools, encompassing various orthographies and styles, pose additional challenges for text editing systems. We decided to enhance the conventional approach of treating standard language as the only correct spelling option.

#### 3.1 Task Formalization

Before defining the SC task, we must establish the *correct spelling* notion we employ in this work. Instead of rigorously normalizing all supposedly erroneous lexemes to the standard language, we propose distinguishing unintentional spelling violations from intentional ones. Plain language, colloquialisms, dialectisms, and abbreviations are examples of the latter. They can express emotions and endow a text with distinct stylistic features. Since the act of intentional violation of spelling can hardly be expressed in terms of strict rules, it seems nearly impossible to distinguish intentional errors automatically. Instead, following (Martynov

<sup>2</sup>[https://www.dialog-21.ru/evaluation/2016/spelling\\_correction/](https://www.dialog-21.ru/evaluation/2016/spelling_correction/)

et al., 2023), we use manual labeling and consider a sentence annotated and amended by native experts as correct. Given a correct sentence, any sentence obtained from the correct one by (probably) multiple insertions, deletions, substitutions, or transpositions of characters is considered erroneous. This leads to the following definition of SC task that we use in this paper:

Let  $X = [x_1, \dots, x_N] = X_{corr.} \cup X_{incorr.}$ , where  $x_1, \dots, x_N$  is an ordered sequence of lexemes,  $X_{corr.} = \{x_i\}_{i=1}^k$  is a set of correct lexemes,  $X_{incorr.} = \{x_j\}_{j=1}^p$  is a set of incorrect lexemes,  $p + k = N, p \geq 0, k > 0$ , be the sentence that may contain spelling errors. The system  $M$  then should produce corresponding sequence (ordered)  $Y = [y_1, \dots, y_M] = Y_{corr.} \cup Y_{incorr.}, Y_{incorr.} = \emptyset$  so that

1. Correct lexemes are not modified:  
 $\exists f : \{x_i\}_{i=1}^k \rightarrow Y, f$ -injective and preserves order and  $f(x_i) = x_i$ ;
2. Original style of a sentence  $X$  is preserved;
3. All the information is fully transferred from  $X$  to  $Y$  and no new information appears in  $Y$ ;

Basically, system  $M$  only corrects unintentional errors and carries stylistic and factological pallet the same from  $X$  to  $Y$ .

## 3.2 Overview

In this paper, we propose a methodology for generative SC, exploring the natural spelling errors across multiple domains and assessing their influence on spell checking quality during pre-training and fine-tuning stages. The method can be summarized as follows:

**Corruption step:** the paper explores the text corruption techniques using two augmentation algorithms described in Section 3.3.

**Generation step:** we pre-train the generative models of different sizes and on the extensive synthetic dataset of diverse domains. The error distribution of the synthetic pre-train data is created by emulating the natural distribution of the errors via a statistic-based approach.

**Fine-tune step:** during the fine-tuning, we investigate the influence of corruption and domains

on the final results. The models are evaluated on fixed single-domain and multiple-domain test sets. The experiments involve training the pre-trained models on various training data from single and multiple domains, as well as using the same data corrupted with the two aforementioned augmentation techniques.

The methodology is explored and tested in the Russian and English languages but can be potentially transferred to any language.

## 3.3 Augmentations Strategies

### 3.3.1 Heuristic-based spelling corruption

The first strategy represents spelling corruption through exploiting various heuristics, common error statistics, and understanding of implicit mechanics of a language. Nlpaug (Ma, 2019) and NeuSpell (Jayanthi et al., 2020) libraries for English and Augmentex (Martynov et al., 2023) for Russian are notable examples of such strategy. In this work, we choose Augmentex for experiments with Russian LLMs. This library is accompanied with proven effectiveness for the Russian language (Martynov et al., 2023) and provides a flexible interface to its interior methods. Each method is responsible for modeling a specific type of error, including inserting random characters, replacing correctly spelled words with their incorrect counterparts, inserting nearby keyboard characters, and replacing a character with another based on the probability of its erroneous use. Augmentex allows researchers to control the distribution of error noise on word and sentence levels as well. In our experiments, we investigate Augmentex in depth by augmenting fine-tune datasets and studying its impact on models' performance. See details of its configurations used at the augmentation stage in A.3.

### 3.3.2 Statistic-based spelling corruption

We choose statistic-based spelling corruption (SBSC) from (Martynov et al., 2023) as an attempt to reproduce errors from a particular piece of text. The method mimics human behavior when committing an error by scanning distributions of errors in a given text and then reapplying them on correct sentences. The algorithm requires a parallel corpus of sentence pairs (corrupted\_sentence, correct\_sentence): it builds a Levenshtein matrix between prefixes of sentences in each pair, then it traverses this matrix back along the main diagonal starting from the bottom right entry. At each step,

the algorithm detects the position of an error in a sentence and its corresponding type based on surrounding entries. Our work employs statistic-based spelling corruption to prepare pre-training datasets for both English and Russian generative models. The experiments’ results discussed in Section 5.2 suggest SBSC’s ability to be transferred to another language other than Russian. We also investigate the capacity of this noising strategy by experimenting with augmentation through spelling corruption while fine-tuning.

### 3.4 Datasets

For multi-domain spell checking experiments, we developed three distinct data suites.

**Golden Test Sets:** Fixed datasets, including both single-domain and multiple-domain texts, used for evaluation purposes.

**Pre-trained Data:** Synthetic data generated to emulate natural and random noise misspellings, employed during the pre-training stage to assess their impact on model performance.

**Training Data for fine-tuning:** Collected using the same method as the test sets, also corrupted with the proposed augmentation strategies to introduce diverse errors. Used during the fine-tuning stage to explore the impact of the different noises on the model performance across domains.

#### 3.4.1 Golden Test Sets

The datasets for the golden test set are chosen in accordance with the specified criteria. First, *domain variation*: half of the datasets are chosen from different domains to ensure diversity, while the remaining half are from a single domain. This is done separately for English and Russian languages. Another criterion is *spelling orthographic mistakes*: the datasets exclusively comprised mistyping, omitting grammatical or more complex errors of non-native speakers. This focus on spelling errors aligns with the formalization of the task as described in section 3.1.

For the Russian language, we choose four different sets:

**RUSpellRU** – the single-domain open source dataset for social media texts presented in the Shared Task (Sorokin et al., 2016).

**MultidomainGold** – the dataset first presented in the paper (Martynov et al., 2023). It’s a multi-domain corpus comprising the domains: internet domain presented by the Aranea web-corpus, literature, news, social media, and strategic docu-

ments. We followed the methodological criteria of the paper and reproduced the two-stage annotation project via a crowd-sourcing platform Toloka<sup>3</sup>: at the first stage, annotators are asked to correct the mistakes, on the second – to validate the results from the previous step. The statistics and details of the instructions and annotation schema are presented in Appendix A.1 and A.2. Following the annotation methodology, we extend the authors’ dataset with two more domains: reviews (the part of the Omnia set (Pisarevskaya and Shavrina, 2022)) and subtitles (the part of the Russian part of the OpenSubtitles set<sup>4</sup>).

**GitHubTypoCorpusRu** – we take the Russian part of the corpora introduced in work (Hagiwara and Mita, 2019). Additionally, we validate the parallel data of this corpus by the same Toloka project, but only the second step from the methodology.

**MedSpellChecker**<sup>5</sup> (Pogrebnoi et al., 2023) is a single-domain set of a specific lexicon of the medical domain; the multi-domain set above does not cover that. The set contains the medical texts of anamnesis. The data was verified via a two-stage annotation pipeline as well.

For the English language, we used two sets: **BEA60K** is a multi-domain dataset corpus for spelling mistakes in English.

**JHU FLuency-Extended GUG Corpus (JF-LEG)** is a single domain set, the spelling part. The dataset contains 2K spelling mistakes (6.1% of all tokens) in 1601 sentences.

The test datasets statistics are presented in the Table 5 of the Appendix, the annotation details in Appendix A.2.

#### 3.4.2 Pre-training Data

To prepare pre-training datasets, we take correct samples and then corrupt them employing augmentation strategies described in 3.3. As for correct samples for experiments in Russian, we use twelve gigabytes (12GB) of raw Russian Wikipedia dumps and an open source dataset of transcribed videos in Russian<sup>6</sup> of three and a half million (3.5M) texts. We remove all the sentences with characters other than Russian and English alphabets, digits, and punctuation or under forty characters. We balance

<sup>3</sup><https://toloka.ai/tolokers>

<sup>4</sup><https://opus.nlpl.eu/OpenSubtitles-v2016.php>

<sup>5</sup><https://github.com/DmitryPogrebnoy/MedSpellChecker/tree/main>

<sup>6</sup>[https://huggingface.co/datasets/UrukHan/t5-russian-spell\\_I](https://huggingface.co/datasets/UrukHan/t5-russian-spell_I)

both datasets to roughly 3.3 million sentences, resulting in a pre-training corpus of 6.611.990 texts. Then statistic-based spelling corruption is applied. We scan statistics from the train split of RUSpellRU, multiply the number of errors per sentence distribution by ten to ensure we induce a much denser noise in the pre-training corpus than it is in fine-tuning datasets, and apply to the pre-training corpus to get corrupted sentences. As a result, the pre-training dataset is a collection of 6.611.990 text pairs, each consisting of corrupted sentences and corresponding correct sentences.

For pre-training in the English language, we combine clean Leipzig Corpora Collection<sup>7</sup> (News domain) and English Wikipedia dumps, preprocess them the way we applied for Russian and create a parallel corpus using a statistic-based augmentation technique based on a 5k subset of BEA60K. We result in six gigabytes (6GB) of data for pre-training.

### 3.4.3 Training Data for fine-tuning

As for the datasets for fine-tuning, we use train splits of RUSpellRU and MultidomainGold and a combination of both (details in Table 6 of Appendix). We also employ spelling corruption methods from 3.3 for augmentation purposes in two separate ways. First, we introduce misspellings in erroneous parts of train splits of fine-tuned datasets, inducing more errors without expanding the dataset itself. In the second strategy, we expand train splits of fine-tuned datasets. We obtain correct sentences from a particular dataset, corrupt spelling, and append pairs of corrupted sentences and corresponding correct sentences to the same dataset. In Tables 4 and 10 of Appendix, the first strategy is marked as *Add* and the second as *Concat*.

We do not prepare fine-tuned datasets for the English language since we do not conduct fine-tuning in our experiments.

## 4 Experiments

We conducted a comprehensive series of experiments involving diverse spelling corruption strategies over the encoder-decoder generative models of different sizes throughout the pre-training and fine-tuning phases as well as zero-shot evaluation of the pre-trained models. The models' statistics are presented in Table 8. We compared performance based on single-domain and multi-domain test sets. Fur-

<sup>7</sup><https://corpora.uni-leipzig.de>

thermore, we conducted a comparative evaluation of the OpenAI models utilizing different prompts and standard open source models.

### 4.1 Models

The generative models of different sizes used as pre-trained models in the experiments are the following for the Russian language:

**M2M100<sub>1.2B</sub>**<sup>8</sup> (Fan et al., 2020) M2M100 is a multilingual encoder-decoder (seq-to-seq) model primarily intended for translation tasks proposed by the Meta team. The model contains 1.2B parameters.

**M2M100<sub>418M</sub>**<sup>9</sup> is a 418M parameters model of the M2M100 models family.

**Fred-T5**<sup>10</sup> (Full-scale Russian Enhanced Denoisers T5) (Zmitrovich et al., 2023) is a Russian 820M parameters generative model. The model is trained on a mixture of 7 denoisers like UL2 on extensive Russian language corpus (300GB). The model is inspired by the ideas from the work (Tay et al., 2022) and one of the top<sup>11</sup> generative models according to the RussianSuperGLUE benchmark (Shavrina et al., 2020).

In the case of the English language, the utilization of only one pre-trained model was decided due to the considerable environmental impact caused by the training process (see section 6 *Energy Efficiency and Usage* for details).

**T5<sub>large</sub>**<sup>12</sup> is the English encoder-decoder 770M parameters model introduced by Google's AI research team (Raffel et al., 2020).

### 4.2 Russian experiments

For each of the three models M2M100<sub>418M</sub>, M2M100<sub>1.2B</sub>, FredT5<sub>large</sub>, the performance on the SC task was compared with and without pre-training, and using different training data for fine-tuning.

**Pre-training.** We use the same data and pre-training scheme for each model. We train our models in sequence-to-sequence manner with corrupted sentence as an input and correct sentence as label with a standard Cross Entropy loss.

We pre-train FredT5<sub>large</sub> model with a total *batch size* of 64, *AdamW optimizer* (Loshchilov and Hut-

Table 3: The results of the models on different golden tests. We report the comparative results of our best model, which is pre-trained  $M2M100_{1.2B}$  fine-tuned on RUSpellRU and MultidomainGold, OpenAI models and the open source standard solutions for the Russian language. Metrics are reported in format **Precision**, **Recall**, **F1**-measure from (Sorokin et al., 2016).

ter, 2017) with an initial *learning rate* of  $3e-04$  and *linear decay* with no warm-up steps and *weight decay* 0.001 applied to all the parameters but those in LayerNorm (Ba et al., 2016) and biases, and two steps to accumulate gradients for 5 *epochs*. The pre-train procedure took 180 hours on eight Nvidia A100 GPUs.

Both  $M2M100_{418M}$  and  $M2M100_{1.2B}$  were pre-trained with a total *batch size* of 64, *AdamW optimizer* (Loshchilov and Hutter, 2017) with an initial *learning rate* of  $5e-05$ , *weight decay* of 0.001 applied to all the parameters but those in LayerNorm (Ba et al., 2016) and biases, and *linear decay* for learning rate without warm-up steps. We also used 8 and 2 *gradient accumulation steps* for  $M2M100_{418M}$  and  $M2M100_{1.2B}$  accordingly.  $M2M100_{418M}$  pre-training procedure took five *epochs* and 332 hours on two Nvidia A100 GPUs, and the corresponding procedure for  $M2M100_{1.2B}$  lasted for seven *epochs* and 504 hours on eight Nvidia A100 GPUs.

**Fine-tuning.** We fine-tune pre-trained and non-pre-trained models using one of three sets: *RUSpellRU*, *MultidomainGold(MDG)*, and *RUSpellRU + MDG*. We also use the augmentation strategies for the training data presented in section 3.3 and obtain additional training data to fine-tune the pre-trained models (see section 3.4 Training Data for fine-tuning for details).

We fine-tune models and take the best-performing checkpoint according to the metrics on the corresponding development set. The models’ metrics on the development set are presented in the Appendix A.4. We also used the development set to

select the optimal hyperparameter values. We use *AdamW optimizer* (Loshchilov and Hutter, 2017) with  $\beta_1 = 0.9$ ,  $\beta_2 = 0.99$  and  $\epsilon = 1e-8$  and a linear learning rate scheduler to fine-tune models. All hyperparameters for fine-tuning models are contained in Appendix A.7.

**Model comparison.** We compare the performance of fine-tuned models with pre-trained models in a zero-shot setting, Yandex.Speller<sup>13</sup>, JamSpell<sup>14</sup>, Hunspell<sup>15</sup>, and OpenAI<sup>16</sup> models via API (namely, *gpt-3.5-turbo-0301*, *gpt4-0314*, *text-davinci-003*) with different prompts (see Appendix A.6 for the details) using single-domain and multi-domain test sets (see section 3.4 Golden Test Sets for the details).

### 4.3 English experiments

We pre-train  $T5_{large}$  model as described in 3.4.2 with the following hyperparameters: *batch size* 64, *learning rate*  $3e-04$  with *linear decay* and no warm-up steps, *weight decay* 0.001 applied analogously as in experiments with the Russian language, 2 *gradient accumulation steps*, 5 *epochs*. Pre-training is done in mixed-precision with data type `bfloat16`<sup>17</sup>. The procedure took 360 hours on eight Nvidia A100 GPUs.

We compare the performance of several models on two datasets: BEA60k and JFLEG. The models are as follows: eight NeuSpell models:

Table 4: Pre-trained models’ performance on test datasets for the Russian language after fine-tuning on augmented datasets. *Augmentex* and *SBSC* represent different methods of augmentation described in 3.3. *Add* and *Concat.* represent different strategies of augmentation described in 3.4 in the section Training Data for fine-tuning. Metrics reported in format **Precision**, **Recall**, **F1** from (Sorokin et al., 2016).

BERT, CNN-LSTM, SC-LSTM, Nested-LSTM, SC-LSTM + BERT at input/output, and SC-LSTM + ELMO at input/output. Additionally, we evaluate OpenAI models via API (namely, *gpt-3.5-turbo-0301*, *gpt4-0314*, *text-davinci-003*) with different prompts: Full, Short, and Cut (see Appendix 9 for the details). Finally, we compare the obtained results on the Full prompt with models from NeuSpell and T5<sub>large</sub> model.

## 5 Evaluation

### 5.1 Metrics

For the evaluation, we use the script from the Dialogue Shared Task (Sorokin et al., 2016).

As a result, the *F1-measure* as the harmonic mean between *Precision* and *Recall* is calculated. *Precision* amounts for the number of correct lexemes the spellchecker system has not altered, while *Recall* reflects the share of appropriately rectified errors. The evaluation script reported all three metrics.

We also evaluated models for the English language with *accuracy* (correct words among all words) and *correction rate* (misspelled tokens corrected), as it was proposed by (Jayanthi et al., 2020).

### 5.2 Results

Table 1 presents the results of experiments conducted on the Russian language. The findings indicate superior dominance of pre-trained (+PT.) models over the bare fine-tuning. Moreover, larger models generally perform better though this trend is only observed for M2M100 models. The Fred-T5 model, despite its larger size compared to the M2M100<sub>418M</sub> model, demonstrates poorer quality on *RuspellRU* and *MedSpellChecker* datasets. This difference in performance may be attributed to the multilingual architecture of the M2M100 model. In our experimental setup, we emulated errors in the pre-trained models using the *RuspellRU* dataset. This may cause the scores of the models on this specific domain to be substantially higher than those obtained on other datasets.

Including corruption strategies (Table 4) during the fine-tuning stage improves scores. This trend persists consistently across different domains. In the case of the heuristic-based approach, *Add* strategy celebrates most of the performance improvements. In contrast, the statistic-based approach manifests equal contribution of both strategies.

Table 3 demonstrates that non-generative models in the Russian language perform comparably to generative OpenAI models, but they are lightweight and more efficient. However, our best M2M100 model configuration significantly outperforms these solutions.

According to Table 2, the pre-trained T5 model shows comparable with OpenAI models results. We emulated the error distribution based on the BEA60K set during pre-training. However, the final evaluation of the JFLEG set is slightly better than the BEA60K.

The Tables 9,11 presented in the Appendix A.4 demonstrate a notable gap in performance between OpenAI models for English and Russian. In English, the results indicate higher performance when punctuation is not considered. Furthermore, three models demonstrate comparable performance across all models, employing more specific prompts shows better results. However, for Russian the *text-davinci-003* model with punctuation performs better. While analyzing the results, we observed that the generated outputs are sensitive to the prompts. The results contain clichés phrases, forcing additional filtering to obtain accurate results. The observed discrepancy can be attributed to the pre-trained nature of the OpenAI models primarily trained on English language data.

## 6 Conclusion

In this paper, we have presented a novel methodology for generative SC. The approach involves emulating natural spelling errors during large generative model pre-training and has shown state-of-the-art results in addressing text editing tasks. We use two augmentation techniques for text corruption to improve the results. Conducting the experiments in two languages, we have demonstrated the effectiveness of these techniques and the impact of different corruption strategies across different domains. As for the research’s practical impact, we proposed the library SAGE for automatic SC, including the Russian data hub, proposed methods, and the family of generative models. The work contributes significantly to the SC field and opens routes for further exploration.

### Limitations

The proposed generative methodology of SC and the created models have certain limitations that should be considered:

**Decoding strategies and parameters.** The choice of the decoding strategy affects the quality of generated texts (Ippolito et al., 2019). However, our current methodology only comprises part of the spectrum of decoding strategies, limiting our evaluation’s extent. During the pre-training and fine-tuning stages, the choice of each model’s parameters is limited due to the significant computational costs associated with training and processing.

**Text Corruptions and data.** A limitation of our study is the availability of different data and the variety of specific domains for the training, fine-tuning stages, and annotated data. We tried to address the issue of data diversity by incorporating single-domain and multi-domain datasets in the proposed research. As for data augmentation, the heuristic approach covers only limited augmentation methods.

**Context.** The SC model may struggle with word context due to the two main factors: 1) the model’s context length is constrained (for example, T5 is limited for 512 sequence length); 2) the data used for the fine-tuning is limited to the text’s length of the examples in the dataset, which can lead to bad performance on longer texts if the models saw only short ones. We added the domains of various text lengths to address this problem in the Multidomain-Gold set.

**Languages.** The methodology employed in our study primarily focuses on investigating the applicability of our spell SC methodology within the Russian language, examining its transferability to the English language. The generalizability of the method across diverse language families remains to be determined. We leave these aspects for future work.

## Ethics Statement

In our research on generative SC, we prioritize addressing ethical implications and ensuring responsible technology use.

**Datasets and Crowdsourcing annotation.** Responses of human annotators are collected and stored anonymously, eliminating personally identifiable information. The annotators are warned about potentially sensitive topics in data (e.g., politics, culture, and religion). The average annotation pay rate exceeds the hourly minimum wage in Russia twice. The data are published under an

MIT license. We secured access to public datasets, adhering to relevant terms of service and usage policies.

**Energy Efficiency and Usage.** Training large-scale LLMs consumes significant computational resources and energy, producing substantial carbon emissions. The decision was made to limit the number of pre-trained models employed for English to minimize the ecological footprint of the research. The CO2 emission of pre-training the M2M100 (Fan et al., 2021) and T5 (Raffel et al., 2020) models in our experiments is computed as Equation 1 (Strubell et al., 2019):

$$CO2 = \frac{PUE * kWh * I^{CO2}}{1000} \quad (1)$$

The resulting CO2 emissions are listed below:

1.  $M2M100_{1.2B} = 87.09$  kg;
2.  $M2M100_{418M} = 57.37$  kg;
3.  $T5_{large} = 62.21$  kg;
4.  $FredT5_{large} = 31.11$  kg;

Data centers’ power usage effectiveness (*PUE*) is at most 1.3. Despite the costs, spelling models can efficiently adapt to users’ needs, bringing down potential budget costs in modern applications.

**Biases.** Our datasets reflecting the Internet domain may contain stereotypes and biases similar to the pre-trained models. Risks of misuse in generative LLMs are a well-discussed concern (Weidinger et al., 2021; Bommasani et al., 2021). We recognize the potential for biases in both training data and model predictions. Proper evaluation is crucial to uncover any vulnerabilities in generalizing new data.

**Possible Misuse.** We are aware that the results of our work could be misused for harmful content. We emphasize that our research should not harm individuals or communities through legislation, censorship, misinformation, or infringing on information access rights. We offer a novel, broadly applicable methodology that is especially valuable for Russian. While it can enhance written communication, ongoing ethical evaluation is crucial to address emerging challenges.

## 7 Acknowledgements

The authors sincerely thank Alexey Sorokin for providing us with the evaluation script from the Dialogue Shared task. The authors would also like to extend their appreciation to the teams of the authors of the datasets we took for the training and testing parts. We thank Dmitry Pogrebnoy, the author of anamnesis medical data validated and included in our MedSpellChecker set. The authors are grateful for Ibragim Badertdinov's ideas of heuristic-based corrupted method in the texts. The authors would like to thank Denis Kulagin and his "kartaslov"<sup>18</sup> git-project for the data and statistics on typos. The authors are deeply grateful for the valuable contributions of everyone mentioned above. Their efforts played a crucial role in completing this research.

Table 6: The train sets statistics. The sizes of the train sets parts in the number of examples (primarily sentences).  $1S - A$  represents if the dataset was validated on the first annotation step.  $2S - A$  represents if the dataset was validated on the second annotation step.  $Length$  is the average number of symbols in one dataset’s example.

### A.2 Annotation

For the extension of the gold test set and the MultidomainGold train part, we use the two-stage annotation setups via a crowd-sourcing platform Toloka<sup>19</sup> (Pavlichenko et al., 2021) similarly to the work (Martynov et al., 2023):

1. **Data gathering stage:** the texts with possible mistakes are provided, and the annotators are asked to write the sentence correctly;

<sup>19</sup><https://toloka.ai/tolokers>

2. **Validation stage:** the pair of sentences (source and its corresponding correction from the previous stage) are provided, and the annotators are asked to check if the correction is right.

The annotation costs and the details for the created sets in the current work are presented in Table 7.

Params	S1.Tr	S2.Tr	S1.Te	S2.Te
<b>IAA</b>	82.06	85.20	82.34	91.78
<b>Total</b>	720\$	451\$	732\$	947\$
<b>Overlap</b>	3	3	3	3
$N_T$	7	7	8	8
$N_{page}$	4	5	4	5
$N_C$	50	46	50	46
$N_U$	12	10	10	9
<b>ART</b>	102	71	95	60

Table 7: Details on the data collection projects for the Golden Test sets and the Train MultidomainGold for both parts of the annotation pipeline ( $S1.Tr$  is the first annotation stage of train set;  $S2.Te$  is the second annotation step of the test set respectively). **IAA** refers to the average IAA confidence scores, %. IAA of the first step is calculated as the expected value of annotators’ support of the most popular correction over all labeled texts. IAA of the second step is calculated as an average value of confidence scores overall labeled texts. **Total** is the total cost of the annotation project. **Overlap** is the number of votes per example.  $N_T$  is the number of training tasks.  $N_{page}$  denotes the number of examples per page.  $N_C$  is the number of control examples.  $N_U$  is the number of users who annotated the tasks. **ART** means the average response time in seconds.

Model	Speed	Size	Params
M2M100 <sub>1.2B</sub>	175.73	4.96	1.2B
M2M100 <sub>418</sub>	326.16	1.94	418M
Fred-T5 <sub>large</sub>	177.12	3.28	820M
T5 <sub>large</sub>	190.96	2.95	770M

Table 8: The Models’ statistics.  $Speed$  is the speed of the model on inference on a single Nvidia A100 in symbols per second.  $Params$  represents the number of the models’ parameters.  $Size$  is the size of the models’ checkpoint weights in GB.

### A.3 Augmentation strategies details

In the diverse array of settings available within Augmentex, customization options include the percentage of phrase changes, the maximum and minimum

Table 9: OpenAI models’ performance on SC tasks in English. *W/O Punctuation* and *With Punctuation* reflect the absence and presence of punctuation in the sentence, respectively. Metrics are reported in format **Precision, Recall, F1**-measure from (Sorokin et al., 2016).

number of errors, and the proportion of phrases eligible for modifications. Among its various augmentation strategies, we choose the word-level approach (replacing the symbols with a probability of their mistaken use) and the sentence-level approach (substituting words with frequent incorrect alternatives). We configured the first setup with the parameters: `aug_rate=0.1`, `min_aug=1`, `max_aug=3`, `mult_num=5`, `action="orfo"` and `aug_prob=0.7`, and the second: `aug_rate=0.6`, `min_aug=1`, `max_aug=5`, `action="replace"` and `aug_prob=0.7`.

#### A.4 Experiments evaluation results

The evaluation of all the experiments discussed in the section 4 that are not covered in the main text are presented in the Tables 9, 11. The evaluation on development sets during the training is presented in Table 10.

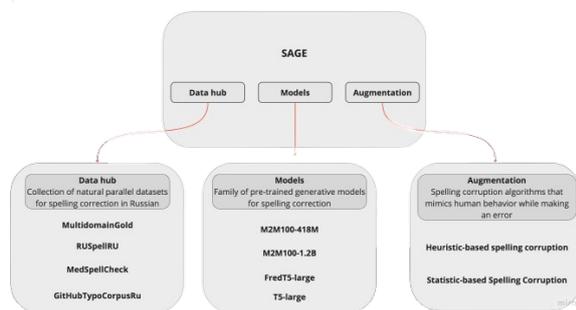

Figure 1: The architecture overview of the SAGE library.

#### A.5 SAGE library

As the practical result of the introduced methodology, we present SAGE<sup>20</sup> (Spell checking via Aug-

<sup>20</sup><https://github.com/ai-forever/sage>

mentation and Generative distribution Emulation). The library consists of three parts: data hub, augmentation strategies, and the family of the models. The architecture is presented on a Figure 1. The data hub includes the whole collection of natural parallel datasets for SC in Russian that were created within the frame of our research. The family of pre-trained generative models for SC involves all the best models trained during the current research for the Russian and English languages. The models are assessed with the inference code from the HuggingFace library<sup>21</sup> and the evaluation script. The last part is the augmentation methods included in SAGE. The statistic-based approach is presented for emulating the user’s parallel corpus distribution and provides the emulation algorithm on new data. The heuristic-based approach is presented for producing the noise via different strategies on a word and sentence level in the non-labeled text data.

#### A.6 OpenAI models prompts experiments

We conduct experiments 9, 11 varying different prompts OpenAI models to evaluate their performance on Golden test sets in Russian and English. For both English and Russian sets, we try three types of prompts: 1) **Cut prompt** for Russian: "Perepishi tekst bez orfograficheskij, grammaticheskij oshibok i opechatok, sohranjaja ishodnyj stil’ teksta, punktuaciju, ne raskryvaja abbreviatur i ne izmenjaja korrektnyj tekst:"; for English: "Correct spelling and grammar in the following text:". 2) **Short prompt** for Russian: "Perepishi tekst bez orfograficheskij, grammaticheskij oshibok i opechatok, sohranjaja ishodnyj stil’ teksta, punktuaciju, ne raskryvaja abbreviatur i ne izmenjaja korrektnyj tekst:"; for English: "Correct spelling

## Abstract

Fine-tuning large language models is becoming ever more impractical due to their rapidly-growing scale. This motivates the use of parameter-efficient adaptation methods such as prompt tuning (PT), which adds a small number of tunable embeddings to an otherwise frozen model, and in-context learning (ICL), in which demonstrations of the task are provided to the model in natural language without any additional training. Recently, Singhal et al. (2022) propose “instruction prompt tuning” (IPT), which combines PT with ICL by concatenating a natural language demonstration with learned prompt embeddings. While all of these methods have proven effective on different tasks, how they interact with each other remains unexplored. In this paper, we empirically study when and how in-context examples improve prompt tuning by measuring the effectiveness of ICL, PT, and IPT on five text generation tasks with multiple base language models. We observe that (1) IPT does *not* always outperform PT, and in fact requires the in-context demonstration to be semantically similar to the test input to yield improvements; (2) PT is unstable and exhibits high variance, but combining PT and ICL (into IPT) consistently reduces variance across all five tasks; and (3) prompts learned for a specific source task via PT exhibit positive transfer when paired with in-context examples of a different target task. Our results offer actionable insights on choosing a suitable parameter-efficient adaptation method for a given task.

## 1 Introduction

As large language models (LLMs) continue to grow in scale (Brown et al., 2020; Chowdhery et al., 2022), it is quickly becoming infeasible to fine-tune all of their parameters to solve a new task. As such, developing methods that *efficiently* adapt LLMs to downstream tasks is critical. In this paper, we study the relationship between three such methods:

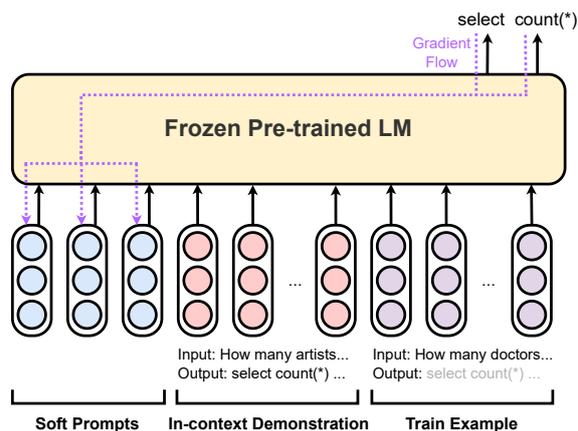

Figure 1: An illustration of instruction prompt tuning (IPT). Soft tunable prompt embeddings are prepended to a retrieved in-context demonstration, which is followed by the training example. In this paper, we study the mutual effect of the soft prompts and the discrete demonstrations in instruction prompt tuning.

- **In-context learning (ICL):** The simplest method is to leverage *in-context learning*, in which LLMs are prompted with instructions or demonstrations to solve a new task without any additional training (Brown et al., 2020). ICL can be further improved by dynamically retrieving demonstrations that are similar to a particular test input, rather than choosing demonstrations at random (Liu et al., 2022b). However, it still struggles on complex and out-of-domain downstream tasks (An et al., 2022; Liu et al., 2022a).
- **Prompt tuning (PT):** The limitations of ICL beg the question of whether a small amount of training can help. In *prompt tuning*, the vast majority of the LLM is kept frozen while a small number of new tunable embeddings are concatenated to every test input (Lester et al., 2021). While PT generally outperforms ICL, it is unstable and difficult to optimize (Ding et al., 2022).
- **Instruction prompt tuning (IPT):** More re-

cently, Singhal et al. (2022) combine ICL and PT into *instruction prompt tuning*, which concatenates retrieved in-context demonstrations with tunable prompt embeddings, and they show its effectiveness at adapting LLMs to the medical domain.

Despite the progress in these LLM adaptation methods, little is known about the conditions in which any of these methods outperforms the other; more generally, the mutual effect of in-context learning and prompt tuning remains understudied. We shed light on these questions by comparing ICL, PT, and IPT across five text generation tasks using three base LMs of comparable size (BLOOM 1.1B, OPT 1.3B, and GPT2 XL 1.5B). We focus mainly on out-of-distribution language generation tasks that challenge the limits of parameter-efficient adaptation methods, including ToTTo (Parikh et al., 2020) and DART (Nan et al., 2021) for data-to-text generation, Logic2Text (Chen et al., 2020) for logic-to-text generation, and Spider (Yu et al., 2018) and MTOP (Li et al., 2021) for semantic parsing.

We summarize our findings as follows:

- Both PT and IPT consistently outperform ICL across all five tasks. This result demonstrates the value of training at least a small set of parameters for out-of-domain tasks.
- That said, there is no clear winner between PT and IPT, as performance is highly dependent on the task and experimental configuration (e.g., number of tunable embeddings).
- IPT outperforms PT on examples for which the in-context demonstration is highly similar to the test input.
- PT exhibits high variance, especially when there are more tunable parameters. IPT reduces variance, and its performance is less dependent on the number of prompt embeddings than PT.
- While prompt embeddings learned via PT cannot be directly transferred to unseen tasks, we discover that they are transferable to new tasks given in-context demonstrations, and that combining source task prompts with target task demonstrations outperforms ICL in this transfer setting.

## 2 Background

Parameter-efficient fine-tuning methods (Houlsby et al., 2019; Karimi Mahabadi et al., 2021; Ben Zaken et al., 2022) specialize LLMs to a target task

while keeping most of their parameters frozen and adjusting just a small number of task-specific parameters. Since full-model fine-tuning is prohibitively expensive on consumer-grade hardware for most LLMs, such methods increase the accessibility of LLM research and deployment. Here, we give a more formal specification of the parameter-efficient tuning methods that we experiment with in this paper.

**In-context learning:** Brown et al. (2020) show that their 175B-parameter GPT-3 model is capable of solving unseen tasks by leveraging information from in-context instructions (*zero-shot*) and/or demonstrations (*few-shot*). Inserting  $k$  in-context input-output pairs  $[\mathbf{X}_{icl}; \mathbf{Y}_{icl}]$  before the test input significantly improves the performance of solving a target task:

$$\text{Input}_{\text{ICL}} = \text{concat}([\mathbf{X}_{icl}; \mathbf{Y}_{icl}]_1^k; \mathbf{X}_{test})$$

**Prompt tuning:** In-context learning struggles on out-of-domain tasks, which motivates alternate approaches that tune a small fraction of the LLM’s parameters (Ding et al., 2022). In this paper, we focus on prompt tuning (PT) (Lester et al., 2021; Liu et al., 2021), which prepends soft tunable prompt embeddings to the input tokens  $\mathbf{X}_{test}$ . PT is easy to implement and, unlike adapter-based (Bapna and Firat, 2019) and LoRA (Hu et al., 2022) approaches, does not change the internal model structure. Formally, let  $\mathbf{E} = \{\mathbf{e}_1, \dots, \mathbf{e}_k\}$  be a sequence of new tunable prompt embeddings optimized over a training set, while  $\mathbf{X} = \{\mathbf{x}_1, \dots, \mathbf{x}_m\}$  denote the token embeddings of the input of an example. Then, the input to PT at inference time can be expressed as

$$\text{Input}_{\text{PT}} = \text{concat}(\mathbf{E}; \mathbf{X}_{test}).$$

**Instruction Prompt Tuning.** More recently, Singhal et al. (2022) proposes instruction prompt tuning (IPT), which concatenates the soft prompts with hard in-context demonstrations. Using the notation from above, the input of IPT is:

$$\text{Input}_{\text{IPT}} = \text{concat}(\mathbf{E}; [\mathbf{X}_{icl}; \mathbf{Y}_{icl}]_1^k; \mathbf{X}_{test}).$$

Note that in our experiments, the prompt embeddings  $\mathbf{E}$  are task-specific, whereas Singhal et al. (2022) share them across multiple tasks in the medical domain. The hybrid of soft and hard prompt tokens has been previously employed by Gu et al. (2022) and Han et al. (2021). IPT resembles

Table 1: Providing a retrieved in-context demonstration significantly outperforms a random in-context training demonstration, although both PT and IPT generally outperform ICL. Here, we only report the performance of PT and IPT with 25 tunable prompt embeddings. Tuning the number of prompt embeddings further improves performance for both methods, as shown in Figure 4 and Figure 6.

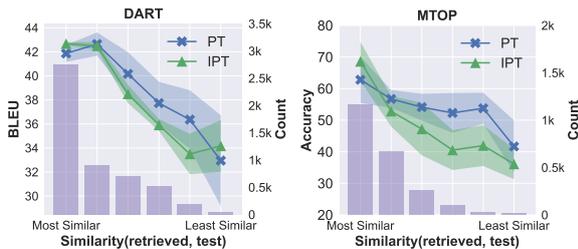

Figure 2: IPT performs better than PT on examples for which the input of retrieved in-context demonstration is very similar to the test input. However, IPT degrades quickly as the retrieved example becomes less similar.

MetaICL (Min et al., 2022b) and in-context tuning (Chen et al., 2022) in that in-context demonstrations are part of the input during training; however, IPT tunes just the prompt embeddings.

### 3 Experimental setup

How can a soft prompt benefit from the added information provided by a retrieved in-context demonstration? We run experiments comparing the performance of ICL, PT, and IPT across a variety of tasks, configurations, and base language models.

**Dataset:** While past research into prompt tuning has mostly focused on natural language understanding tasks (Lester et al., 2021; Vu et al., 2022b), we focus on *language generation* tasks, with a specific focus on tasks where either the input or output is (relatively) out-of-domain, which challenges the limits of methods for adapting LLMs. The

tasks we explore are: DART (Nan et al., 2021), ToTTo (Parikh et al., 2020), Spider (Yu et al., 2018), MTOp (Li et al., 2021), and logic-to-text task (Chen et al., 2020). More details about each task are included in Appendix A.

**Models:** We experiment with the BLOOM-1.1B (Scao et al., 2022), OPT-1.3B (Zhang et al., 2022), and GPT-2-XL-1.5B (Radford et al., 2019) models on all our tasks. For our fine-grained analysis, we focus on the BLOOM checkpoint. We provide training details in Appendix B. For IPT, we use dense retrieval to select in-context examples. To avoid the order of in-context examples (Liu et al., 2022b) complicating the experiments, we only provide one in-context demonstration per example. Following Liu et al. (2022b), we use dense retrieval to select good in-context examples for instruction prompt tuning. We encode the input of each example with a large language model<sup>1</sup> and extract the last token representation as the dense representation for the encoded sequence. We then use FAISS (Johnson et al., 2019) to retrieve the nearest-neighbor training example as an in-context demonstration. More details about retrieving examples for DART are included in Appendix C. The input format of IPT for each task is presented in Table 3.

<sup>1</sup>We use GPT-neo-1.3b <https://huggingface.co/EleutherAI/gpt-neo-1.3B> in our experiment.

## 4 Analysis

Table 1 shows that both PT and IPT (with 25 soft prompt tokens each) significantly outperform ICL with randomly retrieved in-context demonstrations on all five tasks, which supports conclusions drawn from prior studies on prompt tuning. While ICL can be further improved with semantically-similar in-context demonstrations, it still lags behind PT and IPT on most tasks.

**In-context learning underperforms prompt tuning:** In line with experiments from prior work (Liu et al., 2022a), we observe that ICL performs consistently worse than PT and IPT, even when using retrieved demonstrations instead of random demonstrations. This result shows the value of training a small number of new parameters to specialize a language model to the target task, especially for out-of-distribution generation. The lone exception is ToTTo, for which ICL is competitive with PT.

**No clear winner between PT and IPT:** Despite receiving additional signal from the retrieved in-context demonstration, IPT does not consistently outperform PT. Our results in Table 1, also visualized for the BLOOM model in Figure 6, show that the relative performance of these two methods highly depends on the task and the number of tunable parameters. For instance, IPT performs better than PT with OPT-1.3B on Logic2Text (84.6 vs. 80.6), whereas it is worse than PT if using GPT-2-XL as the base model (85.8 vs. 87.2).

**IPT helps when the in-context demonstration is similar to the test input:** To understand the effect of in-context demonstrations in IPT, we evaluate the examples grouped by the *semantic similarity*<sup>2</sup> between the input of in-context example and the input of test example. Figure 2 demonstrates that PT and IPT perform worse when in-context examples are less similar to test inputs. IPT with highly-similar examples outperforms PT, but degrades when the examples become less similar. PT outperforms IPT on OOD examples (right-most bin). This suggests that low-quality in-context examples can confuse the base LM, which motivates future work on dynamic methods to selectively include examples based on a similarity threshold.

**Overlap in ToTTo inflates IPT performance**  
As shown in Table 1, IPT significantly outperforms

<sup>2</sup>We provide more details in Appendix E

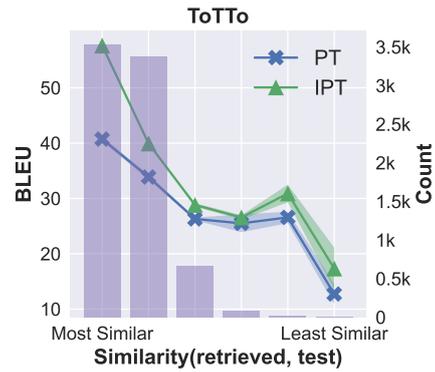

Figure 3: Over 85% of test inputs in ToTTo have highly-similar training examples, which is an explanation for IPT’s significantly higher performance on ToTTo.

PT on ToTTo (e.g., 48.0 vs. 37.3 with GPT-2-XL). We attribute this gap to substantial overlap between training and testing tables, along with very formulaic outputs. Table 5 contains an example where the train and test input belong to the same parent page, and the output format is identical; all that is needed is to copy the training output and edit the named entities and numerics according to the table. This gives IPT a big advantage: as shown in Figure 3, IPT outperforms PT when the in-context demonstration is very similar to the evaluated input, which constitutes over 85% of total evaluation examples in ToTTo. On the other hand, when the in-context examples become less similar to the test input, PT and IPT achieve similar performance.

**IPT is more stable than PT with more soft prompt tokens:** We notice that the variance of PT consistently increases as the number of prompt tokens increases (Figure 4).<sup>3</sup> On the other hand, IPT is more stable with more prompt tokens, and also reaches its best performance with more soft prompt tokens than PT. We conjecture that additional parameters (i.e., soft prompt tokens) are necessary to learn proper integration of dynamically-retrieved in-context demonstrations. Overall, IPT’s improved stability is a clear positive especially when applying parameter-efficient tuning methods to large LMs, where hyperparameter selection can be computationally infeasible.

**Prompt embeddings are transferable to new tasks provided with in-context demonstrations**  
We are interested in how much soft prompts learned

<sup>3</sup>This is consistent with findings in previous works (Min et al., 2022a; Vu et al., 2022b,a) Results on all tasks are included in Appendix E.

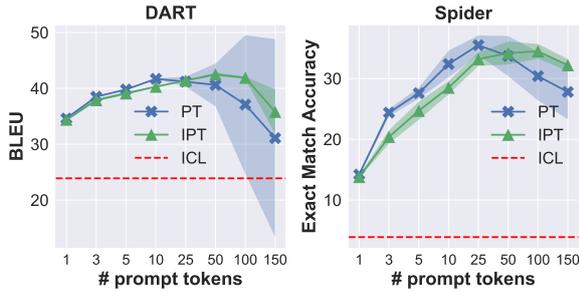

Figure 4: PT exhibits increasing variance as the number of tunable parameters increases, whereas IPT is relatively more stable.

for a *source* task can help improve performance on a different low-resource *target* task, for which it may not be possible to learn powerful soft prompts. We simulate this setting via cross-task evaluations. Figure 5 shows that embeddings learned via PT alone are generally not transferable to new tasks. However, pairing the prompt embeddings learned on a source task with a target task in-context demonstration often performs better than just the latter (right heatmap). These results show that although the learned prompt embeddings are task-specific, they encode information applicable to other tasks and help take better advantage of in-context demonstrations.

## 5 Conclusion

In this paper, we empirically analyze the effect of in-context demonstrations on prompt tuning for five language generation tasks. Our experiments reveal that while instruction prompt tuning and prompt tuning perform competitively with each other, IPT is more stable, yielding lower variance when varying hyperparameters. IPT also significantly improves over PT when the in-context demonstration closely resembles the test input, which is frequently the case in the ToTTo dataset. Finally, soft prompts learned for a source task can exhibit positive transfer to new target tasks when paired with in-context demonstrations.

## Limitation

While we have examined the interplay of prompt tuning and in-context learning on more general datasets than previous work, our experiments were limited to only  $\sim 1$ B parameter language models without further instruction fine-tuning due to limited compute budget. Future research on larger models is necessary to see if our findings scale with

Source Task	W/o in-context example					W/ in-context example				
	ToTTo	DART	Spider	MTOP	Logic2Text	ToTTo	DART	Spider	MTOP	Logic2Text
Logic2Text	13.2	14.4	0.0	0.0	<b>85.8</b>	<b>42.1</b>	<b>29.2</b>	1.3	11.0	<b>79.1</b>
MTOP	1.1	2.4	0.0	12.9	31.1	20.6	15.1	1.5	<b>31.9</b>	63.9
Spider	1.5	3.4	<b>35.6</b>	0.0	29.2	<b>37.9</b>	<b>27.2</b>	<b>18.3</b>	<b>22.3</b>	<b>73.2</b>
DART	2.7	<b>40.6</b>	0.0	0.0	45.4	<b>41.7</b>	<b>35.9</b>	1.8	16.8	62.6
ToTTo	<b>36.0</b>	12.0	0.0	0.0	32.2	<b>38.9</b>	20.0	2.6	6.8	<b>70.6</b>

Figure 5: Cross-task evaluation of prompt tuning with (right) and without (left) a target in-context example.. Numbers better than the corresponding ICL baseline for the target task are bolded. Pairing source task embeddings with target task in-context demonstrations increases task transfer.

parameter count. In our experiments, we only explore IPT given one in-context demonstration due to the limited model context size and bounded hardware memory, however we find that having good retrieved single example can yield significant gains. That said, performance of IPT with multiple in-context demonstration is open for exploration. Finally, although we have shown instruction prompt tuning is more stable than prompt tuning, its training is also slower than vanilla prompt tuning.

## Ethics Statement

In this paper, we conduct an empirical analysis of the mutual effect between in-context learning and prompt tuning on models containing  $\sim 1$  billion parameters. While we use these models entirely for scientific purposes, similar to other large language models, these models are vulnerable to generating hallucinations and misinformation. Although the experiments presented in this paper entail significant energy consumption, it is our hope that our findings can shed light on future research on parameter-efficient fine-tuning, thereby contributing to the reduction of computational costs.

## Acknowledgements

We thank the anonymous reviewers for the thoughtful comments on the draft of this paper. We thank Tu Vu, Kalpesh Krishna, Andrew Drozdov, and other members from UMass NLP group for the helpful discussions. This project was partially supported by awards IIS-1955567 and IIS-2046248 from the National Science Foundation (NSF).

## A Datasets

We explore three kinds of tasks: data-to-text generation, logic-to-text generation, and semantic parsing. In *data-to-text* generation, the input is of structured data, either expressed as sets of triplets as in **DART** (Nan et al., 2021) or as linearized table strings as in **ToTTo** (Parikh et al., 2020). The output of both tasks are short sentences describing the data or table, which is evaluated with BLEU (Papineni et al., 2002). For *semantic parsing*, in which a natural language utterance is mapped to a logical form, we evaluate on **Spider** (Yu et al., 2018) and **MTOP** (Li et al., 2021) and report exact match accuracy. Finally, in the **Logic2Text** *logic-to-text* task (Chen et al., 2020), we use the metric BLEC to be consistent with other works (Xie et al., 2022). For Spider, MTOP, and Logic2Text, we include knowledge information, such as linearized table schema, before the textual input. We use the processed data in <https://github.com/HKUNLP/UnifiedSKG>. For ToTTo, we use the processed data provided by Liu et al. (2022b). More details about each dataset are presented in Table 2.

## B Experiment Details

We experiment with the BLOOM-1.1B<sup>4</sup>, OPT-1.3b<sup>5</sup>, and GPT-2-XL-1.5B<sup>6</sup> models on all our tasks. For our fine-grained analysis, we focus on the BLOOM checkpoint, which has 24 Transformer

<sup>4</sup><https://huggingface.co/bigscience/bloom-1b1>

<sup>5</sup><https://huggingface.co/facebook/opt-1.3b>

<sup>6</sup><https://huggingface.co/gpt2-xl>

	#Train	#Test	Avg. len $X_{PT}$	Avg. len $X_{IPT}$
ToTTo	120,761	7,700	95	202
DART	62,659	5,097	41	106
Spider	7,000	1,034	109	244
MTOP	15,667	2,235	680	1,390
Logic2Text	8,566	1,095	56	136

Table 2: Dataset statistics. We provide the average length of each example for both prompt tuning and instruction prompt tuning. IPT has a longer input length on average because one retrieved demonstration is included with the soft prompt and the test input.<sup>9</sup>

layers, an embedding dimensionality of 1536, and 16 attention heads, and is trained on multilingual text as well as programming language corpora.<sup>7</sup> For stabler and faster prompt tuning convergence, we employ the reparameterization trick introduced by Li and Liang (2021) by adding two feed-forward layers atop the initial prompt embeddings; the transformed prompt embeddings are then fed as input to the model.<sup>8</sup> For both PT and IPT, we randomly initialize all prompt embeddings, use a batch size of 8, and evaluate the best checkpoint selected by dev loss after training for 5 epochs with the AdamW optimizer (Loshchilov and Hutter, 2019). For both prompt tuning and instruction prompt tuning, we set batch size 8 and grid search learning rate over  $\{5e-5, 5e-4, 1e-3\}$  and weight decay over  $\{0.0, 0.01, 0.1\}$ . The adopted hyperparameters for each task and each approach is presented in Table 4. For each configuration, we report the averaged performance over three runs. Experiments were conducted on V100 GPUs.

## C Retrieve in-context demonstration for DART

As DART contains examples sharing the same input, i.e., the same input corresponds to different outputs, examples having the same input will be selected as the in-context demonstration of each other. However, our earlier experiments indicated that prepending these examples leads to convergence to higher losses, and worse performance overall on evaluation set. Therefore, for this dataset, we exclude same-input examples and select the top

<sup>7</sup><https://huggingface.co/spaces/bigscience/BigScienceCorpus>

<sup>8</sup>Unlike Liu et al. (2022c), we modify only the input layer of the language model instead of every layer. A similar approach is also used by An et al. (2022).

<sup>9</sup>Due to the longer input length, we notice IPT takes longer to train than PT.

Task	Input format

Table 4: Hyperparameters of PT and IPT for each task.

semantically-similar examples from the rest as in-context demonstration.

## D Overlap in ToTTo inflates IPT performance

### E Analysis Experiment Details

In Section 4, to divide examples by semantic similarity between the in-context demonstration and test input, we encode the input of each example with large pre-trained LM by extracting the last token representation, and measure the similarity in latent space, which is also used for ICL demonstration retrieval as described in section 3. For this analysis, to eliminate potential confounder, we select two task and model configurations on which IPT and PT achieve almost identical average performance (DART with 25 prompt tokens, and MTOP with 100 prompt tokens) while having the same number of tunable parameters.

	Input	Output

Test	<pre>&lt;page_title&gt;List of Governors of South Carolina &lt;section_title&gt;Governors under the Constitution of 1868 &lt;table&gt;&lt;cell&gt;76 &lt;col_header&gt;# &lt;col_header&gt;74 &lt;col_header&gt;75 &lt;cell&gt;Daniel Henry Chamberlain &lt;col_header&gt;Governor &lt;row_header&gt;76 &lt;/row_header&gt; &lt;cell&gt;December 1, 1874 &lt;col_header&gt;Took Office &lt;row_header&gt;76 &lt;/row_header&gt;</pre>	Daniel Henry Chamberlain was the 76th Governor of South Carolina from 1874.

Table 5: An example from ToTTo dev set and its corresponding top retrieved in-context example. IPT and in-context learning have a significant advantage over PT due to the presence of the in-context demonstration, which has high word overlap and follows the same template as the test output.

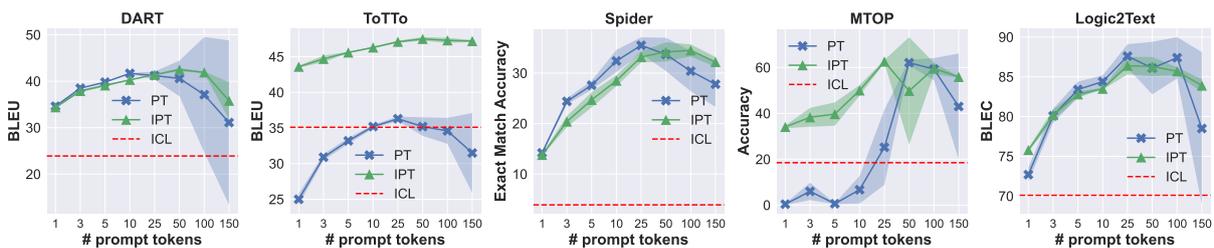

Figure 6: Comparing the performance of prompt tuning, instruction prompt tuning, and in-context learning, where the latter two methods are provided with one retrieved in-context demonstration, on five language generation tasks varying the number of soft prompt tokens. The best PT and IPT configurations always outperform ICL. PT exhibits increasing variance as the number of tunable parameters increases, whereas IPT is relatively more stable. IPT is less sensitive overall to the number of prompt tokens, which makes it preferable in situations where hyperparameter tuning is computationally expensive.

# Large Language Models for Psycholinguistic Plausibility Pretesting

## Abstract

In psycholinguistics, the creation of controlled materials is crucial to ensure that research outcomes are solely attributed to the intended manipulations and not influenced by extraneous factors. To achieve this, psycholinguists typically *pretest* linguistic materials, where a common pretest is to solicit plausibility judgments from human evaluators on specific sentences. In this work, we investigate whether Language Models (LMs) can be used to generate these plausibility judgements. We investigate a wide range of LMs across multiple linguistic structures and evaluate whether their plausibility judgements correlate with human judgements. We find that GPT-4 plausibility judgements highly correlate with human judgements across the structures we examine, whereas other LMs correlate well with humans on commonly used syntactic structures. We then test whether this correlation implies that LMs can be used instead of humans for pretesting. We find that when coarse-grained plausibility judgements are needed, this works well, but when fine-grained judgements are necessary, even GPT-4 does not provide satisfactory discriminative power.

## 1 Introduction

Psycholinguistic research explores humans' exceptional language comprehension abilities, aiming to uncover underlying mechanisms through experiments and cognitive modelling (Frazier, 1987; Lewis and Vasishth, 2005; Gibson, 2000; Levy, 2008; MacDonald et al., 1994; Futrell et al., 2020; Tabor and Hutchins, 2004). Researchers use measures such as reading times and comprehension accuracy to compare sentences with distinct processing demands. As an example, Ness and Meltzer-Asscher (2019) investigated reading times to determine if sentences with two animate nouns (e.g., (1a), (2a)) pose greater processing challenges than those with one animate and one

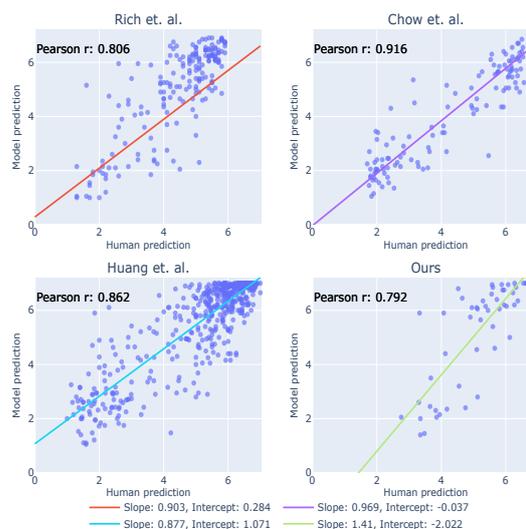

Figure 1: Correlation between average human plausibility ratings and average LLM plausibility ratings across four pretesting datasets, along with the fitted linear regression and Pearson correlation. We plot the LLM with the highest correlation (GPT-4 in all cases, except for the bottom right where GPT-3.5 is shown).

inanimate noun (e.g., (1b), (2b)). Longer reading times in the (a) sentences would indicate that similarity between the noun phrases interferes with processing.

- (a) The photographer that the manager sent was helpful.  
(b) The contract that the manager sent was helpful.
- (a) The worker that the contractor brought fell down.  
(b) The ladder that the contractor brought fell down.

Careful construction of linguistic stimuli is crucial in psycholinguistic studies to minimize confounding factors. Controlling sentence plausibility ensures that processing differences stem from ex-

perimental manipulations rather than external factors (plausibility, length of the sentence, grammatically of the sentence)... In our example, making sure that the sentences “the manager sent the photographer” and “the manager sent the contract” have roughly the same plausibility, and likewise that “The photographer was helpful” and “The contract was helpful” have roughly the same plausibility, is necessary to attribute processing variations to the similarity in animacy. Moreover, maintaining overall high sentence plausibility prevents unrelated processing difficulties and reduces data noise.

Controlling sentence plausibility is therefore essential in sentence processing experiments, and is typically accomplished through pretests, where participants rate sentence plausibility on a scale, guiding the selection of materials for the main experiment. However, plausibility pretesting is a time- and resource-consuming process, involving multiple iterations and prolonged data collection with different participant groups.

Recently, Large Language Models (LLMs) (Vaswani et al., 2017; Devlin et al., 2019; Lewis et al., 2020; Raffel et al., 2020; Touvron et al., 2023) have shown human-like performance on various language understanding tasks without task-specific training (Brown et al., 2020). Previous studies have established a strong correlation between LMs’ predicted probabilities and human reading time (Fernandez Monsalve et al., 2012; Smith and Levy, 2013; Hofmann et al., 2020; Hao et al., 2020; Hollenstein et al., 2021; Shain et al., 2022). Thus, it is natural to ask – *can LMs provide plausibility judgements that are similar to human judgments and consequently be used to reduce the cost of psycholinguistic pretesting?*

In this study, we investigate the correlation between LMs and human plausibility judgments. To accomplish this, we examine four sets of sentences that represent a variety of syntactic structures and plausibility levels, for which human judgments have been collected in prior work in the course of pretesting (Chow et al., 2016; Rich and Wagers, 2020; Huang et al., 2023). We then gather multiple LM judgements for these sets from a wide range of LMs, and compare average human plausibility ratings and average LLM plausibility ratings.

Our findings indicate that while several LLMs exhibit high correlation with human judgments on common syntactic structures, only GPT-4 shows

strong correlation on the rarer syntactic structures. Figure 1 displays the average plausibility ratings of the LLM with the highest correlation against average human ratings, along with a linear regression model. The Pearson correlation between LLM and human judgments is consistently high across all the datasets. Interestingly, the fitted linear regressions are quite similar across three of the datasets, indicating robustness in the translation of LLM judgements into human judgements.

Based on these findings, we examine if using LLMs instead of humans can lead to similar outcomes when filtering materials in the course of pretesting. We find that when pretesting requires coarse-grained plausibility judgements, i.e., when it is used to filter out implausible sentences, LLMs perform well. However, when fine-grained plausibility judgements are needed, e.g., to ensure that a pair of sentences has similar plausibility ratings, even GPT-4’s performance is not satisfactory yet.

To summarize, in this work we thoroughly investigate the correlation between human and LM plausibility judgements across a wide range of LMs and syntactic structures. We find that many LLMs perform well on simple syntactic structures, and GPT-4 performs well across-the-board. We translate this finding into a method for using LLMs to provide plausibility judgements, and find that performance is high when coarse-grained judgements are needed, but still lagging behind when fine-grained judgements are necessary.

## 2 Experimental Setup

An experiment is defined by instantiating three parameters: (a) the LM used for eliciting plausibility judgements, (b) the prompt provided as input to the LM, and (c) the linguistic dataset used. We leverage data from existing pretests for which human plausibility ratings were already collected (Chow et al., 2016; Rich and Wagers, 2020; Huang et al., 2023), and also create our own pretest materials and collect human plausibility judgements for them.

In all experiments, we generate 20 plausibility ratings per sentence per LM, using a scale from 1 to 7. We now describe the datasets (§2.1), LMs (§2.2), and prompts (§2.3).

### 2.1 Datasets

We use four datasets, which cover a wide range of linguistic phenomena. Table 1 provides examples

Dataset	Structure	Plaus.	Example	Num.
<b>Chow et al. (2016)</b>	Emb. Obj. Quest.	Plaus	The park ranger documented which eagle the hunter had shot.	60
	Emb. Obj. Quest.	Implaus	The park ranger documented which hunter the eagle had shot.	60
<b>Huang et al. (2023)</b>	Emb. Decl.	Plaus	The suspect showed that the file deserved further investigation during the murder trial.	24
	Emb. Decl.	Implaus	The new doctor demonstrated that the melon appeared increasingly likely to succeed.	24
	Adj. Cl.	Plaus	Once the new chef started, the restaurant separated mediocre cooks from gifted ones.	24
	Adj. Cl.	Implaus	After the technician called, the smile stopped working almost immediately to his surprise.	24
	Pass. Rel. Cl.	Plaus	The patient who was refused the treatment continued causing uncomfortable scenes in the ER.	24
	Pass. Rel. Cl.	Implaus	The yoga instructor who was offered the beard demanded immense physical effort from everyone.	24
	Adj. Cl.	Plaus	After the esteemed reviewer reads, the book gains more attention due to his glowing praise.	18
	Adj. Cl.	Implaus	Even if the mother calls, her boys continue causing problems with the other kids on the playground.	18
	Sim. Trans. Cl.	Plaus	The suspect changed the file.	108
	Sim. Cl. w. Mod.	Plaus	The technician stopped working almost immediately after the argument.	81
	Sim. Cl. w. Mod.	Implaus	The tournaments remain essentially the same for the rest of the year.	18
	Intrans. Cl.	Plaus	The producer starts.	24
	Intrans. Cl.	Implaus	The dog hatched.	6
	Ditrans. Pass.	Plaus	The operator was brought the machine.	42
	Ditrans. Pass.	Implaus	The clerk was granted the finger.	6
	Trans. Cl.	Implaus	The cleaner ate the book.	15
Mul. Mod.	Implaus	A prodigious profile quietly lay ahead of the unstoppable crowd.	11	
<b>Rich and Wagers (2020)</b>	Passive	Plaus	The knife had been recently sharpened.	144
	Passive	Implaus	The shirt had been recently sharpened.	48
<b>Ours</b>	Simple	Plaus	The nurse fetched the patient.	10
	Simple	Plaus	The nurse fetched the intern.	40

Table 1: Breakdown of the data we used based on origin, syntactic structure, plausibility, and number of items, along with examples for each type. Emb. : Embedded, Obj.: Object, Quest.: Question, Decl.: Declarative, Adj.: Adjoined, Cl.: Clause, Pass: Passive, Rel.: relative, Sim.: Simple, Trans.: Transitive, Mod.: Modification, Mul.: Multiple

from all datasets.

1. **Chow et al. (2016)**: 60 sentence pairs from Experiment 1 in **Chow et al. (2016)**, consisting of semantically plausible and implausible sentences with an embedded object question structure. Each sentence has 30 plausibility ratings, collected for a subsequent experiment.
2. **Huang et al. (2023)**: 491 sentences from the Syntactic Ambiguity Processing benchmark (**Huang et al., 2023**), consisting of disambiguated garden-path sentences or parts of these sentences. Each sentence has 19.6 plausibility ratings on average.
3. **Rich and Wagers (2020)**: 48 sets of 4 sentences each consisting of three semantically plausi-

ble and one semantically implausible sentences with a common syntactic structure. Each sentence has 10 plausibility ratings.

4. **Our data**: 50 plausible sentences with a simple syntactic structure, composed for a future experiment on similarity-based interference. These materials consist of 40 sentence pairs (one sentence is shared among 4 pairs). Each sentence has 40 plausibility ratings.

Table 1 showcases examples of sentences from the different datasets for each syntactic structure and plausibility variation that was tested. The table also includes the corresponding item counts for each sentence structure.

## 2.2 Models

We test the following LMs:

### Closed-source models:

- **GPT-4** (OpenAI, 2023), a LLM released by OpenAI, available through an API.<sup>1</sup> This LM is widely considered to be one of the best existing LMs, if not the best (Bubeck et al., 2023).
- **ChatGPT** (GPT-3.5), a chat LLM released by OpenAI, available through an API
- **InstructGPT** (text-davinci-003) (Ouyang et al., 2022), an instruction-finetuned LLM released by OpenAI, available through an API

The best results were achieved using OpenAI’s GPT4. The cost of getting plausibility judgements for a single sentence is 0.02\$ on average. Though not cost-free, this expense is substantially lower compared to employing human evaluators for judgements. The total cost of OpenAI calls for this project was 2.7k \$.

**Open-source models:** We also used several open-source models available on the HuggingFace Hub (Wolf et al., 2019), through the FastChat (Zheng et al., 2023) servers (allowing simulating the OpenAI API):

- **LLaMa** (Touvron et al., 2023), a foundation model released by Meta Research, trained on non-proprietary open-domain data.
- **Alpaca** (Taori et al., 2023), a model based on LLaMa, instruction fine-tuned based on instruction data generated by InstructGPT.
- **Vicuna** (Chiang et al., 2023), a model based on LLaMa, fine-tuned on chat data from ChatGPT, available through ShareGPT.<sup>2</sup>
- **Falcon-Instruct** (Almazrouei et al., 2023), based on the Falcon foundation model released by Abu Dhabi TII, fine-tuned on a mix of chat and instruction data.
- **StableLM**,<sup>3</sup> a model released by Stability AI, fine-tuned on instruction and chat data.
- **MPT Chat**,<sup>4</sup> a model based on MosaicML’s MPT foundation model, finetuned on chat and instruction data.

<sup>1</sup><https://openai.com/blog/openai-api>

<sup>2</sup><https://sharegpt.com/>

<sup>3</sup><https://huggingface.co/stabilityai/stablelm-tuned-alpha-7b>

<sup>4</sup><https://huggingface.co/mosaicml/mpt-7b-chat>

Data	Best corr.	Model	Prompt	SH
Chow et al.	0.850	GPT-4	Glob.	0.943
Rich et al.	0.793	GPT-4	Glob.	0.868
Huang et al.	0.835	GPT-4	Glob.	0.898
Ours	<b>0.792</b>	GPT-3.5	Glob.	0.912
Chow et al.	<b>0.916</b>	GPT-4	Spec.	0.943
Rich et al.	<b>0.806</b>	GPT-4	Spec.	0.868
Huang et al.	<b>0.852</b>	GPT-4	Spec.	0.898
Ours	0.778	GPT-4	Spec.	0.912

Table 2: Highest Pearson correlation achieved for each of the datasets along with the split-half (SH) correlation analysis of human judgements, which provides an approximate upper bound. GPT-4 is the best LM in all cases, except for our dataset with a global prompt. In that case the correlation of GPT-4 is 0.761.

We decode from the LMs by sampling with a temperature, which is set to 1.5 for closed-source models and 0.3 for open-source models.

## 2.3 Prompts

Our prompts start with an instruction for the LM to provide a plausibility score on a scale from 1 to 7 (see exact prompts in Appendix A). We then provide examples for plausibility judgements, which are either global and fixed across datasets, or specific for each dataset:

- **Global:** We provide four examples for each possible plausibility score (28 examples overall). Examples include a wide range of syntactic structures, inspired by the four datasets, but including additional structures.
- **Specific:** For each dataset, we provide three examples (21 overall) that illustrate syntactic structures that appear in this dataset.

## 3 Results

Table 2 presents the highest Pearson correlation between average human and LLM ratings for each dataset and each prompt. The top half presents the highest correlation using the global prompt, whereas the bottom half uses the specific prompt. Additionally, the table includes the *split-half correlation* of human plausibility judgements, i.e. we randomly split human data in each example into two halves and measure the correlation between simulated sets of humans. This provides a rough upper bound on the correlation that can be achieved with a model.

Overall, The correlation of the highest-scoring model with human judgements is high, hovering

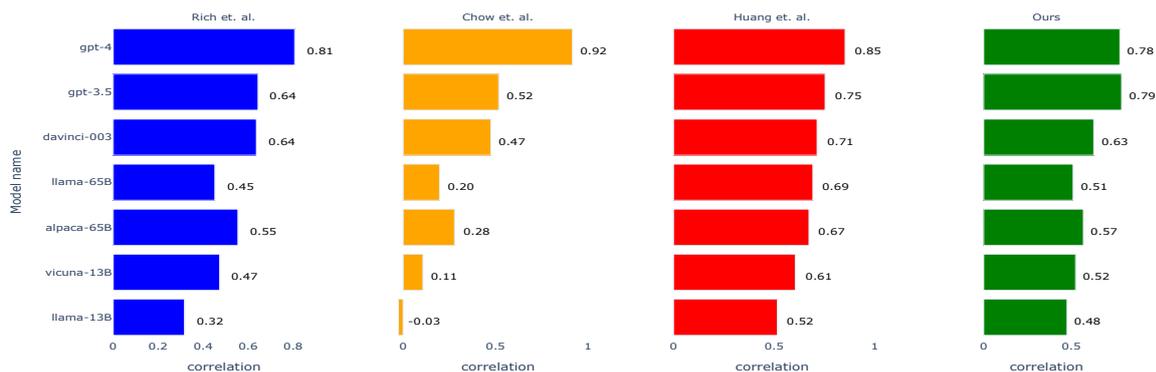

Figure 2: A breakdown of the correlation for the specific prompt for a subset of the models.

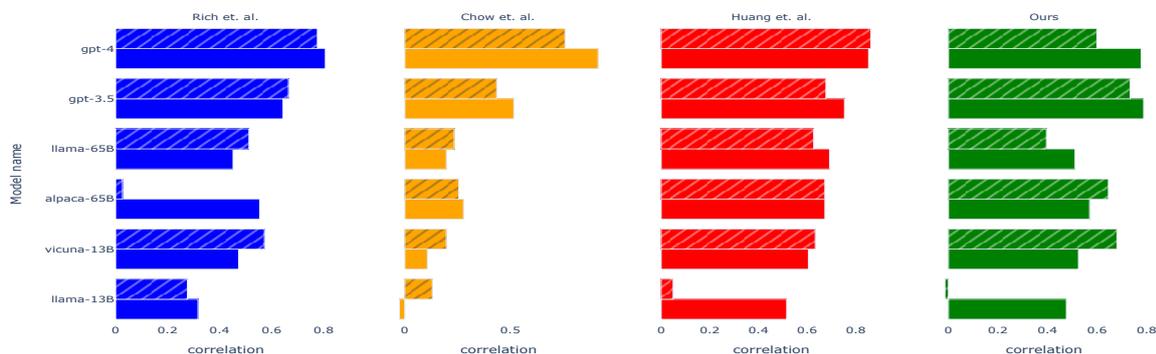

Figure 3: The correlation of the model that uses specific prompt when examples are included (full bar) versus when they are excluded (hatched bar).

around 0.8-0.9. Moreover, this correlation is typically just a few points under the split-half correlation.

Table 2 also shows that GPT-4 is a strong and robust baseline for human judgements, since it achieves the highest correlation in almost all the setups. When using our dataset with global prompts, the best model is GPT-3.5, where GPT-4 is slightly behind with a correlation of 0.761.

Finally, the results suggest an advantage to the specific prompt, with the highest correlation achieved by prompts with examples resembling the judged sentences for almost all datasets.

Next, we will further analyse the performance of the different models and the importance of having examples in the prompt.

### 3.1 Model breakdown

Figure 2 shows the Pearson correlation with the specific prompt for 7 selected models across our 4 datasets (Results for all models and for the global prompt are provided in Appendix B).

First, as previously evidenced in Table 2, GPT-4 is a strong baseline, with a high correlation with

human performance across all datasets. The other models from OpenAI also perform well, except on Chow et al. (2016) where a big drop in performance is noted for all the models that are not GPT-4. We conjecture that this is due to rarity of the syntactic structure of the sentences from Chow et al. (2016).

Figure 2 also shows that Alpaca and Vicuna have a better performance than LLaMa, their base model, at equivalent sizes, showing that instruction or chat fine-tuning improves correlation with human judgements.

Falcon-40B-Instruct is the best open source model, with performance comparable to text-davinci-003 model which is 4.5 times larger. Alpaca-65B, LLaMa-65B and Vicuna-13B also have a decent correlation with human judgements for the datasets with simple syntactic structures but perform poorly on data from Chow et al. (2016). The correlation of all the other open source models with human judgements is relatively low across all the datasets and is reported in Appendix B.

### 3.2 Importance of prompt examples

To analyze the importance of examples in the prompt, we ran experiments on a prompt that includes only the instruction, without examples, and compared its correlation to the correlation achieved with the specific prompt. Results for this experiment are in Figure 3.

Unsurprisingly, for most of the models and datasets, the prompt with examples has higher correlation with human judgments than the prompt without examples.

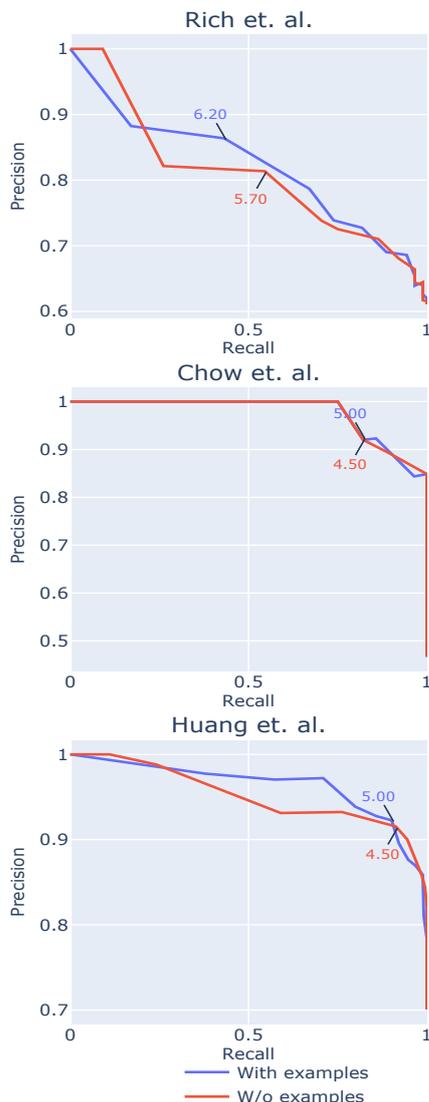

Figure 4: Recall-precision curve when filtering out implausible sentences. Blue is for the specific prompt, red is for the global prompt. We also mark for a few points the threshold value that results in a particular recall-precision result. For Chow et al. and Huang et al. we reach very high precision while keeping a large fraction of the sentences. For Rich et al. we can keep roughly half the sentences with precision of 0.8-0.9.

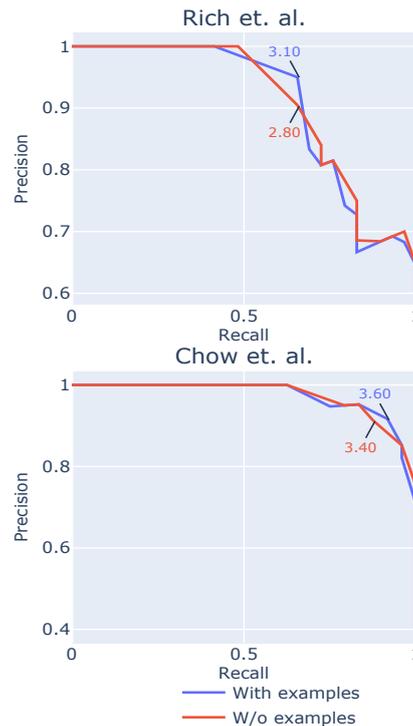

Figure 5: Recall-precision curve when filtering out plausible sentences. Blue is for the specific prompt, red is for the global prompt. We also mark for a few points the threshold value that results in a particular recall-precision result. In both setups, we can obtain very high precision while keeping most of the sentences.

### 3.3 Finetuning

One might hypothesize that finetuning the language model on a small amount of plausibility labels (in some labeled dataset) will lead to higher correlation in plausibility judgements overall.

To test that, we perform a simple fine-tuning experiment. We use GPT4, the model that demonstrated the highest correlation, and fine-tune it using the OpenAI fine-tuning API. We finetune GPT4 on 3 out of the 4 different datasets and then test it on the remaining dataset (using the prompt that contains four in-context examples).

As depicted in Table 3, fine-tuning does not appear to be beneficial when transferring to the target dataset, particularly for test sentences with highly unique structures. Notably, psycholinguistic experiments often involve sentences with distinctive structures, and fine-tuning GPT4 on data from other experiments may potentially impair downstream performance.

Data	ICL only	Finetuned	Diff.
Chow et al.	<b>0.916</b>	0.621	-0.295
Rich et al.	<b>0.806</b>	0.723	-0.083
Huang et al.	0.852	<b>0.883</b>	+0.031
Ours	<b>0.778</b>	0.525	-0.253

Table 3: Comparison of the Pearson correlations achieved with a fine-tuned GPT4 vs. a base GPT4 (using a prompt that contains in-context examples). In each line we finetune on three datasets and test on the remaining one.

## 4 Methodology

In §3, we saw significant correlation between plausibility judgments of humans and GPT-4. We now evaluate directly the performance of LLM judgments when replacing human judgements. Plausibility judgements can be used in different ways for constructing experimental materials.<sup>5</sup> Three common uses are: (a) filtering out implausible sentences by requiring a minimum average plausibility rating, (b) filtering out plausible sentences by requiring a maximum average plausibility rating, and (c) filtering out sentence pairs that have dissimilar average plausibility ratings. We evaluate the performance of LLMs across these operations.

### 4.1 Mapping LLM judgements to human judgements

We simulate using LLM judgements in two setups: (a) assuming no human ratings are collected, and (b) assuming a minimal amount of human ratings. We then evaluate the performance of LLMs with recall-precision curves, to see if we can achieve high precision (i.e., accepting only “good” sentences), while retaining high recall (i.e., keeping most of the ‘good’ sentences).

**No human ratings:** We collect LLM ratings from GPT-4 with the specific prompt. We then linearly map the LLM ratings into human ratings by fitting for every dataset a linear regression model on data from the other three datasets.

**With human ratings:** We assume access to a small amount of human ratings. Specifically, if  $D$  is the size of a dataset, we use human ratings for  $\max(0.1 \cdot D, 15)$  sentences. Then, we collect LLM

<sup>5</sup>In some cases, judgements are not used to control experimental materials, but are rather entered as predictors in the analysis of the main experiment, accounting for some of the variability.

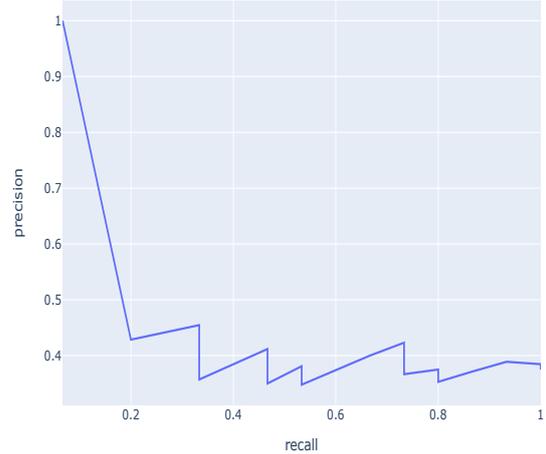

Figure 6: Recall-precision curve for classifying if a pair of sentences has different plausibility ratings.

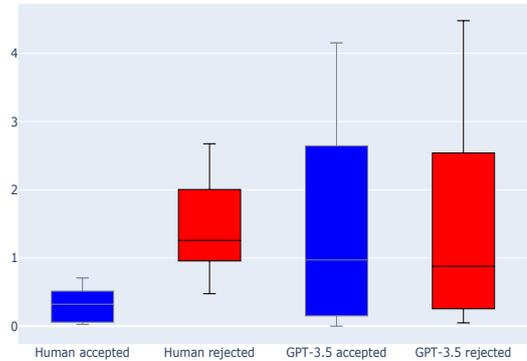

Figure 7: Difference between the average plausibility for pairs of sentences in our dataset. The blue boxes represent pairs that the t-test did not reject, the red represents pairs the t-test rejected.

ratings with different OpenAI models and prompts and select the model and prompt combination that leads to the highest correlation with human ratings. We can also learn a linear map from LLM ratings to human ratings with this small amount of data.

### 4.2 Filtering out implausible sentences

The first pretest use we discuss is filtering implausible sentences by rejecting sentences under a given threshold (e.g. 5, as in Huang et al. (2023)). We map LM ratings to human ratings with the linear regression model and then apply a threshold to filter out implausible sentences.<sup>6</sup>

<sup>6</sup>Since we evaluate with a recall-precision curve, the linear mapping is not necessary but is helpful for having the output label in a similar scale to humans.

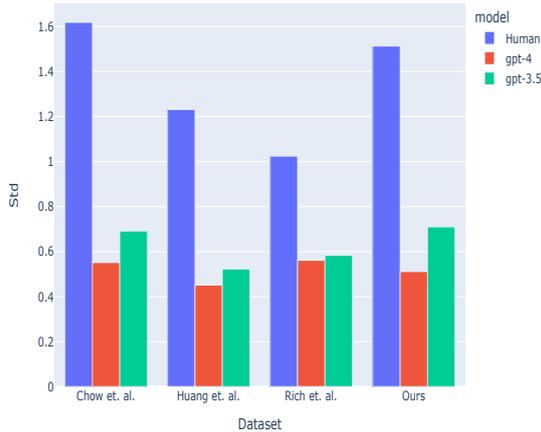

Figure 8: The average standard deviation of the judgments collected with the specific prompt for GPT-4 and GPT-3.5 along with the average standard deviation for human judgements.

Figure 4 shows recall-precision curves for the aforementioned datasets, varying the threshold for classifying a sentence as plausible (the positive class in the recall-precision curve is plausible sentences). Overall, GPT-4 exhibits high performance in this setup. For [Chow et al. \(2016\)](#) and [Huang et al. \(2023\)](#), we can achieve very high precision, while keeping most of the sentences. For [Rich and Wagers \(2020\)](#), performance is lower, but still we can cover roughly half the dataset with precision around 0.8-0.9. This aligns with the fact that this dataset has the lowest correlation with human judgments and includes rarer syntactic structures compared to the other two datasets.

### 4.3 Filtering out plausible sentences

The second pretesting scenario is the opposite of the first one – when the experiment requires implausible sentences, plausible sentences are filtered out by rejecting sentences with an average rating over some threshold (e.g. 3). We apply the same procedure for mapping LLM ratings to human ratings.

Figure 5 shows recall-precision curves for these datasets, varying the threshold for classifying a sentence as implausible (here the positive class are implausible sentences). We observe high performance overall, suggesting that predicting implausibility is easier than predicting plausibility.

### 4.4 Comparing plausibility of sentence pairs

The last pretest use we examine is comparing the plausibility of a pair of sentences and verifying that it is roughly similar. This is typically done by obtaining human ratings for both sentences, and running a t-test to check if the null hypothesis that they originate from the same underlying distribution is rejected, in which case the pair is filtered out.<sup>7</sup>

Using a t-test with LMs is non-trivial, because (as we discuss in §5) the variance in plausibility ratings for LMs is dramatically lower compared to humans, which in turn affects the t-test results. Instead, we propose to set a threshold for the difference between the average plausibility ratings of the two sentences, and examine if there exists a threshold for which we can reject/accept the same sentence pairs that are rejected/accepted using t-test with human ratings. Specifically, we will draw a recall-precision curve, where the positive class are sentence pairs accepted according to the human rating t-test.

We apply this method for our dataset, using *GPT-3.5-Turbo* with the *global* prompt, which obtained the highest correlation with human judgements (0.792). We find the performance is low – we are unable to find a point on the recall-precision curve where precision is high and recall is substantial. Figure 6 shows the recall-precision curve, and as is evident, precision quickly drops to around 0.4-0.45, and the maximal  $F_1$  obtained is 0.55, which is achieved when the difference between plausibility ratings is larger than 3.69.

To analyze this, we label each pair with its human-based gold label, and plot in Figure 7 the difference in average plausibility judgements for both humans and our LM. Clearly, the difference is a good discriminating feature for human ratings, but is a bad discriminating feature for the LM. This shows that while correlation between human ratings and LM ratings is high (0.792), it captures mostly coarse-grained structure, but is not powerful enough to make fine-grained distinctions like predicting if two sentences have the same level of plausibility. Moreover, when we measure the correlation between the difference in average plausibility ratings between humans and LMs, we find only a moderate Pearson correlation of 0.312.

<sup>7</sup>It is also possible to use cumulative link models ([Taylor et al., 2021](#)) to test the difference between sentences, but this is currently less common

## 5 Variance of Humans vs. LMs

Thus far, we saw that the average plausibility ratings of humans and LLMs correlate well. It is important to note that this is not the case w.r.t *variance*. Explicitly, human variance is much higher than the variance of LMs, despite the high temperature used for sampling, which is 1.5. Figure 8 shows the standard deviation for GPT-4 and GPT-3.5 on all the datasets when using the specific prompt, as well as the standard deviation for human judgements. Standard deviation for these LMs is dramatically lower than humans, i.e., we obtain relatively similar plausibility judgements when sampling multiple times from the model.

A possible theoretical explanation for this phenomenon is that the outputs of LMs can be viewed as an average over multiple samples, since pre-training is done on texts from many authors. Thus, when sampling plausibility ratings from a LM, we are sampling from an average of plausibility ratings. Let each human rating  $r_i$  be a sample from a distribution with mean  $\mu$  and variance  $\sigma^2$ . We can view each sample from a LM as an average of  $N$  human ratings:  $\frac{1}{N} \sum_{i=1}^N r_i$ . This is a random variable with mean  $\mu$  and variance  $\frac{\sigma^2}{N}$ . This observation can be used to estimate for a particular sentence what is the number  $N$  of humans that the LM is averaging over, by computing the ratio between the observed variance of humans and the observed variance of the LM for that sentence.

## 6 Conclusion

We investigate the correlation between plausibility judgements of humans and language models and find high correlation for simple syntactic structures overall, and high correlation throughout for GPT-4. We show language models can be used to provide coarse-grained plausibility judgements, which can reduce the cost of and accelerate psycholinguistic research. We view this work as a first step in this direction, where future work can improve the correlation through finetuning and prompt engineering and further investigate the utility of language models for conducting psycholinguistic research.

## 7 Future work and Limitations

While this study represents an initial exploration into the feasibility of employing LLMs for psycholinguistic pretesting, we acknowledge that the

primary advantage of LLM use might lie in low-resource or less widely spoken languages, where recruiting human labelers might be challenging. That interesting question, though not covered in this paper, presents a significant avenue for future research.

As shown in Section 4, sentences judged as plausible by the model may not align with human judgments. Setting the threshold significantly influences the percentage of accepted data that humans might disagree with. It is at the researcher’s discretion to determine the acceptable level noise to include in their experiment.

## Acknowledgements

We would like to thank Ori Yoran for help in formulating the original idea. We would like to thank Tal Ness, Wing-Yee Chow, Cybelle Smith, Ellen F. Lau, Colin Phillips, Kuan-Jung Huang, Suhas Arehalli, Mari Kugemoto, Christian Muxica, Grusha Prasad, Brian Dillon, Tal Linzen, Stephanie Rich and Matt Wagers for open sourcing their sentences and the pretesting results on them. This research was supported by the Tel Aviv University Center for AI and Data Science (TAD). This work is part of Samuel Joseph Amouyal’s doctoral research.

## A Prompt examples

We experimented with various prompts, some specific for the syntactic structure under study and one **global** prompt meant to range over a wide array of syntactic structures and be general enough to capture all of them. We also experimented with a prompt without examples. The instructions remain the same across the prompts; the only changed elements are the examples.

In all the showcased prompts we show only 1 example per score.

### A.1 Global prompt

We created a prompt showcasing a variety of syntactic structures, in an attempt to create a general prompt that will be diverse enough to fit a large number of pretesting samples. There are at most 4 examples per score. Figure 9 shows an example of the prompt.

### A.2 Prompt for our data

For our data, we wrote a prompt using the specific syntactic structure used in the materials. There are at most 3 examples per score. Figure 10 shows a prompt with 1 example per score.

### A.3 Prompt for Chow et al.

For [Chow et al. \(2016\)](#) data, we wrote a prompt using the specific syntactic structure used in the materials. There are at most 3 examples per score. Figure 11 shows a prompt with 1 example per score.

### A.4 Prompt for Huang et al.

For [\(Huang et al., 2023\)](#), given the wide array of syntactic structures present in the data, we covered the different types of syntactic structures in the examples for each of the scores. There are at most 3 examples per score. Figure 12 shows a prompt with 1 example per score.

## B Full results

The correlation for all the models and the datasets are presented in Table 4.

You will read sentences and judge how natural they sound. You will need to judge, on a scale from 1 to 7, how natural/plausible the presented sentence sounds, and explain yourself shortly.

All presented sentences will be grammatically correct.

Important: you are encouraged to use the whole scale.

Here are some examples:

They spent their week-end at the beach, sipping iced tea.

The plausibility score is 6 (it is plausible that people would spend their week-end at the beach).

The farmer planted the fruits from which the seeds came.

The plausibility score is 3 (it's more likely to plant seeds than fruits).

The table occupied most of the space in the kitchen.

The plausibility score is 5 (it is a somewhat plausible situation, maybe it is a small kitchen).

Because he slept nine hours, he woke up completely exhausted.

The plausibility score is 1 (sleeping is not supposed to make you tired).

The policeman stopped the plane.

The plausibility score is 4 (it is a situation that might happen but is a bit unlikely).

The witness observed which policeman the robber had caught.

The plausibility score is 2 (in general, policemen catch robbers, not the other way around).

I'm so thirsty, can you please pour me a glass of water?

The plausibility score is 7 (it is highly plausible that someone thirsty would like to drink water).

The sentence:

The chef prepared the meal

The plausibility score is:

Figure 9: Example of a global prompt

You will read sentences and judge how natural they sound. You will need to judge, on a scale from 1 to 7, how natural/plausible the presented sentence sounds, and explain yourself shortly.

All presented sentences will be grammatically correct.

Important: you are encouraged to use the whole scale.

Here are some examples:

The librarian ordered the audio book.

The naturalness score is 5 (a librarian might order an audio book but in general they order physical books)

The farmer bought a ski.

The naturalness score is 2 (it is an unnatural/implausible situation)

The handyman repaired the car.

The naturalness score is 3 (it is a somewhat unnatural, handymen repair things in houses)

The barista prepared the cappuccino.

The naturalness score is 6 (it is likely that a barista would prepare a cappuccino)

The teacher scolded the shoe.

The naturalness score is 1 (it is really unnatural/implausible situation)

The policemen caught the thief.

The naturalness score is 7 (it is highly likely that policemen would try and catch a thief)

The cook prepared the cocktail.

The naturalness score is 4 (a cook might prepare a cocktail but it is a bit unlikely)

The sentence: The nurse fetched the intern. The plausibility score is:

Figure 10: Example of a prompt for our data

You will read sentences and judge how natural they sound. You will need to judge, on a scale from 1 to 7, how natural/plausible the presented sentence sounds, and explain yourself shortly.

All presented sentences will be grammatically correct.

Important: you are encouraged to use the whole scale.

Here are some examples:

The director recalled which scene the editor had cut.

The plausibility score is 6 (it is plausible that a director knows which scene has been cut from the movie).

The tour guide guessed which landmark the visitor had photographed.

The plausibility score is 5 (it is relatively plausible that a tour guide might guess which landmark a tourist might photograph).

The detective identified which officer the suspect had recognized.

The plausibility score is 4 (suspects might know some police officer and recognize them)

The zoologist noted which lion the antelopes had hunted.

The plausibility score is 1 (lions hunts antelopes, not the other way around).

The journalist revealed which lobbyist the politician had influenced.

The plausibility score is 3 (it can happen that politicians influence lobbyists but it's supposed to be the other way).

The accountant knew which employee the CEO had promoted.

The plausibility score is 7 (it is highly plausible that an accountant would know who got promoted since he handles the money).

The pilote remembered which plane the airline had represented.

The plausibility score is 2 (planes represent airlines in general, not the opposite).

The sentence:

The park ranger documented which eagle the hunter had shot.

The plausibility score is:

Figure 11: Example of a prompt for Chow et al.'s data

You will read sentences and judge how natural they sound. You will need to judge, on a scale from 1 to 7, how natural/plausible the presented sentence sounds, and explain yourself shortly.

All presented sentences will be grammatically correct.

Important: you are encouraged to use the whole scale.

Here are some examples:

The firefighter who was denied the transplant went to the moon.

The plausibility score is 2 (people really rarely go to the moon).

The prison guard, which the inmate despised, robbed a bank.

The plausibility score is 4 (a prison guard robbing a bank might happen but is unlikely).

The firefighters put out the fire.

The plausibility score is 7 (it is really plausible, the role of firefighters is to put out fires).

The mechanic fixed the problematic cars with his eyes closed.

The plausibility score is 1 (it is highly unlikely that a mechanic can fix cars without seeing).

The teacher left.

The plausibility score is 5 (it is a somewhat plausible situation, maybe the class is over).

The fish ate the sponge.

The plausibility score is 3 (it is somewhat unlikely that a fish would eat a sponge but it might happen).

The scientist showed that the invention worked well.

The plausibility score is 6 (it is plausible that a scientist would show the efficiency of an invention).

The sentence:

The new chef started.

The plausibility score is:

## Abstract

Aspect sentiment coherency is an intriguing yet underexplored topic in the field of aspect-based sentiment classification. This concept reflects the common pattern where adjacent aspects often share similar sentiments. Despite its prevalence, current studies have not fully recognized the potential of modeling aspect sentiment coherency, including its implications in adversarial defense. To model aspect sentiment coherency, we propose a novel local sentiment aggregation (LSA) paradigm based on constructing a differential-weighted sentiment aggregation window. We have rigorously evaluated our model through experiments, and the results affirm the proficiency of LSA in terms of aspect coherency prediction and aspect sentiment classification. For instance, it outperforms existing models and achieves state-of-the-art sentiment classification performance across five public datasets. Furthermore, we demonstrate the promising ability of LSA in ABSC adversarial defense, thanks to its sentiment coherency modeling. To encourage further exploration and application of this concept, we have made our code publicly accessible. This will provide researchers with a valuable tool to delve into sentiment coherency modeling in future research.

## 1 Introduction

Aspect-based sentiment classification (Pontiki et al., 2014, 2015, 2016) (ABSC) aims to identify sentiments associated with specific aspects within a text, as highlighted in several studies (Ma et al., 2017; Fan et al., 2018; Zhang et al., 2019; Yang et al., 2021). In this work, we make efforts to address an intriguing problem within ABSC that has been overlooked in existing research, i.e., “*aspect sentiment coherency*”, which focuses on modeling aspects that share similar sentiments. For instance, in the sentence “*This laptop has a lot of storage, and so does the battery capacity,*” where “*storage*”

and “*battery capacity*” aspects both contain positive sentiments. We show more examples of aspect sentiment coherency in Fig. 1 and the case study section.

The study of aspect sentiment coherency has not been investigated in existing research. Yet, some strides have been made on a similar topic, namely sentiment dependency. These approaches, featured in several studies (Zhang et al., 2019; Huang and Carley, 2019; Phan and Ogunbona, 2020), hypothesize that sentiments of aspects may be dependent and usually leverage syntax trees to reveal potential sentiment dependencies between aspects. However, sentiment dependency remains a somewhat ambiguous concept in the current research landscape. Furthermore, previous methods (Zhou et al., 2020; Zhao et al., 2020; Tang et al., 2020; Li et al., 2021a,a) tend to model context topological dependency (e.g., context syntax structure) rather than sentiment dependency directly. These techniques are resource-intensive and computation-intensive. Besides, they can suffer from token-node misalignment caused by conflicts in tokenization methods in syntax tree construction.

As a further contribution to current ABSC research, we propose aspect sentiment coherency learning and posit that modeling sentiment coherency can provide valuable insights. Modeling sentiment coherency often presents challenges for traditional ABSC methods due to the complexity of aspect sentiment coherency. To efficiently address the aspect sentiment coherency task, we shed light on a simple yet effective approach, namely local sentiment aggregation (LSA). More specifically, we introduce a local sentiment aggregation paradigm powered by three unique sentiment aggregation window strategies based on various aspect-based features to guide the modeling of aspect sentiment coherency. To comprehensively evaluate LSA, we conduct experiments for the aspect sentiment coherency extraction subtask and the tradi-

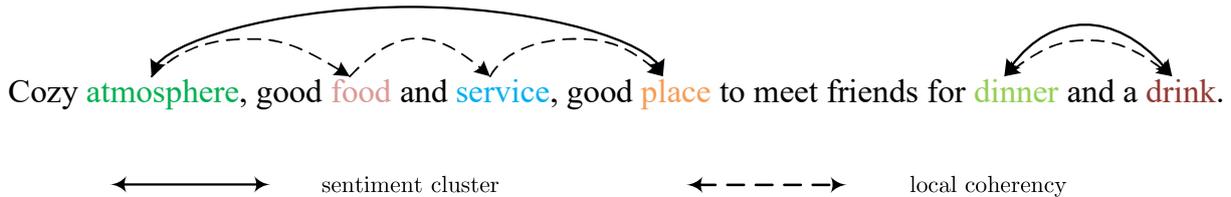

Figure 1: An example of aspect sentiment clusters and aspect sentiment coherency.

tional aspect sentiment classification subtask. Our experimental results indicate that these strategies significantly enhance sentiment coherency modeling. LSA achieves impressive performance in aspect sentiment coherency extraction and sentiment classification, setting new state-of-the-art results on five widely-used datasets based on the latest DeBERTa (He et al., 2021) model. Our work offers a new perspective on aspect-based sentiment analysis.

In conclusion, the main contributions of our work are as follows:

- **Formulation:** We highlight the existence of sentiment coherency in ABSC and formulate the aspect sentiment coherency modeling task. Besides, we introduce a local sentiment aggregation mechanism to address this task.
- **Method:** To implement the local sentiment aggregation mechanism, we introduce three strategies for constructing sentiment aggregation windows, demonstrating the effectiveness of our model in sentiment coherency modeling. We enhance this mechanism through differential weighted sentiment aggregation, allowing for dynamic adjustment of the aggregation window construction.
- **Evaluation:** According to our extensive experimental results, LSA achieve impressive aspect sentiment coherency prediction results. Besides, our ensemble LSA model also obtains state-of-the-art aspect sentiment classification performance on five public datasets.

The codes and datasets related to this work are open-sourced at <https://github.com/yangheng95/PyABSA>.

## 2 Sentiment Coherency

We first introduce the concept of sentiment coherency and then formulate two sentiment coherency patterns. In the review about a restaurant in Fig. 1, the reviewer expresses positive sentiments about the atmosphere, food, and service but remains neutral about dinner and drinks. This tendency to express similar sentiments about re-

lated aspects (e.g., atmosphere, food, and service) is what we refer to as *sentiment coherency*. We calculate the number of sentiment clusters across all experimental datasets to prove this is a common phenomenon. The statistics are available in Table 1.

Our aim is to study the extraction of aspect sentiment coherency and the improvement of ABSC performance by incorporating sentiment coherency. We formulate two sentiment coherency patterns in the following sections.

### 2.1 Aspect Sentiment Clusters

Consider the example in Fig. 1. We notice that similar sentiments about different aspects tend to stick together, which is called *sentiment cluster*. The formulation of aspect sentiment clusters is as follows:

$$\mathcal{C} = \{C_i \mid C_i = \{a_1, a_2, \dots, a_j\}\}, \quad (1)$$

where  $C_i$  is the  $i$ -th aspect sentiment cluster and  $a_j$  is the  $j$ -th aspect in  $C_i$ ,  $1 \leq j \leq m$ .  $m$  is the number of identified aspects in the sentence. Aspect sentiment clustering aims at concurrently predicting all sentiment clusters based on the provided aspects. Aspect sentiment clusters can be regarded as a coarse-grained manifestation of sentiment coherency. However, directly extracting these clusters can be quite challenging. We explain the challenges in the Appendix A. In consequence, we focus on asynchronous sentiment cluster prediction based on local sentiment coherency.

### 2.2 Local Sentiment Coherency

We propose “local coherency” to simplify the modeling of aspect sentiment cluster extraction. Local coherency utilizes the aspect features to predict the sentiment iteratively. Finally, the aspects with the same sentiments are aggregated to predict sentiment clusters. There are two advantages of local sentiment coherency modeling. First, it helps us infer the sentiment about an aspect even when it isn’t explicitly stated (e.g., deriving that the reviewer had a positive dining experience without saying it

outright). Second, it smooths out the sentiment predictions, reducing errors caused by random noise or adversarial attacks. As a result, we can have a more accurate understanding of sentiments.

Table 1: The statistics of aspect sentiment clusters. "Cluster size" indicates the number of aspects in clusters with different sizes.

Dataset	Cluster Size					Sum
	1	2	3	4	$\geq 5$	
Laptop14	791	799	468	294	614	2966
Restaurant14	1318	1050	667	479	1214	4728
Restaurant15	617	406	229	163	326	1741
Restaurant16	836	539	314	210	462	2361
MAMS	6463	2583	1328	746	1397	12517

### 3 Methodology

In this section, we propose a local sentiment aggregation method for sentiment cluster prediction, which is based on the local sentiment coherency pattern. We first introduce the implementation of local sentiment aggregation, which is based on sentiment window aggregation. Then, we present the aspect feature learning method used for sentiment aggregation window construction in Section 3.2. Finally, we describe the implementation details of our model.

#### 3.1 Local Sentiment Aggregation

To leverage local sentiment coherency, we extract the local sentiment information of each aspect and build a sentiment aggregation window (which will be clarified in Section 3.2) to aggregate coherent sentiments. In essence, the sentiment aggregation window is created by concatenating the feature representation of the aspect’s local sentiment information (i.e., aspect feature in the following sections). We propose three variants,  $LSA_P$ ,  $LSA_T$ , and  $LSA_S$ , to construct sentiment aggregation windows. Fig. 5 illustrates the architecture of  $LSA_P$ , while Fig. 2 presents the architecture of both  $LSA_T$  and  $LSA_S$ . The difference between  $LSA_T$  and  $LSA_S$  is in the aspect feature used for local sentiment aggregation.

#### 3.2 Aspect Feature Learning

Inspired by the existing studies, we employ the following aspect feature representations for local sentiment aggregation:

- Sentence pair-based (BERT-SPC) aspect feature (Devlin et al., 2019) (employed in  $LSA_P$ )

- Local context focus-based (LCF) aspect feature (Yang et al., 2021) (employed in  $LSA_T$ )
- Syntactical LCF-based (LCFS) based aspect feature (Phan and Ogunbona, 2020) (employed in  $LSA_S$ )

We also present an ensemble model ( $LSA_E$ ) that make use of the three variants of aspect-specific features.

##### 3.2.1 Sentence Pair-based Aspect Feature

A straightforward way to obtain aspect features is to utilize the BERT-SPC input format (Devlin et al., 2019), which appends the aspect to the context to learn aspect features. For example, let  $\mathcal{W} = \{[CLS], \{w_i^c\}_{i=1}^n, [SEP], \{w_j^a\}_{j=1}^m, [SEP]\}$  be the BERT-SPC format input,  $i \in [1, n]$  and  $j \in [1, m]$ , where  $w_i^c$  and  $w_j^a$  denote the token in the context and the aspect, respectively. A PLM (e.g., BERT) can learn the aspect feature because the duplicated aspects will get more attention in the self-attention mechanism (Vaswani et al., 2017). As it is shown in Fig. 5, we simply apply the sentiment aggregation to BERT-SPC-based aspect features. Note that we deploy a self-attention encoder before each linear layer to activate hidden states. We show the architecture of  $LSA_P$  in Fig. 5.

##### 3.2.2 Local Context-based Aspect Feature

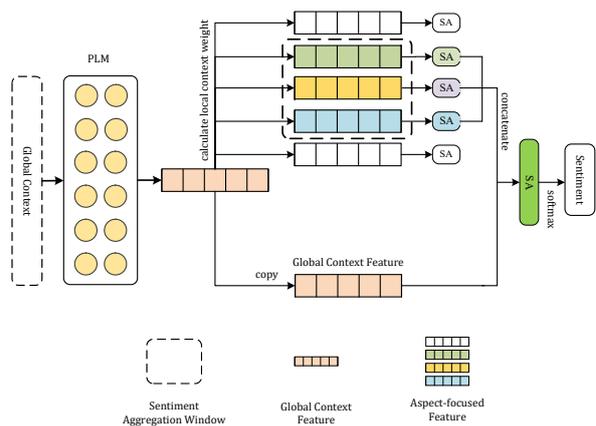

Figure 2: The local sentiment aggregation paradigm based on LCF/LCFS, denoted as  $LSA_T$  and  $LSA_S$ .

The second implementation of our model is referred to as  $LSA_T$ . The local context-based aspect feature is derived by position-wise weighting the global context feature, where the weights are calculated using the relative distance of token-aspect pairs. Let  $\mathcal{W} = \{w_1^c, w_2^c, \dots, w_n^c\}$  be the tokens after tokenization. We calculate the position weight

for token  $w_i^c$  as follows:

$$\mathbf{H}_{w_i^c}^* := \begin{cases} \mathbf{H}_{w_i^c}^c & d_{w_i^c} \leq \alpha \\ 1 - \frac{(d_{w_i^c} - \alpha)}{n} \cdot \mathbf{H}_{w_i^c}^c & d_{w_i^c} > \alpha \end{cases}, \quad (2)$$

where  $\mathbf{H}_{w_i^c}^*$  and  $\mathbf{H}_{w_i^c}^c$ ,  $i \in [1, n]$ , are the hidden states at the position of  $w_i^c$  in the aspect feature and global context feature, respectively.  $d_{w_i^c}$  is the relative distance between  $w_i^c$  and the aspect. We concatenate  $\mathbf{H}_{w_i^c}^*$  to obtain the aspect feature  $\mathbf{H}^*$ .  $\alpha = 3$  is a fixed distance threshold. If  $d_{w_i^c} \leq \alpha$ ,  $\mathbf{H}_{w_i^c}^c$  will be preserved; otherwise, it decays according to  $d_{w_i^c}$ .

In equation (2), the relative distance  $d_{w_i^c}$  between  $w_i^c$  and the aspect is obtained by:

$$d_{w_i^c} := \frac{\sum_{j=1}^m |p_i^c - p_j^a|}{m}, \quad (3)$$

where  $p_i^c$  and  $p_j^a$  are the positions of the  $w_i^c$  and  $j$ -th token in the aspect. As shown in Fig. 2, we take the global context feature as a supplementary feature to learn aspect sentiments.

### 3.2.3 Syntactical Local Context-based Aspect Feature

The final variant of our model is  $LSA_S$ , which adopts the syntax-tree-based local context feature to construct a sentiment aggregation window. The distance between the context word  $w_i^c$  and the aspect can be calculated according to the shortest node distance between  $w_i^c$  and the aspect in the syntax tree. To leverage the syntactical information without directly modeling the syntax tree,  $LSA_S$  calculates the average node distance between  $w_i^c$  and the aspect:

$$d_{w_i^c} = \frac{\sum_{i=j}^m dist(w_i^c, w_j^a)}{m}, \quad (4)$$

where  $dist$  denotes the shortest distance between the node of  $w_i^c$  and the node of  $w_j^a$  in the syntax tree; the calculation of  $\mathbf{H}_{w_i^c}^*$  follows  $LSA_T$ .

## 3.3 Sentiment Aggregation Window

The sentiment aggregation window consists of  $k$ -nearest aspect feature vectors. Given that most of the clusters are small, we only consider  $k = 1$  in this study:

$$\mathbf{H}_{aw}^o := [\{\mathbf{H}_k^l\}; \mathbf{H}^t; \{\mathbf{H}_k^r\}], \quad (5)$$

$$\mathbf{H}^o := W^o \mathbf{H}_{aw}^o + b^o, \quad (6)$$

where  $\mathbf{H}_{aw}^o$  is the feature representation learned by local sentiment aggregation; ";" denotes vector concatenation.  $\mathbf{H}_k^l$  and  $\mathbf{H}_k^r$  are the  $k$  nearest left and right adjacent aspect features, respectively.  $\mathbf{H}^t$  is the targeted aspect feature.  $\mathbf{H}_*$  is the representation learned by the sentiment aggregation window, and  $W^o$  and  $b^o$  are the trainable weights and biases.

### 3.3.1 Aggregation Window Padding

To handle instances with no adjacent aspects, we pad the sentiment aggregation window. Fig. 3 illustrates three padding strategies. Instead of zero

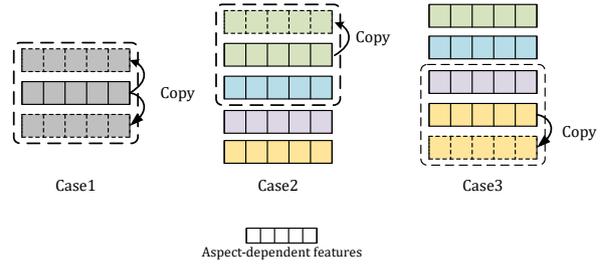

Figure 3: Window padding strategies for different situations.

vectors, we pad the window using the targeted aspect's feature to highlight the local sentiment feature of the targeted aspect and prevent the model's performance from deteriorating. Case #1 indicates a single aspect in the context, in which we triple the targeted aspect's feature to build the sentiment aggregation window. Case #2 and Case #3 duplicate the targeted aspect's feature to the left and right slots in the window, respectively.

### 3.3.2 Differential Weighted Aggregation

It is reasonable to assume that the importance of sentiment information from different sides may vary. Therefore, we introduce differential weighted aggregation (DWA) to control the contribution of sentiment information from the adjacent aspects on different sides. We initialize learnable  $\eta_l^*$  and  $\eta_r^*$  to 1 and optimize them using gradient descent. The differential weighted sentiment aggregation window is obtained as follows:

$$\mathbf{H}_{dwa}^o := [\eta_l^* \{\mathbf{H}_k^l\}; \mathbf{H}^t; \eta_r^* \{\mathbf{H}_k^r\}], \quad (7)$$

where  $\mathbf{H}_{dwa}^o$  is the aggregated hidden state learned by the differential weighted aggregation window.

## 3.4 Output Layer

For sentence pair-based sentiment aggregation, we simply apply pooling and softmax to predict the

sentiment likelihood. For the local context feature-based sentiment aggregation, we adhere to the original approach of combining the global context feature and the learned feature to predict sentiment polarity as follows:

$$\mathbf{H}^{out} := W^d[\mathbf{H}^o; \mathbf{H}^c] + b^d, \quad (8)$$

where  $\mathbf{H}^{out}$  is the output hidden state;  $\mathbf{H}^o$  and  $\mathbf{H}^c$  are the features extracted by a PLM (e.g., DeBERTa). We use the feature of the first token (also known as the head pooling) to classify sentiments:

$$\hat{y} := \frac{\exp(\mathbf{h}^{head})}{\sum_1^{\tilde{C}} \exp(\mathbf{h}^{head})}, \quad (9)$$

where  $\mathbf{h}^{head}$  is the head-pooled feature;  $\tilde{C}$  is the number of polarity categories.  $W^d \in \mathbb{R}^{1 \times \tilde{C}}$ ,  $b^d \in \mathbb{R}^{\tilde{C}}$  are the trainable weights and biases.  $\hat{y}$  is the predicted sentiment polarity.

### 3.5 Training Details

The variants of our model based on different PLMs are denoted as LSA-BERT, LSA-RoBERTa, LSA-DeBERTa, etc. LSA-X-DeBERTa represents our model based on the large version of PLM<sup>1</sup>.

We train our model using the AdamW optimizer with the cross-entropy loss function:

$$\mathcal{L} = - \sum_1^{\tilde{C}} \hat{y}_i \log y_i + \lambda \|\Theta\|_2 + \lambda^* \|\eta_l^*, \eta_r^*\|_2, \quad (10)$$

where  $\lambda$  is the  $L_2$  regularization parameter;  $\Theta$  is the parameter set of the model. As we employ gradient-based optimization for  $\eta_l^*$  and  $\eta_r^*$ , we also apply a  $L_2$  regularization with  $\lambda^*$  for  $\eta_l^*$  and  $\eta_r^*$ .

## 4 Experiments

In this section, we introduce the settings of our experiments and report the experimental results. We report all implementation details in the appendix, e.g., hyperparameter settings (Appendix 4.2), baseline introduction (Appendix 4.3) and additional experiments, etc.

### 4.1 Datasets

To evaluate the efficacy of the local sentiment aggregation, we conducted experiments on

<sup>1</sup><https://huggingface.co/microsoft/deberta-v3-large>

five popular ABSC datasets <sup>2</sup>: Laptop14, Restaurant14, Restaurant15 and Restaurant16 datasets, and MAMS dataset (Jiang et al., 2019), respectively. The statistics of these datasets are shown in Table 2.

Table 2: The statistics of all datasets used in our experiments. Note that in our experiments, only the MAMS dataset has a validation set.

Datasets	Positive		Negative		Neutral	
	Train	Test	Train	Test	Train	Test
Laptop14	994	341	870	128	464	169
Restaurant14	2164	728	807	196	637	196
Restaurant15	909	326	256	180	36	34
Restaurant16	1240	468	437	117	69	30
MAMS	3379	400	2763	329	5039	607

### 4.2 Hyperparameter Settings

We introduce the hyperparameter settings in fine-tuning experiments.

- We set  $k = 1$  in sentiment aggregation window construction.
- The learning rate for pre-trained models (e.g., BERT and DeBERTa) is  $2 \times 10^{-5}$ .
- The learning rates for  $\eta_l^*$  and  $\eta_r^*$  are both 0.01.
- The batch size and maximum text modeling length are 16 and 80, respectively.
- The  $L_2$  regularization parameters  $\lambda$  and  $\lambda_*$  are both  $10^{-5}$ .

We conduct experiments based on multiple PLMs. We implement our model based on the transformers: <https://github.com/huggingface/transformers>.

### 4.3 Baselines

In our comparative analysis, we evaluate the performance of LSA in relation to several state-of-the-art ABSC models, many of which are syntax-based methods. These models include SK-GCN-BERT (Zhou et al., 2020), which utilizes graph convolutional networks (GCN) to incorporate syntax and commonsense information for sentiment learning. DGEDT-BERT (Tang et al., 2020) is a dual-transformer-based network enhanced by a dependency graph, while SDGCN-BERT (Zhao et al., 2020) is a GCN-based model designed to capture sentiment dependencies between aspects. Dual-GCN (Li et al., 2021a) is an innovative

<sup>2</sup>We evaluate LSA on the Twitter (Dong et al., 2014) dataset and report the experimental results in Section C.5. The processed datasets are available with the code in supplementary materials.

GCN-based model that enhances the learning of syntax and semantic features.

Additionally, we include models improved by Dai et al. (2021), such as RGAT-ROBERTa, PWCN-ROBERTa, and ASGCN-ROBERTa, which leverage ROBERTa to induce syntax trees that align with ROBERTa’s tokenization strategy. TGCN-BERT (Tian et al., 2021) introduces a type-aware GCN that uses an attention mechanism to measure the importance of each edge in the syntax structure graph. SARL-ROBERTa (Wang et al., 2021) employs adversarial training to mitigate sentiment bias and align aspects with opinion words using span-based dependency. Finally, dotGCN-BERT (Chen et al., 2022), SSEGCN-BERT (Zhang et al., 2022), and TGCN-BERT (Li et al., 2021a) are also included in our comparison. These models represent the current landscape of ABSC research, allowing us to assess the effectiveness of LSA against well-established approaches.

We do not compare with Cao et al. (2022) because we fail to find the source code of their model.

## 4.4 Main Results

We report sentiment coherency modeling performance and sentiment classification performance in this section.

Table 3: The exact match score (EM) of sentiment cluster prediction on five public datasets. The best results are highlighted in **bold** font. Rest14, Rest15 and Rest16 indicate Restaurant14, Restaurant15 and Restaurant16, respectively.

Model	Laptop14	Rest14	Rest15	Rest16	MAMS
	EM	EM	EM	EM	EM
BERT	75.08	78.75	80.00	87.60	79.26
DeBERTa	79.61	83.88	84.05	89.72	81.16
LSA <sub>P</sub> -BERT	78.14	82.24	82.76	88.96	82.35
LSA <sub>T</sub> -BERT	78.06	82.96	82.66	90.02	82.46
LSA <sub>S</sub> -BERT	78.63	83.09	83.30	88.75	82.73

LSA <sub>T</sub> -DeBERTa	81.96	86.26	87.03	91.72	83.38
LSA <sub>S</sub> -DeBERTa	82.94	85.90	87.13	91.87	83.92
LSA <sub>E</sub> -DeBERTa	<b>83.73</b>	<b>86.53</b>	<b>87.91</b>	<b>92.57</b>	<b>84.12</b>

### 4.4.1 Cluster Prediction Performance

We utilize LSA to classify aspect sentiments and aggregate the sentiment clusters. The cluster prediction performance in Table 3 shows that our models consistently outperform the baseline models on all datasets. The performance of LSA is dependent on the base model. It is observed that the sentiment clusters predicted by LSA are very close to the ground truth, which demonstrates the effectiveness

of our models in modeling sentiment coherency. The small clusters (e.g., clusters containing 1 or 2 aspects) are more easy to predict, while the large clusters (e.g.,  $\geq 3$ ) are more difficult to predict.

### 4.4.2 Sentiment classification performance

When it comes to sentiment classification performance, the results in Table 4 clearly demonstrate the superiority of our models over significant baselines, particularly in the case of the LSA<sub>E</sub> model. The experimental results are as expected and show the proficiency of LSA.

One of the primary concerns associated with LSA is its occasional inability to outperform certain baselines based on the BERT model. We attribute this observation to two main reasons. Firstly, LSA is a quite simple mechanism and relies on relatively basic aspect features to construct sentiment aggregation windows, which may not be as competitive as state-of-the-art methods that employ more complex features. Secondly, the current sentiment aggregation window, although intuitive, may not be perfect and could potentially lead to the loss of some sentiment information. Nevertheless, the performance of the three LSA variants may not consistently surpass some baselines, our models offer notable advantages in terms of efficiency and ease of integration with existing models. With the improvement in the base model’s performance (e.g., DeBERTa, DeBERTa-Large), LSA achieves impressive results across all datasets. Furthermore, it’s worth noting that methods such as ASGCN-ROBERTa, RGAT-ROBERTa, and PWCN-ROBERTa, while showing promising improvements, come at the cost of significantly higher resource requirements compared to other models.

In summary, LSA presents a compelling choice for a trade-off between performance and resource efficiency with the potential to be integrated into existing models with minimal effort.

## 4.5 Practice in Adversarial Defense

Recent works have highlighted the threat of textual adversarial attacks (Xing et al., 2020) as critical threats. In this section, we embark on a pioneering exploration of LSA’s capabilities, focusing on its ability to defend against adversarial attacks in ABSC. To evaluate the robustness of LSA in the face of these attacks, we employ existing adversarial attack datasets, specifically Laptop14-ARTS and Restaurant14-ARTS.

Table 4: The traditional aspect sentiment classification performance on five public datasets, and the best results are heightened in **bold font**. † indicates the results are the best performance in multiple runs, while other methods report the average performance. ‡ indicates the experimental results of the models implemented by us.

Table 5: Performance comparison of different models for adversarial defense on the Laptop14-ARTS and Restaurant14-ARTS datasets. The adversarial datasets are from Xing et al. (2020).

Model	Laptop14-ARTS		Restaurant14-ARTS	
	Acc	F1	Acc	F1
BERT	63.98	56.11	72.01	65.62
DeBERTa	67.71	65.60	74.97	66.48
LSA <sub>P</sub> -BERT	72.31	68.94	78.06	70.23
LSA <sub>T</sub> -BERT	72.12	68.05	77.57	70.72
LSA <sub>S</sub> -BERT	70.88	65.98	77.99	71.01
LSA <sub>E</sub> -BERT	<b>74.32</b>	<b>69.57</b>	<b>78.41</b>	<b>72.04</b>
LSA <sub>P</sub> -DeBERTa	73.34	68.46	81.19	72.54
LSA <sub>T</sub> -DeBERTa	73.58	69.28	80.31	71.37
LSA <sub>S</sub> -DeBERTa	72.31	67.03	79.13	71.82
LSA <sub>E</sub> -DeBERTa	<b>74.47</b>	<b>69.79</b>	<b>81.55</b>	<b>72.95</b>

The results presented in Table 5 serve as a testament to the superior performance of our models when compared to the baseline models, i.e., BERT and DeBERTa. Notably, when considering the DeBERTa-based models, LSA<sub>P</sub>-DeBERTa, LSA<sub>T</sub>-DeBERTa, and LSA<sub>S</sub>-DeBERTa consistently outperform the baselines, underscoring the robustness of LSA in defend against adversarial attack.

#### 4.6 Ablation Study

In this section, we study how gradient-based aggregation window optimization influences LSA. We begin by presenting the trajectory of  $\eta_l^*$  and  $\eta_r^*$  during the training process, as depicted in Fig. 4, which illustrates how LSA dynamically constructs the optimal window. This observation suggests that

the model initially prioritizes the side aspects during early training stages, gradually shifting focus towards the central aspects. To further investigate the impact of gradient-based aggregation window optimization, we conduct a comparative analysis by evaluating LSA’s performance with and two ablated models without DWA. Specifically, we assess the model’s performance when employing fixed static weights  $\eta_l$  and  $\eta_r$  to create sentiment aggregation windows, as opposed to the DWA. The experimental results provided in Fig. 6 demonstrate a consistent performance drop when DWA is omitted. In most scenarios, we observe a modest yet notable improvement of approximately 0.2% to 0.5% when DWA is incorporated into our model. We also present the experimental results for an ablated version of LSA featuring a simplified sentiment aggregation window in Table 10. This comparison underscores the superior performance of LSA with DWA over its simplified counterpart. Consequently, we can conclude that gradient-based aggregation window optimization proves effective in facilitating implicit sentiment learning.

#### 4.7 Case Study

In this section, we delve into a case study to validate the capability of our model in learning local sentiment coherency. We present a series of examples in Table 6, which showcase instances where LSA excels in identifying aspect sentiment coherency.

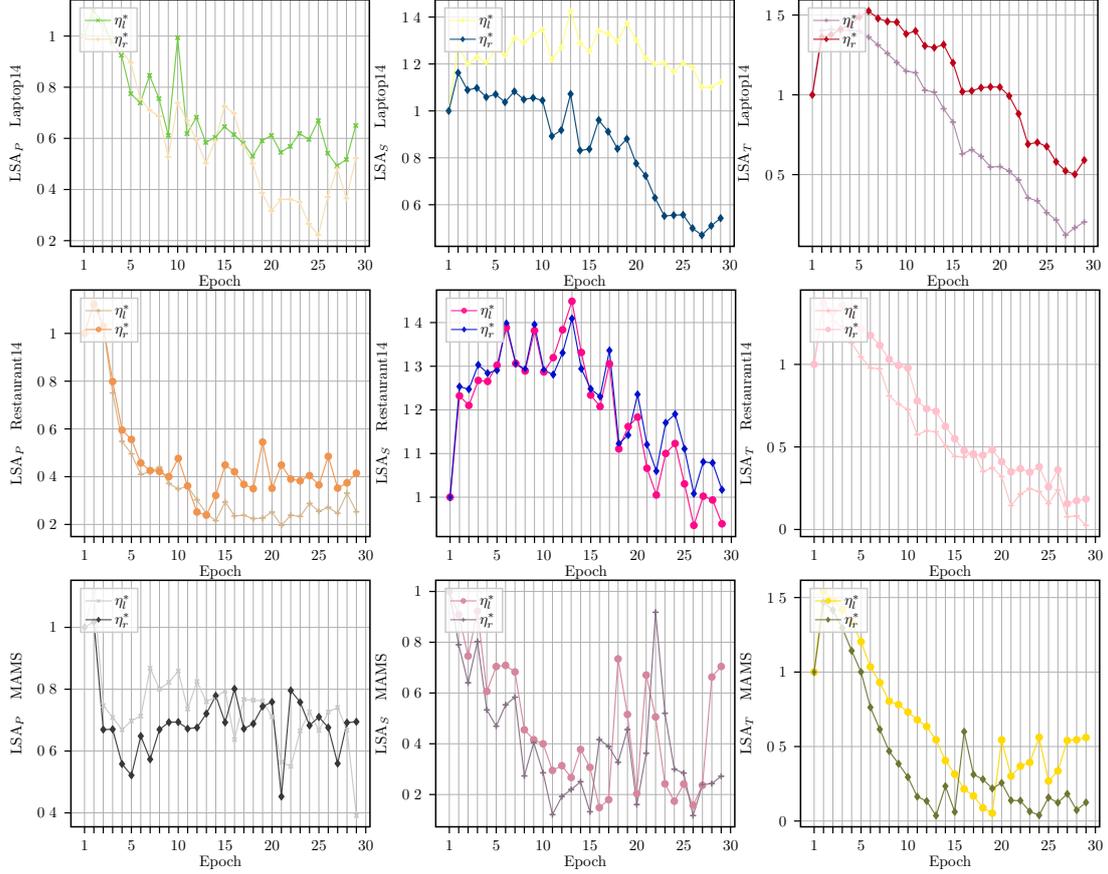

Figure 4: Trajectory visualization of learnable weights in gradient-based sentiment aggregation window optimization.

Table 6: The examples for aspect sentiment coherency found by LSA. The target aspects are denoted in **bold** and the underlined words indicates the aspects with coherent sentiments. “Pos”, “Neg” and “Neu” represent positive, negative and neutral, respectively.

No.	Domain	Examples	Model	Prediction
1	Restaurant	Not only was the <b>food</b> <u>outstanding</u> , but also the <b>coffee</b> and <b>juice</b> !	LSA <sub>P</sub> -BERT	Pos(Pos) ✓, Pos(Pos) ✓
		Not only was the <b>food</b> <u>terrible</u> , but also the <b>coffee</b> and <b>juice</b> !	LSA <sub>P</sub> -BERT	Neg(Neg) ✓, Neu(Neg) ✗
2	Restaurant	The servers always <b>surprise</b> us with a different <b>starter</b> .	LSA <sub>S</sub> -BERT	Pos(Pos) ✓
		The servers always <b>temporize</b> us with a different <b>starter</b> .	LSA <sub>S</sub> -BERT	Neg(Neg) ✓
3	TV	The speakers of this TV is <b>great</b> ! Just like its <b>screen</b> .	LSA <sub>T</sub> -DeBERTa	Pos(Pos) ✓
		The speakers of this TV <b>sucks</b> ! Just like its <b>screen</b> .	LSA <sub>T</sub> -DeBERTa	Neg(Neg) ✓
4	Camera	If you are worried about <b>usability</b> , think about the <b>quality</b> !	DeBERTa	Neu(Pos) ✗
		If you are worried about <b>usability</b> , think about it good <b>quality</b> !	DeBERTa	Pos(Pos) ✓

These examples offer compelling evidence of the effectiveness of our model, as compared to a baseline LSA model (DeBERTa). For instance, in example #4, the DeBERTa model produces two inference errors in recognizing coherent sentiments, while all our model variants based on the DeBERTa model yield correct results. Furthermore, LSA<sub>P</sub>, LSA<sub>T</sub>, and LSA<sub>S</sub> models demonstrate remarkable robustness in handling perturbed examples that involve local sentiment coherency. While it is challenging to present a comprehensive list of sentiment cluster

prediction examples, the consistent observations obtained in these experiments align with those in Table 6. Based on these experimental results, we confidently assert the model’s proficiency in learning sentiment coherency within ABSC.

## 5 Discussions

### 5.1 How can LSA help to existing methods?

The primary function of LSA lies in aggregating aspect features based on local sentiment coherency. Thanks to its straightforward implementation, integrating LSA into existing models is a seamless process. In practice, once aspect features have been extracted using any existing methods, LSA can be effortlessly applied to extract aspect sentiment clusters, enhancing the overall performance of aspect sentiment classification.

A simple yet effective way to incorporate LSA into existing models involves removing their output layer and passing the learned feature representations of adjacent aspects to LSA. Subsequently, LSA can construct the sentiment aggregation window and derive the weights for each aspect feature using the Differential Weighted Aggregation

(DWA) method.

## 5.2 How does LSA works on adverse sentiment aggregation?

In this section, we justify why LSA works for adjacent but inconsistent sentiment. It is intuitively that not all aspect sentiments in adjacent positions are similar but sometimes be opposite. However, LSA learns to discriminate whether they share similar sentiments based on the training data. If no local sentiment coherency is detected, LSA learns a weight close to 0 to the feature of adjacent aspects in the DWA.

We have conducted experiments on a sub-dataset extracted from the MAMS dataset that only includes both marginal aspects in clusters, denoted as `Margin` dataset. We evaluate the sentiment prediction accuracy of aspects near inconsistent sentiment clusters. The results are available in Table 7, and the performance of classifying margin aspects is still comparable to global performance in Table 4, indicating that differentiated weighting for LSA effectively mitigates the challenge of adverse sentiment aggregation.

Table 7: The performance of sentiment predictions for margin aspects in various models on the MAMS dataset.

Model	Margin		MAMS	
	Acc	F1	Acc	F1
LSA <sub>p</sub> -DeBERTa	83.49	82.71	<b>83.91</b>	<b>83.31</b>
LSA <sub>r</sub> -DeBERTa	82.58	81.79	<b>84.28</b>	<b>83.70</b>
LSA <sub>s</sub> -DeBERTa	<b>83.87</b>	<b>83.11</b>	83.61	83.07

## 6 Related Works

The related works in this field can be broadly divided into three categories: sentiment dependency-based methods, sentiment coherency modeling, and implicit sentiment learning.

Although sentiment coherency is prevalent in ABSC, it has received limited attention in recent years. However, the progress of sentiment dependency-based methods, such as the work by Zhang et al. (2019); Zhou et al. (2020); Tian et al. (2021); Li et al. (2021a); Dai et al. (2021), has contributed to the improvement of coherent sentiment learning. These studies explored the effectiveness of syntax information in ABSC, which mitigates issues related to sentiment coherency extraction.

For refining syntax structure quality in sentiment dependency learning, Tian et al. (2021) employ type-aware GCN to distinguish different relations in the graph, achieving promising results.

Similarly, Li et al. (2021a) propose `SynGCN` and `SemGCN` for different dependency information. `TGCN` model alleviates dependency parsing errors and shows significant improvement compared to previous GCN-based models. Despite the aforementioned advances, transferring the new techniques proposed in these studies is not straightforward. Dai et al. (2021) propose employing the pre-trained `RoBERTa` model to induce trees for ABSC, effectively solving the node alignment problem. However, the efficiency of inducing trees needs improvement.

Compared to coarse-grained implicit sentiment research (de Kauter et al., 2015; Zhou et al., 2021; Liao et al., 2022; Zhuang et al., 2022), the aspect’s implicit sentiment learning in ABSC remains challenging. LSA leverages coherency to aggregate implicit sentiments efficiently. Some researchers have formulated tasks aimed at modeling implicit sentiments and opinions. For instance, Cai et al. (2021) proposed a quadruple extraction task (aspect, category, opinion, and sentiment), while Muradha et al. (2022) proposed a unified framework that crafts auxiliary sentences to aid implicit aspect extraction and sentiment analysis. In contrast to these works, LSA sidesteps the efficiency bottleneck of syntax modeling by eliminating structure information and proves to be adaptable to existing methods as it is a transferable paradigm independent of base models. Li et al. (2021b) presents a supervised contrastive pre-training mechanism to align the representation of implicit sentiment and explicit sentiment. However, it relies on fine-tuning a large-scale sentiment-annotated corpus from in-domain language resources, which may be resource-intensive and inefficient.

## 7 Conclusion

Aspect sentiment coherency has been overlooked in existing studies. We introduced the concept of LSA, a novel approach that brings the nuance of local sentiment coherency into the foreground of ABSC. LSA achieves state-of-the-art performance when combined with various aspect-specific features, especially based on the `DeBERTa` models. Furthermore, we also introduce a practice of LSA in the realm of adversarial defense. We hope that our work will inspire further research into sentiment coherency modeling in the future.

## 8 Limitations

Although LSA achieves impressive performance for multiple-aspects situations, e.g., SemEval-2014 datasets. However, while being applied in mono aspect situations, such as the Twitter dataset, LSA degenerates to be equivalent to a prototype model, e.g., the local context focus model.

Another limitation is that LSA is a quite simple mechanism and relies on relatively basic aspect features to construct sentiment aggregation windows, which may not be as competitive as state-of-the-art methods that employ more complex features. Besides, the current sentiment aggregation window is intuitive but may not be perfect and could potentially lead to the loss of some sentiment information. In the future, we will explore more advanced sentiment aggregation windows to improve the performance of LSA.

## A Challenges of Aspect Sentiment Cluster Extraction

The challenges of concurrent aspect sentiment cluster extraction can be summarized in the following three aspects:

- **Data Annotation:** Currently, there is no existing aspect cluster dataset in the literature since addressing sentiment coherence is a novel topic. Re-annotating cluster data and labels presents a significant challenge, and modeling these clusters is notably more complex when contrasted with local sentiment coherence aggregation.
- **Data Insufficiency:** Even after completing the data re-annotation process, the clusters within the datasets might still be insufficient for effectively training the model.
- **Modeling Difficulty:** Cluster mining is a hard task compared to text classification, but it is worth studying in the near future.

## B Implementation Details

### B.1 Model Architecture

We show the brief architecture of  $LSA_P$  (based on the BERT-SPC input format) in Fig. 5. The input of  $LSA_P$  is the same as BERT-SPC, which is a sequence of tokens with the aspect marked by the [ASP] token.

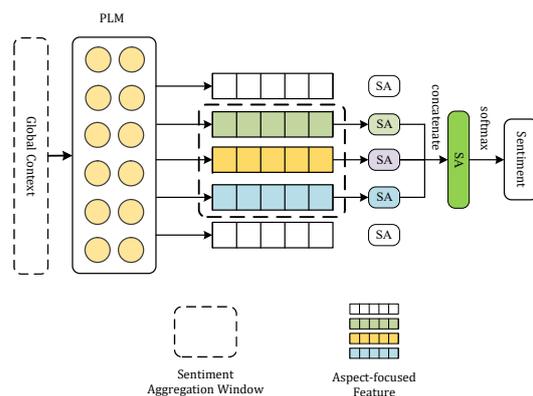

Figure 5: The local sentiment aggregation paradigm based on BERT-SPC, denoted as  $LSA_P$ . “SA” indicates the self-attention encoder.

## C Additional Experimental Results

### C.1 Resource Occupation of LSA

The experiments are based on RTX2080 GPU, AMD R5-3600 CPU with PyTorch 1.9.0. The orig-

inal size of the `Laptop14` and `Restaurant14` datasets are `336kb` and `492kb`, respectively.

Table 8: The resources occupation of state-of-the-art ABSC models. “Proc.T.” and “Add.S.” indicate the dataset pre-processing time (sec.) and additional storage occupation (MB), respectively. “\*” represents non-syntax tree based models, and “†” indicates our models.

Model	Laptop14		Restaurant14	
	Proc.T.	Add.S.	Proc.T.	Add.S.
BERT-BASE *	1.62	0	3.17	0
LCF-BERT *	2.89	0	3.81	0
ASGCN-BERT	13.29	0.01	0.02	9.4
RGAT-BERT	<b>35.4k</b>	157.4	<b>48.6k</b>	188
<b>LSA<sub>T</sub></b> -BERT*†	3.16	0	4.32	0
<b>LSA<sub>S</sub></b> -BERT*†	20.56	0	30.23	0
<b>LSA<sub>P</sub></b> -BERT*†	0.20	0	0.32	0

## C.2 Experiment of Static Weighted Sentiment Aggregation

Besides the dynamic sentiment window differential weighting, we also try static weight to control the contribution of adjacent aspects’ sentiment information. We first initialize  $\eta_l, \eta \in [0, 1]$ , for the left-adjacent aspects, while  $\eta_r = 1 - \eta_l$ . In this case, a greater  $\eta_l$  means more importance of the left-adjacent aspect’s feature and vice versa. However, it is difficult to search for the optimal static weights for many scenarios via grid search. We even found that the performance trajectory is non-convex while  $\eta_l \in [0, 1]$ , indicating the  $\eta_l$  on a dataset will be difficult to reuse on another dataset. Fig. 6 shows the performance curve of LSA based on DeBERTa under different  $\eta_l$ .

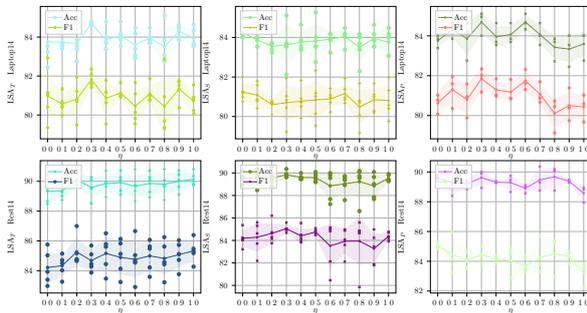

Figure 6: Visualization of performance under static differential weighting.

In other words, static differential weighting is inefficient and unstable. We recommend applying an automatic weights search to find a better construction strategy for the sentiment window.

## C.3 Clarification of Hyper-parameter “k” Setting

In this work, all experiments are implemented with  $k = 1$ . The term “ $k = 1$ ” indicates that we only consider one-hop adjacent aspects for learning sentiment coherency. When  $k = 2$ , LSA will consider five aspects in the sentiment aggregation windows. This setting performs well for handling sentiment clusters containing fewer than five aspects ( $k = 2$ ). We did not conduct an ablation study of  $k$  because the clusters in most datasets are not very large, and efficiency could be a problem. Below, we show the ratio of clusters with fewer than 5 aspects versus those with 5 or more aspects. It is observed that only a few sentiment clusters contain more than five aspects. Additionally, efficiency significantly decreases when the sentiment aggregation window increases to 5 (i.e.,  $k = 2$ ).

Table 9: The proportion of aspect clusters with different sizes in different public ABSC datasets.

Dataset	Cluster Size < 5	Cluster Size $\geq 5$
	Acc	Acc
Laptop14	79.30	20.70
Restaurant14	74.32	25.68
Restaurant15	81.28	18.72
Restaurant16	80.43	19.57
MAMS	88.84	11.16

## C.4 Experiment of Simplified Sentiment Aggregation Window

To investigate the necessity of bidirectional aggregation, we assess the effectiveness of the streamlined aggregation window. We simply concatenate the left or right adjacent aspect’s feature with the targeted aspect’s feature and then change the output layer to accommodate the new feature dimension of the simplified aggregation window.

Table 10: The average performance deviation of ablated LSA baselines. “LA” and “RA” indicates the simplified aggregating window constructed only exploits the left-adjacent aspect or right-adjacent aspect, respectively.

Model	Laptop14		Restaurant14	
	Acc	F1	Acc	F1
<b>LSA<sub>P</sub></b> -DeBERTa	<b>84.33(0.37)</b>	<b>81.46(0.52)</b>	<b>89.91(0.33)</b>	<b>84.90(0.49)</b>
-w/LA	83.65(0.47)	80.48(0.62)	89.20(0.28)	84.26(0.31)
-w/RA	83.86(1.25)	80.41(1.26)	88.57(0.65)	83.16(0.78)
<b>LSA<sub>T</sub></b> -DeBERTa	84.16(0.31)	81.40(0.55)	<b>89.91(0.43)</b>	<b>84.96(0.40)</b>
-w/LA	84.08(1.25)	81.21(1.51)	89.55(0.62)	84.68(1.13)
-w/RA	<b>84.39(0.78)</b>	<b>81.54(1.22)</b>	89.38(0.45)	83.99(0.68)
<b>LSA<sub>S</sub></b> -DeBERTa	<b>84.33(0.31)</b>	<b>81.68(0.44)</b>	<b>90.27(0.76)</b>	<b>85.78(0.56)</b>
-w/LA	83.57(1.10)	80.44(1.14)	89.29(0.89)	84.00(1.22)
-w/RA	83.95(0.47)	80.89(0.88)	89.55(0.40)	84.26(0.39)

Table 10 shows the experimental results. From the performance comparison of simplified aggregation, we observe that the full LSA is optimal

in most situations, despite the underlying PLM or training dataset. Moreover, to our surprise, LSA with “RA” outperforms LSA with “LA” in some situations.

### C.5 Experiments on Twitter Dataset

The experimental results on the Twitter dataset reveal that the extended LSA-X models, with LSA<sub>T</sub>-X-DeBERTa demonstrating the best performance, effectively leverage local sentiment coherency to achieve competitive accuracy and F1 scores while maintaining consistent results across different runs.

Table 11: The performance of LSA models on the Twitter datasets, and the best results are heightened in **bold**. Numbers in parentheses denote IQR.

Model		Twitter	
		Acc	F1
LSA <sub>P</sub> -DeBERTa	LSA	76.91(0.36)	75.90(0.41)
LSA <sub>T</sub> -DeBERTa		76.61(0.20)	76.12(0.27)
LSA <sub>S</sub> -DeBERTa		76.61(0.52)	75.84(0.64)
LSA <sub>P</sub> -X-DeBERTa	LSA-X	76.81(0.76)	76.09(0.50)
LSA <sub>T</sub> -X-DeBERTa		<b>77.17(0.71)</b>	<b>76.45(0.65)</b>
LSA <sub>S</sub> -X-DeBERTa		77.06(0.26)	76.23(0.29)

# An Examination of the Robustness of Reference-Free Image Captioning Evaluation Metrics

## Abstract

Recently, reference-free metrics such as CLIPScore (Hessel et al., 2021), UMIC (Lee et al., 2021), and PAC-S (Sarto et al., 2023) have been proposed for automatic reference-free evaluation of image captions. Our focus lies in evaluating the robustness of these metrics in scenarios that require distinguishing between two captions with high lexical overlap but very different meanings. Our findings reveal that despite their high correlation with human judgments, CLIPScore, UMIC, and PAC-S struggle to identify fine-grained errors. While all metrics exhibit strong sensitivity to visual grounding errors, their sensitivity to caption implausibility errors is limited. Furthermore, we found that all metrics are sensitive to variations in the size of image-relevant objects mentioned in the caption, while CLIPScore and PAC-S are also sensitive to the number of mentions of image-relevant objects in the caption. Regarding linguistic aspects of a caption, all metrics show weak comprehension of negation, and CLIPScore and PAC-S are insensitive to the structure of the caption to a great extent. We hope our findings will guide further improvements in reference-free evaluation of image captioning. Our code and dataset are publicly available at: <https://github.com/saba96/img-cap-metrics-robustness>.

## 1 Introduction

Image caption quality has been traditionally evaluated using a reference-based approach, with metrics like BLEU (Papineni et al., 2002), ROUGE (Lin, 2004), METEOR (Banerjee and Lavie, 2005), and CIDEr (Vedantam et al., 2014) assessing the lexical overlap between generated and reference captions. However, this approach is restrictive as the set of references may not capture the full range of valid captions, and furthermore, lexical overlap-based metrics tend to favor captions with similar vocabulary but different meanings. To address these limitations, recent studies like CLIPScore (Hessel

Candidate Captions	CLIPScore	UMIC	PAC-S
The title of the book is topology.	0.472	0.347	0.555
The title of the book is muffin.	0.546	0.446	0.623

Figure 1: Recently proposed reference-free image captioning evaluation metrics such as CLIPScore, UMIC, and PAC-S are far from perfect. This figure shows how these metrics cannot tell apart an incorrect caption (shown in red) from a correct caption when there is a high lexical overlap between them.

et al., 2021), UMIC (Lee et al., 2021) and PAC-S (Sarto et al., 2023) have proposed reference-free approaches for evaluating image caption quality, which more closely aligns with human judgments. These approaches leverage large pretrained image-text matching models to measure the similarity between a given image and a candidate caption. However, the evaluation benchmarks for these metrics do not necessarily involve differentiating between captions with significant lexical overlap but vastly different meanings (Fig. 1). In this work, we evaluate the robustness of these reference-free metrics in scenarios where the correct and incorrect captions have high lexical overlap. To our surprise, we found that **all metrics fail to distinguish between correct and incorrect captions ~46% of the time**.

In a pursuit to identify what aspects of a caption (e.g., plausibility, visual grounding, number and size of objects mentioned in the caption, negation and sentence structure) these metrics are most sensitive to, we conduct several controlled experiments, varying one aspect at a time. We found that:

- All metrics show limited sensitivity to caption implausibility errors but a heightened sensitivity to visual grounding errors.

- CLIPScore and PAC-S show high sensitivity to the number of image-relevant objects mentioned in the caption while UMIC shows limited sensitivity.
- All metrics are sensitive to the size of image-relevant objects mentioned in the caption.
- All metrics exhibit a weak understanding of negation.
- UMIC is sensitive to sentence structure, whereas CLIPScore and PAC-S demonstrate limited sensitivity.
- UMIC prioritizes correct sentence structure over mentions of larger objects or number of objection mentions in captions, whereas CLIPScore and PAC-S exhibit the opposite behavior.

Our primary contribution is highlighting specific areas where reference-free metrics exhibit limitations so that caution can be exercised when using these metrics for image captioning evaluation. We hope our findings will guide further improvements in reference-free evaluation of image captioning.

## 2 Related Works

**Reference-free metrics:** We study the robustness of CLIPScore (Hessel et al., 2021), UMIC (Lee et al., 2021) and PAC-S (Sarto et al., 2023). CLIPScore measures the similarity between the image and the candidate caption using a scaled cosine similarity of the image and text representations from the CLIP (Radford et al., 2021) model. On the other hand, UMIC utilizes the UNITER (Chen et al., 2020) model, which is pretrained to align image and text pairs, and finetunes it via contrastive learning to distinguish reference captions from its hard negatives. PAC-S (Sarto et al., 2023) introduces a novel metric that strategically curates positive pairs for contrastive learning, enhancing the multimodal embedding space of CLIP. PAC-S employs scaled cosine similarity, akin to CLIPScore, to evaluate the similarity between the candidate caption and the provided image. SMURF (Feinglass and Yang, 2021) is another recently proposed metric for image caption evaluation, which has a reference-free evaluation of the fluency of the caption; however, the evaluation of the semantic correctness of the caption is still reference-based. Also, InfoMetIC (Hu et al., 2023) has the capability

Support Examples	<p>Please summarize the question and answer in one sentence.          Question: What color is the table?          Answer: brown          Long answer: The color of table is brown.</p> <p>Question: What color is the front of the train?          Answer: red and black          Long Answer: The color of the front of the train is red and black.</p>
Prompt	<p>Question: What color of shirt is this tennis player wearing?          Answer: red</p>

Figure 2: Generating caption-like sentences by transforming visual question-answer pairs using GPT-J.

to pinpoint incorrect words and overlooked image areas at a fine-grained level while also providing an overall quality score at a coarse-grained level.

**Vision-language benchmarks:** Recently, a number of vision-language benchmarks have been proposed to evaluate the fine-grained understanding of relations, attributes, actions, and visio-linguistic compositionality in vision-language models, such as CAB (Yamada et al., 2022), Winoground (Thrush et al., 2022), ARO (Yuksekgonul et al., 2023), VL-checklist (Zhao et al., 2022), CREPE (Ma et al., 2023) and VALSE (Parcalabescu et al., 2022). Although these evaluations also highlight the limitations of current models towards fine-grained understanding, our focus is specifically on evaluating the robustness of recently proposed reference-free image-captioning *metrics*. Our goal is to identify the scenarios where these metrics fail to distinguish between correct and incorrect captions to ensure the cautious use of these metrics in such scenarios.

## 3 Datasets Used to Conduct the Examination

### 3.1 Dataset Creation

To conduct our examination of the robustness of the metrics, we use a dataset of generated image captions. We generate image captions in one of the following ways, depending on the question we are trying to answer (see section 4 for more details):

**QA to caption conversion:** We employ GPT-J prompting to transform visual question-answer pairs into caption-like sentences. We use the questions from the popular VQAv2 (Goyal et al., 2016) dataset, and the answers could either be ground-

truth answers or model-generated, depending on the analysis. Figure 2 shows an example caption-like sentence generated by GPT-J along with the prompt and support examples. The support examples are specific to the question type of the input question. More details about support example selection can be found in Appendix A.1.

To clarify the motivation to generate captions in this manner, it is essential to outline the limitations of existing captioning datasets such as FOIL (Shekhar et al., 2017), ARO, and Winoground. These datasets mostly rely on modifying ground-truth captions by shuffling or swapping words to create incorrect captions. While these evaluation methods offer valuable insights, they are limited in their ability to comprehensively assess image-captioning metrics as these incorrect captions are out-of-distribution and easy for models to identify as incorrect (Hsieh et al., 2023).

For our study, we generate captions from VQA question-answer pairs instead of using these existing datasets for two primary reasons. Firstly, leveraging the VQAv2 dataset facilitates a comprehensive evaluation of image-captioning metrics’ robustness across various skills, such as color recognition, counting, etc. Moreover, using model-generated answers to create incorrect captions helps us construct a dataset that mirrors real-world use cases of image captioning metrics, i.e., using metrics to evaluate model-generated responses (note that the VQA answers are obtained from a model that was first pretrained for image captioning and then finetuned for VQA). Specifically, the incorrect captions generated using our approach contain plausible errors. This is attributed to the model’s tendency to produce reasonable responses, such as providing a color for a color-related question or a numerical answer for a counting inquiry. Furthermore, the model typically generates answers that are visually relevant to the image, even if they do not precisely match the query. For example, for an image containing a person wearing yellow pants and a red car, the model might incorrectly respond with "red." to a question asking about the color of the pants. Thus, our dataset holds value as the generated captions are plausible as well as contain visually relevant errors. For a detailed comparison of our dataset with FOIL, ARO, and Winoground, please refer to Appendix A.2.

**Caption templates:** To conduct a controlled study of robustness of image captioning metrics

towards specific factors such as number and size of objects mentioned in the caption, we generate captions using templates in the format of the “There is a/an [object name].”. We utilized the COCO detection dataset (Lin et al., 2014) to extract the names of objects in each image. This dataset provides object tags across 90 categories and attributes like objects’ areas. The sentence construction process is elaborated within each baseline description.

We will make the dataset containing all the generated captions publicly available for the purpose of reproducibility and future use by the community.

### 3.2 Dataset Analysis

We conduct the following analyses of our generated captions dataset:

**Human verification:** We collected human annotations for 2000 captions: 1000 corresponding to correct VQA answers and 1000 incorrect ones. We asked five workers to determine whether the sentence is correct or incorrect. If it is incorrect, we additionally asked them to identify all relevant issues: 1) it is grammatically incorrect, 2) it is incomplete, i.e., it misses some information present in the original question-answer pair, 3) it hallucinates information, i.e., it contains information not present in the original question-answer pair or misrepresents information present in the question-answer pair. The majority voting across the workers’ responses for each caption indicated that 255 instances were incorrect. Among these, 30 captions were identified as grammatically incorrect, 24 captions were deemed incomplete, and 17 captions were flagged for hallucinating information, where a caption was counted towards a particular incorrectness category if at least two annotators voted for that category.

We extended this analysis to 100 randomly sampled captions generated using the *caption template* method, and all samples were found to be correct, benefiting from their straightforward format.

**Comparing generated captions with human written captions:** For the captions generated using the *QA to caption conversion* method, it is worth asking how the distribution of such captions compares with that of human written captions in existing datasets, such as, COCO captions (Chen et al., 2015). To throw light on this, we refer to (Antol et al., 2015) where they compared the distributions of nouns, verbs, and adjectives mentioned in

COCO captions with those mentioned in the VQA questions and answers, and found that they are statistically significantly different from each other (Kolmogorov-Smirnov test,  $p < 0.001$ ). Consequently, we expect the captions generated through our *QA to caption conversion* method to exhibit different distributions of nouns, verbs, and adjectives compared to the human-written captions. However, (Antol et al., 2015) also show that the VQA questions and answers require a deeper understanding of images beyond what (human written) image captions typically capture. Thus, in spite of the differing word distributions between our generated captions and human written captions, we posit that our captions can be extremely valuable in **stress testing the robustness of image caption evaluation metrics**.

## 4 Experiments and Results

**Preliminary experiment:** First, we describe our preliminary experiment that served as a motivation for the rest of the study. We were interested in examining how different the scores assigned by reference-free image captioning metrics are for correct/incorrect captions created by converting questions and correct/incorrect answers from the VQAv2 dataset to caption-like sentences. Captions generated in this way are unique in that even for incorrect captions, a significant portion of it (corresponding to the question part) is still correct. Thus, such a dataset of captions serves as a good *stress test* dataset for examining the robustness of reference-free image captioning metrics.

To obtain correct and incorrect answers, we obtained predictions from the ALBEF (Li et al., 2021) visual question answering model on the validation splits of the VQAv2 (Goyal et al., 2016) dataset. We fine-tuned ALBEF on this dataset and conducted IID evaluation. We then converted each question and its corresponding ALBEF answer into a caption-like sentence as described in Section 3. We only use answers that match with either three or more human answers (and we classify them as correct answers) or that do not match with any human answers (and we classify them as incorrect answers), resulting in a total of 179,297 answers (43389 incorrect and 135908 correct). The histograms of results for the VQAv2 dataset are presented in Figure 3. We see a significant overlap between the distributions of scores for correct and incorrect captions for all metrics, highlighting the

Answer Type	CLIPScore	UMIC	PAC-S
VQAv2- Correct	0.480	0.394	0.558
VQAv2- Incorrect	0.481	0.403	0.549

Table 1: CLIPScore, UMIC, and PAC-S comparison for caption-like sentences for incorrect and correct answers generated by ALBEF model for VQAv2 dataset.

Answer Type	CLIPScore	UMIC	PAC-S
Correct yes/no	0.457	0.355	0.540
Incorrect yes/no	0.470	0.392	0.547
Correct numbers	0.468	0.354	<b>0.561</b>
Incorrect numbers	0.477	0.387	0.553
Correct others	0.512	0.452	0.578
Incorrect others	0.485	0.411	0.548

Table 2: CLIPScore, UMIC, and PAC-S comparison for correct and incorrect caption-like sentences generated with different answer types from VQAv2 dataset.

limitations of these metrics in precisely assessing caption quality.

**Score normalization:** The UMIC final score, which is an output of a sigmoid function, has a value range between 0 and 1. On the other hand, the CLIPScore and PAC-S use the cosine similarity score scaled by a factor of 2.5 and 2, respectively. Although theoretically, CLIPScore can vary between -2.5 and 2.5, and PAC-S can vary between -2 and 2, we have not observed negative scores, and they rarely exceed 1.0. The distributions of metrics are illustrated in Figure 3. While we do not directly compare the values of these metrics in this paper, we aim to contrast their sensitivity to different factors. To achieve this, we apply the min-max normalization separately to each metric for every experiment. This method allows us to evaluate the respective sensitivities of the metrics effectively. Please note that all reported scores are normalized, but the histograms are plotted using the original scores to accurately represent the original distributions.

**Score normalized results:** As shown in Table 1, CLIPScore and UMIC assign higher average scores to incorrect captions compared to correct captions; however, PAC-S assigns higher average scores to correct captions. We conducted further analysis by examining the average scores assigned by these metrics for different answer types of the VQAv2 dataset (please refer to Table 2 for detailed scores). Specifically, we observed that for the ‘yes/no’ answer type, on average, all the metrics assign higher scores to incorrect captions. For the ‘number’ an-

what is/are the	0.497	0.543	0.436	0.468	0.559	0.605
others	0.480	0.471	0.412	0.370	0.549	0.550

Table 3: CLIPScore, UMIC, and PAC-S for correct and incorrect caption-like sentences generated for different question types of VQAv2.

swer type, only PAC-S was able to assign higher average scores to correct captions. However, for the ‘others’ answer type, all the metrics assign higher average scores to correct captions.

For further investigation, we look at results for specific question types for VQAv2. As illustrated in Table 3), for CLIPScore, we observe that incorrect captions received higher scores on average for three question types: ‘how many’, ‘what time’ and ‘others’. Also, UMIC assigns higher scores on average to incorrect captions for four question types: ‘how many’, ‘what time’, ‘which’, and ‘others’. On the other hand, PAC-S assigns higher scores on average to incorrect captions for ‘what time’ and ‘others’ question types, suggesting **all metrics show poor performance for ‘what time’ questions**, which is considered to be a hard question type. Moreover, **CLIPScore and UMIC show poor performance for ‘how many’ questions**. Although PAC-S assigns higher average to correct captions over incorrect captions for ‘how many’

question type, the gap between the absolute values of average scores for correct and incorrect captions for ‘how many’ question is less than that for other question types.

**Controlled investigation to identify sensitivity to various factors:** Having established that these metrics struggle to distinguish the set of incorrect captions from the set of correct captions, in the following sections, we delve deeper into understanding the underlying reasons for their failure. To validate the comparisons made between different group means and ensure the reliability of our claims, we conducted a **t-test** for each comparison, using a p-value threshold of 0.01 (p-value < 0.01). Notably, all reported comparisons successfully satisfied this predetermined threshold, affirming the robustness of our statistical analyses.

#### 4.1 Sensitivity to fine-grained errors

The primary objective of this section is to determine the sensitivity of these metrics to fine-grained

Answer Type	CLIPScore	UMIC	PAC-S
Ground Truth	0.479	0.422	0.542
Incorrect from ALBEF	0.468	0.404	0.535

Table 4: CLIPScore, UMIC, and PAC-S comparison for caption-like sentences for incorrect answers generated by ALBEF model for VQA<sub>v2</sub> and captions generated with its ground truth counterpart.

errors. An incorrect caption is said to have “fine-grained errors” if it has high lexical overlap with a correct caption. To obtain such pairs of correct and incorrect captions, we first generate incorrect captions corresponding to the questions for which ALBEF produced incorrect responses. Then, we generate correct captions using ground-truth answers for the same set of questions. We convert the questions and answers into captions using the method described in Section 3. We excluded questions with yes/no answers from this study as we discuss them in Section 4.4. In total, we analyzed 38383 samples for this experiment.

We quantify the **degree of lexical overlap** between a pair of correct and incorrect captions in our dataset by measuring the F1 score between them. The mean F1 score across all such pairs in our dataset is 0.725. To place this in context, we measure the F1 score between pairs of correct (human-written) and incorrect (generated by image captioning models) captions from the Composite dataset (Aditya et al., 2017), a widely-used dataset for evaluating image captioning metrics (see Appendix A.3 for more details on F1 score computation for Composite dataset). The mean F1 score across all such pairs from the Composite dataset is 0.224, which is significantly lower than that for our dataset. This highlights the difficulty of our dataset making it suitable for stress testing the robustness of image captioning metrics.

As demonstrated in Table 4, for all metrics, captions with ground truth answers received a higher average score compared to captions with fine-grained errors. Despite the higher average scores assigned to correct captions, the ranking results reveal that these metrics often fail to prioritize correct captions over incorrect ones. CLIPScore fails to rank correct captions above incorrect captions in 46.34% of cases, while UMIC fails to do so in 45.99% of cases. Also, PAC-S ranks incorrect captions over correct captions in 46.84% of times. Thus, **all metrics show weak sensitivity to detecting fine-grained errors.**

We also report a **human baseline** for the task of distinguishing correct captions from the ones with fine-grained errors. We collected five human annotations for 2000 examples using the Amazon Mechanical Turk platform, each example consisting of an image, a correct caption and an incorrect caption. We asked humans to indicate the best matching description. Majority voting across the worker responses for each caption revealed humans fail to identify correct caption from incorrect caption in 15.4% cases. This shows human performance is far better than the metrics’ performance which fail to rank correct captions above incorrect captions around 46% of the time.

## 4.2 Are metrics differently sensitive to different kinds of fine-grained errors?

Candidate Captions	CLIPScore	UMIC	PAC-S
 <b>Ground Truth:</b> The color of the grass is brown.	0.405	0.475	0.532
<b>Plausible Answer:</b> The color of the grass is green, white.	0.440	0.197	0.512
<b>Image Object:</b> The color of the grass is giraffe.	0.736	0.384	0.620
<b>Random Answer:</b> The color of the grass is grill.	0.367	0.147	0.540

Figure 4: Captions from ground truth, plausible answer, an object from the image and a random answer of VQA<sub>v2</sub>.

The main aim of this experiment is to assess if the metrics exhibit varying sensitivity to different types of fine-grained errors, in particular visual grounding errors and caption implausibility errors. To assess this, we generated three types of incorrect captions for each correct caption by replacing the ground-truth answer in the correct caption with: a plausible but incorrect answer (visual grounding error), an object found in the image (caption implausibility error), and a random answer (see Figure 4 for an example and see Appendix A.4 for more details on plausible answers).

For this experiment, we limited our investigation to the following question types: ‘what number is’, ‘what time’, ‘what color’, and ‘what brand’, as their answers are non-object entities and, therefore, are not present in the COCO Detection dataset. Thus, when constructing a sentence using an object in the image, we can be sure that it would result in an incorrect caption for the image. We analyzed 23841 sets of 4 captions each for this experiment.

Answer Type	CLIPScore	UMIC	PAC-S
Ground Truth	0.501	0.487	0.576
Plausible	0.474	0.242	0.527
Object from Image	0.526	0.354	0.601
Random	0.458	0.275	0.522

Table 5: CLIPScore, UMIC, and PAC-S comparison for caption-like sentences from VQAv2 ground truth, plausible, object from image and random answers.

As illustrated in Table 5, the score difference between the correct captions and the captions with implausibility errors is significantly smaller than the difference between the correct captions and the captions with visual grounding errors. This indicates that the metrics exhibit **lower sensitivity to caption implausibility errors** and **higher sensitivity to visual grounding errors**. Notably, both CLIPScore and PAC-S assigned higher average scores to captions with implausibility errors compared to ground truth answers, and only UMIC assigned higher average score to captions with ground truth answers. In the following sections, we further examine the sensitivity of the metrics to various visual and linguistic aspects.

### 4.3 Visual Aspects

In this section, our objective is to assess the sensitivity of the metrics to the size and number of objects mentioned in the caption. Importantly, we would like to highlight that our focus is on analyzing how the size and number of objects mentioned in captions affect metric robustness and sensitivity. We refrain from making value judgments about whether these effects are good or bad.

#### 4.3.1 Sensitivity to the number of object mentions in the caption

In this section, we aim to evaluate the sensitivity of the metrics to the number of objects mentioned in the caption. To conduct this evaluation, we filter images from COCO Detection dataset (Lin et al., 2014) having a minimum of three object tags and randomly select three object tags for each image and utilize their corresponding object names to form sentences, depicting one, two, and three objects presented in the image (see Figure 5). We analyzed 19412 images for this experiment.

As presented in the first three rows of Table 6, CLIPScore and PAC-S scores for captions with three objects are significantly higher than for captions with two objects. Also, captions with two ob-

Number of Objects	CLIPScore	UMIC	PAC-S
One Object	0.449	0.205	0.500
Two Objects	0.512	0.212	0.540
Three Objects	0.561	0.195	0.578
Shuffled One Object	0.445	0.139	0.503
Shuffled Two Objects	0.499	0.148	0.541
Shuffled Three Objects	0.540	0.169	0.576

Table 6: CLIPScore, UMIC, and PAC-S comparison for sentences with various number of objects name, and their shuffled counterparts.

Candidate Captions	CLIPScore	UMIC	PAC-S
<b>One Object:</b> There is a person.	0.374	0.142	0.472
<b>Two Objects:</b> There is a person and a sports ball.	0.530	0.156	0.468
<b>Three Objects:</b> There is a person, a sports ball and a baseball bat.	0.692	0.149	0.560

Figure 5: Captions referring to different number of objects from the image.

jects score significantly higher than those with one object. In contrast, for UMIC, captions with one, two, and three objects received average scores of 0.205, 0.212, and 0.195, respectively. Although the t-test indicated statistically significant differences between scores across different object counts, the gap between absolute score values is smaller for UMIC than for CLIPScore and PAC-S. In conclusion, **CLIPScore and PAC-S display a heightened sensitivity to the number of image-relevant objects mentioned in the caption, while UMIC shows limited sensitivity towards this factor.**

#### 4.3.2 Sensitivity to size of objects mentioned in the caption

In this experiment, our primary goal is to examine the effect of object size mentioned in captions on the metrics. To achieve this, we utilize the COCO Detection dataset (Lin et al., 2014) to select one

Candidate Captions	CLIPScore	UMIC	PAC-S
<b>Small Object:</b> There is a knife.	0.460	0.507	0.561
<b>Big Object:</b> There is a pizza.	0.632	0.469	0.718
<b>Shuffled Small Object:</b> A there knife is.	0.480	0.268	0.561
<b>Shuffled Big Object:</b> A there pizza is.	0.664	0.250	0.719

Figure 6: Captions referring to small and large area of the image and their shuffled counterparts.

Object Size	CLIPScore	UMIC	PAC-S
Small Object	0.396	0.317	0.492
Big Object	0.434	0.232	0.580
Shuffled Small Object	0.390	0.205	0.495
Shuffled Big Object	0.436	0.170	0.590

Table 7: CLIPScore, UMIC, and PAC-S comparison for captions referring to small and a big objects in the image, and their shuffled counterparts.

small and one large object from the same image with a noticeable difference in the area (see Figure 6 for an example and for detailed explanation see Appendix A.5.). As a result, we selected 24610 images for further analysis.

As demonstrated in the first two rows of Table, 7, for CLIPScore and PAC-S, captions with smaller objects received a lower average score than those with bigger objects. On the other hand, UMIC assigned a higher average score to captions with smaller objects compared to captions with bigger objects. Overall, **all metrics demonstrate sensitivity to the size of image-relevant objects mentioned in the caption.**

## 4.4 Linguistic Aspects

### 4.4.1 Sensitivity to negation

To assess the ability of metrics to distinguish between correct captions and their negated versions, we created 80530 captions-like sentences by using the questions with ‘yes’ or ‘no’ ground-truth answers from the validation split of VQAv2. Additionally, we generated negated captions by negating the ground truth answer.

For CLIPScore, correct captions received a higher score of 0.457, and their negated versions got 0.450 on average. For UMIC, correct captions received a higher average of 0.359, and their negated versions got 0.335 on average. Correct captions received a higher average of 0.556 for PAC-S, and their negated versions got 0.548 on average. Although the correct captions scored statistically significantly higher than the negated ones, CLIPScore, UMIC, and PAC-S ranked the negated caption above the correct caption incorrectly in 41.36%, 44.24%, and 41.83% of cases, respectively. Thus, **all metrics exhibit a weak understanding of negation.**

### 4.4.2 Sensitivity to the sentence structure

To evaluate the sensitivity of the metrics to sentence structure, we generated 214354 caption-like sen-

tences with VQAv2 ground truth answers and then shuffled them. For CLIPScore, correct captions received 0.469, and their shuffled version got 0.450 on average. For UMIC, correct captions received 0.400, and their shuffled version got 0.211 on average. Correct captions received 0.548 for PAC-S, and their shuffled version got 0.539 on average. Despite higher average scores assigned to correct captions, the ranking results reveal that CLIPScore fails to rank the correct caption higher than the shuffled one in 34.32% of cases, contrasting with UMIC, where this occurs in only 9.18% of cases. Additionally, PAC-S falls short, assigning a higher score to the correct caption than the shuffled one in 43.05% of cases. This indicates that **UMIC is more responsive to the structure of the sentence compared to CLIPScore and PAC-S.**

## 4.5 Visio-Linguistic Aspects

### 4.5.1 Sentence Structure versus Visual Aspects

In order to compare the sensitivity of metrics to sentence structure and object size, we conducted a sentence shuffling experiment using captions that contained objects of varying sizes, as described in Section 4.3. We shuffle both big and small object captions in the same order (see Figure 6). As shown in Table 7, our results demonstrate that CLIPScore and PAC-S assign the highest scores to captions referring to a larger area of the image, regardless of whether they are shuffled or not. In contrast, UMIC exhibits the opposite trend, with the highest scores assigned to correct (i.e., unshuffled) sentences, regardless of the size of the objects mentioned in the captions. This highlights that **UMIC is more sensitive to sentence structure than the size of the objects mentioned in the caption, whereas for CLIPScore and PAC-S, the behavior is just the opposite.**

To compare the sensitivity of metrics to sentence structure and the number of object mentions, we conducted a sentence shuffling experiment using captions that varied in the number of object mentions. As shown in Table 6, UMIC assigns the lowest scores to shuffled captions, regardless of the number of objects mentioned in the captions. **This indicates that UMIC prioritizes sentence structure over the number of object mentions.** In contrast, CLIPScore and PAC-S assign the highest scores to captions with three objects, regardless of whether they are shuffled or not. Similarly, the

captions with two objects have the second highest CLIPScore and PAC-S, regardless of the correctness of the sentence structure. This reveals that **CLIPScore and PAC-S places greater importance on the number of object mentions than the sentence structure.**

## 5 Conclusion and Discussion

In conclusion, recently proposed reference-free image captioning evaluation metrics are far from perfect; they cannot distinguish an incorrect caption from a correct caption when the difference between them is fine-grained. The sensitivity of CLIPScore, UMIC, and PAC-S varies across different error types: they are less affected by plausibility errors yet more by visual grounding errors. All metrics struggle with understanding negation. All metrics are influenced by the size of the relevant objects mentioned in the caption, and CLIPScore and PAC-S also responds to the number of object mentions. UMIC is responsive to sentence structure, while CLIPScore and PAC-S disregards it often. Moreover, UMIC prioritizes sentence structure over the number and size of objects mentioned in the caption; in contrast CLIPScore and PAC-S prioritize the object size and number of object mentions over sentence structure.

Our primary contribution is highlighting specific areas where reference-free metrics exhibit limitations. The root cause of these limitations is traced to the insufficient fine-grained understanding of the CLIP and UNITER models upon which these reference-free metrics rely. In order to improve the reference-free metrics, we believe that underlying models need to become better at fine-grained understanding of objects, attributes, relationships etc., so that they can better distinguish fine-grained differences between captions. Promising avenues for enhancing this understanding include exploring object-centric representations (Locatello et al., 2020; Greff et al., 2019; Burgess et al., 2019) and incorporating training with hard negatives (Yuksekonul et al., 2023; Zhang et al., 2023; Bugliarello et al., 2023), allowing the model to learn to discern fine-grained differences and errors. Given the restricted fine-grained understanding of the underlying models shaping these metrics, caution is advised when employing them as evaluation metrics for image captioning.

## Limitations

As a limitation, it is important to consider that responses marked as incorrect may not always be incorrect due to the stringent nature of VQA evaluation metrics (Agrawal et al., 2023). Our approach does not account for this factor. However, for our experiments, since we fine-tune ALBEF for each domain, the risk of this issue is low. To get a quantitative sense, we randomly sampled 100 incorrect answers (as deemed by the VQA automatic metric) generated by ALBEF for VQAv2, and in only 10% of cases, the answer was actually correct (as deemed by an expert human). Furthermore, it is important to note that we do not account for the saliency of objects mentioned in the caption, which could be a confounding factor in our evaluation.

## Ethics Statement

To enhance transparency and explainability, we conducted experiments aimed at shedding light on the evaluation process of the metric. By doing so, we aimed to provide insights and explanations that enable users to better comprehend and trust the metric’s evaluations. Furthermore, we evaluated the robustness of the metrics, contributing towards the development of less biased evaluation metrics.

While we assess various aspects of existing metrics, it is important to note that our evaluation does not specifically examine metrics’ potential biases across different demographics, including gender or race. While our research does not include an explicit experiment on bias perpetuation or amplification, we strongly encourage future studies to investigate how metrics may interact with biases present in datasets. This research direction is crucial in developing metrics that are less biased and more inclusive towards diverse demographics.

## Acknowledgements

We express our gratitude to Stefan Lee for providing constructive feedback. The technical support extended by the Mila IDT team in managing the computational infrastructure is greatly appreciated. The authors acknowledge the material support of NVIDIA in the form of computational resources. Throughout this project, Aishwarya Agrawal received support from the Canada CIFAR AI Chair award.

## A Appendix

### A.1 Generating Caption-like Sentences

To generate caption-like sentences from each question and answer pair of VQA datasets, we utilize pretrained GPT-J (Wang and Komatsuzaki, 2021) in a few-shot manner. To accomplish this, we first constructed a support examples dataset using the VQAv2 (Goyal et al., 2016) training split. For each of the sixty-four predefined question types in the VQAv2 dataset, we randomly selected four examples from the VQAv2 training split. Then, we transformed both the questions and answers into single sentences, which we wrote ourselves. When generating captions for VQAv2 validation split, we first match the question type to one of the predefined sixty-four question types. Then, we select four support examples associated with that question type and prompt GPT-J to generate a transformed sentence. If the question type does not match any of our predefined question types, we randomly select eight support examples from the entire pool of support examples. Please see Figure 2 and note that we visualized a 2-shot prompt for simplification.

## A.2 Comparison with FOIL, Winoground and ARO

- **FOIL:** The distinction between our dataset and the FOIL dataset lies in their respective approaches to altering captions. While FOIL primarily focuses on changing nouns in MS-COCO captions, encompassing 73 out of the 91 MS-COCO categories, our setup, utilizing the VQA dataset, allows for a more diverse analysis. In our study, we go beyond changing nouns and explore variations in captions related to colors, time, count, and more. Notably, even in terms of nouns, our dataset exhibits greater diversity as we are not constrained to object types present in MS-COCO annotated categories.
- **ARO:** ARO dataset incorporates tests focusing on attribution, relations, and order. In the attribution test, distinctions are drawn between phrases like "The paved road and the white house." and "The white road and the paved house.". Meanwhile, the relation test explores understanding relationships, as seen in examples like "The horse is eating the grass." and the contrasting, implausible statement "The grass is eating the horse.". As shown by (Hsieh et al., 2023), the hard-negative captions present in these benchmarks are easily identifiable by vision-language models as they are out-of-distribution (OOD) w.r.t the training data seen by the language encoder in these models. While our correct and incorrect pairs of captions are both plausible sentences where only the incorrect caption exhibits a fine-grained error that stems from a lack of precise visual grounding.
- **Winoground:** Winoground dataset is meticulously curated by humans specifically for testing visio-linguistic compositionality. While it maintains a high level of quality, it comprises only 1600 samples, which, regrettably, is insufficient for robust statistical analyses. Furthermore, it lacks detailed annotations for aspects such as color, time, and counting in comparison to VQAv2. Importantly, as indicated by (Diwan et al., 2022), this dataset introduces challenges that go beyond fine-grained understanding, including issues like out-of-domain challenges and ambiguous captions. These challenges significantly confound the study's

results.

## A.3 F1 score computation for the Composite Dataset

We calculated the F1 score between the human-written correct captions and model-generated incorrect captions in the Composite dataset (Aditya et al., 2017). We used the captions generated by the Karparthy model (Karpathy and Li, 2015) as they were better in quality. In the Composite dataset, each model-generated caption has an associated correctness score (provided by humans) ranging from 1 ('The description has no relevance to the image') to 5 ('The description relates perfectly to the image'). For our F1 score computation, we considered all captions with score less than or equal to 4 as incorrect captions.

## A.4 Plausible Answers

To generate plausible captions for each question type, we first compiled a list of plausible answers derived from the ground truth multiple-choice answer of the same question type in the validation split of VQAv2. Subsequently, an answer was randomly selected from this list of plausible answers. This chosen answer was used to replace the ground truth answer in the original caption, thus generating a plausible alternate caption.

## A.5 Picking a large and small object from the image

In this experiment, our primary objective is to investigate how the object size mentioned in captions affects the scores assigned by CLIPScore and UMIC. To select small and large objects that are distinctly different in size, we could sort the objects by their associated area in the COCO Detection dataset. However, this approach may not always yield accurate results because multiple objects with the same name may appear in an image. For instance, if there are two cars in an image, one smaller but further away and the other larger but closer, sorting by area would lead to incorrect identification of the smallest and largest objects. This would result in identical captions for both objects, such as "There is a car." which is not ideal for comparison.

To overcome this issue, we added up the area of all object categories with the same name and sorted the total areas of each object category in the image. We then calculated the difference between the areas associated with the largest and smallest categories. If the difference exceeded our threshold,

we selected those objects for analysis. As a result, we selected 24610 images for further analysis (See Figure 6).

### **A.6 Computational Resources**

In all experiments detailed in this paper, we employed a single NVIDIA Quadro RTX 8000 with 48 GB GDDR6 GPU Memory. Specifically, for the primary task of generating caption-like sentences from the VQAv2 dataset, we performed inference using the GPT-J model with 6 billion parameters, executing the process over a duration of 24 hours.

### **A.7 Dataset Terms of Use**

We will distribute our datasets (both generated with caption template and QA to caption conversion method) under the Creative Commons Attribution 4.0 License. It is noteworthy to mention that this licensing choice aligns with the terms of use governing both the COCO and VQAv2 datasets, foundational to the creation of our datasets.

### **A.8 Editorial Assistance**

We would like to disclose that ChatGPT was utilized for refining the language and structure of this academic paper. While the primary content and research remain the work of the authors, the assistance provided by ChatGPT was limited to the improvement of writing quality.

# Barriers to Effective Evaluation of Simultaneous Interpretation

<sup>2</sup>{tei,colincherry,jjuraska,padfield,wmach}@google.com

## Abstract

Simultaneous interpretation is an especially challenging form of translation because it requires converting speech from one language to another in real-time. Though prior work has relied on out-of-the-box machine translation metrics to evaluate interpretation data, we hypothesize that strategies common in high-quality human interpretations, such as summarization, may not be handled well by standard machine translation metrics. In this work, we examine both qualitatively and quantitatively four potential barriers to evaluation of interpretation: disfluency, summarization, paraphrasing, and segmentation. Our experiments reveal that, while some machine translation metrics correlate fairly well with human judgments of interpretation quality, much work is still needed to account for interpretation strategies during evaluation. As a first step to addressing this problem, we develop a fine-tuned model for interpretation evaluation, which achieves better correlation with human judgments than state-of-the-art machine translation metrics.

## 1 Introduction

Simultaneous interpretation is an especially difficult type of translation because it requires the system or human to convey the ideas from one language to another in real time. Due to the cognitive load and constraints on memory associated with the act of human interpretation, the number of errors increases exponentially after only minutes of interpreting (Moser-Mercer et al., 1998). To compensate for these challenges, interpreters often make use of a range of strategies, such as summarization and segmentation (He et al., 2016), to concisely provide the gist of what is being said in the source language.

Despite the prevalence of both human simultaneous interpretation and automatic interpretation

models, investigations into how to effectively evaluate the quality of interpretation data are extremely limited.<sup>1</sup> Recent work suggests that standard automatic machine translation metrics are appropriate for interpretation, due to a correlation of select MT metrics (namely BLEU (Papineni et al., 2002), NIST (Doddington, 2002), and METEOR (Banerjee and Lavie, 2005)) with human judgments of interpretation quality (Lu and Han, 2023) and the use of METEOR for interpreter quality assessment (Stewart et al., 2018).

Recent work has also argued that simultaneous interpretation evaluation systems should be trained and tested on interpretation data as opposed to translation data (Zhao et al., 2021). In support of this argument, Zhao et al. (2021) demonstrate that there is a sizable difference in BLEU score (13.83 points) when evaluating based on interpretation or translation data.

Given the strategies unique to human interpretation and indications in prior work as to the potential utility of machine translation (MT) metrics, our goal in this work is to investigate the applicability of both (1) interpretation data as references, and (2) existing machine translation metrics for evaluation of interpretation. We argue that the strategies that interpreters leverage to be able to perform live interpretation are critical to the task and should not be penalized by the evaluation metric.

Thus, we pose three primary questions:

1. Do human interpretations collected for other purposes have sufficient quality to be considered for use as references in evaluation?
2. Can we use existing machine translation metrics—as they are—to evaluate interpretation data?

<sup>1</sup>The study of the evaluation of simultaneous translation **latency** is quite active. However, this paper concerns itself only with evaluating the quality (i.e. adequacy and fluency) of an interpretation, ignoring the temporal axis altogether.

\*Work completed while interning at Google.

3. Can we develop a refined automatic metric that achieves higher correlation with human judgments of interpretation quality and accounts for common features of interpretations?

To carry out these research questions, we analyze and evaluate both human interpretations and machine translations, identifying potential interpreter strategies that may degrade metric effectiveness (Section 3.4). For meta-evaluation, we conduct a human evaluation on the quality of both human interpretation and machine translation to see how those metrics correlate with human judgments (Section 4.1). We then conduct a study to assess the sensitivity of the metrics when these strategies are present in an interpretation (Section 4.2). Finally, in order to further improve the correlation with human judgments, we adapt the method from MetricX (Juraska et al., 2023) and create a fine-tuned model using our interpretation data and human annotations (Section 4.3). We demonstrate that our new metric is better at assessing interpretation quality, achieving higher correlation with human judgments, suggesting that fine-tuned neural metrics can be valuable tools for assessing interpretation.

## 2 Related Work

Common strategies in interpretation include segmentation, passivization, generalization, and summarization (He et al., 2016; Al-Khanji et al., 2000). Bernardini et al. (2016) also show that interpretations are consistently simpler than their translated counterparts, having lower lexical density, lower mean sentence length, and greater use of frequent words.

Regarding the use of interpretation data as references, Zhao et al. (2021) show that there is a 13.83 gap in BLEU score when evaluating simultaneous machine translation output against interpretation transcripts versus the revised text translation. The decrease in system performance when evaluating against interpretation data can also be observed in Macháček et al. (2021) and Xiong et al. (2019). The differences between how translators and interpreters translate speech is notable; still, there is no consensus on how to use automatic metrics to evaluate interpretation.

Within the realm of interpretation evaluation, Fantinuoli and Prandi (2021) adapt a framework developed for human interpreter assessment and perform a human evaluation of both interpreters

and machine translation systems. They find that interpreters perform better in intelligibility than machine translation systems, but worse in terms of informativeness. Macháček et al. (2023) recommends COMET (Rei et al., 2020) as a metric for assessing automatic simultaneous speech translation, though the systems considered do not mimic interpreter strategies such as summarization.

Recent work has also perturbed machine translation data in order to investigate the sensitivity of MT evaluation metrics to different types of errors (Karpinska et al., 2022). We adapt this idea in our work to investigate the sensitivity of MT metrics to different interpretation strategies. Per the results of WMT22, MetricX and COMET are the highest ranked automatic MT evaluation metrics when ranked via agreement with human judgments of machine and human translations (Freitag et al., 2022).

A number of multilingual interpretation corpora have been developed in prior work. Shimizu et al. (2014) collect an English↔Japanese interpretation corpus and show that the most experienced interpreter achieves the highest BLEU score. Doi et al. (2021) present the NAIST dataset, which is a larger English↔Japanese interpretation corpus, and using a similar setup as Shimizu et al. (2014), show that the most experienced interpreter also has a higher BERTScore (Zhang et al., 2019). However, they point out that BERTScore fails when interpreters use a strategy like summarization. The VoxPopuli corpus includes simultaneous interpretation data of European Parliament event recordings in 24 languages (Wang et al., 2021). Zhang et al. (2021) also collect a Chinese to English interpretation corpus with three experienced interpreters. Depending on whether the interpreters’ performance is based on human judgments or BLEU scores, the interpreters rank differently in terms of performance.

## 3 Methodology

In order to assess the presence of barriers to effectively evaluating interpretation data, we leverage comparisons between simultaneous interpretation data and machine translation data (as described in Section 3.1); we perform a human evaluation study on the interpretations and machine translation data (Section 3.2) to collect human judgments of both fluency and adequacy. We use five machine translation metrics (Section 3.3) to assess the applicability of existing metrics in evaluating interpretation

data, and identify features in the interpretation data which may impact metric correlation with human judgments (Section 3.4).

### 3.1 Data

We use the European Parliament Translation and Interpreting corpus (EPTIC; Bernardini et al., 2016) to create three data points: (1) the reference, (2) the interpretation, and (3) an in-house machine translation. The original source data are Italian remarks, read from a pre-written script. We take as our reference the provided human English translations of the Italian script. The interpretations are real-time English simultaneous interpretations produced by expert interpreters. The machine translations were obtained by translating the provided transcriptions of the Italian source audio, using the publicly available Google Translate API.<sup>2</sup> The dataset consists of 67 documents. We chose to use the EPTIC dataset for our experiments because of its size and the comparatively (against similar corpora) high quality of the included simultaneous interpretations.

In order to facilitate manual analysis, we break the documents in the EPTIC remarks down to the sentence level. Splitting these documents into aligned sentence pairs is difficult due to various interpretation strategies, such as summarization, omission, and segmentation. Therefore, we first align the unsegmented interpretation with the reference sentences by minimizing word error rate (WER; Matusov et al., 2005). This automatic alignment worked well for shorter documents, but it required extensive manual corrections for about half of the documents. From the 67 documents, we obtained 590 aligned sentence triplets (with each triplet again consisting of the reference, interpretation, and machine translation).

### 3.2 Human Evaluation Study

We collect sentence-level judgments of the interpretations and machine translations described in Section 3.1. The machine translation and interpretation are presented to the raters side-by-side, as well as the reference. In order to mask the identity of the interpretation and limit bias in annotation, we remove minor disfluencies (e.g. ‘uhm’) and randomize the presentation of the data such that the side that the translation appears on is consistent. We collect judgments from 1-4 for fluency and adequacy, with adequacy evaluated in comparison to

<sup>2</sup><https://translate.google.com/>

the reference. In addition, examples are given in the rater template for each choice. The judgments are collected from two fluent speakers of English and are z-normalized. For adequacy, raters were instructed that omission of non-essential or non-core content is acceptable for the “Most” grade, and disfluency and segmentation errors (e.g. words from other sentences incorrectly appended to the example) should also be ignored. Four adequacy options are presented to raters:

1. **None:** Absolutely none of the meaning of the input is represented by the output. The two texts are totally unrelated.
2. **Little:** Some of the meaning of the input is conveyed by the output, but much is missing, or a lot of extra meaning has been added.
3. **Most:** Most of the meaning of the input is conveyed by the output. Some detail or nuance may be lost, or the output might include a little extra meaning absent from the input.
4. **All:** All of the meaning and nuance of the input is conveyed by the output, with no extra meaning added.

For fluency, four choices are given:

1. **Nonsense:** Not understandable as English text.
2. **Poor:** Many or serious spelling, grammar, or other mistakes, which make the text difficult to understand or hard to read. It seems to be written by somebody who doesn’t know English well.
3. **Good:** Few or minor spelling or grammar mistakes; the text is still mostly understandable and readable.
4. **Flawless:** Perfect use of English with no mistakes at all.

### 3.3 MT Metrics

In order to investigate the utility of existing machine translation metrics for evaluating interpretation data, we employ five machine translation metrics:

1. BLEU<sup>3</sup> (Papineni et al., 2002)

<sup>3</sup>For BLEU scores, we use sacreBLEU (Post, 2018) version v2.3.0.

2. METEOR<sup>4</sup> (Banerjee and Lavie, 2005)
3. BERTscore<sup>5</sup> (Zhang et al., 2019)
4. MetricX<sup>6</sup> (Juraska et al., 2023)
5. COMET<sup>7</sup> (Rei et al., 2020)

BLEU and METEOR are both n-gram-based metrics that calculate the similarity between the hypothesis translation and the reference n-grams.

BERTScore computes the similarity of the candidate and reference as the sum of cosine similarities between their token embeddings.

MetricX and COMET are both neural metrics which rely on contextual language model embeddings and are fine-tuned with human assessments. While MetricX and COMET differ in their neural network architectures, both optimize regression objectives on direct assessment (DA) data and Multi-dimensional Quality Metrics scores (Lommel et al., 2014; Freitag et al., 2021) that have been collected by WMT over the years. However, no interpretation data has thus far been used to train these metrics.

In Section 4.3, we adopt MetricX with an mT5 XL backbone (Xue et al., 2021) for further fine-tuning with interpretation data. Our first approach uses the z-normalized human annotation scores of our interpretation data (from Section 3.2) to fine-tune the base model. Our second approach fine-tunes the base model first with WMT DA data and then with our annotations. In this way, the model first learns the translation assessment task, which is then adapted to handle interpretations.

### 3.4 Measuring Metric Sensitivity to Interpretation Features

To investigate how well these MT metrics accommodate the strategies interpreters use to be able to translate in real time, we compare metric scores for human interpretation of audio against the output of machine translation applied to a human transcript of the same audio. We do this by manually iterating item-by-item through every interpretation/

translation pair, noting instances where the machine translation score is much higher than the interpretation score. This allows us to identify features of interpretation which may degrade their scores according to current metrics. Then, we classify the type of difference between the interpretation and MT sentences to identify common individual features that seem to be having an effect on evaluation.

Through this rigorous manual process, we identify four features of interpretation that may degrade their scores according to current metrics: (1) disfluency, (2) summarization, (3) paraphrasing, and (4) segmentation.

Though we have identified these features as potentially having an impact qualitatively on metric score, we set out to quantitatively measure the impact of each feature. To see how each feature of interpretations impacts metrics, we use automatic methods to either remove the feature from our interpretation data, or add the feature to our machine translation data, and then re-compute the metric scores. This enables us to quantify the specific impact of the feature on the metric score.

For disfluency, we use the 12-layer small-vocab BERT disfluency detection model from Rocholl et al. (2021) to remove disfluencies from the interpretation.

For summarization and paraphrasing, we use the instruction-tuned PaLM-2 Bison LLM (Anil et al., 2023) to perturb machine translation data, prompting the model to apply summarization or paraphrasing. We iterate over multiple prompts and manually verify the quality of the LLM output in order to ensure that we have engineered the most effective prompt for this task. Specifically, we verify that the selected prompt sufficiently maintains meaning and fluency in the summarized/paraphrased output through manual analysis. Once we selected the specific prompt (“Apply summarization to the following sentence: [sentence to be summarized]. Do not include the word summarization in the response, just output the summarized sentence.”), we ran the LLM over all of the machine translation data to collect a summarized and paraphrased version of each item. The paraphrase prompt was analogous, swapping in the word ‘paraphrasing’ for ‘summarization.’

Lastly, for segmentation, we employ document-level automatic MT metrics to evaluate the document pairs.

<sup>4</sup>We use the implementation of METEOR from NLTK (Bird and Klein, 2009) version 3.8.1.

<sup>5</sup>We re-implement the BERTScore algorithm, using the pre-trained model “BERT-Base, Multilingual Cased” from Turc et al. (2019).

<sup>6</sup>We use an internal implementation of sentence-level and document-level MetricX models from Juraska et al. (2023).

<sup>7</sup>For COMET, we use wmt22-comet-da.

Metric	SI	MT
BLEU	0.1811	0.3276
METEOR	0.3966	0.6226
BERTScore	0.8122	0.8812
MetricX	0.5928	0.7351
COMET	0.6809	0.7818

Table 1: Average scores for simultaneous interpretation (SI) and machine translation (MT) data on automatic machine translation metrics.

## 4 Results

In the subsections that follow, we address each of our research questions. Namely, in Section 4.1 we address whether human interpretations (collected for other purposes) have sufficient quality to be considered for use as references in evaluation. Then, in Section 4.2, we ascertain whether we can use existing machine translation metrics—as they are—to evaluate interpretation data. Finally, in Section 4.3, we develop a refined automatic metric which achieves higher correlation with human judgments of interpretation quality and accounts for common features of interpretations.

### 4.1 Evaluating Human Interpretation

To address our first research question (whether interpretations have sufficient quality to be used as references), we evaluate the interpretation data and machine translation data using the MT metrics. Then, we contrast both sets of scores to reveal any deficiencies in individual interpretations.

As shown in Table 1, all metrics score the machine translation data higher than the interpretation data. This finding is in line with previous work (Xiong et al., 2019; Zheng et al., 2020).

This observation may reflect a flaw in the metrics rather than the interpretations; therefore, we move to our human evaluation, shown in Table 2. Via our human evaluation, we find that 350 out of 590 of the interpretations are missing full adequacy/meaning preservation, whereas this is the case for only 133 of the 590 machine translations. All human ratings are lower for the interpretation than for the MT, with adequacy being the primary issue. We also observe numerous low quality interpretations in the dataset such as the example in Table 3, calling into question whether we can use interpretations as references. In this drastic example, the interpretation has a MetricX score of 0.4691 and the MT has a MetricX score of 0.7913.

Ultimately, our findings both from the automatic

	Avg Fluency	Avg Adequacy
Interpretation	3.733	3.173
MT	3.848	3.748

Table 2: Average human evaluation scores for fluency and adequacy of the interpretation and machine translation data.

Ref: “Your collective efforts were crucial in reaching a turning point in negotiations between the European institutions on this extremely technical dossier.”

MT: “Collective efforts, your collective efforts have been instrumental in reaching a breakthrough during the negotiations between the institutions on this highly technical dossier.”

SI: “The collective efforts of honourable members were crucial in achieving ehm crossroads and making process in what i- progress in what is an extremely technical... issue”

Table 3: Example of a low quality interpretation found in the EPTIC dataset.

metrics and our human evaluation suggest that there are issues in the interpretation data that make it unsuitable for use as a reference. Specifically, the issue of low adequacy, due to content dropping and high cognitive load, causes interpretations to be insufficiently reliable to serve as references in system evaluation. While omission and summarization are to be expected in real-time interpretation, low-quality interpretations (such as the interpretation featured in Table 3) are also present.

### 4.2 Suitability of MT Metrics for Interpretation

To address our second research question (should we use MT metrics to evaluate interpretations), we first ask: do metrics actually correlate well with human judgments of interpretation quality?

Table 4 shows segment-level correlation between our human judgments and the automatic metrics. We find that the correlation is low compared to previous work (e.g. Sellam et al. (2020)). By examining cases where human and automatic judgments disagree, we can easily find cases where the interpreter is doing a good job, but the metric scores are low. This suggests that metric scores are overly sensitive to features of interpretation that appear in high-quality interpretations. Through qualitative analysis, we find four features of interpretation that metrics may not be handling well (potential “metric failures”): (1) segmentation, (2) minor disfluencies, (3) summarization, and (4) paraphrasing.

Next, we quantify the sensitivity of metrics to each of these four features by using the experi-

Metric	SI Fluency	SI Adequacy	MT Fluency	MT Adequacy
BLEU	0.1321	0.3999	0.0755	0.2872
METEOR	0.0819	0.5913	0.0368	0.3746
BERTScore	0.1181	0.5985	0.0843	0.3781
MetricX	0.2290	0.6023	0.1935	0.4436
COMET	0.2397	0.6306	0.1773	0.4451

Table 4: Pearson’s correlation between human judgments of fluency and adequacy for the simultaneous interpretation (SI) and machine translation (MT) data.

	Avg Sent-Level Document Correlation	Doc-Level Correlation
BLEU	0.5834	0.6312
COMET	0.8343	0.6626
MetricX	0.7635	0.5765

Table 5: For the simultaneous interpretation (SI) data, we derive document-level metric scores for BLEU, COMET, and MetricX in two ways: (1) by computing the average of sentence-level metric scores across the document, and (2) by applying the metrics to the entire document. The human rating for each document is calculated as the average of all its sentence ratings. We then calculate Pearson’s correlation between each document-level metric and the human adequacy ratings.

mental designs detailed in Section 3.4. As we saw in Table 4, COMET and MetricX correlate similarly well with human judgments of fluency and adequacy, outperforming all other metrics; when measuring metric sensitivity to the four potential metric failures in Section 4.2.2 and Section 4.2.3, we focus on the MetricX metric for brevity and clarity.

#### 4.2.1 Segmentation

One issue that we observe in the interpretation data is the presence of segmentation errors. Interpreters may break the speech into smaller segments and/or translate them into separate sentences. Although the machine translation system translates each verbatim transcript sentence into a translation sentence, it may still have a different number of sentences than the reference. We find that in the interpretation data, there are 11 documents where the ratio of interpreter sentences to reference sentences is greater than or equal to 1.25, while in the machine translation, there are only 6 documents with a sentence ratio greater than or equal to 1.25. Segmentation differences pose a challenge to the performance of MT metrics, because the metrics often expect a one-to-one alignment between hypothesis and reference sentences. Other datasets face the same issues of segmentation; for example, we observe similar issues in the NAIST (Doi et al., 2021) and VoxPopuli (Wang et al., 2021) datasets.

To see whether metrics are sensitive to these segmentation issues, we employ metrics which are appropriate for both sentence and document-level evaluations: BLEU, COMET, and MetricX. BLEU

has no input length restriction, while COMET and MetricX have a 512-token limit. We exclude the documents exceeding this limit, resulting in a set of 59 documents. For COMET, we compute both average sentence-level scores and document-level scores. Following the findings of Deutsch et al. (2023), we use sentence-level and document-level MetricX models to score each document. For human annotations, we average the scores across all sentences within a document.

Table 5 shows the results on metric sensitivity to segmentation. For the correlation of adequacy, we see BLEU improve, while COMET and MetricX both greatly degrade. This indicates that moving from the sentence-level to the document-level does not necessarily resolve the issue of segmentation in metric score, and the effect of shifting from sentence to document-level evaluation differs substantially by metric. However, segmentation differences pose issues beyond the question of sentence boundary, as segmentation is also associated with omission and summarization (discussed in Section 4.2.3).

#### 4.2.2 Disfluency

Now, we assess the impact of the remaining features (disfluency, summarization, and paraphrasing) on metric scores, with a focus on MetricX. These results are summarized in Table 6.

Minor disfluency arises in the interpretation process as the interpreter either misspeaks or is not yet sure what the speaker will say. An example of minor disfluency is shown in Table 7; the MetricX score for the interpretation is 0.5756 and for the

Data	MetricX
MT	0.7351
MT summarized by PaLM	0.6816
MT paraphrased by PaLM	0.7589
SI	0.5928
SI disfluency removed	0.6217

Table 6: Impact on the MetricX scores from perturbations with different interpretation features to the translation data.

MT is 0.7035.

To measure the impact of disfluencies, we automatically remove them from interpretations (through the process described in Section 3.4). We find that disfluency removal improves MetricX scores by 3%. While this is a very small change, this does indicate that even imperfect disfluency removal leads to an increase in MetricX score, thus demonstrating that MetricX is in fact sensitive to disfluencies.

Again, though only a small change in MetricX score results from the presence of disfluencies, disfluencies can easily be mitigated with disfluency removal, and as they are an organic part of the live interpretation process which do not affect meaning, we argue that these disfluencies should be resolved prior to evaluation. The presence of these disfluencies does not impact the meaning of the interpretation, and we do not expect the machine interpretations to need to produce disfluencies. We also recommend that when creating interpretation datasets, the data curators clean up disfluencies during transcription, or alternatively annotate the disfluencies as in the NAIST dataset (Doi et al., 2021).

#### 4.2.3 Summarization and Paraphrasing

In addition to issues of segmentation and disfluency, we also noted instances of summarization and paraphrasing affecting metric scores.

One such example of summarization can be found in Table 8, for which the interpretation MetricX score is 0.6485 and the MT MetricX score is 0.7710.

Paraphrasing also appears to affect MetricX score, such as in Table 9, where the MetricX score for the interpretation is 0.7171 and for the MT is 0.8215.

To quantify the impact of summarization and paraphrasing on MetricX, we use LLMs to add summarization and paraphrasing to non-simultaneous machine translations as described in Section 3.4,

Ref: “The alderman for the region has already travelled to Brussels 3 times and has already completed a good proportion of the schedule of works that was outlined in a hearing held before the committee on Petitions in July.”

MT: “the regional councilor has already come 3 times here in Brussels and has already implemented a large part of the ‘timeline’ which was illustrated during a hearing in July before the petitions committee.”

SI: “The regional assessor has been 3 times to Brussels and has already done a fair amount of programme put out during a hearing in July in the **peti- Petitions committee.**”

Table 7: Example of minor disfluency—indicated in bold—occurring in the simultaneous interpretation (SI), as well as the corresponding machine translation (MT) and reference (Ref) text.

and then observe the impact on MetricX score. The results for this experiment are as shown in Table 6.

Our results indicate that summarization does have a notable impact on MetricX score. Without summarization, the average MetricX score was 0.7351 and after applying summarization this drops to 0.6816. Table 10 breaks the scores down by amount of summarization. We measure summarization via sentence compression ratio, defined as token count in the translation divided by token count in the reference (using the NLTK tokenizer). Interestingly, we find that more summarization leads to a more diminished MetricX score, further confirming that summarization is a weakness of MetricX when evaluating interpretation.

We argue that if no meaning is lost, interpretation metrics should not penalize summarization, as this is again a necessary feature of interpretation, and this therefore needs to be addressed. Still, it is worth noting that we are not able to guarantee that there is no loss of information due to summarization. While our results of sentence compression ratio do indicate the impact of token count on MetricX score, it is possible that in some cases, meaningful information is lost.

When performing the same experiment for paraphrasing, we find that MetricX does handle paraphrasing well, as one would hope. The original MT MetricX score was 0.7351, and after applying paraphrasing via the PaLM model, the MetricX score was 0.7589. Given that paraphrasing actually results in a *higher* MetricX score, paraphrasing is not an issue facing MetricX for interpretation evaluation. Therefore, these sets of experiment indicate that while summarization does pose an issue for MT metrics (in particular with regard to evaluation of interpretation data), paraphrasing does not.

Ref: “The fact that the crisis has hit Naples while the situation is very different in the rest of Italy, for example, in my region, Veneto, where separate collection has been taking place for years without any problems and with a very high recycling rate, means that the **responsibility for the crisis lies with Campanian policy making, with local government officials and, above all, with the serious collusion with the underworld**, which as always sought and made **huge profits from the waste business thanks to Camorra’s infiltrating local policy making and local government.**”

MT: “If the emergency hit Naples while things are going very differently in the rest of Italy, for example in my region, Veneto, where separate waste collection has been done for years without problems and with a very high recycling rate, it means that the **responsibilities of ‘emergency falls on politics and local administrators and, above all, on the heavy connivance with the underworld** which has always sought and obtained **huge profits from the waste business thanks to the infiltration of the Camorra in politics and local administrations.**”

SI: “It means that the **responsibility is due to local administration in Campania and operation with criminal elements** that are obtaining **big profits through the in- infiltration of the Camorra into local authorities and government.**”

Table 8: Example of summarization—indicated in bold—occurring in the simultaneous interpretation (SI), as well as the corresponding machine translation (MT) and reference (Ref).

### 4.3 Fine-tuned Metrics for Interpretation Assessment

In order to address our third research question (can we develop a refined automatic metric which achieves even higher correlation with human judgments), we present a pilot experiment that makes use of fine-tuning for interpretation quality assessment. We utilize our z-normalized human annotation scores (from Section 3.2) along with the interpretation and reference pairs to fine-tune a MetricX model. We employ 3-fold cross-validation for our fine-tuning experiments. In each fold, 33% of the annotated data is held out as the test set, while the remaining 67% is used to fine-tune the model. The average correlation across all three folds is reported in Table 11, marked with asterisks. We avoid fine-tuning on MT annotations to ensure the models are directed towards the task of interpretation evaluation. We do additionally apply our fine-tuned models to MT data and report the resulting correlations.

We take two approaches to fine-tuning the base MetricX model: (1) directly fine-tune the base model with our human annotations, and (2) first fine-tune with the DA data from WMT, and then

Ref: “We set out to achieve the goal of recognising the right of all patients to cross-border healthcare, thus preventing medical tourism.”

MT: “The goal which we have tried to achieve is to recognize all patients the right to cross-border healthcare, avoiding healthcare tourism.”

SI: “The objective which we were striving towards was to recognise for all patients the right to cross-border healthcare, but avoiding medical tourism.”

Table 9: Example of paraphrasing occurring between the simultaneous interpretation (SI) and reference (Ref), plus the corresponding machine translation (MT).

Sentence Compression	MetricX
Overall	0.6816
$Ratio \leq 0.25$	0.5456
$0.25 < Ratio \leq 0.5$	0.5950
$0.5 < Ratio \leq 0.75$	0.6824
$0.75 < Ratio$	0.7419

Table 10: Summarization ULM experiment and MT MetricX after summarization.

fine-tune with our annotations. We use either adequacy or fluency score to fine-tune the model. The results can be found in Table 11.

For adequacy assessment, we find that the fine-tuned models correlate better with human judgments than off-the-shelf MT metrics. The WMT DA data is helpful in this case. The highest correlation for the interpretation data is achieved by fine-tuning the “DA 15-20 z clipped” model from Juraska et al. (2023) on our z-normalized human annotations. As for fluency, the fine-tuned models also achieve higher correlation with human ratings. However, for fluency, we find that fine-tuning with the DA data does not lead to improved correlation with human judgments. This demonstrates that with just a very small amount of human annotation, we can create a reasonable metric to evaluate interpretation quality. This suggests that future work can make use of quality-annotated interpretation data to overcome the barriers to interpretation data that we have outlined, thus accounting for features commonly found in high-quality interpretations which affect metric scores.

## 5 Conclusion

In this work, we have performed extensive qualitative and quantitative experimentation to measure the impact of common features of interpretation on metric scores.

We have studied the sensitivity of MT metrics to interpretation features, including disfluency, seg-

Metric	SI Fluency	SI Adequacy	MT Fluency	MT Adequacy
MetricX	0.2988	0.6178	0.1595	0.3133
COMET	0.3011	0.6211	0.1466	0.3422
mT5 + Adequacy ratings		0.6718*		0.4989
mT5 + DA + Adequacy ratings		<b>0.7031*</b>		0.4528
mT5 + Fluency ratings	<b>0.4067*</b>		0.2325	
mT5 + DA + Fluency ratings	0.4017*		0.1023	

Table 11: Pearson’s correlation between metric scores and human judgments of fluency and adequacy for the simultaneous interpretation (SI) and machine translation (MT) data. The last four rows show the performance of our fine-tuned models. The base model (mT5) is fine-tuned with either adequacy or fluency human ratings, and optionally we fine-tune the base model with DA scores as the first stage fine-tuning. Asterisks indicate the average correlation across all three folds of cross-validation (described in Section 4.3).

mentation, summarization, and paraphrasing. We argue that common interpreter features should not be penalized if the original gist is successfully conveyed, and we find that off-the-shelf MT metrics are indeed sensitive to disfluency and summarization.

Our evaluation shows that the quality of human interpretations is worse than machine translations according to both automatic MT metrics and human evaluation. The low scores are caused not only by the sensitivity of MT metrics to interpretation features (as demonstrated in Section 4.2), but also by persistent errors made by interpreters (as illustrated in Section 4.1). Given this finding, though recent work has argued that human interpretations should be used as references in simultaneous interpretation evaluation (Zhao et al., 2021), we advise against using existing interpretations as references for evaluation. Better data collection procedures and annotations are required to ensure that the interpretation data is of high quality.

Ultimately, though prior work has assumed the functionality of MT metrics for evaluating interpretation data, our findings reveal that minor disfluencies and summarization are unduly punished by existing metrics. In order to perform an accurate evaluation of interpretation data, these features must be addressed.

We propose using fine-tuned learned metrics to assess interpretation quality. With human annotations, even flawed interpretation data can be used to fine-tune a model. As our results show, we are able to achieve higher correlation with human judgments using our fine-tuned models than the state-of-the-art MT metrics.

## Limitations

While our work provides critical insights into barriers to evaluation of interpretation data and in-

roduces a new metric which accounts for these barriers, it is important to note that our results are on English data. Future work extending our experiments to other languages and domains will give indication into how our insights can be extrapolated to other languages.

## Abstract

One critical issue for chat systems is to stay consistent about preferences, opinions, beliefs and facts of itself, which has been shown a difficult problem. In this work, we study methods to assess and bolster utterance consistency of chat systems. A dataset is first developed for studying the inconsistencies, where inconsistent dialogue responses, explanations of the inconsistencies, and recovery utterances are authored by annotators. This covers the life span of inconsistencies, namely introduction, understanding, and resolution. Building on this, we introduce a set of tasks centered on dialogue consistency, specifically focused on its detection and resolution. Our experimental findings indicate that our dataset significantly helps the progress in identifying and resolving conversational inconsistencies, and current popular large language models like ChatGPT which are good at resolving inconsistencies however still struggle with detection.<sup>1</sup>

## 1 Introduction

For years, inconsistencies in human-to-chatbot conversations have been evident (Dziri et al., 2019; Qin et al., 2021; Ji et al., 2023), even in the era of large language models (Mündler et al., 2023). We categorize these inconsistencies as either extrinsic or intrinsic. *Extrinsic* inconsistencies (Rashkin et al., 2021; Santhanam et al., 2021) arise when there’s a discrepancy between a statement and an external source of information, such as a knowledge base. On the other hand, *intrinsic* inconsistencies (Dziri et al., 2019; Nie et al., 2021; Zheng et al., 2022) occur within the dialogue itself. These can manifest in two ways: through an intra-utterance contradiction (Zheng et al., 2022), where a single sentence contains conflicting information, or a history contradiction (Nie et al., 2021), where a current state-

\*Work done as an intern at Tencent AI Lab.

<sup>1</sup>The dataset and codebase are released at <https://github.com/mianzhang/CIDER>.

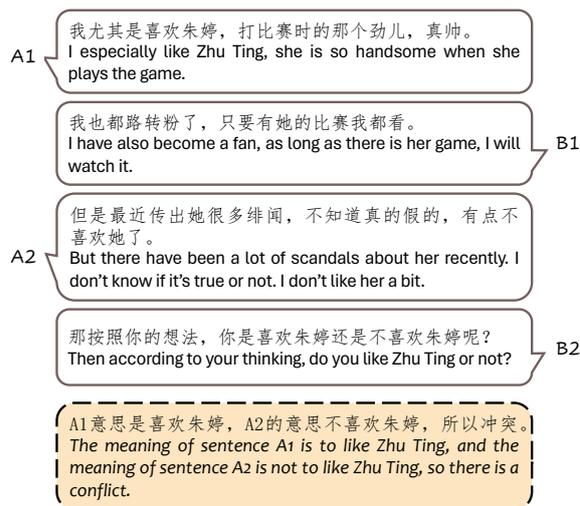

Figure 1: An instance in **CIDER** dataset.  $\{A, B\}_x$  denotes the  $x$ -th utterance of one of the two speakers (A or B). An inconsistent utterance (A2 in this case), an explanation of the inconsistency (the dotted box), and a clarification response (B2 in this case) are written for each dialogue.

ment conflicts with a previous one. Our study particularly addresses history contradictions, a persistent challenge in conversational models due to the nature of language modeling: models could forget what they said due to intervening context (Roller et al., 2021).

Researchers have been actively exploring how to resolve inconsistencies between utterances generated by conversational models in recent years. Li et al. (2020); Rashkin et al. (2021) has made progress in this domain by enhancing the training of these models, incorporating additional features and objectives to bolster self-consistency. Furthermore, Lee et al. (2022); Su and Collier (2022) introduced innovative decoding algorithms aimed at fostering greater coherence in utterances. These preemptive approaches are designed to mitigate conversational inconsistencies by reducing the likelihood of generating responses that contradict pre-

vious dialogue. However, these approaches cannot resolve the inconsistencies that do occur, possibly from the user or from model errors. Therefore it’s equally important to robustly address inconsistencies that do arise. Various remedial techniques have shown promise in other tasks, from grammar error correction (Wu et al., 2023) and moderating inappropriate dialogue content (Zhang et al., 2023), to generating clarifying questions in information retrieval (Zamani et al., 2020a) and conversational question answering (Guo et al., 2021). However, there seems to be a significant gap in the research when it comes to directly addressing inconsistencies that do arise between utterances.

In this work, we first propose a human-authored dataset with 27,180 dialogues to study the inconsistencies between utterances. At a high level, the dataset, called **CIDER**, covers the whole life span of inconsistencies, encompassing their **I**ntroduction, **u**n**D**erstanding, and **R**esolution. Specifically, for each dialogue, annotators are first asked to write an utterance with inconsistent content regarding one utterance in the history to continue the conversation (A2 in Figure 1), and then explain why the two utterances are inconsistent with natural language (the dotted box in Figure 1), and finally provide a clarification response to continue the dialogue to resolve the inconsistency<sup>2</sup> (B2 in Figure 1). Given its large collection of inconsistent utterances paired with clarifying responses, **CIDER** stands out as a valuable resource for researching strategies to mitigate conversational inconsistencies.

Utilizing the **CIDER** dataset, we conduct comprehensive experiments and analyses to study dialogue inconsistencies. Our findings underscore that **CIDER** can facilitate the development of robust inconsistency checkers compared to models trained on comparable public datasets. In addition, our research indicates that classic models like T5 and BART face challenges in adeptly resolving inconsistencies by providing clarifying responses. When assessing the proficiency of large language models (LLMs) in identifying and resolving conversational inconsistencies, we discerned two key points: 1) LLMs, when employed as inconsistency checkers, still leave much to be desired in terms of performance. 2) In contrast, as resolvers of inconsistency, LLMs exhibit a higher success rate compared to

<sup>2</sup>The dialogues and annotation in the dataset are in Chinese. We also offer an English version translated by ChatGPT to facilitate research.

the fully supervised BART resolver.

## 2 Related work

**Consistency checking.** Natural Language Inference (NLI) (Hu et al., 2020; Saha et al., 2020) is a task closely related to our work, where a provided hypothesis is evaluated for its logical consistency with a given premise, with both presented in natural language. Within the context of dialogues, Welleck et al. (2019) framed the consistency checking in dialogue as NLI and annotated binary consistency labels between dialogue-persona or persona-persona sentence pairs from the Persona-Chat dataset (Zhang et al., 2018). Dziri et al. (2019) employed NLI models to assess topic coherence between a current response and the preceding dialogue history. Meanwhile, Shuster et al. (2022) delved into the issue of role confusion, where dialogue systems might inadvertently adopt the identity of the other party involved, and proposed a reranker trained with human judgments of identity consistency. The most relevant works are from (Nie et al., 2021) and (Zheng et al., 2022), where they created datasets providing supervision for contradiction detection between conversational sentences. Our work distinguishes itself by providing more extensive annotations, including explanations and clarification responses.

**Consistency resolving in dialogue.** To enhance the self-consistency of conversational models, Rashkin et al. (2021) employed controllable features, steering models towards generating more consistent responses. Lee et al. (2022) introduced factual-nucleus sampling and factuality-enhanced continued training to augment the reliability of language models during both decoding and training phases. Shuster et al. (2022) encouraged the conversational models to maintain an identity with the help of a role-playing accuracy classifier. Li et al. (2020) explored unlikelihood training (Welleck et al., 2020) to curb inconsistencies in dialogue. However, given computational constraints, contemporary conversational models tend to rely predominantly on recent dialogue history when formulating responses. This predisposes them to produce content that may contradict earlier parts of the dialogue, especially distant sections. Generating clarification questions has emerged as a strategy to address communication breakdowns in dialogues, such as resolving ambiguities in a query during conversational information retrieval (Zamani et al., 2020b)

or clarifying ambiguous user questions in conversational question answering (Guo et al., 2021) scenarios. In this research, we propose an approach to recover from conversational inconsistencies by generating clarification questions, with the support of the proposed dataset.

**Large language models.** Recent advancements in AI have been dominated by the rise of large language models, notably ChatGPT (Ouyang et al., 2022), GPT-4 (OpenAI, 2023) and others. They have shown that by scaling up language models, they can be equipped to tackle intricate tasks, such as question answering, machine translation, and numerical reasoning. In this study, leveraging the extensive annotations of our proposed dataset, **CIDER**, we assess these models’ proficiency in detecting and addressing conversational inconsistencies.

### 3 Data collection

The candidate conversations for annotation are sampled from two open-source conversation datasets: LCCC and NaturalConv. LCCC (Wang et al., 2020) is a large collection of short conversations from the Chinese social media platform Weibo. NaturalConv (Wang et al., 2021) is an annotator-written dataset containing conversations around news items on topics like film and sports. They are different in content and style. LCCC conversations tend to be short in number of turns, and more in the style of daily chitchat. NaturalConv conversations, in contrast, are two to five times longer and contain more serious discussions about events in sports, films, and other areas. 20,000 and 10,000 conversations are sampled from the LCCC and NaturalConv respectively for annotation. When sampling, conversations that are shorter than 4 turns or contain utterances shorter than 5 words are filtered out.

The sampled conversations are generally consistent, therefore the goal of data annotation is to create an alternative conversation that contains inconsistent utterances. To achieve this, we truncate the original conversation to create a common conversation context. For LCCC, the last utterance is truncated for inconsistent continuation writing; for NaturalConv, a random turn between 8 and  $l - 4^3$  and the following turns are chosen for truncation, where  $l$  is the length of the conversation.

Finally, a specified source turn is sampled from the last turn or the turn before the last. This source

<sup>3</sup>The last turns of NaturalConv tend to be goodbyes, therefore we choose to truncate before such utterances.

Len. is the average explanation length; Ave. Res. Len. is the average resolution question length. They correspond to the outcome from the three annotation tasks.

turn is designated to be the source of the inconsistency where the following inconsistent continuation needs to form inconsistency with the utterance from the same speaker in this turn.

### 4 Annotation guidelines

The annotation process has been divided into three different tasks: inconsistent continuation, inconsistency explanation, and inconsistency resolution, which are required to be performed to each candidate conversation by one annotator when given a candidate conversation and a specified source turn.

**Inconsistent continuation.** The annotator first tries to create a natural continuation of the conversation by providing a possible utterance to the candidate conversation, but forms an inconsistency with the specified source utterance (A2 in Figure 1 is the continuation, and A1 is the source.) The annotators are instructed to write the utterance with contradictory viewpoints, reasoning, and argumentation, instead of providing simple negation to the source utterance. For example, for the specified utterance *I went to the supermarket yesterday.*, the continuation meeting the annotation requirement is *I have been staying home for the past four days, not really wanting to go anywhere*, instead of *I didn’t go to the supermarket yesterday.*

**Inconsistency explanation.** After writing the continuation of the candidate conversation, the annotator is instructed to write down the rationale behind the created inconsistency (the dashed box in Figure 1). They are asked to follow this template when writing the rationale: *The specified utterance means X, but the continuation utterance means Y, which is in contradiction with X.*, where the utterance meanings should be explicit. In the example above, the explanation one may write is *The specified utterance indicates that I went out of my home*

Table 2: Dataset statistics for checking tasks. Pos/Neg corresponds to label *inconsistent/consistent*.

yesterday, but the continuation utterance means that I didn't go out for many days including yesterday, which is in contradiction with the previous statement.

**Inconsistency resolution.** Finally, the annotator provides another utterance to expose and question the inconsistency from a different party than the continuation party (B2 in Figure 1). The annotator is asked to write the resolution question naturally with the main purpose being clarifying the situation instead of complaining. They are also asked to try varying how the clarification question is raised, because the most intuitive way is asking by providing a binary choice. The resolution question for the example above is *So were you home yesterday or did you go to the supermarket?*

Twelve examples collected from the two data sources and annotated by the authors were provided to the annotators along with the guidelines, which cover a number of common mistakes that the authors discovered in the trial annotation. The annotation project lasted two months, with six annotators<sup>4</sup> participating in the project from a commercial annotation provider, who was chosen amongst three providers based on the performance in the trial annotation task. The items for annotation were segmented into batches, each with 3000 conversations. The annotated items are checked first by quality assurance specialists from the annotation provider by batch, and then spot-checked by the authors with the acceptance rate setting at 95%.<sup>5</sup> Candidate conversations which are not possible to form inconsistencies, such as conversations containing mostly utterances of simple greeting or agreeing,

<sup>4</sup>The chosen provider created a qualification test based on the annotation guidelines for selecting annotators. The annotators with the highest agreement with the authors were then chosen as annotators. They then went through an online training session with the authors to align with the understanding of guidelines from the authors. They were paid twice the local average monthly salary for their contributions.

<sup>5</sup>The spot-check rate is 10%.

are dropped in the annotation process.

## 5 Data overview

After annotation, 17,806 conversations from LCCC and 9,374 conversations from NaturalConv have valid annotation. They are further split into train, dev and test sets, shown in Table 1. The average continuation and explanation lengths from LCCC conversations are substantially shorter than from NaturalConv, indicating the simple nature of social media conversations. The resolution question lengths are closer than the other lengths, showing that resolution questions tend to be less influenced by context and style.

## 6 Consistency checking

In this section, we experimentally verify whether the proposed **CIDER** could help the detection of inconsistency in conversation via two task settings: (1) checking the consistency between two sentences (*Pair-Check*); (2) checking the consistency between an utterance and its preceding context (*Diag-Check*). The (in)consistency checker is initialized as RoBERTa-base (Liu et al., 2019) with a linear binary classification head on the top. The input of the encoder for *Pair-Check* is formatted as "[CLS] {sentence 1} [SEP] {sentence 2} [SEP]" while for *Diag-Check*, "[CLS] {context} [SEP] {utterance} [SEP]", where the [CLS] and [SEP] are special tokens.

**Baselines.** We compare **CIDER** with several related datasets:

- CDConv (Zheng et al., 2022): a dataset with 12K dialogues for conversational contradiction detection. Compared to **CIDER**, CDConv covers another two types of contradiction: intra-sentence contradiction and role confusion. Each dialogue of CDConv contains two turns of utterances between a user and a bot

and annotation of *consistent* or *inconsistent* between the replies of the bot.

- **STANCE**<sup>6</sup>: a dataset for stance classification of articles of debating topics from online forums, where sentence pairs against each other are marked as *inconsistent* and otherwise *consistent*.
- **OCNLI** (Hu et al., 2020): a large-scale natural language inference (NLI) dataset, consisting of about 56,000 annotated sentence pairs. We regard sentence pairs with *contradiction* label as *inconsistent* and others as *consistent*.

**Implementation details.** For **CIDER**, when creating *consistent* training instances of *Pair-Check*, we regard all the utterances in the context of the

<sup>6</sup>[www.fudan-disc.com/sharedtask/AIDebater21/tracks.html](http://www.fudan-disc.com/sharedtask/AIDebater21/tracks.html)

same speaker without *inconsistent* label as being consistent with the current response; and when creating the training instances of *Diag-Check*, we drop current response with inconsistency and regard the previous response as being consistent with the context. Table 2 shows the statistics of the datasets for these two checking tasks.

We adopt AdamW (Loshchilov and Hutter, 2019) to optimize models for 50 epochs with a learning rate of 1e-6 and a batch size of 16. We evaluate the model on the validation set at each epoch and keep the one with the best performance with an early stop patience of 3. All the results are averaged over three runs. Our experiments are run on two Nvidia V100 GPUs.

**Results for *Pair-Check*.** The performance of checkers trained on different datasets for *Pair-*

*Check* is demonstrated in Table 3a. For each checker, we show its performance on all the test sets of the evaluating datasets.

There is a substantial distribution difference between the datasets with the checker trained on one dataset performing the best on the corresponding test set.  $C_{\text{CIDER}}^{\text{Turn}}$  has the largest exceeding F1 points over the second best, 36.1, indicating that the checker trained on other datasets is not good at detecting the consistency in the test set of **CIDER** and the training set of **CIDER** could provide useful supervision for it. Moreover, we compare the 0-shot transfer ability of checkers across the datasets. Results show that  $C_{\text{CIDER}}^{\text{Turn}}$  has the best transfer results on all the other three datasets, surpassing the second best by 18.0, 38.0, and 5.6 F1 points, respectively, demonstrating  $C_{\text{CIDER}}^{\text{Turn}}$  covering many similar linguistic phenomena in other datasets. On the whole, **CIDER provides robust supervision to check whether a pair of sentences are consistent, regardless of they are in a dialogue or not.**

**Results for *Diag-Check*.** The performance of the checkers trained on different datasets for *Diag-Check* is demonstrated in Table 3b. The results of  $C_{\text{CDConv}}^{\text{Diag}}$  and  $C_{\text{CIDER}}^{\text{Diag}}$  indicates again the distribution difference between **CIDER** and CDConv also being significant for *Diag-Check* task: **CIDER** do not cover role confusion and intra-sentence contradiction these two types of inconsistency while being much larger than CDConv. In addition,  $C_{\text{CIDER}}^{\text{Diag}}$  outperforms  $C_{\text{CDConv}}^{\text{Diag}}$  on *STANCE Test* by 30.6 F1 points and on *OCNLI Test* by 11.7 F1 points, which demonstrates better transferring ability of  $C_{\text{CIDER}}^{\text{Diag}}$  to non-conversational scenarios. Therefore, along with the transferring results in Table 3a, **CIDER offers more transferable patterns for checking consistency, and may be complementary to CD-Conv in the conversational scenarios.** We also notice that  $C_{\text{OCNLI}}^{\text{Turn}}$  is superior to  $C_{\text{CIDER}}^{\text{Diag}}$  on *CD-Conv Test (Diag)* and to  $C_{\text{CDConv}}^{\text{Diag}}$  on *CIDER Test (Diag)*, showing that the knowledge of inconsistency between sentences in OCNLI is also useful for the inconsistency checking in dialogue.

**Role of extra data.** We are interested in whether other datasets could improve the performance of  $C_{\text{CIDER}}$ . We leverage the training data of STANCE, OCNLI, and CDConv via two ways: 1) directly merging one of them into the training data of **CIDER (Merge)**; 2) pretraining the checker on one of them before training on **CIDER (Pretrain)**.

The results are presented in Table 4. It’s evident that **incorporating additional data generally enhances the overall performance of  $C_{\text{CIDER}}$** . The only exception is that only pretraining on OCNLI could improve the checker for *Diag-Check* task, which indicates better supervision signal from OCNLI for checking the inconsistency of an utterance. Compared with pretraining on extra data, directly merging them is superior, which could be ascribed to the phenomenon of catastrophic forgetting (Kirkpatrick et al., 2017) of pretrained models. Moreover, *Pair-Check* generally benefits from the extra datasets more than *Diag-Check* because most of the extra datasets are intrinsically designed for checking of sentence pairs and in large quality so models could learn generalized patterns from them.

**LLMs as consistency checker.** We investigated the potential of large language models (LLMs) to function as robust consistency checkers. We pre-examine five human-crafted prompts for each task using a small-scale test set (50 instances) and select the best. The prompts applied for the checking tasks are illustrated in Figure 2. The evaluating LLMs are ChatGPT and GPT4<sup>7</sup>. As shown in Table 5, LLM-based checkers significantly lag behind the fully supervised  $C_{\text{CIDER}}$ , indicating that there is still much room for improvement. Moreover, the higher performance of GPT4 over ChatGPT underscores that larger LLMs possess a better capability to detect inconsistencies.

<i>Pair-Check</i>	Whether the following two sentences are semantically related and have semantic inconsistencies, please answer "yes" or "no". sentence 1: {sentence 1} sentence 2: {sentence 2}
<i>Diag-Check</i>	Please answer "yes" or "no" if the speaker of the last sentence in the following dialogue contradicts himself, and give an explanation. {dialogue}

Figure 2: Prompts of checking tasks.

## 7 Consistency resolution

Inconsistent responses of a conversational model could be detected by a consistency checker in advance, avoiding being exposed to users. However, inconsistent responses from a user can not be ignored by chat systems. The existence of inconsistent content may confuse the conversational model

<sup>7</sup>We use the versions gpt-3.5-turbo-0613 and gpt-4-0613 across our experiments.

	<i>Pair-Check</i>			<i>Diag-Check</i>		
	Pre.	Rec.	F1	Pre.	Rec.	F1
C <sub>CIDER</sub>	<b>76.2</b>	69.3	<b>72.6</b>	<b>89.4</b>	<b>91.6</b>	<b>90.5</b>
ChatGPT	42.0	<b>79.0</b>	54.8	57.2	84.9	68.4
GPT4	49.9	76.2	60.3	68.8	82.1	74.8

Table 5: Performance of LLMs on checking tasks.

and induce undesired responses. Resolving the occurred inconsistency is necessary to maintain a smooth dialogue flow with clear semantics. The proposed **CIDER** dataset contributes to resolving the occurred inconsistency in a dialogue with *clarification responses*, which is a valuable source to train an inconsistency resolution model.

We choose the base version of two representative conditional generative models to initialize the resolver: BART (Lewis et al., 2020) and T5 (Raffel et al., 2020). They both follow an encoder-decoder structure and generate clarification responses in a sequence-to-sequence fashion: the conversational text with inconsistency is fed into the encoder and the clarification response is generated aggressively by the decoder. Like the checking experiments in section 6, we consider two task settings: (1) generating a clarification response for a pair of inconsistent utterances (*Pair-Resolve*); (2) generating a clarification response for a dialogue, of which the current response is inconsistent to the preceding context (*Diag-Resolve*). The input of the encoder for *Pair-Resolve* is formatted as "[CLS] {utterance 1} [SEP] {utterance 2} [SEP]" while for *Diag-Resolve*, "[CLS] {context} [SEP] {response} [SEP]".

**Implementation details.** We use the same optimization configuration of checkers to train the resolvers, except that a learning rate of  $3e-4$  is used for T5. BART and T5 are loaded with pretrained parameters from Zhao et al. (2019) and Shao et al. (2021), respectively. In decoding, we adopt Nucleus Sampling (Holtzman et al., 2020) with top-0.90 probability mass across the experiments.

**Evaluation.** We use BLEU (Papineni et al., 2002) and ROUGE (Lin, 2004), including ROUGE-1 (R-1), ROUGE-2 (R-2) and ROUGE-L (R-L), to measure the similarity between the generated text and the ground truth.

**Results.** According to rows #1 and #2 in Table 6, BART shows better performance in both

*Pair-Resolve* and *Diag-Resolve* tasks than T5, indicating the pretrained parameters of BART are more suitable to inconsistency resolving. Meanwhile, the points of *Pair-Resolve* are higher than those of *Diag-Resolve*, which could be ascribed to *Diag-Resolve* being a more difficult task than *Pair-Resolve* because recognizing inconsistent contents between conversational context and a response is harder than between a pair of sentences. We also try appending *explanations* to the input of the encoder to aid the generation process. Specifically, the input becomes "[CLS] {utterance 1} [SEP] {utterance 2} [SEP] {explanation} [SEP]" for *Pair-Resolve* and "[CLS] {context} [SEP] {response} [SEP] {explanation} [SEP]" for *Diag-Resolve*. The models with *explanation* are denoted as T5<sub>oracle</sub> and BART<sub>oracle</sub>, whose performances are shown at rows #3 and #4 in Table 6. We could see that T5<sub>oracle</sub> and BART<sub>oracle</sub> surpass T5 and BART by a significant margin, showing that with *explanations* informing what inconsistency the input delivers, the models are able to produce clarification responses more semantically similar to the ground truth. Moreover, BART<sub>oracle</sub> performs better than T5<sub>oracle</sub> across all the metrics, demonstrating BART is better at exploiting *explanations* to resolve semantic inconsistency.

**Analysis.** We go through 200 randomly selected instances (100 from *Pair-Resolve* and 100 from *Diag-Resolve*) of the best-performing BART resolver to 1) check whether the generated responses successfully clarify the inconsistent content and 2) explore the possible reasons that the clarification fails. The numbers of successful instances are presented in Table 7. We could see **BART faces challenges in inconsistency resolution** and there is still large room for improvement. The higher success count for *Pair-Resolve* compared to *Diag-Resolve* indicates again that resolving inconsistencies between a response and its context poses greater challenges. We summarise the main types of failed clarification as follows:

1. The resolver misses inconsistent content and just picks irrelevant semantic units to form a clarifying response. For instance, the user first says *I want to buy a cup of coffee because I'm so sleepy.* and then *Great, let's try Chinese tea!*. The resolver responds with *Are you on earth sleepy or not?* This error type is common in *Diag-Resolve* because long context contains irrelevant information that interferes with locating inconsistent content.

Model	Pair-Resolve				Diag-Resolve			
	BLEU	R-1	R-2	R-L	BLEU	R-1	R-2	R-L
#1 T5	26.9	55.3	33.0	52.2	14.8	43.0	20.6	40.4
#2 BART	28.2 $\uparrow$ 1.3	57.2 $\uparrow$ 1.9	34.8 $\uparrow$ 1.8	53.7 $\uparrow$ 1.5	14.9 $\uparrow$ 0.1	43.7 $\uparrow$ 0.7	21.7 $\uparrow$ 1.1	41.0 $\uparrow$ 0.6
#3 T5 <sub>oracle</sub>	46.2	71.5	53.0	68.3	46.7	71.7	53.2	68.3
#4 BART <sub>oracle</sub>	49.4 $\uparrow$ 3.2	74.4 $\uparrow$ 2.9	56.2 $\uparrow$ 3.2	70.7 $\uparrow$ 2.4	47.4 $\uparrow$ 0.7	72.4 $\uparrow$ 0.7	53.9 $\uparrow$ 0.7	68.7 $\uparrow$ 0.4
#5 ChatGPT	14.3	45.2	22.2	41.4	5.3	29.8	9.9	26.9
#6 GPT4	10.8	42.7	20.2	38.0	4.1	28.0	9.8	24.2

Table 6: Performance of resolvers on the test set of **CIDER**. The relative increasing ( $\uparrow$ ) points of BART (BART<sub>oracle</sub>) are calculated based on the performance of T5 (T5<sub>oracle</sub>).

Model	#Succ. / #Total	
	Pair-Resolve	Diag-Resolve
BART	56 / 100	36 / 100
BART <sub>oracle</sub>	91 / 100	82 / 100
ChatGPT	76 / 100	64 / 100
GPT4	92 / 100	79 / 100

Table 7: The number of successfully resolved instances.

2. The resolver includes the inconsistent content in the response but fails to form a fluent, contextual coherent response. For example, the user first says *Are you free? I want you to do me a favor.* and then *I am busy now.* and the resolver replies with *Can you do a favor at all?.* In this case, the resolver misunderstands who is the subject of the action, thus providing a response incoherent to the context.

**LLMs as consistency resolver.** We examine the consistency resolution ability of LLMs by asking LLMs to form a clarification response for the two resolving tasks via the prompts shown in Figure 3 (one in-context example is included in the prompts to ensure a fixed output format).

We report automatic evaluation results in rows #5 and #6 of Table 6. On the selected instances in subsection **Analysis**, we conduct the same human evaluation of the generated clarification response of the LLMs and show the results in Table 7. Results indicate that: **while ChatGPT and GPT4, both cutting-edge LLMs, score lower in BLEU and ROUGE compared to T5 and BART, they excel in addressing inconsistencies in dialogue history**, whose performance rivals that of the oracle resolvers. The lower BLEU and ROUGE scores of LLMs can be attributed to their tendency to produce more varied and extensive sentences. To illustrate, consider the reference clarification sentence: *Do you really want to eat hot pot or barbecue?.* BART’s response is, *Do you really want to eat hot*

<b>Pair-Resolve</b>	<p>You will be given two contradictory sentences from a person, and you need to reply to him and ask him what he really thinks. Like the following example:</p> <pre>{sentence 1} {sentence 2} {reply} {sentence 1} {sentence 2} What is the reply?</pre>
<b>Diag-Resolve</b>	<p>You will be given a dialogue between A and B, in which the current speaker says something contradictory, and you need to generate a reply from another person to ask him what he really thinks. Like the following example:</p> <pre>{dialogue1} {reply} {dialogue2} What is the reply?</pre>

Figure 3: Prompts of resolving tasks.

*pot or not?.*, whereas GPT4 offers, *So, are you more attracted to hot pot, or does barbecue appeal to you more?.*

## 8 Conclusion

We present **CIDER**, a comprehensive dialogue dataset comprising 27,180 annotated dialogues to investigate conversational inconsistencies. The annotations of **CIDER** cover the whole life span of inconsistencies: the human-authored utterances with inconsistent content demonstrate the introduction of inconsistencies; the explanations help understand the inconsistencies; and the clarification responses exemplify how to resolve the inconsistencies. Through rigorous experiments and analysis, we show that **CIDER** significantly advance the detection and resolution of conversational inconsistencies, and large language models, ChatGPT and GPT4, exhibit commendable performance in resolving these conversational inconsistencies but struggle with identifying them.

## Limitation

Our work has following limitations:

- Our proposed dataset emphasizes contradictions between utterances. For a truly effective system that detects or resolves inconsistencies, it is essential to incorporate resources that address other types of inconsistencies, such as intra-utterance or extrinsic discrepancies.
- We’ve currently evaluated the ability of LLMs to function as independent resolvers under specific prompts to generate clarification questions. The potential for these models to autonomously identify and clarify inconsistencies remains an intriguing avenue for future exploration. Moreover, while our evaluation of LLMs relies on the optimal prompts chosen from several human-crafted options, a more rigorous approach to prompt engineering could potentially yield superior outcomes.

## Ethical consideration

Our dataset, along with the LCCC (Wang et al., 2020) and NaturalConv (Wang et al., 2021) sources, have been cleaned to ensure no breaches of privacy (further details are available in their respective papers). All annotation guidelines (as detailed in Section 4) have received approval from the ethics review committee. We are confident that **CIDER** will play a pivotal role in crafting more human-friendly conversational models.

## Abstract

We present MUG, a novel interactive task for multimodal grounding where a user and an agent work collaboratively on an interface screen. Prior works modeled multimodal UI grounding in one round: the user gives a command and the agent responds to the command. Yet, in a realistic scenario, a user command can be ambiguous when the target action is inherently difficult to articulate in natural language. MUG allows multiple rounds of interactions such that upon seeing the agent responses, the user can give further commands for the agent to refine or even *correct* its actions. Such interaction is critical for improving grounding performances in real-world use cases. To investigate the problem, we create a new dataset that consists of 77,820 sequences of human user-agent interaction on mobile interfaces in which 20% involves multiple rounds of interactions. To establish benchmark, we experiment with a range of modeling variants and evaluation strategies, including both offline and online evaluation—the online strategy consists of both human evaluation and automatic with simulators. Our experiments show that iterative interaction significantly improves the absolute task completion by 18% over the entire test set and 31% over the challenging split. Our results lay the foundation for further investigation of the problem.

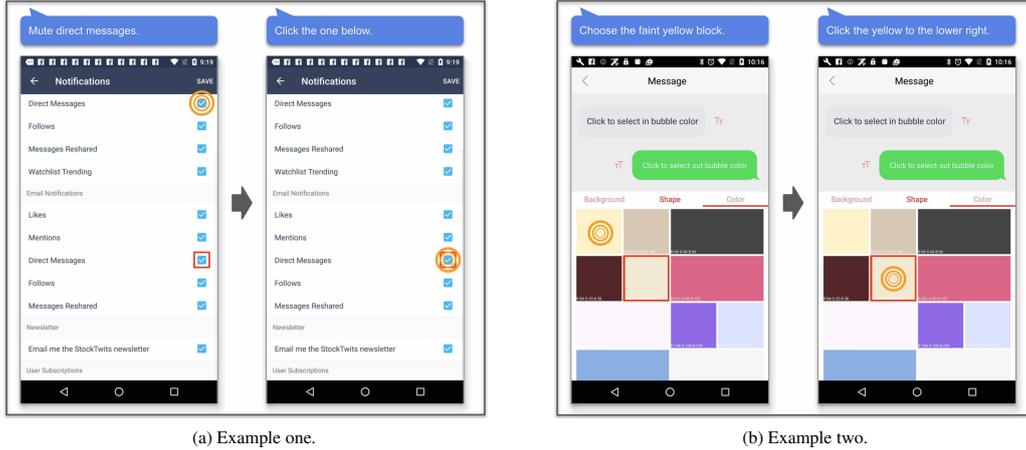

## 1 Introduction

Natural language understanding on graphical user interfaces (GUIs) is crucial for realizing human-computer interaction and assisting scenarios that have accessibility difficulties (Sarsenbayeva, 2018). Specifically, interpreting user commands into executable actions has drawn increasing interests as it manifests rich research problems including multimodal modeling and natural language grounding (e.g., Li et al., 2017; Gur et al., 2019; He et al., 2020; Li et al., 2020a, 2021). Prior works often consider UI grounding in a single-

pass fashion where the model predicts actions with a given instruction without looking backward to refine prediction. However, in a realistic scenario, user instructions can be *ambiguous* or *imprecise* when the target action is difficult or inconvenient to articulate. Reasoning in such cases is inherently iterative. Therefore, it is important and beneficial to incorporate interaction for resilient grounding (Suhr et al., 2019; Chandu et al., 2021).

In this paper, we investigate interactive grounding on GUIs, which aligns multimodal input to actionable objects of a screen. We focus on single-screen interaction which is the building block of UI reasoning. Specifically, we introduce the MUG (Multi-turn UI Grounding) task in which the user iteratively guides the agent to select a desired UI object (see Fig. 1). With a given UI and a target object, the user instructs the agent via natural language, ranging from casual intent to more descriptive commands. The agent infers which UI object is intended by the user and highlights it. If the agent is correct, the user can confirm the selection and the grounding is completed. Otherwise, the user issues further guidance, e.g., "*Click the one below*", to the agent to refine its selection. We collect the MUG dataset from live interaction sessions between pairs of human annotators—one acts as the user and the other as the agent. Our dataset has 77,820 examples, each records the transaction history in a session. Specially, 20% of the dataset are challenging ones as their human commands need multiple rounds to ground, even for human agents.

To establish the benchmark, we experiment with a range of variants to model the dynamics between the two roles. While the main goal of the task is to develop agent models for grounding, we also develop the user models for online instruction simulation. We build our models upon a Transformer-based encoder-decoder architecture (Li et al., 2021), and experiment with

(a) Example one.

(b) Example two.

Figure 1: Two illustrations of MUG with two turns in each. Interactions happen on the same screen. User commands are shown above the screens. The target object is bounded in  $\square$ . Agent choices are marked with  $\odot$ .

various learning methods, including traditional sequence modeling and reinforcement learning. To fully examine the model performances, we evaluate the agent model with a spectrum of evaluation strategies, including both offline and online evaluations. For the online evaluation, we employ both automatic and human evaluations, which include interactions between the agent and the user (either a human or the user model) and offer a comprehensive probe into model understanding. Our experiments show that incorporating interaction substantially improves UI grounding task completion by 18% on the entire dataset and 31% on the challenging set, both in absolute scales. Furthermore, our robustness measurements suggest MUG, while being a seemingly easy single-screen task, is actually difficult since neural agents sometimes struggle to correct themselves, resulting in repeated wrong selections across multiple turns. This suggests large rooms for future improvement in grounding agents.

In summary, our key contributions<sup>1</sup> are:

1. We introduce MUG, a novel interactive vision-language task that focuses on multi-turn language grounding on a graphical UI screen, which is a challenging task to improve language grounding in realistic UIs.
2. We create a rich dataset that includes 77,820 examples recorded from live sessions between pairs of human users and agents. And 20% of the data are challenging for both human annotators and neural agents.

<sup>1</sup>The dataset and code for reproducing our experiments are at <https://github.com/to-be-de-anonymized>.

3. We experiment with a range of model variants and evaluation strategies, showing that iterative interaction significantly improves grounding accuracy by 18% and 31% on the entire and challenging test sets respectively, with automatic assistance from our user models. Our work lays a foundation for future investigations on collaborative grounding.

## 2 Background

Multi-modal modeling has a long history of research (e.g., Winograd, 1972; Barnard and Forsyth, 2001; Lavrenko et al., 2003; Plummer et al., 2015; Yu et al., 2016). One important area focuses on grounding objects in images where the natural language is used as an additional input (Chen et al., 2017; Yu et al., 2016, 2018; Fukui et al., 2016; Deng et al., 2021).

**Interactive Multimodal Grounding** Prior works have formulated grounding as a multi-step reasoning task, e.g., navigation via multiple steps of grounding (e.g., Ku et al., 2020; Gur et al., 2019). Our work differs by focusing on agent’s ability to self-correct in synchronized turns of interaction on a UI screen. It is also conceptually linked to repeated reference game (Hawkins et al., 2020), except we use a different form of communication (language-action) instead of dialogue (language-language). Our task leverages iteratively refined instructions on atomic action instead of the increased instruction utility over multi-step actions (Effenberger et al., 2021). We model both the user and the agent, and let them communicate online. This is different from

single-sided modelings (Suhr et al., 2019; Kojima et al., 2021). Our observation that interaction improves grounding is also in line with dialogue-based works (e.g., Haber et al., 2019; Takmaz et al., 2020).

**UI Grounding** Grounding UI objects involves automatic completion of actions on web or mobile interfaces (e.g. Pasupat et al., 2018; Li et al., 2020a; He et al., 2020). It is also an important accessibility task for users who are situationally impaired when they are occupied by real-world tasks at hand (Sarsenbayeva, 2018). Compared to grounding on natural images, these tasks usually take well-specified user commands and aim to select the object that best matches the command. The UI image is often encoded via ResNet (He et al., 2016) or ViT (Dosovitskiy et al., 2020). The structure and text features of UI are often encoded by Transformer model (Vaswani et al., 2017). Fusing multimodal information is widely handled by cross-attention (e.g. He et al., 2020; Li et al., 2021; Bai et al., 2021). We adopt these neural components in our benchmark.

**Mobile UI Datasets** Many grounding tasks, while covering multiple screens, remain one-pass reasoning, such as PIXELHELP (Li et al., 2020a) and MOTIF (Burns et al., 2022). Prior works (e.g., Todi et al., 2021) used reinforcement learning (RL) in design space. In contrast, MUG focuses on correcting a single action on one screen. Tab. 1 summarizes key differences among other Mobile UI datasets. Importantly, MUG is a challenging task as it enables corrective interaction in synchronized turn between user and agent.

Data	Screen	Instr	Natural	Corrective
RICO	multi	✗	✗	✗
PIXELHELP	multi	✓	✓	✗
MOTIF	multi	✓	✓	✗
RICOSCA	single	✓	✗	✗
REFEXP	single	✓	✓	✗
MUG (Ours)	single	✓	✓	✓

Table 1: Comparison to prior mobile UI Datasets, including RICO (Deka et al., 2017), RICOSCA (Li et al., 2020a), and REFEXP (Bai et al., 2021).

Our dataset further differentiate from later works (e.g. Deng et al., 2023). While tasks are formulated as multi-step navigation in both, we focus more on corrective interactions for a single action.

### 3 Task Formulations

As a grounding task, MUG involves two participants: a user and an agent. Our formulation includes both roles to provide a holistic view of interactive grounding. The user’s goal is to instruct, via natural language, the agent to select the desired object  $g$  on the UI screen  $S$ . The unique aspect of MUG is that it allows the user to guide the agent *iteratively* to identify the target action by issuing a series of commands, each in response to the agent’s prior inference.

We separate such user-agent interaction into turns. At turn  $t$ , the interaction consists of:

$$\begin{cases} c_t : \text{user command,} \\ a_t : \text{agent action.} \end{cases}$$

where the user first instructs the agent with command  $c_t$ , and the agent responds with a suggestion of action  $a_t$ . Here  $a_t$  is essentially the index of object. The task is completed when  $a_t = g$ .

#### 3.1 Agent Task

In MUG, the action space for the agent consists of a set of UI objects to click on the interface, e.g., in Fig 1. Intuitively, we would want the agent to take the desired action  $g$  as early as possible. Thus, at turn  $t$ , the agent models

$$P_{\theta}(a_t|S, c_{[0,t]}, a_{[0,t-1]}) \quad (1)$$

where  $\theta$  denotes the agent parameters. This iterative grounding early stops once  $a_t = g$  or  $t$  reaches a maximum number of turns allowed.

#### 3.2 User Task

The user’s role is to provide guidance to the agent through iteratively refined instructions. In contrast to one-pass prediction tasks (e.g. Pasupat et al., 2018; He et al., 2020) where the agent makes a one-shot guess, a MUG user issues follow-up commands that are dependent of prior instructions  $c_{[0,t-1]}$  and agent actions  $a_{[0,t-1]}$ , which is formalized as the following:

$$P_{\phi}(c_t|S, g, c_{[0,t-1]}, a_{[0,t-1]}) \quad (2)$$

where  $\phi$  denotes the user. Here, the user model is aware of the target object  $g$ .

**Interplay between User and Agent** The agent task (Eq. 1) is the pivot of MUG. The user task (Eq. 2) aims to guide agent towards task completion, which potentially includes online training. In

our benchmark, we let the user and agent play together. Although automatic evaluation is not as realistic as human evaluation, it offers a fast, low-cost, and reproducible environment. This setting also allows us to study various questions surrounding the interplay between the two, e.g., whether an automatic user can assist an agent? and whether agent errors would confuse the user?

## 4 Dataset Creation

As there is no available dataset for model training and evaluation, we developed an interactive labeling interface to collect data for MUG. Our data collection involves two human annotators to play the roles of the user and the agent respectively in a live session. The user and the agent have two separate views, running on different machines (Appx. A). Both views share the same UI screen and a message box showing instruction history. Our task embodies the *eyes-on, hands-free* situation for mobile interaction where the user is required to only use language for the task, and the machine responds its prediction by highlighting. The user can commit the action if the prediction is confirmed. In a session, only the user can see the target; and the message box is read-only to the agent so no language-based dialogue would happen.

### 4.1 Annotation Workflow

We use the UI corpus, mobile UI screenshots and view hierarchies, from RICO (Deka et al., 2017) and auxiliary object features from the CLAY dataset (Li et al., 2022). Each session starts with a randomly sampled UI object (e.g., a *button*), from the visible view hierarchy, as the target object  $g$ . User annotators are encouraged to articulate their initial command ( $c_0$ ) casually or goal-oriented. We consider such design to cover the realistic scenarios discussed in Sec. 1, and free users from composing long and precise instructions.

In the agent view, all clickable objects on the UI screen are revealed with their bounding boxes highlighted, which show what objects the agent can select, without indicating which one is the target  $g$ . The current agent selection is reflected on both the user and the agent’s view. The session continues to the user’s turn if the agent selection does not match  $g$ . In follow-up turns, the user is not allowed to repeat a command issued in previous turns, and likewise the agent is not allowed to select an previously chosen object. Upon the agent

selection matching the target in the user view, the task is completed. Each session allows up to 5 turns and we filter out those unfinished. We refer to Appx. C for labeling details.

### 4.2 Data Analysis

We collected 77,820 examples based on 31,265 unique screens from 7,132 apps (see details in Table 2). We split the dataset into the training, development, and test sets. We use app-wise split (Li et al., 2020b) to avoid potential leaking across sets. As shown in Table 2, the splits have a similar distribution of number of turns per example. Simple statistics on vocabulary distribution is in Appx. D.

**Human performance establishes a high upper bound.** While users tend to provide short and sometimes vague instructions ( $\sim 4$  words),  $\sim 80\%$  of the tasks are solved in one turn by human agents. A critical question we aim to answer is that *can agent models approach this bar?*. In Sec. 6, we will show that agent models are far behind human performances, especially for examples that requires more turns for human agents (i.e., the rest  $\sim 20\%$ ). We will call this 20% as the *Challenging* subset. Detailed examples are in Appx. H.

**Multi-turn interaction is long-tailed.** While the 20% multi-turn ratio seems a low percentage but it can lead to large impact in practice. Real-world navigation problems often span over multiple screens with individual instruction on each screen. If we assume the 20% multi-turn ratio on each screen, the probability for multi-turn interaction to happen in a navigation task can be significantly larger, e.g., 67% with 5 screens.

In Appx B, we categorize 200 Challenging examples from the development split. We found follow-up commands are mainly for spatial adjustments or asking for extra information.

## 5 Grounding Models

We aim to have a general architecture for the UI domain and explore its variants to model multi-turn interaction. Our agent model is based on a transformer encoder-decoder network, inspired by (Li et al., 2021). Specifically, we extend the architecture to handle interaction history as input in the decoder.

### 5.1 Multimodal Encoder for UI

Our encoder processes the interface  $S$ . Each  $S$  consists of two modalities of information, i.e., a

Split	Statistics of examples					Distribution of Turns (%)				
	Apps	Screens	Interactions	Avg. #Turns	Avg. #Token/Turn	1	2	3	4	5
Train	6,039	26,090	65,235	1.24	4.26	78.91	18.31	2.37	0.35	0.06
Dev	544	2,625	6,377	1.23	4.18	79.99	17.77	1.91	0.27	0.06
Test	549	2,550	6,208	1.23	4.18	80.20	16.82	2.55	0.40	0.03
All	7,132	31,265	77,820	1.24	4.25	79.10	18.15	2.35	0.35	0.06

Table 2: Dataset statistics. Interaction is encouraged in multiple and short communication. Human performance establishes a practical upper bound  $\sim 80\%$  in solving the task in 1 turn. Agent models aim to approach this bar.

screenshot  $I_S$  and view hierarchy features  $\psi$  (Deka et al., 2017; Li et al., 2022). The concrete list of  $\psi$  is in Appx. E. The output is an encoding  $v^k$  for each object indexed by  $k$ , similar to (e.g., Li et al., 2020a; He et al., 2020; Li et al., 2020b):

$$\Phi_S = \text{ResNet}(I_S) \quad (3)$$

$$v = T_{\text{enc}}(\{\text{ROI}^k(\Phi_S)|\psi^k\}) \quad (4)$$

For the image, we use a pre-trained ResNet-50 (He et al., 2016) which is fine-tuned with other modules. The resulted  $\Phi_S$  (grid size of  $h \times w$ ) is then mapped to object level by region-of-interest (ROI) pooling (Ren et al., 2015). The multimodal features for each object are fused by a transformer encoder  $T_{\text{enc}}$ . The final  $v$  stands for a sequence of objects which are interaction-agnostic.

## 5.2 Grounding Decoder

We use a causal transformer  $T_{\text{dec}}$  to predict click action from interaction history. We extend the architecture of (Li et al., 2021) to incorporate multi-turn interaction as input (instead of single grounding statement). Specifically, we concatenate  $c_{[0,t]}$  and  $a_{[0,t-1]}$ , and combine it with imitation/reinforcement learning losses (instead of direct supervision loss). The output of  $T_{\text{dec}}$  is a vector  $z_t$  that summarizes prior interaction up to  $c_t$ :

$$z_t = T_{\text{dec}}(v, c_0, v^{a_0}, c_1, \dots, v^{a_{t-1}}, c_t) \quad (5)$$

where  $a_t$  denotes object index, either from model prediction or human selection. The specific input to Eq. 5 will be subject to modeling variants in Sec 6.1. For classification, we use a linear layer  $f$  to score the  $k$ -th object:

$$a_t = \arg \max_k f([z_t|v^k]) \quad (6)$$

## 6 Experiments

The goal of our experiments is to explore training and evaluation methods for MUG and establish a benchmark. For a naive baseline, one could

simply match the instruction tokens to the object texts on the screen. However, this turns out to be insufficient due to the often incomplete element attributes<sup>2</sup>. In Sec. 6.1, we explore multiple modeling variants for the agent. In Sec. 6.2, we present a simple and effective heuristics-based user model and a neural version for automatic evaluation. Lastly, we show extensive F1 results in Sec. 6.4 and 6.5, robustness in 6.6, ablations in 6.7 and 6.8. We refer readers to appendices for hyperparameters (Appx. F), sample predictions (Appx. I), error analysis (Appx. G).

**Separation of User and Agent Modeling** We train user model and agent model separately to avoid test leakage when using user models in automatic benchmark. Such setup limits our agent choices to offline ones. Future work can explore online agent (e.g., DAGGER (Ross et al., 2011)) with separate treatment on user models during training and inference.

To avoid confusion, we thereafter use  $a'_t$  to refer to the selection predicted by the agent model at turn  $t$ , while  $a_t$  to the human agent’s selection. Similarly, we refer  $c'_t$  to instruction generated by user model while  $c_t$  to the one by human user.

### 6.1 Agent Models

Our agent models use the  $T_{\text{enc}}$  and  $T_{\text{dec}}$  (in Sec. 5) as a backbone, denoted as  $\theta$ . Recall that  $T_{\text{enc}}$  processes  $S$  while  $T_{\text{dec}}$  processes interaction. Here, we discuss different handlings of  $T_{\text{dec}}$ .

**Single or Multi-turn Model** The first factor we investigate is how allowing multiple turns helps grounding. For each example, we can feed the entire interaction history as input to the agent model and supervise agent selection on the last turn  $T$ :

$$P(a'_T = g|S, c_{[0,T]}, a_{[0,T-1]}; \theta) \quad (7)$$

<sup>2</sup>For instance, the validation split has 46% objects missing text, and a deterministic classifier using METEOR (Banerjee and Lavie, 2005) has only 21% F1.

We can further reduce the input to be  $(S, c_0)$  only, making a single-turn model. To evaluate single-turn model with multi-turn examples, we simply concatenate all  $c_t$  into one instruction.

**Instruction-only Model** To understand how it helps grounding by taking into account of previous actions of the agent in the multi-turn model (Eq. 7), we introduce the command-only baseline, which ignores agent actions (selections) in the interaction history:

$$P(a'_T = g | S, c_{[0,T]}; \theta) \quad (8)$$

**Imitation Model** Instead of supervising the agent only at the last turn, we can model the entire action sequence as an imitation model:

$$\prod_t P(a'_t = a_t | S, c_{[0,t]}, a_{[0,t-1]}; \theta) \quad (9)$$

This variant investigates whether the supervision of the intermediate actions helps.

**Offline RL** Lastly, because each turn the agent action affects how the user responds, MUG can be formulated as a RL problem where the user and the UI constitute the environment. We use the Decision Transformer (Chen et al., 2021) for offline RL. In addition to imitation learning, we use it to promote early tasks completion by following the standard configuration: inserting extra learnable return tokens  $w_t$  to the  $T_{\text{dec}}$  before each action, i.e.,  $T_{\text{dec}}(v, c_0, w_0, v^{a_0}, \dots, c_t, w_t)$ . The model is:

$$\prod_t P(a'_t = a_t | S, c_{[0,t]}, w_{[0,t]}, a_{[0,t-1]}; \theta) \quad (10)$$

The encoder-decoder construction remains same as the above. Possible discrete return tokens are  $\{1, 2, 3, 4\}$  where 1 on the last turn. During testing, we follow Chen et al. (2021) to force the current turn to have return 1 and adjust prior returns.

## 6.2 User models

Here, we design a simple and effective heuristics-based user model, and then develop a neural version. To show automatic online evaluation is a promising direction for MUG, we also conducted human evaluation on a shared set of 500 examples from the test split (Sec. 6.7).

**Heuristics-based Model** We observe that, when the selection  $a'$  is incorrect, we can deterministically devise a follow-up instruction by using a template as below:

Not the  $a'_t$ , click the  $g$  to/on the  $dir$ .

This template is to be instantiated on view hierarchy features (in Appx. E). Compared to human follow-ups, heuristic ones are more specific and longer, such as:

- Not the *icon*, click the *action notifications* on the *top right of the screen*.
- Not the *text*, click the *input search* to the *slight right and below of your choice*.

**Neural Instruction Model** We extend the *Multi* agent architecture to model follow-up commands:

$$P(c'_t = c_t | S, g, c_{[0,t-1]}, a_{[0,t-1]}; \phi) \quad (11)$$

which uses  $T_{\text{dec}}(v, v^g, c_0, v^{a_0}, c_1, \dots, v^{a_{t-1}})$  at turn  $t$ . For training, we teacher-force at each turn ( $t > 0$ ). We found that using heuristics as prompt greatly boosts development CIDEr (Vedantam et al., 2015) to from 70 to 78. For inference, we use greedy decoding with a maximum length 12.

## 6.3 Metrics

We focus on evaluating the agent model as it is the pivot task of MUG. Intuitively, we want the agent to take the desired action  $g$  with less turns:

$$F1_t = \sum_t P(a_t = g | S, c_{[0,t]}, a_{[0,t-1]}) \quad (12)$$

where, in practice, we compute  $F1_t$  with early stop over turns to avoid double counting. Clearly, an agent with high F1 and a lower value of  $t$  is better than an agent that requires more turns for the same accuracy. With  $t$  limited to 0, the task is reduced to a one-pass grounding task.

In an extreme case, we consider an agent with high  $F1_0$  but flat changes in  $F1_{t > 0}$  to be problematic, since it questions the agent’s understanding about the interface. For more comprehensive testing, we also use a simple robustness metric for prediction changes across turns:

$$\Gamma = P(|\{a_t\}| \neq T) \quad (13)$$

which is the percentage of examples that have duplicate actions within  $T$  valid turns. We expect a robust agent model is able to understand previous errors and failed attentions so as not to repeat the same mistake. Furthermore, this metric is useful as we observe that neural users can issue the same instruction across turns. In this case, errors on the user side is further complicated when agents repeat the same error.

## 6.4 Offline Results

Tab. 3 presents offline results on the test set, over the *Challenging* (see Sec. 4) and the *All* sets. During inference, we use instructions from the human user and actions from the human agent for turns in between and ask an agent model to predict at each turn. Doing so requires agent models to correct human agent actions, instead of the model’s own. Clearly, the models that take into account interaction history outperform those use none or partially. While the *Ins-only* and the *Imitation* models perform closely on the *All* set, they bear larger margins on the *Challenging* and online tests.

## 6.5 Online Results

Tab. 4 presents online test scores. In general, models that are supervised by action sequences (i.e., *Imitation* and *Offline RL*) perform better. Both heuristics-based and neural user models are able to guide agents towards task completion. Comparing *Single*’s F1<sub>0</sub> and *Imitation*’s F1<sub>4</sub>, we see that properly using interaction boosts task completion by 18 and 31 on the *Challenging* and *All* test sets.

The average F1<sub>4</sub>’s show that heuristics-based user works better, except that the *Imitation* collaborates better with the neural user. This might be attributed to the neural user is trained to mimic human command patterns which can be ambiguous and short, while heuristics are more precise while

being artificial. This also implies that a large room for further improvement to the user modeling.

Overall, we can see interactive grounding is a challenging task, even on a single screen. The agent modeling involves robust multimodal understanding to self-correct. The user modeling requires controlled language generation, which is still an open problem. The best task completion rate on the *Challenging* subset is only  $\sim 55\%$ , suggesting a large room for future improvements.

## 6.6 Agent Robustness

We take a deeper look at agent behavior in Tab. 8. We observe that agents with higher F1 tend to be more robust (lower  $\Gamma$ ). The best agent model (*Imitation*) repeats the same mistake for only 16.8% on the *All* test set. However, if we ignore those examples finished in 1 turn i.e.,  $T > 1$  columns, the repeating rate rises to  $\sim 40\%$ . The *Heuristics* user, while generally improves agent F1 more than the *Neural* user, has a mixed robustness impact on the *Imitation* and *Offline RL* agents. On weaker agents (the first 3 rows), the *Heuristics* user leads to more salient robustness. These observations suggest improving agent F1 has a more direct and positive impact on robustness.

## 6.7 Automatic v.s. Human Evaluation

To show automatic online test is a promising surrogate for human-in-the-loop evaluation, we com-

Table 5: Agent  $\Gamma \downarrow$  on the test split. Results are from 5 random runs. Smaller  $\Gamma$  means more robust. *Single/Multi*: single/multi-turn model.

pare *Single* with *Multi*<sup>3</sup> with a group of human annotators (acting as the *user*) (Tab. 6). We ask the user annotators to follow the same annotation interface and guideline in Sec. 4, and let them to use the trained agent model to ground their commands. That is, human plays the user role and a trained agent model plays the agent role. This setting maximally mimics a realistic situation where a human user guides the agent to locate a target solely using language commands. The results (Tab. 6) are generally consistent with those from the automatic evaluation (Tab. 4). We should also note that such human study is not meant to reflect every minor differences in automatic evaluations.

Model	F1 <sub>0</sub>	F1 <sub>1</sub>	F1 <sub>2</sub>	F1 <sub>3</sub>	F1 <sub>4</sub>	$\Gamma \downarrow$
Single	<b>50.0</b>	56.4	58.2	58.4	59.4	42.6
Multi	49.6	<b>58.4</b>	<b>60.4</b>	<b>62.2</b>	<b>62.6</b>	<b>39.4</b>

Table 6: Human-in-the-loop evaluation on 500 examples from the *All* test set. Models are trained with seed 1.

## 6.8 Ablation on Heuristics

To show agent improves from follow-up instructions effectively, instead of overfitting potential artifacts in the dataset, we report our ablation studies in Tab. 9. Specifically, we focus on the heuristics-based user since it offers well-controlled instruction generation. We can see that random heuristics underperform by  $\sim 14\%$  and repeating the initial instruction is even worse. The  $\Gamma$  scores also suggest that randomly instantiated instructions are less effective in guiding the agent.

## 7 Analysis

Tab. 8 shows how model predictions are affected by corrective instructions generated by heuristics or the neural instruction model. On the challenging subset, there are about half of examples where

<sup>3</sup>We choose these two models as a pilot study since they perform consistently different in all our metrics.

<i>Multi</i>	F1 <sub>0</sub>	F1 <sub>1</sub>	F1 <sub>2</sub>	F1 <sub>3</sub>	F1 <sub>4</sub>	avg <sub>std</sub>	$\Gamma \downarrow$
Heuristics	25.2	<b>47.8</b>	<b>50.9</b>	<b>51.7</b>	<b>52.4</b>	-	<b>40.0</b>
Random	25.2	32.7	34.3	34.7	35.1	35.6 <sub>0.9</sub>	51.6 <sub>1.5</sub>
Repeat $c_0$	25.2	29.3	30.9	31.6	32.0	-	-

Table 7: Ablation of instructions using heuristics-based user model for the *Multi* agent (trained with seed 1) on the *Challenging* test set. *Random*: randomly instantiated heuristics for  $c_{t>0}$  across 5 seeds.

our agent models make repeatedly the same incorrect selection, irrespective of the corrective instruction. Even considering the entire test set, there are still  $\geq 26\%$  such cases. We broadly attribute this observation to the difficulty of the task as well as the challenge in multimodal modeling.

	Challenging		All	
	Heuristics	Neural	Heuristics	Neural
Single	57.8	56.6	33.4	34.0
Ins-only	48.4	53.3	27.0	30.4
Multi	49.5	52.9	27.4	30.6
Imitation	57.8	<b>45.3</b>	26.6	<b>26.2</b>
RL	<b>47.3</b>	50.8	<b>26.0</b>	29.0

Table 8: Percentage of example have duplicated predictions across turns. Lower values indicates less robustness.

<i>Multi</i>	F1 <sub>0</sub>	F1 <sub>1</sub>	F1 <sub>2</sub>	F1 <sub>3</sub>	F1 <sub>4</sub>	%Dup $\downarrow$
Heuristics	25.2	<b>47.8</b>	<b>50.9</b>	<b>51.7</b>	<b>52.4</b>	<b>49.5</b>
Random	25.2	34.0	37.4	38.2	38.6	62.7
Reuse 1st	25.2	29.3	30.9	31.6	32.0	70.2

Table 9: Heuristics v.s. immediate alternatives on the *Challenging* split using the *Multi* model. *Random*: instruction templates instantiated with random target object on the interface. *Reuse 1st*: reusing the first instruction across turns.

Tab. 9 compares our heuristics-based online evaluation against immediate alternatives. The large and consistent performance gaps suggest our agent models follow the hints in corrective instructions instead of random-guessing. For brevity, we used the *Multi* model to demonstrate. Other multi-turn models performed in a similar pattern (e.g., 15 $\sim$ 20% better F1<sub>4</sub> with Heuristics).

In Appx. I, we demonstrate predictions from the *Imitation* model with successfully solved examples as well as failed ones.

## 8 Conclusions

In this paper, we presented MUG, a novel and challenging task for multimodal grounding on UI. MUG requires a grounding agent being able to correct its own prediction, and allows a user to guide the agent via natural language instructions. For the task, we contribute a new dataset, investigate modeling options for the agent, and propose evaluation strategies along with two user models for automatic online testing. We found that interaction greatly improves grounding accuracy in the UI domain. Our experiments and analyses also suggest large room for grounding performances, even on a seemingly easy single screen task, which calls for future investigation. Our work also contributes to the general effort of multimodal language understanding and its robustness by enabling synchronized multi-turn interactivity.

### Limitations

**English-only Dataset** While non-English examples exist, we acknowledge that MUG mostly consists of English UI. Other languages do exist in the dataset, but consist of a small portion. Specifically, our instructions are English-only. Future extensions to our work should address or alleviate this issue.

**Platform-specific Interfaces** Our interfaces, since coming from RICO, only consist of Android screens. In practice, it is also difficult to obtain non-Android interfaces. We acknowledge this is an application limitation. And the bias from the top and bottom banner of Android could make trained model brittle in other domains.

**Going beyond Single Screen** We aim to establish the task and report baseline performances for future work. The interaction in MUG happens within the same user interface. A natural extension would be extending the task to span over sequence of interfaces. Indeed, the task would become more challenging, and potentially require large offline training data and reliable online simulation.

**Better User Model** The current best neural instruction generation we use has a CIDEr 78.0 on the validation set. We acknowledge there is space

for further improvement. Note that our neural instructions are trained on multi-turn examples in MUG, which amounts to  $\sim 20\%$  of the training data. It suggests external resources could be useful for improving user model performances.

### Interaction Dynamics between User and Agent

It would be helpful to study how/why the agent sometime repeatedly makes incorrect actions in Tab. 8, such as whether repeated mistakes are due to the lack of language utility/diversity in user instruction or the lack of understanding in the agent.

**Online Learning for Agent** As a starting point, we explored modeling variants that are immediate to the multi-turn interaction problem on UI. Since agent model is the pivot, future work should experiment agent models in an online setting where automatic interaction traces can be used to augment human annotations (e.g., DAGGER (Ross et al., 2011)). This, however, requires carefully separating the use of user model during training and automatic evaluation.

**Focus on Correcting Single Action** In this paper, we exclusively focused on the corrective interaction between user and agent models centered on a single action on a screen. Such focus, in the future, could be extended to fit the multi-screen navigation test case of generalist agents.

## A Labeling Interface

Fig. 2 presents the user and agent views in our data collection interface. In the user view, the user can send commands in the message box, to instruct the agent to select the target object as highlighted by a red bounding box on the UI screen. On the agent’s view, the agent annotator can respond the user request by performing object selection on the UI screen, which has all the clickable objects highlighted. But there is no indication of the target object so the agent annotator has to guess from the user instruction. The agent is not allowed to text back to the user. The agent’s current selection is reflected on the UI screen so the user understands how to further instruct the agent. The annotation task is designed based on the eyes-on hands-free situation of mobile interaction.

## B Manual Analysis on the Challenging Subset

In Tab. 10, we categorize 200 Challenging examples from the development split. We found follow-up commands are mainly for spatial adjustments or asking for extra information.

Percentage	Attribution	Example
50%	Adjusting relative position in the layout.	<i>the value before the text.</i>
31%	Providing more information of the target.	<i>show me channels. → click tv icon.</i>
10%	Adjusting direction/position on the screen.	<i>not reward but collect at the bottom.</i>
3%	Rephrasing the instruction.	<i>go to books. → show me books logo.</i>

Table 10: Major categories for the second turn from 200 examples in the development split.

## C Details of the Labeling Task

The labelers of the task were native English speakers and had experience using mobile phones. They were trained with a few pilot tasks to get familiar with the task, during which we also improved the labeling interface and the guidelines based on labelers’ feedback. The dataset was completed by 30 labelers in 10 batches. The labeling quality was monitored by sampling examples from each batch for manual examination.

## D Vocabulary Diversity

The word-level vocabulary in the training set consists of 13,794 unique words. Fig. 3 shows the distribution of the 50 most frequent words in the training split with certain non-content words (e.g., *is, of, comma*) filtered out.

## E View Hierarchy Features

Tab. 11 lists the complete view hierarchy features we used. We unify each feature into a real-valued vector. These view hierarchy features are first represented with trainable embeddings, and then encoded by the transformer model (Sec. 6.1). For text attributes (e.g., *text*), we max-pool their non-contextualized token embeddings, which are randomly initialized and trained. For discrete-valued attributes (e.g., *type*), we use a trainable vector for each possible value. The ordering of objects in transformer input follows the pre-order traversal in the view hierarchy (which is a tree structure). We then combine the vision representations of individual UI objects via ROI pooling over ResNet featuremap of the encoded screenshot image, and view hierarchy encoding to form a multimodal representation of each UI object for the downstream computation of the model.

We consider these view hierarchy features to be auxiliary. There is often a huge gap between what command the user would issue based on what they see on the UI, and what the underlying information is for the UI. As we discussed in Sec. 6, about 46% of UI objects do not have a text label, and the user

would need to come up with their own language description about the object, which is why the text matching baseline fails. Even when there are text descriptions, they are not necessarily what the user would articulate since a user command can be abstract. Fundamentally, the internal representation of the UI is often inaccessible or uninterpretable to the user, thus calling for the help of multimodal modeling and interaction modeling.

Feature	Example
bounding box	[xmin, xmax, ymin, ymax]
leaf	true/false
type	button/checkbox/...
clickable	true/false
text	email address/passcode
resource id	login_icon
dom	[pre/post-order index]

Table 11: Features  $\psi$  used for visual structure.

## F Hyperparameters & Training

For all our agent models, we use the same configurations, which are grid-searched based on models’ offline validation performances. Our hyperparameters are chosen from the best offline development F1 scores. For the number of self-attention modules, we grid-searched in  $\{1, 2, 4, 6\}$ , which resulted in 2 hidden layers for the user interface Transformer encoder and 6 hidden layers for the grounding decoder. Each self-attention module uses 8-head self and encoder-decoder attention with a 256 hidden size. The dropout rate for attention and MLP layers is 0.1, which is grid-searched in  $\{0.1, 0.2, 0.5\}$ . For learning rate, we grid-searched from  $\{1e-3, 3e-4, 1e-4, 3e-5, 1e-5\}$ , and use  $3e-4$  with linear warmup with cosine annealing for the first 10k steps. All the models are trained to 100k steps with a batch size of 128 on a 32-core Google Cloud TPUv3. Models are evaluated every 1k steps and the version with the best development offline F1<sub>4</sub> is saved. The training time for our agent model is around 8 hours.

Our neural user model has the same grid-searched configuration as the agent, i.e., 2 encoder

layers, 6 decoder layers, 0.1 for dropout, and the same warmup scheduling. The best learning rate is  $1e-4$ . Different from the agent model, we found the neural user model’s development CIDEr score quickly drops after 6k steps, possibly due to overfitting and data sparsity, thus its training early-stops there.

## G Error Analysis

We manually analyze errors from the best agent (*Imitation*). In Tab. 12, we inspect 30 failed development examples (i.e., unfinished after 5 turns) that are subject to the *Neural* user. Due to the role interplay, we also count problematic commands. We observe that the user model sometimes issues repetitive or uninformative instructions starting from the 3rd turn, leading the agent to the same wrong selection. This might be caused by the data sparsity for examples with  $\geq 3$  turns.

	Agent				User	
	text	icon	UI layout	pos/dir	wrong $c_t$	stale $c_t$
#Example	6	7	9	7	15	27

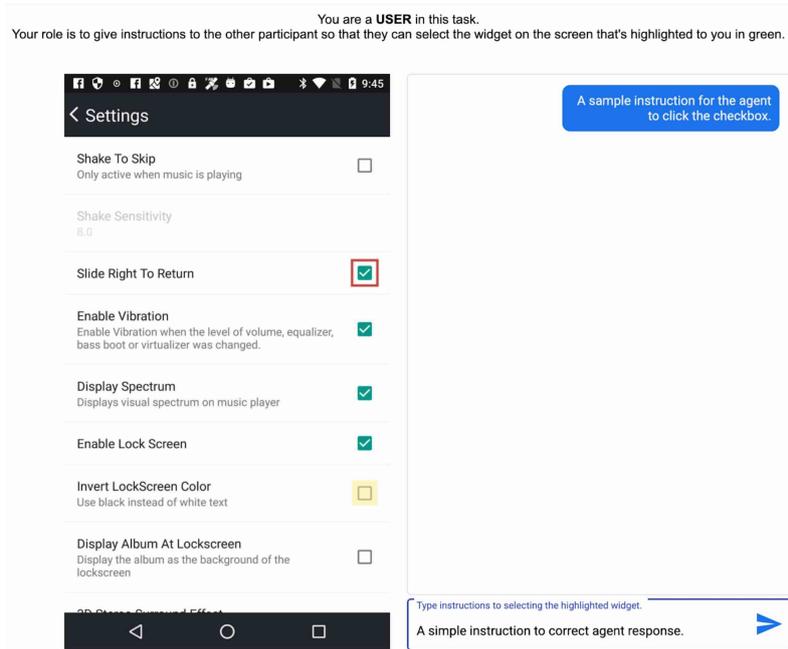

Table 12: Major error categories of the *Imitation* model on 30 failed development examples (150 turns). *stale  $c_t$* : repetitive/uninformative instruction. Model is trained with random seed 1.

## H Examples in the MUG Dataset

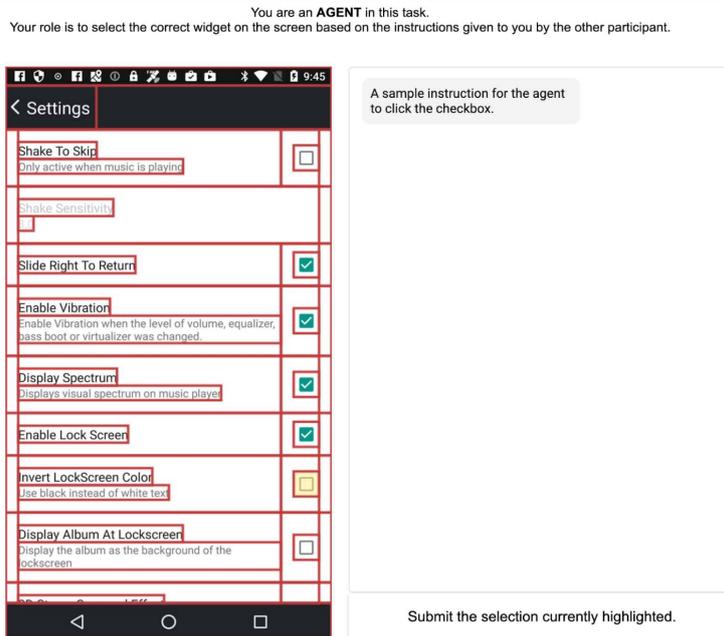

We present some examples from the MUG dataset in Fig. 4 and 5. Each example contains instructions and selections from human user and agent annotators.

## I Prediction Examples

Here, we demonstrate predictions from the *Imitation* model. Fig. 6 demonstrates successfully solved examples following the instructions generated by the *Heuristic* user model, while failed ones are in Fig. 7. Similarly, Fig. 8 demonstrates solved ones following the instructions generated by the *Neural* user model, and failed ones are in Fig. 9.

(a) The user sees the target object (boxed in red) and the agent selection in the previous round (boxed in yellow). The user can issue commands in the message box.

(b) The agent sees the user commands, and all the available candidates (clickable objects) on the screen, which are all boxed in red, and the current selection boxed in yellow.

## Abstract

With the proliferation of large pre-trained language models (PLMs), fine-tuning all model parameters becomes increasingly inefficient, particularly when dealing with numerous downstream tasks that entail substantial training and storage costs. Several approaches aimed at achieving parameter-efficient fine-tuning (PEFT) have been proposed. Among them, Low-Rank Adaptation (LoRA) stands out as an archetypal method, incorporating trainable rank decomposition matrices into each target module. Nevertheless, LoRA does not consider the varying importance of each layer. To address these challenges, we introduce PRILoRA, which linearly allocates a different rank for each layer, in an increasing manner, and performs pruning throughout the training process, considering both the temporary magnitude of weights and the accumulated statistics of the input to any given layer. We validate the effectiveness of PRILoRA through extensive experiments on eight GLUE benchmarks, setting a new state of the art.

## 1 Introduction

The current paradigm for natural language processing tasks is to exploit pre-trained models, which were trained using large amounts of data and expensive resources, and fine-tune them to various downstream tasks (Brown et al., 2020; Liu et al., 2019; Radford et al., 2019; He et al., 2021b; Devlin et al., 2019). Such fine-tuning was traditionally conducted by gradient update of all parameters of the model (Dodge et al., 2020; Raffel et al., 2020; Qiu et al., 2020). With the ever increasing size of models, such as Llama 7B-65B (Touvron et al., 2023), Palm 540B (Chowdhery et al., 2022), and others, trained with resources consisting of hundreds of GPUs in parallel, which are available only to some institutions and corporations, full fine-tuning can become prohibitive, lengthy, and with

high carbon footprint (Luccioni et al., 2022). Additionally, fully fine-tuning this way requires storing all parameters of the fine-tuned model for every downstream task.

To tackle the aforementioned challenges, a few research directions for Parameter-Efficient Fine-Tuning (PEFT) were proposed. These directions aim to maintain or even improve the accuracy of a full fine-tuning approach, while training only a small fraction of the parameters. One approach is to add small modules to the base model, which is kept frozen throughout the training process. Such adapter tuning techniques (Rebuffi et al., 2017; Houlsby et al., 2019; Pfeiffer et al., 2020; He et al., 2022) add modules between the layers. The implication, due to increased model depth, is longer training time and higher latency during inference. Alternatively, prompt and prefix tuning (Lester et al., 2021; Li and Liang, 2021) attach trainable tokens to the beginning of layers in the model, thus potentially reducing its effective maximal token length.

LoRA (Hu et al., 2022) fine-tunes linear layers by viewing each layer as a matrix of weights  $W_0$ , freezing it, and adding to it a small rank matrix, with the same shape as the original weight matrix, that is obtained as a product of two low-rank matrices  $A$  and  $B$ . The low-rank  $r$  is chosen to be much smaller than the input dimension to the layer, thereby significantly reducing the number of trainable parameters. During LoRA training, only the two low-rank matrices are updated, which are usually 0.01% to 1.00% of the original parameter count, depending on the low-rank of the two matrices. In addition to being efficient and often exceeding the performance of full fine-tuning (Hu et al., 2022), this method has the advantage of being able to be merged back to the original matrix during inference, without increasing latency. LoRA has been used in various downstream tasks successfully (Schwartz et al., 2022; Lawton et al., 2023;

Dettmers et al., 2023)

One limitation of LoRA is that the low-rank  $r$  is an arbitrarily set parameter, and in the original LoRA it is set to be fixed across layers and weights.

Efforts were made to address the issue of the fixed rank of LoRA. AdaLoRA (Zhang et al., 2023) starts from an initial parameter budget, which is slightly higher than the final budget, and then gradually reduces it until matching the target by removing weights based on SVD.

In this work, we encourage the usage of linearly increasing the rank from one layer to the next while concurrently adhering to the same budget of parameters. As we show, this strategy provides a distribution of the learned parameters that is better than a uniform placement, or even the learned alternatives.

A second contribution is obtained by pruning matrix  $A$ . This is done by considering both the elements of  $A$  and an exponential moving average over the layer’s input. Although we prune, in most cases, half of the elements of  $A$ , the main metric we seek to improve by pruning is the overall accuracy obtained after pruning.

We conduct extensive experiments over eight different General Language Understanding Evaluation (Wang et al., 2019) benchmarks, and present evidence that the proposed method outperforms LoRA and its recent variants, that both the linear distribution of ranks and the specific pruning approach are beneficial, and that the method does not require more GPU memory or training time than the conventional LoRA, unlike recent extensions of LoRA.

## 2 Related Work

In recent years, Parameter Efficient Fine-Tuning (PEFT) has garnered increasing interest among researchers as a means to reduce both the expenses associated with fine-tuning and storing large-scale pre-trained models and the time required for training. Various approaches have emerged, each exhibiting distinct characteristics pertaining to memory utilization, storage requirements, and computational overhead during inference. These approaches can be classified into two primary categories, namely, selective and additive PEFT methods, based on whether the original model parameters undergo fine-tuning during the training phase.

**Selective methods** involve the selection and modification of a model based on its original pa-

rameters. An early instance of this concept was observed in the fine-tuning of only a subset of the top layers of a network, as demonstrated by Donahue et al. (2014), and by more recent work (Gheini et al., 2021). In more recent developments, various approaches have been proposed, each targeting specific layers or internal modules of the model. For instance, the BitFit method (Zaken et al., 2021) updates only the bias parameters, resulting in a substantial reduction in the number of trainable parameters, but at the cost of suboptimal performance. Other methods use a scoring function when selecting trainable parameters (Guo et al., 2020; Sung et al., 2021; Vucetic et al., 2022), while others select top parameters based on a Fisher information calculation (Sung et al., 2021).

**Additive methods** represent an alternative to full-parameter fine-tuning by introducing additional trainable parameters into the backbone network. Adapters are a type of trainable component initially applied in the context of multi-domain image categorization by Rebuffi et al. (2017), that were subsequently integrated into Transformer networks, specifically in the attention and feed-forward layers (Houlsby et al., 2019). Prefix-Tuning and Prompt-Tuning (Li and Liang, 2021; Lester et al., 2021) involve the addition of trainable parameters preceding the sequence of hidden states across all layers. LST (Ladder Side-Tuning) (Sung et al., 2022) operates by short-cutting hidden states from the original network into a compact trainable side network, eliminating the need for backpropagating gradients through the backbone network.

LoRA (Hu et al., 2022) emulates the adjustment of the weight matrix in the model through the multiplication of two low-rank matrices. Notably, the trained parameters resulting from this process can be incorporated seamlessly into the original network during the inference phase without incurring additional computational overhead.

Recently, hybrid approaches have emerged, combining the selective and additive methods and presenting a unified framework (Chen et al., 2023; He et al., 2022; Mao et al., 2021). Other methods are based on the hypothesis that parameter redundancy exists in PEFT modules, therefore pruning the trainable parameters to achieve superior fine-tuning performance (Bai et al., 2022).

**Network pruning** methods (Molchanov et al., 2016; Hassibi et al., 1993; Frankle and Carbin, 2019; Liu et al., 2018; Han et al., 2015b) reduce the size of the network by removing or shrinking

matrices from the network, which effectively is equivalent to setting them to zero. Such methods require further full re-training, or other computationally intensive iterations.

**Magnitude Pruning** (Han et al., 2015a; Gale et al., 2019) removes individual parameter weights when the magnitude is below a certain threshold. The threshold is determined either based on the relative magnitude to other weights in the same parameter or layer (Zhu and Gupta, 2018), or for the whole network (Liu et al., 2018).

### 3 Background

**Transformer Models.** Transformer (Vaswani et al., 2017) is a sequence-to-sequence architecture that makes use of self-attention. Typically, it consists of several stacked blocks, where each block contains two sub-modules: a multi-head attention (MultiHead) and a fully connected feed-forward network (FFN). Given the input sequence  $\mathbf{X} \in \mathbb{R}^{n \times d}$  of  $n$  tokens of dimension  $d$ , MultiHead performs the attention function using  $h$  heads, allowing each segment of the  $d$  space to attend to a different value projection of another token:

$$\text{MultiHead}(\mathbf{X}) = [\text{head}_1, \dots, \text{head}_h] \mathbf{W}_o \in \mathbb{R}^{n \times d}$$

$$\text{head}_i = \text{Softmax} \left( \frac{\mathbf{X} \mathbf{W}_{q_i} (\mathbf{X} \mathbf{W}_{k_i})^\top}{\sqrt{d_h}} \right) (\mathbf{X} \mathbf{W}_{v_i})$$

where the square brackets denote a concatenation along the second dimension,  $\mathbf{W}_o \in \mathbb{R}^{d \times d}$  and  $\mathbf{W}_{q_i}, \mathbf{W}_{k_i}, \mathbf{W}_{v_i} \in \mathbb{R}^{d \times d_h}$  are parameters of head  $i$ , per block, and the softmax is applied to each row.  $d_h$  is typically set to  $\frac{d}{h}$ . The output of the MultiHead is fed into the FFN, consisting of two linear transformations with a ReLU non-linearity in between:

$\text{FFN}(X) = \text{ReLU}(\mathbf{X} \mathbf{W}_1 + \mathbf{b}_1) \mathbf{W}_2 + \mathbf{b}_2$ , where  $\mathbf{W}_1 \in \mathbb{R}^{d \times d_m}$  and  $\mathbf{W}_2 \in \mathbb{R}^{d_m \times d}$  are parameters of the block. Lastly, a residual connection is applied and a layer normalization (Ba et al., 2016).

**Adapters.** (Houlsby et al., 2019; Pfeiffer et al., 2020) The adapter technique injects a module between the transformer layers, such that the input is down-projected to a lower-dimensional space using  $\mathbf{W}_{down} \in \mathbb{R}^{d \times r}$ , followed by non-linearity  $\sigma$ , and up-projected using  $\mathbf{W}_{up} \in \mathbb{R}^{r \times d}$ , combined with a residual connection:

$$\mathbf{h} = \mathbf{x} + \sigma(\mathbf{x} \mathbf{W}_{down}) \mathbf{W}_{up} \quad (1)$$

**Low Rank Adaptation.** LoRA (Hu et al., 2022) freezes the pre-trained model weights and injects two trainable rank decomposition matrices into each layer of the Transformer architecture, greatly reducing the number of trainable parameters for fine-tuning tasks. For a linear layer  $\mathbf{h} = \mathbf{W}_0 \mathbf{x}$ , the LoRA-modified forward function is:

$$\mathbf{h} = \mathbf{W}_0 \mathbf{x} + \Delta \mathbf{W} \mathbf{x} = \mathbf{W}_0 \mathbf{x} + \mathbf{B} \mathbf{A} \mathbf{x} \quad (2)$$

where  $\mathbf{W}_0, \Delta \mathbf{W} \in \mathbb{R}^{d_1 \times d_2}$ ,  $\mathbf{A} \in \mathbb{R}^{r \times d_2}$  and  $\mathbf{B} \in \mathbb{R}^{d_1 \times r}$  with  $r \ll \{d_1, d_2\}$ .  $\mathbf{A}$  is Gaussian initialized and  $\mathbf{B}$  is zero initialized, in order to have  $\Delta \mathbf{W} = 0$  at the beginning of the fine-tuning training. Hu et al. (2022) apply LoRA to the query and value parameters (i.e.  $\mathbf{W}_q$  and  $\mathbf{W}_v$ ) in the multi-head attention, without modifying the other weights. He et al. (2022) extend it to other weight matrices of the feed-forward network, for an increased performance.

## 4 Method

Our proposed method, PRILoRA (Pruned and Rank-Increasing Low-Rank Adaptation), is comprised of two main components that integrate with the LoRA fine-tuning: (i) Linear distribution of low ranks across the layers in the network, and (ii) Ongoing pruning of the  $\mathbf{A}$  matrix of the LoRA, based on the layer’s input activations and the weights of the LoRA  $\mathbf{A}$  matrix.

### 4.1 Linear Distribution of Ranks

While LoRA distributes the learned parameters uniformly, one can distribute these differently. For example, one can assign a lower rank to some of the layers and a higher rank to others.

Recall that the trainable parameters in LoRA are the matrices  $\mathbf{A}$  and  $\mathbf{B}$ . Each has one dimension that is fixed according to the layer’s structure, and one dimension that is the low rank  $r$ . Since both the time complexity (train or test) and the memory complexity of a layer are linear in both the input and the output dimensions of each layer, and since only one dimension of  $\mathbf{A}$  and  $\mathbf{B}$  depends on  $r$ , the overall complexity of LoRA is linearly dependent on the sum of the ranks in all modified layers.

The way that we distribute the learned parameters is motivated by the results provided by (Zhang et al., 2023), which demonstrate that the top layers require more adaptation. Considering that one cannot focus only on the top layers, since the other

layers also need to adapt (see Sec. 6), and to promote simplicity, we employ a linear distribution of ranks.

In the linear distribution of ranks, we allocate a different low-rank for every layer in the model, in a linearly increasing manner. Specifically, for the DeBERTaV3-base model, we start from the first layer, applying a low-rank of  $r_s = 4$ , and growing linearly, up to the twelfth layer, where we apply  $r_f = 12$ , such that the average rank across layers is 8. We allocate the same low-rank to all weights in a given layer, regardless of the matrix type (query, key, value, etc.). This makes the total number of parameters identical to the LoRA method.

## 4.2 Ongoing Importance-Based A-weight Pruning

We employ pruning as a form of dynamic feature selection, which allows the fine-tuning process to focus on some of the layer’s input at each bottleneck index at every pruning iteration. The intuition is that since the capacity of the update matrix  $BA$  is low, it would be beneficial to attend only to the important input dimensions.

### 4.2.1 Importance Matrix

Each transformer layer, whether it is a projection associated with key, query, or value, or one of the FFN layers has some weight matrix  $W$ . It also has some input  $\mathbf{X} \in \mathbb{R}^{b \times n \times d}$ , where  $b$  is the batch size,  $n$  is the number of tokens, and  $d$  is the dimension. We abuse the notation slightly and also write  $\mathbf{X}$  for the second layer of the FFN, although, in this case, the dimension is  $d_m$ , which is typically larger than  $d$ . In our framework we maintain, throughout the training process, an Exponential Moving Average of the  $L_2$  norm of the rows of each such input  $\mathbf{X}$ , as depicted in Figure 1.

For each batch, we consider the tensor that has a dimension of  $b \times n \times d$ , square all elements, sum across the first and second dimensions, obtaining a vector of size  $d$ , and take the square root of each vector element, to get  $\mathbf{x}$ .

The exponential moving average  $\bar{\mathbf{x}}$  is updated between batches by the following rule

$$\bar{\mathbf{x}} = 0.9\bar{\mathbf{x}} + 0.1\mathbf{x} \quad (3)$$

We next compute, for every weight matrix  $W$ , or, more specifically, for  $A \in \mathbb{R}^{r \times d_2}$ , which is the associated half-decomposition of  $\Delta W$ , an importance matrix  $S$  of the same size as  $A$ .  $S$  is inspired

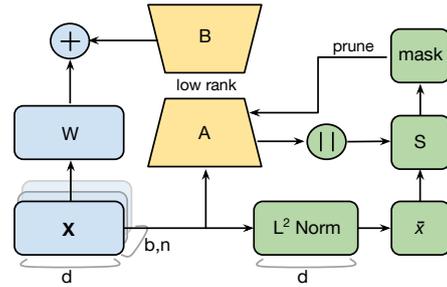

Figure 1: The schematics of PRILoRA on a single layer. The blue path demonstrates a frozen linear layer. We omitted the bias for simplicity. The yellow path depicts LoRA; dropout and scaling were omitted for simplicity. In the green path of PRILoRA, the input tensor  $\mathbf{X}$  of the layer is fed into  $L_2$  norm calculation. Then, the exponential moving average vector  $\bar{\mathbf{x}}$  is updated and kept as a state of the layer. When it is time for pruning, the absolute value of the elements of  $A$  is calculated, and together with  $\bar{\mathbf{x}}$ , the importance matrix  $S$  is computed. In every row of  $S$ , the lowest elements, as defined by the *prune ratio*, are being selected to form the mask. The mask is used to zero out elements in the  $A$  matrix.

by Wanda (Sun et al., 2023), and is the element-wise multiplication of the absolute value of  $A$  with the relevant moving average vector  $\bar{\mathbf{x}}$  (recall that there is one  $\bar{\mathbf{x}}$  to each weight matrix  $W$ ):

$$S_{ij} = |A_{ij}| \bar{x}_j \quad (4)$$

Note that all values of  $\bar{\mathbf{x}}$  are positive, since they represent a mean norm. Therefore, all elements of  $S$  are positive, too.

### 4.2.2 Pruning

Every 40 steps in the training process, we prune each of the  $A$ -matrices, in accordance with the associated importance matrix  $S$ . To do so, we consider the  $n$  lowest elements of every row  $i = 1 \dots r$  of  $S$  and create a binary mask  $M \in \mathbb{R}^{r \times d_2}$ . Each mask element  $M_{ij}$  indicates whether  $S_{ij}$  is among the  $n$  lowest values of row  $i$  of  $S$ .  $n$  is determined by the *prune ratio*; a higher ratio means more weights are being zeroed out. We then zero out the elements in  $A$  using the mask  $M$ .

Note that zeroing out an element of  $A$  does not prevent this element from becoming non-zero immediately in the next training step. However, pruning this way changes the training dynamics and encourages  $A$  to be sparse. Figure 2 shows five random weights during training of different datasets. It can be seen that some weights can survive pruning, some weights remain in the pruning region since

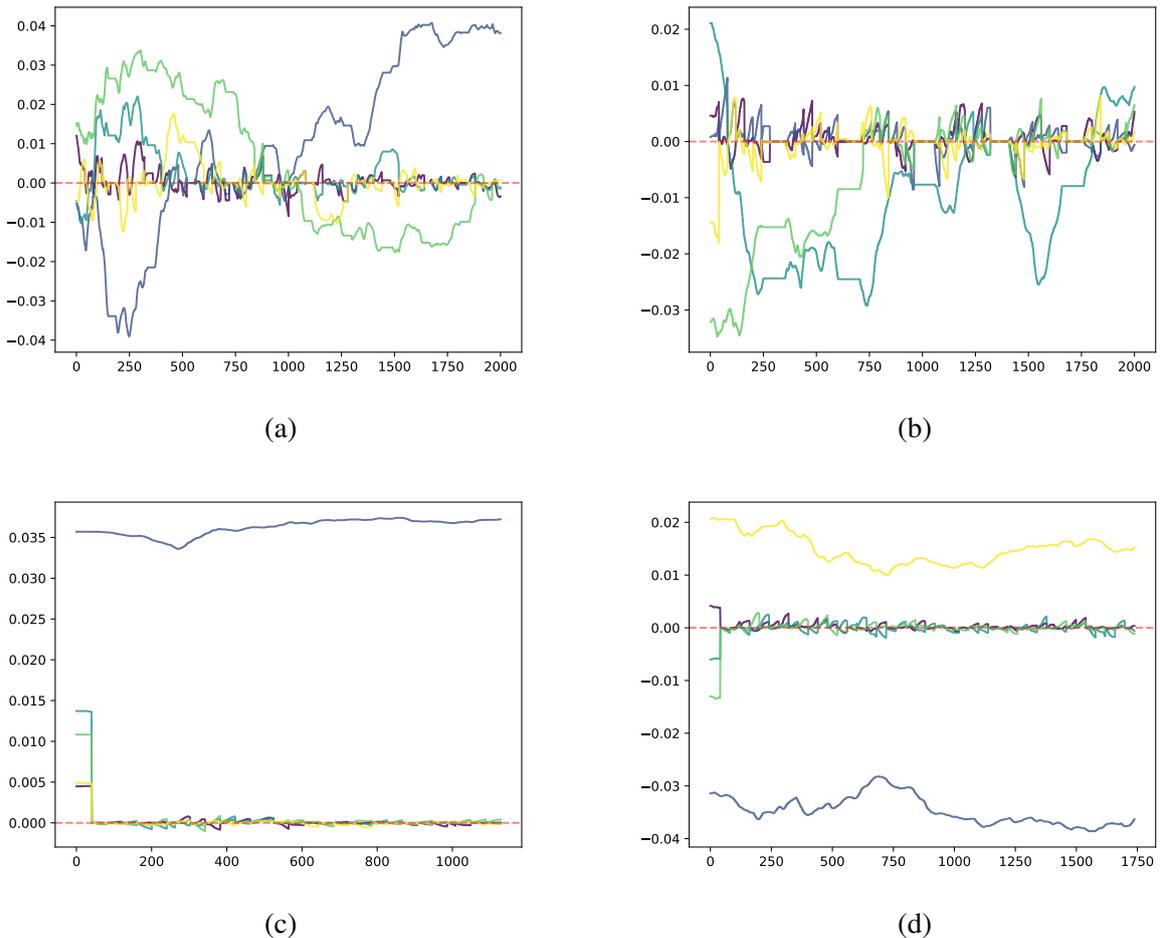

Figure 2: Five weights values over time on four different GLUE tasks: (a) RTE task, in layer 5, value\_proj parameter; (b) MRPC task, in layer 6, query\_proj parameter; (c) SST-2 task, in layer 7, key\_proj; (d) CoLA task, in layer 8, attention.output parameter.

they cannot escape fast enough, and some weights avoid being pruned completely.

## 5 Experiments

We apply PRILoRA to DeBERTaV3-base (He et al., 2021a) (184 million parameters), and evaluate the method on eight natural language understanding benchmarks included in the General Language Understanding Evaluation - GLUE (Wang et al., 2019). Summary of the GLUE benchmarks can be found in Table 6. We use PyTorch (Paszke et al., 2019) and Hugging Face Transformers (Wolf et al., 2019) to implement the algorithms. All the experiments are conducted on NVIDIA GeForce RTX 2080 Ti GPUs. Due to limited GPU memory size, we leave similar analysis of large-scale models, such as T5-3B, Llama, and others, to future research.

### 5.1 Baselines

**Full fine-tuning:** In the fine-tuning stage, the model is initialized with the pre-trained parameters, and all model parameters go through gradient updates.

**Bitfit:** (Zaken et al., 2021) A sparse fine-tuning method where only the bias-terms of the model (or a subset of them) are being modified.

**HAdapter:** (Houlsby et al., 2019) Inserts adapter layers between the self-attention module, the FFN module, and the subsequent residual connection. There are two fully connected layers with biases in an adapter layer with a non-linearity in between.

**PAdapter:** (Pfeiffer et al., 2020) Inserts the adapter after the FNN module and LayerNorm.

**LoRA:** (Hu et al., 2022) Adds trainable pairs of rank decomposition matrices in parallel to existing weight matrices. The number of trainable param-

eters is determined by the rank  $r$  and the shape of the original parameters.

**AdaLoRA:** (Zhang et al., 2023) Parameterizes the incremental updates in the form of singular value decomposition, for a given parameter.

## 5.2 Implementation details

In our research, we experimented with different distributions while keeping the total number of parameters invariant and found that the configuration  $\{r_s = 4, r_f = 12\}$  was optimal, together with the hyper-parameters which are specified in Table 7. The fact that higher layers require more parameters for LoRA fine-tuning may indicate that higher layers in Transformer-based models capture deeper levels of understanding, and therefore when fine-tuning a pre-trained language model, more focus must be put on deeper layers than on lower layers that require less modification or adaptation to the downstream task in question.

## 5.3 Main results

We compare PRILoRA with the baseline methods. Table 1 shows our results on the GLUE development set (Appendix A). PRILoRA achieves best average score, best result in six out of the eight datasets, and in all datasets better results than HAdapter, PAdapter and LoRA, with approximately the same number of parameters.

Note that when counting the number of parameters, we do not discount for pruned parameters. However, with a pruning ratio of 0.5 in most benchmarks, a quarter of the learned parameters (half the parameters of the  $A$  matrices) are zero. A more precise count of parameters would, therefore, be closer to one million parameters and not 1.33M.

### 5.3.1 Ablation Study

In table 2 we present an ablation study for PRILoRA, on four GLUE tasks: SST-2, CoLA, RTE and MRPC. We aim to analyze both the rank distribution across layers and the pruning method.

For the rank distribution study we: (i) remove the linear distribution component of our method, retaining the pruning component alone with identical rank at each layer; (ii) replace the  $4 \rightarrow 12$  distribution by  $12 \rightarrow 4$ ; (iii) attach LoRA adapter to only the last layer, with a higher rank of 24 (Concentrated Distribution).

For the pruning method study we: (i) remove the importance pruning component, retaining increasing rank distribution  $4 \rightarrow 12$ ; (ii) prune the rows of

$B$  matrix instead of  $A$ , by collecting an exponential moving average of  $B$  input norm, instead of the input to  $A$  (or the layer); (iii) similarly, prune  $B$  columns instead of rows; (iv) prune the columns of  $A$  randomly, instead of PRILoRA method, but with the same *prune ratio*. During all ablation tests, per benchmark, we keep the same hyper-parameters and change only a single component. For all cells in the table, the same single seed is used.

**Rank Distribution** As can be seen, removing the linear distribution of the low-rank and fixing a constant rank across all layers, such that the total number of parameters stays the same as in LoRA, but applying pruning, reduces the results in all tests. Removing the linear distribution nonetheless outperforms LoRA results, signalling that pruning is indeed an essential component of the method. For example, PRILoRA with no linear distribution on the SST-2 benchmark reaches 96.10, while LoRA is 94.95, and on CoLA it is 72.17 versus 69.82.

Interestingly, changing the order of the rank allocation, to be  $12 \rightarrow 4$ , reduces the performance significantly; for example, a decrease of  $73.08 \rightarrow 69.73$  on the CoLA benchmark, and  $93.14 \rightarrow 91.91$  on the MRPC benchmark. Inverting the rank allocation order diminishes performance below fixed-rank allocation across layers. This provides additional support in the need to allocate more parameters to the top layers.

Lastly, attaching LoRA only to the last layer yields the lowest average results across the rank distribution ablation study, for example 89.95 versus 93.14 on MRPC when the full method is used.

**Pruning Method** Ablating pruning completely, reduces the performance. For instance, on CoLA it is reduced  $73.08 \rightarrow 71.31$ . This is higher than LoRA (69.82), pointing to the positive effect of the rank-increasing distribution. When we prune matrix  $B$  instead of  $A$ , we obtain results similar to no pruning at all, suggesting that pruning  $B$  did not yield any discernible benefits.

A plausible argument is that the input activation shape of  $A$  and  $B$  is very different, for example 768 versus 8, in the case of most weights in DeBERTaV3-base model, and a low-rank of 8. Choosing to row-prune matrix  $B$  with a *prune ratio* of 0.5, essentially means eliminating 4 out of 8 cells in every  $B$  row, which can be too aggressive. Additionally, doing the same process on  $B$  columns can create situations where a complete row of  $B$  is zeroed out, which means that the cor-

Table 1: Results with DeBERTaV3-base on GLUE development set. The best results on each dataset are shown in **bold**. We report the average correlation for STS-B (Pearson, Spearman). We report matched accuracy for MNLI. *Full FT*, *HAdapter* and *PAdapter* represent full fine-tuning, Houslyby adapter, and Pfeiffer adapter, respectively. We report the mean and standard deviation of three runs using different random seeds. We report the baseline results from Zhang et al. (2023). Higher is better for all metrics.

Method	#Param	MNLI	SST-2	CoLA	QQP	QNLI	RTE	MRPC	STS-B	All

PRILoRA	1.33M	90.75	<b>96.21</b>	<b>72.79</b>	<b>92.45</b>	94.44	<b>89.05</b>	<b>92.49</b>	<b>91.92</b>	<b>90.01</b>
[PRILoRA SD]		±0.03	±0.30	±1.28	±0.05	±0.14	±1.04	±0.57	±0.14	±0.44

Table 2: Ablation study results on the same single seed.

	SST-2	CoLA	RTE	MRPC
PRILoRA	<b>96.44</b>	<b>73.08</b>	<b>90.25</b>	<b>93.14</b>
Fixed distribution	96.10	72.17	88.81	92.16
Inverted distribution	95.99	69.73	88.09	91.91
Concentrated dist.	95.07	69.92	87.73	89.95
No pruning	96.22	71.31	89.89	92.09
Prune B rows	96.10	71.41	89.89	91.67
Prune B cols.	96.22	71.46	88.81	91.42
Prune A rand cols.	94.84	70.75	88.09	89.22

responding output cell of LoRA will be zero as well. Furthermore, the compressed low-rank latent input to matrix  $B$  already encapsulates the essential information, so pruning it deteriorates the performance.

Finally, performing a random pruning of columns in  $A$  with the same *prune ratio*, produces the lowest results in the Pruning Method ablation study.

### 5.3.2 Pruning Ratio Study for PRILoRA

We would like to learn how aggressive pruning should be, that is, how much sparsity should be injected into the LoRA weights in order to reach peak performance. We chose four GLUE tasks, and for each task and for each *prune ratio* in {0.25,

0.50, 0.75} we ran the fine-tuning three times, each time with a different seed. We report the average result and standard deviation across the different seeds.

Table 3 shows that for the selected tasks, the optimal pruning ratio is 0.5. However, specifically for the STS-B task, a random hyper-parameter search yielded an optimal pruning ratio of 0.75, as can be seen in Table 7.

### 5.3.3 Training Cost Study for PRILoRA

We present the training cost comparison between PRILoRA and LoRA, using the DeBERTaV3-base model, on NVIDIA GeForce RTX 2080 Ti GPUs. For the two methods, the batch size is 32.

Table 4 shows that PRILoRA has zero increase in number of trainable parameters in comparison to LoRA, and a negligible increase in training time per epoch.

For comparison, AdaLoRA (Zhang et al., 2023) speed per batch is 11% slower than LoRA in the MNLI benchmark and 16% slower in the SST-2 benchmark, and with a slightly larger memory footprint.

However, analyzing the training time per batch does not suffice. Once we know that the training step time in PRILoRA is similar to LoRA, we want to delve deeper and analyze the number of steps required until reaching peak performance on the evaluation metric.

Table 5 presents the number of steps required

Table 3: Performance vs Pruning Ratio. Each cell in the table shows the average across three different seeds, together with the standard deviation.

	SST-2	CoLA	RTE	MRPC
Prune 0.25	96.10 $\pm$ 0.34	71.43 $\pm$ 0.30	87.73 $\pm$ 1.25	91.34 $\pm$ 0.99
Prune 0.50	<b>96.21 <math>\pm</math> 0.30</b>	<b>72.79 <math>\pm</math> 1.28</b>	<b>89.05 <math>\pm</math> 1.04</b>	<b>92.49 <math>\pm</math> 0.57</b>
Prune 0.75	95.95 $\pm$ 0.17	70.63 $\pm$ 1.56	87.73 $\pm$ 0.73	90.85 $\pm$ 0.51

Table 4: Comparison of memory consumption and time per epoch in training, between PRILoRA and LoRA on NVIDIA GeForce RTX 2080 Ti GPU, with a batch size of 32. All models have 1.33M parameters.

Dataset	Method	GPU Mem	Time/epoch
MNLI	LoRA	9.559 GB	117 min
	PRILoRA	9.559 GB	120 min
SST-2	LoRA	9.559 GB	24 min
	PRILoRA	9.559 GB	23 min
QQP	LoRA	9.559 GB	109 min
	PRILoRA	9.559 GB	110 min

Table 5: Number of steps to evaluation peak point, on four selected GLUE tasks.

	SST-2	CoLA	RTE	MRPC
PRILoRA	9875	12375	1875	1750
LoRA	6500	8000	3250	1250

for each method until reaching its peak evaluation performance. Evidently, there is no clear winner with respect to the number of steps or time required to reach peak performance. Both LoRA and PRILoRA have the same order of magnitude. Since one often trains beyond the peak point, the table does not indicate that one method is preferable to the other in this respect.

## 6 Discussion

Moving from one task to another requires an adaptation of both the input and the output domain. While the input domain of large language models may be comprehensive enough to support new downstream tasks, the generation of the output is very much context-and-task-dependent.

Therefore, it should not come as a surprise that fine-tuning requires more adaptation of the top lay-

ers, which are closer to the output, than of the earlier, input-processing, layers.

However, if one is to change only the top layers, as we showed in the ablation study, there would not be enough co-adaptation of the earlier layers to enable the top layers to produce the required output. It seems, therefore, that the gradual increase in the allocated resources, which we apply, is a reasonable strategy.

## 7 Conclusions

In this paper, we introduced PRILoRA, a novel, yet simple and parameter-efficient method for improving low-rank adaptation during fine-tuning. Our extensive experiments encompass eight GLUE benchmarks across multiple seeds, illustrating the effectiveness of PRILoRA. Notably, we achieve superior performance compared to state-of-the-art metrics while maintaining the same number of trainable parameters, reducing the non-zero parameters by a quarter on most benchmarks, and adhering to the same memory constraints and running time per epoch.

## 8 Limitations

Our work has some limitations. We pushed the limits of our computational resources, utilizing NVIDIA GeForce RTX 2080 Ti GPUs, to conduct the experiments presented in this study across the eight GLUE benchmarks. We employed the PRILoRA-modified DeBERTaV3-base model, which consists of 184 million parameters.

These experiments are of the same scale as the most related work (Zhang et al., 2023). However, the full potential of the method could be realized on larger models trained on more extensive datasets, and by using larger batches that can fit into GPU memory, allowing examination of the method on additional downstream tasks, such as question answering and text summarization.

## A GLUE Dataset

Here is a summary of the benchmarks and metrics we used from the GLUE (Wang et al., 2019) dataset.

## B PRILoRA GLUE Training Details

For all benchmarks we used a linear rank distribution from 4 to 12 (4,5,6,6,7,8,8,9,10,10,11,12), such that the average rank is 8 (ranks rounded to integers). All eight benchmarks were trained using linear learning-rate scheduling, with the initial learning rate reported as *learning rate*, and the number of epochs for the scheduler as *epochs*. The runs were stopped after *stop epoch* epochs. Hyper-parameters: learning rate, batch size, # epochs, decay and prune ratio were randomly searched over the space  $\{6 \times 10^{-5}, 1 \times 10^{-4}, 2 \times 10^{-4}, 6 \times 10^{-4}, 1 \times 10^{-3}, 1.2 \times 10^{-3}, 1.5 \times 10^{-3}, 2 \times 10^{-3}, 2.3 \times 10^{-3}\}$ ,

$\{4, 8, 16, 32\}$ ,  $\{10, 30, 50, 60, 70\}$ ,  $\{0, 0.1, 0.01\}$ ,  $\{0.25, 0.50, 0.75\}$  correspondingly. For all benchmarks and methods the *max seq length* is 128.

Table 6: Summary of the GLUE dataset

## Abstract

Despite the fact that multilingual agreement (MA) has shown its importance for multilingual neural machine translation (MNMT), current methodologies in the field have two shortages: (i) require parallel data between multiple language pairs, which is not always realistic and (ii) optimize the agreement in an ambiguous direction, which hampers the translation performance. We present **Bidirectional Multilingual Agreement via Switched Back-translation (BMA-SBT)**, a novel and universal multilingual agreement framework for fine-tuning pre-trained MNMT models, which (i) exempts the need for aforementioned parallel data by using a novel method called switched BT that creates synthetic text written in another source language using the translation target and (ii) optimizes the agreement bidirectionally with the Kullback-Leibler Divergence loss. Experiments indicate that BMA-SBT clearly improves the strong baselines on the task of MNMT with three benchmarks: TED Talks, News, and Europarl. In-depth analyzes indicate that BMA-SBT brings additive improvements to the conventional BT method.

## 1 Introduction

Conventional multilingual neural machine translation (MNMT) leverages independent parallel data during the training process. In comparison, the multilingual agreement (MA) explicitly minimizes the output difference between two source inputs written in different languages but with the same meaning. Despite its success in from-scratch training on MT (Yang et al., 2021c), current methodologies suffer from at least two disadvantages that limit their scope of usage. Firstly, conventional

\*This research/paper was partially supported by the Center for Perceptual and Interactive Intelligence (CPII) Ltd. under the Innovation and Technology Commission’s InnoHK scheme.

<sup>†</sup>Contribution during an internship at Microsoft Research Asia.

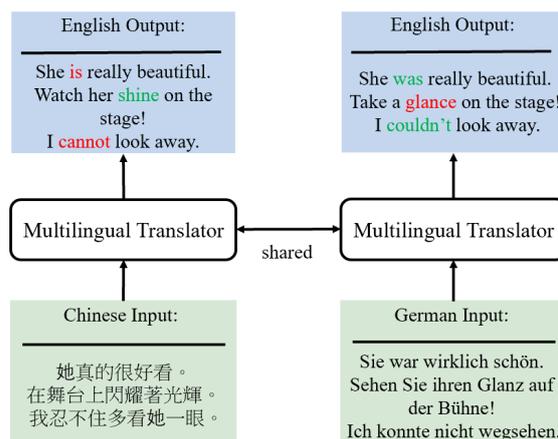

Figure 1: An illustrated example that can be benefited from Multilingual Agreement optimized in a bidirectional manner. The words in green are the correct translation, and the words in red are the wrong translation. Here, Chinese is incorrectly translated since it does not have past tense for verbs, and German is incorrectly translated due to the shared subword unit with different meanings between Glanz (German, shine) and Glance (English, take a brief look at). Best viewed in colour.

MA leverages word alignment tools to create code-switching sentence-level data (Yang et al., 2021c). This process usually requires authentic parallel data between multiple language pairs. For example, assuming we would like to enhance Chinese to English and German to English, conventional MA assumes the existence of parallel data from Chinese to German, which however sometimes does not exist. Secondly, the direction of agreement-based learning can be bidirectional (Zhang et al., 2019), while the direction of conventional multilingual agreement is usually ambiguous. However, since languages usually have different linguistic clues and they are helpful to each other, we argue that optimizing the multilingual agreement explicitly in a bidirectional manner can help the languages to learn from each other and hence further enhance cross-lingual learning.

Figure 1 depicts such a case that can be benefited from bidirectionally enhanced MA. The underlying reason is that both of the source inputs have cross-lingual ambiguities here. Since Chinese does not have past tense verbs, it is intuitive to use some auxiliary languages with past tense. Furthermore, since German shares partial vocabulary subwords with English under MNMT, this introduces cross-lingual ambiguities and using a language that does not share its vocabulary subwords with English, e.g., such as Chinese, could be helpful.

As a side note, since MA was proposed as a method for from-scratch training for MT, it was unclear whether conventional MA is also effective as a fine-tuning technique for pre-trained models.

Furthermore, how to appropriately apply back-translation to a multilingual setting is also an understudied subject despite its importance.

This paper proposes BMA-SBT, a novel MNMT framework that (i) exempts the need for parallel data between multiple language pairs and (ii) optimizes the MA in a bidirectional manner. To exempt the need for parallel data, we propose switched back-translation to produce synthetic text in some different auxiliary source languages with the translation target.<sup>1</sup> To optimize the MA in an explicit bidirectional manner, we use a bidirectional Kullback–Leibler Divergence loss instead of the code-switching for conventional MA. This enforces the original source language and the synthetic auxiliary language to have the same outputs as the target reference translation in a bidirectional manner.

We conduct experiments on three MT benchmarks: TED Talks (Cettolo et al., 2015), News benchmark (News-commentary) and Europarl (Koehn, 2005). Experimental results indicate that BMA-SBT clearly improves the strong pre-trained baselines on all three benchmarks. In-depth analyses indicate that BMA-SBT effectively mitigates cross-lingual ambiguities.

In summary, we make three key contributions:

- This paper proposes a novel framework called BMA-SBT, the first MNMT framework that achieves MA without the requirement of extra parallel data and explicitly optimizes the MA in a bidirectional manner.
- BMA-SBT yields clear improvement on SOTA pre-trained MT model on three MT benchmarks: TED Talks, News, and Europarl.

<sup>1</sup>For example, Chinese as the source, English as the target, and Japanese as the auxiliary source.

- We conduct in-depth analyses of BMA-SBT. Results indicate that BMA-SBT brings additive improvement to conventional BT and bidirectionality is important for MA.

Also, this is the first work that demonstrates the usefulness of MA as a fine-tuning technique.

## 2 Bidirectional Multilingual Agreement via Switched Back-translation

### 2.1 Multilingual Neural Machine Translation

We conduct our experiments on the task of MNMT on large-scale pre-trained multilingual translation model (Yang et al., 2021a; Lu et al., 2023) that handles multiple languages by sharing a universal subword dictionary among all the languages. For both training and inference, given  $I$  languages  $\{L_1, \dots, L_I\}$ , we prefix a special target language token  $L_t$  to the source inputs to signal the multilingual model that we are translating from an arbitrary source language to the target language  $L_t$ .

Given a bilingual dataset for machine translation that consists of  $\mathcal{N}$  training instances  $\{\mathcal{T}_1, \dots, \mathcal{T}_\mathcal{N}\}$ , each of the bilingual translation pairs  $\mathcal{T}_i$  in the source bilingual dataset  $\mathcal{D}_\mathcal{M}$  contains a source input  $x$  and the corresponding translation target  $y$ . With a Seq2Seq generation model (Sutskever et al., 2014) with parameters  $\theta$ , we train the model by optimizing the following likelihood:

$$\mathcal{L}_{main} = \sum_{n=1}^{\mathcal{N}} \mathbb{E}_{x_n, y_n \in \mathcal{D}_\mathcal{M}} [-\log P_\theta(y | x)], \quad (1)$$

where  $\mathcal{L}_{main}$  denotes the standard training loss that we adopt for MNMT.

### 2.2 BMA-SBT

In this subsection, we introduce our novel framework **Bidirectional Multilingual Agreement via Back-translation (BMA-SBT)**. Compared to the conventional multilingual agreement, BMA-SBT exempts the need for parallel data and specifies the direction of the multilingual agreement in a bidirectional manner. We first introduce how we use BT to create synthetic parallel data which are appropriate for the use of the multilingual agreement, and we then introduce how to leverage KL divergence loss to make the multilingual agreement bidirectional.

**Switched Back-translation** The conventional multilingual agreement (MA) requires authentic parallel data, which could be commonly unrealistic

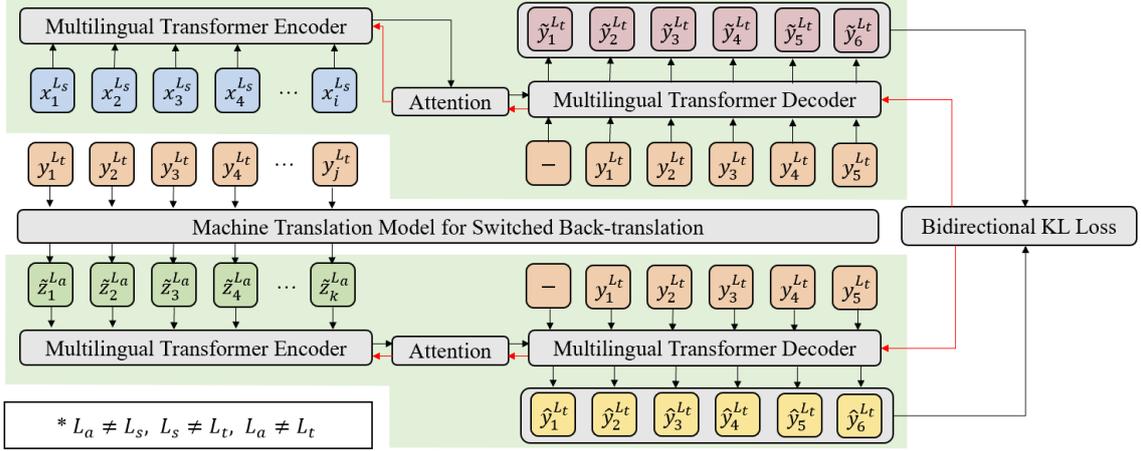

Figure 2: Overview of our proposed BMA-SBT framework.  $x$  and  $y$  denote the original source and target text written in the source language  $L_s$  and target language  $L_t$ .  $\tilde{z}$  denotes the synthetic text translated from the original target text into language  $L_a$ .  $\tilde{y}$  denotes the translation output from the original source text produced by the multilingual Transformer and  $\hat{y}$  denotes the translation output from the synthetic text. The letters with subscripts such as  $x_i$  denote the  $i$ -th token in the original source text. The red arrows denote the backward gradient flow computed by the bidirectional KL loss that updates the shared multilingual Transformer encoder and decoder. Best viewed in colour.

in a real-world setting. Formally, for the translation pair  $x$  and  $y$  in Equation 1, conventional MA requires another instance  $z$ , which is written in a different language and in the equivalent meaning to  $x$  and  $y$ . This process was designed and experimented on from-scratch training. These facts limit the use of the conventional MA.

To mitigate the above-mentioned shortages, we propose a novel method called switched back-translation that creates synthetic text  $\tilde{z}$  written in different source languages by feeding the translation target  $y$  to a machine translation model through back-translation.<sup>2</sup> Note that  $\tilde{z}$ ,  $x$ , and  $y$  are equivalent in their meanings, but they are written in different languages.

This helps us to establish a synthetic bilingual auxiliary dataset  $\mathcal{D}_A$  that is consisted of  $\mathcal{M}$  training instances. We then train the multilingual model by maximising the following likelihood:

$$\mathcal{L}_{auxiliary} = \sum_{n=1}^{\mathcal{M}} \mathbb{E}_{\tilde{z}_n, y_n \in \mathcal{D}_A} [-\log P_{\theta}(y | \tilde{z})]. \quad (2)$$

We also differentiate the switched back-translation we propose here from the conventional BT. For BT which was originally proposed for bilingual MT (Sennrich et al., 2016), we usually obtain

<sup>2</sup>While we can use the translation source  $x$  to create  $\tilde{z}$ , we empirically have found that this degrades the improvement. We postulate that if the source text has ambiguities, then this is less helpful to create the auxiliary text with the source text.

$x'$  from the original monolingual target  $y$ , where  $x'$  should be written in the same source language in our interest. In contrast, BMA-SBT creates  $\tilde{z}$  that should have the equivalent meaning as  $y$ , but it should be written in different languages from both the original source and target languages for the purpose of applying the multilingual agreement.<sup>3</sup>

In conclusion, this evolves the conventional MA into a universal fine-tuning technique for MNMT which does not need extra parallel data. BMA-SBT fits the real-world setting and can be applied with some modifications to other generation tasks for cross-lingual learning.

**Bidirectional Multilingual Agreement** The direction for agreement-based learning can be bidirectional (Zhang et al., 2019). However, the conventional multilingual agreement has an ambiguous direction due to the nature of code-switching. By using parallel data, conventional MA constructs code-switching data  $c$  from  $x$  and  $z$ , which denotes the translation source and the authentic auxiliary text respectively. Note that  $x$  and  $z$  have the same meaning to the translation target  $y$ , but they are written in different languages. The code-switching is then done with a word alignment tool between  $x$  and  $z$  at the word level, usually with a low code-switching replacement ratio as low as 10% (Yang

<sup>3</sup>For a fair comparison, we use the Baseline Model and the monolingual English sentences in the downstream dataset for data augmentation with BT (Sennrich et al., 2016) and SBT.

et al., 2021c). Formally, conventional MA trains MNMT by maximising the following likelihood:

$$\mathcal{L}_{MA} = \sum_{n=1}^Q \mathbb{E}_{c, y_n \in \mathcal{D}_C} [-\log P_\theta(y | c)], \quad (3)$$

where  $y$  denotes the translation target,  $\mathcal{D}_C$  denotes the code-switching dataset automatically constructed, and  $Q$  denotes the number of samples in the code-switching dataset.

In addition to the fact that conventional MA requires authentic data  $z$  which is not always realistic, we also argue that code-switching optimizes in an ambiguous direction, usually with a low code-switching ratio as low as 10%. Therefore, we consider that cross-lingual learning could be less efficient in this manner. As depicted in Figure 1, MNMT can be benefited by encouraging multilingual agreement in a bidirectional manner. Hence, we use a KL divergence loss to specify the direction of multilingual agreement in a clear bidirectional manner. Since the authentic parallel text  $z$  is not always available, we use the aforementioned synthetic auxiliary text  $\tilde{z}$  to calculate a bidirectional MA (BMA) divergence loss:

$$\mathcal{L}_{BMA} = \alpha \mathcal{L}_{KL_1} + (1 - \alpha) \mathcal{L}_{KL_2}, \quad (4)$$

where  $\mathcal{L}_{KL_1}$  and  $\mathcal{L}_{KL_2}$  represents the KL divergence loss in two directions:

$$\mathbb{E}[KL(P_\theta(y | x) || P_\theta(y | \tilde{z}))] \quad (5)$$

for  $\mathcal{L}_{KL_1}$ , which means that we enforce the original source text  $x$  to learn from the synthetic  $\tilde{z}$ . Note that  $x$  and  $\tilde{z}$  have the same meaning, but they are written in different languages. We also optimize in the other direction:

$$\mathbb{E}[KL(P_\theta(y | \tilde{z}) || P_\theta(y | x))] \quad (6)$$

for  $\mathcal{L}_{KL_2}$ .<sup>4</sup> In contrast to  $KL_1$ , this means that the synthetic text  $\tilde{z}$  should learn from the original text  $x$ . Bidirectionality is necessary to enforce both languages to learn from each other. Here,  $x$  and  $y$  denote the original translation source and target respectively, and  $\tilde{z}$  denotes the synthetic auxiliary text created by BMA-SBT via translation.

<sup>4</sup>Empirically, we have found that setting a balanced value with  $\alpha = 0.5$  brings a good performance.

**BMA-SBT** Overall, we propose a novel BMA-SBT framework that optimizes the MNMT models with the following combinatory loss:

$$\mathcal{L}_{BMA-SBT} = \mathcal{L}_{main} + \mathcal{L}_{auxiliary} + \mathcal{L}_{BMA} \quad (7)$$

Figure 2 depicts the overview of BMA-SBT. The final KL loss at the right edge of the figure refers to  $\mathcal{L}_{BMA}$ ,  $\mathcal{L}_{main}$  is calculated with the training instance at the top, and  $\mathcal{L}_{auxiliary}$  is calculated with the training instance at the bottom.

BMA-SBT can be improved with multiple auxiliary languages for agreement in an ensemble manner. This requires more tuning and computational costs. We leave this to future work.

## 3 Experiments

### 3.1 Implementation Details

**Model Configuration** The Transformer architecture we use is composed of 24 encoder layers and 12 interleaved decoder layers. Furthermore, the architecture has an embedding size of 1024, with a dropout rate of 0.1. The feed-forward network has a size of 4096, with 16 attention heads. For parameter initialization, we follow Ma et al. (2021) and Yang et al. (2021b) to pre-train a strong MT system with sentence-level bilingual data. For the rest of this paper, We call it the Baseline Model and use it as a strong pre-trained baseline system.

**Data Pre-processing** For all of the experiments conducted in this paper, we use SentencePiece (Kudo and Richardson, 2018) for tokenization. The SentencePiece model we use is the same as Yang et al. (2021b). Also, we follow prior works to prefix the source input translation texts with a language tag that indicates the target language of the outputs.

**Evaluations** We use the BLEU scores (Papineni et al., 2002) computed with the script from SacreBLEU for evaluation.<sup>5</sup>

**Training Details** We use the Adam optimizer (Kingma and Ba, 2014) and set it with the hyperparameter  $\beta_1 = 0.9$  and  $\beta_2 = 0.98$  for downstream fine-tuning. We set the learning rate as  $1e-5$ , with a warmup step of 4000. We use the label smoothing cross-entropy for the standard translation loss and we set label smoothing with a ratio of 0.1 for model training. All of the fine-tuning experiments reported in this paper are conducted on 8

Table 1: Test results on TED Talks in the direction of (X → En). †: scores are taken from the official papers for these models. -: the scores are not reported or the language is not supported. \*: the score is not directly comparable due to the use of document-level parallel corpora for pre-training. The Baseline Model refers to the model described in Section 3.1, which is used for parameter initialization for BMA-SBT. BT refers to the conventional back-translation method described in Section 2.2.  $KL_1$  and  $KL_2$  refers to the loss described in Equation 5 and Equation 6 respectively. We train our system BMA-SBT at the document level.

NVIDIA V100 GPUs. We set the batch size as 512 tokens per GPU. Furthermore, to simulate a larger batch size, we update the models every 128 steps. For bilingual back-translation models, we use the downstream datasets for training on the same Transformer architecture.

### 3.2 TED Talks

**Experimental Settings** We use the IWSLT15 Campaign for the evaluation of TED Talks, on the task of multilingual MT. Prior systems have reported scores on only 1 or 2 translation directions (Lee et al., 2022; Sun et al., 2022), and Lee et al. (2022) supports only the translation direction into English (X → En). We report a wider range of language directions on the benchmark. We split all documents into sub-documents with a maximum of 512 tokens for all train/dev/test sets during training and inference. We use the official parallel training data from IWSLT15 with no additional monolingual data and the official 2010 dev set and 2010-2013 test set for evaluation (Liu et al., 2020; Lee et al., 2022). We use the Baseline Model to generate all the BT data and the SBT data used for multilingual agreement in BMA-SBT. We fine-tune

our model BMA-SBT at the document level. We report d-BLEU (Liu et al., 2020) using SacreBLEU.<sup>6</sup> d-BLEU score is a BLEU score for documents.

**Baseline Systems** We report strong baselines evaluated at both sentence and document levels. Evaluating at the sentence level means that we split documents into sentences for training and inference. In contrast, evaluating at the document level means that we split all documents into sub-documents with a maximum of 512 tokens as described in the Experimental Settings. We compare to the following baselines: M2M-100 (Fan et al., 2022), mBART (Liu et al., 2020), HAN† (Yang et al., 2016), MARGE† (Lewis et al., 2020), and the Baseline Model that we use to initialize the weights for BMA-SBT. †: the scores are taken from existing papers. We also report performance with Multilingual Agreement (Yang et al., 2021c) fine-tuned on Baseline Model with BT using synthetic parallel text. For a fair comparison, we do not directly compare to the SOTA model DOCmT5† (Lee et al., 2022), as it uses a large amount of bilingual parallel document data for a document-level multi-

<b>BMA-SBT (Ours) + BT</b>	<b>37.26</b>	<b>34.58</b>	<b>26.31</b>	<b>37.58</b>	<b>33.93</b>

Table 2: Test results on the News benchmark in the direction of ( $X \rightarrow \text{En}$ ).

lingual pre-training. The corpus used by DOCmT5 is not publicly available yet, and our methodology does not make use of such data. See Appendix A for the number of model parameters.

**Results** Table 1 presents the evaluation results of TED Talks in the direction of ( $X \rightarrow \text{En}$ ). BMA-SBT clearly surpasses the baselines. BMA-SBT surpasses the Baseline Model when both are fine-tuned at the document level by an average of 1.20 points in the score. BMA-SBT surpasses the Baseline Model fine-tuned at the sentence level by an average of 0.34 points in the score. Here, the Baseline Model fine-tuned at the document level is no better than that of the sentence level. We postulate that the underlying reason is that previous works have reported that directly optimizing the MNMT model at the document level can be challenging due to the long input problem (Koehn and Knowles, 2017). For a fair comparison, we add the conventional back-translation (BT) to both BMA-SBT and the Baseline Model. See Section 2.2 for more explanation on the difference between BT and the SBT methods used to achieve multilingual agreement.

In addition to the fact that BMA-SBT clearly improves the Baseline Model, which is a strong pre-trained MT system, BMA-SBT also beats other baselines such as HAN, M2M-100, mT5, and mBART, both fine-tuned at the sentence level and at the document level. Indeed, the Baseline Model itself is already quite competitive with these models, and being able to improve such a model is a piece of clear evidence for the effectiveness of BMA-SBT. The final results we obtain are close to the SOTA system DOCmT5, which uses a large amount of bilingual document translation pairs for multilingual pre-training.

**Ablation Study** The ablation study in Table 1 supports three points of view: (i) the bidirection-

ality of the multilingual agreement is necessary, (ii) the synthetic additional parallel data created by the BT used for MA is useful, and (iii) BMA-SBT brings additional improvements to the BT.

Firstly, the row of (-w/o  $KL_1$ ) and the row of (-w/o  $KL_2$ ) represent the ablations when the KL loss in the directions described in Equation 5 and Equation 6 are ablated respectively. Here, we can see that both lead to a degradation in the results. Clearly, using  $KL_2$  solely without  $KL_1$  seems to degrade the performance. This is not surprising, as  $KL_1$  pushes the output distributions of authentic data to be close to that of auxiliary text, which helps the model to use more linguistic clues in the auxiliary text. Also, using  $KL_2$  solely pushes the outputs of synthetic auxiliary data to be close to that of the authentic data unidirectionally, which can be less helpful to the original authentic data. Removing  $KL_2$  and using  $KL_1$  solely also degrades the results, which aligns with our original motivation depicted for the bidirectionality as in Figure 1.

Secondly, the row of (- w/o  $KL_1 \& KL_2$ ) brings improvements compared to Baseline Model + BT, which means that the auxiliary parallel data itself created by switched back-translation is useful.

Finally, BMA-SBT + BT brings clear improvements to the Baseline Model + BT. Since both models have used the conventional BT (See Section 3.1 for more details), the comparison is fair, which means that the BMA-SBT framework is effective and brings additive improvement to BT.

### 3.3 News

**Experimental Settings** For evaluation on the News benchmark, we use News Commentary v11 as the training set, following Sun et al. (2022). We employ newstest2015 as the dev set, and newstest2016/newstest2019 as the test set respectively for Cs and De. We use newstest2013 as the dev

Table 4: A Chinese-to-English case study from TED Talks demonstrates that BMA-SBT captures better noun-related issues. We highlight the correct translation in cyan (the darker one when printed in B&W), and the mistakes in lime (the lighter one when printed in B&W). Google Translate: <https://translate.google.com/>, Microsoft Translator: <https://www.bing.com/translator>, DeepL Translate: <https://www.deepl.com/translator>. Time-stamped on 15th June 2023, can be subject to change.

set and newstest2015 as the test set for Fr. We use newstest2019 as the dev set and newstest2020 as the test set for Zh. The remaining settings follow the same as the evaluation on TED Talks.

**Baseline Systems** As the weights for DOCmT5 are not available at the time of writing, we compare our system to various strong baselines such as M2M-100, mBART and the Baseline Model. We run the fine-tuning process on the official checkpoints to obtain the scores. For a fair comparison, we apply BT to the Baseline Model.

**Results** Table 2 compares BMA-SBT to strong baselines, and we see that the improvements with BMA-SBT are clear, and the final results surpass all the strong baselines. This validates BMA-SBT's effectiveness as a novel framework.

### 3.4 Europarl

**Experimental Settings** For the Europarl dataset (Koehn, 2005), we use Europarl-v7 Sun et al. (2022). We experiment with (X → En) where we test nine languages: Da, De, El, Es, Fr, It, Nl, Pt, and Sv. Like previous works (Bao et al., 2021; Sun et al., 2022), the dataset is randomly partitioned

into train/dev/test divisions, and we split by English document IDs to avoid information leakage to better support the multilingual setting.

**Baseline Systems** As the weights for DOCmT5 are not available at the time of writing, we compare our system to various strong baselines such as M2M-100 and the Baseline Model. We run the fine-tuning process on the official checkpoints to obtain the scores. For a fair comparison, we apply BT to the Baseline Model.

**Results** Table 3 compares BMA-SBT to strong baselines, and we see that the improvements with BMA-SBT are obvious, and the final results surpass all the strong baselines.

### 3.5 Case Study

Table 4 depicts a Zh→En case study on TED Talks. In addition to the Baseline Models, we also compare BMA-SBT to various commercial systems such as Google Translate. In this case, we see that the Chinese text does not differentiate plural from single. Among all cases, it is clear that BMA-SBT works the best and can effectively resolve such ambiguity. We also observe that BMA-SBT perfectly

capture the context and attaches the definite article ‘the’ to ‘light’. This aligns with our original intention depicted in Figure 1 to help the models to improve cross-lingual learning via BMA-SBT.

### 3.6 Coherence and Consistency Evaluation

Figure 3 depicts the evaluations in the averaged scores from six translation directions on TED Talks with BlonDe scores (Jiang et al., 2022). BlonDe is an evaluation metric designed for MT which considers document-level coherence and consistency issues that require the model to resolve cross-lingual ambiguities. We see that BMA-SBT brings effective improvements to the metric.

## 4 Related Work

### 4.1 Multilingual Neural Machine Translation

Conventional bilingual machine translation models deal with two languages: one as the input, and one as the output. In comparison, multilingual neural machine translation (MNMT) has achieved great success in handling multiple languages with a single model. Recently, there have been many pre-training works on MNMT through multilingual pre-training models that leverage unsupervised pre-training objectives on monolingual corpora in many different languages (Conneau et al., 2020; Liu et al., 2020; Xue et al., 2021b). Following the calls that the unsupervised scenario is not strictly realistic for cross-lingual learning (Artetxe et al., 2020), subsequent works use parallel corpora with translation pairs for multilingual pre-training (Reid and Artetxe, 2022; Lee et al., 2022).

While pre-training has shown great success for MNMT (NLLB-Team, 2022), it is unclear whether the previous methods for from-scratching training on MNMT are still useful on pre-trained models. Multilingual agreement (Yang et al., 2021c) is perhaps the closest work to ours among those methods for from-scratching training. However, conventional MA requires authentic parallel data among many language pairs, which does not always guarantee to exist. In comparison, we focus on a more recent fine-tuning setting on popular pre-training models as well as a realistic setting with no presumption on the existence of the additional parallel data.

### 4.2 Agreement-based Learning

Agreement-based learning has been proven as a useful paradigm in the language community (Liang et al., 2006, 2007; Cheng et al., 2016). The core

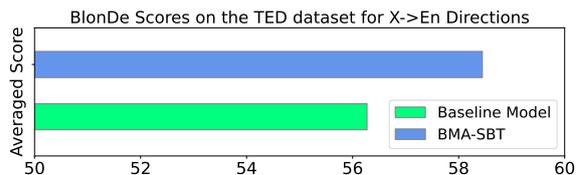

Figure 3: Averaged BlonDe scores from six directions in ( $X \rightarrow \text{En}$ ) on the dataset of TED Talks evaluated with BMA-SBT and the Baseline Model (Document-level).

idea is to minimize the difference in the representations between the inputs with the same meaning. Some multilingual pre-training methods such as Chi et al. (2021) are relevant to agreement-based learning in the way that they shrink the distance of cross-lingual representations between parallel data. Zhang et al. (2019) proposed to enforce an agreement on the output with left-to-right and right-to-left inputs on recurrent neural networks for machine translation. Yang et al. (2020) proposed to use phrase-level agreement for machine translation.

Still, Yang et al. (2021c) is the closest work to ours, which encourages agreement between parallel data in different languages to have the same translation outputs. A very recent concurrent work uses MA to close the gap between source and target languages (Gao et al., 2023). Our work creates synthetic data and employs bidirectional KL loss to enforce the multilingual agreement bidirectionally.

## 5 Conclusions

Despite the fact that multilingual agreement (MA) has shown its effectiveness in from-scratching training for MNMT, the conventional MA has at least two shortages that limit its usages: (i) needs authentic extra parallel data, which can be often unrealistic and (ii) has an ambiguous direction for agreement-based learning. We propose BMA-SBT as a novel and universal fine-tuning framework for pre-trained MT models that (i) exempts the need for authentic parallel data by creating synthetic parallel text written in a different source language and (ii) specifies the direction of agreement-based learning with bidirectional KL divergence loss. Experimental results on three multilingual machine translation datasets illustrate that BMA-SBT can obviously improve the strong pre-trained baseline system. An in-depth investigation indicates that BMA-SBT brings additive improvements to the conventional BT methods for neural machine translation.

## Limitations

The proposed method requires generating synthetic auxiliary parallel data using translation models, which requires extra computational costs. The proposed method requires generating synthetic auxiliary parallel data using translation models, which requires extra computational costs.

**Large Language Models** Large language models (LLMs) such as ChatGPT have shown good translation abilities (Lu et al., 2023), while they still lag behind supervised systems (Jiao et al., 2023; Zhu et al., 2023). We do not directly compare them, as they are much larger in their number of parameters than the systems described in this work.

## Ethics Statement

We honour and support the EAACL Code of Ethics. The datasets used in this work are well-known and widely used, and the dataset pre-processing does not make use of any external textual resource. In our view, there is no known ethical issue. End-to-end pre-trained generators are also used, which are subjected to generating offensive context. But the above-mentioned issues are widely known to commonly exist for these models. Any content generated does not reflect the view of the authors.

## Abstract

Recent multilingual pretrained language models (mPLMs) have been shown to encode strong language-specific signals, which are not explicitly provided during pretraining. It remains an open question whether it is feasible to employ mPLMs to measure language similarity, and subsequently use the similarity results to select source languages for boosting cross-lingual transfer. To investigate this, we propose mPLM-Sim, a language similarity measure that induces the similarities across languages from mPLMs using multi-parallel corpora. Our study shows that mPLM-Sim exhibits moderately high correlations with linguistic similarity measures, such as lexicostatistics, genealogical language family, and geographical sprachbund. We also conduct a case study on languages with low correlation and observe that mPLM-Sim yields more accurate similarity results. Additionally, we find that similarity results vary across different mPLMs and different layers within an mPLM. We further investigate whether mPLM-Sim is effective for zero-shot cross-lingual transfer by conducting experiments on both low-level syntactic tasks and high-level semantic tasks. The experimental results demonstrate that mPLM-Sim is capable of selecting better source languages than linguistic measures, resulting in a 1%-2% improvement in zero-shot cross-lingual transfer performance.<sup>1</sup>

## 1 Introduction

Recent multilingual pretrained language models (mPLMs) trained with massive data, e.g., mBERT (Devlin et al., 2019), XLM-R (Conneau et al., 2020) and BLOOM (Scao et al., 2022), have become a standard for multilingual representation learning. Follow-up works (Wu and Dredze, 2019; Libovický et al., 2020; Liang et al., 2021; Chang et al., 2022)

show that these mPLMs encode strong language-specific signals which are not explicitly provided during pretraining. However, the possibility of using mPLMs to measure language similarity and utilizing the similarity results to pick source languages for enhancing cross-lingual transfer is not yet thoroughly investigated.

To investigate language similarity in mPLMs, we propose mPLM-Sim, a measure that leverages mPLMs and multi-parallel corpora to measure similarity between languages. Using mPLM-Sim, we intend to answer the following research questions.

**(Q1)** *What is the correlation between mPLM-Sim and linguistic similarity?*

We compute Pearson correlation between similarity results of mPLM-Sim and linguistic similarity measures. The results show that mPLM-Sim has a moderately high correlation with some linguistic measures, such as lexical-based and language-family-based measures. Additional case studies on languages with low correlation demonstrate that mPLMs can acquire the similarity patterns among languages through pretraining on massive data.

**(Q2)** *Do different layers of an mPLM produce different similarity results?*

Jawahar et al. (2019); Sabet et al. (2020); Choenni and Shutova (2022) have demonstrated that different linguistic information is encoded across different layers of an mPLM. We analyze the performance of mPLM-Sim across layers and show that mPLM-Sim results vary across layers, aligning with previous findings. Specifically, the embedding layer captures lexical information, whereas the middle layers reveal more intricate similarity patterns encompassing general, geographical, and syntactic aspects. However, in the high layers, the ability to distinguish between languages becomes less prominent. Furthermore, we observe that clustering of languages also varies by layer, shedding new light on how the representation of language-specific information changes throughout layers.

<sup>\*</sup>Equal contribution.

<sup>1</sup>Our code is open-sourced at <https://github.com/cisnlp/mPLM-Sim>.

**(Q3)** *Do different mPLMs produce different similarity results?*

We make a comprehensive comparison among a diverse set of 11 mPLMs in terms of architecture, modality, model size, and tokenizer. The experimental results show that input modality (text or speech), model size, and data used for pretraining have large effects on mPLM-Sim while tokenizers and training objectives have little effect.

**(Q4)** *Can mPLM-Sim choose better source languages for zero-shot cross-lingual transfer?*

Previous works (Lin et al., 2019; Pires et al., 2019; Lauscher et al., 2020; Nie et al., 2022; Wang et al., 2023; Imai et al., 2023) have shown that the performance of cross-lingual transfer positively correlates with linguistic similarity. However, we find that there can be a mismatch between mPLM subspaces and linguistic clusters, which may lead to a failure of zero-shot cross-lingual transfer for low-resource languages. Intuitively, mPLM-Sim can select the source languages that boost cross-lingual transfer better than linguistic similarity since it captures the subspaces learned during pretraining (and which are the basis for successful transfer). To examine this, we conduct experiments on four datasets that require reasoning about different levels of syntax and semantics for a diverse set of low-resource languages. The results show that mPLM-Sim achieves 1%-2% improvement over linguistic similarity measures for cross-lingual transfer.

## 2 Setup

### 2.1 mPLM-Sim

Generally, a transformer-based mPLM consists of  $N$  layers:  $N - 1$  transformer layers plus the static embedding layer. Given a multi-parallel corpus<sup>2</sup>, mPLM-Sim aims to provide the similarity results of  $N$  layers for an mPLM across  $L$  languages considered. In this context, we define languages using the ISO 639-3 code combined with the script, e.g., “eng\_Latn” represents English written in Latin.

For each sentence  $x$  in the multi-parallel corpus, the mPLM computes its sentence embedding for the  $i$ th layer of the mPLM:  $\mathbf{h}_i = E(x)$ . For mPLMs with bidirectional encoders, including encoder architecture, e.g., XLM-R, and encoder-decoder architecture, e.g., mT5,  $E(\cdot)$  is a mean

<sup>2</sup>Monolingual corpora covering multiple languages can be also used to measure language similarity. Our initial experiments (§B.1) show that parallel corpora yield better results while using fewer sentences than monolingual corpora. Therefore, we use parallel corpora for our investigation.

pooling operation over hidden states, which performs better than [CLS] and MAX strategies (Reimers and Gurevych, 2019). For mPLMs with auto-regressive encoders, e.g., mGPT,  $E(\cdot)$  is a position-weighted mean pooling method, which gives later tokens a higher weight (Muennighoff, 2022). Finally, sentence embeddings for all sentences of the  $L$  languages are obtained.

For  $i$ th layer, the similarity of each language pair is computed using the sentence embeddings of all multi-parallel sentences. Specifically, we get the cosine similarity of each parallel sentence of the language pair, and then average all similarity scores across sentences as the final score of the pair. Finally, we have a similarity matrix  $\mathbf{S}_i \in \mathbb{R}^{L \times L}$  across  $L$  languages for the  $i$ th layer of the mPLM.

### 2.2 mPLMs, Corpora and Languages

We consider a varied set of 11 mPLMs for our investigation, differing in model size, number of covered languages, architecture, modality, and data used for pretraining. Full list and detailed information of the selected mPLMs are shown in Tab. 1.

We work with three multi-parallel corpora: the text corpora Flores (Costa-jussà et al., 2022) and Parallel Bible Corpus (PBC, (Mayer and Cysouw, 2014)) and the speech corpus Fleurs (Conneau et al., 2022). Flores covers more than 200 languages. Since both PBC and Fleurs are not fully multi-parallel, we reconstruct them to make them multi-parallel. After reconstruction, PBC covers 379 languages, while Fleurs covers 67 languages. PBC consists of religious text, and both Flores and Fleurs are from web articles. The speech of Fleurs is aligned to the text of Flores, enabling us to compare text mPLMs with speech mPLMs. We use 500 multi-parallel sentences from each corpus. Languages covered by mPLMs and corpora are listed in §A.

### 2.3 Evaluation

**Pearson Correlation** We compute Pearson correlation scores to measure how much mPLM-Sim correlates with seven linguistic similarity measures: LEX, GEN, GEO, SYN, INV, PHO and FEA. LEX is computed based on the edit distance of the two corpora. The six others are provided by lang2vec. GEN is based on language family. GEO is orthodromic distance, i.e., the shortest distance between two points on the surface of the earth. SYN is derived from the syntactic structures of the languages. Both INV and PHO are phonological features. INV

is derived from PHOIBLE, while PHO is based on WALS and Ethnologue. FEA is computed by combining GEN, GEO, SYN, INV and PHO.

For each target language, we have the similarity scores between the target language and the other  $L - 1$  languages based on the similarity matrix  $S_i$  for layer  $i$  (see §2.1), and also the similarity scores based on the considered linguistic similarity measure  $j$ . Then we compute the Pearson correlation  $r_i^j$  between these two similarity score lists. We choose the highest correlation score across all layers as the result of each target language since the results for different languages vary across layers. Finally, we report MEAN (M) and MEDIAN (Mdn) of the correlation scores for all languages. Here, we consider 32 languages covered by all models and corpora.

**Case Study** In addition to the quantitative evaluation, we conduct manual analysis for languages that exhibit low correlation scores. We apply complete linkage hierarchical clustering to get the similar languages of the analyzed language for analysis. Specifically, the languages which have the most common shared path in the hierarchical tree with the target language are considered as similar languages. To analyze as many languages as possible, we consider the setting of Glot500 and PBC.

**Cross-Lingual Transfer** To compare mPLM-Sim with linguistic measures for zero-shot cross-lingual transfer, we run experiments for low-resource languages on four datasets, including two for sequence labeling, and two for text classification. Details of the four tasks are shown in Tab. 2.

We selected six high-resource and typologically diverse languages, namely Arabic (arb\_Arab), Chinese (cmn\_Hani), English (eng\_Latn), Hindi (hin\_Deva), Russian (rus\_Cyrl), and Spanish (spa\_Latn), as source languages. For a fair comparison, we use the same amount of source language data for fine-tuning and validation as shown in Tab. 2.

The evaluation targets all languages that are covered by both Glot500 and Flores and have at least 100 samples, excluding the six source languages. The language list for evaluation is provided in §A.

We obtain the most similar source language for each target language by applying each of the seven linguistic similarity measures (LEX, GEN, GEO, SYN, INV, PHO, FEA) and our mPLM-Sim. Here, we consider the setting of Glot500 and Flores for mPLM-Sim since extensive experiments (see §B.2) show that Flores provides slightly better similarity results than PBC. For the linguistic similarity mea-

Table 3: Comparison across mPLMs: Pearson correlation between mPLM-Sim and seven similarity measures for all mPLMs and Flores/Fleurs on 32 languages. mPLM-Sim strongly correlates with LEX, moderate strongly correlates with GEN, GEO, and SYN, and weakly correlates with INV, PHO, and FEA.

tures, if the most similar source language is not available due to missing values in lang2vec, we use eng\_Latn as the source language. We also compare mPLM-Sim with the ENG baseline defined as using eng\_Latn as the source language for all target languages.

We use the same hyper-parameter settings as in (Hu et al., 2020; FitzGerald et al., 2022; Ma et al., 2023). Specifically, we set the batch size to 32 and the learning rate to 2e-5 for both NER and POS, and fine-tune Glot500 for 10 epochs. For MASSIVE, we use a batch size of 16, a learning rate of 4.7e-6, and train for 100 epochs. For Taxi1500, we use a batch size of 32, a learning rate of 2e-5, and train for 30 epochs. In all tasks, we select the model for evaluating target languages based on the performance of the source language validation set.

### 3 Results

#### 3.1 Comparison Between mPLM-Sim and Linguistic Similarity

Tab. 3 shows the Pearson correlation between mPLM-Sim and linguistic similarity measures of 11 mPLMs, and also the average correlations of all 11 mPLMs. We observe that mPLM-Sim

strongly correlates with LEX, which is expected since mPLMs learn language relationships from data and LEX similarity is the easiest pattern to learn. Besides, mPLM-Sim has moderately strong correlations with GEN, GEO, and SYN, which shows that mPLMs can learn high-level patterns for language similarity. mPLM-Sim also has a weak correlation with INV, and a very weak correlation with PHO, indicating mPLMs do not capture phonological similarity well. Finally, mPLM-Sim correlates with FEA weakly since FEA is the measure combining both high- and low-correlated linguistics features.

To further compare mPLM-Sim with linguistic similarity measures, we conduct a manual analysis on languages for which mPLM-Sim has weak correlations with LEX, GEN, and GEO. As mentioned in §2, with the setting of Glot500 and PBC, we apply hierarchical clustering and use similar results for analysis.

We find that mPLM-Sim can deal well with languages that are not covered by lang2vec. For example, Norwegian Nynorsk (nno\_Latn) is not covered by lang2vec, and mPLM-Sim can correctly find its similar languages, i.e., Norwegian Bokmål

(nob\_Latn) and Norwegian (nor\_Latn). Furthermore, mPLM-Sim can well capture the similarity between languages which cannot be well measured by either LEX, GEN, or GEO.

For LEX, mPLM-Sim can capture similar languages written in different scripts. A special case is the same languages in different scripts. Specifically, mPLM-Sim matches Uighur in Latin and Arabic (uig\_Arab and uig\_Latn), also Karakalpak in Latin and Cyrillic (kaa\_Latn and kaa\_Cyrl). In general, mPLM-Sim does a good job at clustering languages from the same language family but written in different scripts, e.g., Turkic (Latn, Cyrl, Arab) and Slavic (Latn, Cyrl).

For GEN, mPLM-Sim captures correct similar languages for isolates and constructed languages. Papantla Totonac (top\_Latn) is a language of the Totonacan language family and spoken in Mexico. It shares areal features with the Nahuatl languages (nch\_Latn, ncj\_Latn, and ngu\_Latn) of the Uto-Aztecan family, which are all located in the Mesoamerican language area.<sup>3</sup> Esperanto (epo\_Latn) is a constructed language whose vocabulary derives primarily from Romance languages, and mPLM-Sim correctly identifies Romance languages such as French (fra\_Latn) and Italian (ita\_Latn) as similar. The above two cases show the superiority of mPLM-Sim compared to GEN.

The GEO measure may not be suitable for certain language families, such as Austronesian languages and mixed languages. Austronesian languages have the largest geographical span among language families prior to the spread of Indo-European during the colonial period.<sup>4</sup> Moreover, for mixed languages, such as creole languages, their similar languages are often geographically distant due to colonial history. In contrast to GEO, mPLM-Sim can better cluster these languages.

The above analysis shows that it is non-trivial to use either LEX, GEN, or GEO for measuring language similarity. In contrast, mPLM-Sim directly captures similarity from mPLMs and can therefore produce better similarity results.

However, we observe that obtaining accurate similarity results from mPLMs using mPLM-Sim can be challenging for certain languages. To gain further insights into this issue, we examine the

<sup>3</sup>[https://en.wikipedia.org/wiki/Mesoamerican\\_language\\_area](https://en.wikipedia.org/wiki/Mesoamerican_language_area)

<sup>4</sup>[https://en.wikipedia.org/wiki/Austronesian\\_languages](https://en.wikipedia.org/wiki/Austronesian_languages)

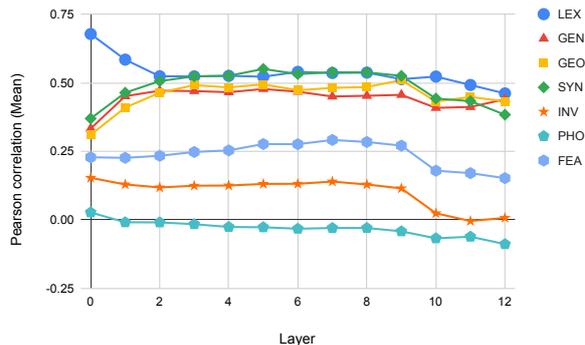

Figure 1: Comparison across layers: Pearson correlation (MEAN) between mPLM-Sim and linguistic similarity measures across layers for Glot500 and Flores on 32 languages. Correlation between mPLM-Sim and LEX peaks in the first layer and decreases, while the correlation with GEN, GEO, and SYN slightly increases in the low layers before reaching its peak.

correlation between performances, specifically the correlation between mPLM-Sim and GEN, and the sizes of the pretraining data. Surprisingly, we find a remarkably weak correlation (-0.008), suggesting that differences in pretraining data sizes do not significantly contribute to variations in performances.

Instead, our findings indicate a different key factor: the coverage of multiple languages within the same language family. This observation is substantiated by a strong correlation of 0.617 between the diversity of languages within a language family (measured by the number of languages included) and the performance of languages belonging to that particular language family.

### 3.2 Comparison Across Layers for mPLM-Sim

We analyze the correlation between mPLM-Sim and linguistic similarity measures across different layers of an mPLM, specifically for Glot500. The results, presented in Fig. 1, demonstrate the variation in mPLM-Sim results across layers. Notably, in the first layer, mPLM-Sim exhibits a high correlation with LEX, which gradually decreases as we move to higher layers. Conversely, the correlation between mPLM-Sim and GEN, GEO, and SYN shows a slight increase in the lower layers, reaching its peak in layer 1 or 2 of the mPLM. However, for the higher layers (layers 10-12), all correlations slightly decrease. We also performed further visualization and analysis across layers using the setting of Glot500 and Flores for mPLM-Sim (§C). The findings are consistent with our observations from Fig. 1.

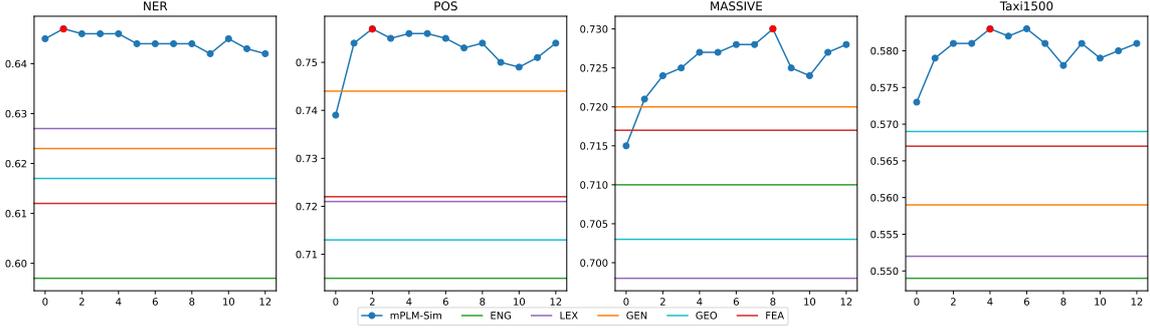

Figure 2: Macro average results (averaged over target languages) on cross-lingual transfer for baselines and for mPLM-Sim in all layers of Glot500. ENG represents using English as the source language. LEX, GEN, GEO, and FEA indicate using the most similar languages based on the corresponding similarity measures as the source language. The red dots of mPLM-Sim highlight the layer with the highest score.

Furthermore, our case study shows that the layers which have highest correlations between mPLM-Sim and LEX, GEN, or GEO vary across languages. For example, Atlantic–Congo languages achieve highest correlation with GEN at the 1st layer, while Mayan languages at the 6th layer. This finding demonstrates that language-specific information changes across layers.

### 3.3 Comparison Across Models for mPLM-Sim

Tab. 3 presents a broad comparison among 11 different mPLMs, revealing several key findings.

Firstly, the decoder architecture has a negative impact on performance due to the inherent difficulty in obtaining accurate sentence-level representations from the decoder. For example, the decoder-only mPLM mGPT performs worse than encoder-only mPLMs such as XLM-R and mBERT. This observation is reinforced by the comparison between XLM-R-Large and mT5-Base, which have nearly identical model sizes. Remarkably, XLM-R-Large outperforms mT5-Base on AVG by 5% for both Mean (M) and Median (Mdn) scores.

Additionally, tokenizer-free mPLMs achieve comparable performance to subword-tokenizer-based mPLMs. Notably, mPLMs such as mBERT, CANINE-S, and CANINE-C, which share pretraining settings, exhibit similar performances.

The size of mPLMs also influences mPLM-Sim in terms of LEX, GEN, and SYN. Comparing XLM-R-Base with XLM-R-Large, higher-level language similarity patterns are more evident in larger mPLMs. Specifically, XLM-R-Large shows a higher correlation with high-level patterns such as GEN and SYN, while having a lower correla-

tion with low-level patterns like LEX, compared to XLM-R-Base.

The training objectives adopted in mPLMs also impact the performance of mPLM-Sim. Task-specific mPLMs, such as NLLB-200, perform slightly worse than general-purpose mPLMs. Besides, XLM-Align, which leverages parallel objectives to align representations across languages, achieves comparable results to XLM-R-Base. This highlights the importance of advancing methods to effectively leverage parallel corpora.

The choice of pretraining data is another important factor. For example, mBERT uses Wikipedia, while XLM-R-Base uses CommonCrawl, which contains more code-switching. As a result, XLM-R-Base has a higher correlation with GEO and achieves higher AVG compared to mBERT.

The speech mPLM, i.e., XLS-R-300M, exhibits lower correlation than text mPLMs, consistent with findings from Abdullah et al. (2023). XLS-R-300M learns language similarity from speech data, which is biased towards the accents of speakers. Consequently, XLS-R-300M has a higher correlation with GEO, which is more related to accents, than other similarity measures.

Factors such as the number of languages have minimal effects on mPLM-Sim. Glot500, covering over 500 languages, achieves comparable results with XLM-R-Base.

### 3.4 Effect for Cross-Lingual Transfer

The macro average results of cross-lingual transfer across target languages for both mPLM-Sim and baselines are presented in Fig. 2. Among the evaluated tasks, ENG exhibits the worst performance in three out of four tasks, emphasizing the importance

		Language	GEN		mPLM-Sim		$\Delta$		Language	GEN		mPLM-Sim		$\Delta$

Table 4: Results for three languages each with the largest (high end) and smallest (low end) gains from mPLM-Sim vs. GEN for four tasks. mPLM-Sim’s gain over GEN is large at the high end and smaller negative at the low end. We report both the selected source languages and the results on the evaluated target languages. For mPLM-Sim, the results are derived from the layers exhibiting the best performances as shown in Fig. 2. See §E for detailed results for each task and each target language.

of considering language similarity when selecting source languages for cross-lingual transfer. mPLM-Sim surpasses all linguistic similarity measures in every task, including both syntactic and semantic tasks, across all layers except layer 0. This indicates that mPLM-Sim is more effective in selecting source languages that enhance the performance of target languages compared to linguistic similarity measures.

For low-level syntactic tasks, the lower layers (layer 1 or 2) exhibit superior performance compared to all other layers. Conversely, for high-level semantic tasks, it is the middle layer of the mPLM that consistently achieves the highest results across all layers. This can be attributed to its ability to capture intricate similarity patterns.

In Tab. 4, we further explore the benefits of mPLM-Sim in cross-lingual transfer. We present a comprehensive analysis of the top 3 performance improvements and declines across languages. We compare mPLM-Sim and GEN across four cross-lingual transfer tasks. By examining these results, we gain deeper insights into the advantages of mPLM-Sim in facilitating effective cross-lingual transfer.

The results clearly demonstrate that mPLM-Sim has a substantial performance advantage over GEN for certain target languages. On one hand, for languages without any source language in the same language family, such as Japanese (jpn\_Jpan), mPLM-Sim successfully identifies its similar language, Chinese (cmn\_Hani), whereas GEN fails to do so. Notably, in the case of Japanese, mPLM-Sim outperforms GEN by 27.5% for NER, 36.9%

for POS, and 6.4% for MASSIVE.

On the other hand, for languages having source languages within the same language family, mPLM-Sim accurately detects the appropriate source language, leading to improved cross-lingual transfer performance. In the case of Burmese (mya\_Mymr), mPLM-Sim accurately identifies Hindi (hin\_Deva) as the source language, while GEN mistakenly selects Chinese (cmn\_Hani). This distinction results in a significant performance improvement of 15.3% for NER and 9.1% for MASSIVE.

However, we also observe that mPLM-Sim falls short for certain languages when compared to GEN, although the losses are smaller in magnitude compared to the improvements. This finding suggests that achieving better performance in cross-lingual transfer is not solely dependent on language similarity. As mentioned in previous studies such as Lauscher et al. (2020) and Nie et al. (2022), the size of the pretraining data for the source languages also plays a crucial role in cross-lingual transfer.

## 4 Related Work

### 4.1 Language Typology and Clustering

Similarity between languages can be due to common ancestry in the genealogical language tree, but also influenced by linguistic influence and borrowing (Aikhenvald and Dixon, 2001; Haspelmath, 2004). Linguists have conducted extensive relevant research by constructing high-quality typological, geographical, and phylogenetic databases, including WALS (Dryer and Haspelmath, 2013), Glottolog (Hammarström et al., 2017), Ethnologue (Saggion et al., 2023), and PHOIBLE (Moran et al.,

2014; Moran and McCloy, 2019). The lang2vec tool (Littell et al., 2017) further integrates these datasets into multiple linguistic distances. Despite its integration of multiple linguistic measures, lang2vec weights each measure equally, and the quantification of these measures for language similarity computation remains a challenge.

In addition to linguistic measures, some non-linguistic measures are also proposed to measure similarity between languages. Specifically, Holman et al. (2011) use Levenshtein (edit) distance to compute the lexical similarity between languages. Lin et al. (2019) propose dataset-dependent features, which are statistical features specific to the corpus used, e.g., lexical overlap. Ye et al. (2023) measure language similarity with basic concepts across languages. However, these methods fail to capture deeper similarities beyond surface-level features.

Language representation is another important category of language similarity measures. Before the era of multilingual pretrained language models (mPLMs), exploiting distributed language representations for measuring language similarity have been studied (Östling and Tiedemann, 2017; Bjerva and Augenstein, 2018). Recent mPLMs trained with massive data have become a new standard for multilingual representation learning. Tan et al. (2019) represent each language by an embedding vector and cluster them in the embedding space. Fan et al. (2021b) find the representation sprachbund of mPLMs, and then train separate mPLMs for each sprachbund. However, these studies do not delve into the research questions mentioned in §1, and it motivates us to carry out a comprehensive investigation of language similarity using mPLMs.

## 4.2 Multilingual Pretrained Language Models

The advent of mPLMs, e.g., mBERT (Devlin et al., 2019), XLM (Conneau and Lample, 2019), and XLM-R (Conneau et al., 2020), have brought significant performance gains on numerous multilingual natural language understanding benchmarks (Hu et al., 2020).

Given their success, a variety of following mPLMs are proposed. Specifically, different architectures, including decoder-only, e.g., mGPT (Shliazhko et al., 2022) and BLOOM (Scao et al., 2022), and encoder-decoder, e.g., mT5 (Xue et al., 2021), are designed. Tokenizer-free models, including CANINE (Clark et al., 2022), ByT5 (Xue et al., 2022), and Charformer (Tay et al., 2022),

are also proposed. Clark et al. (2022) introduce CANINE-S and CANINE-C. CANINE-S adopts a subword-based loss, while CANINE-C uses a character-based one. Glot500 (Imani et al., 2023) extends XLM-R to cover more than 500 languages using vocabulary extension and continued pretraining. Both InfoXLM (Chi et al., 2021a) and XLM-Align (Chi et al., 2021b) exploit parallel objectives to further improve mPLMs. Some mPLMs are specifically proposed for Machine Translation, e.g., M2M-100 (Fan et al., 2021a) and NLLB-200 (Costa-jussà et al., 2022). XLS-R-300M (Babu et al., 2021) is a speech (as opposed to text) model.

Follow-up works show that strong language-specific signals are encoded in mPLMs by means of probing tasks (Wu and Dredze, 2019; Rama et al., 2020; Pires et al., 2019; Müller et al., 2021; Liang et al., 2021; Choenni and Shutova, 2022) and investigating the geometry of mPLMs (Libovický et al., 2020; Chang et al., 2022; Wang et al., 2023). Concurrent with our work, Philippy et al. (2023) have verified that the language representations encoded in mBERT correlate with both linguistic typology and cross-lingual transfer on XNLI for 15 languages. However, these methods lack in-depth analysis and investigate on a limited set of mPLMs and downstream tasks. This inspires us to conduct quantitative and qualitative analysis on linguistic typology and cross-lingual transfer with a broad and diverse set of mPLMs and downstream tasks.

## 5 Conclusion

In this paper, we introduce mPLM-Sim, a novel approach for measuring language similarities. Extensive experiments substantiate the superior performance of mPLM-Sim compared to linguistic similarity measures. Our study reveals variations in similarity results across different mPLMs and layers within an mPLM. Furthermore, our findings reveal that mPLM-Sim effectively identifies the source language to enhance cross-lingual transfer.

The results obtained from mPLM-Sim have significant implications for multilinguality. On the one hand, it can be further used in linguistic study and downstream applications, such as cross-lingual transfer, as elaborated in the paper. On the other hand, these findings provide valuable insights for improving mPLMs, offering opportunities for their further development and enhancement.

## Limitations

(1) The performance of mPLM-Sim may be strongly influenced by the quality and quantity of data used for training mPLMs, as well as the degree to which the target language can be accurately represented. (2) The success of mPLM-Sim depends on the supporting languages of mPLMs. We conduct further experiment and analysis at §D. (3) As for §3.3, we are unable to conduct a strictly fair comparison due to the varying settings in which mPLMs are pretrained, including the use of different corpora and model sizes.

Table 12: Comparison of pearson correlation result: Pearson correlation between seven similarity measures and mPLM-Sim (500 multi-parallel sentences), Mono (Monolingual corpora) and the results of using different amounts (1, 5, 10) of multi-parallel sentences.

## B Comparison Across Corpora for mPLM-Sim

### B.1 Monolingual vs. Parallel

Both monolingual and parallel corpora can be exploited for obtaining sentence embeddings for measuring language similarity. We conduct experiments of exploiting monolingual corpora for measuring similarity across languages, and also provide the results of using different amounts (1, 5, 10, 500) of multi-parallel sentences.

For the experiment of pearson correlation in Sec. 3.1, the results (MEAN) are shown in Tab. 12. For the experiment of cross-lingual transfer in Sec. 3.4, the results are shown in Tab. 13. Based on these two experiments, we have the conclusions below:

- mPLM-Sim using multi-parallel corpora achieves slightly better results than using monolingual corpora.
- mPLM-Sim (500 sentences) requires less data than exploiting monolingual corpora. Besides, using mPLM-Sim (10 sentences) can achieve comparable results with mPLM-Sim (500 sentences). While including a truly low-resource language for similarity measurement, mPLM-Sim requires around 10 sentences parallel to one existing language, while monolingual corpora requires massive sentences.

In a word, exploiting parallel corpora is better for measuring language similarity than monolingual corpora.

### B.2 Flores vs. PBC

To investigate the impact of multi-parallel corpora on the performance of mPLM-Sim, we compare

	mPLM-Sim	Mono	1	5	10
NER	0.647	0.644	0.644	0.646	0.647
POS	0.751	0.737	0.748	0.753	0.752
Massive	0.730	0.730	0.723	0.728	0.730

AVG	0.451	0.508	0.414	0.453

Table 14: Comparison across corpora: Pearson correlation between mPLM-Sim and linguistic similarity measures for Glot500 and all corpora on 32 languages. Flores achieves higher correlations than PBC.

the results of Glot500 with Flores and PBC on 32 languages that are covered by both corpora.

Tab. 14 shows that Flores outperforms PBC across all similarity measures, except for PHO. To gain further insights, we conduct a case study focusing on languages that exhibit different performances between the two corpora.

In comparison to PBC, Flores consists of text that is closer to web content and spans a wider range of general domains. For example, a significant portion of Arabic script in Flores is written without short vowels, which are commonly used in texts requiring strict adherence to precise pronunciation, such as the Bible.<sup>5</sup> This discrepancy leads to challenges in tokenization and representation for languages written in Arabic, such as Moroccan Arabic (ary\_Arab) and Egyptian Arabic (arz\_Arab), resulting in poorer performance.

---

## C Visualization and Analysis Across Layers

### C.1 Hierarchical Clustering Analysis

We conducted hierarchical clustering analysis at different layers (0, 4, 8, and 12) using the setting of Glot500 and Flores for mPLM-Sim. The results, shown in Fig. 3, reveal distinct patterns of language clustering. In layer 0, the clustering primarily emphasizes lexical similarities, with languages sharing the same scripts being grouped together. As we progress to layers 4 and 8, more high-level similarity patterns beyond the surface-level are captured. For instance in these layers, Turkish (tur\_Latn) and Polish (pol\_Latn) are clustered with their Turkic and Slavic relatives although they use different writing systems. The similarity results of layer 12 are comparatively worse than those of the middle layers. For instance, English (eng\_Latn) deviates from its Germanic and Indo-European relatives and instead clusters with Malay languages (ind\_Latn, zsm\_Latn). This phenomenon can be attributed to the higher layer exhibiting lower inter-cluster distances (comparison between the y-axis range across figures of different layers), which diminishes its ability to effectively discriminate between language clusters.

### C.2 Similarity Heatmaps

Fig. 4-7 show the cosine similarity values in heatmaps at layer 0, 4, 8 and 12, using the Glot500 and Flores settings for mPLM-Sim.

Generally, as the layer number increases, higher cosine similarity values are observed. Layer 0 exhibits a significant contrast in similarity values, whereas layer 12 demonstrates very low contrast. Notably, Burmese (mya\_Mymr) consistently receives the lowest values across all layers, indicating the relationship between Burmese and other languages may be not well modeled.

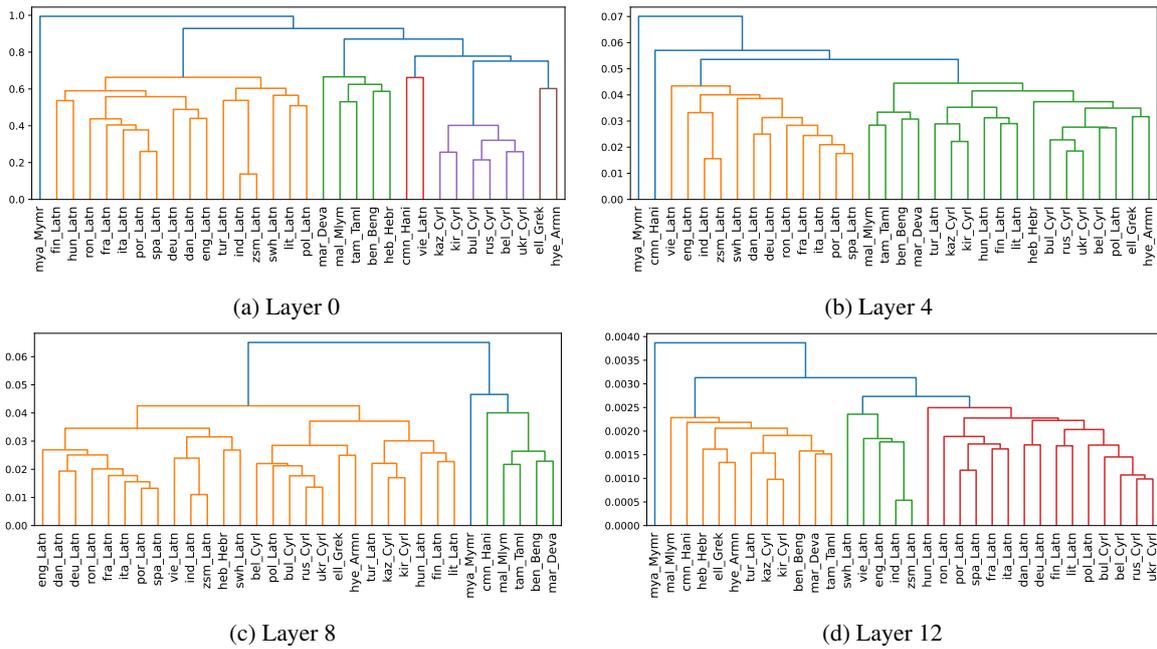

Figure 3: Dendrograms illustrating hierarchical clustering results at layer 0, 4, 8, and 12 for Glot500 and Flores across 32 languages.

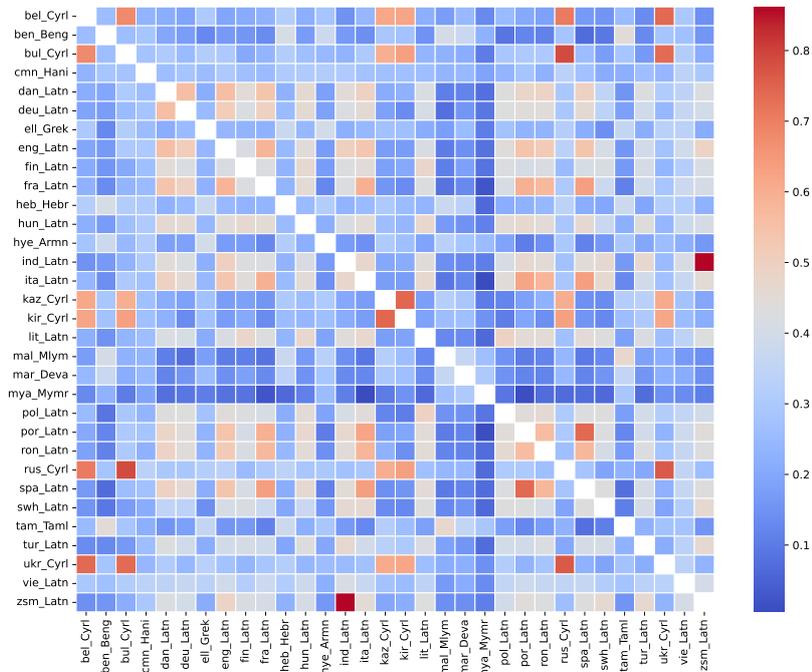

Figure 4: Heatmaps of cosine similarity results at layer 0 for Glot500 and Flores across 32 languages.

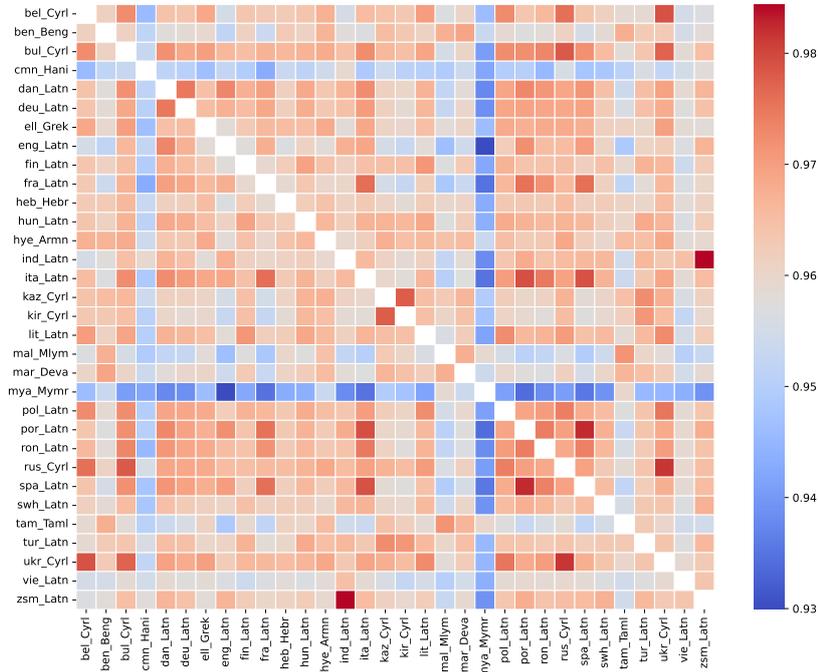

Figure 5: Heatmaps of cosine similarity results at layer 4 for Glot500 and Flores across 32 languages.

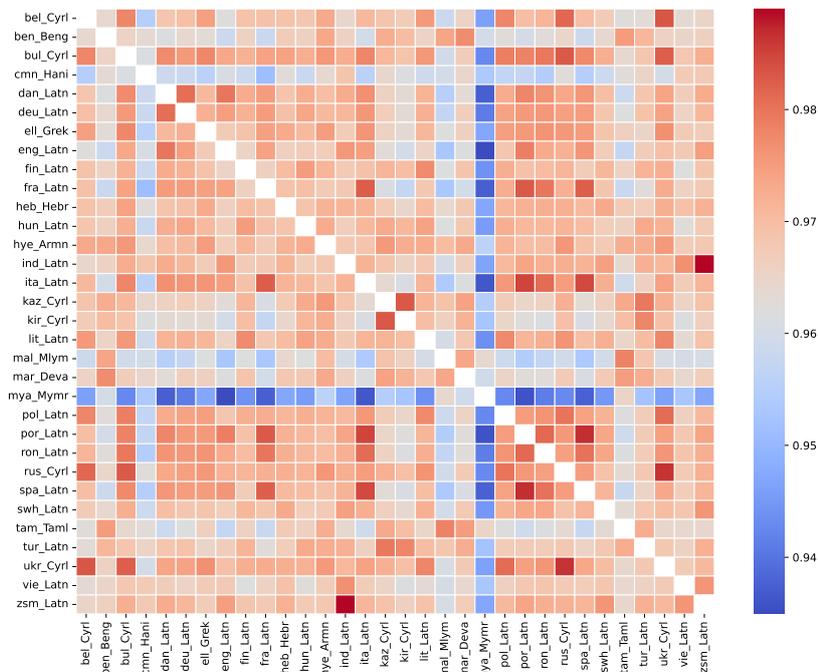

Figure 6: Heatmaps of cosine similarity results at layer 8 for Glot500 and Flores across 32 languages.

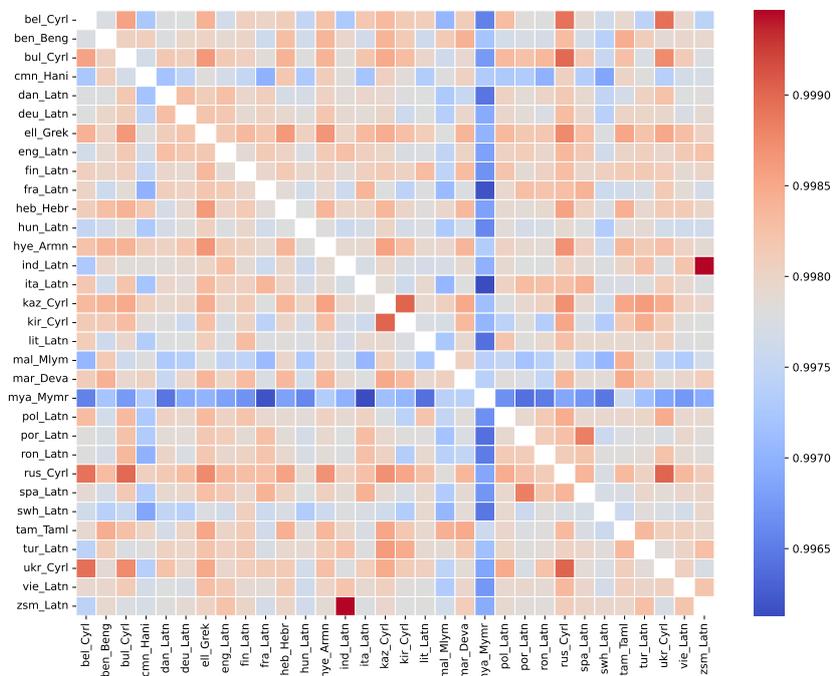

Figure 7: Heatmaps of cosine similarity results at layer 12 for Glot500 and Flores across 32 languages.

## **D Analysis on Unseen Languages of mPLMs**

The success of mPLM-Sim depends on the supporting languages of mPLMs. To get more insights about languages which are this not supported by a specific mPLM, we conduct a new Pearson correlation experiment based on 94 languages unseen by XLM-R. Among 94 languages, there are 24 (25.5%) languages that achieve higher correlation than the average level of seen languages. These 24 languages usually have close languages seen by XLM-R, e.g, the unseen language, Cantonese (yue\_Hani) is close to Mandarin (cmn\_Hani). It shows that mPLM-Sim can be directly applied to some unseen languages which have close seen languages.

For the unseen languages which mPLM-Sim performs poorly, we can connect it to seen languages using traditional linguistic features, e.g., language family, and then use or weight the similarity results of seen languages as the results of the unseen languages. Since it is shown that mPLM-Sim provides better results than traditional linguistic features in our paper, connecting unseen languages to seen languages would be beneficial for unseen languages.

## **E Detailed Results of Cross-Lingual Transfer**

We report the detailed results for all tasks and languages in Tab. 15-16 (NER), 17 (POS), 18 (MAS-SIVE), 19-21 (Taxi1500).

## Abstract

This paper serves as a foundational step towards the development of a linguistically motivated and technically relevant evaluation suite for Greek NLP. We initiate this endeavor by introducing four expert-verified evaluation tasks, specifically targeted at natural language inference, word sense disambiguation (through example comparison or sense selection) and metaphor detection. More than language-adapted replicas of existing tasks, we contribute two innovations which will resonate with the broader resource and evaluation community. Firstly, our inference dataset is the first of its kind, marking not just *one*, but rather *all* possible inference labels, accounting for possible shifts due to e.g. ambiguity or polysemy. Secondly, we demonstrate a cost-efficient method to obtain datasets for under-resourced languages. Using ChatGPT as a language-neutral parser, we transform the Dictionary of Standard Modern Greek into a structured format, from which we derive the other three tasks through simple projections. Alongside each task, we conduct experiments using currently available state of the art machinery. Our experimental baselines affirm the challenging nature of our tasks and highlight the need for expedited progress in order for the Greek NLP ecosystem to keep pace with contemporary mainstream research.

## 1 Introduction

It is a well known fact that the natural language processing world is running at multiple speeds. A select few languages claim the lion's share in the literature, boasting a plethora of models and a constant stream of results, while others are struggling to keep up with last year's state of the art. Meanwhile, multilingual models, despite being heralded as the end-all solution to the issue, often fall short of expectations (Wu and Dredze, 2020; Ogueji et al., 2021; Pfeiffer et al., 2021; España-Bonet and Barrón-Cedeño, 2022; Havaladar et al., 2023; Papadimitriou et al., 2023, *inter alia*). The assumption that one-size-fits-all multilingual models can effectively bridge the language gap is hard to either refute or validate, given the disproportionate distribution of training and evaluation resources among languages (Joshi et al., 2020; Yu et al., 2022; Kreutzer et al., 2022). Further muddying the waters is the dubious quality of the increasingly trending multi- and mono-lingual resources generated through minimally supervised machine translations from English (Artetxe et al., 2020; Wang and Herscovich, 2023). While such endeavors can certainly make for good first steps, they are neither sufficient nor without risks. The wide adoption of the practice threatens resource plurality, as more and more "new" datasets are in fact old in all but language. Furthermore, it condones the accumulation of academic authority to a select few, namely the

authors of the originals, promoting the unhindered perpetuation of their biases and oversights as universal across languages. Worse yet, it outsources linguistic expertise to machine labor, as we are now entrusting our automated processes with capturing the nuances of under-represented languages; exactly *those* languages that require opinionated and targeted expert attention the most.

And while a discussion on the structural causes behind the problem and the ways to incentivize change is long overdue, here we set our aims towards something more actionable. Noting the striking absence of evaluation benchmarks for modern Greek, and the language’s limited presence in multi-lingual resources, we set out to develop a linguistically motivated and technically relevant suite of evaluation tasks. This paper aims to kickstart this endeavor, while serving as an open invitation to interested parties. Concretely, we set the pace with four evaluation tasks:

1. a handcrafted dataset for inference, consisting of 1 762 sentence pairs, each pair adorned with a linguistic characterization in the form of tags *à la* SuperGlue and labeled with a subset (rather than an element) of {Neutral, Entailment, Contradiction}, aiming to account for all possible inference relations between premise and hypothesis
2. a structured translation of the Dictionary of Standard Modern Greek, from which we project into three tasks:
  - (i) a word sense disambiguation task *à la* Words-in-Context, consisting of 117 662 phrase pairs that correspond to two usage examples for a single word, where the system is tasked with telling whether the two occurrences have the same meaning or not
  - (ii) a more compact & linguistically informed version of the same task consisting of 14 416 unique phrases containing polysemous words, each word associated to a number of senses and their periphrastic definitions, where the system is tasked with telling which word sense is associated with each usage example
  - (iii) a metaphor detection task, associating each of the previous phrases to a boolean label indicating whether the word in focus is used metaphorically or not

To facilitate research with these tasks, we supply accessible entry points to the raw data in the form

of Python interfaces. For each task, we conduct experiments using the currently available state of the art machinery and establish baseline scores for comparisons.<sup>1</sup>

## 2 OYXOY

Inspired by Glue and SuperGlue (Wang et al., 2018, 2019), our goal is to develop a language-adapted suite that selects and extends a few key aspects of the original. Our project, which we lightly dub OYXOY (pronounced /<sup>h</sup>u.xu/), is not primarily focused on offering general diagnostics, but rather on highlighting the semantic, syntactic, and morphological attributes of the Greek language, and quantifying their impact on NLP systems. To that end, we present four high-level tasks that require varying degrees of lexical & sentential meaning comprehension.

### 2.1 Natural Language Inference

Our first task is a staple of computational semantics that has endured the test of time: natural language inference (NLI). In their most common form, NLI tasks present the system with an ordered pair of sentences (called a premise and a hypothesis), and request one of three inference relations that must hold between premise to hypothesis: Entailment, Contradiction and Neutral/Unknown. Despite its apparent simplicity and the heaps of progress in modern NLP, the conquest of NLI has proven challenging to this day. Neural systems show a tendency to abuse spurious data patterns over actually performing the (often complicated) reasoning required to solve the problem, resulting in limited generalization capacity across datasets. For our dataset, we follow Wang et al. (2018, 2019) in establishing a hierarchy of rudimentary but descriptive linguistic tags that encompass an array of phenomena that can influence the direction of inference. For a glimpse at the full hierarchy of tags used, refer to Table 2. These tags are intended to find use outside the model’s input/output pipeline, providing a guide for categorizing results and drawing finer-grained quantitative evaluations. Where our dataset diverges from established practices is in providing an explicit account of inference-level ambiguities not only through the tagging but also through the labeling scheme. Rather than annotating each example pair with any *one* inference label,

<sup>1</sup>Data, interfaces and the code necessary to replicate our experiments is available at <https://github.com/StergiosCha/OYXOY/>.

we instead specify *all* possible labels that may hold. To do so, we implicitly consider the product space of all possible readings of both premise and hypothesis, and construct the label set arising out of all pairwise interactions; Figure 1 shows two concrete examples under different settings, as rendered in the dataset.

To create the collection of samples that make up the dataset, we follow a three stage process. At the first stage, each author independently wrote a number of sentence pairs together with a suggested set of tags and labels.<sup>2</sup> Afterwards, each author was given a collection of sentence pairs from other authors with the tags and labels hidden, and was tasked with assigning the tags and labels they deemed most appropriate. This way, we end up with four unique tag and label sets for each pair. Finally, we perform an aggregation of the proposed annotations and jointly go through any and all examples that contain at least one tag or label that does not reach a majority (i.e. counts less than three votes). We spot We resolve disagreements by adding or removing annotations, thus ensuring internal consistency within the dataset. At the end of the process, we end up with 1 049 samples, of which 110 contain more than a single label. The dataset as a whole contains 454 Neutral, 414 Entailment and 292 Contradiction assignments.

In parallel to the above, we re-annotate the Greek version of FraCaS (Amanaki et al., 2022) according to our format specifications, skipping directly to the third stage of the pipeline described earlier. The derived dataset contains an additional 713 examples, revealing 30 of them as multi-labeled, with a label distribution of 264 Neutral, 345 Entailment and 134 Contradiction. We serve the two datasets independently, but as a single resource.

## 2.2 Repurposing the Lexicon

Transitioning to our next objective, a resource targeting lexical semantics, we immediately run into a roadblock. The construction of a sufficiently large dataset centered on the *word* requires a prohibitive investment of time and effort. Facing the very same challenge, contemporary contributions have established the practice of turning to either machine translation or crowd-sourced labor, with hired workers being overlooked by applied prac-

tioners (at best, if at all). Albeit pragmatic, this approach compromises the quality of the generated resources, dismissing domain expertise in the pursuit of improved cost efficiency (a prerequisite, in turn, for quantity). As an alternative, we redirect our focus towards a frequently-overlooked traditional resource: the *lexicon*. Reputable lexica offer a rare mixture of linguistic rigor and extensive coverage virtually for free, making them a prime candidate for adaptation and repurposing into modern applications. In what follows, we showcase how this insight can be put into practice, enacting a sensible and effective way forward for under-resourced languages.

We begin by procuring a copy of the Dictionary of Standard Modern Greek (Triantafyllides, 1998).<sup>3</sup> The dictionary is provided in the form of a minimally structured SQL database, associating each lemma with its lexical entry, a raw text field containing a periphrastic definition and a few usage examples for each of its senses. Unfortunately, senses and examples are not structurally differentiated by the database, but are rather presented in the same field, further intertwined with supplementary details such as usage conditions, morphological information, etc. Instead, the database relies on a combination of formatting strategies, including enumeration and styling, to differentiate between definitions and examples. However, these strategies are not consistently applied across the lexicon. To make matters worse, definitions and examples are often woven together (that is, they materialize as non-contiguous strings), and can at times follow ad-hoc hierarchical arrangements. Consequently, even though the textual content effectively conveys information visually, parsing this content with traditional methods proves nigh impossible. As a workaround, and considering that parsing unstructured data is a staple task for large language models, we employ ChatGPT (Brown et al., 2020) for the problem at hand.

Our pipeline is as follows. We first utilize the existing database fields to filter the lexical entries that seem to contain at least one example. This results in a collection of 28 831 unique lemmata, each mapped to its lexical entry. We randomly sample 100 of them, which we then manually convert into a succinct and minimally structured JSON format, specifying (i) the *lemma* and (ii) a list of

<sup>2</sup>The generation/annotation guidelines handed out are available online with the rest of the data.

<sup>3</sup>Hosted online at [www.greek-language.gr/greekLang/modern\\_greek/tools/lexica/triantafyllides](http://www.greek-language.gr/greekLang/modern_greek/tools/lexica/triantafyllides).

```

{"samples": [
  {"premise": "Ο Κυριάκος φίλησε την Αντιγόνη.",
    % Kyriakos kissed Antigone.
    "hypothesis": "Ο Κυριάκος και η Αντιγόνη φιλήθηκαν.",
    % Kyriakos and Antigone kissed [each other].
    "labels": ["Entailment", "Unknown"],
    "tags": ["Lexical Entailment:Symmetry/Collectivity"]
  },
  {"premise": "Ο Γιώργος είπε στη Μαρία ότι ξέρει να παίζει κιθάρα.",
    % Giorgos told Maria that [he/she] knows how to play the guitar.
    "hypothesis": "Η Μαρία ξέρει να παίζει κιθάρα.",
    % Maria knows how to play the guitar.
    "labels": ["Entailment", "Unknown"],
    "tags": ["Lexical Entailment:Factivity:Factive",
      "Predicate-Argument Structure:Anaphora/Coreference"]
  }
]
}

```

Figure 1: NLI examples 761 and 879, showcasing multiple inferences. In the first example, *φιλώ* (*to kiss*) can be a unidirectional or a reciprocal action (i.e., *to give a kiss to* vs. *to exchange kisses with*). In the second example, pro-drop allows for two possible readings, where either Giorgos or Maria can be the subject of the embedded clause. Translations (in gray font as TeX-style comments) are ours, included for presentation purposes.

senses, each sense structured as a *definition* and a list of *examples*. We put extra effort into disentangling hierarchical senses, repeating the elided parts of non-contiguous definitions and examples and removing enumeration identifiers. The yield of this process then serves as the training set for a quick one-shot tuning of ChatGPT<sup>4</sup>, the input being the raw text (stripped of HTML tags for token economy) and the target being the structured JSON representation. We pass all remaining entries through the trained model. From the model output, we filter out senses that contain no examples and entries that contain less than two senses, and end up with 16 079 examples spread over 7 677 senses and 2 512 entries. Finally, we manually check each and every example and entry, fixing the occasional parsing error, homogenizing the presentation and fixing the JSON formatting as needed. The result is 14 416 examples spread over 6 896 senses and 2 326 entries, from which we derive the three evaluation tasks described in the subsections to follow. An example entry, as produced and rendered by the system, is presented in Figure 2.

**The Role of ChatGPT** Our decision to incorporate a large language model into our data preparation process does not entail any of the epistemological risks commonly associated with generative models and/or data augmentation. In our use case, the model does not need a deep understanding of the Greek language, the expertise of a trained linguist, or the creativity required of a human annotator, as it’s neither generating new examples nor annotating existing ones per se. Rather,

<sup>4</sup>We use model gpt-3.5-turbo via the fine-tuning API.

it suffices for it to recognize the inconsistent yet intuitive hierarchical enumeration patterns present in the data, and to convert them into recurring structures with consistent formatting. Large language models’ attested proficiency in this scenario align them perfectly with our needs, allowing us to utilize the authoritative resource of the lexicon while minimizing tedious human labor and cost expenditure. Indeed, our inspection of the model’s output shows a generally high-quality translation, strictly faithful to the original input, with only a few minor occasional inconsistencies<sup>5</sup>.

### 2.2.1 Words-in-Context

The first task is essentially a replica of the Words-in-Context (WiC) part of SuperGlue. It is formulated as a binary classification problem, where the system is presented with two sentences containing the same (potentially polysemous) word, and is tasked with telling whether the two occurrences correspond to the same meaning or not. In order to successfully resolve the task, the system needs a dynamic embedding strategy, capable of disambiguating words depending on their surrounding context. As such, it serves as a primitive test suite for the lexical semantic capacities of bidirectional transformers.

Obtaining the task from our dataset is trivial; it suffices to consider the sum of the product space of examples for each lexical entry (with the diagonals removed), zipped with a boolean sign indicat-

<sup>5</sup>The model is sometimes overeager, extending the output specification with additional fields, in what seems like an attempt to capture all the information provided in the raw input.

```

{"lemma": "αστικοποίηση",
"senses": [
  {"definition": "η ένταξη στην αστική τάξη ενός ατόμου που ανήκει συνήθως στην αγροτική ή στην εργατική",
    % One's transition from the rural or working class into the urban class.
    "examples": ["Η αύξηση του εισοδήματος συντελεί στην αστικοποίηση."]
    % The increase in income contributes to urbanization.
  },
  {"definition": "αποδοχή των αστικών ιδεωδών και συνθηκών",
    % The acceptance of middle class ideals and habits.
    "examples": ["Η αστικοποίηση του πρώην αναρχικού"]
    % The urbanization of the ex-anarchist.
  },
  {"definition": "διαρκής συγκέντρωση πληθυσμού σε αστικά κέντρα",
    % The accumulation of population into urban centers.
    "examples": ["Η αστικοποίηση είναι χαρακτηριστικό φαινόμενο της μεταπολεμικής περιόδου."]
    % Urbanization is a characteristic trait of the post-war era.
  }
]
}

```

Figure 2: The processed dictionary entry for *αστικοποίηση* (*urbanization*), containing a definition and one example for each of its three senses. Translations (in gray font as TeX-style comments) are ours, included for presentation purposes.

ing whether the two examples stem from the same sense. Doing so yields 117 662 data points (i.e., one order of magnitude larger than the corresponding fragment of SuperGlue), with a label ratio of 1 positive to about 6 negative.

### 2.2.2 Sense Selection

The above formulation is straightforward, and directly compatible with the standard sequence classification pipeline commonly employed by NLP architectures. As such, it makes for an accessible entry point for evaluation. However, it represents a dramatic simplification of the disambiguation problem, requiring two usages in juxtaposition and providing little information on *what* the sense of each usage is. Our source dataset allows us to do better. Given that we have periphrastic definitions for all<sup>6</sup> the possible meanings of each word, we can reframe the task as sense selection. Given a word, the set of its possible meanings and a usage context, we can prompt a model to predict the meaning most likely employed in the given context. Using periphrastic definitions as a proxy for meaning induces a better informed and more realistic evaluation task, requiring and benefiting from high-quality contextual representations both at the lexical and the sentential level (since the word under scrutiny will now need to be contrasted to the full set of “meanings”). It is also more faithful to the source dataset, since the count of data points is now in alignment with the number of distinct usage examples (as duplication is no longer necessary). Each of the 14 416 points is associated with 3.8 candidate definitions, on average.

<sup>6</sup>Excluding the ones removed by the filtering process.

### 2.2.3 Metaphor Detection

Our projection of the raw textual entries into structured JSON entries has done away with most fields irrelevant to word disambiguation. However, we have consciously kept markers of metaphorical usage, and homogenized their presentation.<sup>7</sup> This enables us to filter senses (and by extension, usage examples) that are used metaphorically, providing the means for another kind of task altogether: metaphor detection. Making the simplifying assumption that metaphor is only present in those examples where the word defined is used in a metaphorical sense, we end up with 1 017 examples of metaphor (7% of the total of all examples) concentrated around 571 senses and associated with 499 entries, yielding a heavily imbalanced dataset for metaphor detection.

## 3 Experimental Baselines

To quantitatively evaluate the difficulty of the tasks described in the previous section, and in order to facilitate future research in this direction, we set up some experimental baselines using the current state-of-the-art machinery available for modern Greek. All our experiments rest on the tried and tested fine-tuning process for BERT-like models (Kenton and Toutanova, 2019), using Greek BERT as our universal core model (Koutsikakis et al., 2020).

### 3.1 Natural Language Inference

Despite our efforts to create a comprehensive evaluation suite for natural language inference, the

<sup>7</sup>They are indicated with (μτφ.) in the periphrastic definition.

practical use of our dataset presents several challenges. First and foremost, its comparatively small size renders it unsuitable for fine-tuning purposes. This becomes especially problematic considering the lack of NLI datasets tailored specifically for Greek. Compounding these challenges is the fact that our dataset utilizes a multi-label setup, which complicates direct cross-dataset evaluations. To address these challenges, we have chosen to leverage XNLI (Conneau et al., 2018), a cross-lingual dataset for language inference of substantial size; while XNLI was not initially designed for training purposes, it presents a viable solution considering the constraints we face. We employ an iterative approaching when splitting our dataset, aiming for a 30/70 division and taking care to keep the ratio consistent for each of the linguistic tags used. We then fine-tune BERT, training on the joined test set of XNLI and the smaller of the two splits, evaluating on the dev set of XNLI, and testing on the larger split. This setup accounts for domain adaptation, while allowing us to frame the problem as multi-label classification (where the XNLI problems are “coincidentally” single-label).

Concretely, we independently contextualize the premise and hypothesis sentences, concatenate their [CLS] tokens and project them into three independent logits via an intermediate feed-forward layer of dimensionality 64, gated by the GELU activation function (Hendrycks and Gimpel, 2016). We train using AdamW (Loshchilov and Hutter, 2018) with a batch size of 32 and a learning rate of  $10^{-5}$ . Despite heavy regularization (weight decay of 0.1, dropout of 0.33 and early stopping), the model is quick to overfit the training set, with development set performance lagging significantly behind (despite the matching domain). Since accuracy is no longer a suitable performance metric, owing to the multi-label setup we have adopted, we report per-class precision, recall and F1 scores over the test set instead, averaged over three repetitions. The results, presented in Table 1, are largely underwhelming, indicative of the difficulty of the dataset and confirming the inadequacy of (the Greek fragment of) XNLI as a training and evaluation resource – a fact also noted by Evdaimon et al. (2023) and consistent with the comparatively low scores of Amanaki et al. (2022). To gain a better understanding of the trained model’s behavior across different linguistic phenomena, we group samples according to their linguistic tags,

Label	Prec.	Rec.	F1
Unkn.	$0.32 \pm 4.9\%$	$0.41 \pm 1.0\%$	$0.35 \pm 3.7\%$
Ent.	$0.52 \pm 2.8\%$	$0.46 \pm 2.7\%$	$0.48 \pm 1.1\%$
Contr.	$0.20 \pm 0.7\%$	$0.26 \pm 7.6\%$	$0.23 \pm 0.6\%$

Table 1: Per-label test metrics for NLI.

and measure the average Jaccard similarity coefficient between predicted and true labels (i.e., the length of the intersection over the length of the union between the two sets). As Table 2 suggests, performance is consistently low across the board. The model seems to especially struggle with recognizing the effect of embedded clauses (regardless of whether they are restrictive or not), focus associating operators, non-intersective adjectives, hypo- and hypernymy, antonymy and negation.

### 3.2 Sense Disambiguation

For both variants of the sense disambiguation task, we split the dataset’s examples into three subsets: a 60% training set, a 20% development set, and a 20% test set. Additionally, we designate 10% of the total lexical entries as test-only, and move the associated examples from the training set to the test set. This will allow us to evaluate the model’s performance separately on in- and out-of-vocabulary examples (IV and OOV, respectively), i.e. involving words that have or have not been encountered during training.

To find the relevant word within each example, we lemmatize examples using SpaCy (Honnibal et al., 2020, model `en_core_news_sm`) and identify the element within each sequence that corresponds to the source entry’s lemma, falling back to the element with the minimal edit distance if no absolute match can be found. Following tokenization, this permits us to create a boolean mask for each example, selecting only these tokens that are associated with the word/lemma of interest.

**Words-in-Context** For the WiC variant, we gather minibatches consisting of all examples that belong to the same lexical entry. We contextualize examples independently, and extract the representations of the words of interest by mean pooling the last layer representations of the tokens selected by each example’s mask. We then compute pairwise similarity scores between pairs in the cartesian product of examples by applying the dot-product operator on the extracted representations, scaling the results by the inverse of the square root of the

Tag	Jaccard Index (ave.)
Logic	
Disjunction	0.32±3.2%
Conjunction	0.41±1.6%
Negation	
Single	0.30±1.6%

Core Arguments	0.55±5.0%
Common Sense/Knowledge	0.36±0.3%

Table 2: Per-tag test metrics for NLI. The tag hierarchy follows along Wang et al. (2019), with few divergences. For Logic, we replace Double Negation with Multiple Negations and differentiate it from Negative Concord. We add a tag for Non-Standard Quantification, and drop the Numeral/Interval tag. For Lexical Entailment, we substitute Morphological Negation with the (more general) Morphological Modification. We subcategorize Lexical Semantics, specifying left-to-right or premise-to-hypothesis (directional) lexical relations. Finally, we merge Common Sense and World Knowledge into a single meta-tag.

model’s dimensionality. These similarity scores serve as logits for binary cross entropy training, predicting whether the two occurrences of the word share the same sense between the two examples.

**Sense Selection** For the sense selection variant, we create batches by (i) sampling over training examples and (ii) constructing the set union of all related (candidate) definitions, together with a binary boolean relation specifying whether an example and a definition belong to the same entry. We then independently contextualize all examples and definitions, extracting contextual word representations for each example as before, and taking each definition’s [CLS] token representation as a proxy for the sense’s meaning. We compare each word (in the context of a single example) to each meaning using the same scaled dot-product mechanism as before, masking out invalid pairs according to the example-to-definition relation mentioned earlier. We finally obtain softmax scores for each example yielding a probability distribution over candidate meanings, which serves as the model outputs for standard negative log-likelihood training.

We train on either task using AdamW with a learning rate of  $10^{-5}$ , a weight decay of  $10^{-2}$  and a 25% dropout applied at the dot-product indices, and perform model selection on the basis of development set accuracy; once more, development and training set performances quickly diverge after a few epochs. At this point, we note that both tasks use the same notion of sense agreement and both our models approximate it by means of the same vector operation; their difference lies in the fact that one compares a word occurrence to a word occurrence (or: an example to an example), whereas the other compares a word occurrence to a set of “meanings” (or: an example to all candidate definitions) (Hauer and Kondrak, 2022). Intuitively, it would make sense that a model that has acquired the sense selection task should be able to perform adequately on the WiC task without further training; indeed, if two word occurrences select the same meaning (i.e., maximize their similarity to the same vector), they must also be similar to one another. To test this hypothesis, we simply apply the model obtained by fine-tuning on the sense selection task, except now recasting the test set in the form of the WiC task.

We report repetition-averaged aggregates in Table 3. Performance is not astonishing, but remains

Subset	Sense Selection		Words-in-Context		
	# examples	accuracy	# pairs	accuracy <sup>1</sup>	accuracy <sup>2</sup>
IV	2 494	0.63±0.20%	8 274	0.50±0.41%	0.51±1.7%
OOV	1 289	0.64±0.41%	9 954	0.48±1.77%	0.54±0.2%
Total	3 784	0.63±0.29%	18 678	0.49±1.09%	0.53±0.86%

<sup>1</sup> In-domain evaluation of the words-in-context model.

<sup>2</sup> Transfer evaluation of the sense selection model.

Table 3: Test set sizes and performance metrics for the two sense disambiguation tasks.

well above the random baselines for both tasks (25% for sense selection and 16.7% for WiC), indicating that the core model has some capacity for learning and generalization. Sense selection may initially appear as the more challenging of the two tasks, seeing as it involves selecting one target out of multiple options. Nonetheless, the model achieves a consistently higher absolute accuracy there; evidently, comparing one example to a fixed set of senses is easier than comparing two ad-hoc usage examples. To our surprise, we find that the task transfer setup works straight out of the box, to the point where the transfer model in fact outperforms the in-domain model without as much as recalibrating the sigmoid classification threshold. One might hypothesize that this is due to the model memoizing a fixed set of senses and their representations. However, this is not entirely the case: interestingly, accuracy now improves instead of declining in the OOV fragment of the test set. We interpret this as evidencing that the sense selection formulation produces a higher quality error signal, which induces a better informed disambiguation prior during fine-tuning, allowing the (more rudimentary) WiC task to be captured without additional effort.

### 3.3 Metaphor Detection

The last task, metaphor detection, is also the simplest one, being essentially a case of sequence classification. We start by filtering all entries that have at least one metaphoric sense, so as to alleviate the severe class imbalance of the full dataset. From the 499 filtered entries, we reserve 5% for use as an OOV test set. We extract all examples from all entries, and assign to each example a boolean label, indicating whether the sense the example is associated with is metaphoric or not. This produces 3 015 examples (2 856 IV and 159 OOV), with a class distribution of about 1 positive to 2 negative. We proceed with training using once more a 60/20/20

Subset	# Examples	Accuracy
IV	572	0.84±6.29%
OOV	159	0.71±2.94%
Total	731	0.82±4.29%

Table 4: Test set performance on the metaphor detection task.

split on the IV set.

We attach a feedforward classifier to the contextualized [CLS] token and train using binary cross entropy, optimizing with the same hyper-parameter setup as before. Our results, presented in Table 4, showcase a good ability to recognize metaphoric senses in the words trained on, and a decent generalization potential to unseen words. Unlike prior experiments, we detect a high variability in the results between repetitions; one model instance has a moderate performance that does not differ between the two subsets of the test set, whereas another achieves a near-perfect score on the IV subset while being barely above the random baseline in the OOV subset.

## 4 Related Work

NLI is widely considered one of the core problems towards natural language understanding, with a plethora of evaluation suites (Bowman et al., 2015; Conneau et al., 2018; Wang et al., 2018, 2019; Nie et al., 2020) which continue to pose significant challenge for current state-of-the-art models (Glockner et al., 2018; Talman and Chatzikiriakidis, 2019; Belinkov et al., 2019; McCoy et al., 2019; Richardson et al., 2020, *inter alia*). Like GLUE and SuperGlue, our inference examples come packed with linguistic tags to facilitate diagnostic analysis. Unlike other datasets, our examples may specify more than one inference label, accounting for all possible sentence readings. At the time of writing, other than a fragment of XNLI (produced by automatic

translation), the only NLI dataset for Greek we are aware of is by Amanaki et al. (2022) (which we adapt here to our format).

Sense repositories, i.e., mappings between words and sets of meanings are often framed as dictionary-like structures (Fellbaum, 1998; Navigli and Ponzetto, 2012). Our dataset stands out in providing both a definition and a collection of examples for each sense, allowing the incorporation of either or both into various possible tasks and model pipelines; we show three concrete examples of how this can be accomplished. The tasks obtained, namely words-in-context, sense selection and metaphor detection, are of prime importance for the experimental validation of the lexical semantic capacities of language processing systems (Ma et al., 2021; Zhang and Liu, 2023; Choi et al., 2021; Sengupta et al., 2022; Luo et al., 2023). To the best of our knowledge, this is the first dataset of its kind, and among the first lexical resources for Greek in general.

## 5 Conclusions and Future Work

Our vision is that of an open-source, community-owned, dynamically adapted, gold-standard suite that enables the linguistically conscious evaluation of the capacities of Greek language models. We have presented four novel tasks and corresponding baselines towards that goal. While our results aren't directly comparable to existing benchmarks, they do highlight the significant challenge our tasks present. This underscores the urgency for accelerated progress within the Greek NLP ecosystem to stay aligned with contemporary mainstream research.

Pending community feedback, we hope to enrich the existing datasets by scaling them up, correcting possible artifacts and extending the language domain with regional and dialectal variations. Possible tasks that we would like the project to eventually incorporate include gender bias detection, paraphrase identification, and natural language inference with explanations, among others. We are curious to continue experimenting with ways to utilize traditional resources, and exploring their potential as dataset generators for under-resourced languages in conjunction with large language models.

## Limitations

The NLI dataset's limited size renders it inadequate as a comprehensive resource for training and evaluating NLI systems from scratch. Furthermore, the examples were crafted by the authors of this paper, who belong to a distinct demographic, unavoidably introducing our own cultural, sociopolitical, and linguistic biases. The focus is exclusively on standard modern Greek, omitting examples of regional or dialectal language use. Finally, while the tag set employed may provide valuable information, it offers only a coarse and incomplete summary of the full range of linguistic phenomena observed in the wild.

The lexical dataset, conversely, is not indicative of our opinions as authors; the source dictionary may contain language use that is outmoded or socially exclusive. The dataset structure is sufficient for us to extract the three tasks we have presented, but might prove lacking for more complex tasks (like tasks requiring hierarchical or clustered sense arrangements, for instance). Despite efforts to ensure semantic accuracy in every entry, sense, and example, occasional mistakes may have gone unnoticed. Users should approach the resource critically, keeping this in mind.

Regarding our baselines, we have experimented with only a single model. While we acknowledge this might entangle the effects of dataset difficulty and model robustness, we justify ourselves in refraining from experimenting with more models, since this is neither the prime concern of this paper, nor a practice that we necessarily agree with.

## Abstract

Inductive reasoning is fundamental to both human and artificial intelligence. The inductive reasoning abilities of current Large Language Models (LLMs) are evaluated in this research. We argue that only considering induction of rules is too narrow and unrealistic, since inductive reasoning is usually mixed with other abilities, like rules application, results/rules validation, and updated information integration. We probed the LLMs with a set of designed symbolic tasks and found that even state-of-the-art (SotA) LLMs fail significantly, showing the inability of LLMs to perform these intuitively simple tasks. Furthermore, we found that perfect accuracy in a small-size problem does not guarantee the same accuracy in a larger-size version of the same problem, provoking the question of how we can assess the LLMs' actual problem-solving capabilities. We also argue that Chain-of-Thought prompts help the LLMs by decomposing the problem-solving process, but the LLMs still learn limitedly. Furthermore, we reveal that few-shot examples assist LLM generalization in out-of-domain (OOD) cases, albeit limited. The LLM starts to fail when the problem deviates from the provided few-shot examples.

## 1 Introduction

Recently, the development of LLMs has made great progress in various areas of artificial intelligence (AI), especially in Natural Language Processing (NLP). The performance of LLMs like GPT-3.5 (Brown et al., 2020) and GPT-4 (OpenAI, 2023) can even outperform humans on some professional tests, proving their ability to understand and solve complex natural language questions. One of the intriguing abilities of LLMs is reasoning, which is also one of the core abilities of human intelligence.

Reasoning, following this definition (Hurley, 2000), consists of deductive reasoning (Johnson-Laird, 2010), inductive reasoning (Hawthorne, 2021), and abductive reasoning (Douven, 2021).

LLMs show surprisingly high performance on tasks requiring high-level reasoning ability, like programming (Xu et al., 2022) and mathematical problem solving (Imani et al., 2023). However, as the LLMs memorize the statistical word co-occurrences from the pre-training corpora containing such examples, it is hard to know the real reasoning ability of LLMs as they always generate specious answers. Therefore, evaluation at a fundamental level, e.g. symbolic level, is needed to accurately understand the reasoning abilities of LLMs.

This research focuses on inductive reasoning, which is the ability to derive common principles from finite observations. Recent inductive reasoning research in NLP (Yang et al., 2022; Li et al., 2023) focused mainly on rules induction from observations, but inductive reasoning in the real world is more complex than just rules induction.

As inductive reasoning is based on finite observations, which may contain only partial information, we cannot always expect the induced rules or results to be fully correct. Therefore, in the real world, under the surface of rules induction, the ability to validate induced rules/results and merge new rules with previous rules is equally important, and such ability to adapt to changing circumstances is important for building AI models suitable for real-world usage. To evaluate these abilities, we designed three symbolic tasks: 1) Grouping Polygons, 2) ordering named colors (Color Ordering), and 3) shifting characters in English text (Character Mapping).

We then define 3x5 experiments called Rules Application, Rules Induction, Results Validation, Rules Validation, and Rules Incorporation to evaluate the ability to apply rules, induce rules, validate induced results/rules, and merge new rules with previous rules, as depicted in Figure 1. We observe the LLMs failing on these tasks. Subsequent experiments explored the role of few-shot examples for generalization, the scalability of LLM perfor-

mance with problem size, and the impact of the Chain-of-Thought prompts, namely:

1. For evaluated LLMs, the performance varies a lot between different experiments. This unstable LLM performance on symbolic inductive reasoning tasks is in contrast to their stable/robust performance on NLP tasks. Besides the instability, the task accuracy is low even for SotA LLMs, illustrating the weakness of LLMs in symbolic reasoning tasks.
2. In addition to low accuracy in Rules Induction and Rules Application, LLMs also perform poorly in Results/Rule Validation and Rules Incorporation. This suggests that besides focusing on the accuracy of LLMs, their ability to validate and check the generated results should be paid attention to.
3. LLMs can learn from few-shot examples and generalize beyond the given few-shot examples, but they still fail to learn scalable solutions from the examples, even when decomposing the problem-solving procedures through Chain-of-Thought (CoT) prompting.
4. While the LLMs may solve small-sized problems perfectly, the accuracy drops drastically when increasing the problem size. This provokes the question, "How can we prove that the LLM really holds the solution to solve specific types of problems?"

## 2 Related Research

### 2.1 Reasoning in LLMs

Reasoning is a core ability of human intelligence and an established research area in machine learning. Previously, even simple natural language reasoning tasks were very challenging for neural models (Santoro et al., 2018; Saxton et al., 2019).

However, the appearance of pre-trained language models like BERT (Devlin et al., 2019), with the commonsense knowledge encoded in the model through pre-training, largely improved the performance on NLP tasks, including reasoning tasks (Helwe et al., 2021). In recent years, with the scaling of model size, data size, and development of new architectures, different abilities have emerged from LLMs (Wei et al., 2022). Reasoning is one of those emerging abilities. Combining tricks like Chain-of-Thought (Wei et al., 2023) and In-Context

Learning (Dong et al., 2023), the performance on natural language reasoning tasks is largely improved, even for tasks like mathematical reasoning (Lu et al., 2023), which was hard for neural models.

Evaluating LLMs on natural language reasoning tasks makes it difficult to know their reasoning abilities as they learn word co-occurrence relations from the pre-training corpus to aid in NLP reasoning tasks. To avoid the benefit of the encoded word/sentence/knowledge from pre-training and evaluate the reasoning ability at a more basic level, we create symbolic tasks to isolate semantic meaning to better evaluate LLMs' reasoning abilities.

### 2.2 LLM Probing

Probing is an important method to understand black-box neural networks with millions of parameters (Alain and Bengio, 2017). It is impossible to analyze them from a purely mathematical standpoint. Using probing tasks and analyzing the results gives us a peek hole to obtain insights into the inner mechanism of LLMs. Probing has proven to be an effective tool for analyzing the behavior of neural networks and their mechanisms since RNN-based networks (Nelson et al., 2020), Transformer-based Pre-trained Models (Johnson et al., 2020; Vulić et al., 2020), and then current, much larger LLMs (Kondo et al., 2023; Wei et al., 2023).

This study centers on symbolic task-based probing of LLMs. Recently, Anil et al. (2022) illustrated LLMs' limitations in tackling long-length problems in parity checking and variable assignment tasks. Additionally, Dziri et al. (2023) examined LLM's capabilities using computational graph-based symbolic tasks like logical grids and multiplication computation. Their findings show that LLMs solve tasks by breaking them into linearized subgraphs and matching each subgraph in the pre-trained corpus. The lack of genuine systematic problem-solving skills is evident when accuracy decreases as the graph depth increases.

Differing from previous research in symbolic probing, we do not aim at evaluating a single or specific ability, rather we set up different experiment configurations to evaluate multiple abilities centered around inductive reasoning.

## 3 Problem Formulation

### 3.1 Symbolic Tasks

We argue inductive reasoning requires various abilities. To evaluate those abilities, we designed three

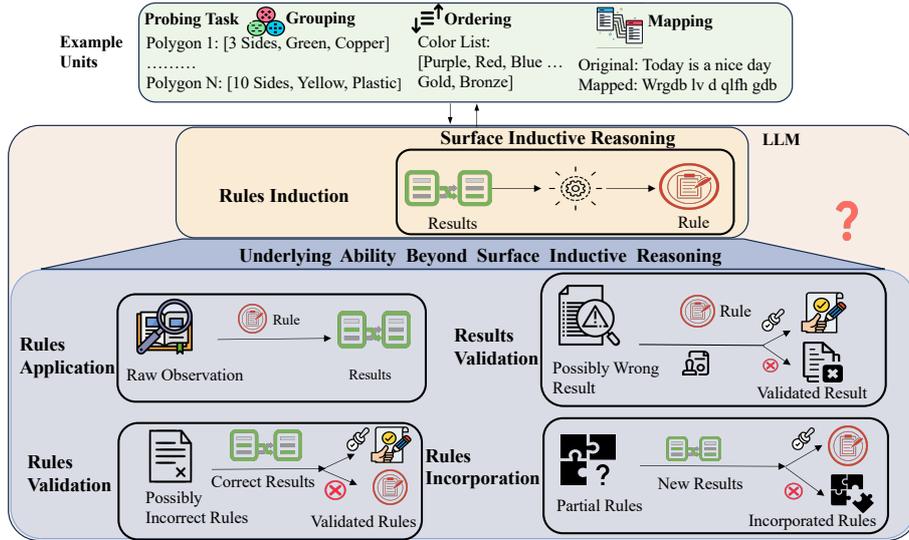

Figure 1: Evaluation Framework

symbolic tasks, explained in the following section.

**Polygons Grouping** In this task, we describe 30 polygons with different numbers of sides, colors, and material attributes. We also generate 15 grouping rules and the corresponding grouping results from following those rules.

**Color Ordering** In this task, we automatically generate a color priority dictionary with 20 colors in which a high-priority color should be given a high preference. We also generate corresponding sorted or unsorted color lists with 20 colors based on the color priority. Since we prompt both unsorted color list and color priority into the LLM, to prevent the LLM from just replicating the color priority list from the prompt to achieve a perfect sorted result, we remove five colors and duplicate five color units in the unsorted color lists.

**Character Mapping** In this task, we form character mapping rules by mapping each English character to its three-index right-shifted counterpart, with a wrap-around between Z and A. We sample sentences from the App-Review (Grano et al., 2017) dataset with character lengths from 20 to 100 and mapped results following mapping rules.

### 3.2 Prompt Formulation

The prompt contains information about the target task to posit the LLM adapt to the task. Additionally, we may add few-shot question/prediction pairs for different tasks, named few-shot examples  $F = \{f_1, f_2 \dots f_5\}$  to help the LLM respond with

accurate answers. We use five examples for all few-shot experiments. Unless mentioned specifically, the prompt contents introduced below is the default prompt to the LLM in all tasks.

**Task Illustration ( $T$ )** The text prompt  $T$  sent to the LLM contains other necessary information consisting of four parts  $T = \{T_d, T_i, T_f, T_r\}$ .  $T_d$  is the Task Description with general information about the task.  $T_i$  is the Response Instruction, which states the LLM responses' expected content.  $T_f$  states the expected Response Format, and  $T_r$  is an optional Rules Text with the rules used in the tasks.

**Units ( $S$ )** Units  $S$  are the available symbolic units in a given task. The LLM  $L$  needs to know all symbolic units  $S = \{s_1, s_2, \dots s_n\}$  prior to solving the corresponding symbolic task. For example, each polygon in the Grouping task is a unit.

**Problem ( $X$ )** After the Task Illustration and Units, we attach the problem text  $X$  to the prompt's end, and the LLM's prediction is denoted as  $Y = \{y_1, y_2 \dots y_n\}$ . The problem text, task illustration, and units differ based on task settings.

### 3.3 Scalable Solution ( $H$ )

As LLM solves the problem internally, we call such a hidden problem-solving procedure a solution, which is not a part of the prompt. In our task setting, we expect the LLM to have the Scalable Solution  $H$  that can be used to solve the prompted problem in any unit size. The Scalable Solution differs from Rules  $T_r$ . For example, in the Mapping

<b>Role Positioning</b>	You are a helpful assistant and you are supposed to follow the instructions that I give to you and perform the task as far as you can. Here we want to group different polygons into different groups based on their characteristics.
<b>Problem Description</b>	<p>Problem Description</p> <p>-----</p> <p>You will be given the possible attributes of different polygons with different Sides Numbers, Colors, and Materials. You will also be given the grouping rules that describe what types of polygons should be grouped together. You are supposed to group those polygons into different groups based on the grouping rules.</p> <p>Attributes</p> <p>Sides Numbers: {SidesNumber}</p> <p>Colors: {Colors}</p> <p>Materials: {Materials}</p>
<b>Response Instruction</b>	<p>Response Instruction</p> <p>-----</p> <p>Your final answer to this problem should contain the following information:</p> <p>1. The polygons that belong to each group.</p>
<b>Response Format</b>	<p>Response Format</p> <p>-----</p> <p>Following the Response Instruction, the format should be:</p> <p>Grouping Result:</p> <p>Group 0: Polygon x1, Polygon x2, ...</p> <p>Group 1: Polygon y1, Polygon y2, ...</p> <p>...</p> <p>The above format is just an example, you should replace x1, x2, y1, y2 with actual polygons based on your analysis. The order of polygons in each group does not matter.</p>
<b>Few-Shots Examples (Optional)</b>	<p>Below are the grouping rules that describe what types of polygons should be grouped together:</p> <p>{First Example Rules}</p> <p>Now try your best to use those grouping rules for the group following polygons, your response should follow the Response Format.</p> <p>{First Example Polygons}</p> <p>Grouping Results:</p> <p>Group 0: Polygon 1, Polygon 2</p> <p>.....</p>
<b>Prompted Problem</b>	<p>Below are the grouping rules that describe what types of polygons should be grouped together:</p> <p>{Rules}</p> <p>Now try your best to use those grouping rules for the group following polygons, your response should follow the Response Format.</p> <p>{Polygons}</p>

Figure 2: Prompt Template for Rules Application Task of Polygon Grouping

task, the Scalable Solution is *mapping each character using its corresponding rules*, where mapping rules  $T_r$  serve as an input of the scalable solution.

### 3.4 Task Setting

We set up tasks to probe the LLM’s inductive reasoning abilities in applying, inducing, validating, and rectifying results/rules, identifying new rules, and merging them with previous rules. Examples are shown in Table 1. Those tasks are designed on the principle that if the LLM holds the scalable solution  $H$ , these tasks are intuitively simple. The same solution can apply to every example, yielding perfect accuracy, as the scalable solution and the tasks remain constant regardless of unit size changes.

**Rules Application** In this task, we evaluate the ability to apply rules, and the problem text of this task is  $X_f$ . The LLM is asked to apply the given rules  $T_r$  to those symbolic units  $S$  and expect to obtain the correct results  $Y$ , formulated as:

$$L(T; S; X) = L(\{T_d, T_f, T_i, T_r\}; S; X_f) \xrightarrow{H} Y$$

**Rules Induction** In this task, we evaluate the ability to induce rules. We present the correct results  $Y$  obtained by applying the (hidden) rules to the given units. We denote the problem text for this task as  $X_l$ . We prompt the LLM to induce the (hidden) rules by observing the relation between units

and the correct results, which can be formulated as:

$$L(T; S; X; Y) = L(\{T_d, T_f, T_i\}; S; X_l; Y) \xrightarrow{H} T_r$$

**Results Validation** In this task, we evaluate the ability to validate the results’ correctness and correct the **results** if an error exists. The problem text of this task is  $X_r$ . We prompt the LLM with the rules and a (probably) wrong result  $\hat{Y}$  with three errors generated randomly with 50% chance. The LLM is required to validate and/or correct the given result  $\hat{Y}$ . The LLM first answers whether the given result is correct. It is a binary classification problem denoted as  $U_r = \{Yes, No\}$ . If  $U_r = Yes$ , the LLM quits generation by outputting words like *None*. If  $U_r = No$ , the LLM applies rules to rectify the error and obtain new results  $\bar{Y}$ , formulated as:

$$\text{Let } L(\{T_d, T_f, T_i, T_r\}; S; X_r; \hat{Y}) \xrightarrow{H} U_r$$

$$\bar{Y} = \begin{cases} L(T; S; X_r; \hat{Y}; U_r) & \text{if } U_r = No \\ None & \text{if } U_r = Yes \end{cases}$$

**Rules Validation** In this task, we evaluate the ability to validate the correctness of the rules and correct the **rules** if errors exist and the problem text of this task is  $X_e$ . The prompted rules  $\hat{T}_r$  are possibly wrong and may have three error rules generated randomly in 50% of the experiments, and the prompted correct result can help validate the correctness of the rules. Knowing whether the rules are correct is the first step for solving the problem, so we call that result  $U_e = \{Yes, No\}$ . If

	Task Illustration	Units	Problems		Predictions
<b>Rules Induction</b>	Inducing grouping rules through observing the grouping results.	Polygon 1: [3 Sides, Green, Copper], Polygon 2: [5 Sides, Red, Iron], ... Polygon N: [10 Sides, Yellow, Plastic]	Group 1:[Polygon 1, Polygon 3, ...] ... Group N:[Polygon 7, Polygon N, ...]	Induce the grouping rules by observing the above results.	Induced Rules: Rule 1: 3 Sides, Green and Copper Rule 2: 5 Sides, Red and Iron ...
<b>Rule Application</b>	Applying grouping rules to given polygons to obtain the grouping results		Rule 1: 3 Sides, Green and Copper Rule 2: 5 Sides, Red and Iron ...	Apply the above grouping rules to the given polygons and give the results	Grouping Results: Group 1:[Polygon 1, Polygon 3, ...] ... Group N:[Polygon 7, Polygon N, ...] Correction Results Or Not: No
<b>Results Validation</b>	Validate the correctness of grouping results and rectify them if they are wrong		Rule 1: 3 Sides, Green and Copper ... Group 1:[Polygon 1, Polygon 2, ...] Group 2:[Polygon 3, Polygon 6, ...]	Validate the correctness of the result first and rectify them if it is wrong	Corrected Results: Group 1:[Polygon 1, Polygon 3, ...] ... Group N:[Polygon 7, Polygon N, ...]
<b>Rules Validation</b>	Validate the correctness of rules and correct them if they are wrong		Rule 1: 3 Sides, Green and Copper ... Group 1:[Polygon 1, Polygon 3 ...] Group 2:[Polygon 2, Polygon 6, ...]	Validate the correctness of rules first and rectify them if it is wrong	Correction Rules Or Not: Yes Rules do not need correction
<b>Rules Incorporation</b>	Find whether new rules exist in the new results or not if so, induce new rules.		Rule 1: 3 Sides, Green and Copper ... Group 1:[Polygon 1, Polygon 3, ...] Group 2:[Polygon 2, Polygon 6, ...]	Find whether there exist new rules or not and induce them if necessary	New Rules Or Not: Yes New Inducted Rules: Rule 2: 5 Sides, Red and Iron ...

Table 1: Different Task Examples in Polygons Grouping

$U_e = Yes$ , the LLM finishes generation by outputting words like *None* as correct rules do not need correction. If  $U_e = No$ , the LLM corrects the wrong rules and obtain corrected rules  $\hat{T}_r$  based on the correct results  $Y$ , which can be formulated as:

$$\text{Let } L(T = \{T_d, T_f, T_i, \hat{T}_r\}; S; X_e; Y) \xrightarrow{H} U_e$$

$$\hat{T}_r = \begin{cases} L(T; S; X_e; Y; U_e) & \text{if } U_e = No \\ None & \text{if } U_e = Yes \end{cases}$$

**Rules Incorporation** In this task, we evaluate the ability to identify new rules and merge new rules with previous rules if new rules exist where the problem text of this task is  $X_i$ . The prompted rules  $\hat{T}_r$  and the results are correct, but the rules may be a part of the entire rule-set since we withhold three new rules in the given new result with a 50% chance. The LLM refers to the new result and identifies whether we can induce new rules from it or not. Identifying whether new rules exist is the first step, so we denote this binary classification results as  $U_i = \{Yes, No\}$ . If  $U_i = No$ , the LLM finishes generation with the word *None*. If  $U_i = Yes$ , the LLM should induce new rules  $\ddot{T}_r$  based on the new given results  $Y$ , formulated as:

$$\text{Let } L(\{T_d, T_f, T_i, \hat{T}_r\}; S; X; Y) \xrightarrow{H} U_i$$

$$\ddot{T}_r = \begin{cases} L(T; S; X_i; Y; U_i) & \text{if } U_i = Yes \\ None & \text{if } U_i = No \end{cases}$$

We show an example of the prompt formulation in Figure 2 for the Rules Application Task for Polygon Grouping. As illustrated in the figure, the prompt first indicates the role of the LLM to posit the LLM in a position to solve the task. The following Problem Description contains the Task Illustration  $T$  and Units  $S$  which in this example is to group different polygons. Then Response Instruction tells how the model should respond so that

the answer generated can be extracted easily. Then Few-Shot examples are optional depending on the experiment setting. Finally, the Prompted Problem contains the Problem  $X$  that the LLM should answer following all the information contained in the prompt. The content of each part changes with the different task settings, but all share the same backbone structure. <sup>1</sup>

## 4 Experiments<sup>2</sup>

In this study, all those tasks are automatically generated and can be automatically solved by the corresponding program as the solution for each problem is the same. Though humans may not solve the problem with perfect 100% accuracy due to humans making mistakes in following solution procedures like overlooking some rules, this does not mean humans cannot solve this problem as it is not caused by the inability of inductive reasoning. In the optimal situation, the performance for humans should be perfect as the program which is 100%.

### 4.1 Evaluated LLMs

**Davinci (Brown et al., 2020)** is a GPT3-based LLM trained with instruction tuning (Ouyang et al., 2022). We use the Text-Davinci-003 version<sup>3</sup> which has 175B parameters size.

**GPT-3.5 (Brown et al., 2020)** is one of the SotA LLMs currently. It is trained with both instruction tuning (Zhang et al., 2023) and RLHF, meaning reinforcement learning from human feedback (Christiano et al., 2023). Compared to Davinci, it is specially trained for chat purposes but still uses GPT-3 as a backbone structure.

<sup>1</sup>More details are in the Appendix A.3.

<sup>2</sup>Please refer to the Appendix for detailed settings of experiments and symbolic tasks.

<sup>3</sup>For brevity, Davinci is used to denote Text-Davinci-003.

Model	Task	Rules Application				Rules Induction			
		Zero-shot		Few-Shot		Zero-shot		Few-Shot	
		Par Acc	Full Acc						
Davinci	Grouping	<u>75.6</u>	<u>10.0</u>	<u>87.9</u>	<u>24.0</u>	23.5	1.3	85.4	11.2
	Ordering	36.7	0.0	29.6	0.0	<u>56.5</u>	<u>39.7</u>	87.0	<u>82.1</u>
	Mapping	6.4	0.0	10.1	0.0	33.0	3.0	<u>90.4</u>	2.0
GPT-3.5	Grouping	<u>88.5</u>	<u>23.7</u>	<u>90.6</u>	<u>33.4</u>	88.6	24.2	91.4	24.4

	Mapping	62.3	30.6	67.1	47.3	49.4	17.1	93.8	21.7

Table 2: Accuracy on Rules Application and Rules Induction. The best results for one LLM in different tasks in either Rules Application or Rules Induction are underlined, and the best results of all models are bold and underlined. Par Acc and Full Acc means Partial and Full Accuracy.

**GPT-4 (OpenAI, 2023)** is the current SotA LLM with a strong performance in various tasks. It even performs well on professional tests that require a high-level understanding of natural language.<sup>4</sup>

## 4.2 Evaluation Criteria

**Validation Accuracy** means the number of validation problems  $U$  that the LLM correctly predicts divided by the total number of examples.

**Partial Accuracy** means the percentage of sub-problems the LLM correctly predicted. It is only counted when sub-problems exist. For example, in the rule correction problem,  $U_e = Yes$  means the prompted rules are correct, therefore the sub-problems do not exist so such an example is not counted into the calculation of Partial Accuracy.

**Full Accuracy** means the percentage that the LLM can correctly predict all sub-problems in a given problem. The Full Accuracy is only calculated for examples that have sub-problems.<sup>5</sup>

## 4.3 Results

### 4.3.1 Rules Application and Rules Induction

We discuss the Rules Application and Rules Induction together in Table 2 due to their contrasting nature that apply and induce rules and found:

1. For Rules Application, Grouping has the highest accuracy, followed by Mapping, then Ordering. For Mapping, applying mapping rules to text leads to unsemantic text, but LLMs are

<sup>4</sup>The evaluated Llama2 gives extremely low accuracy and we put its experiment results and analysis in the Appendix.

<sup>5</sup>We abbreviate Validation Accuracy, Partial Accuracy, and Full Accuracy as Valid Acc, Partial Acc, and Full Acc.

trained to generate meaningful text using Language Modelling, thus generating unsemantic mapped text is not straightforward. For the Ordering, the same color units exist in the unsorted list. The LLM needs to clarify and put the same colors together, but the LLMs struggle to find such a hidden procedure.

2. In Rules Induction, Ordering has the highest accuracy, followed by Grouping, then Mapping. In Ordering, the prompted ordered list equals directly telling the rules even with the deletion and repetition of some colors, leading to high accuracy. In Grouping, the LLM needs to check three polygon attributes to derive the rules, which lowers accuracy. In Mapping, the duplicated and mixed-case characters require the LLM to merge characters and induce case-insensitive rules. Such hidden steps make Mapping the most challenging task.
3. The accuracy for Rules Induction is lower than for Rules Application except for Ordering, which we have explained above, showing that Rules Induction is harder. GPT-4 performs better than GPT-3.5 and Davinci in both tasks, possibly due to a much larger pre-train size, instruction tuning size, and model size.
4. A high Partial Acc does not mean high Full Acc shows the prediction error scatters in each example rather than converging in several examples, meaning that the LLM tends to make small mistakes in each example.

(a) Results Validation							
Model	Task	Zero-Shot			Few-Shot		
		Valid Acc	Partial Acc	Full Acc	Valid Acc	Partial Acc	Full Acc

Table 3: Model accuracy on Results Validation and Rules Validation. The best results for one LLM between different tasks are underlined, and the best results of all models are both bold and underlined.

### 4.3.2 Results Validation and Rules Validation

The Results Validation and Rules Validation are discussed concurrently due to their contrasting nature. The outcomes are presented in Table 3.

1. In Results Validation, Mapping has the lowest accuracy, followed by Grouping and Ordering. For Mapping, locating an error requires applying rules to the character at the corresponding index, requiring the LLM to count the sequence length and locate it, but LLMs struggle to do such precise manipulation. For Grouping, the LLM needs to check three attributes to locate the error, which is comparatively easier. For Ordering, identifying an error merely needs checking color units sequentially with the prompted color preference.
2. For Rules Validation, Grouping has the lowest accuracy, followed by Mapping and Ordering. For Grouping, LLM has to induce rules from grouping results first and compare them with the possible wrong rules, and such a hidden step increases the difficulty. For Mapping, just apply the rule to each original and mapped character to check if conflicts exist. It is relatively easier to locate and correct the error. For Ordering, similarly, an ordered color list is another representation of rules, making it easy to both validate and correct.
3. LLMs give a low Valid Acc in all tasks except Ordering for reasons explained above. As validation is a binary classification problem, such accuracy means LLMs struggle to validate the correctness of results even for GPT-4, even though GPT-4 scores are slightly better.
4. Rules Validation have a higher Partial and Full Acc than Results Validation. This is because the rule sizes are much smaller than the unit size and we have several rules but dozens of units, making Rule Validation easier due to the smaller prediction space.
5. In all LLMs, the few-shot can boost the accuracy in Partial Acc and Full Acc while the improvement in Valid Acc differs, showing that

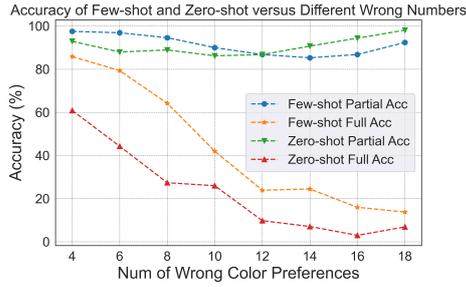

Figure 3: Accuracy Change in Few-Shot Generalization

the ability to learn to validate the results/rules from examples varies.

### 4.3.3 Rules Incorporation

The Rule Incorporation task can be considered a variant of Rules Induction where the LLM knows partial rules but may need to complete them based on whether the given results contain new rules. From the results in Table 4, we can see:

1. In the Zero-Shot setting, LLMs show no obvious preference regarding Valid Acc in either task, while Few-Shot improves it in the Ordering task, but Davinci and GPT-3.5 still fail to identify new rules from results. GPT-4 shows a high Valid Acc, meaning that the ability to validate new rules may be an emergent ability when LLMs reach a certain model size.
2. In contrast to Rules Induction, a decrease in Full Acc in Ordering and Grouping tasks is observed, which is counter-intuitive given the partial rules should enhance results as it reduces the prediction space for rules. This may be because even though the prediction space is narrowed, identifying new rules and merging them with existing rules poses another difficulty for LLMs. Conversely, the Mapping tasks benefit from given partial rules, which reveals that rules can be completed by right-shifting three indices, thereby simplifying the rule inference compared to other tasks.

### 4.3.4 Few-Shot Generalization

The task accuracy of LLMs can be largely improved by adding few-shot examples. However, this is when the few-shot examples are not out-of-distribution with the problem prompted. This leaves a question: *Does the LLM learn the scalable solution of the task or just fit into the answer pattern from few-shot examples?* We discuss this

problem using GPT-4 and the Rules Validation of the Ordering tasks. We set the few-shot examples with three error color preferences, but the final problem includes more. We compare the zero-shot and few-shot settings results depicted in Figure 3:

1. The few-shot setting has higher accuracy than the zero-shot setting, proving that the LLM learns to generalize beyond the few-shot examples with three wrong color preferences. Notably, the few-shot setting initially exhibits an accuracy advantage exceeding 20%.
2. Providing few-shot examples does not make the LLM generalize to all situations as the accuracy decreases like in the zero-shot setting and even gets close to that accuracy in extreme situations, suggesting LLM only learns limitedly from few-shot examples.
3. The increasing trend in Partial Acc after 12 wrong preferences is because the random chance of picking out a wrong color preference increases with more wrong colors.

### 4.3.5 Increased Unit Size

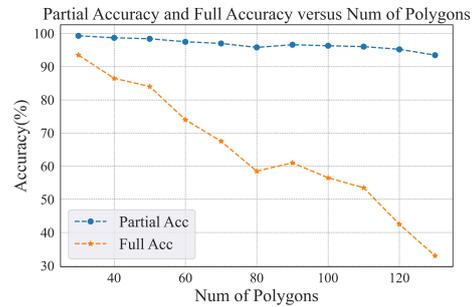

Figure 4: Accuracy Regarding Increased Polygons Size

Instead of increasing the task’s difficulty, we evaluate the situation in which the underlying structure of the task remains fixed, but the unit size increases. GPT-4 has near-perfect Rules Application accuracy in the Polygon Grouping task, indicating it may hold a scalable solution for this. We want to see whether the performance remains stable when the unit sizes increase. The results in Figure 4 show the GPT-4’s accuracy with increased polygon size:

1. The Full Acc decreases, showing the LLM cannot scale its performance with increased unit size even when small and larger problems share the same structure. This shows that the LLM does not hold the scalable solution despite its high accuracy in small-size problems.

Model	Task	Zero-shot			Few-Shot		
		Valid Acc	Partial Acc	Full Acc	Valid Acc	Partial Acc	Full Acc
Davinci	Grouping	<u>51.0</u>	30.1	3.9	52.0	37.2	5.8
	Ordering	49.2	<u>37.9</u>	0.5	<u>87.5</u>	26.1	3.4
	Mapping	49.3	<u>49.0</u>	<u>5.6</u>	49.3	<u>87.4</u>	<u>34.5</u>
GPT-3.5	Grouping	50.3	33.4	10.9	54.8	42.5	16.9
	Ordering	51.1	33.3	8.0	<u>66.0</u>	72.0	39.1
	Mapping	<u>51.4</u>	<u>78.7</u>	<u>28.8</u>	<u>52.0</u>	<u>91.4</u>	<u>55.2</u>
GPT-4	Grouping	99.7	<u>96.1</u>	<u>89.5</u>	99.5	<u>98.0</u>	<u>94.6</u>
	Ordering	<u>100</u>	96.2	82.8	<u>100</u>	96.1	89.9
	Mapping	95.1	94.4	56.0	97.2	95.9	62.3

Table 4: Model Accuracy on Incorporation. The best results for one LLM between different tasks are underlined and the best results of all models are both bold and underlined.

CoT Few-Shot Num	Partial Acc	Full Acc
w/o CoT 5 Shot	52.4	28.9
CoT-1 Shot	82.6	58.6
CoT-2 Shot	83.0	57.7
CoT-3 Shot	84.6	55.8
CoT-4 Shot	84.9	62.2
CoT-5 Shot	<b>85.0</b>	<b>62.3</b>

Table 5: Chain-of-Thought Experiment

2. The Partial Acc is relatively stable, meaning the LLM predicts with stable accuracy for each sub-problem. However, the increased unit size enlarges the sub-problem size, which increases the expectation value of prediction error, naturally reducing the Full Acc.

#### 4.3.6 Does Chain-of-Thought help?

In this experiment, we discuss to what extent the Chain-of-Thought (CoT) helps the LLM to solve the task. We evaluate GPT-4 in the Ordering of Rules Application task as even GPT-4 performs poorly in the few-shot setting. The CoT prompt shows the process of checking each color’s preference and reordering the list based on acquired preferences. We reveal information on the scalable resolution to the LLM through those intermediate steps. From results in Table 5, we can see that:

1. From the results, the CoT-prompted model greatly improves the accuracy, leading to more than 35% accuracy gain in the 5-shot. This shows that the LLM learns to follow intermediate steps exposed by the CoT prompt, but it is still far from perfect accuracy, showing that a scalable solution is not learned.
2. We observe an inconsistency in accuracy improvement with increased few-shots. The

accuracy decreases in the two or three-shot settings compared to one-shot, while the enhancement in the five-shot setting over one-shot is just 3.5%. This could be because each Color Ordering example has a different color preference and an unordered list (independent and not correlated with each other), so information from five examples is not substantially better than from just one.

## 5 Conclusion

In this research, through designed symbolic probing tasks, we probed the LLMs’ abilities centered around inductive reasoning, including Rules Induction, Rules Application, Results/Rules Validation, and Rules Incorporation. We found that LLMs fail to correctly induce or apply rules in simple symbolic tasks and cannot or even fail to validate the correctness of results/rules or identify and merge new rules given new results. This suggests that not just improving prediction accuracy, but also making the LLM identify what is correct and wrong, and being able to identify new information from new examples are important.

Our experiments show that near-perfect accuracy in small-sized tasks does not imply that LLM performance scales well to a larger sized task. In this sense, it raises the question: *how can we prove that the LLM knows how to solve a problem/task?*

We also notice that few-shot examples help the model to generalize to unseen situations, but do not make the model able to solve the problem in all situations. Through the CoT-enhanced prompt, we see a significant performance improvement, stating that CoT helps the model to understand the scalable solution of a task in which the CoT prompt exposed more information about scalable solutions.

## 6 Limitations

We did not evaluate all available LLMs due to limited computational resources and service-restrictions (area limitation, wait-list, etc.). Instead, we selected several representative and strong LLMs that are easy to access. We are only able to run Llama2 models up to 13B, but we found that they do not even understand the prompt instructions correctly at those model sizes. This is despite following the correct way to prompt it, as described in the Llama2 paper (Touvron et al., 2023)<sup>6</sup> and in discussions<sup>7</sup> in the research community<sup>8</sup>. Please refer to Appendix A.1.2 for the results analysis of Llama2. Additionally, as probing research, our final goal was not actually to try to solve the symbolic tasks proposed in this paper, but that may be a separate goal in more powerful future research.

It is also possible that the accuracy can be further improved by using different prompts. We have tried various prompt designs and multiple prompts to make the LLMs give their best performance. The current prompt design gives the best accuracy among the prompts we have experimented with, though we do not deny that other prompts can improve the performance further. However, due to the number of possible prompts being infinite, we cannot exhaust them. We chose the best prompt among all the ones we have tried so far, and keep using it right now.

Additionally, all proposed symbolic tasks may be completely solvable if we prompt the LLM to use an external API like a sorting function or a pre-programmed function or even write its own code/program that can solve the given task. We argue that using such a tool to solve this problem is based on human-constructed knowledge, which equals making the human solve the task, not testing if the model can solve it. From a human perspective, those tasks are solvable even without external tools. Understanding rules, applying rules, discovering errors, and concluding on a general solution to a problem are fundamental aspects of intelligence that should be achieved even without external assistance from outside the model/brain.

## 7 Ethical Considerations

According to the terms-of-service of the OpenAI-provided API, its output (obtained data, model, etc.) cannot be used to compete with OpenAI.

We declare that we have no such intention of doing so. The purpose of this research is not to develop or produce any model or any data nor any method that aims to compete with OpenAI produced model, including the GPT3 (Text-Davinci) series, GPT-3.5 series, GPT-4 series, and all other OpenAI products (current or future improvements), released or coming models. We ask any follow-up researchers who cite this paper to also refrain from such competition in their follow-up research.

## A Appendix

### A.1 Experiment Settings

#### A.1.1 Model Setting

For the Text-Davinci-003, we set the LLM to have zero temperature. For the GPT-3.5, we used the gpt-3.5-turbo-16k version. We set the temperature as 0 since we want to output for LLM to be stable, deterministic, and reproducible. Additionally, we want the LLM to follow the instructions given in the prompt exactly. Setting the temperature is a good solution to make the LLM follow the instructions exactly.

For the GPT-4, we used the June 2023 version. Similarly, we also set the temperature as 0 to make the LLM produce deterministic results.

#### A.1.2 Llama2

For the Llama2-13b model, we show its experiment results in Table 6 and Table 7 and Table 8.

Regarding the results in Rules Application and Rules Induction, we can see that:

1. From the results in Table 6, we can see that Llama2 fails significantly in both the zero-shot and the few-shot settings. Especially in the Rules Application, the Llama2 gives zero Full Accuracy. Additionally, the Partial Accuracy is also low in Rules Application, even with few-shot examples showing that Llama2 may not be able to learn from those examples.

2. Regarding the Rules Induction, the accuracy is slightly better, even though it is far from satisfying. We can see that except for Ordering, in which the rules are easy to obtain from the prompted ordered color lists, the Llama2 also fails significantly in other tasks. For the Grouping and Mapping task, even with few-shot examples, the Full Accuracy is still only 2.9% and 2.0%.

Regarding the results in Results Validation and Rules Validation. From the results in Table 7.

1. Firstly, the Llama2 also fails to validate the correctness of results or rules in both the zero-shot setting and the few-shot setting.
2. Similarly, it also fails to correct the results. Even in the Grouping with the few-shot setting, its performance is still just 8.9%. In other tasks, the performance is simply zero accuracy or close to zero accuracy.
3. In the Rules Validation, we have similar results. The Llama2 is also not able to validate the correctness of rules. Additionally, the Full Accuracy is also low.

Regarding the results of Rule Incorporation. From the results in Table 8, we can see:

1. The Llama2 also fails to identify new rules. This means that Llama2 cannot find new rules in the given results.
2. Additionally, the performance is also low in both the zero-shot setting and the few-shot setting.
3. The few-shot examples improve the Partial Accuracy a little, but do not improve the Full Accuracy.

We also did a brief case analysis of Llama2, and we found that in most cases, even following the desired response format to generate the answer is difficult. This means that it is hard to extract Llama2's prediction for the problem as it can be expressed in various ways even when we set its temperature parameter as zero, expecting it to follow the instructions. Additionally, Llama2 seems to repeat some tokens and also generate meaningless noise random tokens, which cannot be considered as an answer since it is meaningless.

Model	Task	Rules Application				Rules Induction			
		Zero-shot		Few-Shot		Zero-shot		Few-Shot	
		Par Acc	Full Acc	Par Acc	Full Acc	Par Acc	Full Acc	Par Acc	Full Acc
Llama2	Grouping	1.7	0.0	2.7	0.0	12.6	0.0	24.3	2.9
	Ordering	<b>34.4</b>	0.0	<b>35.4</b>	0.0	<b>38.9</b>	<b>29.7</b>	59.4	<b>40.4</b>
	Mapping	8.6	0.0	2.5	0.0	8.3	0.5	<b>89.8</b>	2.0

Table 6: Accuracy on Rules Application and Rules Induction. The best results are bold and underlined. Par Acc and Full Acc mean Partial and Full Accuracy respectively.

(a) Results Validation

Model	Task	Zero-Shot			Few-Shot		
		Valid Acc	Partial Acc	Full Acc	Valid Acc	Partial Acc	Full Acc
Llama2	Grouping	<b>58.0</b>	2.0	0.0	<b>58.0</b>	<b>23.5</b>	<b>8.9</b>
	Ordering	52.3	<b>3.4</b>	0.0	54.6	12.7	1.3
	Mapping	48.7	0.0	0.0	50.0	0.8	0.0

(b) Rules Validation

Model	Task	Zero-Shot			Few-Shot		
		Valid Acc	Partial Acc	Full Acc	Valid Acc	Partial Acc	Full Acc
Llama2	Grouping	49.3	<b>9.0</b>	0.0	50.2	<b>28.9</b>	1.3
	Ordering	49.3	8.4	0.0	48.4	0.0	0.0
	Mapping	<b>50.3</b>	8.3	3.4	<b>55.3</b>	15.8	<b>8.9</b>

Table 7: Model Accuracy on Results Validation and Rules Validation. The best results are both bold and underlined.

## A.2 Task Setting

For the tasks evaluated in this research, we all randomly generated 500 examples for each task. For example, for the Character Mapping task, we randomly sample 500 sentences from datasets with character lengths from 20 to 100. The number of examples is also the same for other tasks. To notice that we have made sure that the possible combination of units is much larger than 500 examples so that it is not likely that we may generate the same examples twice in an experiment. Additionally, we use five random seeds [714, 123, 889, 912, 743], and the results are averaged over 5 random seeds. By fixing random seeds, we can make sure that each run produces the same generation of units, the errors in rules or results, and the new rules in the new given results.

### A.2.1 Polygon Grouping Setting

We generate 30 polygons for each input example. Those polygons are randomly generated from the provided color list, sides number list, and material list.

The sides number list is [3, 4, 5, 6, 7, 8, 9, 10, 11, 12]

The color list is ['red', 'blue', "while", "black", "yellow", "purple", "gray", "cyan", "brown", "indigo"]

The material list is ['metal', 'plastic', "glass", "sliver", "gold", "copper", "bronze", "diamond", "jade"]

A polygon is generated through sampling from each attribute.

### A.2.2 Character Mapping Setting

The text is chosen from the aforementioned App-Review dataset. We filter out sentences with character lengths either longer than 100 characters or shorter than 20 characters. Based on such conditions, we sample 500 examples from the filtered dataset as the data to be evaluated.

### A.2.3 Color Ordering Setting

The color list that is used in this research contains the following colors ['Red', 'Blue', 'Green', 'Yellow', 'Orange', 'Purple', 'Pink', 'Brown', 'Black', 'White', 'Gray', 'Silver', 'Gold', 'Indigo', 'Turquoise', 'Cyan', 'Magenta', 'Lavender', 'Maroon', 'Beige', 'Teal', 'Navy', 'Olive', 'Coral', 'Salmon', 'Peach', 'Ivory', 'Tan', 'Lilac', 'Skyblue', 'Mint', 'Slate', 'Turmeric', 'Ruby',

'Emerald', 'Tangerine', 'Pewter', 'Champagne', 'Mauve', 'Brick', 'Forest', 'Mustard', 'Chocolate', 'Sapphire', 'Blush', 'Ash', 'Coral', 'Steel', 'Apricot', 'Pearl']. Each time, we randomly sample 20 colors from the whole list and randomly rank each color in the list to form the color preference dictionary. When prompting the LLM to induce rules based on correct output examples, we partition long color lists into several sub-lists to prevent the model from directly copying the given results to obtain the correct color preference without reasoning. The LLM should be able to merge those lists to produce the whole color preferences list.

### A.3 Prompt Examples

As illustrated in the examples, first, we prompt the Role of the LLM to posit its general target of the task. Then, we prompt with a more detailed explanation of the tasks and provide detailed information about what the task is. After the Problem Description, we write the Response Instruction, which illustrates what answer we expect the model to respond with. We also added the Response Format to the LLM to make it generate the content following that format to let us extract the answers easily by parsing the output of the LLM. Then, depending on the task setting, we may attach the optional Few-Shots Examples after the Response Format. Notice that any content that is closed by the "" bracket pair is a placeholder. It will be replaced by the actual answer or prompted units. For example, "First Example Rules" means that this is the first example among few-shots examples. In the actual prompt, it will be replaced by actual rules. Also, the same for the "First Example Polygons", in which we will prompt the model with actual polygons that the model needs to group using the rules. Finally, after the Few-Shots Examples, we attach the actual prompted problem to the model with corresponding rules and polygons by replacing "Rules" and "Polygons" with the actual initiated rules and polygons for the problem.

We also show the prompt of other symbolic tasks. The prompts used for Character Mapping in all tasks are in Figure 5 and 6, which shows the prompt for Rules Application, Rules Induction, Results Validation, Rules Validation, and Rules Incorporation, respectively.

The prompts used for Polygons Grouping in all tasks are in Figure 7 and 8, which shows the prompt for Rules Application, Rules Induction, Results Val-

idation, Rules Validation, and Rules Incorporation, respectively.

The prompts used for Color Ordering in all tasks are in Figure 9 and 10, which shows the prompt for Rules Application, Rules Induction, Results Validation, Rules Validation, and Rules Incorporation, respectively.

Model	Task	Zero-shot			Few-Shot		
		Valid Acc	Partial Acc	Full Acc	Valid Acc	Partial Acc	Full Acc
Llama2	Grouping	48.0	2.7	0.0	50.6	13.4	0.0
	Ordering	42.1	4.4	0.0	42.1	4.6	0.0
	Mapping	<u>51.3</u>	<u>8.5</u>	0.0	<u>51.3</u>	<u>21.1</u>	<u>7.7</u>

Table 8: Model Accuracy on Incorporation. The best results for one LLM between different tasks are underlined, and the best results of all models are both bold and underlined.

Mapping Rule Application	Mapping Rules Induction	Mapping Results Validation
<p>You are a helpful assistant, and you are supposed to follow the instructions that I give to you and perform the task as far as you can. Here, we want to transform the source text to the altered text by following the rules given below.</p> <p><b>Problem Description</b></p> <p>-----</p> <p>You will be given a set of rules that maps an English character to another character. You are supposed to follow the rules and transform the source text into the altered text.</p> <p><b>Rules</b></p> <p>-----</p> <p>Below are the character mapping rules that map each English character to another English character. Those rules work for both Uppercase and Lowercase: {Rules}</p> <p><b>Response Instruction</b></p> <p>-----</p> <p>Your final answer to this problem should contain the following information:</p> <ol style="list-style-type: none"> <li>The text that is mapped.</li> </ol> <p><b>Response Format</b></p> <p>-----</p> <p>Following the Response Instruction, the format should be:</p> <p><b>Result:</b> Altered: MappedText</p> <p>The above MappedText is just a variable which is the text that is mapped from the original text. Replacing it with the text that is mapped.</p> <p><b>Question</b></p> <p>-----</p> <p>Now try your best to map the Original text to the Altered text using the above rules and Response Format:</p> <p><b>Original:</b> {Original}</p> <p>Remember your response must follow the response format.</p>	<p>You are an inductive reasoner, and you can induct rules from examples correctly. You are given pairs of source text and altered text, and you are supposed to find the rules that map each English character to another.</p> <p><b>Problem Description</b></p> <p>-----</p> <p>You are given a set of pairs of source text and altered text, and you are supposed to find out the rules that map each English character in the source text to the corresponding altered text. You should ignore the non-English characters like space, numbers, question marks, etc. You should also ignore the case of the English character, which means you should treat the uppercase and lowercase as the same character.</p> <p><b>Response Instruction</b></p> <p>-----</p> <p>Your final answer to this problem should contain the following information:</p> <ol style="list-style-type: none"> <li>The rules are used to map each English character to another.</li> <li>Do not produce redundant rules, which means if there are two rules that map the same character to the same character, you should only respond to one of them.</li> <li>The mapping character should be an uppercase English character.</li> </ol> <p><b>Response Format</b></p> <p>-----</p> <p><b>Rules:</b></p> <p>Original: x1 -&gt; Altered: y1</p> <p>Original: x2 -&gt; Altered: y2</p> <p>-----</p> <p>Above Sides x1, y1, x2, and y2 are just variables, replacing them with English characters, which should be only uppercase English characters.</p> <p><b>Question</b></p> <p>-----</p> <p>Now try your best to induct the mapping rules from the following Original and Altered pair:</p> <p><b>Original:</b> {Original}</p> <p><b>Altered:</b> {Altered}</p> <p>Remember your response should follow the response format.</p>	<p>You are an accurate error-checking assistant, and you can identify errors correctly. You have access to several pre-defined rules that map each English character to another English character, and you are given an Original and Altered text pair. The Altered string is obtained by mapping each English character in the Original text one by one using those pre-defined rules. However, the mapping for each character may not be correct. You are supposed to find out whether the mapping from the Original to the Altered text is correct or not. If not, locate the positions of the error character and rectify it.</p> <p><b>Problem Description</b></p> <p>-----</p> <p>You are given a set of rules that maps each English character to another English character. You are supposed to check whether we can get the altered text from the original text using those rules. If not, where is wrong and locate the error.</p> <p><b>Rules</b></p> <p>-----</p> <p>Below are the rules that map each English character to another English character. Those rules work for both Uppercase and Lowercase: {Rules}</p> <p><b>Notice:</b> Those rules only work for the English alphabet, and if you encounter non-English characters like space, numbers, question marks, etc, you don't have to check it.</p> <p><b>Response Instruction</b></p> <p>-----</p> <p>Your final answer to this problem should contain the following information:</p> <ol style="list-style-type: none"> <li>Whether we can obtain the altered text by following the rules given above.</li> <li>If the result is invalid, respond with the rectified Altered result.</li> </ol> <p><b>Response Format</b></p> <p>-----</p> <p>Following the Response Instruction, the format should be:</p> <p><b>Validation Result:</b> Valid or Invalid</p> <p><b>Rectified Results:</b></p> <ol style="list-style-type: none"> <li>If the result is Valid, you respond with There is no character to correct.</li> <li>If the result is Invalid, you respond with the rectified altered text in the following format: <p><b>Altered:</b> RectifiedAlteredText</p> <p>The above RectifiedAlteredText is just a variable, and you should replace it with the actual rectified altered text.</p> </li> </ol> <p><b>Question</b></p> <p>-----</p> <p>Now try your best to answer the question for the following Original and Altered pair:</p> <p><b>Original:</b> {Original}</p> <p><b>Altered:</b> {Altered}</p> <p>Remember your response should follow the response format.</p>

Figure 5: Prompt Template for Mapping in Rules Application, Rules Induction and Results Validation

Mapping Rules Validation	Mapping Rules Incorporation
<p>You are an error rectifier. You have access to several pre-defined rules that map each English character to another English character, and you are given an Original and Altered text pair. The Altered string is obtained by mapping each English character in the Original text one by one using those pre-defined rules.</p> <p><b>Problem Description</b></p> <p>-----</p> <p>Some problems may happen to those rules due to some unexpected reasons; some of those rules may be disturbed, so the rules may not be correct anymore. You are supposed to rectify those rules by observing the Original and Altered string pair, where the Altered string pair is mapped by previous undisturbed correct rules. By checking the rules and the Original and Altered string pair, you can identify whether the given rules are correct or not.</p> <p><b>Response Instruction</b></p> <p>-----</p> <p>Your final answer to this problem should contain the following information:</p> <ol style="list-style-type: none"> <li>Are the rules correct or not?</li> <li>If not correct, what is/are the rectified one/s.</li> <li>If there are examples provided, follow the procedure for how examples solve the problem.</li> </ol> <p><b>Response Format</b></p> <p>-----</p> <p><b>Correct Rules or Not:</b> Yes or No</p> <p><b>Rectified Rules:</b></p> <ol style="list-style-type: none"> <li>If the result is Yes, you should respond with there is no rule to correct.</li> <li>If the result is No, you should respond to the rectified rule/rules.</li> </ol> <p>For example: Original: x1 -&gt; Altered: y1</p> <p>Here, x1 and y1 are just variables that represent English characters and do not have actual meanings; you should replace them with actual English characters based on your analysis.</p> <p><b>Question</b></p> <p>-----</p> <p>Try your best to answer the question using the above Response Format to determine whether the following rules contain incorrect rules or not:</p> <p>{Rules}</p> <p>Following is the correct ordered list of colors:</p> <p><b>Original:</b> {Original}</p> <p><b>Altered:</b> {Altered}</p> <p>Now, you need to induct whether there are wrong rules existing in the given pre-defined mapping rules, and your response should follow the response format.</p>	<p>You are an inductive reasoner. You have access to several pre-defined rules that map each English character to another English character, and you are given an Original and Altered text pair. The Altered string is obtained by mapping each English character in the Original text one by one using those pre-defined rules.</p> <p><b>Problem Description</b></p> <p>-----</p> <p>We have derived several rules based on previous Original and Altered pairs observations. Now, we have new data, and the problem is whether the new data can provide new rules or not. You are supposed to analyze whether the new pair can provide additional information or not. If the new pair presents new mapping rules, you should be able to identify them and incorporate them into the rules.</p> <p><b>Response Instruction</b></p> <p>-----</p> <p>Your final answer to this problem should contain the following information:</p> <ol style="list-style-type: none"> <li>Does the Original and Altered pair provide new information or not?</li> <li>If it provides new information, what new rule can be inducted?</li> <li>If there are examples provided, you should try to follow the procedure of how examples solve the problem.</li> </ol> <p><b>Response Format</b></p> <p>-----</p> <p><b>New Information Contained:</b> Yes or No</p> <p><b>New Rules Inducted:</b></p> <ol style="list-style-type: none"> <li>If you answer No in New Information Contained, you should respond with No.</li> <li>If the answer Yes in New Information Contained, respond with the new inducted rules in the following format: <p>Original: x1 -&gt; Altered: y1</p> <p>Here, x1 and y1 are just variables that represent English characters and do not have actual meanings, and you should replace them with actual English characters based on your analysis.</p> </li> </ol> <p><b>Question</b></p> <p>-----</p> <p>You have access to the following rules:</p> <p>{Rules}</p> <p>You have access to the following Original and Altered pairs:</p> <p><b>Original:</b> {Original}</p> <p><b>Altered:</b> {Altered}</p> <p>Now, you need to check whether we can induct new rules from the given Original and Altered pair. Remember your response should follow the response format.</p>

Figure 6: Prompt Template for Mapping in Rules Validation and Rules Incorporation

Grouping Rules Application	Grouping Rules Induction	Grouping Results Validation
<p>You are a helpful assistant, and you are supposed to follow the instructions that I give to you and perform the task as far as you can. Here, we want to group different polygons into different groups based on their characteristics.</p> <p><b>Problem Description</b> ----- You will be given the possible attributes of different polygons with different Sides, Numbers, Colors, and Materials. You will also be given the grouping rules that describe what types of polygons should be grouped together. You are supposed to group those polygons into different groups based on the grouping rules.</p> <p><b>Attributes</b> ----- Sides Numbers: {SidesNumber} Colors: {Colors} Materials: {Materials}</p> <p><b>Response Instruction</b> ----- Your final answer to this problem should contain the following information: 1. The polygons that belong to each group.</p> <p><b>Response Format</b> ----- Following the Response Instruction, the format should be: <b>Grouping Result:</b> Group 0: Polygon x1, Polygon x2, ... Group 1: Polygon y1, Polygon y2, ... ..... The above format is just an example, and you should replace x1, x2, y1, and y2 with actual polygons based on your analysis. The order of polygons in each group does not matter.</p> <p><b>Question</b> ----- Below are the grouping rules that describe what types of polygons should be grouped together: {Rules}</p> <p>Now try your best to use those grouping rules to group the following polygons. Your response should follow the Response Format. {Polygons}</p>	<p>You are an inductive reasoner, and you can induct rules from examples correctly. You are given several polygons with different attributes like the Number of Sides, Colors, and Materials of Polygons. Additionally, you will be given a grouping result that those polygons are classified into different groups. You are supposed to find the grouping rules.</p> <p><b>Problem Description</b> ----- We first let you know the possible attributes for those polygons. Each polygon is a combination of those attributes. Then, we give you all the polygons that might be used for this problem. Now you have all the attributes and all the polygons, we give you the grouping results, and you are supposed to find the grouping rules that can be applied to those polygons to obtain the grouping results.</p> <p><b>Attributes</b> ----- Sides Numbers: {SidesNumber} Colors: {Colors} Materials: {Materials}</p> <p><b>Response Instruction</b> ----- Your final answer to this problem should contain the following information: 1. The rules that are used to group those polygons.</p> <p><b>Response Format</b> ----- <b>Grouping Rules:</b> 1. Polygons with x Sides, y Color, and z should be grouped together. ..... Above Sides x, y, and z are just variables, replacing them with actual numbers, color, and materials when producing the answer</p> <p><b>Question</b> ----- You have access to the following polygons: {Polygons}</p> <p>These are the grouping results for the above polygons with those attributes: {GroupingResult}</p> <p>Now, you need to induct the grouping rules following the above Problem Description, Response Instruction, and Response Format.</p>	<p>You are an accurate error-checking assistant, and you can identify errors correctly. You have access to several pre-defined rules that illustrate the grouping rules that you can use to group different polygons into different groups. You will be given grouping results and grouping rules and polygons. However, the grouping may not be correct. You are supposed to find out whether the grouping results are correct or not. If not, locate the error and rectify it.</p> <p><b>Problem Description</b> ----- You are given a set of grouping results of different polygons. You know the grouping rules and information about all the polygons. However, the grouping results may not be correct. You are supposed to find out whether the grouping results are correct or not. If it is incorrect, you should be able to locate and rectify the error.</p> <p><b>Attributes</b> ----- Below are all the attribute options for a polygon to have: Sides Numbers: {SidesNumber} Colors: {Colors} Materials: {Materials}</p> <p><b>Response Instruction</b> ----- Your final answer to this problem should contain the following information: 1. Is the grouping result of polygons correct or not. 2. If the grouping results are not correct, give the rectified grouping result.</p> <p><b>Response Format</b> ----- Following the Response Instruction, the format should be: <b>Validation Result:</b> Correct or Incorrect <b>Rectified Results:</b> 1. If the result is Correct, you respond with None. 2. If the result is Invalid, you respond with a new grouping result. Group x: Polygon x_1, Polygon x_2, Polygon x_3, ... Group y: Polygon n_1, Polygon n_2, Polygon n_3, ... ..... Above Group x, y, z, x and n_x are just variables, replacing it with actual group name when producing an answer</p> <p><b>Question</b> ----- You have access to the following polygons: {Polygons}</p> <p>Below are the rules that are used to group different polygons into different groups: {Rules}</p> <p>These are the grouping results for the above polygons with those attributes following the above rules: {GroupingResult}</p> <p>Now you need to check whether the grouping results are correct or not based on given polygons and rules. If not, give the rectified results, and your response must follow the response format.</p>

Figure 7: Prompt Template for Grouping in Rules Application, Rules Induction and Results Validation

Grouping Rules Validation	Grouping Rules Incorporation
<p>You are an error rectifier. You have access to several pre-defined rules that illustrate the grouping rules you can use to group different polygons into different groups. You will be given the grouping results, grouping rules, and polygons. However, the grouping rules may not be correct. You are supposed to find out whether we can obtain the grouping results following the grouping rules. If not, locate the error of the rules and rectify it.</p> <p><b>Problem Description</b> ----- Some problems may happen to group rules due to some unexpected reasons. Some of those rules may be disturbed, so the rules may not be fully correct. You are supposed to rectify those rules by observing the grouping results of polygons. By checking the rules and the grouping results, you can identify whether or not the given rules are correct.</p> <p><b>Attributes</b> ----- Below are all the attribute options for a polygon to have: Sides Numbers: {SidesNumber} Colors: {Colors} Materials: {Materials}</p> <p><b>Response Instruction</b> ----- Your final answer to this problem should contain the following information: 1. Are the rules correct or not. 2. If not correct, what is/are the rectified one/s.</p> <p><b>Response Format</b> ----- Following the Response Instruction, the response format is as follows: <b>Correct Rules or Not:</b> Yes or No <b>Rectified Rules:</b> 1. If the result is Yes, you should respond with "There is no rule to correct". 2. If the result is No, you should respond with the rectified rule/rules in the following format: 1. The wrong rule: x1 Sides, y1 Color, and z1 -&gt; The correct rule: x2 Sides, y2 Color, and z2 ..... The above x1 and x2, y1 and y2, z1 and z2 are just variables. You should replace it with the actual number of sides, colors, and materials. Remember, the wrong rule and the correct rule should be separated by "&gt;" and are in one line. Especially, x1, y1, and z1 are the variables for wrong sides, color, and material, and x2, y2, and z2 are the variables for correct sides, color, and material.</p> <p><b>Question</b> ----- Below are the polygons for this example: {Polygons}</p> <p>Below are the rules that are used to group different polygons into different groups, which may be incorrect: {Rules}</p> <p>These are the correct grouping results for the above polygons with those attributes: {GroupingResult}</p> <p>Now, you need to check whether the grouping rules are correct or not. If not, give the rectified results, and your response must follow the response format.</p>	<p>You are an inductive reasoner. You have access to several pre-defined rules that illustrate the grouping rules that group different polygons into different groups. You will be given the grouping results, grouping rules, polygons, and available attributes of polygons. However, the grouping rules may not be complete. You are supposed to find out whether we can obtain new grouping rule/rules from the grouping results. If yes, discover new rules.</p> <p><b>Problem Description</b> ----- We have derived several rules based on previous observations of the grouping results of polygons. Now, we have new data, and the problem is whether the new data can provide new rules or not. You are supposed to analyze whether the new grouping results can provide additional information or not. If the new grouping results present new grouping rules, you should be able to identify them and incorporate them into the current rules.</p> <p><b>Attributes</b> ----- Below are all the attribute options for a polygon to have: Sides Numbers: {SidesNumber} Colors: {Colors} Materials: {Materials}</p> <p><b>Response Instruction</b> ----- Your final answer to this problem should contain the following information: 1. Do the grouping results provide new information or not? 2. If given grouping results provide new rule/rules, what is/are the new rule/rules that can be inducted from the grouping results?</p> <p><b>Response Format</b> ----- Following the Response Instruction, your response should follow the following format: <b>New Rules or Not:</b> Yes or No <b>Added Rules:</b> 1. If the above result is No, you should respond with "There is no rule to add" after Added Rules. 2. If the above result is Yes, you should respond with the added rule/rules after Added Rules in the following format: 1. Polygons with x Sides, y Color, and z should be grouped together. ..... Above x, y, and z are just variables, replacing them with actual numbers, colors, and materials when producing answers.</p> <p><b>Question</b> ----- Below are the polygons for this example: {Polygons}</p> <p>Below are the rules that are used to group different polygons into different groups, which may be incomplete: {Rules}</p> <p>Below are the grouping results for the above polygons with those attributes: {GroupingResult}</p> <p>Now you need to check whether the grouping results provide new rules or not and your response must follow the response format.</p>

Figure 8: Prompt Template for Grouping in Rules Validation and Rules Incorporation

Ordering Rules Application	Ordering Rules Induction	Ordering Results Validation
<p>You are a helpful assistant, and you are supposed to follow the instructions that I give to you and perform the task as far as you can. Here, we want to sort the given color lists that follow certain color preferences.</p> <p><b>Problem Description</b> ----- You will be given a set of rules that presents the color preferences. You will be given an unordered color list, and you should output the ordered list following the color preferences.</p> <p><b>Color Set</b> ----- You have access to the following colors: {colors}</p> <p><b>Response Instruction</b> ----- Your final answer to this problem should contain the following information: 1. The sorted color list that is based on the given color preferences and unordered color list.</p> <p><b>Response Format</b> ----- Following the Response Instruction, the format should be: Sorted Color List: 1. Color_1 2. Color_2 3. Color_3 ----- The above Color_x is just a variable here that does not hold any actual meaning. You should replace Color_x with actual colors from the given data.</p> <p><b>Question</b> ----- You have access to the following color preference rules that describe the correct color preference rank that you can use to sort the following unordered color list but do not output the color preference rank directly, and you should sort the following color list according to the following color preference rules: {color_preference}</p> <p>Now try your best to sort the following unordered color list according to the given color preference rules above, and your response should follow the response format. Don't just copy the color preference rank above, but try to sort the following color list according to the given color preference rules above: {UnOrderedLists}</p>	<p>You are an inductive reasoner, and you can induct rules from examples correctly. You are given an ordering result that the elements of the ordered result are different colors. You are supposed to find out the preference of the different colors, which means what color has the highest rank.</p> <p><b>Problem Description</b> ----- You are given an ordered list where, instead of ordering the numbers, the elements of the ordered list are colors. Through analyzing the unordered list and the ordered list, you are required to find out the rank of different colors.</p> <p><b>Color Set</b> ----- You have access to the following colors: {colors}</p> <p><b>Response Instruction</b> ----- Your final answer to this problem should contain the following information: 1. The analyzed ranks of different colors.</p> <p><b>Response Format</b> ----- <b>Color Ranking:</b> 1. Rank 1 Color_1 2. Rank 2 Color_2 3. Rank 3 Color_3 4. Rank 4 Color_4 ----- Color_x above is just a variable here that does not hold any actual meaning. You should replace Color_x with actual colors from the given data.</p> <p><b>Question</b> ----- Now try your best to induct the mapping rules from the following Original and Altered pair: Original: {Original} Altered: {Altered}</p> <p>Remember your response should follow the response format.</p>	<p>You are an accurate error-checking assistant, and you can identify errors correctly. You have access to pre-defined ordering rules that show the preference of colors, and you are given ordering results based on those pre-defined ordering rules. However, the grouping results may not be correct. You are supposed to find out whether the given ordering results are correct or not. If not, you should be able to identify the errors and correct them.</p> <p><b>Problem Description</b> ----- You are given pre-defined ordering preferences that show the preference of colors, and you are given ordering results based on those pre-defined ordering rules. ## Abstract

Self-supervised learning has achieved impressive results in speech processing, but current models are computationally expensive, generating environmental concerns because of their high energy consumption. Therefore, we propose an efficient self-supervised approach to address high computational costs, using a single GPU during 24 to 48 hours of pretraining. The proposed approach combines linear, convolutional, and self-attention layers with several optimizations, including dynamic batching, flash attention, mixed-precision training, gradient accumulation, and acoustic feature extraction with input preprocessing. Computational cost estimations for our proposed model represent up to two orders of magnitude improvements in computational efficiency against existing speech models.

## 1 Introduction

Self-supervised models generate impressive results when learning latent representations, but their training is computationally expensive (Peng et al., 2023). Yet, their results in speech processing are astounding because downstream tasks strongly benefit from their learned representations (Mohamed et al., 2022; Parcollet et al., 2023b).

Self-supervised approaches for speech representation learning can be based on consistency or self-training (Zhang et al., 2020). Whether using consistency or self-training, large training costs represent a challenge. Indeed, most existing models require several GPUs for days to pretrain their neural architectures. This requirement causes several limitations. First, it hinders the training and deployment of speech models in computing platforms with low resources, such as edge devices and mobile platforms (Gaol et al., 2023; Mohamed et al., 2022). Secondly, reproducibility is challenging, as few labs can afford large computational resources (Lin et al., 2023). Last but not least, it creates environ-

mental concerns because of the high energy consumption during training (Parcollet et al., 2023b).

To address those limitations, we propose an efficient self-supervised model to learn speech representations. Instead of focusing on the model performance in downstream tasks, the proposed model focuses primarily on computational costs, limiting the resources available for pretraining. We set a pretraining limit based on cramming (Geiping and Goldstein, 2023): we use a single GPU for 24 to 48 hours to train the model.

## 2 Related work

Several models have been recently proposed for self-supervised learning of speech representations, including CombinedSSL (Zhang et al., 2020), Mockingjay (Liu et al., 2020), Spiral (Huang et al., 2022), Data2vec2 (Baevski et al., 2023), and DinoSR (Liu et al., 2023a). But two approaches have clearly emerged (Mohamed et al., 2022): Hidden unit BERT (HuBERT) (Hsu et al., 2021) and wav2vec2 (Baevski et al., 2020b). However, self-supervised models are quite costly, requiring a lot of computational resources for training. One alternative to reduce training costs is knowledge distillation (Allen-Zhu and Li, 2023), where a small student model learns from a large teacher model, which has been pretrained previously (Peng et al., 2023).

Using knowledge distillation, LightHuBERT (Wang et al., 2022) improves HuBERT with a once-for-all transformer model. The teacher is a HuBERT base model, while the student learns by predicting masked inputs in an iterative process. The transformer in LightHuBERT comprises subnets with sharable weights and several configuration parameters, enabling a random search to adjust the model to different resource constraints.

The student architecture in knowledge distillation methods is manually designed, and it does not

change during training. However, modifying student architectures can have a considerable impact on model results, even for student architectures with similar sizes (Ashihara et al., 2022). Therefore, a joint distillation and pruning approach for speech SSL has been recently proposed, using HuBERT (DPHuBERT) or WavLM (DPWavLM) as the teacher models (Peng et al., 2023).

Yet, knowledge distillation approaches need a pretrained teacher model because student models can not be trained standalone (Chen et al., 2023). Thus, computational costs do not improve as they should include teacher model training. In contrast, MelHuBERT (Lin et al., 2023) proposes a simplified version of HuBERT that has twelve self-attention layers and a weighted sum of all the layers for downstream tasks. The input is a 40-dimensional Mel log spectrogram, so input sequences are shorter, reducing the multiplication and addition calculations by 33% (Lin et al., 2023).

There are also efforts to improve the wav2vec architecture. Proposed approaches improving wav2vec include squeezed and efficient wav2vec2 with disentangled attention (SEW-D) (Wu et al., 2022) and stochastic squeezed and efficient wav2vec2 (S-SEW) (Vyas et al., 2022).

Despite existing efforts to improve self-supervised model efficiency, there is still room to reduce the computational costs of self-supervised models. Computational costs create challenges when using these models in mobile devices and for training on very large datasets (Mohamed et al., 2022; Parcollet et al., 2023b). They also hinder the development of new approaches, the study of other training recipes, and the reproduction of experimental results, as few researchers can afford the cost (Chen et al., 2023; Lin et al., 2023; Parcollet et al., 2023b; Wang et al., 2023). Besides, computational costs have environmental implications, as training requires considerable amounts of energy (Parcollet et al., 2023b).

Likewise, few existing self-supervised models use half-precision numbers, even though this technique can half the memory requirements and accelerate the arithmetic computations on recent GPUs (Micikevicius et al., 2018). A similar issue happens with dynamic batching (Gaol et al., 2023; Tyagi and Sharma, 2020), a procedure that avoids wasting computing resources on the padded portion of speech mini-batches. Also, most models use standard self-attention layers, though efficient alternatives have been proposed recently, without

using approximations (Dao et al., 2022; Parcollet et al., 2023a).

We address these limitations in the following section, proposing an efficient model for self-supervised learning of speech representations.

### 3 Efficient self-supervised approach

In this section, we describe our proposed model: efficient self-supervised learning (ESSL). We also summarize the optimizations used to improve model efficiency.

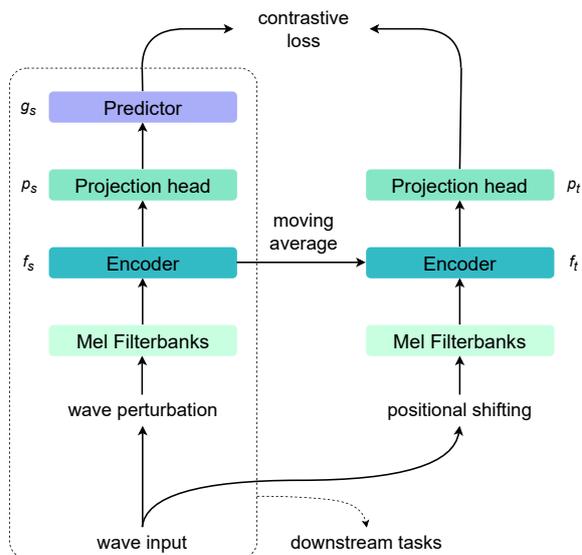

Figure 1: Neural architecture for our proposed ESSL approach, based on a teacher – student configuration (Huang et al., 2022).

#### 3.1 Model architecture

The architecture uses a teacher – student configuration based on recent work for speech processing (Huang et al., 2022). The student part comprises an encoder, a projection head, and a predictor, while the teacher part comprises an encoder and a projection head (Figure 1). Following a conformer configuration (Gulati et al., 2020), the encoder has 3 convolutional layers, followed by 2 self-attention layers, 2 convolutional layers, and 10 self-attention layers. Projection heads are linear layers, and the predictor has 3 convolutional layers (Huang et al., 2022). Self-attention layers use relative position embeddings to better capture the sequence ordering of input sequences (Chen et al., 2022).

Pretraining relies on a contrastive loss to force the student latent representation to converge to the latent representation of the teacher part of the

model, updating teacher weights with an exponential moving average of student weights (Chen et al., 2020; Huang et al., 2022). A contrastive loss in the teacher – student configuration is defined as follows (Chen et al., 2020; Huang et al., 2022):

$$\phi(a, b) = \frac{a^T b}{\|a\| \|b\|} \quad (1)$$

$$\mathcal{L} = - \sum_{i=1}^T \log \frac{e^{\phi(z_i, z'_i)/\tau}}{\sum_{j \in D_i} e^{\phi(z_i, z'_j)/\tau}} \quad (2)$$

where  $z$  is the latent representation from the student network and  $z'$  is the latent representation from the teacher network,  $\tau$  represents a temperature parameter, and  $D_i$  is the set of distractors for the  $z_i$  representation.

Regularization for the proposed model includes dropout, SpecAugment (Park et al., 2019), random positional shifting (Huang et al., 2022), and multicondition training (Chiba et al., 2019) through noise addition. For noise addition, audio data comes from the DNS 2021 challenge (Reddy et al., 2021), adding noise audio to the utterances in the input dataset. Noise addition is performed randomly, with a probability of 0.5 (Huang et al., 2022).

After noise addition, random positional shifting is also used on the input sequences. Random shifting avoids the model exploiting positional information from input sequences. The shifting of input sequences forces the model to focus on speech data, and the sequences for the teacher model are readjusted before calculating the pretraining loss (Huang et al., 2022). Likewise, SpecAugment randomly masks the input audio sequence in the time and frequency domains (Park et al., 2019). Masks use zero values in the time domain, while Gaussian noise replaces the speech data of the masks in the frequency domain. Finally, dropout is applied in the self-attention layers of the model (Park et al., 2019).

### 3.2 Model optimizations

Optimizations in our proposed model include flash attention (Dao et al., 2022), mixed precision training (Micikevicius et al., 2018), dynamic batching (Tyagi and Sharma, 2020), gradient accumulation (Huang et al., 2023), and acoustic feature extraction (AFE) with input preprocessing (Parcollet et al., 2023b). AFE comprises the first part of the neural model, processing the input signal before feeding it to the subsequent layers. The best-performing

approaches for AFE combine Mel Filterbanks for preprocessing the raw waveform before the convolutional module (Parcollet et al., 2023b), as we do in ESSL.

Batch sizes have a considerable impact on training performance (Chen et al., 2023; Hsu et al., 2021). To deal with the high memory requirements of large batch sizes with a single GPU, gradients are accumulated for a few training steps before applying them to update the parameters of the model (Huang et al., 2023). This approach enables the increase in batch size to get close to batch sizes used in large models (Liu et al., 2023a).

Another optimization involving training batches is dynamic batching (Ravanelli et al., 2021). Based on the duration of each audio file, dynamic batching packages one or several files into a single batch, keeping the total batch duration under a specified maximum duration. By doing so, dynamic batching minimizes the amount of padding that fixed batch sizes must use. This optimization reduces the amount of RAM required to train a model. It also eliminates the GPU iterations wasted when processing the padding data in fixed batch sizes.

Concerning the number format for model parameters and data, mixed precision training uses the floating point 16 (FP16) format. FP16, also known as half-precision, diminishes the size of the model and the batches, using less RAM during training than the floating point 32 (FP32) commonly used in computations. FP16 also enables faster training in the GPU, without affecting the convergence of the model (Micikevicius et al., 2018; Narayanan et al., 2021).

Lastly, FlashAttention (Dao et al., 2022) improves the efficiency of self-attention layers by focusing on the optimization of the input-output (IO) memory operations in the GPU. In general, GPUs have two kinds of memories. A small SRAM is associated with each kernel, and a large high-bandwidth memory, which is slower and is shared between all the kernels. Memory-intensive operations, like the matrix operation of the self-attention layers, have their bottleneck at the read-write RAM access. In contrast, compute-intensive operations have their bottleneck in the number of arithmetic operations that must be realized. As self-attention is primarily a memory-intensive operation, FlashAttention reduces the number of IO operations by tiling, assigning a matrix operation to a single kernel, and saving some results from the forward pass to share in the subsequent backward pass.

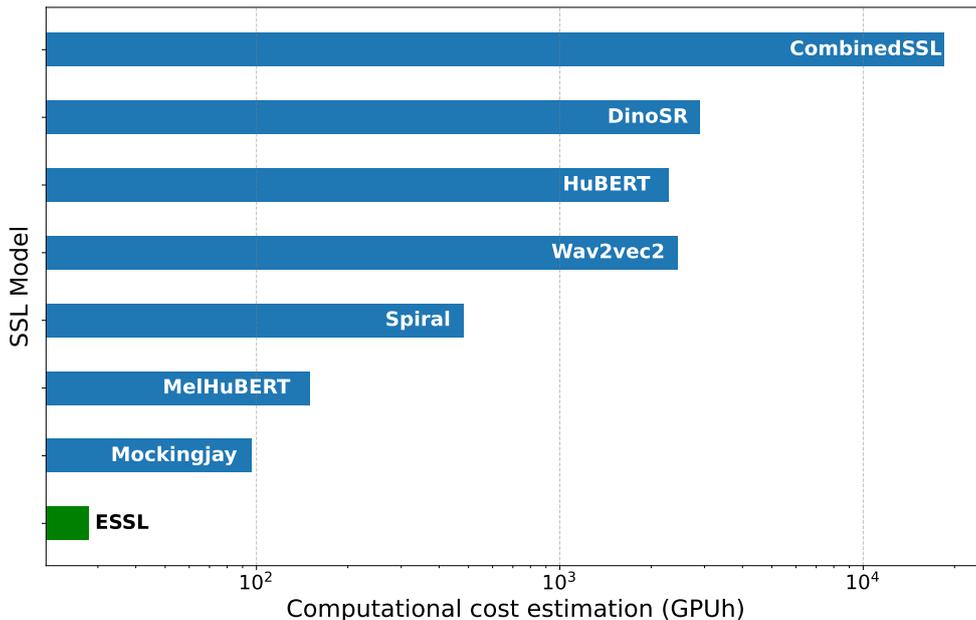

Figure 2: Cost estimation for pretraining speech SSL models. ESSL represents a remarkable reduction in computational costs against existing models.

#### 4 Results and discussion

All experiments run on a single GPU, an NVIDIA GeForce RTX 3090 Ti, with 24 GB of memory and 1.56GHz of base clock rate. Considering training data, LibriSpeech 960h provides speech utterances for unsupervised pretraining. Finetuning for Automatic Speech Recognition (ASR) is performed with LibriSpeech 100h (Panayotov et al., 2015), using a CTC loss (Yan et al., 2023). Regarding training configuration, pretraining requires 60k iterations, which is equivalent to 15k pretraining steps because we do four gradient accumulations. The learning rate warms up the first 8% of the iterations to a maximum of  $3e-4$ . For finetuning, 160k iterations are performed. This is equivalent to 40k finetuning steps with four gradient accumulations. The learning rate warms up the first 10% of the iterations to a maximum of  $3e-5$  (Huang et al., 2022). Code is publicly available<sup>1</sup> to facilitate the replication of experimental results.

Efficiency gains of ESSL are remarkable (Figure 2). Though metrics degrade against large speech models (Table 1), the computational cost estimation represents a fifth of recent work (Lin et al., 2023), diminishing from 150 GPUh to only 28 GPUh, and about a third of recent work (Liu et al., 2020). When doing a comparison against large

<sup>1</sup><https://github.com/Orange-OpenSource/essL>

SSL Model	ASR
Mockingjay (Liu et al., 2020)	15.48
wav2vec (Schneider et al., 2019)	11.00
vq-wav2vec (Baevski et al., 2020a)	12.80
wav2vec2 Base (Baevski et al., 2020b)	4.79
HuBERT Base (Hsu et al., 2021)	4.79
Spiral Base (Huang et al., 2022)	3.30
WavLM Base (Chen et al., 2022)	3.40
CombinedSSL (Zhang et al., 2020)	1.60
ESSL	10.69

Table 1: WER for LibriSpeech test-clean dataset (Yang et al., 2021). Models are pretrained with LibriSpeech 960h. ASR results use a language model for decoding.

models, their computational cost estimations are around one or two orders of magnitude larger. For example, Spiral takes 480 GPUh, which is 17 times larger than our proposed approach. Similarly, CombinedSSL takes 18432 GPUh, which is 658 times larger than ESSL.

As mentioned, batch size is crucial for training speech processing models (Chen et al., 2023). Using dynamic batching, half-precision, and gradient accumulation enables ESSL to get close to the batch sizes used in large speech models – but using one GPU only. The batch size has 18 minutes of audio data. With 4 gradient accumulations, it gets to 72 minutes. This size is close to batch sizes used

in recent speech models, such as 47 minutes in HuBERT, 96 minutes in wav2vec2, or 187 minutes in WavLM (Liu et al., 2023a).

Perturbations on input speech sequences are also crucial for the performance of ESSL. Removing them makes WER degrade from 29.91% to 40.08% (Table 2). This drop in performance indicates the importance of SpecAugment, random positional shifting, and multicondition training through noise addition in the pretraining process.

Other experiments to analyze ESSL include random initialization and MelHuBERT configuration. For experiments with MelHuBERT configuration, we used 40 Mel Filterbanks, with a 20ms hop length (Lin et al., 2023). Though training steps can be up to 36% faster given shorter input sequence lengths, WER drops considerably, going from 29.91% down to 51.09%. Concerning random initialization, we discarded pretrained weights and finetuned from a model with random weights. Results suggest finetuning only is not enough for speech processing. A WER of 99.7% highlights the importance of pretraining in final ESSL results.

Configuration	dev-other	dev-clean
ESSL	<b>28.18</b>	<b>10.38</b>
- w/o perturbations	40.08	17.88
- w/ 40 Mel Filterbanks	51.09	26.41
- random initialization	99.70	99.78

Table 2: Analysis of different configurations for ESSL. Results include WER performance on LibriSpeech dev-other and dev-clean datasets.

## 5 Limitations

Very-low data settings are challenging. The limited availability of data hinders research in speech processing for under-resourced languages (Liu et al., 2023b; Shi et al., 2021). We tested finetuning ESSL for ASR with the Librilight dataset (Kahn et al., 2020). Librilight has 10 hours, 1 hour, and 10 minutes datasets to finetune models, in contrast with the 100 hours available in LibriSpeech. Results indicate ESSL struggles in very-low data settings, with a WER of 97.30% in LibriSpeech dev-other (Table 3). This performance degradation is too high to perform ASR for under-resourced languages.

Method	dev-clean	dev-other
Librilight 10 min		
ESSL	96.41	97.30
wav2vec2 Base	8.9	15.7
HuBERT Base	9.1	15.0
Librilight 1 hr		
ESSL	96.05	96.41
wav2vec2 Base	5.0	10.8
HuBERT Base	5.6	10.9
Librilight 10 hr		
ESSL	70.45	81.62
wav2vec2 Base	3.8	9.1
HuBERT Base	3.9	9.0

Table 3: WER results for LibriSpeech dev-other and dev-clean datasets, using the Librilight very-low data settings of 10 minutes, 1 hour, and 10 hours for model finetuning.

## 6 Conclusion

In this work, we proposed ESSL, an efficient approach for self-supervised learning of speech representations. ESSL addresses high computational costs by combining several model optimizations and fixing a limit on computational resources available for pretraining. Estimations of computational cost reduction reveal up to two orders of magnitude improvements against existing speech SSL models. Overall, ESSL is a step in the process of reducing computational costs in SSL models, enabling their training in edge devices, facilitating the development of new approaches, and making them more environmentally friendly.

For future work, we will investigate our efficient approach for other speech processing tasks, including intent classification, keyword spotting, query by example, and other downstream tasks. We will also explore architectural modifications to improve model performance in very-low data settings.

# Improving Cross-Domain Low-Resource Text Generation through LLM Post-Editing: A Programmer-Interpreter Approach

Zhuang Li, Levon Haroutunian,  
Raj Tumuluri, Philip Cohen, Gholamreza Haffari

Openstream.ai

{zhuang.li, levon, raj, phil.cohen, reza.haffari}@openstream.com

## Abstract

Post-editing has proven effective in improving the quality of text generated by large language models (LLMs) such as GPT-3.5 or GPT-4, particularly when direct updating of their parameters to enhance text quality is infeasible or expensive. However, relying solely on smaller language models for post-editing can limit the LLMs’ ability to generalize across domains. Moreover, the editing strategies in these methods are not optimally designed for text-generation tasks. To address these limitations, we propose a neural programmer-interpreter approach that preserves the domain generalization ability of LLMs when editing their output. The editing actions in this framework are specifically devised for text generation. Extensive experiments demonstrate that the programmer-interpreter significantly enhances GPT-3.5’s performance in logical form-to-text conversion and low-resource machine translation, surpassing other state-of-the-art (SOTA) LLM post-editing methods in cross-domain settings.

## 1 Introduction

Large pre-trained language models like GPT-3.5<sup>1</sup> or GPT-4<sup>2</sup> have gained significant attention in natural language research. However, fine-tuning these models for specific tasks is challenging due to limited computational resources or inaccessible parameters. Consequently, many researchers resort to using web APIs for instructing LLMs, leveraging zero-shot or few-shot in-context learning, enabling the LLMs to tackle tasks they weren’t explicitly trained for. Unfortunately, this approach falls short when tackling some low-resource sequence generation tasks in machine translation (MT), and logical form (LF)-to-text translation, as shown in Lai et al. (2023); Haroutunian et al. (2023). In such cases, minimal task-specific data was available during the

<sup>2</sup><https://platform.openai.com/docs/models/gpt-4-and-gpt-4-turbo>

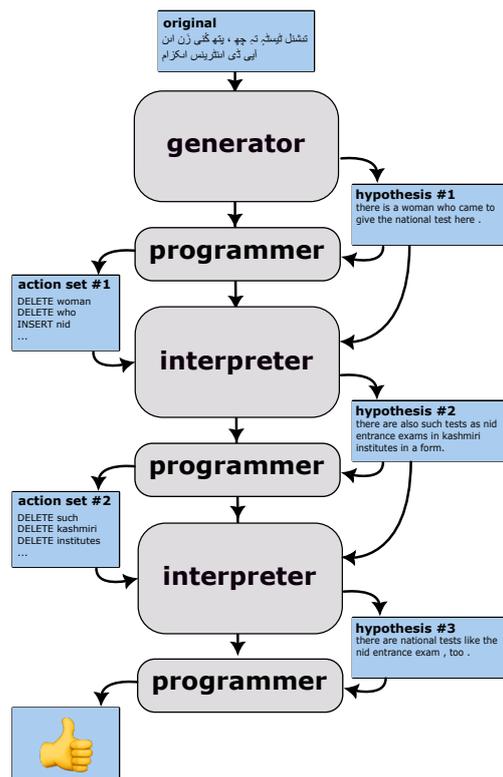

Figure 1: The diagram of our post-editing architecture.

LLMs’ pre-training phase. The output quality of LLMs for such tasks is compromised due to the absence of task-specific knowledge.

To address this challenge, a promising set of solutions suggests integrating task-specific knowledge into language models through post-editing the generated text using a smaller model fine-tuned on task-specific data. Yet, these methods are not without their drawbacks. Our findings indicate that exclusive reliance on a smaller model for editing, e.g. Self-Correct (Welleck et al., 2022), results in suboptimal performance in domain generalization scenarios, likely due to the inherently limited domain knowledge within these smaller models.

As LLMs (i.e. GPT-3.5 or GPT-4) have shown superior domain generalization ability (Wang et al.,

2023; Yang et al., 2023) over the fine-tuned model, we introduce an innovative approach based on the programmer-interpreter framework (Reed and de Freitas, 2016), which benefits from the domain generalization ability from LLMs. The programmer component - a smaller language model fine-tuned on task-specific data - delivers precise edit instructions to the larger language model, thus infusing the large model with task-specific knowledge. The interpreter, in turn, edits the large model’s output given the provided instructions. Contrary to the Self-Correct (Welleck et al., 2022) approach that utilizes smaller, fine-tuned models for editing, our interpreter is also an LLM. The editing is accomplished through the use of prompts that include editing instructions, eliminating the need for any additional fine-tuning. This distinct framework guarantees the preservation of the LLM’s domain generalization ability while simultaneously benefiting from the task-specific knowledge encoded by the programmer. Our method distinguishes itself from approaches like PiVe (Han et al., 2023), which also employ an LLM as the interpreter but focus on graph generation tasks. In contrast, our approach specifically designs word-level editing actions in the instructions, tailored to enhance text generation. This targeted strategy renders our method more effective for text-generation tasks.

Overall, our key contributions are as follows:

- We introduce a novel programmer-interpreter method that enhances LLM in low-resource cross-domain text generation tasks. This approach capitalizes on the programmer’s ability to encode task-specific knowledge and the interpreter’s prowess in domain generalization.
- We design editing operations optimized for text generation tasks, leading to substantial text quality improvements by simply prompting the LLMs with action instructions.
- In scenarios where training and test data span different domains, our comprehensive empirical studies confirm that the method outperforms all existing LLM post-editing baselines in low-resource MT and LF-to-Text.

## 2 Programmer-Interpreter Approach

The objective in LF-to-text and MT tasks using LLMs is to generate a high-quality output text  $\mathbf{y}$ , denoted as  $\mathbf{y}' = \arg \max_{\mathbf{y} \in \mathcal{Y}} P(\mathbf{y}|\mathbf{x}, \mathcal{C})$ , given an input  $\mathbf{x}$  (e.g., LF, source-language utterance) and an

exemplar pool  $\mathcal{C} = \{(\mathbf{x}_j, \mathbf{y}_j, \mathbf{y}_j^*, \mathbf{a}_j^*)\}_{j=1}^{|\mathcal{C}|}$ . Here,  $\mathbf{x}_i$  and  $\mathbf{y}_j$  are the ground truth input-output pairs,  $\mathbf{y}_j^*$  is the imperfect translation of  $\mathbf{x}_i$ , and  $\mathbf{a}_j^*$  represents the Oracle edit actions that can modify  $\mathbf{y}_j^*$  into  $\mathbf{y}_j$ . Our approach focuses on achieving high-quality generation through iterative refinement of the initial output text produced by an LLM. Specifically, the iterative refinement framework includes three-parameterized modules: a Generator, a Programmer, and an Interpreter,<sup>3</sup>

$$P(\mathbf{y}^t|\mathbf{x}, \mathcal{C}) = \overbrace{P(\mathbf{y}^0|\mathbf{x}, M(\cdot))}^{\text{Generator}} \times \sum_{\{\mathbf{a}, \mathbf{y}\}} \prod_{i=0}^{t-1} \overbrace{P(\mathbf{y}^{i+1}|\mathbf{a}^i, \mathbf{y}^i, \mathbf{x}, A(\cdot))}^{\text{Interpreter}} \times \overbrace{P(\mathbf{a}^i|\mathbf{y}^i, \mathbf{x})}^{\text{Programmer}} \quad (1)$$

$$(2)$$

The Generator corresponds to the LLM (e.g. GPT-3.5, GPT-4). It produces the initial output text,  $\mathbf{y}^0$ , given the input  $\mathbf{x}$ , a set of examples retrieved by the function  $M(\mathbf{x}, \mathcal{C})$  when performing in-context learning. The Programmer, a module that creates editing actions  $\mathbf{a}^i$  given  $\mathbf{x}$  and the current imperfect output  $\mathbf{y}^i$ , is a pre-trained Sequence-to-Sequence (Sutskever et al., 2014) language model, such as mT5 (Xue et al., 2021) or flan-T5 (Chung et al., 2022), fine-tuned on a synthetic dataset. The Interpreter, essentially also an LLM, refines the imperfect intermediate output  $\mathbf{y}^i$  by processing instructions that incorporate predicted editing actions and few-shot editing examples, retrieved via the function  $A(\mathbf{x}, \mathcal{C})$ . Please note that the Programmer has much fewer parameters than the LLM used by the Generator and Interpreter. After several iterative refinements, we arrive at the final output  $\mathbf{y}^t$  generated by the LLM. During generation, we assume no access to the parameters of the LLMs but only obtain the output text by providing prompting instructions. The implementation details of each module are as follows:

**Generator.** To generate the initial output, we supply a prompt composed of a few-shot set of exemplar pairs, denoted as  $M(\mathbf{x}, \mathcal{C}) = \{(\mathbf{x}_j, \mathbf{y}_j)\}_{j=1}^m$ , selected from a pool of reference pairs  $\mathcal{C}$ . This is accompanied by an instruction prompting the LLM to produce output  $\mathbf{y}^0$  based on the input  $\mathbf{x}$ . The retrieval function identifies the closest pairs by calculating the cosine similarity of TF-IDF features between  $\mathbf{x}$  and other instances of  $\mathbf{x}$  in  $\mathcal{C}$ .

<sup>3</sup>To save space, we simplify the marginalization notation.

**Programmer.** After obtaining the initial or intermediate output  $\mathbf{y}^i$  from either the Generator or the Interpreter, we combine the input  $\mathbf{x}$  and  $\mathbf{y}^i$  into a single sequence and feed it to the Programmer to generate a sequence of edit actions  $\mathbf{a}^i$ . We create a synthetic training set  $\mathcal{T}$ , extracted from the example pool  $\mathcal{C}$ , for fine-tuning the Programmer. Each pair in  $\mathcal{T}$  is defined as  $(\mathbf{x}_{concat}, \mathbf{a}^*)$ , where  $\mathbf{x}_{concat}$  is the concatenated sequence of  $\mathbf{x}$  and  $\mathbf{y}^*$ , serving as the input for the Programmer. The output  $\mathbf{a}^*$  is the sequence of Oracle edit actions, synthetically generated based on the reference pairs in  $\mathcal{C}$ . For each reference  $\mathbf{y} \in \mathcal{C}$ , we calculate the word-level edit distance to the imperfect translation  $\mathbf{y}^*$ , generating intermediate edit actions. Only *INSERT*-word and *DELETE*-word actions are retained in the sequence, forming the final training sequence  $\mathbf{a}^*$  for the Programmer. If  $\mathbf{y}^*$  is identical to the reference  $\mathbf{y}$ , the action is labeled as “NoAction”, indicating that no refinement is needed for that instance. Unlike PiVe, which generates the imperfect translation  $\mathbf{y}^*$  by scrambling the original  $\mathbf{y}$ , we directly use the initial output  $\mathbf{y}^0$  from the Generator as  $\mathbf{y}^*$  in both  $\mathcal{C}$  and  $\mathcal{T}$ . This approach enables the Programmer to learn an action distribution that more effectively corrects translation errors from LLMs.

**Interpreter.** To edit the intermediate output  $\mathbf{y}^i$ , we engage the LLM in the Interpreter role by providing it with prompting instructions. Given the edit instructions  $\mathbf{a}^i$  and a pair  $(\mathbf{y}^i, \mathbf{x})$ , the LLM can *INSERT* or *DELETE* words *in order* to generate the modified text  $\mathbf{y}^{i+1}$ . We also incorporate a few-shot examples that demonstrate editing procedures, extracted from  $\mathcal{C}$  and denoted as  $A(\mathbf{x}, \mathcal{C}) = \{(\mathbf{x}_j, \mathbf{y}_j, \mathbf{y}_j^*, \mathbf{a}_j^*)\}_{j=1}^n$ . These examples are selected based on the cosine similarity between the TF-IDF features of  $\mathbf{x}$  and those in  $\mathcal{C}$ . Furthermore, to mimic action prediction errors from the Programmer, we adopt an *adversarial in-context learning* strategy, similar to the approach in Zhuo et al. (2023). This involves corrupting the action sequence by deleting Oracle actions with a certain probability  $d\%$ . If an action is not deleted, we swap it with other actions from  $\mathcal{C}$  at the same probability  $d\%$ . Through this manipulation, we have discovered that the LLM’s exceptional text generalization ability enables it to effectively comprehend the editing instructions. As a result, it can generate high-quality text after performing the necessary edits, even if the predicted actions from the Programmer are not completely accurate. See

Figures 2 and 3 in the Appendix for zero/few-shot instruction examples.

### 3 Experiments

**Setup.** In our experiments, we default to using GPT-3.5-turbo-0301 as the LLM for the Generator in both the zero-shot and few-shot settings. For the Interpreter, we use GPT-3.5-turbo-0301 in the zero-shot setting and GPT-3.5-turbo-16k<sup>4</sup> in the few-shot setting. For the Generator used across all settings and baselines, we consistently use 0 and 5 shots for MT and LF-to-Text, respectively. For the Interpreter in the few-shot setting, we apply 10 and 5 action examples for MT and LF-to-Text, respectively, with a 50% action corruption probability. For the MT and LF-to-Text tasks, we employ mT5-base and flan-T5-base as the backbones of the Programmers, respectively. These backbone choices are driven by our emphasis on a computationally efficient setup, ensuring the models fit within an Nvidia V100 with 16GB memory. We train our programmers with a development set to select the optimal model. Our search for the best learning rate includes [5e-5, 1e-4, 2e-4], while the range of epochs considered is [5, 10, 20], with batch sizes 4. GPTs require no fine-tuning. Each generation of 1096 tokens costs approximately \$0.0015. For Self-Correct and Self-Refine, we perform five editing iterations. Prog-Refine and Algo-Refine stop when more than 95% of action is ‘NoAction’.

**Datasets.** To simulate low-data scenarios, in the context of **MT**, we utilize a Kashmiri-English dataset from IndicTrans2 (Gala et al., 2023). Since Kashmiri is a notably low-resource language, translating it poses a formidable challenge for LLMs. The dataset provides 26,016 training pairs, which we use to generate synthetic data for action generation. The development set consists of 997 pairs. The dataset includes two distinct test sets, GEN and CONV, with 1,024 and 1,503 pairs, respectively. Each of the training, development, and test sets originates from different domains. For **LF-to-Text**, we employ the AMR-LDC2.0<sup>5</sup> dataset, which contains 22,550 AMR-English pairs for training and 1,368 pairs for development. For testing, we turn to a separate dataset, Bio-AMR<sup>6</sup>, which offers 500 pairs in a different domain. Likewise, the AMR-to-Text task poses a low-resource challenge for LLMs.

Prog-Refine (Few-shot Act.)	16.32	<b>90.36</b>	<b>42.44</b>	<b>14.78</b>	<b>90.19</b>	<b>35.48</b>	<b>13.64</b>	89.27	<b>47.69</b>
Prog-Refine (ORACLE)	43.48	92.11	65.29	42.42	93.00	42.42	27.77	90.01	52.86

Table 1: The main results of MT on GEN and CONV test sets, and LF-to-Text on Bio-AMR test set.

**Baselines.** We evaluate our approach, Prog-Refine, which utilizes zero-shot action exemplars (Zero-shot Act.) and few-shot action exemplars (Few-shot Act.) for Interpreters, against five baseline methods and an ORACLE setting

i) **Fine-tuned Models** include mT5-base for MT and flan-T5-base for LF-to-Text generation, both of which are fine-tuned on the training set consisting of pairs  $(x, y) \in \mathcal{C}$ . These baseline models do not perform any refinement.

ii) **GPT-3.5 + Initial** simply applies the GPT-3.5 as the Generator to obtain the text without any further refinement.

iii) **GPT-3.5 + Self-Correct (Welleck et al., 2022)** fine-tunes smaller models to be the Interpreter, fixing the output errors of the large models given the feedback. Here, we supply the edit actions produced by our Programmer as feedback to the fine-tuned Interpreters. These Interpreters are also built upon mT5-base or flan-T5-base.

iv) **GPT-3.5 + Algo-Refine** directly ‘Insert’ or ‘Delete’ specific words in certain positions of the generated text instead of using an Interpreter to rewrite. Therefore, in this baseline, we also apply the Interpreter to predict the indices of words for actions. This method is prevalent in the MT literature; e.g. see [Vu and Haffari \(2018\)](#).

v) **GPT-3.5 + Self-Refine (Madaan et al., 2023)** leverages an LLM to provide feedback for its own output, enabling self-refinement without the need for additional fine-tuning.

vi) **GPT-3.5 + Prog-Refine (ORACLE)** applies the ORACLE actions generated by comparing the reference in the test set with the initial output of the Generator, allowing for optimal refinement after one iteration in the Zero-shot Act. setting.

**Evaluation Metrics.** For LF-to-Text and MT tasks, we utilize three evaluation metrics to assess the quality of the final output text generated by the

Programmer-Interpreter framework: BLEU ([Papineni et al., 2002](#)), BERTScore ([Zhang et al.](#)) and ChrF++ ([Popović, 2017](#)).

### 3.1 Main Results and Analysis

Table 1 shows that *GPT-3.5 + Prog-Refine* notably boosts the Generator’s performance (i.e., *GPT-3.5 + Initial*), underlining our method’s effectiveness in cross-domain scenarios by enhancing initial GPT-3.5 outputs. Moreover, the few-shot setting (Few-shot Act.) significantly outperforms both the zero-shot (Zero-shot Act.) setting and all other refinement baselines. It’s also noteworthy that applying ORACLE action to our method can lead to a roughly 30-point increase in BLEU score, suggesting substantial potential for improvement in our approach. In comparison, *Self-Refine* shows minimal improvement, possibly due to its limited integration of task-specific knowledge. *Algo-Refine* inconsistently improves the initial text, lacking the robustness seen in our method. We note that rewriting Interpreters, as in our approach and Self-Correct, can eliminate invalid actions, thus enhancing editing quality. However, *Algo-Refine* does not possess this capability and is susceptible to incorrect feedback actions. The *Self-Correct* method, using a fine-tuned Interpreter, along with fine-tuned mT5/flan-T5 models, demonstrates better performance than other baselines across various tasks. This underscores the importance of learning task-specific knowledge, especially in low-resource scenarios. Nonetheless, these methods face significant challenges in cross-domain applications, as further evidenced by our analysis in Table 4.

### 3.2 Ablation Study

**Refinement Iterations.** In Table 2, we observe that Prog-Refine significantly improves the initial output generated by the Generator. However, it only demonstrates marginal improvements in the

#Iter	BLEU	BERT	ChrF++	NoAct%
Iter 0	5.92	89.00	33.27	17.70
Iter 1	11.01	89.18	33.05	79.71
Iter 2	11.87	89.36	33.41	90.67
Iter 3	12.09	89.41	33.41	95.28
Iter 4	12.26	89.45	33.43	97.21
Iter 5	12.36	89.47	33.39	-

Table 2: The influence of multiple iterations on main results of MT using Prog-Refine (Zero-shot Act.) on CONV test set. NoAct%: The percentage of utterances requiring no refinement, as indicated by ‘NoAction’.

	BLEU	BERT	ChrF++
Initial	5.92	89.00	33.27
Edit: DEL, INS	12.36	89.47	33.39
Edit: DEL	12.27	89.42	33.21
Edit: INS	12.18	89.45	33.42
Unordered: DEL, INS	7.12	87.86	29.21
Unordered: DEL	6.52	87.51	26.46
Unordered: INS	7.14	88.04	30.38

Table 3: The results of MT using Prog-Refine (Zero-shot Act.) on CONV test set with different types of actions. Edit: Actions are generated based on edit distance. Unordered: Actions without any specific order. INS: Insertion. DEL: Deletion.

subsequent outputs from the Interpreter, even after four additional iterations. We hypothesize that this limited improvement may be attributed to training the model solely on synthetic data generated by the Generator, so the action distribution might be different to the ones for modifying the output of the Interpreter in the subsequent iterations.

**Action Types.** We further examine the impact of solely utilizing one type of action and the influences of disregarding the sequence of these actions. In the setting with unordered actions, oracle actions are generated by simply contrasting the differences within two sentences’ unordered sets of words. As depicted in Table 3, the *Delete* and *Insert* actions, when used individually, can deliver performance metrics on par with when they are combined. However, ignoring the order of actions can lead to a substantial decline in the refinement performance. This highlights that LLM editing methods like PiVe, which utilize unordered insertions, are not optimally suited for our tasks. Further analysis is in Appendix A.5.

**Domain Discrepancy.** As shown in Table 4, a domain shift dramatically impacts the performance of flan-T5 and Self-Correct. While both baseline models show markedly superior performance on

Method	BLEU	BERT	ChrF++
Fine-tuned flan-T5	<b>34.63</b>	<b>95.05</b>	<b>66.97</b>
GPT-3.5			
Initial	19.67	92.10	55.98
Self-Correct	34.49	94.68	66.81
Self-Refine	16.16	91.08	52.78
Prog-Refine	29.12	94.01	64.85

Table 4: LF-to-Text results using Prog-Refine (Zero-shot Act.) on the in-domain LDC test.

Rate	BLEU	BERT	ChrF++
0.0	12.06	89.31	46.23
0.2	12.35	<b>89.36</b>	46.49
0.5	<b>13.64</b>	89.27	<b>47.69</b>
1.0	11.97	89.32	46.13

Table 5: LF-to-Text results using Prog-Refine (Few-shot Act.) vary with different corruption probabilities for the action sequence in the adversarial in-context examples used for the Interpreter.

the in-domain test set relative to our model, ours either surpasses or equals their performance in the cross-domain MT and AMR-to-Text test sets. This disparity in performance is likely due to the smaller models’ limited cross-domain generalization. Similarly, in MT tasks, our preliminary experiments show that fine-tuned mT5 achieves 30 points of BLEU on the in-domain test but only 16 and 13 on out-of-domain tests. For further details on domain discrepancies, see Appendix A.3.

**Adversarial In-context Learning.** Table 5 indicates 0.0 for no corruption and 1.0 for complete discarding of exemplar actions, leaving only  $(\mathbf{x}_j, \mathbf{y}^*j, \mathbf{y}j)_{j=1}^n$ . Rates between 0.0 and 1.0 represent partial corruption of Oracle actions. The results suggest that neither full application nor total corruption of Oracle actions is optimal. However, partial corruption leads to improved performance. Additionally, across all corruption rates, few-shot settings consistently outperform zero-shot settings.

## 4 Conclusions

We present a programmer-interpreter method that iteratively refines LLM outputs using edit actions from a fine-tuned programmer and an LLM interpreter. Our approach combines the task-specific encoding capacity of a fine-tuned model with the domain generalization strength of the LLM, incorporating specifically designed actions for text generation. The experiments confirm its efficacy, showing significant improvements in LLM-generated text quality for low-resource MT and LF-to-Text tasks. Moreover, our approach outperforms established baselines in cross-domain scenarios.

## 5 Limitations

This work has two primary limitations. First, in in-domain tests, our approach does not outperform smaller models, such as mT5 and flan-T5. Considering the performance improvements we observed when using ORACLE actions, we believe there is substantial potential to further enhance our method for text generation in the in-domain evaluation setting. Second, our approach requires internet transmission of prompt instructions to the servers of ChatGPT. This could potentially lead to a risk of privacy leakage, which is a critical concern in data-sensitive applications.

## A Appendix

### A.1 Prompt Example for Editing Text

Figures 2 and 3 depict the exemplary zero/few-shot prompt employed in LF-to-Text.

You are a AMR translator and you are proficient with both AMR and English.

You are given the following AMR logical form:

```
( q / quote-01 : arg0 ( r / report ) : arg2 ( a2 / and : op1 ( g / government-organization : arg0-of ( g4 / govern-01 : arg1 ( c / country : wiki `` greece `` : name ( n2 / name : op1 `` greece `` ) ) ) ) : op2 ( g2 / government-organization : arg0-of ( g5 / govern-01 : arg1 ( c2 / country : wiki `` turkey `` : name ( n4 / name : op1 `` turkey `` ) ) ) ) : op3 ( g3 / government-organization : arg0-of ( g6 / govern-01 : arg1 ( c3 / country : wiki `` belarus `` : name ( n6 / name : op1 `` belarus `` ) ) ) ) : arg3 ( a / acknowledge-01 : arg0 a2 : arg1 ( m / miss-02 : arg0 a2 : arg1 ( d / deadline ) ) ) ) )
```

You are given the following English translation:

the report quotes the governments of greece , turkey and belarus acknowledging that they missed the deadline .

Please improve the above English translation using the following edit rewriting actions:

```
DELETE : quotes
INSERT : quoted
INSERT : as
DELETE : they
...
INSERT : missed
```

Please only show the English sentence:

Figure 2: The zero-shot exemplary prompt for LF-to-Text.

Here are the edit rewriting examples:

```
### Example 1:

You are a AMR translator and you are proficient with both AMR and English.
You are given the following AMR source logical form:

( i / increase-01 : arg1 ( e / express-03 : arg2 ( p / protein ) ) : arg2 ( p2 / product-of : op1 10 ) : arg1-of ( s / statistical-test-91 : arg2 ( l / less-than : op1 0.05 ) ) )

You are given the following English translation:

there was a statistically significant increase in protein expression ( 10 fold , p < 0.05 ) .

Please improve the above English translation using the following edit rewriting actions:

DELETE "was" from the translation
DELETE "significant" from the translation
DELETE "fold" from the translation
DELETE "increase" from the translation

Please provide a fluent English sentence that is semantically equivalent to the AMR logical form after editing its corresponding English translation.

Improved English sentence:

protein expression increased 10-fold ( p < 0.05 ) .

### Example 2:
...
### Example 3:
...
### Example 4:
...

```

Figure 3: The few-shot exemplary prompt for LF-to-Text.

### A.2 Adaption of Self-Corrector

In our experiment, we adapted the implementation of the Self-Corrector to better suit our specific requirements. To customize it for our context, we constructed the training set for the Self-Corrector’s Interpreter as follows: the input consists of a concatenation of Kashrimi/AMR, text produced by the

splits compared	KL-div ↓	MAUVE ↑
train, dev	2.23	0.006
dev, test <sub>gen</sub>	1.97	0.231
train, test <sub>gen</sub>	1.94	0.005
dev, test <sub>conv</sub>	2.97	0.040
train, test <sub>conv</sub>	2.98	0.007

Table 6: Measures of domain difference across different splits of the machine translation datasets. KL-divergence scores are calculated for the English sentences in each data split, with additive smoothing ( $\alpha = 1 \times 10^{-4}$ ). For MAUVE, 5000 sentences are sampled from the training set.

splits compared	KL-div ↓	MAUVE ↑
train, dev	2.00	0.512
dev, test <sub>i.d.</sub>	2.39	0.327
train, test <sub>i.d.</sub>	1.97	0.342
dev, test <sub>bio</sub>	6.01	0.004
train, test <sub>bio</sub>	5.48	0.004

Table 7: Measures of domain difference across different splits of the AMR dataset. KL-divergence scores are calculated for the English sentences in each data split, with additive smoothing ( $\alpha = 1 \times 10^{-4}$ ). For MAUVE, 5000 sentences are sampled from the training set.

Generator, and edit actions. The output, on the other hand, is the ground truth text. For a fair comparison with our approach and to minimize training and data collection expenses, models are trained only during the first iteration. Additionally, the generation of the training set solely utilizes text from the Generator in the initial iteration, without using text from the Interpreter in subsequent refinement iterations.

### A.3 Measures of Domain Discrepancy

Tables 6 and 7 present domain discrepancies for the training/development/testing sets for the MT and LF-to-text generation tasks. The domain discrepancy measures include the KL-divergence (based on the unigram distributions) and MAUVE (Pillutla et al., 2021). KL-divergence scores are higher when two distributions are more different from each other. MAUVE scores, which have a range (0,1), are lower when two distributions are more different from each other.

Based on Table 6, we observe that the domain of test-gen is closer to the training set compared to that of the test-conv. This is pronounced in higher KL-divergence and lower MAUVE numbers for the test-conv compared to test-gen, with respect to

	INSERT	DELETE	Total
MT	33.64	83.73	62.57
NLG	24.52	60.48	44.90

Table 8: The F1 scores of comparing the predicted actions with the ORACLE actions in the GEN test set.

LF-to-Text (AMR to English)			
	BLEU	BERT	ChrF++
GPT-3.5-turbo-16k	11.43	89.30	45.44
GPT-4-turbo	11.72	89.36	45.58

Table 9: LF-to-Text results of Prog-Refine (Zero-shot Act.) in zero-shot setting with different LLMs as Interpreters.

only a 0.3 increase in BLEU score. Moreover, this comes at a higher cost of 0.06 per 1000 characters, compared to 0.0015 for GPT-3.5.

the training set.

Based on Table 7, we observe a higher difference for the domain of the biology-AMR test compared to the LDC2.0-AMR test set, with respect to the training/development sets of the LDC2.0-AMR dataset. This is pronounced in larger KL divergence and lower MAUVE numbers compared to those for the LDC2.0-AMR test set.

#### A.4 F1 Definition for Action Prediction

$$F1 = 2 \times \frac{P_{act} \times R_{act}}{P_{act} + R_{act}} \quad (3)$$

Here,  $P_{act}$  represents action precision, defined as the ratio of predicted actions present in the reference action sequence to the total number of predicted actions.  $R_{act}$  denotes action recall, which is the ratio of predicted actions that appear in the reference action sequence to the total number of actions in the reference sequence. The F1 score, thus, provides a harmonious mean of these two metrics.

#### A.5 F1 for Action Prediction

Table 8 reveals that predicting INSERT actions is a relatively easier task compared to predicting DELETE actions. This observation is reasonable since the Programmer only needs to learn how to DELETE words from the text with a fixed vocabulary, whereas, for INSERT actions, the Programmer must learn to INSERT arbitrary words.

#### A.6 Comparing GPT-4 and GPT-3.5 as Interpreters

Table 9 illustrates the performance differences in the LF-to-Text task when using GPT-4 and GPT-3.5 as Interpreters for Prog-Refine (Zero-shot Act.). While GPT-4 offers a slight performance boost, the improvement is not substantial, amounting to

# Noise Contrastive Estimation-based Matching Framework for Low-Resource Security Attack Pattern Recognition

Huawei R&D Munich

{tu.nguyen, nedim.srndic, alexander.neth}@huawei.com

## Abstract

Tactics, Techniques and Procedures (TTPs) represent sophisticated *attack patterns* in the cybersecurity domain, described encyclopedically in textual knowledge bases. Identifying TTPs in cybersecurity writing, often called *TTP mapping*, is an important and challenging task. Conventional learning approaches often target the problem in the classical multi-class or multi-label classification setting. This setting hinders the learning ability of the model due to a large number of classes (i.e., TTPs), the inevitable skewness of the label distribution and the complex *hierarchical* structure of the label space. We formulate the problem in a different learning paradigm, where the assignment of a text to a TTP label is decided by the direct semantic similarity between the two, thus reducing the complexity of competing solely over the large labeling space. To that end, we propose a neural matching architecture with an effective sampling-based learn-to-compare mechanism, facilitating the learning process of the matching model despite constrained resources.

## 1 Introduction and Background

Cyber Threat Intelligence (CTI), an essential pillar of cybersecurity, involves collecting and analyzing information on cyber threats, including threat actors, their campaigns, and malware, helping timely threat detection and defense efforts. Textual threat reports or blogs are considered an important source of CTI, where security vendors diligently investigate and promptly detail intricate attacks. A key sub-task in extracting CTI from these textual sources involves the identification of Tactics, Techniques, and Procedures (TTP) of the threat actors, i.e. comprehending descriptions of low-level, complex threat actions and connecting them to standardized attack patterns. One of the popular standard knowledge frameworks widely adopted in the CTI community is MITRE ATT&CK (Storm et al., 2020). Within this framework, a technique repre-

*[...] We witnessed that the botnet was spread via mass phishing, using a VB-scripted Excel attachment to download the second stage from xx.warez22.info. The same domain was used for C&C via HTTP. The botnet distributed a file encryption module we named VBenc. [...]*

Figure 1: A fictional attack described in typical cybersecurity threat report writing style.

sents a specific method used to achieve an objective, with its corresponding tactics and sub-techniques covering broader strategies and variations. Fig. 1 illustrates an example of a text in a threat report, which indicates two attack patterns, among others, i.e., (1) the use of a malicious email attachment to take control of a victim’s system (T1566<sup>1</sup>), and (2) encrypting data on the victim’s system, presumably for ransom demands (T1486<sup>2</sup>).

As of 2024, there are over 600 techniques, together with 14 high-level tactics described in MITRE ATT&CK. In its ontology, a technique is associated to at least one tactic (e.g., the technique “Hijack Execution Flow” is listed under three distinct tactics: Persistence, Privilege Escalation and Defense Evasion) and may have several sub-techniques. Mining techniques from CTI reports poses significant challenges due to several factors. Firstly, the large number of techniques, coupled with their diverse nature, intricate interdependencies, and hierarchical structure, renders the task complex and laborious. Secondly, the analysis of CTI reports necessitates the expertise of security professionals. The reports focus on delineating low-level threat actions rather than explicitly mentioning the associated techniques and tactics. Consequently, extracting relevant techniques and tactics from these reports requires diligent inference by the reader. Employing an automated approach to TTP mapping presents inherent chal-

<sup>1</sup>[attack.mitre.org/techniques/T1566](https://attack.mitre.org/techniques/T1566)

<sup>2</sup>[attack.mitre.org/techniques/T1486](https://attack.mitre.org/techniques/T1486)

allenges. One major hurdle is the *low-resource* nature of the task, due to the limited availability of labeled data and the extensive label space. Moreover, the presence of long-tail infrequent TTPs adds complexity to the learning process.

Due to these challenges, TTP mapping has not been fully solved in related work. Most recent works use a classical *document*-level multi-label (Li et al., 2019) or *sentence*-level multi-class classification (Orbinato et al., 2022; You et al., 2022) learning setting. These granularity choices, however, either introduce unneeded complexity of long-form text representation (for *document*-level) or make the task inapplicable to mapping complex TTPs, which often require longer text (for *sentence*-level). Moreover, the main learning issues in these settings are: (i) the aforementioned problems of label scarcity and long-tailedness, and (ii) the learning complexity costs of the softmax-based learning approaches grow proportionally to the number of classes. In the wider literature i.e., extreme multi-label text classification (XMTC), the problems are addressed by (i) capturing the label correlation and (ii) partitioning and handling the sub-label spaces separately. They are, however, most effective in relatively resource-rich settings, and have drawbacks when applied to *label-scarce* scenarios, as the signal-to-noise ratio increases (Bamler and Mandt, 2020). In the multi-label context, learning is greatly affected, additionally, by the frequent presence of *missing* labels, which is a common trait observed in human-curated datasets.

In this work we propose an alternative learning setting which avoids the direct optimization for discriminating between data points in a large label space. Concretely, we transform the task into a *text matching* problem (Tay et al., 2018; Wang et al., 2017), allowing us to utilize the direct semantic similarity between the *input-label* pairs to derive a calibrated assignment score. The framework inherently incorporates an *inductive bias*, encouraging the capture of nuanced similarities even in the presence of limited labeled data, enhancing its ability to generalize to long-tail TTPs. This transformation is achieved by leveraging the *textual profile* of a TTP (i.e., *textual description*<sup>3</sup> in ATT&CK), a resource that is often neglected in related work.

**Label-efficient text matching:** Our approach — dynamic *label-informed* text matching — empow-

<sup>3</sup> A technique, its description and procedure examples: [attack.mitre.org/techniques/T1021/](https://attack.mitre.org/techniques/T1021/)

ered by Noise Contrastive Estimation (NCE) (Gutmann and Hyvärinen, 2010), exploits the shared information between a pair of texts (*text matching*) in the learning phase, and altogether attempts to discriminate between the positive labels versus the rest in the label space (*classification*).

Conventionally, NCEs are used to alleviate computational challenges in parameter estimation for large target spaces. In this work, we apply NCEs uniquely in a **moderately sized label space**, navigating data scarcity and noise constraints. We demonstrate experimentally that our *ranking*-based NCEs, characterized by their probabilistic nature and ability to capture global patterns, can overcome these low-resource constraints and help the matching model perform particularly well. In contrast, common contrastive loss variants, i.e., Triplet Losses lacking these properties, surprisingly performed even worse than we anticipated.

To this end, we summarize our contributions:

- We formally redefine the challenging task of TTP mapping as a *paragraph-level hierarchical* multi-label text classification problem and propose a new learning paradigm that works effectively on the nature of the task.
- We introduce robust ranking-based NCE losses, designed not only to effectively handle the large label space but also the *scarce* and *missing* labels problem specific to this task. Additionally, we present a multi-task learning strategy that adeptly captures the intrinsic hierarchical structure within the label semantics.
- We curate and publicize an expert-annotated dataset that emphasizes on the multi-label nature, with approximately two times more labels per sample than existing datasets.
- Lastly, we conduct extensive experiments to prove our learning methods outperform strong baselines across real-world datasets.

## 2 Related Work

**TTP Mapping and CTI Extraction** Several works target TTP mapping on the *document level*. (Husari et al., 2017) used a probabilistic relevance framework (Okapi BM25) to quantify the similarity between *BoW* representations of TTPs and the target text. However, this approach is limited to the oversimplified vocabulary of threat actions within an *ad-hoc* ontology. Ayoade et al. (2018); Niakanlahiji et al. (2018) used a TF-IDF-based document

representation and leveraged classical (i.e., tree-based, margin-based) ML for (multi-label) classification. Li et al. (2019) used latent semantic analysis to extract topics from target articles, and compared the topic vectors with the TF-IDF vectors of ATT&CK description pages to obtain cosine similarity. They used the similarity vectors with Naïve Bayes and decision trees to classify TTPs. However, the choice of document-level granularity introduces additional unneeded complexity of long-form text representation. Recent works leverage transformers for *sentence-level* text representation learning (Orbinato et al., 2022; You et al., 2022), using the encoded representation in the multi-class classification setting. However, with limited available data, they restrict the task to only a small number of TTPs.

**Extreme Multi-label Text Classification.** XMTC, or generally extreme multi-label classification is a line of research targeting extremely large label spaces, e.g., product categorization in e-commerce or web page categorization. The main challenges for XMTC are computational efficiency and data skewness. Common techniques for XMTC are tree-based (You et al., 2019; Jasinska-Kobus et al., 2020; Wydmuch et al., 2018), sampling-based (Jiang et al., 2021) and embedding-based (Chang et al., 2021) that attempt to partition the label space and thus reduce the computational complexity. However, generally, these methods assume the sufficient availability of supervision and still suffer in the long-tail performance.

**Matching Networks.** Deep matching networks have witnessed rapid progress recently, finding applications in various conventional (e.g., retrieval (Wang et al., 2017)) or emerging tasks (e.g., few-shot (Vinyals et al., 2016) and self-supervised learning (Chen et al., 2020)). They can be architecturally categorized as *cross-* vs *dual-*encoder networks and can be optimized in tandem with the *triplet* (Schroff et al., 2015) or *contrastive loss* (Chopra et al., 2005). The former loss considers triplets of examples (anchor, positive, negative) and is *marginal*-based, whereas the latter, broadly referred to as NCE (Gutmann and Hyvärinen, 2010), utilizes a probabilistic interpretation. Despite demonstrating promising results across various domains and datasets, matching networks necessitate substantial training data. Although the NCE framework partially mitigates this concern, the well-adopted approach by Oord et al. (2018)

remains somewhat limited, especially to the *fully-supervised* settings. Our approach overcomes the present constraints of training matching networks in settings where resources are limited, specifically when there is a scarcity of extensive training data.

### 3 Preliminaries and Problem Setup

We first provide a brief overview of the classification settings with noise contrastive estimation (NCE). These definitions then subsequently help us in formulating our *matching* problem.

**Classification:** Let  $\mathbf{X}$  and  $\mathbf{Y}$  denote the *input* and *label* spaces,  $|\mathbf{Y}| < \infty$ . We define a score function  $g_\theta : \mathbf{X} \rightarrow \mathbf{Y}$ . In this setting, the *label* space  $\mathbf{Y}$  is categorical. Specifically,  $\mathbf{X} \in \mathbb{R}^{n \times m}$ , whereas  $\mathbf{Y} \in \{0, 1\}^{n \times |L|}$ , with  $n$  being the number of samples and  $L$  being the label set.

**Matching:** In this setting,  $\mathbf{X}$  and  $\mathbf{Y}$  represent the same *input* space. The matching function  $g_\theta : \mathbf{X} \times \mathbf{Y} \rightarrow \mathbb{R}$ , is differentiable in  $\theta \in \mathbb{R}^{|\mathcal{D}|}$ , where  $\mathcal{D}$  is the parameter space. In order to cast a *classification* problem as a *matching* one, we assume there is an invertible and smooth *projection* function  $\pi$  that transforms the discrete categorical representation  $\mathbf{Y}$  into the same continuous space as  $\mathbf{X}$ .

**Cross-entropy Loss and NCE:** In either *classification* or *matching* settings, our goal is to estimate whether  $\theta : x \mapsto \max_{y \in \mathbf{Y}} g_\theta(x, y)$  has optimal 0-1 loss. This can be reduced to conditional density estimation. Let  $p_\theta(y|x) = \frac{\exp(g_\theta(x, y))}{\sum_{\tilde{y} \in \mathbf{Y}} \exp(g_\theta(x, \tilde{y}))}$ , the cross-entropy loss is then defined as:

$$J_{CE}(\theta) = \mathbb{E}_{(x, y) \sim (X \times Y)} [-\log p_\theta(y|x)] \quad (1)$$

When  $\mathbf{Y}$  is large,  $J_{CE}(\theta)$  is difficult to compute as the computation of the normalization term of  $p_\theta(y|x)$  becomes expensive. This issue is addressed by NCE through sub-sampling  $p(X, Y)$ , and shifting the focus towards estimating the probabilities of the true data samples.

**Multi-label Classification.** The vanilla classification problem can be defined as follows: Let  $\{X, Y\}$  be the problem space, where the feature space  $\mathbf{X} \in \mathbb{R}^{n \times |\mathcal{D}|}$ , and the label space  $\mathbf{Y} \in \{0, 1\}^{n \times |L|}$ , with  $|L| \ll \infty$  being the number of TTPs in the KB. The goal is to learn a function  $f : \mathcal{D} \mapsto \mathbb{R}^{|L|}$  that accurately predicts the multi-label one-hot vector output  $y \in \mathbf{Y}$ , given  $x \in \mathbf{X}$ .

**Problem Reformulation.** Given the training data  $\mathbf{X} \in \mathbb{R}^{n \times |\mathcal{D}|}$ , and  $\mathbf{Y} \in \mathbb{R}^{|\mathbf{L}| \times |\mathcal{D}|}$ , with  $y \in \mathbf{Y}$  derived from the TTP *textual profile*, and  $|L| \ll \infty$  along with a set of supervisions  $\{x \mapsto y\}^n =$

$\{0, 1\}^n$ , such as  $x \in X$  and  $y \in Y$ , our target is to learn *matching*-based scoring functions  $g_\theta(x, y)$  that model the relationship between  $x$  and  $y$  within the same feature space, aiming for  $g_\theta(x, y) \approx \{x \mapsto y\}^n$ . The use of the *textual profile* inherently eliminates the need for a *projection* function  $\pi$ , as it directly aligns the discrete categorical representation  $Y$  with the same continuous space as  $X$ . In the context of cross-entropy loss,  $p_\theta(y|x)$  is now linked to  $p_\theta(x \mapsto y|x, y)$ .

## 4 Methodology

Here we describe our architectural choice for the matching function  $g_\theta(x, y)$ , and our learning paradigm that approximates  $p_\theta(x \mapsto y|x, y)$  to simultaneously match and compare TTPs labels.

### 4.1 Matching Network

The architecture of our matching network is built upon the *dual*-encoder framework, which typically employs a Siamese network. This shared network is used for learning the representations of both the target text segment and the TTP *textual profile*. As depicted in Fig. 2, at a high level, our network comprises an embedding component and an alignment component. Each includes specific layers aimed at enhancing the connectivity between the two sub-network sides. Finally, the two sides are merged (by, i.e., a dot product) to output a (probabilistic) *matching* score. We detail the architectural choice for our matching network below.

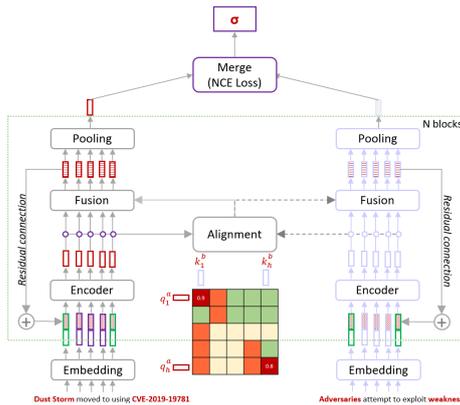

Figure 2: The dual-encoder matching network.

**Encoder.** The encoder has two modes: (1) *scratch* and (2) *scratch* with a pre-trained transformer (i.e., SecBERT) combined. *Scratch* indicates that the token embeddings are learnt (with the embedding layer). We then apply a simple CNN on top of the embedding layer. With *scratch* alone,

a specialized tokenizer (that respects CTI entities, e.g., URL, vulnerability identifier..) is used. While using together with the transformer, the tokenizer of the transformer is used. For (2), we simply stack the encoded vectors from the two sources together.

**Alignment Network.** Formally, given the input representation of the text-TTP pair as  $x_t = (\hat{a}_1, \dots, \hat{a}_l)$  and  $y_{ttp} = (\hat{b}_1, \dots, \hat{b}_l)$ , the unnormalized attention weights are decomposed into:  $e_{ij} = W^{align}(\hat{a}_i) \cdot W^{align}(\hat{b}_j)$ , whereas  $W^{align}$  is a trainable projection matrix,  $\cdot$  is the dot product. Then, we derive the normalized weights for each token  $a_i$  and  $b_j$ , and achieve the corresponding alignment features. Similar to (Yang et al., 2019), we further use the block-based residual architecture with skip connections. Our block consists of the encoder, alignment and fusion layers. The fusion layer does various comparisons of local and aligned representations (i.e., the Hadamard product) and finally fuses the interaction vectors together using the concatenation operator. Then *pooling*, i.e., (non-) weighted average or max-pooling, is applied to attain fixed-length vector representations.

### 4.2 Learning to Match and Contrast

Our efficient learning method aims to circumvent the computational complexities that arise in the large label space, whether in the proper multi-label setting or its reduced multi-class version. The new learning paradigm is shifted from multi-label classification to the so-called *dynamic* label-informed text matching, in which negative labels are drawn dynamically at every step. The *ranker*, acting as a simultaneous matcher, strategically assigns higher probabilities to positive pairs and lower probabilities to negative pairs. Finally, the top- $n$  positive pairs are selected based on a cut-off threshold. We detail our learning mechanism below.

**Partial-ranking-based NCE.** The general idea of NCE in our scenario is to avoid an exhaustive ranking (or partitioning) in the large label space, i.e., in the vanilla multi-label classification setting. Instead, a matching-based classifier,  $p((x \mapsto y)|x, y)$ , is trained to differentiate between samples from the true distribution and a noise distribution,  $q(y)$ , and inherently approximate the underlying ranking function. By utilizing Monte Carlo sampling, the NCE loss is formulated as follows:

$$J_{NCE}(\theta) = E_{(x,y) \sim (X \times Y)} (\log p((x \mapsto y) = 1|x, y) + \sum_{i=1, y_i \sim q}^k \log p((x \mapsto y) = 0|x, y_i)) \cdot (2)$$

While the NCE loss in Equation 2 is calculated by learning  $p((x \mapsto y)|x, y)$  for every data point (so-called *local*), we opt for a *ranking* setting where data points in the same batch *compete* in a contrastive setting. One way of achieving this is to leverage the mutual information  $\mathcal{I}$ , as utilized in InfoNCE (Oord et al., 2018), to encourage informative representations for the positive samples  $\mathcal{I}(z(x, y); z(x, y^{(+)}))$  (assuming multi-label setting) and contrast them with negative ones  $\mathcal{I}(z(x, y); z(x, y^{(-)}))$ . The ranking NCE loss is then defined as:

$$J_{NCE}^{global} = -\mathbb{E}_{(x,y)} \left[ \log \frac{\exp(g_\theta(x, y))}{\gamma \sum_{j:(x \mapsto y_j)=0} \exp(g_\theta(x, y_j))} \right], \quad (3)$$

whereas,  $g_\theta(x, y)$  is the *matching* function. Consequently, minimizing the loss promotes simultaneously a lower  $g_\theta$  for negative pairs and a higher  $g_\theta$  for positive pairs. The scaling factor  $\gamma$ , which is absent in InfoNCE, is introduced to account for the need to reduce the impact of the *considerably larger* portion of negative samples. This adjustment aims to emphasize the top- $n$  *partial* ranking, where it is assumed that the positive samples are concentrated in the distribution. Subsequently, with  $\gamma$ , the loss is denoted as  $\alpha$ -**balanced** NCE.

**Asymmetric Focusing.** Given the limited availability of reliable labels, our objective is to (i) reduce the impact of straightforward negative samples, and (ii) simultaneously mitigating the influence of potentially *mislabeled* (due to *missing* or *wrong* labels) samples on the loss function. While (i) can be achieved by applying a (hard) cut-off on very low values of  $p(0|x, y_i)$ , (ii) is often attributed to the high  $p(1|x, y_i)$ , with  $y_i \sim q$ . Thus, we opt for an *asymmetric* approach for the design of the NCE loss, wherein we prioritize the challenging mislabeled samples. In doing so, we explicitly differentiate the focusing (scaling) levels between the positive and negative groups. The idea originated in Ridnik et al. (2021), for vanilla cross-entropy. In our case, the negative samples derived from our negative sampling strategy in the NCE context. Our hypothesis is that this asymmetric mechanism helps stabilize the learning towards the *noisy*<sup>4</sup> sampled negative labels. Let  $\gamma^+$  and  $\gamma^-$  be the positive and negative scaling parameters, respectively. The sample-level *asymmetric* loss is achieved as follows:

$$\begin{aligned} J^{(+)} &= (1-p)^{\gamma^+} \log(p); \\ J^{(-)} &= p^{\gamma^-} \log(1-p), \end{aligned} \quad (4)$$

<sup>4</sup>Which *negative* samples are not exclusively negative?

where  $\gamma_-$  is often set larger than  $\gamma_+$  and  $p$  is short for  $p((x \mapsto y)|x, y)$ . The NCE loss is obtained by aggregating  $J$  over all samples.

$$J_{NCE} = J^{(+)}(x, y) + \sum_{i=1, y_i \sim q}^k J^{(-)}(x, y_i). \quad (5)$$

To this end, we show in Algorithm 1 our NCE-based training procedure. The convergence analysis can be further found in Appendix B.

### 4.3 Sampling Strategies

**Corpus-level negative sampling.** Due to memory constraints, the conventional negative sampling method is often applied *in-batch* (Yih et al., 2011; Gillick et al., 2019). One limitation of the *in-batch* sampling is the number of negative samples are bounded to the batch size. Whereas, the *corpus-level* sampling provides a broader context for negative sampling, inherently leading to a more diverse set of negative examples. In our low-resource context, the *diversified* negative samples are extremely useful in enhancing the discriminative power of the dataset, that is likely not evident within a single batch. In effect, we assume that a larger part of the TTP corpus is *irrelevant* to the positive paired sample. We also assume that noisy samples will inherently be canceled out while learning signals remain in our training paradigm (Rolnick et al., 2017). While being simple, the policy *augments* our dataset with a substantial supervision signal stemming from negative samples. We explain the details of our sampling policies below.

**Random sampling.** We select a simple uniform distribution  $q(y) = \frac{1}{\|L\|}$ . To increase the hardness of negative samples, other sampling methods, i.e., retrieval-based (e.g., candidates from a retrieval model) or semantic structure-based (e.g., other sibling TTPs of the same technique) can be applied.

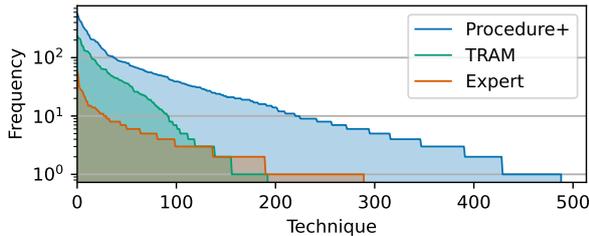

Figure 3: The distributions of the number of samples per technique (TTP) for each dataset.

However, due to the missing label nature of the task, these hard techniques tend to introduce noisy bias and thus are sub-optimal.

**Moderately sized label space.** Formally, the diversity  $D_{div}$  of the set of negative samples  $S$  can *entropy-wise* be defined as:  $D_{div}(S) = -\sum_{y_j \in S} P(y_j|x) \log P(y_j|x)$ , where for uniform sampling,  $D_{div} = \log(\|S\|)$ , with  $\|S\| \approx \|L\|$ . Recalling Equation 3, the denominator involves a summation over the probabilities of negative samples, thus as  $D_{div}$  increases, the negative samples become more evenly distributed, resulting in a more complex summation over the potentially larger number of the exponential terms, as in  $\sum_{j:(x \rightarrow y_j)=0} \exp(g_\theta(x, y_j))$ . In our specific case,  $\|L\|$  (the number of TTPs) is naturally bounded, thus nicely balancing the *trade-off* between the computational complexity and discriminative power that  $D_{div}$  introduces.

#### 4.4 Hierarchical Multi-label Learning

In ATT&CK, TTPs have a hierarchical structure, where different sub-techniques map *many-to-1* to the same technique and techniques map *many-to-many* to tactics. To exploit and encode this structure, we design an *auxiliary* task that predicts the tactics of the textual input, alongside our *matching* task. This auxiliary task is thus also a medium-sized multi-label classification task, and we use the binary cross-entropy loss for the optimization. The two tasks are jointly optimized in a *multi-task* learning manner, where the two losses are linearly combined:  $J_{total} = \alpha J_{NCE} + \beta J_{aux}$ , where  $\alpha$  and  $\beta$  are loss-weighting parameters.

## 5 Experiments

### 5.1 Datasets

We list below the datasets used in our experiments.

**TRAM.** Largest publicly available manual cu-

Table 1: Dataset statistics.  $S+T$  denotes the joint count of techniques and sub-techniques.

Dataset	Texts	S+T	Techniques	Avg. # Labels	Avg. # Tokens
TRAM	4797	193	132	1.16	23
Procedures	11723	488	180	1.00	12
Derived Procedures	3519	374	167	1.22	65
Expert	695	290	151	<b>1.84</b>	<b>72</b>

rated dataset from CTID<sup>5</sup>, commonly used in related work. It comprises mostly short texts, covers only one-third of TTPs with relatively noisy labels, thus appears to have limited application value.

**Procedure+.**<sup>6</sup> *Procedures*: collected from ATT&CK, where techniques have associated manually curated procedure examples<sup>3</sup>. Each example is a one-sentence expert-written summary of the implementation of a technique in real-world attacks. *Derived Procedures*: complements an example with a text that aligns to threat report writing style. We look for evidential paragraphs in the references where the summary example is assumedly derived from, using a per-document search engine.

**Expert.**<sup>6</sup> Our purposefully crafted dataset closely emulates real-world scenarios, providing a practical setting for TTP extraction. Unlike sentence-focused datasets, ours covers entire paragraphs, thus the annotations are inherently multi-label in nature. Annotated by 5 CTI experts using an in-house tool, our dataset triples text length and increases average labels per sample by approximately 60-80% compared to TRAM (see Table 1).

In our experiments, the two procedure examples datasets serve as high-quality *pseudo*-datasets, providing additional training examples, as well as valuable benchmarking perspective. Further descriptions of the overall dataset construction processes can be found in Appendix C.

### 5.2 Metrics and Baselines

The following common metrics in literature are used: the micro-averaged  $\{P, R, F1\}@k$  and mean reciprocal rank (MRR) $@k$ , which measures the relative ordering of a ranked list.

The following baselines are targeted: **Okapi BM25**, adjusted from Husari et al. (2017). The BoW is augmented with  $k$  closest terms from a security GloVe model, enhancing the BM25 retrieval

<sup>5</sup>CTID TRAM: [github.com/CTID/TRAM](https://github.com/CTID/TRAM)

<sup>6</sup>The datasets are publicly shared at [github.com/TTP-Mapping](https://github.com/TTP-Mapping) to foster further research.

Table 2: Results of all models on 3 datasets. *Procedures+* denotes the combined procedure examples datasets. Bold denotes *best* while underscore signifies *second-best* performance. Indented (*w/o*) denotes training **without** the specific option wrt. the preceding model. *Ideal* R@1 on the Expert dataset is 0.504.  $\mathcal{T}$  uses pre-trained SecBERT.

capability. Here, *query* represents the target text, and *documents* refer to TTP descriptions.

**Binary Relevance**, the vanilla multi-label learning approach, similar to Li et al. (2019) for TTP mapping. It has the one side of the text matching architecture and learns a binary classifier for each label separately in a *one-vs-all* manner.

**Dynamic triplet-loss**, a competitive baseline with a similar network architecture to ours, employs a *triplet*-based loss (Schroff et al., 2015). In contrast to the (empirically found) ineffective vanilla setting, we dynamically generate *k*-negative samples (akin to N-pairs loss (Sohn, 2016)) to mimic the NCE mechanism.

In addition, we employ the following state-of-the-art (SoTA) models in XMTC as competitive baselines: **NAPKINXC** (Jasinska-Kobus et al., 2020), a method that generalized the Hierarchi-

cal Softmax, so-called Probabilistic Label Trees (PLT), commonly used in XMTC literature. **XR-LINEAR** (Yu et al., 2022), a model designed for very large output spaces, with 3 phases: semantic label indexing (label clustering), matching (where the most relevant clusters are identified), and ranking (of labels in the matched clusters). **XR-TRANSFORMER** (Zhang et al., 2021), similar to XR-LINEAR, but with a transformer encoder. **exTremeText** (Wydmuch et al., 2018), algorithm-wise relatively similar to NAPKINXC.

### 5.3 Experimental Setup

We use the common security LM SecBERT<sup>7</sup> for the transformer-based models, and grid search determined the best hyperparameters for each model. The rich textual description<sup>3</sup> of a TTP is selected

<sup>7</sup><https://github.com/jackaduma/SecBERT>

for the textual profile. Except for XMTCs and BM25, all models are with the *auxiliary* tasks.

**Data Settings.** For the *Procedure+* and TRAM datasets, each was *stratified*-shuffled and split into training, validation and test sets with ratios of 72.5%, 12.5% and 15%, respectively. The test sets remained fixed for reporting purposes. For training and validation, two modes were considered: *separate* and *combined*. In the former, the datasets are kept distinct, while in the latter, they were merged according to their respective splits.

For the Expert dataset, we utilize a dedicated *held-out* recall-focused test set, with 157 unique paragraph-level samples and 3.3 labels per sample on average. This carefully curated held-out set closely resembles paragraph-level text snippets in complete CTI reports, facilitating a comprehensive analysis of the entire report.

## 5.4 Results and Analysis

Table 2 presents the main experimental results. Overall, our proposed NCE-based models greatly outperform the baselines. Particularly, the *asymmetric* loss-based model achieves the best performance across most metrics and datasets. We also observe the significant improvements of the two loss variants (i.e.,  $\alpha$ -balanced and *asymmetric*) over the vanilla InfoNCE. In addition, the models demonstrates a substantial improvement at the cutoff threshold @1 ( $\sim 10\%$ ) in comparison to @3 ( $\sim 5\%$ ). This supports the effectiveness of our *matching* network in *classification* settings.

The SoTA XMTC baselines perform considerably robust across the three datasets, among these XR-LINEAR perform best. Interestingly, XR-LINEAR demonstrates consistently higher performance than its related transformer-based counterpart (XR-TRANSFORMER), suggesting the challenges of the larger models in our low-resource settings. We also observe the subpar performance of the *triplet*-loss approach, suggesting similar disadvantages in the low-resource settings.

Across the datasets, the overall model performance declines from *Procedure+* to TRAM and Expert, indicating varying complexities within each dataset. Notably, our performance yields compelling results in TRAM, well-surpassing methods commonly reported in related work, i.e., BM25 and Binary Relevance.

Table 4: Model performance on the *head* vs. *tail* parts of the TRAM dataset. *Head* denotes more frequent TTPs ( $> \text{empirical } 7$  samples in the *training* split), whereas *tail* are infrequent TTPs. All are trained in *combined* mode. **Bold** denotes *absolute* best performers.

Methods	TRAM head (94.5%)			TRAM tail (5.5%)		
	F1@1	F1@3	MRR@3	F1@1	F1@3	MRR@3
BM25	.195	.112	.21	+118%	+99.1%	+108%
NAPKINXC	.624	.458	.752	-36.9%	-27.1%	-30.2%
XR-LINEAR	.62	.448	.743	-16.3%	-25.4%	-21.5%
@-balanced	.668	<b>.548</b>	.841	<b>-3.3%</b>	<b>-12.2%</b>	<b>-8%</b>
Asymmetric	<b>.679</b>	.547	<b>.848</b>	-4.9%	-14.3%	-10.4%

## 5.5 Ablation Studies

**Hierarchical Labeling.** We analyze the contributions of our *hierarchical* modeling to the ranking performances. As shown in Table 2, in general, our joint learning with the *auxiliary* task gives a notable performance boost in most scenarios. We report further in Table 3 the models’ results in the *technique*-level of the label hierarchy, where a sub-technique label is resolved to its technique. This is also a common practice in literature to streamline the complexity of the task. Overall, all models present significant improvements in this setting. Interestingly, here the  $\alpha$ -balanced model, without the *auxiliary* task, is the best performer on the Expert dataset. This is, nonetheless, understandable as the original hierarchical structure is semantically one level reduced in this case.

**Transformers.** We observe the positive contributions of SecBERT to the performance of all models in most cases. Nevertheless, without SecBERT (i.e., *w/o* Transformers), our models are still very much on par with the strong XMTC baselines at  $k = 1$  and outperform them at  $k = 3$ , indicating the better ranking capability, specially on the *Expert* dataset.

**Long Tail Analysis.** Tables 4 and 5 provide an analysis on the models’ performances on the classes of *head* versus *tail* frequency distributions visualized in Fig. 3. Overall, *matching*-based approaches, with the inductive bias, are relatively robust, whereas the classification-based XMTC baselines suffer in the long tail.

**Loss Analysis.** In Fig. 4, we present additional analysis on the impact of the *size* of negative samples. The results indicate that as the size increases, the model tends to converge faster and exhibit better performance. However, it appears that there are no additional benefits beyond a size of 60, which corresponds to 10% of the label space.

Table 5: Model performance on the *head* vs. *tail* parts of the Expert dataset. Legend of Table 4 applies.

Methods	Expert head (56.5%)			Expert tail (43.5%)		
	F1@1	F1@3	MRR@3	F1@1	F1@3	MRR@3
BM25	.071	.107	.188	+26%	+28%	+18.6%
NAPKINXC	.334	.381	.655	-40.7%	-23.9%	-16.6%
XR-LINEAR	<b>.335</b>	.407	.676	-31.6%	-22.9%	-14.5%
@-balanced	.302	<b>.426</b>	.819	-18.2%	<b>-11.3%</b>	-2.9%
Asymmetric	.306	.416	<b>.831</b>	<b>-18.9%</b>	-12%	<b>-2.9%</b>

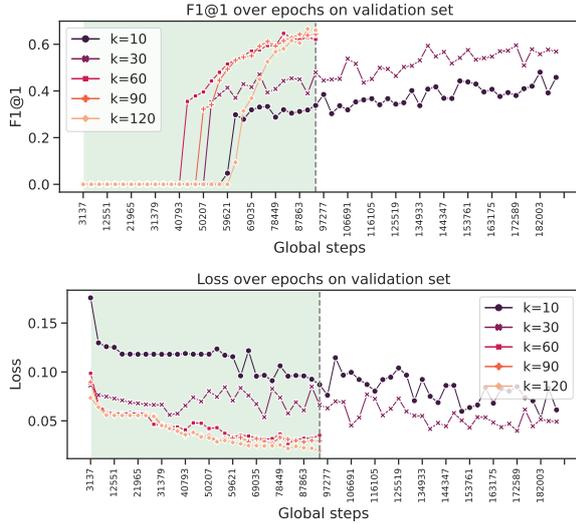

Figure 4: InfoNCE loss and f1@1 performance wrt. different number of negative samples. The network is without transformers. OOM for larger number of negative samples on an NVIDIA V100 32GB RAM.

A further analysis on the score distribution of the ranked lists are reported in Fig. 5. The details are provided in the caption for convenient reference.

**Expert Dataset.** To further examine the difficulties posed by the Expert Dataset, we present the outcomes of models trained on the training splits of *Procedure+* and TRAM, evaluated on the entire Expert dataset. The results are showcased in Tables 6 and 7. Overall, although all models exhibit reduced performance in this scenario, our models demonstrate superior generalization capability. Also, InfoNCE performs rather robustly in this setting, perhaps due to its stable nature to noisy input representation stemming from long-form text.

## 6 Conclusion

We proposed a solution for the TTP mapping task that overcomes low-resource challenges in security domain. This new learning paradigm integrates the inductive bias into the classification task, resulting in significant out-performance of strong baselines.

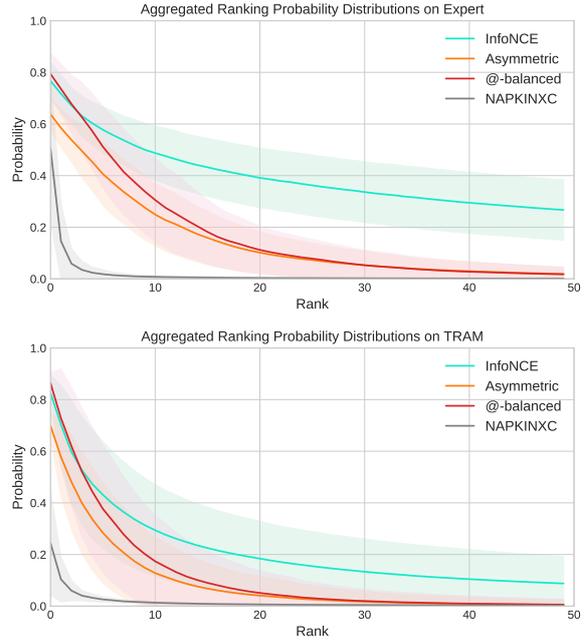

Figure 5: The aggregated probability distribution of the top-50 ranking on different models on the test splits of the TRAM (left) and Expert (right) datasets. While InfoNCE tends to allocate probabilities to labels in the long tail, @-balanced and *asymmetric* exhibit a more pronounced skewness in their distribution, resembling that of a pure classification model like NAPKINXC. The NCE-based models display a broader distribution at the head, indicating their inclination to assign comparable probabilities to multiple labels.

Table 6: Results on the *entire* Expert dataset, trained on the training splits of *Procedure+* and Tram. Bold denotes best-performer.

## 7 Limitations

Despite its label efficiency, our learning approach is not particularly efficient in terms of training. On average, it requires 24 hours for training on a machine equipped with a single NVIDIA-Tesla-V100 32 GB. Nonetheless, its training time is nearly comparable to the baselines employing Transformers. Although our expert dataset closely aligns with the multi-label nature of the task and exhibits higher quality, it remains relatively limited in size, covering just one-third of the TTPs.

## 8 Ethics Statement

Our datasets are constructed from security threat reports published by security vendors, and copyrighted by their respective owners. We scraped and extracted textual contents from these public websites to build the datasets. The criteria for text selection was whether the text discusses TTPs.

Some source reports contain Personally Identifiable Information (PII) of report authors, threat actors (i.e., persons suspected of involvement in cybercrime) or victims (i.e., persons suspected of being targeted by cybercrime). In the text selection process, we screened for any PII and removed all uncovered instances. However, we cannot rule out the possibility that some PII might have been missed in that process. Thus, users wishing to use the data will need to accept our terms of use and report potential remaining instances of PII, which will be removed in a subsequent dataset update. Crucially, the potential remaining PII in the dataset has been originally published by the reports' authors and may still remain public on the original websites even after our dataset updates.

The datasets have been annotated by security experts in our organization as part of their regular work under full-time employment contracts.

The language of the dataset is English, written by native and non-native speakers.

We are not aware of any ethical implications stemming from the intended use of this dataset, i.e., TTP mapping.

## A The Task of TTP Mapping

In the cybersecurity domain, one of the pillars of effective defense is *Cyber Threat Intelligence* (CTI). An analog to military intelligence, CTI is tasked with collecting and organizing information on cyber threats such as *threat actors*, their *threat campaigns*, and malicious software, i.e., *malware*. It can be traced back to ancient military-theoretical

observations that understanding one's enemy is crucial to winning battles<sup>8</sup>.

CTI describes cyber threats on three levels. The *strategic level* (e.g., periodicals on trends in the cyber risk landscape) describes high-level threat information and targets non-technical chief executives. The *tactical level* (e.g., technical reports on individual threat actors) describes details on threat actors' behavior, for use by security managers. The lowest, *operational level* (e.g., lists of malicious internet domains) describes specific threat indicators which may be directly used for defense (e.g., by blocking the offending domains).

While the value of CTI data is roughly proportional to its intelligence level, the difficulty of obtaining it is the opposite. Automated production only exists for operational CTI data, and higher levels require costly manual expert work. However, leading CTI community members regularly publish tactical and strategic CTI information in form of *cybersecurity threat reports* – digital documents with unstructured natural language text along tables and images, written using a domain-specific vocabulary, between hundreds and thousands of words long, and strongly interspersed with technical tokens such as URLs, hashes and similar. Typically they cover profiles of major threat actors, summaries of threat campaigns, and malware analysis reports. An illustrative excerpt is provided in Fig. 1. Thus an opportunity arose for a fruitful application of NLP: automated extraction of high-value CTI data from natural language documents.

In recent years, the NLP and cybersecurity communities have been engaged in exactly this direction. Early work targeted the operational level, extracting *Indicators of Compromise* (IoCs), i.e., threat actor controlled internet domains, IP addresses, file hashes and URLs, from security articles, social media or forum posts. Subsequent efforts targeted the tactical level, but the challenge there remains unsolved.

The tactical level characterizes adversaries' behavior, typically referred to as *attack patterns*. Fig. 1 illustrates, among others, (1) the use of a malicious email attachment to take control of a victim's system, and (2) encrypting data on the victim's system to extort money from the victim.

<sup>8</sup>“If you know the enemy and know yourself, you need not fear the result of a hundred battles. If you know yourself but not the enemy, for every victory gained you will also suffer a defeat. If you know neither the enemy nor yourself, you will succumb in every battle.” (Tzu)

To facilitate reasoning about attack patterns, of which hundreds are documented, the community converged around a common framework called *Tactics, Techniques and Procedures* (TTPs):

- A **tactic** describes the purpose of the actor's behavior – “why?”. For above examples, the tactics are *taking control of the system* and *financial gain*, respectively. Other typical adversarial tactics include *reconnaissance*, *establishing permanent presence*, *command and control*, *data theft*, etc.
- A **technique** describes the method used for the given purpose – “how?”. In our case, those are *malicious email attachment* and *data encryption*. A technique may be assigned to several tactics if it achieves several purposes. Each tactic can be achieved using any of a range of different techniques. Other typical techniques include *collecting victim system information*, *execution on system start*, *encrypted communication*, *password theft*, etc.
- Some ontologies also define a **subtechnique** as a specialized technique. A technique may be specialized by zero or more subtechniques. For example, the technique *input capture* may have subtechniques *keystroke capture* and *screen capture*.
- A **procedure** describes the implementation details of a technique. For example, the email attachment may be a *malicious Excel file*, and the data encryption may be performed using a *custom encryption algorithm*. Each technique can be implemented using any of potentially many different procedures.

Although others exist, MITRE ATT&CK<sup>9</sup> (Storm et al., 2020) is the prevalent knowledge base and taxonomy of TTPs used in the literature. The version 12.0 comprises 14 tactics, 196 techniques, 411 sub-techniques and thousands of procedures, continually curated by community experts.

Retrieval of TTPs from unstructured text is referred to as *TTP mapping* in this work, although *TTP mining/extraction* also occur in the literature. Crucially for TTP mining, threat reports very rarely name actors' TTPs explicitly. Instead, they establish a chronological narrative in terms of *threat*

<sup>9</sup><https://attack.mitre.org/>

actions, i.e., low-level actions taken by the threat actor. Some examples for threat actions from Fig. 1 are *botnet spreading*, *use of phishing emails*, *use of Visual Basic for malicious scripting*, *use of Excel macros*, etc. Not all threat actions are explicitly expressed in the text. For example, although the term “email” is not mentioned, the use of phishing emails is inferred by domain experts because phishing means sending deceptive emails with malicious purposes, therefore sending emails is the technical implementation of phishing and it must have occurred.

Thus, at a high level, TTP mapping from text is a 3-step process:

1. Identification of individual threat actions from paragraphs or longer context
2. Correlation of one or more identified threat actions into procedures
3. Mapping of identified procedures into techniques and tactics.

## B Convergence Analysis

Based on the stability of the NCE losses, we briefly discuss the convergence properties of our adjusted losses.

**Boundedness of Gradients.** *Proof:* Let  $g(x, y)$  be the matching function such that  $0 \leq g(x, y) \leq 1$  for all  $(x, y)$ . Consider the NCE loss, i.e., @-balanced with a scaling factor  $\gamma$ :

$$J_{\text{NCE}}(\theta) = E_{p(x,y)}[\log g(x, y)] - \gamma E_{p(x)}[\log \sum_j g(x, y_j)]$$

We want to prove that the gradients of the NCE loss with respect to the model parameters are bounded. Let  $\nabla J_{\text{NCE}}(\theta)$  denote the gradient vector. Taking the partial derivative of  $J_{\text{NCE}}(\theta)$  with respect to a parameter  $\theta_i$ , we have:

$$\frac{\partial J_{\text{NCE}}(\theta)}{\partial \theta_i} = \frac{\partial}{\partial \theta_i} \left( E_{p(x,y)}[\log g(x, y)] - \gamma E_{p(x)}[\log \sum_j g(x, y_j)] \right)$$

Using the linearity of the derivative, we can rewrite the above expression as:

$$\begin{aligned} \frac{\partial J_{\text{NCE}}(\theta)}{\partial \theta_i} &= E_{p(x,y)} \left[ \frac{\partial}{\partial \theta_i} \log g(x, y) \right] \\ &\quad - \gamma E_{p(x)} \left[ \frac{\partial}{\partial \theta_i} \log \sum_j g(x, y_j) \right] \end{aligned}$$

Since  $0 \leq g(x, y) \leq 1$ , the derivative of  $\log g(x, y)$  with respect to any parameter  $\theta_i$  is bounded between 0 and 1. Similarly, the derivative of  $\log \sum_j g(x, y_j)$  with respect to  $\theta_i$  can be bounded by considering the partial derivatives of  $g(x, y_j)$ .

Therefore, we can conclude that:

$$\left| \frac{\partial J_{\text{NCE}}(\theta)}{\partial \theta_i} \right| \leq \max\{1, \gamma \max_{x,y_j} |\partial_{\theta_i} g(x, y_j)|\}$$

The above inequality implies that the absolute value of the partial derivative of the NCE loss with respect to any model parameter is bounded by a finite value, scaled by  $\gamma$ . Hence, we have shown that the gradients of @-balanced with the scaling factor  $\gamma$  are bounded. The proof for the *asymmetric* loss can be derived in an analogous manner.

**Lemma 1** *The matching function  $g(z_i, z_j)$  is Lipschitz-continuous with a constant  $C$ , meaning that for any  $z_i, z'_i, z_j$ , we have  $|g(z_i, z_j) - g(z'_i, z_j)| \leq C|z_i - z'_i|$ .*

**Informal proof.** Our Siamese neural networks-based matching function  $g(z_i, z_j) \in [0, 1]$ .  $\square$ .

**Lemma 2** *The noise distribution  $q$  satisfies the matching moment condition of the true distribution  $p$ , which, in essence, indicates that the covariance matrices of the two are similar.*

**Informal proof.** Since the noise distribution is sampled over the whole corpus, the lemma holds true for the random sampling strategy.  $\square$ .

Thus, our loss is also Lipschitz-continuous and retains convergence properties of the original NCE losses, when optimized using SGD together with the random negative sampling.

## C Dataset Construction

**Derived Procedure Examples.** The dataset is created as a contextualized version of the original *Procedure* examples. We search for evidential *paragraph-level* text snippets in the references where the summary example is derived from. With this, the examples are contextualized and reflect the true reporting style present in the references. The pre-processing steps are as follows:

- Each example-reference pair is indexed at the *paragraph* level. Any paragraphs that are deemed (1) too short (less than 20 tokens), (2) too long (more than 300 tokens), or (3) have a

Jaccard index with the example exceeding 0.9 (indicating near-*duplicate*) are discarded.

- The remaining paragraphs are ranked based on their relevance to the example using a tailored BM25 retrieval model.
- A maximum of two paragraphs that satisfy a carefully chosen global cut-off threshold are selected.
- Additionally, we eliminate any potential near-duplicates to the TRAM and Expert datasets.

We further assessed the dataset quality on a limited sample set consisting of 50 text snippets. Through this qualitative evaluation, the overall impression of the examined samples is largely positive.

#### **Expert Dataset.**

The Expert dataset comprises relevant text paragraphs from articles of reputable cybersecurity threat researchers, annotated by seasoned cybersecurity experts. The dataset was purposefully designed to closely mimic real-world scenarios, aiming to provide a practical and authentic setting for TTP extraction. Unlike datasets that primarily focus on individual sentences, our dataset encompasses entire paragraphs, and the annotations are inherently multi-label in nature. Rather than concentrating on isolated sentences, this dataset includes entire paragraphs that contain implicit mentions of TTPs, making the annotations inherently multi-label in nature.

The dataset was collected as follows:

1. We scraped 30 thousand articles from the feeds of leading cyber threat research organizations, and heuristically filtered out irrelevant articles, which do not describe attacks related to malware, advanced persistent threats, or cyber threat campaigns.
2. Further heuristics were applied to remove irrelevant paragraphs, i.e., we look for paragraphs which satisfy aforementioned length constraints, and contain at least 3 cybersecurity entities (e.g., malware, URL, etc.). The remaining relevant paragraphs were then randomly sub-sampled for annotation.
3. The expert annotators were tasked with analyzing the paragraph and identifying TTPs. To assist them in this process, an in-house

search engine, powered by the baseline retrieval model BM25, was employed. This search engine allowed the annotators to formulate queries based on the paragraph and retrieve relevant information to aid in their TTP selection.

4. The annotators were instructed to only annotate explicit tactics and techniques in the given paragraph<sup>10</sup>.

Each annotated item, namely a text paragraph, undergoes evaluation by a single annotator. We refrained from implementing extra quality control procedures, such as reviews or reaching consensus among annotators. To ensure quality, we engaged seasoned cybersecurity experts as annotators, rather than relying on crowd-sourced workers.

The choice of text paragraphs is biased by the described selection process towards high-quality writing from expert threat reports, and might not be representative of other writing styles, e.g., micro-blogging posts.

**Expert Dataset: Special Test Split.** In the aforementioned process, it cannot be guaranteed that all annotations will be retrieved accurately due to the extensive task of re-formulating queries and reviewing the lengthy ranked list of TTPs generated by the relatively lower-performing BM25 model. Therefore, in order to enhance the recall of the test split, we substituted BM25 with our *InfoNCE* model, which was trained on the train splits of the *Procedure+* and *Tram* datasets. For every sample, we utilize a deep cut-off approach by selecting the top 20 entries, which are then assigned to annotators for further analysis. We continued to follow the same procedures as before.

In rare cases, relevant labels were missing from the top-20 predictions, but the annotators were not explicitly instructed to manually include those labels in the dataset. Thus the recall of the annotations is inherently imperfect, and the labels tend to be biased towards the use of *InfoNCE*. Nevertheless, based on the annotators' subjective assessment, the estimated annotation recall ranged from 95-100%, indicating that this dataset deviates minimally from a perfect annotation. Consequently, this split contains a significantly higher number of

---

<sup>10</sup>An expert may comprehend from the text that it would be impossible to perform a discussed attack step without another tactic or technique, even if those dependencies were not explicitly written.

labels per sample compared to competing datasets., e.g., TRAM.

In conclusion, our Expert dataset, and particularly the test split, is of relatively small size, but is comprised of fully representative text paragraphs and has exemplary annotation precision and recall.

## D Further Experimental Studies

### D.1 Metrics

The definitions of the used metrics in our experiments are reported below.

**P@k.** Given a ranked list of predicted labels for each sample, the micro precision of the top-k is defined as:  $P@k = 1/k \sum_{i=1}^k 1_{y_i^+}(l_i)$ , whereas  $l_i$  is the i-th label in the ranking and  $1_{y_i^+}$  is the indicator function.

**R@k.** Similarly, the micro recall of the top-k is defined as:  $R@k = 1/|Q| \sum_{i=1}^k 1_{y_i^+}(l_i)$ , whereas  $|Q|$  is the number of positive labels in the sample.

**F1@k.** The metric maintains the harmony between P@k and R@k of a given ranked list, and is calculated as  $\frac{2 \cdot P@k \cdot R@k}{(P@k + R@k)}$ .

**MRR@k.** The metric measures the relative ordering of a ranked list, with RR is the inverse rank of the first relevant item in the top-k ranked list. Accordingly, MRR@k is measured as follows.  $MRR@k = 1/S \sum_{i=1}^S 1/rank_i$ , whereas  $S$  is the number of samples.

### D.2 Training Procedure and Hyperparameters

While InfoNCE and @-balanced are with normal training procedures, to leverage the effectiveness of the *asymmetric* loss, which performs optimally under stable gradient conditions, we adopt a two-step training procedure in our experiments. Initially, the model is trained using an @-balanced loss. Once the training process reaches a stable state, we then introduce the *asymmetric* loss.

We report the best hyperparameter sets for all models in Table 8. For the XMTC baselines, the parameter ranges for the probabilistic-based tree construction (i.e., with Huffman or K-Means) are designed to closely resemble the structure of the ATT&CK taxonomy. This resemblance is achievable thanks to its dot-separated naming convention, where the prefix represents the super technique.

### D.3 Qualitative Studies

In this section, we provide a series of illustrative examples (see Tables 10 to 12) to qualitatively

showcase the practical efficacy of our methodology in addressing the compound TTP-Mapping task. We relate our results with the established LLMs, such as ChatGPT 4<sup>11</sup>, which serve as a reference to the overall intricacy of this task.

For the setup of ChatGPT, for each text, we create a *prompt* in the following format: *What MITRE ATT&CK techniques (TTPs) are explicitly and implicitly mentioned in the following text: [..].* In general, the responses provided by Chat-GPT are remarkable and somewhat accurate in certain instances. However, it is evident that the answers primarily consist of high-level information (sometimes hallucinatory), with a lack of granularity that makes it useful, e.g., for precise modeling of the attack steps.

We provide further a **full report analysis** of a threat report released by Mandiant (see [Wayback machine](#)). Each paragraph in the report is processed by our model and finally techniques were assigned to the *tactic bins* of the MITRE ATT&CK matrix<sup>12</sup>, based on a simple assignment algorithm, with two constraints (1) maximize total relevant score (of each TTP) in the bins and (2) maximize total number of TTP-occurrences in the bins (i.e., a TTP can occur in more than one paragraph). Further details are in Table 9.

<sup>11</sup>While being extensively studied, we opt to exclude its results in our experiments due to the *objective* prompt-sensitive performance limitations.

<sup>12</sup><https://attack.mitre.org/>

Table 8: The default hyperparameters used in the experiments for each model.

Models	Hyperparams	
Ours	@-balanced	{cls-ratio: { $\gamma$ : 0.11}}
	InfoNCE	{cls-ratio: { $\gamma$ : 1.}}
	asymmetric	{ $\gamma_{pos}$ :1, $\gamma_{neg}$ :3, cut-off: 0.1}
	- base settings	{learning_rate: 1e-3, auxiliary_task: { $\alpha$ : 0.6, $\beta$ : 0.4}, batch_size:[2,4,8], negative_samples:[30,60] sampling_method: <i>random</i> }
	- auxiliary	{ $\alpha$ : 0.6, $\beta$ : 0.4}
Dynamic Triplet Loss	{cls-ratio: { $\gamma$ : 0.11} learning_rate: 1e-3, auxiliary_task: { $\alpha$ : 0.6, $\beta$ : 0.4}, batch_size:[2,4,8], negative_samples:[30,60] sampling_method: <i>random</i> }	
NAPKINXC	{model: PLT, tree_type: {"hierarchicalKmeans", "huffman"}, arity:{2,10, 20}, max_leaves:{10, 20}, kmeans_eps=0.0001, kmeans_balanced={True, False}}	
XR-LINEAR	{mode: "full-model", ranker_level: 1, nr_splits: 16}	
XR-TRANSFORMER	{mode: "full-model", negative_sampling: ["tfm", "man"], , do_fine_tune: True, only_encoder: False}	
ExtremeText + Sigmoid	{loss: sigmoid, neg: [0, 100], tfidfWeights: True}	
ExtremeText + PLT	{loss: "plt", neg: [0, 40], tree_type: {"hierarchicalKmeans", "huffman"}, tfidfWeights: True}	

Table 9: A **full report analysis** of the Mandiant threat report (see [Wayback machine](#)). We compare our results with the list of TTPs explicitly provided by the same report, Appendix section, with that, we achieve 90% recall, missing only one technique (Non-Standard Port). All the extracted TTPs from the model are further examined and confirmed correct by our security experts.

Table 10: Example 1: A threat report text is analyzed by ChatGPT and  $\alpha$ -balanced. Here, an important technique is the *Masquerading*, described by MITRE as: “Adversaries may attempt to manipulate features of their artifacts to **make them appear legitimate** or benign to users and/or security tools. Masquerading occurs when the name or location of an object, legitimate or malicious, is manipulated or abused for the sake of evading defenses and observation. This may include manipulating file metadata, tricking users into misidentifying the file type, and giving legitimate task or service names.” This technique is missed by ChatGPT, identified by our model, and is ranked higher than explicit TTPs i.e., Powershell or Visual Basic.

Text *After the .NET PE file has been run, we observed the same behavior as the above QUADAGENT sample of dropping a PowerShell script with the filename SystemDiskClean.ps1 alongside a VBScript file with the same name. The C2 techniques remained identical, with the only change being the server which became cpuproc[.]com.*

ChatGPT

Based on the provided text, we can identify several MITRE ATT&CK techniques, both explicitly and implicitly:

- **Execution** (T1059): The text mentions the execution of a .NET PE file, indicating the execution technique.
- **Scripting** (T1064): The dropping of a PowerShell script (SystemDiskClean.ps1) and a VBScript file suggests the use of scripting techniques.
- **Command and Scripting Interpreter** (T1059.003): Specifically, the use of PowerShell in dropping the SystemDiskClean.ps1 file implies the use of command and scripting interpreters.
- **Deobfuscate/Decode Files or Information** (T1140): The use of a .NET PE file suggests potential obfuscation or encoding that may need to be deobfuscated or decoded.
- **Command and Control** (T1043): The mention of a change in the C2 server (cpuproc[.]com) indicates the use of a different command and control infrastructure.

$\alpha$ -balanced

The top-n ranking is:

1. **Masquerading** (T1036), score: 0.68
2. **PowerShell** (T1059.001), score: 0.58
3. **Visual Basic** (T1059.005), score: 0.52
4. **Obfuscated Files or Information** (T1027), score: 0.47

Table 11: Example 2: A threat report text is analyzed by ChatGPT and  $\alpha$ -balanced. Here, ChatGPT provides a correct justification on the use of the common HTTP port 443. This is a false positive from our model, as a simple text matching fails to **reason** whether a port number is common or uncommon. Our model however, is still able to identify the important technique *Ingress Tool Transfer*, which described by MITRE as: “Adversaries may transfer tools or other files from an external system into a compromised environment. Tools or files may be copied from an external adversary-controlled system to the victim network through the command and control channel or through alternate protocols such as ftp. Once present, adversaries may also transfer/spread tools between victim devices within a compromised environment.”

Text      *The Meterpreter downloader 'TzGG' was configured to communicate with 91.208.184[.]78 over port 443 to download the shellcode (MD5: 659bd19b562059f3f0cc978e15624fd9) for Cobalt Strike BEACON (trial-version).*

ChatGPT

Based on the provided text, we can identify several MITRE ATT&CK techniques, both explicitly and implicitly:

- **Data Obfuscation** (T1001): The use of the term "shellcode" implies the presence of binary code that is typically obfuscated and designed to be directly executed.
- **Standard Application Layer Protocol** (T1071): The communication with IP address 91.208.184[.]78 over port 443 suggests the use of HTTPS, which is a standard application layer protocol.
- **Command and Control** (T1043): The Meterpreter downloader 'TzGG' communicating with an external server over port 443 indicates a command and control channel.
- **Connection Proxy** (T1090.002): The use of port 443 may involve the exploitation of the encrypted communication channel often used for securing web traffic, serving as a form of connection proxy.
- **Impersonation of Legitimate Entity** (T1090.002): The mention of Cobalt Strike BEACON (trial-version) suggests the potential for attackers to impersonate legitimate entities or tools.
- **Application Layer Protocol** (T1071.001): The use of port 443 for communication is specifically associated with the HTTPS protocol at the application layer.
- **Download Evil Content** (T1105): The Meterpreter downloader 'TzGG' is configured to download shellcode for Cobalt Strike BEACON, indicating the download of malicious content.
- **Remote Access Tools** (T1219): Cobalt Strike BEACON is a well-known remote access tool often used by adversaries for post-exploitation activities.

$\alpha$ -balanced

The top-n ranking is:

1. **Non-Standard Port** (T1105), score: 0.76
2. **Ingress Tool Transfer** (T1059.001), score: 0.71
3. **Application Layer Protocol** (T1071), score: 0.59
4. **Web Protocols** (T1071.001), score: 0.57

Table 12: Example 3: A threat report text is analyzed by ChatGPT and  $\alpha$ -balanced. Here interestingly, both answers show certain consensus. Our model is still able to match to low-level techniques i.e., *Symmetric Cryptography*, derived from the use of RC4 for encryption.

**Text** *Unlike previously identified RedDelta PlugX samples, this one uses a legitimate Avast Proxy executable for the second DLL side-loading phase rather than the legitimate Adobe executable used in previously analyzed samples. When loaded into memory, the PlugX payload uses www.systeminfor[.]com for command and control — the same domain used across the Catholic church-themed PlugX samples. Across all four newly analyzed samples, the first stage DLL loader files share an identical, uncommon import hash and rich header with previously observed first stage RedDelta PlugX DLLs. The loaded PlugX payload also matches the custom RedDelta PlugX variant previously described, using RC4 encryption for C2 communications with the same hardcoded RC4 passphrase and configuration block decoding function.*

**ChatGPT**

Based on the provided text, we can identify several MITRE ATT&CK techniques, both explicitly and implicitly:

- **DLL Side-Loading** (T1073.002): The mention of using a legitimate Avast Proxy executable for the second DLL side-loading phase indicates the use of DLL side-loading, a technique where a malicious DLL is loaded into a legitimate process.
- **Masquerading** (T1036): The use of a legitimate Avast Proxy executable for the second DLL side-loading phase is a form of masquerading or disguising the malicious activity to appear legitimate.
- **Command and Control** (T1043): The PlugX payload uses the domain www.systeminfor[.]com for command and control, indicating communication with an external server.
- **Standard Application Layer Protocol** (T1071): The use of a domain for command and control suggests the use of standard application layer protocols for communication.
- **Data Obfuscation** (T1001): The use of RC4 encryption for C2 communications indicates the obfuscation of communication traffic.
- **RC4** (T1027): The mention of using RC4 encryption for C2 communications specifically refers to the use of the RC4 symmetric encryption algorithm.
- **Data Encoding** (T1132): The use of RC4 encryption can be considered a form of data encoding for communication between the implant and the C2 server.
- **Encoded/Encrypted Files or Information** (T1022): The RC4 encryption is used for encrypting communications between the PlugX payload and the C2 server, securing the information exchanged.
- **Registry Run Keys / Startup Folder** (T1060): While not explicitly mentioned in the provided text, the persistence mechanism used by PlugX (loading into memory) often involves leveraging registry run keys or startup folders.

**$\alpha$ -balanced**

The top-n ranking is:

1. **DLL Side-Loading** (T1574.002), score: 0.81
2. **Obfuscated Files or Information** (T1027), score: 0.56
3. **DLL Search Order Hijacking** (T1574.001), score: 0.52
4. **Encrypted Channel** (T1573), score: 0.49
5. **Symmetric Cryptography** (T1573.001), score: 0.45
6. **Deobfuscate/Decode Files or Information** (T1140), score: 0.32
7. **Masquerading** (T1036), score: 0.32
8. **Registry Run Keys / Startup Folder** (T1547.001), score: 0.31

# Large Language Models for Scientific Information Extraction: An Empirical Study for Virology

Mahsa Shamsabadi and Jennifer D’Souza and Sören Auer  
TIB Leibniz Information Centre for Science and Technology,  
Hannover, Germany  
{mahsa.shamsabasdi, jennifer.dsouza, auer}@tib.eu

## Abstract

In this paper, we champion the use of structured and semantic content representation of discourse-based scholarly communication, inspired by tools like Wikipedia infoboxes or structured Amazon product descriptions. These representations provide users with a concise overview, aiding scientists in navigating the dense academic landscape. Our novel automated approach leverages the robust text generation capabilities of LLMs to produce structured scholarly contribution summaries, offering both a practical solution and insights into LLMs’ emergent abilities.

For LLMs, the prime focus is on improving their general intelligence as conversational agents. We argue that these models can also be applied effectively in information extraction (IE), specifically in complex IE tasks within terse domains like Science. This paradigm shift replaces the traditional modular, pipelined machine learning approach with a simpler objective expressed through instructions. Our results show that finetuned FLAN-T5 with 1000x fewer parameters than the state-of-the-art GPT-davinci is competitive for the task.

## 1 Introduction

Scholarly communication in the digital age is facing significant challenges due to the overwhelming volume of publications (Johnson et al., 2018) thereby creating the need for efficient access to relevant knowledge. In this regard, next-generation scholarly digital libraries, such as the Open Research Knowledge Graph (ORKG) (Auer et al., 2020; Stocker et al., 2023), offer a promising solution by adopting semantic publishing principles (Shotton, 2009). The ORKG stores *scholarly contributions* in a structured and semantic way, leveraging a knowledge graph (KG) representation (Ehrlinger and Wöß, 2016; Fensel et al., 2020). The fine-grained semantic contribution representation in the ORKG utilizes property-value

tuples, capturing important aspects and corresponding observations of research contributions. This representation enhances understanding and navigation of scholarly content by both humans and machines. With selected properties that apply universally to research on a specific problem, the ORKG enables intelligent exploration and assistance services, including [research comparisons](#) based on shared properties, e.g., [Figure 1](#). Its novel information access methods provide condensed overviews of the state-of-the-art, supporting strategic reading (Renear and Palmer, 2009) in the ever-growing publication landscape.

This work, as a text mining service toward producing scalable solutions for the ORKG, for the first time, introduces a complex information extraction (IE) task. Our notion of complex IE entails joint entity and relation extraction in a single objective aligned with the structured property-value format of contributions in the ORKG. We defined the complex IE task w.r.t. a key research problem in the domain of Epidemics & Virology, i.e. estimating the basic reproduction number ( $R_0$ ) for infectious diseases. This  $R_0$  estimate research topic was brought to common knowledge during the recent Covid-19 pandemic by the Centers for Disease Control and Prevention (CDC) as a [key informant](#). Important to infectious disease epidemiology, gen-

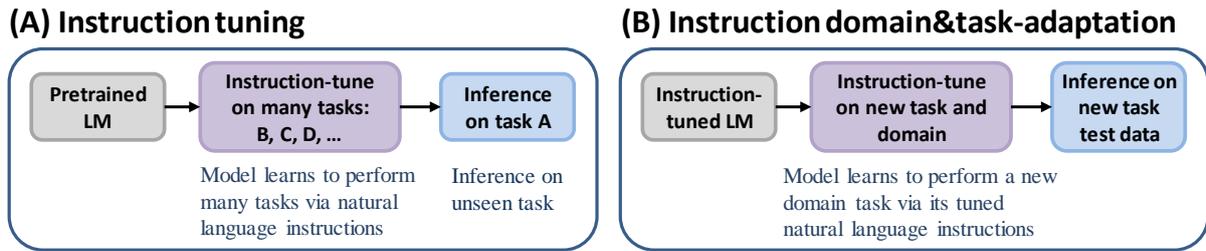

Figure 2: Comparing (A) instruction tuning with (B) instruction-tuned LLM domain- and task-tuning of this work.

erally, the  $R_0$  estimate represents the average number of secondary infections caused by a single infected individual (Foppa, 2017). In other words, it is an estimate of disease progression in a given population. E.g., the estimated  $R_0$  for COVID-19 has been reported between 2.5 to 5.7 (Sanche et al., 2020). It varies for different infectious diseases and populations. For researchers in Epidemics & Virology, it is interesting to be able to compare the  $R_0$  of different viruses facilitated by structured contribution data available in the ORKG. The alternative, traditional, and seemingly impossible knowledge comprehension task, would be to scour for vital information buried in unstructured text across the 44k articles by Covid-19  $R_0$  estimate Google search.

To define our complex IE task, an expert semantic modeler created a research comparison based on structured property-value pairs for Covid-19  $R_0$  estimate contributions across 30 abstracts. Consequently, six properties were modeled: *disease name, location, date,  $R_0$  value, %CI values,*<sup>1</sup> and *method*. The semantic modeling aimed to identify properties that were both generic enough to structure most related research on the  $R_0$  estimate (in the context of a research comparison) and specialized enough to reflect the vital details of the  $R_0$  contribution (by identifying commonalities in observations reported across 30 different abstracts). This structured format is called ORKG- $R_0$ . Thus our complex IE task focused on extracting property-value pairs for ORKG- $R_0$  contributions in scholarly article abstracts. To address this task, a larger gold-standard corpus was annotated (details in section 3) and an LLM-based solution was optimally designed (introduced next, details in section 4).

The complex IE task introduced earlier is addressed as single-task instruction-based finetuning of an instruction-tuned Large Language Model (LLM) with the primary objective of *better aligning the LLM to our task and domain*. Our approach is

characterized in Figure 2. We chose LLMs for their rich parameter spaces and ability to handle complex IE tasks with simple instruction prompts (Ouyang et al., 2022). Unlike traditional pipelined-based IE, which are prone to error propagation and require extensive manual engineering, LLMs offer flexibility, adaptability, and the ability to handle a wide range of tasks in zero- and few-shot settings through instructions (Radford et al.; Brown et al., 2020; Wei et al., 2021). By relying on instruction prompting, we can effectively address complex inter-relations without the need for an exhaustive enumeration of all possible relations or preliminary named entity recognition (NER). We finetune an LLM from the sequence-to-sequence encoder-decoder-based T5 model class (Raffel et al., 2020) to accept a research paper title and abstract and instruct it to write the ORKG- $R_0$  structured “summary” of knowledge in the prompt as either text-based or as a structured JSON object. For the LLM, we specifically select the instruction-tuned FLAN-T5-Large model (Chung et al., 2022) with reported 780M parameters. There could have been one of two directions for this work: scaling the models or instruction fine-tuning of a moderate-sized LLM, i.e. with parameters in millions versus 1000x more in billions. We chose the latter. We believe that our choice makes model tuning more accessible within the research community while empirically proving to be nonetheless effective (experimental details in section 5). Furthermore, our choice of Google’s FLAN-T5, open-sourced and easily accessible in the Transformers library, obviates any paywall that hinders access to LLMs for the research community at large. For instruction-based finetuning, we use applicable instructions from the *open-sourced instruction generalization efforts* introduced as the “Flan 2022 Collection” (Longpre et al., 2023). Our approach differs from finetuning a pretrained LM as we instead finetune an instruction-tuned LM, enabling the model to effectively follow instructions

<sup>1</sup>CI stands for confidence interval.

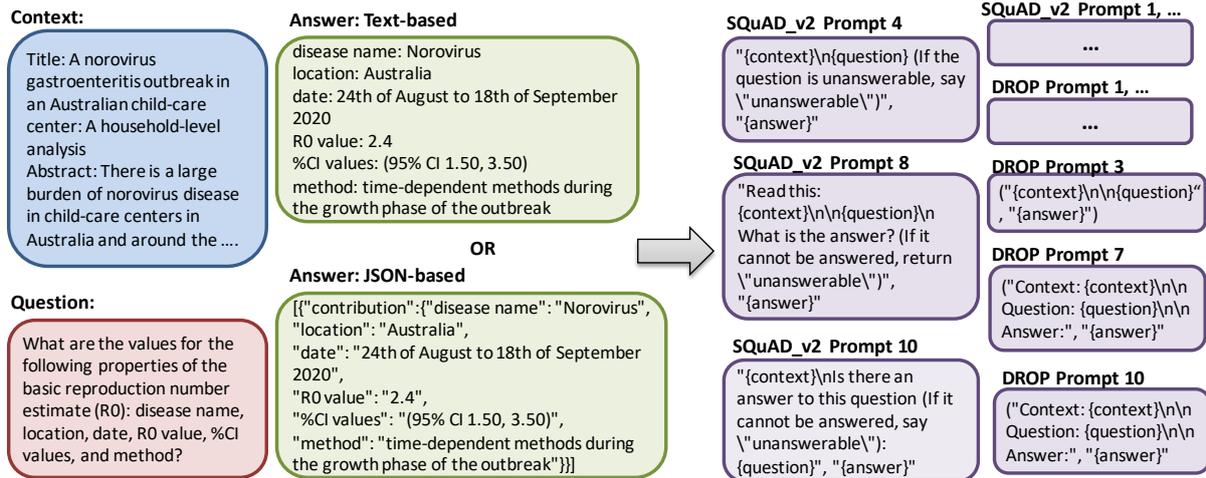

Figure 3: Multiple instruction prompts describing our complex scientific information extraction (IE) task.

it has been trained on and adapt to a new domain and complex IE task, without the need to handle variability in learning new instruction formats. Our approach is shown in Figure 3.

In this context, the central research question (**RQ**) of this work examines: *How does instruction-based finetuning enhance LLM performance in a unique domain, specifically in a complex scientific field like Virology that requires specialized expertise?* Summarily, the main contributions of our work are as follows: 1) **Corpus**: A **gold-standard corpus** of 1,500 annotated structured abstracts based on ORKG-R0. 2) **Methodological**: We adopt “single-task instruction-finetuning” to enhance LLMs’ domain and task adaptation. It involves selecting instructions from the open-sourced FLAN collection and fine-tuning FLAN-T5 780M to respond to those instructions. Our **source code** is released. 3) **Methodological**: Our approach distinguishes itself in the realm of IE research by introducing an LLM-based approach that breaks away from traditional pipeline-based methods for entity and relation extraction. Instead, we propose a single-system approach utilizing a moderately-sized LLM, which holds potential for practical applications. And 4) **Results**: Our instruction-finetuned ORKG-FLAN-T5<sub>R0</sub> 780M outperforms pretrained T5, instruction-tuned FLAN-T5, and GPT3.5-davinci 175B on ORKG-R0 complex IE. The **best model** is released on HuggingFace.

## 2 Background: Scholarly Communication

Semantic scholarly knowledge publishing models, such as the ORKG, specifically the ORKG-R0 in-

stance in this work, and the structured abstracts methodology (e.g., **IMRAD**) employed by publishers like **PubMed** have distinct approaches and serve different purposes in scholarly communication. This section distinguishes the two.

The ORKG (Auer, 2018) and similar semantic knowledge publishing models (Baas et al., 2020; Birkle et al., 2020; Wang et al., 2020a; Aryani et al., 2018; Manghi et al., 2019; Hendricks et al., 2020; Fricke, 2018) aim to create interconnected and machine-actionable representations of scholarly knowledge. They leverage semantic technologies, knowledge graphs (KGs), and ontologies to capture the meaning, context, and relationships between research concepts. The ORKG, for example, stores scholarly contributions as structured property-value pairs, enabling advanced exploration, comparison (Oelen et al., 2019), and analysis via visualizations (Wiens et al., 2020) of research findings. The strength of semantic knowledge publishing models lies in their ability to facilitate interdisciplinary collaborations, data integration, and automated processing of scholarly information. They enhance research transparency, enable advanced search and discovery, and support the development of novel strategic reading tools and services for researchers.

On the other hand, the structured abstracts methodology (Haynes et al., 1990; Hayward et al., 1993; Nakayama et al., 2005; Kulkarni, 1996; Hopewell et al., 2008), e.g., **IMRAD** (Sollaci and Pereira, 2004), focuses on organizing research articles into a specific format. **IMRAD** advocates for a structured abstract based on four points, viz. Introduction, Methods, Results, and Discussion, to

provide a standardized framework for reporting research. The strength of structured abstracts lies in their ability to provide a clear and consistent organization of research findings. They help readers quickly understand the key components of a study and locate specific information within the article. Structured abstracts facilitate efficient scanning and information retrieval.

In summary, semantic scholarly knowledge publishing models enhance the machine-actionability and interoperability of scholarly knowledge, enabling advanced computational exploration and analysis. They offer opportunities for interdisciplinary collaborations and innovative research tools. On the other hand, structured abstracts provide a standardized format for reporting research, facilitating efficient information retrieval.

### 3 Corpus

We aim to create a high-quality corpus for the complex scientific IE task introduced in this work. The corpus creation goal was to obtain gold-standard property-value structured format representation w.r.t. the six predicates in ORKG-R0 from scholarly article abstracts. These structured representations encapsulate the R0 estimate research problem for infectious diseases.

**Base corpus.** Our starting point was the large-scale CORD-19 dataset (Wang et al.) provided by AllenAI. This resource comprised a growing collection of publications and preprints on Covid-19, its variants, related historical coronaviruses such as SARS and MERS, as well as other infectious diseases such as H1N1 Influenza, Dengue, Monkeypox, Ebola, Zika virus, Norovirus, etc. At our download date timestamp 2022-06-02 it comprised over 800,000 total publications. The dataset covered diverse topics such as epidemiology, virology, clinical studies, public health, and more. It served as a valuable resource for researchers, policymakers, and the general public to access and analyze the latest scientific knowledge related to COVID-19. Since CORD-19 contained articles on various themes, as a next step the corpus was filtered to include only articles on the R0 estimate theme.

**Corpus filtering.** Our method for filtering the base corpus to our desired collection was simple. We implemented [pattern-based heuristics](#) using variants of the phrase “R0 estimate” and checked the publication abstract for containment. The base corpus was then reduced to 4590 instances. Post dedupli-

cation, the collection was further reduced to 3967 instances. Other than exact duplicates, there were other near-duplication patterns such as punctuation marks stripped or retained, numbers with or without decimal points served as different data instances. Near-duplicates were also filtered by clustering abstracts that were 95% similar (583 clusters from 1227 articles were created). A human annotator went through all clusters and decided on one abstract to retain while dropping all others. The resulting curated corpus contained 3024 abstracts which included a direct mention or a variant of the phrase “R0 estimate”.

**The ORKG-R0 model.** Here we provide an explanation of ORKG-R0 as an ideal representation of a structured contribution for the research problem of “R0 estimate,” as defined by an expert semantic modeler. The R0 estimate pertains to an infectious disease (*disease name*), for a specific population demographic (*location*), with validity for a specific time period (*date*). It reports a specific value (*R0 value*), along with a confidence interval for the statistical value (*%CI values*), and is computed by a statistical method (*method*).

**Annotation exercise.** To ensure a practical and realistic human annotation target, we selected a sub-sample of 1500 articles from the curated 3024 dataset. This would then serve as the gold-standard dataset for training and development purposes, as an empirical basis for future research. A team of two annotators produced the ORKG-R0 structured annotations with the corpus raw data comprising a paper title and abstract, where each instance is uniquely identified by a *cord\_id*. The overall annotation exercise lasted 3 months. The annotation task began by distinguishing between the papers actually reporting an R0 value as a contribution and those that just mentioned the “R0 estimate” keyword in the abstract, but did not actually report a value as a contribution of the work. Resultingly, we found 652 articles reported an R0 value and thus were annotated for the ORKG-R0 structure (referred to as the “answerable” set, in short *ans*), while 850 did not (referred to as the “unanswerable” set, in short *unans*). Among the 652 articles, approximately 157 had multiple contributions for the “R0 estimate.” Notably, a few articles stood out with 10, 11, or 16 reported contributions. The gold-standard annotated set was made available in two formats: text-based and JSON-based, which are illustrated by the green boxes in [Figure 3](#). In the text-based format, multiple contributions were

separated using a pipe character, while in the JSON format, they were encoded as separate JSON object dictionaries. We observed that the JSON data structure is more conducive for utilization in downstream applications. Therefore, our empirical analysis regarding LLMs aimed not only to assess their ability to generate structured abstract summaries but also to evaluate their compatibility with a specific data structure. This allows for the seamless integration of their output into downstream applications.

**The annotators.** In our annotation process, we first developed a structured summary model for the “R0 estimate for infectious diseases” using both domain experts and a semantic modeler specializing in ontology design. Next, a PhD student populated the model using a dataset of abstracts, treating it as a form-filling task of reported facts. While the task itself is tedious in that the student needed to read all abstracts to populate the properties, the process did not entail much ambiguity in the decisions. The definition of the properties we selected are fairly straightforward and the values are to be directly extracted from the text. For discrepancies in spans for the values selected, the LLM is expected to be robust enough to arrive at the optimal extraction scenario. For any concerns on quality, our gold-standard test dataset annotations versus the LLM predictions eventually obtained can be publicly browsed at this link <https://scinext-project.github.io/#/r0-estimates>.

**Our complex IE task objective.** We phrased the following question to formulate our task objective w.r.t. the ORKG-R0 extraction target: *What are the values for the following properties of the basic reproduction number estimate (R0): disease name, location, date, R0 value, %CI values, and method?* In essence, it encapsulates an IE task.

The ORKG-R0-based complex IE objective presents a unique approach compared to traditional scientific IE, particularly in biomedicine. Common biomedical IE tasks, like those in the BioCreative V chemical disease relation extraction task corpus (BC5CDR) corpus, focus on document-level entity and relation extraction, linking two elements such as a chemical and a disease with semantic interactions like “interacts” (Li et al., 2016). In contrast, the ORKG-R0 IE model aims to establish a multifaceted link among six distinct elements: infectious disease name, study location, study date, R0 estimate value, %confidence interval values, and method. This approach diverges from the se-

mantic interaction model of BC5CDR, as it does not establish semantic relations between its elements. Instead, it aggregates these elements to form a comprehensive summary representation of a work’s contribution to the research problem “R0 estimate for infectious diseases.”

The ORKG-R0 model is characterized by the underlying principles of the ORKG platform from which it is derived, which emphasizes structured, machine-actionable models of scholarly communication beyond traditional formats like PDFs (Auer et al., 2020). The ORKG prioritizes structured representations of a work’s contributions over exhaustive content coverage. In contrast, resources like the BC5CDR corpus (and other similar databases in biomedicine, e.g., BioCreative datasets (Rinaldi et al., 2016; Islamaj Doğan et al., 2019; Krallinger et al., 2017; Miranda et al., 2021)) focus on building extensive knowledge graphs of disease-chemical interactions, with annotations drawn from comprehensive scientific papers. While valuable, these annotations are different in their goal as they do not necessarily provide insights into the specific contributions of a work, such as the discovery of an interaction or the methods used for such discoveries. The ORKG-R0 IE, therefore, aligns more closely with research contribution summarization tasks than with traditional scientific IE tasks in biomedicine. Consequently, models developed for ORKG-R0 IE are unlikely to be directly applicable to conventional biomedical IE tasks.

In terms of objectives, our work is somewhat analogous to Leaderboards in artificial intelligence (AI), which annotate units or tuples comprising Task, Dataset, Metric, and Score (Kabongo et al., 2021a, 2023d,c). However, there are distinct differences in annotation scope: Leaderboards typically utilize the full text of papers, whereas our method relies solely on abstracts. Additionally, the AI community currently lacks a gold-standard dataset for Leaderboard annotations, a gap our dataset aims to fill. We propose our dataset as a pioneering resource in generating structured scientific summaries, addressing the current community need for standardized datasets in this domain.

**Instructions for the LLM.** Instruction tuning is a novel approach (Khashabi et al., 2020; McCann et al., 2018; Keskar et al., 2019) that improves LLMs’ performance by providing explicit instructions during finetuning, guiding the model’s behavior (Ouyang et al., 2022; Chung et al., 2022; Min et al., 2022) and enhancing its adaptability and ef-

fectiveness in diverse learning scenarios. Unlike traditional non-instruction tuning methods (Raffel et al., 2020; Liu et al., 2019; Aghajanyan et al., 2021; Aribandi et al., 2021) that rely solely on unlabeled data, instruction tuning incorporates specific guidance, simplifying the finetuning process and enabling better performance on new tasks and domains (Sanh et al., 2022). It became possible to generically prompt an LLM to perform different tasks with a single instruction. As such it can be considered as a template that encodes the task and its objective, in turn telling the LLM what to do with the given objective.

The “Flan 2022 Collection” was a large-scale open-sourced collection of 62 prior publicly released datasets in the NLP community clustered as 12 task types, such as reading comprehension (RC), sentiment, natural language inference (NLI), struct to text, etc. It is the most comprehensive resource facilitating open-sourced LLM development as generic multi-task models. Importantly, and of relevance to this work, FLAN was not just a super-amalgamation of datasets encapsulating different learning objectives, but also included at least 10 human-curated natural instructions per dataset that described the task for that dataset. As such, we select a set of instructions to guide the LLM for our complex IE task from the FLAN collection. Specifically, we identified the applicable instructions to our task were those designed for the SQuAD\_v2 (Rajpurkar et al., 2016, 2018) and DROP (Dua et al., 2019) datasets. The general characteristic of the selected instructions is that they encode a context (in our case the paper title and abstract) and the task objective, and instruct the model to fulfill the objective. See Appendix B for further details. The purple boxes in Figure 3 show some exemplars. Examples of all instructions are in Appendix A.

Our work is positioned here, coalescing the most relevant collection of instructions that were used to instruction-finetune the T5 (2020) model class, as the strong reference point for any future open source work on single-task instruction finetuning.

## 4 Approach

Our approach is single-task instruction-finetuning for our novel introduced complex IE task. As such it aims to be an incremental progression of the instruction-tuning paradigm introduced as FLAN (Finetuned Language Net) (2021; 2022;

2023). Specifically Chung et al. (2022) ask: *are instruction-finetuned models better for single-task finetuning?* as a recommendation for future work. Our work then is a direct examination of this research question except for a novel task type that we also introduce for the first time in the community.

Now, we outline our methodology. **Step 1.** Collect relevant instructions for ORKG-R0 complex IE to guide an LLM towards the desired objective. **Step 2.** Instantiate the instructions to the LLM using gold-standard structured data and a formulated question (e.g. in Appendix A). **Step 3.** Finetune the LLM with the instruction-instantiated data. Three training strategies are explored: single-instruction tuning, all-instruction tuning, and best-instruction tuning based on evaluation results.

## 4.1 Model

We adopt the FLAN-T5 model (Chung et al., 2022) w.r.t. its public checkpoints. This encoder-decoder sequence generation model is available in a range of sizes: Small 80M, Base 250M, Large 780M, XL 3B, and XXL 11B. We choose the Large model as a middle ground between the Small and XXL models, providing enough parameters for our complex IE task and practicality for deployment. Additionally, we find it inefficient to test extreme scale LLMs for a single task. Our choice of Flan-T5 was motivated by prior empiricism (Longpre et al., 2023) proving instruction-tuned models as more computationally efficient starting checkpoints for new tasks – FLAN-T5 required less finetuning to converge higher and faster than T5 on single downstream tasks (2023). Our model choice builds upon previous research, enhancing the T5 text-to-text sequence generation model (2020) with FLAN-T5 (2022) to improve alignment with instructions in unseen tasks and zero-shot settings. Our resulting model is called ORKG-FLAN-T5<sub>R0</sub>.

## 5 Evaluations

**Dataset.** For evaluations, we created a 70%/10%/20% split as train/dev/test sets, respectively, of the 1500 instances. The dataset comprised 1,082 train (464 ans, 618 unans), 120 dev (53 ans, 67 unans), and 300 test (135 ans, 165 unans) instances.

**Experimental setup.** We used a total of 18 instructions for training, with 9 instructions each from SQuAD\_v2 and DROP, specifically instantiated in appendices A.1 and A.2, respectively, suitable for our task. Among these, 2 DROP instructions were

Table 3: Our top three ORKG-FLAN-T5<sub>R0</sub> single-task instruction-finetuned models, based on the single-instruction tuning setting in descending order of overall partial F1 for the JSON answer. 1st column: models trained on DROP instr. 3 (d3), SQuAD\_v2 instr. 8 (s8), and SQuAD\_v2 instr. 10 (s10). Last column: best inference instructions.

formulated to prompt the LLM to generate a question from a given context. Although indirect to our task, we included them as they were relevant to obtaining capable models, but were excluded from testing. Thus for testing, we had 16 instructions (9 SQuAD and 7 DROP). For training, we had three main experimental settings based on the 18 training instructions. In the first setting, we trained 32 models (16 for text-format and 16 for JSON-format) by tuning FLAN-T5 with a single instruction for our task. Note here models were not trained for the indirect instruction. This setting tested the hypothesis that FLAN-T5 only needed one instruction to perform our task effectively since it already came instruction tuned. In the second setting, we trained two models: one using all 18 instructions with the full training data, and the other using a 50% random sub-sample to prevent overfitting. This resulted in

four models for each answer format. The third setting followed a similar approach, training two models with best SQuAD and DROP instructions based on single instruction inference results. Overall, we trained 40 models. Model hyperparameter details are in Appendix C. In terms of compute, all experiments were run on an NVIDIA 3090 GPU. Training took 12-15 hours on smaller datasets and 30 hours on larger datasets, while inference lasted 15-30 minutes for 300 test instances.

**Metrics.** We experimented in two main settings: zero-shot evaluations and single-task finetuned model evaluations. For the latter, we used recall, precision, and F1 metrics in exact and partial match settings for each of the six ORKG-R0 extraction targets and overall. In the zero-shot evaluations, where models were not guaranteed to respond with the desired structure, we treated the task as struc-

tured summarization. To evaluate these summaries, we used standard summarization ROUGE metrics (Lin, 2004) (details in Appendix D) instead of F1 metrics, which would require complex post-processing and could lead to misinterpretation of the model’s response.

## 5.1 Results and Discussion

**Zero-shot evaluations.** Table 1 results show model’s capacity in generating structured summaries per ORKG-R0. Notably, our single-task instruction-finetuned ORKG-FLAN-T5<sub>R0</sub> model surpasses its incremental predecessors T5 and FLAN-T5 with the same parameter size of 780M, as well as GPT3.5 (with 1000x more parameters at 175B), confirming the effectiveness of instruction-tuned models for single-task finetuning. Additionally, the general accuracy of the model, which distinguishes between answerable and unanswerable contexts, is significantly improved, at nearly 89%. **Single-task finetuning of instruction-tuned LLM.** From the 40 trained models, the best results were achieved in the single-instruction tuning setting, as shown in Table 2 and 3 for text and JSON answers respectively. The best partial overall F1 scores were 55.89% for text answer and 55.28% for JSON answer. Among the 6 properties, extracting R0 and %CI values was relatively easier with higher scores for text than JSON. Extracting the method and date proved to be the most challenging. Since our work builds upon the instruction-tuned FLAN-T5 model, it already possesses the capability to handle the instructions we use. Thus, the best inference instruction was not necessarily the same as the one the model was trained on. More results from the all-instruction and best-instruction models can be found in Appendix E.

**Impact of diverse inference instructions.** Figure 4 offers a look into the inference performance differences from the best ORKG-FLAN-T5<sub>R0</sub> model. As such the model shows better responses to the SQuAD (orange lines) versus DROP (green lines) inference templates in both text (darker lines) and JSON (lighter lines) answers.

## 6 Error Analysis

Based on an analysis of all the erroneous responses on the test set from our best model, we identified five main error types. They were further categorized on their impact on recall or precision. For each, mismatching (prediction, annotated label),

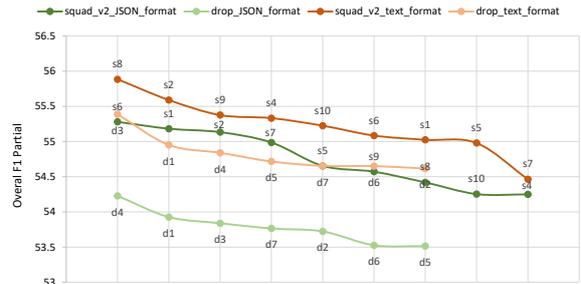

Figure 4: Performances range on inference instructions.

we assigned an error type(s) and on which properties that error had an effect. The five error types are: *Type 1* is where the model answers unanswerable questions (Type 1.1) or fails to provide answers for answerable questions (Type 1.2). *Type 2* is where the model predicts values for a property and the label had no value (Type 2.1) or does not predict a value when the label had a value (Type 2.2). *Type 3* is where the model predicts either more (Type 3.1) or fewer (Type 3.2) contributions than indicated in the label. *Type 4* were inconsistencies between predicted and label values. This may include minor typographical errors (Type 4.1), not fully addressing the label values but still providing a related value in prediction (Type 4.2), including extra related information in prediction (Type 4.3), or generating totally unrelated predicted values (Type 4.4). *Type 5.1* is an invalid predicted JSON.

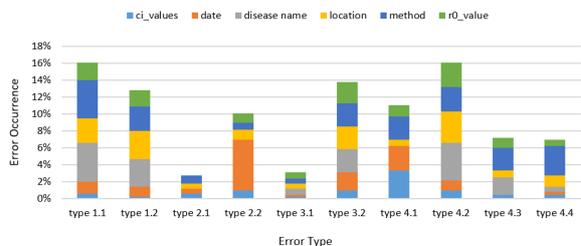

Figure 5: Our best model error types for text format.

**Text Response Format.** As shown in Figure 5, the most frequent errors in the text-based settings are unanswerable labels (Type 1.1) and incomplete predictions (Type 4.2). These two errors have similar distributions across properties and "method" is the most affected property overall. Type 2.2 errors significantly impact the accuracy of extracting "date" values. In contrast, Type 2.1 and Type 3.1 errors are rare, indicating the model’s ability to generate property values and contributions appropriately. Typographical errors (Type 4.1) are common, particularly for "%CI values" and "date,"

suggesting that normalizing label values and using a standard can improve performance in this regard.

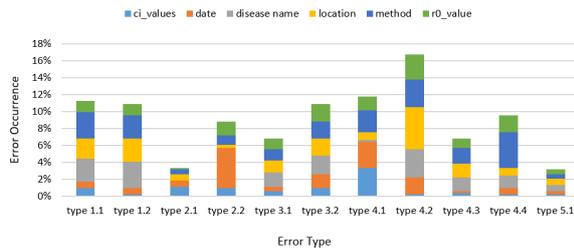

Figure 6: Our best model error types for JSON format.

**JSON Response Format.** Figure 6 shows error Type 4.2 is the primary error affecting properties, similar to text-format errors. The "method" property is the most affected overall, while "date" is particularly impacted by error Type 2.2, highlighting a common issue in JSON-based models. However, JSON models exhibit fewer errors of Type 1 (unanswerable) and instead tend to make more errors in predicting extra text (Type 2.1 and Type 3.1).

## 7 Conclusions and Future Directions

Searching scientific articles for the [Covid-19 R0 estimate](#) yields around 44,000 results. To navigate through this vast amount of information and stay up-to-date with the latest R0 estimates, is undating for researchers. Next-generation digital libraries like ORKG are transforming this traditional paradigm by capturing machine-actionable data, enabling advanced computational tools such as [research comparisons](#). LLM-powered complex IE technologies can play a crucial role in scaling scientific information extraction. We present a concrete use-case in virology, showcasing the acquisition of LLM-powered structured knowledge with the ORKG-R0 model. To facilitate reproducibility and foster future research, we have made available several resources: our dataset (<https://doi.org/10.5281/zenodo.8068441> licensed under CC BY 4.0), [instructions](#), source code (<https://github.com/mahsaSH717/r0-estimates> licensed under MIT), and our optimally finetuned model for the ORKG-R0 IE task at [https://huggingface.co/orkg/R0\\_contribution\\_IE](https://huggingface.co/orkg/R0_contribution_IE). Additionally, for enhanced transparency, a selection of our human-annotated test dataset and its corresponding model predictions can be browsed online here <https://scinext-project.github.io/#/r0-estimates>.

To sum up, our work can be seen as a flavor of meta-learning that was seminaly proposed by [Min et al. \(2022\)](#) as the meta in-context learning paradigm. We explore meta-learning through instruction-finetuning of an instruction-tuned model, and differ in that we use a zero-shot rather than a few-shot training and testing scenario. We relegate few-shot in-context model learning to future work. While this work comprehensively evaluates the T5 class of LLMs, there are other promising LLMs like PaLM ([Chowdhery et al., 2022](#)), Chinchilla ([Hoffmann et al., 2022](#)), and ChatGPT ([Brown et al., 2020](#); [Ouyang et al., 2022](#)) that can be further investigated for NLP tasks with instructions. Exploring alternative model families is a fruitful direction for future research. Additionally, model distillation ([Hinton et al., 2015](#); [Jiao et al., 2020](#); [Sanh et al., 2019](#); [Wang et al., 2020b](#)) holds potential for transferring knowledge from large teacher models to smaller, efficient student models. This approach holds promise, particularly in scenarios where single-task tuned models are desired, as we propose in this study.

## Limitations

This section presents a discussion of the limitations w.r.t. the two main facets of this work: structured scholarly knowledge publishing (paragraph I) and LLM scaling experiments for single-task instruction finetuning (paragraph II).

### I. Structured Scholarly Knowledge Publishing

This work proposes the ORKG-R0 model that records a fine-grained structured representation of the salient facets of a research contribution on the specific research problem of investigating the R0 number of infectious diseases. For such popular research use-cases in the community, e.g., capturing Leaderboards in the empirical AI research as Task, Dataset, Metric, and Score ([Kabongo et al., 2021b, 2023a,b](#)), as another example apart from the one we address in this work, a current limitation that such a contribution-centric fine-grained structured scholarly knowledge publishing model faces is its *adoption and standardization*. The widespread adoption of the semantic scholarly knowledge publishing model is still in its early stages, and achieving consensus on standard formats, ontologies, and metadata remains a challenge. This lack of standardization can hinder interoperability and limit the accessibility of knowledge across different platforms and communities. To

overcome this limitation, i.e. to realize this vision of the publishing of fine-grained structured scholarly contributions to better assist researchers to stay on track with research progress many more collaborative advocacy and community-building efforts would need to be set in place. The trajectory, however, looks promising. The ORKG since its inception in 2018 currently has a knowledge base of roughly 41k structured contributions. More stats here <https://orkg.org/stats>. In addition, yearly paid community curation grants are run inviting researchers from various disciplines to help curate a high-quality knowledge graph ([https://orkg.org/about/28/Curation\\_Grants](https://orkg.org/about/28/Curation_Grants)). Finally, the ORKG has initiated collaborations with various conferences and journals that ask authors to submit research comparisons of their work versus related work to help expedite the peer-review process. E.g., see the last point in the Author Guidelines in the SEMANTiCS 2023 call for papers [https://2023-eu.semantics.cc/page/cfp\\_rev\\_rep](https://2023-eu.semantics.cc/page/cfp_rev_rep). To this end, the platform is integrated with content creator anonymization features to support double-blind review protocols. More information here [https://orkg.org/about/22/Conferences\\_and\\_Journals](https://orkg.org/about/22/Conferences_and_Journals).

As a second limitation of semantic publishing, the ORKG is designed to be a next-generation digital library that supports fine-grained scholarly knowledge publishing stored as a large-scale knowledge graph in the backend (Jaradeh et al., 2019). It is also amenable to be published in the Linked Open Data (LOD) Cloud <https://lod-cloud.net/>. Thus it follows the best practices laid out in Berners-Lee et al.’s (2001) the Semantic Web. As such the engineering of this platform entails a high degree of *technical complexity* compared with the traditional PDF-based publishing platforms. Implementing and maintaining the infrastructure required for semantic publishing models can be technically complex and resource-intensive. It requires expertise in semantic technologies, data management, and ontological engineering. Nevertheless, the ORKG platform supports the integration of widgets for its various features in other platforms. This would lower the technical entrance barrier for other publishers to also support the semantic publishing of scientific contributions.

## II. Scaling Single-Task Instruction-tuning of LLMs

This work has investigated the moderate-

sized FLAN-T5 Large model with 780M parameters. Prior work reported: “we see that increasing model scale by an order of magnitude (i.e., 8B -> 62B or 62B -> 540B) improves performance substantially for both finetuned and non-finetuned models” (Chung et al., 2022). Borrowing insights from the earlier experiments on scaling models, potentially, a single-task finetuned model performance could be boosted if larger scale models were used. This aspect while not analyzed in this work is relegated to future work. However, a more practically viable option would not just be additional scaling investigations, but these combined with model distillation (Hinton et al., 2015).

## A Instructions: Qualitative Examples

In this section, we elicit each of the instructions that were considered in this work as formulated in the FLAN 2022 Collection for the SQuAD\_v2 and DROP datasets.

### A.1 The Stanford Question Answering Dataset (SQuAD\_v2)

#### Instruction 1:

**title:** Estimating the serial interval of the novel coronavirus disease (COVID-19) based on the public surveillance data in Shenzhen, China, from 19 January to 22 February 2020

**context:** The novel coronavirus disease (COVID-19) poses a serious threat to global public health and economics. Serial interval (SI), time between the onset of symptoms of a primary case and a secondary case, is a key epidemiological parameter. We estimated SI of COVID-19 in Shenzhen, China based on 27 ...

**question:** What are the values for the following properties of the basic reproduction number estimate (R0): disease name, location, date, R0 value, %CI values, and method?

#### Instruction:

{title}:\n\n{context}\n\n Please answer a question about this article. If the question is unanswerable, say "unanswerable". {question}

#### Instruction 2:

**context:** Estimating the serial interval of the novel coronavirus disease (COVID-19) based on the public surveillance data in Shenzhen, China, from 19 January to 22 February 2020

The novel coronavirus disease (COVID-19) poses a serious threat to global public health and economics. Serial interval (SI), time between the onset of symptoms of a primary case and a secondary case, is a key epidemiological parameter. We estimated SI of COVID-19 in Shenzhen, China based on 27 ...

**question:** What are the values for the following properties of the basic reproduction number estimate (R0): disease name, location, date, R0 value, %CI values, and method?

**Instruction:** Read this and answer the question. If the question is unanswerable, say "unanswerable".\n\n{context}\n\n{question}

#### Instruction 3:

*This instruction is omitted in this work.*

**Instruction:** (What is a question about this article? If the question is unanswerable, say "unanswerable"),\n\n{context}\n\n{question}

#### Instruction 4:

**context:** Estimating the serial interval of the novel coronavirus disease (COVID-19) based on the public surveillance data in Shenzhen, China, from 19 January to 22 February 2020

The novel coronavirus disease (COVID-19) poses a serious threat to global public health and economics. Serial interval (SI), time between the onset of symptoms of a primary case and a secondary case, is a key epidemiological parameter. We estimated SI of COVID-19 in Shenzhen, China based on 27 ...

**question:** What are the values for the following properties of the basic reproduction number estimate (R0): disease name, location, date, R0 value, %CI values, and method?

**Instruction:** {context}\n\n{question} (If the question is unanswerable, say "unanswerable")

#### Instruction 5:

**context:** Estimating the serial interval of the novel coronavirus disease (COVID-19) based on the public surveillance data in Shenzhen, China, from 19 January to 22 February 2020

The novel coronavirus disease (COVID-19) poses a serious threat to global public health and economics. Serial interval (SI), time between the onset of symptoms of a primary case and a secondary case, is a key epidemiological parameter. We estimated SI of COVID-19 in Shenzhen, China based on 27...

**question:** What are the values for the following properties of the basic reproduction number estimate (R0): disease name, location, date, R0 value, %CI values, and method?

**Instruction:** {context}\n\n Try to answer this question if possible (otherwise reply "unanswerable"): {question}

#### Instruction 6:

**context:** Estimating the serial interval of the novel coronavirus disease (COVID-19) based on

the public surveillance data in Shenzhen, China, from 19 January to 22 February 2020

The novel coronavirus disease (COVID-19) poses a serious threat to global public health and economics. Serial interval (SI), time between the onset of symptoms of a primary case and a secondary case, is a key epidemiological parameter. We estimated SI of COVID-19 in Shenzhen, China based on 27...

**question:** What are the values for the following properties of the basic reproduction number estimate (R0): disease name, location, date, R0 value, %CI values, and method?

**Instruction:** {context}\n\n If it is possible to answer this question, answer it for me (else, reply "unanswerable"): {question}

#### Instruction 7:

**context:** Estimating the serial interval of the novel coronavirus disease (COVID-19) based on the public surveillance data in Shenzhen, China, from 19 January to 22 February 2020

The novel coronavirus disease (COVID-19) poses a serious threat to global public health and economics. Serial interval (SI), time between the onset of symptoms of a primary case and a secondary case, is a key epidemiological parameter. We estimated SI of COVID-19 in Shenzhen, China based on 27...

**question:** What are the values for the following properties of the basic reproduction number estimate (R0): disease name, location, date, R0 value, %CI values, and method?

**Instruction:** {context}\n\n Answer this question, if possible (if impossible, reply "unanswerable"): {question}

#### Instruction 8:

**context:** Estimating the serial interval of the novel coronavirus disease (COVID-19) based on the public surveillance data in Shenzhen, China, from 19 January to 22 February 2020

The novel coronavirus disease (COVID-19) poses a serious threat to global public health and economics. Serial interval (SI), time between the onset of symptoms of a primary case and a secondary case, is a key epidemiological parameter. We estimated SI of COVID-19 in Shenzhen, China based on 27...

**question:** What are the values for the following properties of the basic reproduction number esti-

mate (R0): disease name, location, date, R0 value, %CI values, and method?

**Instruction:** Read this: {context}\n\n {question} \n What is the answer? (If it cannot be answered, return "unanswerable")

#### Instruction 9:

**context:** Estimating the serial interval of the novel coronavirus disease (COVID-19) based on the public surveillance data in Shenzhen, China, from 19 January to 22 February 2020

The novel coronavirus disease (COVID-19) poses a serious threat to global public health and economics. Serial interval (SI), time between the onset of symptoms of a primary case and a secondary case, is a key epidemiological parameter. We estimated SI of COVID-19 in Shenzhen, China based on 27...

**question:** What are the values for the following properties of the basic reproduction number estimate (R0): disease name, location, date, R0 value, %CI values, and method?

**Instruction:** Read this: {context}\n\n Now answer this question, if there is an answer (If it cannot be answered, return "unanswerable"): {question}

#### Instruction 10:

**context:** Estimating the serial interval of the novel coronavirus disease (COVID-19) based on the public surveillance data in Shenzhen, China, from 19 January to 22 February 2020

The novel coronavirus disease (COVID-19) poses a serious threat to global public health and economics. Serial interval (SI), time between the onset of symptoms of a primary case and a secondary case, is a key epidemiological parameter. We estimated SI of COVID-19 in Shenzhen, China based on 27...

**question:** What are the values for the following properties of the basic reproduction number estimate (R0): disease name, location, date, R0 value, %CI values, and method?

**Instruction:** {context}\n\n Is there an answer to this question (If it cannot be answered, say "unanswerable"): {question}

## A.2 Discrete Reasoning over Paragraphs (DROP) Dataset

### Instruction 1:

**context:** Estimating the serial interval of the novel coronavirus disease (COVID-19) based on the public surveillance data in Shenzhen, China, from 19 January to 22 February 2020

The novel coronavirus disease (COVID-19) poses a serious threat to global public health and economics. Serial interval (SI), time between the onset of symptoms of a primary case and a secondary case, is a key epidemiological parameter. We estimated SI of COVID-19 in Shenzhen, China based on 27...

**question:** What are the values for the following properties of the basic reproduction number estimate (R0): disease name, location, date, R0 value, %CI values, and method?

**Instruction:** Answer based on context: \n \n {context} \n \n {question}

### Instruction 2:

**context:** Estimating the serial interval of the novel coronavirus disease (COVID-19) based on the public surveillance data in Shenzhen, China, from 19 January to 22 February 2020

The novel coronavirus disease (COVID-19) poses a serious threat to global public health and economics. Serial interval (SI), time between the onset of symptoms of a primary case and a secondary case, is a key epidemiological parameter. We estimated SI of COVID-19 in Shenzhen, China based on 27...

**question:** What are the values for the following properties of the basic reproduction number estimate (R0): disease name, location, date, R0 value, %CI values, and method?

**Instruction:** {context} \n \n Answer this question based on the article: {question}

### Instruction 3:

**context:** Estimating the serial interval of the novel coronavirus disease (COVID-19) based on the public surveillance data in Shenzhen, China, from 19 January to 22 February 2020

The novel coronavirus disease (COVID-19) poses a serious threat to global public health and economics. Serial interval (SI), time between the onset of symptoms of a primary case and a secondary case, is a key epidemiological parameter. We estimated SI of COVID-19 in Shenzhen, China based on 27...

**question:** What are the values for the following properties of the basic reproduction number esti-

mate (R0): disease name, location, date, R0 value, %CI values, and method?

**Instruction:** {context} \n \n {question}

### Instruction 4:

**context:** Estimating the serial interval of the novel coronavirus disease (COVID-19) based on the public surveillance data in Shenzhen, China, from 19 January to 22 February 2020

The novel coronavirus disease (COVID-19) poses a serious threat to global public health and economics. Serial interval (SI), time between the onset of symptoms of a primary case and a secondary case, is a key epidemiological parameter. We estimated SI of COVID-19 in Shenzhen, China based on 27...

**question:** What are the values for the following properties of the basic reproduction number estimate (R0): disease name, location, date, R0 value, %CI values, and method?

**Instruction:** {context} \n Answer this question: {question}

### Instruction 5:

**context:** Estimating the serial interval of the novel coronavirus disease (COVID-19) based on the public surveillance data in Shenzhen, China, from 19 January to 22 February 2020

The novel coronavirus disease (COVID-19) poses a serious threat to global public health and economics. Serial interval (SI), time between the onset of symptoms of a primary case and a secondary case, is a key epidemiological parameter. We estimated SI of COVID-19 in Shenzhen, China based on 27...

**question:** What are the values for the following properties of the basic reproduction number estimate (R0): disease name, location, date, R0 value, %CI values, and method?

**Instruction:** Read this article and answer this question {context} \n {question}

### Instruction 6:

**context:** Estimating the serial interval of the novel coronavirus disease (COVID-19) based on the public surveillance data in Shenzhen, China, from 19 January to 22 February 2020

The novel coronavirus disease (COVID-19) poses a serious threat to global public health and economics. Serial interval (SI), time between the

onset of symptoms of a primary case and a secondary case, is a key epidemiological parameter. We estimated SI of COVID-19 in Shenzhen, China based on 27...

**question:** What are the values for the following properties of the basic reproduction number estimate (R0): disease name, location, date, R0 value, %CI values, and method?

**Instruction:** {context}\n\n Based on the above article, answer a question. {question}

#### **Instruction 7:**

**context:** Estimating the serial interval of the novel coronavirus disease (COVID-19) based on the public surveillance data in Shenzhen, China, from 19 January to 22 February 2020

The novel coronavirus disease (COVID-19) poses a serious threat to global public health and economics. Serial interval (SI), time between the onset of symptoms of a primary case and a secondary case, is a key epidemiological parameter. We estimated SI of COVID-19 in Shenzhen, China based on 27...

**question:** What are the values for the following properties of the basic reproduction number estimate (R0): disease name, location, date, R0 value, %CI values, and method?

**Instruction:** Context: {context}\n\n Question: {question}\n\n Answer:

#### **Instruction 8:**

*This instruction is omitted in this work.*

**Instruction:** Write an article that answers the following question: {question}

#### **Instruction 9:**

*Note single-instruction finetuned models were not trained on this instruction. This instruction was only used in the all-instruction training setting.*

**context:** Estimating the serial interval of the novel coronavirus disease (COVID-19) based on the public surveillance data in Shenzhen, China, from 19 January to 22 February 2020

The novel coronavirus disease (COVID-19) poses a serious threat to global public health and economics. Serial interval (SI), time between the onset of symptoms of a primary case and a secondary case, is a key epidemiological parameter. We estimated SI of COVID-19 in Shenzhen, China based on 27...

**question:** What are the values for the following properties of the basic reproduction number estimate (R0): disease name, location, date, R0 value, %CI values, and method?

**Instruction:** Write a question about the following article: {context}

#### **Instruction 10:**

*Note single-instruction finetuned models were not trained on this instruction. This instruction was only used in the all-instruction training setting.*

**context:** Estimating the serial interval of the novel coronavirus disease (COVID-19) based on the public surveillance data in Shenzhen, China, from 19 January to 22 February 2020

The novel coronavirus disease (COVID-19) poses a serious threat to global public health and economics. Serial interval (SI), time between the onset of symptoms of a primary case and a secondary case, is a key epidemiological parameter. We estimated SI of COVID-19 in Shenzhen, China based on 27...

**question:** What are the values for the following properties of the basic reproduction number estimate (R0): disease name, location, date, R0 value, %CI values, and method?

**Instruction:** {context}\n\n Ask a question about this article.

## **B ORKG-R0 for the FLAN Collection**

In this section, we discuss the relation of our complex IE task formulated as ORKG-R0 to the task types already in the FLAN collection (2021; 2023) as a new candidate for inclusion. As mentioned earlier, FLAN has 12 task type clusters of 63 datasets. Two of which are reading comprehension (RC) and struct-to-text, among others. In this respect, our task could either be considered part of the RC task or as a new task type i.e. text-to-struct. In an RC task, e.g. SQuAD (2016), a context passage is provided along with a question to test comprehension. Our complex IE task is similar, where given a scholarly paper's title and abstract as context, the machine must generate a structured summary by understanding the context and assigning applicable extracted values for the ORKG-R0 properties. Furthermore, the model must also create ORKG-R0 clusters for abstracts reporting multiple contributions.<sup>2</sup> Otherwise, it could be intro-

<sup>2</sup>Note, there is a subtle difference between RC and the related question-answering (QA) task type. In QA, complex

duced into the FLAN collection as a new task type called text-to-struct. As such, for instance, the WebNLG (Gardent et al., 2017) or DART (Nan et al., 2021) datasets in the struct-to-text cluster, seek to convert structured data in RDF to text. Notably, our task is its direct inverse which seeks to obtain structured property-value tuples which can easily be represented in RDF syntax.

## C Our Experimental Hyperparameters

We had different training experimental settings to train on different datasets with different sizes (single-instruction model tuning, all-instructions model tuning, all-instructions model tuning with 50% subsampled training data, best-instructions model tuning, and best-instructions model tuning with 50% subsampled training data).

The hyperparameters are: batch size and number of training epochs, which differ based on each dataset group mentioned above. the batch size was either 32 or 16 and the number of epochs were one of 10, 15, 20, and 30 values. In all settings we used early stopping which stops the training if the "Overall Partial F1" score dose not improve at least 0.1% after completing 10 consecutive training epochs. For all settings we used AdafactorSchedule and Adafactor optimizer (Shazeer and Stern, 2018) with `scale_parameter=True`, `relative_step=True`, `warmup_init=True`, `lr=None`, which is one of the combinations working well according to the community for T5 finetuning.

The evaluations were done on each epoch on the dev set and we kept two best (the one maximizing the "Overall Partial F1" score) and last checkpoints in each model training process to then use for inference on test set.

## D ROUGE Evaluation Metrics

The ROUGE metrics (Lin, 2004) are commonly used for evaluating the quality of text summarization systems. ROUGE-1 measures the overlap of unigram (single word) units between the generated summary and the reference summary. ROUGE-2 extends this to measure the overlap of bigram (two consecutive word) units. ROUGE-L calculates the longest common subsequence between the generated and reference summaries, which takes into account the order of words. ROUGE-LSum is

---

IE would require breaking down the RC extraction target into multiple questions, such as the disease name or the reported location, etc., unlike in RC.

an extension of ROUGE-L that considers multiple reference summaries by treating them as a single summary. These metrics provide a quantitative assessment of the similarity between the generated and reference summaries, helping researchers and developers evaluate and compare the effectiveness of different summarization approaches. They have become widely used benchmarks in the field of automatic summarization.

## E Additional Results

Finally, in this last appendix section, we show the highest and lowest results obtained from the two other experimental settings discussed in the main paper. I.e. all-instruction model finetuning, in two subsettings: with all the training data and with a 50% random subsample of the training data. These results are presented in Table 4 and Table 5, respectively, for the text format and JSON format responses. And furthermore, results are shown for the best-instruction finetuning setting in two subsettings: with all the training data and with a 50% random subsample of the training data. These results are presented in Table 6 and Table 7, respectively, for the text format and JSON format responses.

## Abstract

Generative retrieval models encode pointers to information in a corpus as an index within the model’s parameters. These models serve as part of a larger pipeline, where retrieved information conditions generation for knowledge-intensive NLP tasks. However, we identify two limitations: the generative retrieval does not account for contextual information. Secondly, the retrieval can’t be tuned for the downstream readers as decoding the page title is a non-differentiable operation. This paper introduces Re3val, trained with generative reranking and reinforcement learning using limited data. Re3val leverages context acquired via Dense Passage Retrieval to rerank the retrieved page titles and utilizes REINFORCE to maximize rewards generated by constrained decoding. Additionally, we generate questions from our pre-training dataset to mitigate epistemic uncertainty and bridge the domain gap between the pre-training and fine-tuning datasets. Subsequently, we extract and rerank contexts from the KILT database using the rerank page titles. Upon grounding the top five reranked contexts, Re3val demonstrates the Top 1 KILT scores compared to all other generative retrieval models across five KILT datasets.

## 1 Introduction

The primary objective of retrieval models is to enhance the accuracy of answers by selecting the most relevant documents retrieved for a given query, ensuring models have sufficient information to help the downstream reasoning process. For instance, DRQA (Chen et al., 2017) introduces a "retrieve and read" pipeline using TF-IDF to return documents for a question answering model to achieve this goal. More recently, NLP researchers have studied neural retrieval models like Dense Passage Retrieval (DPR) (Karpukhin et al., 2020)

<sup>†</sup>Work performed while at KAIST AI.

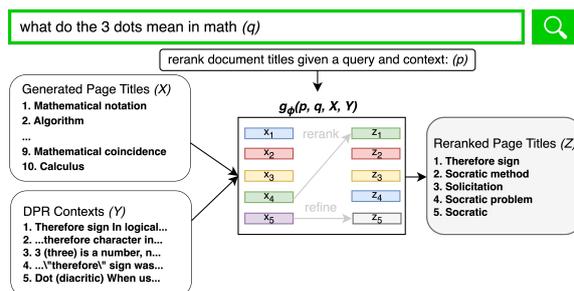

Figure 1: Re3val’s Page Title Reranker ( $g_\phi$ ) enhances generated page titles ( $X$ ) with DPR contextual information ( $Y$ ), producing reranked titles ( $Z$ ). This is crucial when documents in  $X$  lack a suitable answer to a query ( $q$ ), as depicted in the figure.

with a seq2seq model to build retrieval augmented language models.

Rather than using inner-product-based retrieval, generative retrieval models such as GENRE (Cao et al., 2021) and CorpusBrain (Chen et al., 2022) generate page titles through constrained decoding, attaining higher R-Precision and Recall compared to DPR. In our work, we further evaluate how additional contextual information can benefit the generative retrieval models through reranking and how reinforcement learning can enhance relevance through reward signals.

We introduce Re3val: Reinforced and Reranked Generative Retrieval, a novel framework specifically designed to address the challenges in neural information retrieval. Our approach utilizes 500k pre-training data and 48k task-specific data for training. Despite the reduced data used in distant supervision, Re3val achieves exceptional performance. Our contributions are described as below:

- We minimize the entropy of the initially retrieved page titles with contexts obtained from DPR, facilitating the novel generative reranking process. Through this reranking procedure, Re3val outperforms other generative retrieval models, including GENRE, Corpus-

Brain, and SEAL (Bevilacqua et al., 2022) in terms of average R-Precision across five tasks, showcasing an average increase of 1.9%.

- We incorporate REINFORCE (Williams, 1992) to integrate information during the decoding process of generative retrieval. Combined with question generation, REINFORCE enables Re3val to outperform CorpusBrain zero-shot retrieval with an average improvement of 8% in R-Precision across five tasks.
- We suggest a new generative "retrieve and read" pipeline that extracts the contexts for the reranked page titles, applies our context reranker, and grounds answers with the reranked contexts. As a result, Re3val distinguishes itself by achieving the highest KILT scores among other generative retrieval models, with an average increase of 2.1%.

In summary, Re3val uses DPR contexts for reranking page titles, leading to improved R-Precision. Re3val enhances performance by integrating generated questions in pre-training and utilizing REINFORCE during distant supervision. Moreover, Re3val achieves more accurate answers by reading reranked contexts retrieved with the reranked page titles. These advancements enable Re3val to achieve state-of-the-art performance while also offering cost savings by reducing training time and minimizing the need for extensive data labeling.

## 2 Related Work

### 2.1 Document Retrieval

TF-IDF (Johns, 1972) and BM25 (Robertson et al., 2009) assign weight to terms in a document based on their term frequency and inverse document frequency. These methods cannot inherently consider semantic shift or distribution similarity while computing similarity metrics. In light of this limitation, Karpukhin et al. (2020) introduce the Dense Passage Retrieval (DPR), establishing a bi-encoder that creates dense embeddings of questions and related passages within a corpus. These embeddings are subsequently compared using a dot product operation. During inference, DPR retrieves the top-k relevant contexts employing either Nearest Neighbor Search or Maximum Inner Product Search on the FAISS index. Guu et al. (2020) and Lewis et al. (2020) retrieve knowledge from a corpus using DPR and generate an answer using a variant

of the Transformer models. FiD (Fusion in Decoder) (Izacard and Grave, 2021) extends T5 (Wolf et al., 2020) by combining independently encoded queries and retrieved passages to decode an answer. However, these models do not rerank retrieved documents that allow a reader to perform better with fewer contexts utilized for a reader.

### 2.2 Generative Retrieval

Cao et al. (2021) introduce an Autoregressive Entity Retrieval model (GENRE). GENRE utilizes seq2seq language models for page title retrieval and employs a trie-based constrained decoding approach. This allows GENRE to assign a probability of 0 to non-existing page titles, ensuring accurate retrieval. Moreover, Chen et al. (2022) propose CorpusBrain, a generative retrieval model encoding the knowledge about the corpus through pre-training strategies. DEARDR (Thorne, 2022) proposes three distinct pre-training regimens and a data-efficient distant supervision method for generative retrieval. Moreover, SEAL (Bevilacqua et al., 2022) leverages an FM-Index to efficiently generate n-grams within the corpus for fast lookup speed without increasing the index size. The Differentiable Search Index (DSI) (Tay et al., 2022) employs a seq2seq model to map individual queries to atomic document identifiers, which in turn are associated with segmented chunks of the document. Similarly, the Neural Corpus Index (NCI) (Wang et al., 2022) utilizes hierarchical k-means for document representation, generates queries based on content, and trains a transformer model with a Prefix-Aware Weight-Adaptive Decoder using Consistency-based regularization. However, these models overlook the opportunity to minimize additional entropies in retrieved page titles or documents by incorporating contextual information. Leveraging such information reduces randomness and refines the ranking. Moreover, these models overlook the potential benefits of harnessing knowledge during decoding.

### 2.3 Question Generation

In the past, numerous endeavors (Labutov et al., 2015; Chali and Hasan, 2015; Serban et al., 2016; Duan et al., 2017) have been made to generate questions to enhance the task of Question Answering. Recently, studies analyzing questions have attempted to find the relationship with contexts. Mao et al. (2021) propose Generation-Augmented Retrieval (GAR) that generates query contexts. GAR

employs a BM-25 retrieval model and achieves performance comparable to DPR. Sachan et al. (2022) create questions based on the retrieved contexts and rerank contexts based on the log-likelihood score over the generated questions. However, these studies overlook the fact that question generation can address the epistemic uncertainty arising from limited knowledge (Kendall and Gal, 2017) in question answering tasks by minimizing the domain gap between pre-training and fine-tuning data.

## 2.4 Reranking Models

Reranking in information retrieval involves refining the initial ranking of retrieved documents by utilizing scores from a more complex query, as exemplified by Apache Solr<sup>1</sup>. Atlas (Izacard et al., 2022b) retrieves documents with Contriever (Izacard et al., 2022a), reranks the retrieved documents, and reasons with FiD. Re<sup>2</sup>G (Glass et al., 2022) employs a cross-encoder (Rosa et al., 2022; Nogueira and Cho, 2020) to rerank retrieved documents based on softmax probability using  $BM25(q) \cup DPR(q)$ , determining the relevance between a query and context. FiD-Light (Hofstatter et al., 2022) introduces a compression for encoded passages and reranks candidate lists using source pointers. These source pointers are textual indices that represent the relevant context, as initially introduced in FiD-Ex (Lakhota et al., 2021). However, these reranking models do not perform reranking at the page title level and do not make use of a rerank query.

## 2.5 Reinforcement Learning

When framing text generation as a Reinforcement Learning (RL) problem, the state ( $s_t$ ) represents the hidden states of the encoder and previously decoded outputs at time steps  $1, 2, \dots, t - 1$ . The action ( $a_t$ ) encompasses the encoding and decoding behaviors, as well as the decoded word at time step  $t$  (Paulus et al., 2018). This formulation can incorporate non-differentiable feedback, such as common evaluation metrics as reward. Moreover, various RL methodologies such as REINFORCE (Williams, 1992), Advantage Actor-Critic (A2C) (Mnih et al., 2016), and Proximal Policy Optimization (PPO) (Schulman et al., 2017) are being successfully applied in a multitude of scenarios. This study primarily utilizes REINFORCE, a simple yet effective method.

<sup>1</sup><https://solr.apache.org>

## 3 Methodology

The primary contribution of Re3val is its capability to generatively rerank page titles by incorporating contextual information and to apply REINFORCE during distant supervision of a generative retrieval. Additionally, Re3val utilizes question generation for pre-training. Furthermore, Re3val pioneers the reading of contexts retrieved using page titles obtained through a generative retrieval approach.

The following elucidates the function of each component in Figure 2 with respect to its task.

### 3.1 Page Title Retrieval (Stage 1-4)

**Distant Supervision (Stage 1,3)** Following DearDr (Thorne, 2022), we pre-train the generative retrieval. To mitigate the domain shift problem during pre-training for question-answering and dialogue tasks, we generate questions for half of the pre-training passages. We utilize Flan-T5 base (Chung et al., 2022) to create questions given a prompt, "Generate a question related to the following Passage: ". Among generated questions, we employ Spacy's Entity Recognizer of `en_core_web_sm`<sup>2</sup> to filter out ambiguous questions such as "Where is he". Specifically, we remove questions that do not contain entities other than DATE, MONEY, CARDINAL, TIME, QUANTITY, ORDINAL, and PERCENT.

During the pre-training and fine-tuning of Re3val, an instructive prompt - "rank document titles given a query: " - is introduced before each query on the t5-small, t5-base, and t5-large (Wolf et al., 2020). In Few-Shot training, we added labeled data to narrow the range of target candidates.

**REINFORCE (Stage 2,4)** A policy ( $\pi$ ) is parameterized by  $\theta$ , where  $T$  denotes the sequence length. Additionally,  $R(\tau)$  signifies the cumulative reward associated with a trajectory  $\tau$ , characterized as a sequence of actions ( $a$ ) and states ( $s$ ). The formula for calculating the gradient of the REINFORCE objective function is:

$$\nabla J(\theta) = E_{\pi_{\theta}} \left( \sum_{t=1}^T \nabla_{\theta} \log \pi_{\theta}(a_t, s_t) R(\tau) \right) \quad (1)$$

The REINFORCE is employed during training to optimize the black box of zero-shot and few-shot retrieval in Re3val. The REINFORCE utilizes the R Precision of generated page titles as a reward.

<sup>2</sup><https://spacy.io>

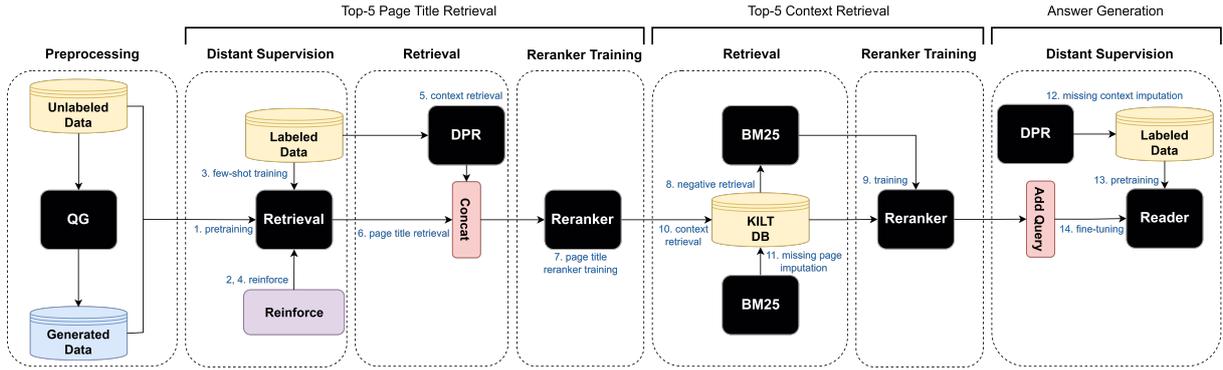

Figure 2: Re3val Training Pipeline. Generated questions after filtering are integrated into pre-training (1), followed by few-shot training (3) with REINFORCE (2, 4). Retrieved DPR contexts (5), perturbed page titles (6), and queries are concatenated for reranker training (7). Gold and negative passages retrieved with BM-25 are employed (8) for context reranker training (9). Contexts are retrieved using the top 5 reranked titles from KILT (10), where missing titles are imputed with BM-25 (11). DPR contexts are imputed (12) if lacking five gold contexts during FiD model pre-training (13). FiD model is fine-tuned using five reranked contexts (14).

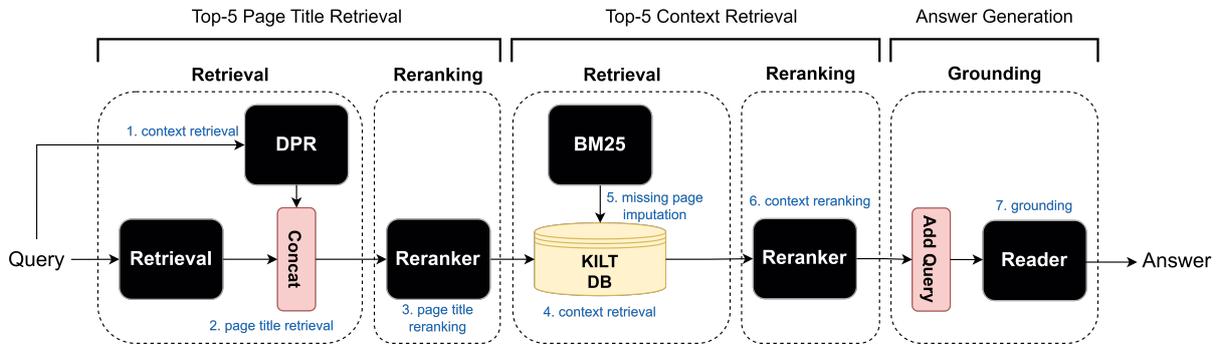

Figure 3: Re3val Inference Pipeline. Reranker concatenates retrieved DPR contexts (1), page titles (2), and query to rerank page titles (3). Contexts retrieved with the top five reranked page titles (4), including BM-25 imputed titles (5), are reranked (6). The top-5 reranked contexts are used to generate an answer (7).

The effectiveness of the REINFORCE is demonstrated in Appendix A.5

### 3.2 Page Title Reranker (Stage 5-7)

Retrieved page titles are initially ranked based on their relevance score, computed by our retrieval model. Then, a reranking query can be introduced to refine the ranking further and increase the likelihood of obtaining the most relevant page titles. However, the KILT datasets do not provide a specific reranking query.

To address the limitation above, our page title reranker leverages contexts retrieved via an auxiliary index, such as the Dense Passage Retrieval multi-set checkpoint<sup>3</sup>, to serve as the reranking query. Unlike the prompt for ranking, which is "rank document titles given a query: ", the prompt for reranking is modified to "rerank document titles

given a query and contexts: ".

We have implemented a new training strategy to improve the refinement and reranking functions of our page title reranker. This strategy combines reinforced few-shot (Stage 4) and zero-shot (Stage 1) retrieved page titles during training. Additionally, we apply uniform shuffling to the page titles in the top half of the training sets generated by our zero-shot and few-shot retrieval.

Mixing titles from different checkpoints and shuffling retrieved page titles introduces noise to the input data. This noise is beneficial as it enables the page title reranker to filter out inconsistencies, outliers, and misleading patterns in the test set, ultimately enhancing its performance.

### 3.3 Context Retrieval (Stage 10-11)

**Preprocessing (Stage 10)** To refine the data for context retrieval for a reader, we divide each context in the KILT Database into chunks, each con-

<sup>3</sup><https://github.com/facebookresearch/DPR>

sisting of 100 words. To ensure data quality and relevance, we filter out sentences that only contain a page title, as well as sentences containing the specific patterns, "Section:::" or "BULLET:::".

**Extraction (Stage 10-11)** After the page title reranking process, we acquire five reranked page titles. Subsequently, we retrieve the corresponding contexts for each page title. In situations where specific page titles are unavailable in the KILT database, we suggest using the BM-25 imputation method. This method employs the BM-25 algorithm to impute the most suitable page title from the KILT database. A detailed analysis of this imputation approach can be found in Appendix A.6.

### 3.4 Context Reranker (Stage 8-11)

To enhance the reader’s experience, we reduce memory and context usage through our Context Reranker. Specifically, we use a cross-encoder to assess the relevance of a query and context pair for reranking the contexts derived from the five page titles. The input structure for our context reranker is as follows: "[CLS] Query [SEP] Context [SEP]".

We utilize gold passages as positive examples for training our Context Reranker on nboost/pt-bert-base-uncased-msmarco<sup>4</sup>. We also include two types of hard negative examples retrieved with BM-25: the top 128 unlabeled context chunks mapped to labeled page titles and the top 128 unlabeled context chunks mapped to the unlabeled page titles retrieved by our Page Title Reranker.

### 3.5 Reader (Stage 12-14)

We employ the Fusion in Decoder (FiD) as our reader for the reading task. During the pre-training phase of FiD, we utilize gold passages and impute DPR contexts for queries with fewer than five available gold contexts. Subsequently, following the pre-training phase, we perform fine-tuning of the FiD model using the top five or ten contexts retrieved by our context reranker.

## 4 Experiments

### 4.1 Datasets

We use datasets from the KILT (Petroni et al., 2021) benchmark. We study Natural Questions (Kwiatkowski et al., 2019), TriviaQA (Joshi et al., 2017), and HotpotQA (Yang et al., 2018) for question answering tasks, FEVER (Thorne et al., 2018)

<sup>4</sup><https://huggingface.co/nboost/>

for a fact-checking task, and WoW (Dinan et al., 2018) for a dialogue task, which are publicly available<sup>5</sup>. Comprehensive details about the datasets are discussed in Appendix A.2.

### 4.2 Evaluation

KILT utilizes a page-level retrieval strategy, and the assessment of page-level retrieval tasks measures the capacity to present a collection of Wikipedia pages as supporting evidence for a prediction, assessed through R-Precision and Recall@k metrics. R-Precision quantifies the proportion of relevant documents retrieved out of the total retrieved documents. However, Recall@k quantifies the proportion of relevant documents retrieved out of the total number of actual documents, taking into account only the top-k retrieved documents. Downstream reading tasks utilize different evaluation metrics depending on the specific task. For example, question-answering tasks are evaluated using Exact Match (EM) and F1 scores. Dialogue tasks employ metrics such as ROUGE-L and F1 scores. Fact verification tasks, on the other hand, are evaluated based on Accuracy. However, KILT has recently introduced the KILT score<sup>6</sup> as a ranking metric for evaluating downstream performance. The KILT score takes into account post-processed Accuracy, EM, ROUGE-L, and F1 scores mentioned in Appendix A.8.3, but only if the R-Precision for a given query is 1. For detailed information regarding the metrics for evaluation, please refer to Appendix A.8.

### 4.3 Page Title Retrieval

**Training** We utilize 250k uniformly sampled June 2017 and August 2019 Wikipedia dumps for the pre-training phase across all datasets. Additionally, we generate questions from an additional 250k uniformly sampled Wikipedia dumps and include them in the training process. For fine-tuning, we utilize 48k uniformly sampled task-specific datasets. Detailed information about the datasets can be found in Appendix A.2 and Table 8. Importantly, we reinforce the zero and few-shot retrieval stages by employing the same dataset for each retrieval stage.

**Evaluation** We employ a multi-beam search approach with a beam size specified in Table 4 to

pt-bert-base-uncased-msmarco

<sup>5</sup><https://github.com/facebookresearch/KILT>

<sup>6</sup><https://eval.ai/web/challenges/challenge-page/689/evaluation>

assess the performance on all development and test sets. In addition, we select the top five page titles from the list of multi-page titles generated per query for evaluation purposes.

#### 4.4 Page Title Reranker

In our experimentation, we explore two types of initialization for our page title reranker. Firstly, we initialize the reranker using the plain t5-small, t5-base, and t5-large models. Secondly, considering the three different model sizes, we utilize the checkpoint from the reinforced few-shot retrieval process. To maintain input compatibility, we limit the query for the reranker’s input to the first 250 words. In addition, the input - consisting of a query, ten page titles, and five contexts - is truncated to a maximum of 512 tokens.

#### 4.5 Context Reranker

We input the first 150 words of a query for question-answering and fact-verification tasks. In the case of a dialogue task, the last 300 words of the query are used, as the final sentence often serves as the closure to the conversation. The maximum sequence length of input is detailed in Table 4 and 6, providing further information on the specific limitations imposed on the input size.

#### 4.6 Reader

Two types of inputs are used for pre-training our two versions of FiD. The first type includes only gold passages, while the second consists of gold passages and top-ranked Dense Passage Retrieval (DPR) contexts. For the Natural Questions (NQ) dataset, pre-training is conducted using the NQ FiD checkpoint, which has been pre-trained on 770 million parameters<sup>7</sup>. For the remaining datasets, pre-training is performed using the TriviaQA FiD checkpoint, which has been pre-trained on 770 million parameters<sup>7</sup>. Regarding the WoW dataset, we retain the last 385 words of the query for input. For other datasets, we use the first 125 words. The maximum sequence length is outlined in Table 4 and 6, providing specific details on the constraints imposed on input size.

An example of an input format is "question: query, title: page\_title, context: retrieved\_context". In this format, "question:", "title:", and "context:" are special tokens, while "query", "page\_title", and "retrieved\_context" represent variables denoting

the respective components of the input.

## 5 Result

### 5.1 Page Title Retrieval

**Zero-shot Retrieval** Based on the findings presented in Table 1, CorpusBrain exhibits an 8% lower R-Precision on average compared to Re3val, despite being trained on more than 500 times more data. We hypothesize that the question-generation process mitigates the epistemic uncertainty resulting from limited training data, thus minimizing the domain shift between the pre-training and task-specific fine-tuning data.

Examining Table 12 in the Appendix, we observe that REINFORCE yields a modest improvement in the performance of zero-shot retrieval, with a few exceptions. Specifically, REINFORCE effectively captures the variability introduced during the constrained beam search exploration, as it utilizes the search results as a reward signal, thereby reducing bias towards the pre-training data in our retrieval model.

**Few-shot Retrieval** However, as indicated in Table 12, the effectiveness of REINFORCE diminishes when applied to the few-shot retrieval scenario. In some instances, REINFORCE results in performance degradation across specific datasets. We postulate that this phenomenon can be attributed to the inherent variance associated with Reinforcement Learning. Furthermore, the performance degradation may arise from the exploration-exploitation trade-off during the multi-beam search, where a broad range of solution spaces is explored, potentially leading to a decreased focus on exploitation. For instance, Appendix A.9 shows that the relative performance ranking can be reversed as the number of samples (K) increases.

### 5.2 Page Title Reranker

The validity of our reranker’s input concatenation is supported by the principles of Mutual Information theory (Shannon, 1948). Let’s define  $X$  as the set of page titles and  $Y$  as the set of DPR contexts, where  $X$  takes values from  $\mathcal{X} = \{x_1, x_2, \dots, x_n\}$  and  $Y$  takes values from  $\mathcal{Y} = \{y_1, y_2, \dots, y_n\}$ . We denote the probability distribution of  $X$  as  $P(x)$ .

The mutual information between  $X$  and  $Y$  is denoted as  $I(X; Y)$ , and it quantifies the amount of shared information between the two variables. It is calculated using the formula:

Table 1: The table above summarizes performance results for generative and bi-encoder retrieval models on KILT test sets. Top-performing models are highlighted in **bold**, and second-best in underline. In Re3val, a reinforced version is used for Zero-shot and Few-shot (48k), while unreinforced version is used for Reranking (48k). Reranking (48k) involves a page title reranker trained using *S* (t5-small), *B* (t5-base), and *L* (t5-large). For WoW dataset, reported scores are few-shot results, except Re3val<sub>L</sub>, denoting the best overall result. Re<sup>2</sup>G and FiD-Light are excluded as they perform reranking on a bi-encoder retrieval model using full data.

$$I(X; Y) = \sum_{x \in \mathcal{X}} \sum_{y \in \mathcal{Y}} P(x, y) \log \frac{P(x, y)}{P(x)P(y)} \quad (2)$$

By considering the joint probability of DPR contexts and page titles,  $I(X; Y)$  allows us to gain insights into the dependency between these two variables. Therefore, our page title reranker leverages this shared information to reduce uncertainty in the ranking of page titles, thus improving the reranking and refinement process.

The results obtained from the dev sets are documented in Table 12. Table 12 indicates that the page title reranker, fine-tuned from the reinforced few-shot retrieval, outperforms the reranker initialized from the T5 pre-trained model when the number of parameters is small. However, the opposite trend is observed as the number of parameters increases. While the knowledge about ranking compensates for the limited capacity to learn complex reranking patterns when the number of parameters is small, prior knowledge about ranking interferes with the

reranking function as the number of parameters grows. In essence, ranking and reranking serve distinct purposes. Ranking focuses on sorting relevant documents, while reranking involves permuting the initially ranked documents.

The dialogue task requires more detailed reasoning over textual information than question-answering and fact-verification tasks. Reranking with a few parameters does not yield improvements in performance for the WoW test set, as indicated in Table 1. Furthermore, the inconsistency between the test set results in Table 1 and the dev set results in Table 12 for the reranking stage of the 770m, 770m parameter configuration highlights the need for further investigation.

### 5.3 Context Reranker

The performance of our Context Reranker, evaluated using gold passages and hard negative passages as described in Section 4.5, is presented in Table 3. Notably, our Context Reranker exhibits a higher precision compared to recall. This charac-

Table 2: The final KILT scores of the test sets are reported above, as presented on the KILT Leaderboard. The best-performing models are indicated in **bold**, while the second-best models are underlined. Additionally, the notation *I* denotes the *Imputation* of DPR contexts for missing gold contexts. |C| represents the number of contexts.

teristic shows that the Context Reranker effectively filters out irrelevant and low-quality results, prioritizing accuracy in retrieving relevant documents, even if they may miss some. The high precision score indicates that relevant documents are ranked at the top. However, further investigation is required to examine the trade-off between precision and recall in the Context Reranker for downstream reading tasks.

#### 5.4 Reader

The slight performance difference observed between the reader with 5 and 10 contexts in Table 2 suggests that our context reranker excels in retrieving highly relevant documents at the top, showcasing its exceptional precision. Moreover, our context imputation pre-training strategy is effective, enabling Re3val to outperform SEAL, although SEAL utilizes 100 contexts for grounding with FiD. Finally, as indicated in Table 2, Re3val achieves superior results with only five passages, underscoring the advantages of our approach.

## 6 Conclusion

This paper presents Re3val, a novel reranking architecture for generative retrieval. Re3val achieves state-of-art performance with question generation, REINFORCE, and reranking. Succinctly, Re3val incorporates question generation to address epistemic uncertainty and domain shift. It utilizes REINFORCE on constrained beam search outputs to enhance exploration. Experimental results demon-

strate Re3val’s superiority over the CorpusBrain zero-shot baseline, with an average 8% R-Precision improvement across five tasks using reduced pre-training data. Re3val also achieves an average 1.9% R-Precision increase compared to other generative models via page title reranking with limited task-specific data. Moreover, by employing a context reranker before grounding, Re3val achieves top-1 KILT scores among generative retrieval models, showing an average 2.1% improvement across five datasets. Re3val’s data-efficient approaches reduce training time and labeling costs, representing notable advancements in generative retrieval.

## Acknowledgement

We express our gratitude to Professor Kee-Eung Kim and Huzama Ahmad from KAIST AI for providing valuable feedback and guidance during the implementation of REINFORCE. We appreciate ChatGPT 3.5’s assistance in correcting writing errors. This work was supported by Institute of Information & communications Technology Planning & Evaluation (IITP) grant funded by the Korea government (MSIT) (No.2019-0-00075, Artificial Intelligence Graduate School Program (KAIST)).

## Limitations

Given this project’s time and resource limitations, a comprehensive comparison of REINFORCE with other reinforcement learning algorithms, such as PPO and TRPO, which require more memory for

their reference model, is not feasible. Furthermore, the observed disparity between the performance on the development and test sets for both the retrieval and reader components necessitates further investigation. Lastly, it is worth noting that specific labeled page titles in the FEVER dataset are not present in the KILT database, introducing a discrepancy that should be considered.

## Ethics Statement

In this study, we utilize datasets obtained from various sources, including Natural Questions, TriviaQA, HotpotQA, FEVER, and Wizard of Wikipedia. These datasets serve as integral components of the KILT benchmark and are derived from the KILT knowledge source, which is based on the August 1st, 2019, Wikipedia dump. In addition to the 2019 Wikipedia dump, we incorporate the June 2017 Wikipedia dump into our pre-training. It is crucial to acknowledge that these datasets may contain instances of incorrect or misconstrued information, which could potentially result in the generation of biased, toxic, or fabricated content. Moreover, the utilization of language models, such as T5, during the training and preprocessing stages introduces the possibility of ethical risks that may be embedded within the internal parameters of these models. Consequently, it is imperative for researchers to exercise caution when employing our paper and the associated outputs and to establish suitable policies to mitigate any potential ethical risks that may arise from the use of these models in real-world production settings.

## A Appendix

### A.1 Hyperparameters

The default hyperparameter settings and hardware configurations employed for the overall tasks are

outlined in Table 4, with further details provided in Tables 5 to 7. Given the limited hardware resources available in our academic environment, we utilize different GPUs for our models, as specified in Table 5. FiD, which uses ten passages, is trained with half of the batch size indicated in Table 4 and 6.

### A.2 Data

The number of data points used for pre-training and fine-tuning the retrieval models for each task are outlined in Table 8. GENRE and CorpusBrain utilize 21 billion data points from the 2019 Wikipedia dump and 9 billion from the Blink dataset. In the case of Re3val pre-training, we use a combination of the June 2017 and August 2019 Wikipedia dumps.

For tasks such as Natural Questions (NQ), Wizard of Wikipedia (WoW), TriviaQA, and FEVER, we pre-train the models using 125,000 samples from the 2017 Wikipedia dump and 125,000 relevant samples from the Wikipedia dump obtained through the Dense Passage Retrieval multi-set checkpoint. An additional 250,000 generated questions from the remaining samples are also included in NQ, WoW, and TriviaQA. For HotpotQA, we use 125,000 original contexts and 125,000 data points from the two Wikipedia dumps, generating questions with the remaining 125,000 original contexts and 125,000 data points from the Wikipedia dumps. All subsets are uniformly sampled.

For the Page Title reranking task, we utilize Hotpot contexts instead of Dense Passage Retrieval (DPR) contexts specifically for HotpotQA. For other tasks, we used the Dense Passage Retrieval multi-set checkpoint.

### A.3 Prefix Tree

To construct and search the Prefix Tree for all tasks, we utilize the KILT knowledge source<sup>8</sup>. This knowledge source is employed as the basis for building and performing Trie Node search.

### A.4 Constrained Decoding

In contrast to GENRE’s constrained decoding (Cao et al., 2021), which predicts a single entity per beam, Re3val decodes a list of page titles per beam similar to DEARDR (Thorne, 2022), as depicted in Figure 4. This approach enables us to capture the variability of related entities, as page titles are mapped to an answer in KILT datasets.

<sup>8</sup>[http://dl.fbaipublicfiles.com/KILT/kilt\\_knowledgesource.json](http://dl.fbaipublicfiles.com/KILT/kilt_knowledgesource.json)

## A.5 REINFORCE

This section presents a formal mathematical proof showcasing the optimization achieved by utilizing the REINFORCE algorithm in our retrieval system.

### A.5.1 Notation

Let  $J(\theta)$  denote the objective function. In the context of Re3val,  $T$  represents the sequence length. The function  $R(\tau)$  represents the return, which is the cumulative reward associated with a trajectory  $\tau$ , defined as a sequence of actions ( $a$ ) and states ( $s$ ). Finally, we denote the policy as  $\pi$  with parameter  $\theta$ , and  $\nabla$  represents the gradient operator.

### A.5.2 Proof

The formula for computing the gradient of the REINFORCE objective function is given by:

$$\nabla J(\theta) = E_{\pi_{\theta}} \left( \sum_{t=1}^T \nabla_{\theta} \log \pi_{\theta}(a_t, s_t) R(\tau) \right) \quad (3)$$

The objective function (3) guides the policy  $\pi_{\theta}$  towards the direction of the gradient. In equation (3),  $R(\tau)$  is a scalar derived from the undifferentiable portion of Re3val, specifically the R-precision calculated using a constrained decoding prefix tree.

Re3val generates a sequence of page titles, represented as  $\tau$ , based on the policy  $\pi$ . The distribution of action  $a$  given a state  $s$  is denoted as  $\pi_{\theta}(a|s)$ . In the case of Re3val, a softmax function is applied to the cross entropy loss to obtain a probability distribution for the action  $a$ . Therefore, the policy parameter can be expressed as:

$$\log \pi_{\theta}(a_t, s_t) = \sum_{i=1}^M y_i \log \bar{y}_i \quad (4)$$

Here,  $M$  represents the vocabulary size, which corresponds to the number of unique elements in the vocabulary.

In scenarios where  $R(\tau_1) < R(\tau_2)$ , the model parameter undergoes a greater number of gradient updates in the direction of  $\nabla_{\theta}(\sum_{j=1}^M \log \pi_{\theta}(a_t, s_t) R(\tau_2))$  compared to  $\nabla_{\theta}(\sum_{j=1}^M \log \pi_{\theta}(a_t, s_t) R(\tau_1))$ , provided that  $R(\tau_1) > 0$  and  $R(\tau_2) > 0$ .

Consequently, the REINFORCE enhances the performance of zero-shot and few-shot retrieval by assigning more updates to samples that yield higher rewards, thereby promoting the learning of

more relevant patterns and improving overall performance.

## A.6 Imputation

### A.6.1 Missing Page Imputation

It has been observed that specific page titles retrieved by our model are absent in the KILT database despite applying the same preprocessing and tokenization procedures to these page titles as those utilized for building the Trie Node. This discrepancy in retrieval is systematically attributed to the labeler’s mistake. Notably, as the missingness of top-ranked retrieved page titles can significantly impact performance, we assert that these page titles exhibit Missing Not At Random (MNAR) characteristics.

Let a dataset be  $D = \{(x_t^{(i)}, o_t^{(i)})_{t=1}^{T_i}, y^{(i)}\}_{i=1}^n$  where  $x$  be a page title,  $o$  be a missing indicator,  $y$  be a relevant context,  $n$  be the number of data,  $T$  be the number of page titles per a query,  $f_{\theta}$  be Re3val’s context reranker that produces a logit, and  $k$  be the KILT database. For classification,  $p(y|x_{1:T}, o_{1:T}, \theta) = \frac{e^{f_{\theta}(k(x_{1:T}, o_{1:T})))_1}}{\sum_{j=0}^1 e^{f_{\theta}(k(x_{1:T}, o_{1:T}))_j}}$ . Then,  $p(x, o|\theta) = p(x|\theta)p(o|x, \phi)$ , indicating missing ( $o$ ) depends on both existing ( $x$ ) and non-existing ( $\phi$ ) page titles in the KILT database. That is, the probability of a missing retrieved page title in the database is related to the page title.

To address this MNAR missingness, we employ the BM-25 algorithm to impute the best matching page title from the KILT database. The outcomes of this imputation strategy are presented in Table 9, illustrating that the performance of our reranker on the test sets improves through the imputation.

### A.6.2 Missing Context Imputation

Within the KILT dataset, contexts may be pertinent to an answer but have remained unlabeled due to biases from the labeler. This particular phenomenon aligns with the characteristics of Missing Not At Random (MNAR) since the absence of these contexts is systematically linked to the actions of the labeler. Table 2 demonstrates a notable performance improvement when utilizing imputation techniques to address sparse contexts in a query using the DPR (Dense Passage Retrieval) method.

## A.7 KILT Leaderboard

Our performance results on the KILT downstream tasks can be found on the eval.ai leaderboard<sup>9</sup>. We

<sup>9</sup><https://eval.ai/web/challenges/>

prioritize the performance values reported in the original papers in Table 1 and 2. In cases where the original papers do not provide specific values, we rely on the results available on the KILT leaderboard. It is important to note that slight variations in the reported values may occur due to minor differences in the model versions used for evaluation across tasks.

## A.8 Metrics

### A.8.1 Page Title Retrieval

Let us assume that  $R$  represents the entire number of retrieved documents, and among these retrieved documents,  $r$  is deemed relevant. In this case, R-Precision is the ratio of relevant retrieved documents to the entire number of retrieved documents, i.e.,  $\frac{r}{R}$ . Similarly, Recall@ $k$  is calculated as  $\frac{w}{n}$ , the ratio of relevant retrieved documents to the entire number of actual documents, assuming there are  $n$  actual documents and  $w$  of these documents were successfully retrieved within a set of  $k$  retrieved documents (Petroni et al., 2021).

### A.8.2 Context Reranker

Let us consider a classification task with the following definitions: TP (True Positive), TN (True Negative), FP (False Positive), and FN (False Negative). Precision is the ratio of true positives to the sum of true and false positives, given by  $\frac{TP}{TP+FP}$ . Similarly, Recall is defined as the ratio of true positives to the sum of true positives and false negatives, denoted as  $\frac{TP}{TP+FN}$ . The F1 score represents a balance between Precision and Recall, computed as the harmonic mean of the two metrics:  $2 \times \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}}$ . Accuracy, on the other hand, is calculated as the ratio of the sum of true negatives and true positives to the sum of true negatives, true positives, false positives, and false negatives, given by  $\frac{TP+TN}{TP+TN+FP+FN}$ .

### A.8.3 Reader

For the downstream reading task, we do not perform any post-processing on the gold and predicted outputs for the training and development sets. However, for the blind test sets, KILT applies post-processing techniques such as lowercase conversion, removal of articles, punctuation, and duplicate whitespace to the gold and predicted outputs. KILT maintains that these post-processing steps ensure consistency and fairness in the evaluation process.

[challenge-page/689/leaderboard](https://kilt-dataset.com/challenge-page/689/leaderboard)

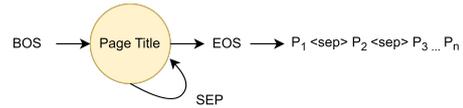

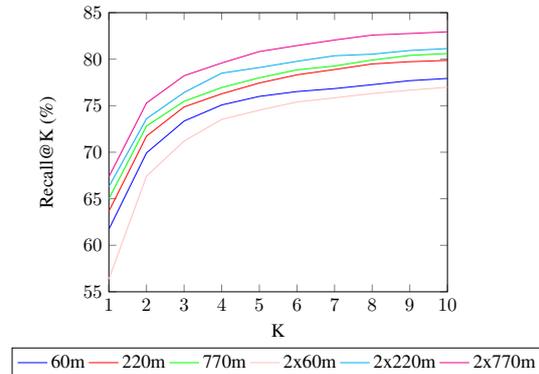

Figure 4: The decoding process in Re3val involves the utilization of DEARDR PTHL state machine decoding. During decoding, each page is conditionally decoded based on the previous page, as there are instances where multiple page titles are mapped to an answer. Furthermore, a query may have various answers, further influencing the decoding process.

**KILT scores** As mentioned in 4.2, the KILT score incorporates post-processed Accuracy, EM, ROUGE-L, and F1 scores mentioned in Appendix A.8.3. However, these scores are considered only if the R-Precision for a given query is 1. The KILT scores provide a comprehensive evaluation of the system’s performance on the KILT tasks by emphasizing high precision and relevance, in addition to other evaluation metrics.

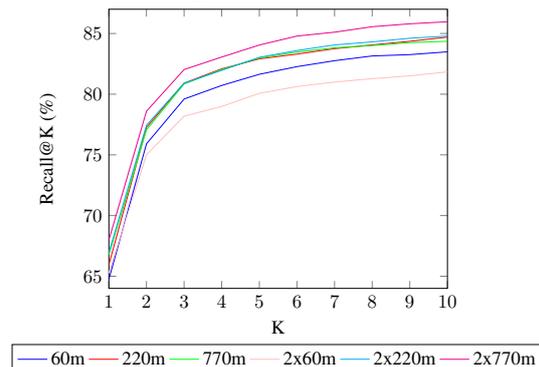

## A.9 Recall Curve of the Page Title Reranker

The plots below demonstrate the impact of different numbers of parameters on recall performance at varying levels of documents retrieved. A detailed discussion and analysis of these findings can be found in 5.1 of this paper.

Table 12: The performance of the development sets is evaluated at each stage of the training, considering different numbers of parameters. The stages include zero-shot retrieval (Z), few-shot retrieval (F), reranking (R), and reinforcement (P). The parameter counts |P| represent the parameters used to train the retrieval and reranker models. The comma (,) in |P| indicates that the retrieval and reranker were initialized separately. In contrast, the absence of a comma (,) signifies that the reinforced few-shot retrieval was fine-tuned with the reranker’s training data.

# Entity Linking in the Job Market Domain

## Abstract

In Natural Language Processing, entity linking (EL) has centered around Wikipedia, but remains underexplored for the job market domain. Disambiguating skill mentions can help us to get insight into the labor market demands. In this work, we are the first to explore EL in this domain, specifically targeting the linkage of occupational skills to the ESCO taxonomy (le Vrang et al., 2014). Previous efforts linked coarse-grained (full) sentences to a corresponding ESCO skill. In this work, we link more fine-grained span-level mentions of skills. We tune two high-performing neural EL models, a bi-encoder (Wu et al., 2020) and an autoregressive model (Cao et al., 2021), on a synthetically generated mention-skill pair dataset and evaluate them on a human-annotated skill-linking benchmark. Our findings reveal that both models are capable of linking implicit mentions of skills to their correct taxonomy counterparts. Empirically, BLINK outperforms GENRE in strict evaluation, but GENRE performs better in loose evaluation (accuracy@*k*).<sup>1</sup>

## 1 Introduction

Labor market dynamics, influenced by technological changes, migration, and digitization, have led to the availability of job descriptions (JD) on platforms to attract qualified candidates (Brynjolfsson and McAfee, 2011, 2014; Balog et al., 2012). It is important to extract and link surface form skills to a unique taxonomy entry, allowing us to quantify the current labor market dynamics and determine the demands and needs. We attempt to tackle the problem of *entity linking* (EL) in the job market domain, specifically the linking of fine-grained span-level skill mentions to a specific taxonomy entry.

Generally, EL is the task of linking mentions of entities in unstructured text documents to their respective unique entities in a knowledge base (KB),

<sup>1</sup>The source code and data can be found at [https://github.com/mainlp/el\\_esco](https://github.com/mainlp/el_esco)

most commonly Wikipedia (He et al., 2013). Recent models address this problem by producing entity representations from a (sub)set of KB information, e.g., entity descriptions (Logeswaran et al., 2019; Wu et al., 2020), fine-grained entity types (Raiman and Raiman, 2018; Onoe and Durrett, 2020; Ayoola et al., 2022), or generation of the input text autoregressively (Cao et al., 2021, 2022).

For skill linking specifically, we use the European Skills, Competences, Qualifications and Occupations (ESCO; le Vrang et al., 2014) taxonomy due to its comprehensiveness. Previous work classified spans to its taxonomy code via multi-class classification (Zhang et al., 2022b) without surrounding context and neither the full breadth of ESCO. Gnehm et al. (2022) approaches it as a sequence labeling task, but only uses more coarse-grained ESCO concepts, and not the full taxonomy. Last, others attempt to match the full sentence to their respective taxonomy title (Decorte et al., 2022, 2023; Clavié and Soulié, 2023).

The latter comes with a limitation: The taxonomy title does not indicate which subspan in the sentence it points to, without an exact match. We define this as an *implicit* skill, where mentions (spans) in the sentence do not have an exact string match with a skill in the ESCO taxonomy. The differences can range from single tokens to entire phrases. For example, we can link “being able to work together” to “plan teamwork”.<sup>2</sup> If we know the exact span, this implicit skill can be added to the taxonomy as an alternative choice for the surface skill. As a result, this gives us a more nuanced view of the labor market skill demands. Therefore, we attempt to train models to the linking of both implicit and explicit skill mentions.

**Contributions.** Our findings can be summarized as follows: ① We pose the task of skill linking as an entity linking problem, showing promising

<sup>2</sup>See example here: <https://t.ly/3VUJG>.

	Instances	Unique Titles	UNK
Train	123,619	12,984	14,641
Dev.	480	149	233
Test	1,824	455	813

Table 1: **Data Statistics.** Data distribution of train, dev, and test splits. UNK indicates skills mentions that are not linked to a corresponding taxonomy title.

results of linking with two entity linking systems.

② We present a qualitative analysis showing that the model successfully links implicit skills to their respective skill entry in ESCO.

## 2 Methodology

**Definition.** In EL, we process the input document  $\mathcal{D} = \{w_1, \dots, w_r\}$ , a collection of entity mentions denoted as  $\mathcal{MD} = \{m_1, \dots, m_n\}$ , and a KB, ESCO in our case:  $\mathcal{E} = \{e_1, \dots, e_{13890}, \text{UNK}\}$ . The objective of an EL model is to generate a list of mention-entity pairs  $\{(m_i, e_i)\}_{i=1}^n$ , where each entity  $e$  corresponds to an entry in a KB. We assume that both the titles and descriptions of the entities are available, which is a common scenario in EL research (Ganea and Hofmann, 2017; Logeswaran et al., 2019; Wu et al., 2020). We also assume that each mention in the document has a corresponding valid gold entity present in the knowledge base, including UNK. This scenario is typically referred to as “in-KB evaluation”. Similar to prior research efforts (Logeswaran et al., 2019; Wu et al., 2020), we also presuppose that the mentions within the document have already been tagged.

**Data.** We use ESCO titles as ground truth labels, containing 13,890 skills.<sup>3</sup> Table 1 presents the train, dev, and test data in our experiments. We leverage the train set introduced by Decorte et al. (2023)<sup>4</sup> along with the dev and test sets provided in Decorte et al. (2022).<sup>5</sup> The train set is synthetically generated by Decorte et al. (2023) with the gpt-3.5-turbo-0301 model (OpenAI, 2023). Specifically, this involves taking each skill from ESCO and prompting the model to generate sentences resembling JD sentences that require that particular skill. The dev and test splits, conversely, are derived from actual job advertisements sourced from the study by Zhang et al. (2022a). These

<sup>3</sup>Per version 1.1.1, accessed on 01 August 2023.

<sup>4</sup><https://t.ly/edqkp>

<sup>5</sup><https://t.ly/LcqQ7>

JDs are annotated with spans corresponding to specific skills, and these spans have subsequently been manually linked to ESCO, as described in the work of Decorte et al. (2022). In cases where skills cannot be linked, two labels are used, namely UNDESPECIFIED and LABEL NOT PRESENT. For the sake of uniformity, we map both of these labels to a generic UNK tag. We used several heuristics based on Levenshtein distance and sentence similarity to find the exact subspans if it exceeds certain thresholds, otherwise, it is UNK. This process is outlined in Appendix A. In addition, some data examples can be found in Appendix B. The number of UNKs in the data is also in Table 1. During inference, the UNK title is a prediction option for the models.

**Models.** We use two EL models, selected for their robust performance in EL on Wikipedia.<sup>6</sup>

**BLINK (Wu et al., 2020).** BLINK uses a bi-encoder architecture based on BERT (Devlin et al., 2019), for modeling pairs of mentions and entities. The model processes two inputs:

[CLS] ctxt<sub>l</sub> [S] mention [E] ctxt<sub>r</sub> [SEP]

Where “mention”, “ctxt<sub>l</sub>”, and “ctxt<sub>r</sub>” corresponds to the wordpiece tokens of the mention, the left context, and the right context. The mention is denoted by special tokens [S] and [E]. The entity and its description are structured as follows:

[CLS] title [ENT] description [SEP]

Here, “title” and “description” represent the word-piece tokens of the skills’ title and description, respectively. [ENT] is a special token to separate the two representations. We train the model to maximize the dot product of the [CLS] representation of the two inputs, for the correct skill in comparison to skills within the same batch. For each training pair  $(m_i, e_i)$ , the loss is computed as  $\mathcal{L}(m_i, e_i) = -s(m_i, e_i) + \log \sum_{j=1}^B \exp(s(m_i, e_j))$ , where the objective is to minimize the distance between  $m_i$  and  $e_i$  while encouraging the model to assign a higher score to the correct pair and lower scores to randomly sampled incorrect pairs. Hard negatives are also used during training, these are obtained by finding the top 10 predicted skills for each training example. These extra hard negatives are added to the random in-batch negatives.

<sup>6</sup>For the hyperparameter setups, we refer to Appendix C.

	Train Source	Acc@1	Acc@4	Acc@8	Acc@16	Acc@32
Random		0.22±0.00	0.88±0.00	1.76±0.00	3.52±0.00	7.04±0.00

BLINK (bert-large)	Wiki + ESCO	<b>23.55±0.14</b>	32.63±0.16	37.38±0.09	<b>43.25±0.13</b>	<b>48.98±0.21</b>
GENRE (bart-base)	ESCO	1.47±0.05	4.84±1.74	10.46±6.81	11.30±4.18	15.51±4.62
GENRE (bart-large)	ESCO	2.33±0.44	5.74±1.43	8.18±2.21	11.13±2.42	15.26±2.66
GENRE (bart-large)	Wiki (0-shot)	6.91±0.00	12.34±0.00	15.52±0.00	21.60±0.00	33.17±0.00
GENRE (bart-large)	Wiki + ESCO	<b>11.48±0.41</b>	<b>21.26±0.43</b>	<b>27.40±0.78</b>	<b>37.21±0.69</b>	<b>49.78±1.05</b>

Table 2: **Skill Linking Results.** We show the results of the various models used. There are two base and four large models. Training sources are either ESCO or a combination of Wikipedia and ESCO. The results are the average and standard deviation over five seeds. For the 0-shot setup, we apply the fine-tuned models from the work of Wu et al. (2020) and Cao et al. (2021) to the ESCO test set once. We have a random and a TF-IDF-based baseline.

**GENRE (Cao et al., 2021).** GENRE formulates EL as a retrieval problem using a sequence-to-sequence model based on BART (Lewis et al., 2020). This model generates textual entity identifiers (i.e., skill titles) and ranks each entity  $e \in \mathcal{E}$  using an autoregressive approach:  $s(e | x) = p_\theta(y | x) = \prod_{i=1}^N p_\theta(y_i | y_{<i}, x)$ , where  $y$  represents the set of  $N$  tokens in the identifier of entity  $e$  (i.e., entity tile), and  $\theta$  denotes the model parameters. During decoding, the model uses a constrained beam search to ensure the generation of valid identifiers (i.e., only producing valid titles that exist within the KB, including UNK).

**Setup.** We train a total of six models: for BLINK, these are BERT<sub>base</sub> and BERT<sub>large</sub> (uncased; Devlin et al., 2019) trained on ESCO, and another large version trained on Wikipedia and ESCO sequentially. GENRE has the same setup, but then with BART (Lewis et al., 2020). Additionally, we apply the released models from both BLINK and GENRE (large, trained on Wikipedia) in a zero-shot manner and evaluate their performance. The reason we use Wikipedia-based models is that we hypothesize this is due to many skills in ESCO also having corresponding Wikipedia pages (e.g., Python<sup>7</sup> or teamwork<sup>8</sup>), thus could potentially help linking. Next, to address unknown entities (UNK), we include them as possible label outputs.

For evaluation, we assess the accuracy of generated mention-entity pairs in comparison to the

<sup>7</sup>[https://en.wikipedia.org/wiki/Python\\_\(programming\\_language\)](https://en.wikipedia.org/wiki/Python_(programming_language))

<sup>8</sup><https://en.wikipedia.org/wiki/Teamwork>

ground truth. Here, we use the evaluation metric Accuracy@ $k$ , following prior research (Logeswaran et al., 2019; Wu et al., 2020; Zaporojets et al., 2022). We calculate the correctness between mentions and entities in the KB as the sum of correct hits or true positives (TP) if the ground truth for instance  $i$  is in the top- $k$  predictions, formally:

$$\text{Accuracy}@k = \frac{1}{n} \sum_{i=1}^n \text{TP in top-}k \text{ for instance } i. \quad (1)$$

### 3 Results

Table 2 presents the results. Each model is trained for five seeds, and we report the average and standard deviation. We make use of a random and TF-IDF-based baseline.

Firstly, we observe that the strict linking performance (i.e., Acc@1) is rather modest for both BLINK and GENRE. But most models outperform the baselines. Notably, the top-performing models in this context are the BERT<sub>large</sub> and BART<sub>large</sub> models, which were further fine-tuned from Wikipedia EL with ESCO. As expected, scores improve considerably as we increase the value of  $k$ . Secondly, for both BLINK and GENRE, model size seems not to have a substantial impact when trained only on ESCO. Specifically for BLINK, the performance remains consistent for Acc@1 and exhibits only a slight decline as we relax the number of candidates for performance evaluation. For GENRE, the observed trend remains largely unchanged, even with a larger  $k$ .

Mention	BLINK	GENRE
① Work in a way that is <b>patient-centred</b> and inclusive.	person centred care (K0913)	work in an organised manner (T)
② You can <b>ride a bike</b> .	sell bicycles (S1.6.1)	drive two-wheeled vehicles (S8.2.2)
③ It is expected that you are a super user of the <b>MS office tools</b> .	use Microsoft Office (S5.6.1)	tools for software configuration management (0613)
④ <b>Picking and packing</b> .	carry out specialised packing for customers (S6.1.3)	perform loading and unloading operations (S6.2.1)
⑤ You are expected to be able to further <b>develop your team</b> - both personally and professionally. <b>GOLD: manage a team (S4.8.1)</b>	manage personal professional development (S1.14.1)	shape organisational teams based on competencies (S4.6.0)
⑥ Our games are developed using Unity so we expect all our programmers to have solid knowledge of mobile game development in Unity3D and <b>C#</b> .	C# (K0613)	C# (K0613)

Table 3: We show six qualitative examples. The mention is indicated with purple and we show the predictions ( $k = 1$ ) of BLINK and GENRE. Green predictions mean correct, and red indicates wrong linking with respect to the ground truth. We also show the ESCO ID, indicating the differences in concepts. The results show successful linking of implicit mentions of skills. In example (5), we show how the linked results are still valid while being different concepts. However, evaluation does not count it as a correct hit.

Remarkably, the zero-shot setup performance of both BLINK and GENRE, when trained on Wikipedia, surpasses that of models trained solely on ESCO. For Wikipedia-based evaluation, GENRE usually outperforms BLINK. We notice the opposite in this case. For BLINK, this improvement is approximately 11 accuracy points for  $k = 1$ . Meanwhile, for GENRE, we observe an increase of roughly 9 accuracy points when trained on both Wikipedia and ESCO. This trend persists for a larger  $k$ , reaching up to a 12.5 accuracy point improvement for BLINK and a 34 accuracy point improvement for GENRE in the case of Acc@32. Furthermore, we show that further fine-tuning the Wikipedia-trained models on ESCO contributes to an improved EL performance at  $k = \{1, 16, 32\}$  for both models. We confirm our hypothesis that Wikipedia has concepts that are also in ESCO, this gives the model strong prior knowledge of skills.

For UNK-specific results, we refer to [Appendix D](#). Additionally, we show a direct comparison to previous work in [Appendix E](#).

## 4 Discussion

**Qualitative Analysis.** We manually inspected a subset of the predictions. We present qualitative examples in [Table 3](#). We found the following trends upon inspection:

- The EL models exhibit success in linking implicit and explicit mentions to their respective

taxonomy titles (e.g., ①, ②, ④, ⑥).

- In cases of hard skills (③, ⑥), BLINK correctly matches “MS office tools” to “using Microsoft Office”, which is not an exact match. Both models predict the explicit mention “C#” correctly to the C# taxonomy title.
- We found that the models predict paraphrased versions of skills that could also be considered correct (④, ⑤), even being entirely different concepts (i.e., different ESCO IDs).

**Evaluation Limitation.** We qualitatively demonstrate the linking of skills that are implicit and/or valid. Empirically, we observe that the strict linking of skills leads to an underestimation of model performance. We believe this limitation is rooted in evaluation. In train, dev, and test, there is only *one* correct gold label. We reciprocate the findings by [Li et al. \(2020\)](#), where they found that a large number of predictions are “technically correct” but limitations in Wikipedia-based evaluation falsely penalized their model (i.e., a more or less precise version of the same entity). Especially ⑤ in [Table 3](#) shows this challenge for ESCO, we can consider multiple links to be correct for a mention given a particular context. This highlights the need for appropriate EL evaluation sets, not only for ESCO, but for EL in general.

## 5 Conclusion

We present entity linking in the job market domain, using two existing high-performing neural models. We demonstrate that the bi-encoder architecture of BLINK is more suited to the job market domain compared to the autoregressive GENRE model. While strict linking results favor BLINK over GENRE, if we relax the number of candidates, we observe that GENRE performs slightly better. From a qualitative perspective, the performance of strict linking results is modest due to limitations in the evaluation set, which considers only one skill correct per mention. However, upon examining the predictions, we identify valid links, suggesting the possibility of multiple correct links for a particular mention, highlighting the need for more comprehensive evaluation. We hope this work sparks interest in entity linking within the job market domain.

## Limitations

In the context of EL for ESCO, our approach has several limitations. Firstly, it only supports English, and might not generalize to other languages. However, several works are working on multilingual entity linking (e.g., Botha et al., 2020; De Cao et al., 2022) and ESCO itself consists of 28 European languages. This work could be extended by supporting it for more languages.

Secondly, our EL model is trained on synthetic training data, which may not fully capture the intricacies and variations present in real-world documents. The use of synthetic data could limit its performance on actual, real JD texts. Nevertheless, we have human-annotated evaluation data.

Moreover, in our evaluation process, we use only one gold-standard ESCO title as the correct answer. This approach may not adequately represent a real-world scenario, where multiple ESCO titles could be correct as shown in Table 3.

In Table 2, we show that providing in-domain data for continuous pre-training shows larger improvements for GENRE than for BLINK. We did not conduct a detailed analysis on the underlying reasons for these positive variations.

## A Data Preprocessing

We outline the preprocessing steps for the training set. In Decorte et al. (2023), there are sentence-ESCO skill title pairs. The data is synthetically generated by GPT-3.5. Where for each ESCO skill title a set of 10 sentences is generated. A crucial limitation for entity linkers is that the generated sentence does not have the ESCO skill title as an exact match in the sentence, but at most slightly paraphrased. To find the most similar subspan in the sentence to the target skill, we have to apply some heuristics. In Algorithm 1, we denote our algorithm to find the most similar subspan. Our method is a brute force approach, where we create all possible n-grams until the maximum length of the sentence, and compare the target subspan against each n-gram. Based on Levenshtein distance, we filter the results, where we only take the top 80% n-grams. Then, we encode both target subspan and n-gram with SentenceBERT (Reimers and Gurevych, 2019), the similarity is based on cosine similarity. If the similarity does not exceed 0.5, the candidate subspan is UNK and the ESCO title will also be UNK, otherwise, we take the most similar n-gram. Empirically, we found that these thresholds worked best. Note that this method is not error-prone, but allows us to generate implicit and negative examples to train entity linkers. We

show two qualitative examples in Figure 1 and discuss the quality in Appendix B.

## B Data Examples

We show a couple of data examples from the training (Figure 1) and development set (Figure 2). In the training examples, we show an example with a mention that is the same as the original ESCO title (“young horse training”). In addition, we have an example where there is an “implicit” mention (i.e., the mention does not exactly match with the label title). This shows that our algorithm works to an extent. For the development example, this is another implicit mention. However, these samples are human annotated. There are also quite some UNKs given the training data. We show that this is helping the model predict UNK.

## C Implementation Details

For training both BLINK<sup>9</sup> and GENRE,<sup>10</sup> we use their respective repositories. All models are trained for 10 epochs, for a batch size of 32 for training and 8 for evaluation. For both BLINK and GENRE we use 5% warmup. For the base models we use learning rate  $2 \times 10^{-5}$  and for the large models we

<sup>9</sup><https://github.com/facebookresearch/BLINK>

<sup>10</sup><https://github.com/facebookresearch/genre>

Table 4: **UNK Linking Results.** We show the results of BLINK and GENRE predicting UNK. We use the best-performing models, based on Table 2.

	Train Source	Acc@1	Acc@4	Acc@8	Acc@16	Acc@32
BLINK (bert-large) UNK	Wiki + ESCO	1.38±0.12	3.32±0.22	4.67±0.33	7.68±0.42	10.70±0.58
GENRE (bart-large) UNK	Wiki + ESCO	1.65±0.20	4.99±0.50	9.23±0.58	16.01±0.48	24.70±2.52

```

1  {
2    "context_left": "we're looking for someone who is passionate
3    about",
4    "context_right": "and eager to share their knowledge with
5    others.",
6    "mention": "young horse training",
7    "label_title": "young horses training",
8    "label": "Principles & techniques of educating young horses
9    important simple body control exercises.",
10   "label_id": 2198
11  }
12  {
13   "context_left": "Hands-on experience with",
14   "context_right": "is a must-have qualification for this
15   job.",
16   "mention": "various hand-operated printing devices",
17   "label_title": "types of hand-operated printing devices",

22  }

```

Figure 1: **Two Training Examples.** The training examples are in the format for BLINK, there is the left context, right context, and the mention. The label title is the ESCO skill, and the label is the description of the label title. The label ID is the ID that refers to the label title.

use  $2 \times 10^{-6}$ . The maximum context and candidate length is 128 for both models. Each model is trained on an NVIDIA A100 GPU with 40GBs of VRAM and an AMD Epyc 7662 CPU. The seed numbers the models are initialized with are 276800, 381552, 497646, 624189, 884832. We run all models with the maximum number of epochs (10) and select the best-performing one based on validation set performance for accuracy@1.

## D UNK Evaluation

In Table 4, we show the performance of both BLINK and GENRE on the UNK label. We use the best-performing models based on Table 2. Generally, we observe that GENRE is better in predicting

UNKs than BLINK. However, the exact linking results (i.e., Acc@1) are low. This can potentially be alleviated by actively training for predicting UNKs (Zhu et al., 2023).

## E Comparison To Previous Work

We argue that an entity linking approach to match skill spans to ESCO taxonomy codes is the correct direction as it could provide more transparency in the linked span in the sentence. Consequentially, this is a more challenging setup. In Table 5, we provide a direct comparison to previous work from Decorte et al. (2023) and Clavié and Soulié (2023), where they link sentences with skills directly. For context, we are not using re-rankers as

```
1 {
2   "context_left": "You must have an",
3   "context_right": "with a high-quality mindset.",
4   "mention": "analytical proactive and structured workstyle",
5   "label_title": "work in an organised manner",
6   "label": "Stay focused on the project at hand, at any time.
7   Organise, manage time, plan, schedule and meet deadlines.",
8   "label_id": 3884
9 }
```

Figure 2: **One Evaluation Example.** The evaluation example is in the format for BLINK, there is the left context, right context, and the mention. The label title is the ESCO skill, and the label is the description of the label title. The label ID is the ID that refers to the label title.

in the previously mentioned works.

<b>Approach</b>	<b>Setup</b>	<b>MRR</b>
<a href="#">Decorte et al. (2023)</a>	SentenceBERT, sentence-level, re-ranking	47.8±0.0

### Abstract

In the *universe* of Natural Language Processing, Transformer-based language models like BERT and (Chat)GPT have emerged as *lexical superheroes* with *great power* to solve open research problems. In this paper, we specifically focus on the temporal problem of semantic change, and evaluate their ability to solve two diachronic extensions of the Word-in-Context (WiC) task: TempoWiC and HistoWiC. In particular, we investigate the potential of a novel, off-the-shelf technology like ChatGPT (and GPT) 3.5 compared to BERT, which represents a family of models that currently stand as the state-of-the-art for modeling semantic change. Our experiments represent the first attempt to assess the use of (Chat)GPT for studying semantic change. Our results indicate that ChatGPT performs significantly worse than the foundational GPT version. Furthermore, our results demonstrate that (Chat)GPT achieves slightly lower performance than BERT in detecting long-term changes but performs significantly worse in detecting short-term changes.

### 1 Introduction

Lexical semantic change is the linguistic phenomenon that denotes words changing their meanings over time (Geeraerts et al., 2024; Bloomfield, 1933). An example is the word *gay* that changed from meaning *cheerful* to *homosexual* in the last century. This change is crucial to our understanding of historical texts. A nuanced grasp of semantic *variation* between groups and genre, and semantic *change* across time allows us to study languages, cultures, and societies through digitized text and opens up a range of research applications. Computational approaches to semantic change are thus tools with immense potential for a range of research fields (Montanelli and Periti, 2023; Tahmasebi et al., 2021; Kutuzov et al., 2018; Tang, 2018). Not only can they broaden the field of historical linguistics and simplify lexicography, but

they can also be fruitfully applied in the fields of sociology, history, and other text-based research. For instance, the computational modeling of semantic change is equally relevant when studying out-of-domain texts where language differs from the general language, like in medical (Kay, 1979) and olfactory (Paccosi et al., 2023; Menini et al., 2022) domains.

The recent introduction of Transformer-based (Vaswani et al., 2017) language models (LMs) has led to significant advances in Natural Language Processing (NLP). These advances are exemplified in Pretrained Foundation Models like BERT (Devlin et al., 2019) and GPT, which “are regarded as the foundation for various downstream tasks” (Zhou et al., 2023). BERT has experienced a surge in popularity over the last few years, and the family of BERT models has repeatedly provided state-of-the-art (SOTA) results for computational modeling of semantic change (Cassotti et al., 2023; Periti et al., 2023). However, research focus is now shifting toward ChatGPT due to its impressive ability to generate fluent and high-quality responses to human queries, making it the fastest-growing AI tool. Several recent research studies have assessed the language capabilities of ChatGPT by using a wide range of prompts to solve popular NLP tasks (Laskar et al., 2023; Kocoń et al., 2023). However, current evaluations generally (a) overlook the fact that the output of ChatGPT is nondeterministic,<sup>1</sup> (b) rely only on contemporary and synchronic text, and (c) consider predictions generated by the ChatGPT<sup>2</sup> web interface, which is based on the Chat version of the GPT foundation model. As a result, these evaluations provide valuable insights into the generative, pragmatic, and semantic capabilities of ChatGPT (Kocoń et al., 2023), but fall short when

<sup>1</sup>[platform.openai.com/docs/guides/gpt/faq](https://platform.openai.com/docs/guides/gpt/faq)

<sup>2</sup>[chat.openai.com](https://chat.openai.com)

Figure 1: The title of this paper draws inspiration by the movie *Batman v Superman: Dawn of Justice*. We leverage the analogy of (Chat)GPT and BERT, powerful and popular LMs, as two lexical superheroes often erroneously associated for solving similar problems. Our aim is to shed lights on the potential of (Chat)GPT for semantic change detection.

it comes to assess the potential of GPT to solve NLP tasks and specifically to handle historical and diachronic text, which constitutes a unique scenario for testing models’ ability to generalize.

In this paper, we propose to evaluate the use of both ChatGPT and GPT - i.e., (Chat)GPT<sup>3</sup> - to recognize (lexical) semantic change. Our goal is not to comprehensively evaluate (Chat)GPT in dealing with semantic change but rather to evaluate its potential as *off-the-shelf* model with a *reasonable* prompts from a human point of view, which may not necessarily be optimized for the model. Recently, a novel evaluation task in NLP, called Lexical Semantic Change (LSC), has been introduced as a shared task at SemEval (Schlechtweg et al., 2020). The LSC task involves considering all occurrences (potentially several thousands) of a set of target words to assess their change in meaning within a diachronic corpus. As a result, this setup is *currently* not suitable for evaluating a GPT model, due to the limited size of its prompts and answers, as well as accessibility limitations such as an hourly character limit and economic constraints. In light of these considerations, we chose to evaluate the potential of (Chat)GPT through the Word-in-Context (WiC, Pilehvar and Camacho-Collados, 2019) task, which has recently demonstrated a robust connection with LSC (Cassotti et al., 2023; Arefyev et al., 2021). In particular, we consider two diachronic extensions of the original WiC setting, namely *temporal* WiC (TempoWiC, Loureiro

<sup>3</sup>Throughout the text, we distinguish between ChatGPT, which is the standard (web) version of GPT, and GPT, which serves as the foundation model. Instances of (Chat)GPT represent both types of models.

et al., 2022) and *historical* WiC (HistoWiC). Our goal is to determine whether a word carries the same meaning in two different contexts of different time periods, or conversely, whether those contexts exemplify a semantic change. While TempoWiC has been designed to evaluate LMs ability to detect short-term changes in social media, HistoWiC is our adaptation of the SemEval benchmark of historical text to a WiC task for evaluating LMs ability to detect long-term changes in historical corpora.

Considering the remarkable performance of contextualized BERT models in addressing WiC and LSC tasks (Montanelli and Periti, 2023; Periti and Dubossarsky, 2023; Periti et al., 2023), we compare the performance of (Chat)GPT in TempoWiC and HistoWiC to those obtained using BERT. While BERT is specifically designed to understand the meaning of words in context, (Chat)GPT is designed to generate fluent and coherent text. Through these two *lexical superheroes* (see Figure 1), we aim to illuminate the potential of (Chat)GPT as *off-the-shelf* model and mark *the dawn of a new era* by assessing whether it *already* makes the approaches to WiC and LSC, which rely on BERT-embedding similarities, outdated.

## 2 Related work

The significant attention garnered by ChatGPT has led to a large number of studies being published immediately after its release. Early studies mainly focused on exploring the benefits and risks associated with using ChatGPT in expert fields such as education (Lund and Wang, 2023), medicine (Antaki et al., 2023), or business (George and George, 2023). Evaluation studies are currently emerging for assessing (Chat)GPT’s generative and linguistic capabilities across a wide range of downstream tasks in both monolingual and multilingual setups (Bang et al., 2023; Shen et al., 2023; Lai et al., 2023). Most evaluations focus on ChatGPT and involve a limited number of instances (e.g., 50) for each task considered (Weissweiler et al., 2023; Zhong et al., 2023; Alberts et al., 2023; Khalil and Er, 2023). When the official API is used to query the GPT foundation model, this limit is imposed by the hourly token processing limit<sup>4</sup> and the associated costs.<sup>5</sup> When the web interface is used instead of

<sup>4</sup>[help.openai.com/en/articles/4936856-what-are-tokens-and-how-to-count-them](https://help.openai.com/en/articles/4936856-what-are-tokens-and-how-to-count-them)

<sup>5</sup>[openai.com/pricing](https://openai.com/pricing)

the API, the limit is due to the time-consuming process of interacting with ChatGPT that keeps humans in the loop. Thus far, even systematic and comprehensive evaluations (Kocoń et al., 2023; Laskar et al., 2023) rely on repetition of a single experiment for each task. However, while individual experiments provide valuable insights into (Chat)GPT’s capabilities, they fall short in assessing the potential of (Chat)GPT to solve specific tasks given its nondeterministic nature. Multiple experiments need to be conducted to validate its performance on each task. In addition, current evaluations generally leverage tasks that overlook the temporal dimension of text, leaving a gap in our understanding of (Chat)GPT’s ability to handle diachronic and historical text.

### Our original contribution.

Our evaluation of (Chat)GPT focuses on two diachronic extensions of the WiC task, namely TempoWiC and HistoWiC. Our aim is to assess the potential of (Chat)GPT for **Semantic Change Detection**. To the best of our knowledge, this paper is the first to investigate the application of (Chat)GPT for historical linguistic purposes. Thus far, only the use of ChatGPT for a conventional WiC task has been evaluated by Laskar et al. (2023) and Kocoń et al. (2023), who reported low accuracy under a single setup. In this paper, we challenge their performance by considering diachronic text and the following setups, totaling 47 experiments each for TempoWiC and HistoWiC:

- **Different prompts.** Like Zhong et al. (2023), we evaluate (Chat)GPT using zero-shot and few-shot prompting strategies, while also exploring many-shot prompting. Our results demonstrate that zero-shot prompting is more effective on HistoWiC, while few-shot prompting is more effective on TempoWiC.
- **Varying temperature.** Like Peng et al. (2023); Liu et al. (2023), we analyze how GPT’s performance varies according to its temperature hyperparameter, which controls the “creativity” or randomness of its answers. Our results indicate that GPT used with low temperature values (i.e., less creativity) is better at handling WiC tasks.
- **GPT API v ChatGPT Web.** We empirically assess whether GPT produces worse results through the OpenAI API compared to Chat-

GPT through the web interface.<sup>6</sup> Our results demonstrate that using GPT through the official API for WiC tasks is better than using ChatGPT through the web interface, as has previously been done (Laskar et al., 2023; Kocoń et al., 2023). Furthermore, our findings suggest that the web interface automatically sets an intermediate temperature for ChatGPT.

- **(Chat)GPT v BERT.** Finally, like Zhong et al. (2023), we compare the performances of (Chat)GPT and BERT. By leveraging the TempoWiC task and introducing the novel HistoWiC task, we shed light on the potential of both models and demonstrate the *current* superiority of BERT in dealing with diachronic text and WiC tasks, compared to *reasonable* GPT prompts templates and strategies.

## 3 Semantic Change Detection

Our evaluation relies on two diachronic definitions of the conventional Word-in-Context (WiC) task, namely TempoWiC and HistoWiC. WiC is framed as a binary classification problem, where each instance is associated with a target word  $w$ , either a verb or a noun, for which two contexts,  $c_1$  and  $c_2$ , are provided. The task is to identify whether the occurrences of  $w$  in  $c_1$  and  $c_2$  correspond to the same meaning or not. Both TempoWiC and HistoWiC rely on the same definition of the task, while being specifically designed for semantic change detection in diachronic text.

### 3.1 Temporal Word-in-Context

NLP models struggle to cope with new content and trends. TempoWiC is designed as an evaluation benchmark to detect short-term semantic changes on social media, where the language is extremely dynamic. It uses tweets from different time periods as contexts  $c_1$  and  $c_2$ .

Given the limits on testing (Chat)GPT, we followed Zhong et al. (2023); Jiao et al. (2023) and randomly sampled a subset of the original TempoWiC datasets. While the original TempoWiC framework provides train, test, and dev sets, here we did not consider the dev set. Table 1 shows the number of positive (i.e., same meaning) and

<sup>6</sup>Discussions on this topic are currently very active, for example, [community.openai.com/t/web-app-vs-api-results-web-app-is-great-api-is-pretty-awful/96238](https://community.openai.com/t/web-app-vs-api-results-web-app-is-great-api-is-pretty-awful/96238)

negative (i.e., different meanings due to semantic change) examples we considered for each set.

Table 1: Datasets used in our evaluation

	TempoWiC			HistoWiC		
	Trial	Train	Test	Trial	Train	Test
<i>True</i>	8	86	73	11	137	79
<i>False</i>	12	114	127	9	103	61
<b>Total</b>	20	200	200	20	200	140

### 3.2 Historical Word-in-Context

Given that NLP models also struggle to cope with historical content and trends, we designed HistoWiC as a novel evaluation benchmark for detecting long-term semantic change in historical text, where language may vary across different epochs. HistoWiC sets the two contexts,  $c_1$  and  $c_2$ , as sentences collected from the two English corpora of the LSC detection task (Schlechtweg et al., 2020).

Similar to the original WiC (Pilehvar and Camacho-Collados, 2019), the annotation process for the LSC benchmark involved usage pair annotations where a target word is used in two different contexts. Thus, we directly used the annotated instances of LSC to develop HistoWiC. Since LSC instances were annotated using the DUREL framework (Schlechtweg et al., 2023) and a four-point semantic-relatedness scale (Schlechtweg et al., 2021, 2020, 2018), we only binarized the human annotations (see Appendix A).

As with TempoWiC, we randomly sampled a limited number of instances to create trial, training, and test sets. Table 1 shows the number of positive and negative examples for each set.

## 4 Experimental setup

In the following, we present our research questions (RQs) and the various setups we considered in our work. In our experiments, we evaluated the performance of (Chat)GPT 3.5 over the TempoWiC and HistoWiC test sets using both the official OpenAI API (GTP API)<sup>7</sup> and the web interface (ChatGPT Web).<sup>8</sup> Of the GPT 3.5 models available through the API, we assessed the performance of gpt-3.5-turbo. Following Loureiro et al. (2022), we employed the Macro-F1 for multiclass classification problems as evaluation metric.

<sup>7</sup>version 0.27.8.

<sup>8</sup>The August 3 Version.

### 4.1 (Chat)GPT prompts

Current ChatGPT evaluations are typically performed manually (Laskar et al., 2023). When automatic evaluations are performed, they are typically followed by a manual post-processing procedure (Kocoń et al., 2023). As manual evaluation and processing may be biased due to answer interpretation, we addressed the following research question:

**RQ1:** *Can we evaluate (Chat)GPT in WiC tasks in a completely automatic way?*

Furthermore, as current evaluations generally rely on a zero-shot prompting strategy, we addressed the following research question:

**RQ2:** *Can we enhance (Chat)GPT’s performance in WiC tasks by leveraging its in-context learning capabilities?*

To address RQ1 and RQ2, we designed a prompt template to explicitly instruct (Chat)GPT to answer in accordance with the WiC label format (i.e., *True*, *False*). We then used this template (see Appendix C.1) with different prompt strategies:

- *zero-shot prompting* (ZSp): (Chat)GPT was asked to address the WiC tasks (i.e., test sets) without any specific training, generating coherent responses based solely on its preexisting knowledge.
- *few-shot prompting* (FSp): since PFMs have recently demonstrated *in-context learning* capabilities without requiring any fine-tuning on task-specific data (Brown et al., 2020), (Chat)GPT was presented with a limited number of input-output examples (i.e., trial sets) demonstrating how to perform the task. The goal was to leverage the provided examples to improve the model’s task-specific performance.
- *many-shot prompting* (MSp): similar to FSp, but with a greater number of input-output examples (i.e., training sets).

### 4.2 (Chat)GPT temperature

The temperature is a hyperparameter of (Chat)GPT that regulates the variability of responses to human queries. According to the OpenAI FAQ, the temperature parameter ranges from 0.0 to 2.0, with lower values making outputs mostly deterministic

and higher values making them more random.<sup>9</sup> To counteract the nondeterminism of (Chat)GPT, we focused only on TempoWiC and HistoWiC and conducted the same experiment multiple times with progressively increasing temperatures. This approach enabled us to answer the following research questions:

**RQ3:** *Does (Chat)GPT demonstrate comparable effectiveness in detecting short-term changes in contemporary text and long-term changes in historical text?*

**RQ4:** *Can we enhance (Chat)GPT’s performance in WiC tasks by raising the “creativity” using the temperature value?*

To address RQ3 and RQ4, we evaluated GPT API in TempoWiC and HistoWiC using eleven temperatures in the range [0.0, 2.0] with 0.2 increments. For each temperature and prompting strategy, we performed two experiments and considered the average performance.

### 4.3 GPT API v ChatGPT Web

Current evaluations typically prompt GPT through the web interface instead of the official OpenAI API. This preference exists because the web interface is free and predates the official API. However, there are differences between using ChatGPT through the web interface (ChatGPT Web) and the official API (GPT API). First of all, the official API enables to query the GPT foundation model, while the web interface enables to query the Chat version. In addition, the GPT API can be set to test at varying temperatures, but the temperature value on ChatGPT Web cannot be controlled. However, while the GPT API allows a limited message history, ChatGPT Web seems to handle an unlimited message history (see Appendix B).

We used the following research question to compare the performance of GPT API and ChatGPT Web:

**RQ5:** *Does GPT API demonstrate comparable performance to ChatGPT Web in solving WiC tasks?*

Testing GPT API with the MSp strategy would be equivalent to testing it with the FSp strategy due to the limited message history. Thus, we evaluated

ChatGPT Web with MSp, aiming to address the following research question:

**RQ6:** *Can we enhance ChatGPT’s performance in WiC tasks by providing it with a larger number of in-context examples?*

To address these research questions, we tested (Chat)GPT using a single chat for each prompting strategy considered. Since testing ChatGPT Web is extremely time-consuming, we conducted one experiment for each prompting strategy.

### 4.4 (Chat)GPT v BERT

The ability of (Chat)GPT to understand has prompted the belief that ChatGPT is a *jack of all trades* that makes previous technologies somewhat outdated. Drawing upon Kocoń et al. (2023), we believe that, when used for solving downstream tasks as *off-the-shelf* model, (Chat)GPT is *currently a master of none*. It works on a comparable level to the competition, but does not outperform any major SOTA solutions.

By relying on multiple experiments on TempoWiC and HistoWiC, we aimed to empirically assess the potential of (Chat)GPT for WiC and LSC tasks. In particular, we addressed the following research question:

**RQ7:** *Does (Chat)GPT outperform BERT embeddings in detecting semantic changes?*

To address RQ7, we evaluated bert-base-uncased on TempoWiC and HistoWiC over different layers. Recent research has exhibited better results when utilizing earlier layers rather than the final layers for solving downstream tasks such as WiC (Periti and Dubossarsky, 2023; Ma et al., 2019; Reif et al., 2019; Liang and Shi, 2023). For each layer, we extracted the word embedding for a specific target word  $w$  in the context  $c_1$  and  $c_2$ . Since the focus of our evaluation was on (Chat)GPT, we did not fine-tune BERT and simply used the similarity between the embeddings of  $w$  in the context  $c_1$  and  $c_2$ . In particular, we followed Pilehvar and Camacho-Collados (2019), and trained a threshold-based classifier using the cosine distance between the two embeddings of each pair in the training set. The training process consisted of selecting the threshold that maximized the performance on the training set. We trained a distinct threshold-based classifier for each BERT layer and for each WiC task (i.e., TempoWiC

<sup>9</sup>[platform.openai.com/docs/api-reference/chat](https://platform.openai.com/docs/api-reference/chat)

and HistoWiC). Then, in our evaluation, we applied these classifiers to evaluate BERT over the TempoWiC and HistoWiC test sets.

Finally, we addressed the following research question:

**RQ8:** *Can we rely on the pretrained knowledge of GPT to automatically solve the LSC task?*

Since (Chat)GPT has demonstrated awareness of historical lexical semantic changes when manually asked about the lexical semantic changes of some words (e.g., *plane*), our goal with RQ8 was to automatically test GPT’s pretrained knowledge of historical semantic changes covered in the English LSC benchmark. In addressing this research question we relied on the LSC ranking task as defined in [Schlechtweg et al. \(2018\)](#). Thus, we specifically asked GPT to rank the set of 37 target words in the English LSC benchmark according to their degree of LSC between two time periods, T1 (1810–1860) and T2 (1960–2010). For each temperature, we repeated the same experiment ten times, totaling 110 experiments. Then, for each temperature, we evaluated GPT’s performance by computing the Spearman correlation using gold scores derived from human annotation and the average GPT score for each target (see Appendix C.2).

## 5 Experimental results

In this section, we report the results of our experiments, while discussing the findings in regard to each research question.<sup>10</sup>

**RQ1:** (Chat)GPT consistently followed our template in nearly all cases, thereby allowing us to evaluate its answers without human intervention. For GPT API, however, we noticed that the higher the temperature, the larger the tendency for deviations from the expected response format (see Figure 2). ChatGPT Web only once answered with an incorrect format. To ensure impartiality, we classified the few (Chat)GPT responses that did not adhere to the required format as incorrect answers.

**RQ2:** Figure 3 shows the rolling average of the performance of GPT API across different temperatures, prompting strategies, and WiC tasks. By using a window size of 4, we were able to consider 8 different experiments per temperature (for each

<sup>10</sup>We provide all our data, code, and results at <https://github.com/FrancescoPeriti/ChatGPTvBERT>

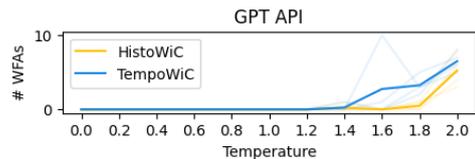

Figure 2: Average number of wrongly formatted answers (WFAs) over the temperature values considered. Background lines correspond to each experiment.

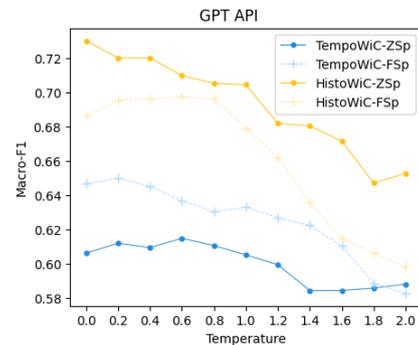

Figure 3: Performance of GPT API (Macro-F1) as temperature increases.

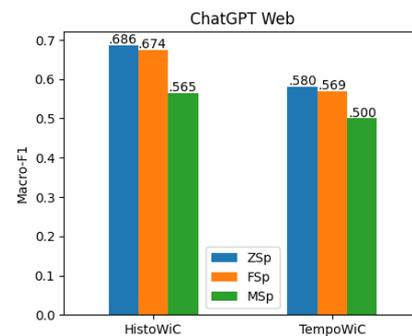

Figure 4: Performance of ChatGPT Web (Macro-F1). Temperature is unknown.

temperature, we ran two experiments)<sup>11</sup>. Figure 4 shows the performance of ChatGPT Web across different prompting strategies and WiC tasks.

Figure 3 and 4 show that ZSp consistently outperforms FSp on HistoWiC. By contrast, FSp consistently outperforms ZSp in TempoWiC when the GPT API is used. This result suggests that the in-context learning capability of GPT is more limited for historical data. In Figure 4, ChatGPT Web’s performance with ZSp outperforms that obtained with FSp for both TempoWiC and HistoWiC, although the discrepancy is smaller.

**RQ3:** Figures 3 and 4 show that (Chat)GPT’s performance on TempoWiC is consistently lower than its performance on HistoWiC. In particular, in our

<sup>11</sup>Except for the first and last two temperatures.

Table 2: Macro-F1 scores obtained by SOTA systems, (Chat)GPT (best score), and BERT (last layer).

	Macro-F1
Chen et al., 2022	.770
Loureiro et al., 2022	.703
Loureiro et al., 2022	.670
Lyu et al., 2022	.625
<i>GPT API</i>	.689
<i>ChatGPT Web</i>	.580
<i>BERT</i>	.743

experiments we observe that (Chat)GPT’s performance ranges from .551 to .689 on TempoWiC and from .552 to .765 on HistoWiC. This suggests that (Chat)GPT is significantly more effective for long-term change detection than for short-term change detection. We believe that this might involve word meanings that were not explicitly covered during training, potentially allowing (Chat)GPT to detect anomalies from the usual patterns. We will further investigate this aspect in our future research.

For the sake of comparison, we report SOTA performance in Table 2. Results from this research are in italics.

**RQ4:** Figure 3 shows that, on average, higher performance is associated with lower temperatures for both TempoWiC and HistoWiC, with accuracy decreasing as temperature values increase. Thus, we argue that high temperatures do not make it easier for GPT to solve WiC tasks or identify semantic changes effectively.

**RQ5:** ChatGPT Web results are presented in Table 3, along with the average performance we obtained through the GPT API across temperature values ranging from 0.0 to 1.0 (API 0–1), from 1.0 to 2.0 (API 1–2), and from 0.0 to 2.0 (API 0–2). As with GPT API, the performance of ChatGPT Web is higher for HistoWiC than for TempoWiC. In addition, our evaluation indicates that ChatGPT Web employs a moderate temperature setting, for we obtained consistent results when using a moderate temperature setting through GPT API. This suggests that the GPT API should be preferred for solving downstream task like WiC. It also suggests that the current SOTA evaluations may achieve higher results if the official API were used instead of the web interface. Thus, this implies that previous results using web interface should be interpreted with caution.

**RQ6:** As shown in Figure 4, the performance of (Chat)GPT Web decreases as the number of example messages increases (from ZSp to MSp).

Table 3: Comparison of GPT API and ChatGPT Web performance (Macro-F1)

Temp.	TempoWiC				HistoWiC			
	API 0–1	API 1–2	API 0–2	web	API 0–1	API 1–2	API 0–2	web
ZSp	.609	.589	.600	.580	.713	.665	.688	.686
FSp	.636	.606	.622	.569	.693	.626	.657	.674
MSp	-	-	-	.500	-	-	-	.565
<b>all</b>	.622	.598	.611	.550	.703	.645	.672	.642

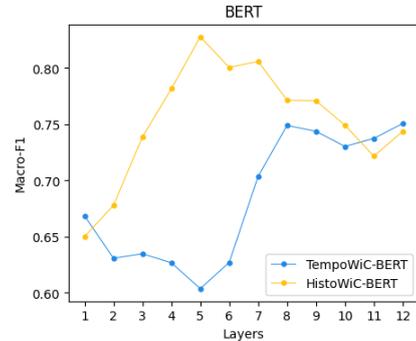

Figure 5: Comparison of BERT Performance (Macro-F1) for TempoWiC and HistoWiC tasks across layers

This suggests that improving the performance of (Chat)GPT requires a more complex training approach than simply providing a few input-output examples. Furthermore, it indicates that the influence of message history is extremely significant in shaping the quality of conversations with (Chat)GPT. Indeed, a limited message history proved to be beneficial for the evaluation of GPT API through FSp.

**RQ7:** Figure 5 shows Macro-F1 scores obtained on TempoWiC and HistoWiC over the 12 BERT layers (see Appendix E). When considering the final layer, which is conventionally used in downstream tasks, BERT obtains Macro-F1 scores of .750 and .743 for TempoWiC and HistoWiC, respectively. Similar to Periti and Dubossarsky (2023), BERT performs best on HistoWiC when embeddings extracted from middle layers are considered. However, BERT performs best on TempoWiC when embeddings extracted from the last layers are used.

We compared the performance of GPT and BERT across their respective worst to best scenarios by sorting the Macro-F1 scores obtained by BERT and GPT in ascending order (bottom x-axis). For ChatGPT, we consider the results obtained through FSp and ZSp prompting for TempoWiC and HistoWiC, respectively. As shown in Figure 6, even when considering the best setting, GPT does not outperform the Macro-F1 score obtained by using the last layer of BERT, marked

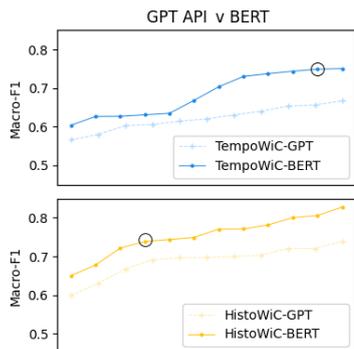

Figure 6: GPT v BERT (Macro-F1). Performance is sorted in ascending order regardless of temperatures and layers. A black circle denotes the use of the last layer of BERT.

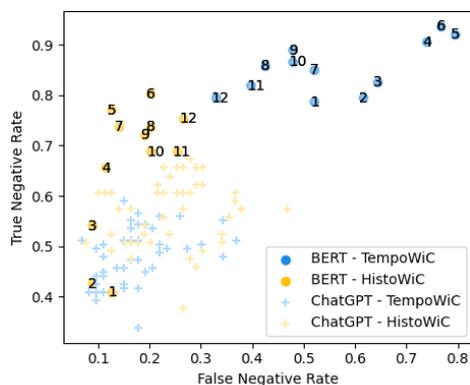

Figure 7: True Negative Rate v False Negative Rate. Each cross represents a (Chat)GPT experiment. Each dot represents the use of a specific layer of BERT.

with a black circle. However, although it exhibits lower performance, the results obtained from GPT are still comparable to BERT results on HistoWiC when embeddings extracted from the last layer of BERT are used.

Since our goal is to evaluate the potential of (Chat)GPT for recognizing lexical semantic changes, we analyzed the true negative rate and false negative rate scores, because *negative* examples represent semantic change in TempoWiC and HistoWiC datasets. As shown in Figure 7, regardless of the temperature and layer considered, (Chat)GPT falls short in recognizing semantic change for both TempoWiC and HistoWiC compared to BERT. However, it produces fewer false negatives than BERT for TempoWiC.

**RQ8:** In our experiment, GPT achieved low Spearman’s correlation coefficients for each temperature when ranking the target word of the LSC

English benchmark by degree of lexical semantic change. Higher correlations were achieved by using low temperatures rather than high ones (see Appendix F). Table 4 shows the GPT correlation for the temperature 0. For comparison, we report correlations obtained by BERT-based systems that leverage pretrained models. Note that, when BERT is fine-tuned, it generally achieves even higher correlation scores (see survey by Montanelli and Periti, 2023).

Table 4: LSC comparison: correlation obtained by SOTA, *pre-trained* BERT systems and GPT (temperature=0).

	Spearman’s correlation
Periti et al., 2023	.651
Laicher et al., 2021	.573
Periti et al., 2022	.512
Rother et al., 2020	.512
GPT API	.251

As shown in Table 4, the BERT-based system largely outperforms GPT, suggesting that GPT is not currently well-adapted for use in solving LSC downstream tasks.

## 5.1 BERT for Semantic Change Detection

There are notable differences between the Macro-F1 for TempoWiC and HistoWiC in terms of how the results increase and decrease across layers (see Figure 5). For TempoWiC the results increase until the 8th layer, after which they remain almost stable. Conversely, for HistoWiC the BERT performance rapidly increases until the 5th layer, after which it linearly decreases until the 12th layer. As regards Tempo WiC, we hypothesize that BERT is already aware of the set of word meanings considered for evaluation as it was pretrained on modern and contemporary texts. As regards HistoWiC, we hypothesize that BERT is not completely aware of the set of word meanings considered for evaluation and that word representations adopted for the historical context of HistoWiC<sup>12</sup> might be slightly tuned. Thus, using medium embedding layers could prove beneficial in detecting semantic changes, as these layers are less affected by contextualization (Ethayarajh, 2019). In other words, for HistoWiC, we hypothesize that the performance diminishes in the later layers due to the increasing contextualization of the medium and final embedding layers, which reduces the presence of noise in untuned word representations. This prompts us to question the ap-

<sup>12</sup>1810–1860, as referenced in Schlechtweg et al. (2020)

propriateness of using the last embedding layers to recognize historical lexical semantic change. We will address this question in future research.

## 6 Conclusion

In this study, we empirically investigated the use of the *current* (Chat)GPT 3.5 to detect semantic change. Our goal is not to comprehensively evaluate (Chat)GPT in dealing with semantic change, but rather to acknowledge its potential while also raising concerns and questions about its off-the-shelf use. In this regard, we used *reasonable* prompts from a human point of view, which may not necessarily be optimized for the model. We used the TempoWiC benchmark to assess (Chat)GPT’s ability to detect short-term semantic changes, and introduced a novel benchmark, HistoWiC, to assess (Chat)GPT’s ability to recognize long-term changes. When considering the standard 12 layer of BERT, our experiments show that (Chat)GPT achieves comparable performance to BERT (although slightly lower) in regard to detecting long-term changes, but performs significantly worse in regard to recognizing short-term changes. We find that BERT’s contextualized embeddings consistently provide a more effective and robust solution for capturing both short- and long-term changes in word meanings.

There are two possible explanations for the discrepancy in (Chat)GPT’s performance between TempoWiC and HistoWiC: i) HistoWiC might involve word meanings not explicitly covered during training, potentially aiding (Chat)GPT in detecting anomalies; ii) TempoWiC involves patterns typical of Twitter (now X), such as abbreviations, mentions, or tags, which may render it more challenging than HistoWiC.

In light of our findings, we argue that *(Chat)GPT 3.5 might be the hero the world deserves but not the one it needs right now*<sup>13</sup>, in particular for computationally modeling meaning over time, and by extension, for the study of semantic change. Nevertheless, during the course of our research, updates to (Chat)GPT became available and gained popularity, leading research and practitioners to conduct new experiments on these updated models. Particularly noteworthy is a recent study by Karjus (2023),

<sup>13</sup>This quote draws inspiration by the movie *Batman: The Dark Knight*. We leverage the analogy of (Chat)GPT achieving lower results than BERT to acknowledge the potential of (Chat)GPT while also raising concerns and questions about its use for Semantic Change detection.

which showcased remarkable performance on LSC using the GPT-4 model. Inspired by this research, our ongoing and future work is focused on further exploring the capabilities of GPT-4 for modeling semantic change.

## Limitations

There are limitations we had to consider in the making of this paper. Firstly, a limitation arises when working with temporal HistoWiC benchmarks. While we ensure the utilization of diachronic data, we cannot guarantee that if the meaning of a word differs across contexts, it unequivocally indicates either the presence of stable polysemy (existing stable multiple meanings) or exemplifies a semantic change (either a new sense that it did not previously possess or a lost sense that it no longer has).

Other limitations are about the use of language models. We could not evaluate (Chat)GPT across different languages due to both price and API limitations. This means that while the results holds for English, we do not know how (Chat)GPT will behave for the other languages. Although we are aware of open source solution such as LLaMA, it still necessitates expensive research infrastructure, and we thus chose to focus on (Chat)GPT.

Like all research on (Chat)GPT (Laskar et al., 2023; Kocoń et al., 2023; Zhong et al., 2023), our work has a significant limitation that we cannot address: our (Chat)GPT results are not entirely reproducible as (Chat)GPT is inherently nondeterministic. In addition, like Zhong et al. (2023); Jiao et al. (2023), we found that time and economic constraints when using (Chat)GPT dictated that our evaluation of the software had to be based on only a subset of the TempoWiC and HistoWiC dataset.

In our study, we utilized (Chat)GPT 3.5. This could be considered a limitation, given the recent release of GPT 4. However, we opted for (Chat)GPT 3.5 based on the guidance provided in the current OpenAI documentation.<sup>14</sup> Additionally, we argue that (Chat)GPT-3.5 is a cheaper alternative than the current GPT-4 model, making the investigation of (Chat)GPT-3.5 still significant for researchers with limited economic resources. We acknowledge that OpenAI continues to train and release new models, which could potentially affect the reproducibility of our results.

<sup>14</sup><https://platform.openai.com/docs/guides/gpt/which-model-should-i-use>

One of the many features of (Chat)GPT is its ability to incorporate the history of preceding messages within a conversation while responding to new input prompts. However, there remain several unanswered questions regarding how this history influences the model's answers. This holds true even for the zero-shot prompting strategy, where a general setting is lacking. Multiple prompts can be provided as part of the same chat or across different chats. For simplicity, and similar to previous research, we assigned only one chat for each ZSP experiment. We intend to use different chats in our future work to examine and investigate the effect of the message history.

Finally, as highlighted by Laskar et al. (2023), since the instruction-tuning datasets of OpenAI models are unknown (that is, not open source), the datasets used for evaluation may or may not be part of the instruction-tuning training data of OpenAI.

Despite these limitations, we argue that our work is significant as it may prompt new discussion on the use of LMs such as BERT and (Chat)GPT, while also dispelling the expanding belief that the use of ChatGPT as *off-the-shelf* model *already* makes BERT an outdated technology.

## Appendix

### A Historical WiC

We shifted from the LSC to the WiC setting as follows. First, we selected only the annotated LSC instances containing contexts from different time periods. We then filtered out all the instances annotated by a single annotator<sup>15</sup> and all the instances that are associated with an average score,  $s$ , such that  $1.5 < s < 3.5$ , which represents ambiguous cases even for humans. Finally, we binarized the LSC annotations by converting each  $s \leq 1.5$  to *False* (i.e. different meanings) and each  $s \geq 3.5$  to *True* (i.e. same meaning). We report in Table 5 the four-point semantic-relatedness used to annotate the LSC instances through the DUREl framework.

	4: Identical
↑	3: Closely related
	2: Distantly related
	1: Unrelated

Table 5: The DUREl relatedness scale used in [Schlechtweg et al. \(2020, 2018\)](#)

### B Message history

Although one of the many features of (Chat)GPT is its ability to consider the history of preceding messages within a conversation while responding to new input prompts, GPT API and the web version handle message history differently. In GPT API, the message history is limited to a fixed number of tokens (i.e., 4,096 tokens for `gpt-3.5-turbo`); however, we are not aware of how the message history is handled in ChatGPT Web, where an unlimited number of message for chat seems to be supported.

In our experiments, we use a single chat for each considered prompting strategy, both for ChatGPT Web and GPT API. However, in ChatGPT Web, we considered the full message history for the ZSp, FSp, and MSp strategies. Instead, to avoid exceeding the token limit set by the OpenAI API, we tested GPT API for the ZSp and FSp strategies by considering a message history of 33 messages. Note that due to the token limit, testing the MSp strategy for GPT API wasn't possible, as the limited message history would make MSp equivalent to FSp. The 33-message history was organized as

a combination of a *fixed* and a *sliding window*. We set the fixed window to ensure the model is always aware of the task we asked it to answer in the early prompts; instead, we set the sliding window to emulate the flow of the conversation as in ChatGPT Web. In particular, i) in ZSp, the fixed window covers our first prompt (i.e., task explanation) and the (Chat)GPT answer, while the sliding window covers the  $i$ -th prompts and the last 30 messages (i.e., 15 prompts and 15 (Chat)GPT answers); ii) in FSp, the fixed window covers the first 26 messages (i.e., task explanation and example instances), while the sliding window covers the  $i$ -th prompts and the last 6 messages. Figure 8 summarizes the message history we set for testing GPT API.

<sup>15</sup>Different instances were annotated by varying numbers of annotators.

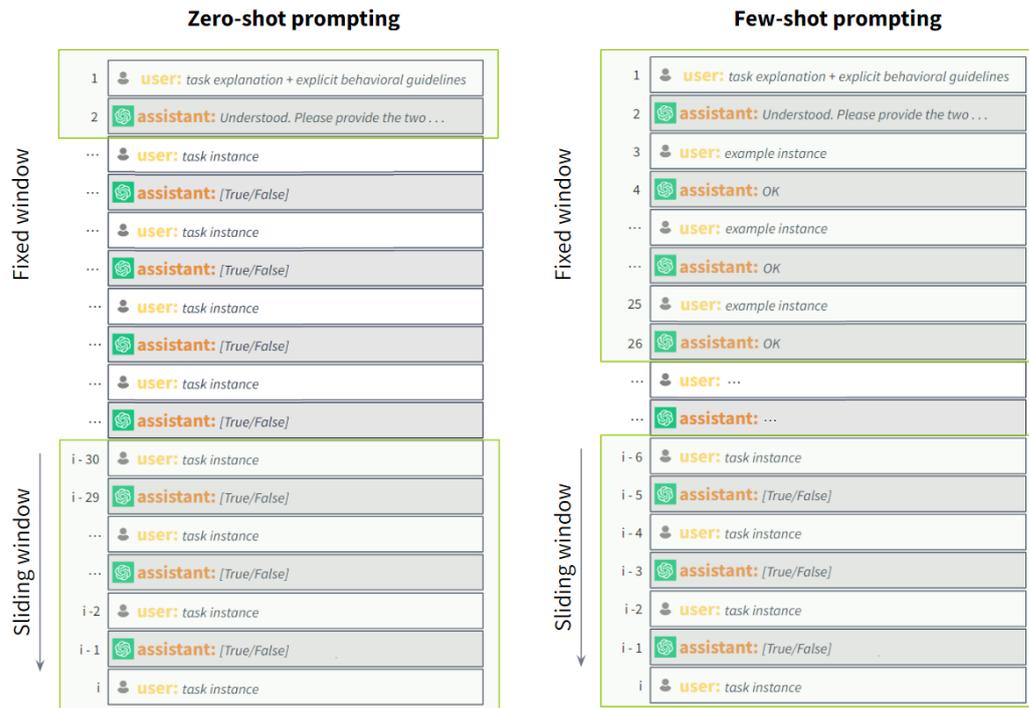

Figure 8: Message history used for GPT API in the zero-shot prompting (ZSp) and few-shot prompting (FSp) strategies. The message history is organized as a combination of a fixed and a sliding window, encompassing a total of 33 messages. The fixed window ensures that the model remains constantly aware of the task we have asked it to address in the initial prompts and the given examples (if any). Conversely, we establish the sliding window to emulate the conversational flow of ChatGPT Web.

## C (Chat)GPT templates

### C.1 WiC template

Description	Template
task explanation	<b>Task:</b> Determine whether two given sentences use a target word with the same meaning or different meanings in their respective contexts.
explicit behavioral guidelines	I'll provide some negative and positive examples to teach you how to deal with the task before testing you. Please respond with only "OK" during the examples; when it's your turn, answer only with "True" or "False" without any additional text. When it's your turn, choose one: "True" if the target word has the same meaning in both sentences; "False" if the target word has different meanings in the sentences. I'll notify you when it's your turn.
example instance	This is an example. You have to answer "OK": <b>Sentence 1:</b> [First sentence containing the target word] <b>Sentence 1:</b> [First sentence containing the target word] <b>Target:</b> [Target word] <b>Question:</b> Do the target word in both sentences have the same meaning in their respective contexts? <b>Answer:</b> [True/False]
task instance	Now it's your turn. You have to answer with "True" or "False": <b>Sentence 1:</b> [First sentence containing the target word] <b>Sentence 1:</b> [First sentence containing the target word] <b>Target:</b> [Target word] <b>Question:</b> Do the target word in both sentences have the same meaning in their respective contexts? <b>Answer:</b> [The model is expected to respond with "True" or "False"]

Table 6: Sections of the prompt template used for testing (Chat)GPT.

ID	Strategy	Prompt
ZSp	zero-shot prompting	task explanation explicit behavioral guidelines task instance ... task instance
FSp	few-shot prompting	task explanation explicit behavioral guidelines example instance ... example instance task instance ... task instance
MSp	many-shot prompting	<i>like FSp</i>

Table 7: Prompt template for each employed prompting strategy.

### C.2 LSC template

Strategy	Template
ZSp	Consider the following two time periods and target word. How much has the meaning of the target word changed between the two periods? Rate the lexical semantic change on a scale from 0 to 1. Provide only a score. <b>Target:</b> [Target word] <b>Time period 1:</b> 1810–1860 <b>Time period 2:</b> 1960–2010 <b>Answer:</b> [The model is expected to respond with a continuous score $s$ , with $0 \leq s \leq 1$ ]

Table 8: Prompt template for LSC.

# Towards Unified Uni- and Multi-modal News Headline Generation

Mateusz Krubiński and Pavel Pecina

Charles University, Faculty of Mathematics and Physics  
Institute of Formal and Applied Linguistics  
{krubinski,pecina}@ufal.mff.cuni.cz

## Abstract

Thanks to the recent progress in vision-language modeling and the evolving nature of news consumption, the tasks of automatic summarization and headline generation based on multimodal news articles have been gaining popularity. One of the limitations of the current approaches is caused by the commonly used sophisticated modular architectures built upon hierarchical cross-modal encoders and modality-specific decoders, which restrict the model’s applicability to specific data modalities – once trained on, e.g., *text+video* pairs there is no straightforward way to apply the model to *text+image* or *text-only* data. In this work, we propose a unified task formulation that utilizes a simple encoder-decoder model to generate headlines from uni- and multi-modal news articles. This model is trained jointly on data of several modalities and extends the textual decoder to handle the multimodal output.

## 1 Introduction

The task of Multimodal Summarization was introduced as an extension of the traditional NLP task of Text Summarization. Early works (e.g., Li et al., 2017; Sanabria et al., 2018; Li et al., 2020a) explored to what extent enriching the textual document with additional context-specific information (e.g., visual clues from images attached to a product/service review or video clips attached to a cooking recipe) helps the automatic systems in refining the summary generation process. Zhu et al. (2018) were the first to notice that the *informativeness* of a summary can be significantly improved by including the visual clues in the output, introducing the task of Multimodal Summarization with Multimodal Output (MSMO). In their formulation, based on a textual document and a set of images, the model is tasked to generate the textual summary and pick a single image as the *pictorial summary*. Li et al. (2020b) introduced a variant of the task

where the input is a pair of textual article and a short video. The following works (e.g., Qiu et al., 2022; Zhang et al., 2023b) explored the challenging problem of multi-modal fusion and alignment by introducing auxiliary tasks during training and extending the model architecture with task-specific blocks. However, by doing so, the model is tailored to a specific data modality.

In this work, we propose a novel MSMO task formulation that supports the most common data modalities (*text+video*→*text+image*, *text+images*→*text+image*, *text*→*text*) with a single sequence-to-sequence model (Section 2). We explore two approaches (Section 3.2): i) extending a text-to-text baseline with visual features and ii) fine-tuning a multimodal foundation model. We show that the proposed unified formulation leads to results competitive with previously introduced task-specific solutions (Section 4) while not being restricted to specific data modalities.

## 2 Unifying MSMO

Previous works explored two variants of the MSMO task: video-based and image-based. In the video-based one, the multimodal article is represented as a pair of a video clip and a textual document. The goal is to generate the textual summary and to choose a single frame that acts as a pictorial summary. In the image-based variant, the input is a *set* of images, i.e., there is no temporal dependency. The second difference comes from the ground truth image: in the image-based variant, we assume that the target is one of the input images. In the video-based one, there is no such assumption<sup>1</sup> – a similarity function is utilized to obtain the per-frame labels for training using the *most similar* one as a positive target. Our goal is to train a system

<sup>1</sup>The target image is often created by applying minimal edits, such as cropping or watermark removal. In addition, computational reasons require to down-sample the input frames, potentially dropping the *exact* one that is used as a target.

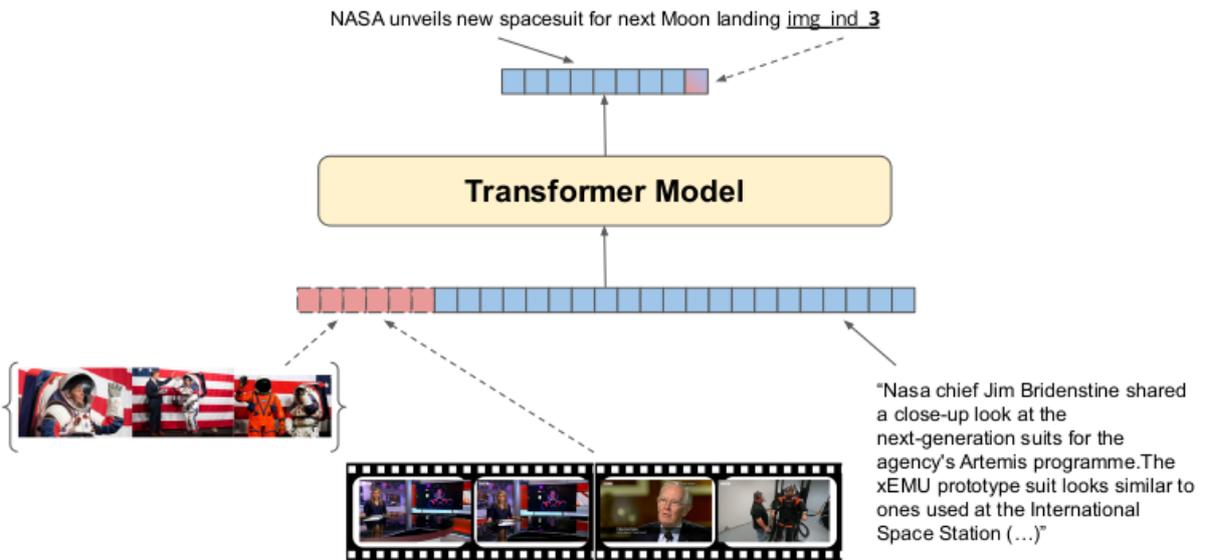

Figure 1: Overview of the proposed unified approach to MSMO. The visual tokens are appended to the text representation. The generated output includes the textual summary and the *index token* that indicates which input image (first, second, third, etc.) is picked as the pictorial summary. During training, a mixture of video-based, image-based, and text-only data is used.

capable of *natively* handling both MSMO variants as well as the basic text-to-text problem (summarization or headline generation). We achieve that by transforming the visual inputs into a sequence of image features that are concatenated with the textual token embeddings.

Instead of using a dedicated module for image scoring, we realize the target image representations by appending an *index token* to the textual target – `img_ind_1` indicates that the *first* image is the target, `img_ind_2` that the *second*, etc. This formulation allows us to use the standard Transformer architecture (Vaswani et al., 2017) trained end-to-end in a multi-task setting (see Figure 1) – for the text-only input, we do not extend the textual embeddings and do not add the index token into the target sequence.

### 3 Experiments

#### 3.1 Data

In our experiments, we use the text-only PENS (Ao et al., 2021) dataset and the video-based MLASK (Krubinski and Pecina, 2023) dataset for training and testing. Since the largest publicly available image-based multimodal summarization dataset M3LS (Verma et al., 2023) lacks the image targets, we extend the English subset of the M3LS dataset by collecting the cover pictures on our own (see Appendix A for details). For brevity, we fol-

low the TL;DW formulation by Tang et al. (2023) and use the article title as the textual target (i.e., the headline), although the proposed methods can also be applied for other summarization tasks, such as abstract generation.

#### 3.2 Implementation

We use the T5 (Raffel et al., 2020) v1.1 base variant (250M trainable parameters) that we enrich with visual features extracted with frozen ViT-L/14 CLIP (Radford et al., 2021), projected with a linear layer to match the hidden dimension size (we refer to this model as T5CLIP). We extract a single vector per image (frame) and, following Wang et al. (2022a), use positional embeddings to indicate the temporal dimension for videos. We extend the model vocabulary with index tokens, i.e., `«img_ind_1, img_ind_2, ...»` that are used for image/frame selection. We train with the Adafactor (Shazeer and Stern, 2018) optimizer using the default parameters from the Transformers (Wolf et al., 2020) package. For the multimodal baseline, we use the Flan T5-XL (Chung et al., 2023) version of BLIP-2 (Li et al., 2023, 3.9B parameters), which we extend to handle multiple images in the input – we concatenate the Q-Former features from multiple images before appending them to the textual embeddings introducing no new parameters. We use the LoRA (Hu et al., 2022) procedure and update only the Q and V matrices in the Q-Former

and Language Model components (5.7M trainable parameters), training with the AdamW (Loshchilov and Hutter, 2019) optimizer with  $\beta=(0.9, 0.999)$ , learning rate of  $1e-5$  and weight decay of  $5e-2$ . We train all the models for up to 10 epochs with early stopping applied if ROUGE-L F1 does not improve for 5 consecutive epochs. We limit the source size to 1024 sub-word tokens and the target length to 128 tokens. We train on a machine with three NVIDIA A40 GPUs and the average training time is 24 hours for the T5 variants (effective batch size 300) and one week for the BLIP-2 variant (effective batch size 60). During decoding, we utilize beam search of size 4, length penalty of 1.0, and repetition penalty (Keskar et al., 2019) of 2.5.

### 3.3 Metrics and baselines

**Metrics** We measure the quality of the textual output with ROUGE-L (Lin, 2004) and BERTScore (Zhang et al., 2020b), reporting the F1 scores. For the pictorial output, we report the cosine similarity (CosSim) between the ViT-L/14 CLIP features of the target image and the one chosen by the model. To measure the multi-modal interactions, we report the CLIPBERTScore (Wan and Bansal, 2022) metric. It is computed as a weighted average<sup>2</sup> of the CLIPScore (Hessel et al., 2021) of the chosen image and the generated summary and the BERTScore precision of the input article and the generated summary. For the image-based data, we also report the top-1 accuracy (Top-1 Acc), i.e., the percentage of predictions where the

target image is correctly retrieved. For details, see Appendix B.

**Baselines** We report two extractive baselines: *Lead* that extracts the first sentence and *Oracle* that picks a sentence maximizing ROUGE-L with the ground truth. For the off-the-shelf textual abstractive baselines, we use the Alpaca (Taori et al., 2023) and BRIO (Liu et al., 2022) models (see Appendix C). For the video-based data, we compare with the MMS model (Krubiński and Pecina, 2023). We also report a trivial baseline *RandomVi* that picks a random image/frame. To further establish a comparison with the recent developments, we also report a generative visual baseline based on Stable Diffusion (Rombach et al., 2022). We employ the stabilityai/stable-diffusion-2-1 model prompted with the textual target (`_TEXT_`) using the following template: “High quality, photorealistic photo of `_TEXT_`”.

## 4 Results

**Textual Output** Table 1 compares the models (see examples of model outputs in Appendix D) trained separately on each task (e.g., T5CLIP<sub>PENS</sub>) with the ones trained in the multi-task fashion (T5CLIP). The results are comparable, with additional textual data improving the performance on the smallest video-based dataset – MLASK. The proposed baselines, besides the *Oracle*, are lagging behind the task-specific models. The highest scores are obtained by the fine-tuned BLIP-2, which integrates the largest language component – Flan T5-XL.

<sup>2</sup>We use the recommended  $\alpha = 0.25$

	CosSim				CLIPBERTScore				Top-1 Acc

Table 2: Evaluation of the visual output quality on the validation and test splits for video-based and image-based datasets (Section 3.1). The highest-scoring system in each column is bolded independently for test-set and dev-set.

**Visual Output** The relatively high scores of the random visual baseline (Table 2) may indicate that the CLIP features are not distinctive enough for the closely related images/frames coming from the same article. The image-specific model (T5CLIP<sub>M3LS</sub>) performs slightly better than the multi-task one (T5CLIP). We attribute this to the potentially easier image-based task formulation (Section 2) where the target input (i.e., one with CosSim = 1.0) is present in the input.

In order to improve the visual performance, we propose to use two methods: smooth labels (see Krubiński and Pecina, 2023) and greater weights  $w$  for the visual tokens when computing loss. Using 10 times greater weight (T5CLIP<sub>w=10</sub>) improves the top-1 accuracy on M3LS, while using 50 times greater weight (T5CLIP<sub>w=50</sub>) brings no further improvement, degrading the quality of textual output. The smooth labels (T5CLIP<sub>Smooth</sub>), designed for video-based data, are not effective on image-based data. The highest similarities on MLASK are achieved by the MMS model, which uses a separate visual encoder and frame-scoring module. The highest CLIPBERTScore is achieved by MMS on MLASK (the best visual output quality) and BLIP-2 on M3LS (the best textual model, a greater weight for the textual component). Masking the visual features with random noise has a negligible effect on the textual output (M3LS test 29.38→29.32), which we attribute to the "greedy learning" hypothesis by Wu et al. (2022), but drops the top-1 accuracy to chance level (M3LS test 88.55→37.9).

## 5 Related Work

Historically, for both the video-based (Li et al., 2020b) and the image-based (Zhu et al., 2018)

MSMO, the attention mechanism (Bahdanau et al., 2015) was used to condition the encoded text representation on the visual information, which in the next step was passed to the autoregressive text decoder. Following works focused on improving the quality and efficiency of this process: Li et al. (2018) and Liu et al. (2020) focused on the filtering mechanism that would allow the model to attend only to chosen relevant features avoiding potential noise. Yu et al. (2021) and Qiao et al. (2022) worked on adapting strong pre-trained language models to the multimodal input. All of those works perturb the textual representation – the model is no longer capable of inference on text-only data. The reverse attention (*vision*→*text*) was used to condition the visual information on the text content. Using a learning signal from the pictorial target, the model was trained to produce image/frame-level scores.

A step towards simplifying these modular approaches was recently made by Jiang et al. (2023), who generate pseudo-captions for input images and then pick the image with the highest similarity between the caption and the generated textual summary, and He et al. (2023), who instead of using a textual decoder, predict sentence-level scores and extract top-k sentences as the textual summary. A one-for-all architectures unifying several vision-and-language tasks have also been explored in a wider context. Cho et al. (2021) introduce visual sentinel tokens corresponding to image regions, allowing them to realize Visual Grounding with a text-only decoder. The Task- and Modality-Agnostic OFA framework (Wang et al., 2022b) unifies the multi-modal and text-only tasks with a sequence-to-sequence Transformer. By design,

it is however limited to tasks dealing with a single image, e.g., Image Captioning or Visual Question Answering, not supporting inputs containing multiple images or videos. A recent line of research on multimodal LLMs (Zhang et al., 2023a; Maaz et al., 2023; Li et al., 2024) transfers the knowledge from image-text models into video-text models.

Inspired by those works and the general-purpose multimodal foundation models (e.g., Bao et al., 2022; Alayrac et al., 2022; Wang et al., 2023a), we propose the unified formulation (Section 2) – the multi-task training with a simplified encoder allows the model to natively handle both multi-modal and text-only input and the usage of *index tokens* that explicitly point to a particular input image allows us to drop the scoring module and train with a single text decoder.

## 6 Conclusions

In this pilot study on multi-task multi-modal summarization, we propose a novel unified formulation for the MSMO task. By training the textual decoder to generate *index tokens*, we make use of the training signal from the visual modality without a dedicated scoring module. Our results indicate that multi-task training, which incorporates text-only data, is an alternative to text-only pre-training, which preserves the *native* capability to handle purely textual input. For the challenging task of video-based MSMO, there is still some gap left when it comes to the visual output quality when compared to sophisticated task-specific architecture. Based on our results, for this specific task, the visual generative approaches are still inferior to extractive ones.

## Limitations

**Multimodal Summarization variants.** In our work, we examine three variants of the multimodal summarization task:  $text+video \rightarrow text+image$ ,  $text+images \rightarrow text+image$ , and  $text \rightarrow text$ . We acknowledge existence of other formulations, such as  $text+video \rightarrow text$  (Qiao et al., 2022),  $images \rightarrow text$  (Trieu et al., 2020) or  $video \rightarrow text+images$  (Lin et al., 2023) that we did not include in our experiments.

**Dataset choice.** Our findings are based on particular datasets, in a particular language (English) and from a particular domain (news articles). The fact that the previously introduced datasets (Li et al.,

2020b; Tang et al., 2023) are not publicly available is a limiting factor.

**Extension of the M3LS dataset.** Since the largest image-based dataset (Section 3.1) lacks the cover pictures in the training data, we collected them by automatically crawling a news website. To check the validity of our setup, we sampled 100 articles and manually checked the collected images, but no large-scale human evaluation was conducted.

**Generative models.** Both of the off-the-shelf generative models that we use: the visual one (*Stable Diffusion v2-1*) and the textual one (*Alpaca*) were trained on data that potentially may include harmful content such as explicit pornographic materials or toxic, stereotyped language. We did not apply any filtering to the model outputs, so the predictions may not be free of bias.

## Acknowledgements

This work was supported by the Czech Science Foundation (grant no. 19-26934X) and CELSA (project no. 19/018). In this work, we used data and tools provided by the LINDAT/CLARIAH-CZ Research Infrastructure (<https://lindat.cz>), supported by the Ministry of Education, Youth and Sports of the Czech Republic (project no. LM2023062).

## A Appendix – Data preparation

### A.1 MLASK

Since the textual part of MLASK<sup>3</sup> – the largest publicly available video-based news summarization dataset – is in the Czech language, we used the CUBBITT (Popel et al., 2020) Machine Translation system<sup>4</sup> to translate articles and summaries (titles) into English. We use the split proposed by Krubiński and Pecina (2023), i.e., 36,109/2,482/2,652 instances for training/validation/testing. In our early experiments, we sampled one of every 25 frames (1 frame per second), which on average produced 86 images (frames) per video, with the longest videos having up to about 300 frames sampled. This number is too large to process with the BLIP-2 model – it uses the Q-Former to map each input image into 32 visual tokens, which would require us to process sequences of length up to 9,600. Therefore, we decided to further down-sample the input by sampling 20 frames evenly spaced across the video. To check whether this affects the model performance, we trained the T5CLIP<sub>MLASK ALL</sub> variant (see Section 3.2) that uses the denser sampling for each video. The results (MLASK dev-set ROUGE-L: 20.79 → 20.55, BERTScore: 25.46 → 25.34, CosSim: 0.64 → 0.61) indicate that the model is not able to make use of the dense frame sampling, showing that the problem of frame-selection requires more work in the future.

### A.2 PENS

The PENS dataset<sup>5</sup> contains 113,762 news articles and was originally introduced for personalized news headline generation. We filtered it by removing articles identified as non-English by the langid<sup>6</sup> language identifier, and those where the title has less than 2 words or more than 25 words. In the next step, we de-duplicated the data based on the article and title fields. We were left with 100,992 documents (89%), out of which 5,000 were used for validation and testing and the remaining ones (90,992) for training.

### A.3 M3LS

The M3LS dataset<sup>7</sup> was introduced recently as the largest resource for image-based multimodal summarization. The data was collected in several languages, including 376,367 documents in English, from the [www.bbc.com/news](http://www.bbc.com/news) website. However, the multimodal information (images) is present only on the source side – the target is purely textual. In order to extend this resource with the visual target, we made use of the URLs that were provided for each article by collecting the content (URL) of the meta element HTML tag with property="og:image". Based on our understanding and manual checks, the URLs correspond to the picture that is used to visually represent the article at the [www.bbc.com/news](http://www.bbc.com/news) main page. In the next step, we collected the images and applied two-step filtering: we kept only those images that had a particular resolution (1024x490), and in the next step, we removed duplicates. Finally, we filtered those multimodal articles that fulfilled two conditions: they had at least a single image in the input and we were able to collect the target image for them. We ended up with 115,432 instances, which we split into training/validation/testing based on the publication date: articles published in January–April of 2021 for validation (5,865 instances) and the ones published in May–October of 2021 for testing (6,854 instances). The remaining data (before January 2021) is used for training (102,713 instances). Following the image-based MSMO formulation (Section 2), we append the target image to the source images, shuffling them during training to avoid positional bias. The quantitative statistics of the number of input images in the extended M3LS dataset are displayed in Table 3.

Min	Q <sub>1</sub>	Mean	Q <sub>3</sub>	Max
2	2	3.79	4	21

Table 3: Quantitative statistics of the number of input images (including the target image) in the subset of the English M3LS dataset that we extended with the multimodal target.

<sup>6</sup><https://github.com/saffsd/langid.py>

<sup>7</sup><https://github.com/Raghvendra-14/M3LS>

## B Appendix – Metrics

We use the ROUGE metric from the TorchMetrics package<sup>8</sup> and the original implementations of BERTScore<sup>9</sup> and CLIPBERTScore<sup>10</sup>. The signature of the BERTScore model that we use is: roberta-large\_L17\_no-idf\_version0.3.12(hug\_trans=4.29.0.dev0)-rescaled. For readability reasons, we re-scale both BERTScore and CLIPBERTScore into the [0–100] range by multiplying the numerical scores by 100.

## C Appendix – Baselines

The Stanford Alpaca model<sup>11</sup> is a text-only, Transformer-based Large Language Model (LLM), fine-tuned from the LLaMA (Touvron et al., 2023) model to follow instructions. It has been trained on the automatically generated data created with the Self-Instruct (Wang et al., 2023b) techniques. In our experiments, we use the following prompt:

```
Below is an instruction that describes a task, paired with an input that provides further context. Write a response that appropriately completes the request.

### Instruction:
Generate a one sentence summary of a given text, using no more than 10 words.

### Input:
__DOCUMENT_TEXT__

### Response:"
```

We report results with the 7B parameter variant and, for generation, utilize beam search of size 4, length penalty of -5.0, and repetition penalty of 2.5. In our early experiments, we noticed that truncating the input at the token level resulted in words and sentences being cut in half, which negatively affected the model performance. To avoid this, we use the wtpsplit package (Minixhofer et al., 2023) to prompt the model with full sentences, capping the input length (i.e., \_\_DOCUMENT\_TEXT\_\_) at 1000 characters.

BRIO (Liu et al., 2022) is a recent encoder-decoder model trained for both summary *generation* and *evaluation*, i.e., the ability to score the quality of candidate summaries. We use the Yale-LILY/brio-xsum-cased variant (568M parameters), which is based upon the pre-trained PEGASUS (Zhang et al., 2020a) model and fine-tuned on the XSum (Narayan et al., 2018) dataset to generate single-sentence summaries.

When generating images with the stabilityai/stable-diffusion-2-1 model, we use the standard inference parameters (guidance\_scale=5 and num\_inference\_steps=50) with the following negative\_prompt: “ugly, tiling, poorly drawn hands, poorly drawn feet, poorly drawn face, out of frame, extra limbs, disfigured, deformed, body out of frame, bad anatomy, watermark, signature, cut off, low contrast, underexposed, overexposed, bad art, beginner, amateur, distorted face”.

## Abstract

The ability of Large Language Models (LLMs) to encode syntactic and semantic structures of language is well examined in NLP. Additionally, analogy identification, in the form of word analogies are extensively studied in the last decade of language modeling literature. In this work we specifically look at how LLMs’ abilities to capture sentence analogies (sentences that convey analogous meaning to each other) vary with LLMs’ abilities to encode syntactic and semantic structures of sentences. Through our analysis, we find that LLMs’ ability to identify sentence analogies is positively correlated with their ability to encode syntactic and semantic structures of sentences. Specifically, we find that the LLMs which capture syntactic structures better, also have higher abilities in identifying sentence analogies.

## 1 Introduction

Analogies facilitate the transfer of meaning and knowledge from one domain to another. Making and identifying analogies is a central tenet in human cognition (Hofstadter, 2001; Holyoak et al., 2001) and is aided by humans’ ability to process the structure of language. In the domain of NLP, several types of textual analogies are identified, such as word analogies (Yuan et al., 2023; Gladkova et al., 2016; Gao et al., 2014), proportional word analogies (Chen et al., 2022; Ushio et al., 2021; Szymanski, 2017; Drozd et al., 2016), sentence-analogies (Afantenos et al., 2021; Zhu and de Melo, 2020; Wang and Lepage, 2020) and more recently analogies of procedural/long text (Sultan and Shahaf, 2022). This work explicitly looks at sentence-level analogies which are sentence pairs that are analogues in meaning to each other <sup>1</sup>.

<sup>1</sup>For more details on sentence analogies please refer to (Wijesiriwardene et al., 2023)

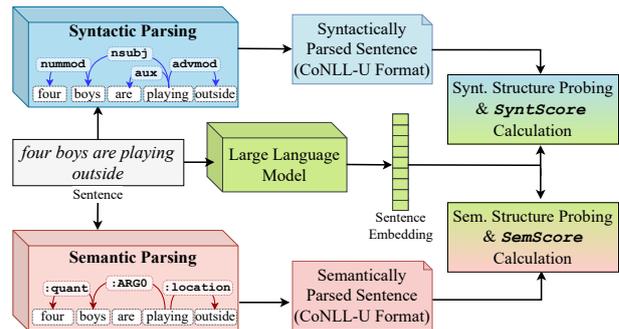

Figure 1: This pipeline details the process of quantifying the LLMs’ abilities to capture sentence structure via SyntScore and SemScore values for a given sentence. In this work, we apply this process to a dataset of 100K sentences. The dataset is divided into 0.8 for training the structure probe and 0.1 for testing.

Despite the existence of several established benchmarks (e.g., SuperGLUE (Wang et al., 2019a) and GLUE (Wang et al., 2018)) which evaluate the abilities of LLMs extrinsically, Wijesiriwardene et al. (2023) propose a more challenging intrinsic benchmark that focuses on LLMs’ ability to identify analogies across a range of complexities.

Identification of analogies relies on the utilization of implicit relational knowledge embedded within the relational structure of language (Gentner, 1983).

In this work we aim to explore the relationship between sentence analogy identification abilities and syntactic and semantic structure encoding abilities of LLMs<sup>2</sup>.

Specifically, our main contribution is an analysis of the relationship between the analogy identification ability and sentence structure encoding abilities of LLMs. Additionally, we extend the sentence structure probing techniques introduced by Hewitt and Manning (2019) (which only supports BERT and ELMo) to further work with encoder-decoder-based LLMs and LLMs that use two transformer

<sup>2</sup>Our code is available at: <https://github.com/Thiliniw/llms-synt-struct-sentence-analogies>

architectures. Finally, we extend the structure probing technique originally used for syntactic structure probing in the novel context of semantic structure probing.

## 2 Related Work

Assessing the ability of Neural Networks (NN) to encode syntactic and semantic structures of language is well examined in NLP (Nivre et al., 2007; Manning and Schütze, 1999; Parsing, 2009). Everaert et al. (2015) emphasize that the meaning of sentences is inferred by the hierarchical structures provided by syntactic and semantic properties of language.

Syntactic parsing aims to derive the syntactic dependencies in a sentence, such as subjects, objects, quantifiers, determiners and other similar elements. Early probing tasks (Adi et al., 2016; Shi et al., 2016) tried to identify NNs’ abilities to capture syntactic structures by classifying sentences with single and plural subjects. Later, Conneau et al. (2018) showed that NNs could capture the maximal parse tree depth. The structure probing technique used and extended in this work (Hewitt and Manning, 2019) is related but distinct due to its ability to implicitly capture the parse tree structures through simple distance measures between the vector representations of the words.

Compared to syntactic parsing, the NLP communities’ interest in semantic parsing is growing. Semantic parsing maps natural language sentences to a complete, formal meaning representation. Semantic parsing is achieved via combining the Semantic Role Labelling (SRL) approaches with syntactic dependency parsing (Hajic et al., 2009; Surdeanu et al., 2008) and more recently via semantic dependency parsing (Oepen et al., 2014, 2015). This work uses the semantic dependency parsing approach based on mean field variational inference (MFVI) augmented with character and lemma level embeddings introduced by Wang et al. (2019b).

## 3 Approach

Our approach to exploring the relationship between analogy identification and sentence structure encoding in LLMs is detailed in the following three subsections. We explain the dataset used, in Section 3.1, the analogy identification abilities of LLMs in Section 3.2 and the sentence structure encoding abilities of LLMs in Section 3.3.

Analogy Taxo. Level	Datasets	# Sentences
Level Three	Random deletion/masking/reorder	69,111
Level Four	Negation	1,245
Level Five	Entailment	29,644
<b>Total # Sentences</b>		<b>100,000</b>

Table 1: Dataset statistics.

### 3.1 Dataset

We experiment on a dataset of 100K English sentences. Specifically, the dataset used in this work is randomly picked from the sentence corpus of levels three, four and five of the analogy taxonomy introduced in (Wijesiriwardene et al., 2023). The composition of the dataset is presented in Table 1 (duplicates removed). Specifically, we obtain sentence-analogy pairs provided by Wijesiriwardene et al. (2023) and split the pairs to obtain single sentences used in this work.

### 3.2 Large Language Models and their Ability to Capture Sentence Analogies

We experiment on the eight language models used in a study by Wijesiriwardene et al. (2023) namely, BERT (Devlin et al., 2018), RoBERTa (Liu et al., 2019), ALBERT (Lan et al., 2019), LinkBERT (Yasunaga et al., 2022), SpanBERT (Joshi et al., 2020) and XLNet (Yang et al., 2019) which are encoder-based LLMs, T5 (Raffel et al., 2020), an encoder-decoder-based LLM and ELECTRA (Clark et al., 2020), an LLM based on two transformer architectures. We refer readers to cited publications for details on the specific LLMs.

Wijesiriwardene et al. (2023) introduced a taxonomy of analogies starting from less complex word-level analogies to more complex paragraph-level analogies and evaluated how each LLM performs on identifying analogies at each level of the taxonomy. An analogy is a pair of lexical items that are identified to hold a similar meaning to each other. Therefore the distance between a pair of analogous lexical items in the vector space should be smaller. The same authors identify Mahalanobis Distance (MD) (Mahalanobis, 1936) to be a better measurement of the distance between two analogous sentences in the vector space. Therefore in this work, the ability of each LLM to identify sentence analogies is represented by the mean MD calculated for the sentence-level datasets (levels 3, 4 and 5) present in the analogy taxonomy. These mean values are calculated based on the reported values by Wijesiriwardene et al. (2023).

### 3.3 Large Language Models and their Ability to Capture Sentence Structures

Hewitt and Manning (2019) introduced a probing approach to evaluate whether syntax trees (sentence structures) are encoded in Language Models’ (LMs’) vector geometry. The probing model is trained on train/dev/test splits of the Penn Treebank (Marcus et al., 1993) and tested on both BERT (Devlin et al., 2018) and ELMo (Peters et al., 2018). An LM’s ability to capture sentence structure is quantified by its ability to correctly encode the gold parse tree (provided in the Penn Treebank dataset) within its embeddings for a given sentence.

The authors introduce a path distance metric and a path depth metric for evaluation. The distance metric captures the path length between each pair of words measured by Undirected Unlabeled Attachment Score (UUAS) and average Spearman correlation of true to predicted distances (DSpr). The depth metric evaluates the model’s ability to identify a sentence’s root, measured as root accuracy percentage. Additionally, the depth metric also evaluates the ability of the model to recreate the word order based on their depth in the parse tree identified as Norm Spearman (NSpr).<sup>3</sup> We refer the readers to Hewitt and Manning (2019) for further details on the technique and evaluation metrics.

## 4 Experimental Setup

Exploring the relationship between analogy identification and sentence structure encoding abilities of LLMs requires a representative score to quantify (i) analogy identification ability (AnalogyScore), (ii) semantic structure identification ability (SemScore), and (iii) syntactic structure identification ability (SyntScore) of each LLM.

We obtain AnalogyScore by calculating the means of reported MD measures obtained for each sentence-level dataset in Wijesiriwardene et al. (2023).

To obtain the SemScore (see Figure 1), we first parse all the sentences in our dataset using the MFVI approach (Wang et al., 2019b). The resulting semantically parsed sentences (in CoNLL-U format)<sup>4</sup> and the LLM embeddings of the original sentences are then sent to the structure probing technique (Hewitt and Manning, 2019). The structure probe is trained on 80K sentences from the dataset and the DSpr and UUAS values representing parse

distance and root accuracy (RootAcc) value representing parse depth are reported on the test split with 10K sentences. Finally, the SemScore is computed as a combined score by taking the mean of the z-score normalizations of these three measures  $Z_{DSpr}$ ,  $Z_{UUAS}$ ,  $Z_{RootAcc}$  (see Table 2).

$$\text{SemScore} = \frac{1}{3}(Z_{DSpr} + Z_{UUAS} + Z_{RootAcc})$$

$$\text{SyntScore} = \frac{1}{3}(Z_{DSpr} + Z_{UUAS} + Z_{RootAcc})$$

To obtain the SyntScore (see Figure 1), we follow the same steps but parse the sentences syntactically. Finally, we calculate the Spearman’s rank correlation (SRC) and Kendall’s rank correlation (KRC) between AnalogyScore and SyntScore, as well as AnalogyScore and SemScore.

### 4.1 Implementation Details

When extending the structure probing technique by Hewitt and Manning (2019) to facilitate additional LLMs, we use the HuggingFace implementation<sup>5</sup> of the LLMs. For semantic parsing, we use the trained mean field variational inference (MFVI) model augmented with character and lemma-level embeddings provided by the SuPar<sup>6</sup>. For syntactic parsing of the sentences we employ Stanford CoNLL-U dependency parser<sup>7</sup>.

## 5 Results

In this section, we look at the findings of this work with regard to semantic and syntactic structure encoding abilities and analogy identification abilities of LLMs.

### 5.1 Semantic and Syntactic Structure Encoding Abilities of LLMs

We tabulate the structure probing results in original metrics (Table 2) and the performance of each LLM in identifying sentence analogies and capturing the semantic and syntactic structures (Table 3). It is interesting to note that RoBERTa, the best-performing LLM for analogy identification (AnalogyScore = 0.458), holds the highest SyntScore and SemScore. XLNet is the lowest-performing model for analogy identification as well as syntactic structure identification. Yet it performs second-best in semantic structure identification. SpanBERT ranks second in both analogy

<sup>3</sup>We do not use NSpr. in this work.

XLNet	0.747	8	-0.64	7	0.32	2

Table 3: The values for AnalogyScore, SyntScore and SemScore and their corresponding rank values. AnalogyScore ranges between [0,1], 0 being the best. For SyntScore and SemScore higher the values better the ability of LLMs to capture sentence structure.

identification and syntactic structure identification but holds the median SemScore.

## 5.2 Analogy Identification and Syntactic Structure Encoding Abilities of LLMs

We use SRC and KRC values to analyze the correlation between LLMs’ ability to identify sentence analogies denoted by AnalogyScore and LLMs’ ability to encode syntactic structures of sentences denoted by SyntScore. Both correlation measures show a significant positive correlation between AnalogyScore and SyntScore. Specifically, the SRC between AnalogyScore and SyntScore is 0.95 ( $p < 0.001$ ). The KRC between AnalogyScore and SyntScore is 0.86 ( $p = 0.002$ ).

## 5.3 Analogy Identification and Semantic Structure Encoding abilities of LLMs

Similar to the previous section, we compute the SRC and KRC values to assess the correlations between AnalogyScore and SemScore. We see that both correlations are positive with SRC of 0.33 ( $p = 0.42$ ) and KRC of 0.28 ( $p = 0.40$ ) between

AnalogyScore and SemScore.

## 6 Limitations

Several contemporary probing techniques, such as those outlined in Voita and Titov (2020) and Pimentel et al. (2020), have emerged subsequent to the methodology employed in the present investigation (Hewitt and Manning, 2019). Nevertheless, in the context of our current study, we have only chosen to employ (Hewitt and Manning, 2019) owing to its adaptable nature, which facilitates extension to various LLMs that are of particular interest to our current research.

Even though Abstract Meaning Representation (AMR) (Banarescu et al., 2013) is a popular and widely used technique to parse sentences semantically, in current work, we use MFVI, a semantic parsing approach introduced by Wang et al. (2019b) because of the limitations posed by the structure probing technique used (Hewitt and Manning, 2019). This technique requires the mapped LLM embeddings and semantic dependency parsed sentences to be of the same length. However, as it is known, AMRs abstract away from the syntactic idiosyncrasies of the language and overlook certain auxiliary words from the parse results, limiting its use in this work.

The present study employs a semantic parsing technique reported to exhibit a high accuracy level of 94% (Wang et al., 2019b). However, it is important to note that for the purposes of our investigation, we make the assumption that the semantically parsed sentences generated by this particular method are entirely accurate, thereby employing them as the gold standard data. It is worth mentioning that this choice may introduce some degree of bias into our examination of the semantic structure

probing.

## 7 Conclusion and Future Directions

This work explores the relationship between LLMs' ability to identify sentence analogies and encode sentence structures in their embeddings. Through detailed experiments, we show that the sentence analogy identification ability of LLMs is positively correlated with their ability to encode syntactic and semantic structures of sentences. Particularly, LLMs that better capture syntactic structures have a higher correlation to analogy identification. In summary this work explores how LLMs utilize the knowledge of semantic and syntactic structures of sentences to identify analogies. Moving forward, we aim to explore the potential of extending the current approach to enhance explainability of LLMs within the broader domain of NLP.

## Abstract

While textual information significantly enhances the performance of pre-trained language models (PLMs) in knowledge graph completion (KGC), the static and noisy nature of existing corpora collected from Wikipedia articles or synsets definitions often limits the potential of PLM-based KGC models. To surmount these challenges, we introduce the *Contextualization Distillation* strategy, a versatile plug-in-and-play approach compatible with both discriminative and generative KGC frameworks. Our method begins by instructing large language models (LLMs) to transform compact, structural triplets into context-rich segments. Subsequently, we introduce two tailored auxiliary tasks—reconstruction and contextualization—allowing smaller KGC models to assimilate insights from these enriched triplets. Comprehensive evaluations across diverse datasets and KGC techniques highlight the efficacy and adaptability of our approach, revealing consistent performance enhancements irrespective of underlying pipelines or architectures. Moreover, our analysis makes our method more explainable and provides insight into generating path selection, as well as the choosing of suitable distillation tasks. All the code and data in this work will be released at <https://github.com/David-Li0406/Contextulization-Distillation>

## 1 Introduction

Knowledge graph completion (KGC) is a fundamental task in natural language processing (NLP), aiming at unveiling hidden insights within diverse knowledge graphs to explore novel knowledge patterns. Traditional KGC methods (Nickel et al., 2011; Bordes et al., 2013) typically predict the missing part of the triplets by learning the representation of each entity and relation based on their structural information. However, such embedding-based methods tend to overlook the rich textual in-

Methods	H@1	H@3	H@8/10
ChatGPT-1-shot	15.6	17.6	19.6
PaLM2-1-shot	15.7	20.8	25.4
KG-S2S (Chen et al., 2022a)	<b>28.5</b>	<b>38.8</b>	<b>49.3</b>

Table 1: ChatGPT and PaLM2’s unsatisfactory performance on the test set of FB15k-237N compared to a smaller KGC model, KG-S2S (Chen et al., 2022a).

formation of the knowledge graph. Therefore, pre-trained language models (PLMs) have been introduced to KGC and achieved promising results (Kenton and Toutanova, 2019; Xie et al., 2022).

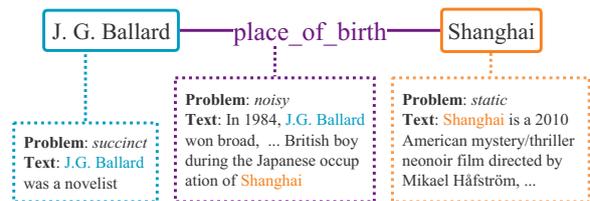

Figure 1: An example to illustrate the limitations of the current textual information for KGC.

While it has been well-discovered that textual information can be beneficial for PLM-based KGC models (Yao et al., 2019; Wang et al., 2021b; Chen et al., 2022a; Li et al., 2022; Chen et al., 2023a), prior attempts to augment KGC models with textual data from Wikipedia article (Zhong et al., 2015) or synsets definitions (Yao et al., 2019) have encountered certain limitations: (i) Entity descriptions, often succinct and static, may inhibit the formation of a comprehensive understanding of entities within KGC models. (ii) The incorporation of triplet descriptions, albeit potentially enriching, can introduce substantial noise, particularly when derived through automatic entity alignment (Sun et al., 2020). Figure 1 demonstrates an example to illustrate the aforementioned limitations. The description for the head “*J. G. Ballard*” is limited and for the tail “*Shanghai*”, it mistakenly uses the definition of the movie also named “*Shanghai*”.

Also, while the two entities show up in the triplet description, it falls short in conveying the semantic essence of the relation “*place\_of\_birth*”.

In light of these limitations, our attention shifts to Large Language Models (LLMs) (Brown et al., 2020; Zhang et al., 2022; Anil et al., 2023; Touvron et al., 2023), renowned for their capability in generating articulate and high-quality data (Dai et al., 2023; Shridhar et al., 2023; Zheng et al., 2023). Our exploration commences with a scrupulous evaluation of LLMs, such as ChatGPT and PaLM2, in KGC, benchmarking them across several esteemed KGC datasets (Dettmers et al., 2018; Garcia-Duran et al., 2018; Mahdisoltani et al., 2013). Utilizing 1-shot In-Context Learning (ICL), we deduce missing heads or tails in triplets and report evaluation metrics. It reveals a significant performance discrepancy of two LLMs in comparison to KG-S2S (Chen et al., 2022a) despite its reliance on a smaller foundational model, T5-base (Raffel et al., 2020). This insight propels us toward the conclusion that direct utilization of LLMs for KGC tasks, while intuitive, is outperformed by the fine-tuning of more diminutive, specialized KGC models. This observation aligns with findings from (Liang et al., 2022; Sun et al., 2023; Zhao et al., 2023), which highlighted the limitations of LLMs in knowledge-centric tasks. Experiment results and analysis on more KGC datasets can be found in Appendix A.

To optimally harness LLMs for KGC, we draw inspiration from recent works (Xiang et al., 2022; Kim et al., 2022a) and introduce a novel approach, *Contextualization Distillation*. Contextualization Distillation first extracts descriptive contexts from LLMs with well-designed prompts, thereby securing dynamic, high-quality context for each entity and triplet. Subsequent to this, two auxiliary tasks are proposed to train smaller KGC models with these informative, descriptive contexts. The plug-in-and-play characteristic of our contextualization distillation enables us to apply and evaluate it on various KGC datasets and baseline models. Through extensive experiments, we affirm that Contextualization Distillation consistently enhances the performance of smaller KGC models, irrespective of architectural and pipeline disparities. Additionally, we provide an exhaustive analysis of each step of Contextualization Distillation, encouraging further insights and elucidations.

The contributions of this work can be summarized into three main aspects:

- We identify the constraints of the current corpus for PLMs-based KGC models and introduce a plug-in-and-play approach, Contextualization Distillation, to enhance smaller KGC models with extracted rationale from LLMs.
- We conduct extensive experiments across several widely recognized KGC datasets and utilize various baseline models. Through these experiments, we validate the effectiveness of Contextualization Distillation in consistently improving smaller KGC models.
- We delve into a comprehensive analysis of our proposed method and provide valuable insights and guidance on generating path selection for distillation, as well as the selection of suitable distillation tasks.

## 2 Related Work

### 2.1 Knowledge Graph Completion

Traditional KGC methods (Nickel et al., 2011; Bordes et al., 2013) involve embedding entities and relations into a representation space. In pursuit of a more accurate depiction of entity-relation pairs, different representation spaces (Trouillon et al., 2016; Xiao et al., 2016) have been proposed considering various factors, e.g., differentiability and calculation possibility (Ji et al., 2021). During training, two primary objectives emerge to assign higher scores to true triplets than negative ones: 1) Translational distance methods gauge the plausibility of a fact by measuring the distance between the two entities under certain relations (Lin et al., 2015; Wang et al., 2014); 2) Semantic matching methods compute the latent semantics of entities and relations (Yang et al., 2015; Dettmers et al., 2018).

To better utilize the rich textual information of knowledge graphs, PLMs have been introduced in KGC. Yao et al. (2019) first propose to use BERT (Kenton and Toutanova, 2019) to encode the entity and relation’s name and adopt a binary classifier to predict the validity of given triplets. Following them, Wang et al. (2021a) leverage the Siamese network to encode the head-relation pair and tail in a triplet separately, aiming to reduce the time cost and make the inference scalable. Lv et al. (2022) convert each triple and its textual information into natural prompt sentences to fully inspire PLMs’ potential in the KGC task. Chen et al. (2023a) design a conditional soft prompts framework to maintain a balance between structural information and textual

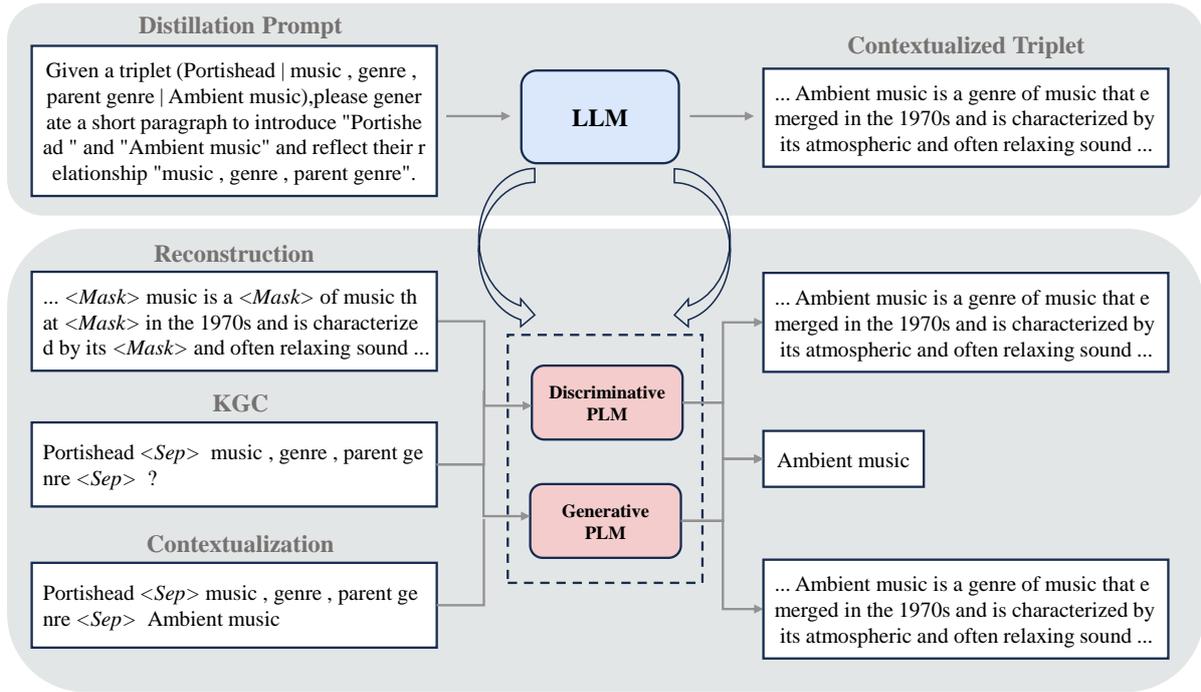

Figure 2: An overview pipeline of our Contextualization Distillation. We first extract descriptive contexts from LLMs (Section 3.1). Then, two auxiliary tasks, reconstruction (Section 3.3.1) and contextualization (Section 3.3.2) are designed to train the smaller KGC models with the contextualized information.

knowledge in KGC. Recently, there are also some works trying to leverage generative PLMs to perform KGC in a sequence-to-sequence manner and achieve promising results (Xie et al., 2022; Saxena et al., 2022; Chen et al., 2022a).

## 2.2 Distillation from LLMs

Knowledge distillation has proven to be an effective approach for transferring expertise from larger, highly competent teacher models to smaller, affordable student models (Buciluă et al., 2006; Hinton et al., 2015; Beyer et al., 2022). With the emergence of LLMs, a substantial body of research has concentrated on distilling valuable insights from these LLMs to enhance the capabilities of smaller PLMs. One of the most common methods is to prompt LLMs to explain their predictions and then use such rationales to distill their reasoning abilities into smaller models (Wang et al., 2022; Ho et al., 2022; Magister et al., 2022; Hsieh et al., 2023; Shridhar et al., 2023). Distilling conversations from LLMs is another cost-effective method to build new dialogue datasets (Kim et al., 2022b; Chen et al., 2023b; Kim et al., 2022a) or augment existing ones (Chen et al., 2022b; Zhou et al., 2022; Zheng et al., 2023). There are also some attempts (Marjeh et al., 2023; Zhang et al., 2023) that focus on

distilling domain-specific knowledge from LLMs for various downstream applications.

Several recent studies have validated the contextualization capability of LLMs to convert structural data into raw text. Among them, Xiang et al. (2022) convert triplets in the data-to-text generation dataset into their corresponding descriptions to facilitate disambiguation. Kim et al. (2022a) design a pipeline for synthesizing a dialogue dataset by distilling conversations from LLMs, enhanced with a social commonsense knowledge graph. By contrast, we are the first to leverage descriptive context generated by LLMs as an informative auxiliary corpus to the KGC models.

## 3 Contextualization Distillation

In this section, we first illustrate how we curate prompts to extract the descriptive context of each triplet from the LLM. Subsequently, we design a multi-task framework, together with two auxiliary tasks—reconstruction and contextualization—to train smaller KGC models with these high-quality context corpus. The overview pipeline of our method is illustrated in Figure 2.

<b>Input</b>	Given a triplet (Portishead   music , genre , parent genre   Ambient music), please generate a short paragraph to introduce "Portishead " and "Ambient music" and reflect their relationship "music , genre , parent genre".
<b>Output</b>	Portishead is a British trip hop band formed in Bristol in 1991. They are considered one of the pioneers of the genre, along with Massive Attack and Tricky. Ambient music is a genre of music that emerged in the 1970s and is characterized by its atmospheric and often relaxing sound. Portishead's music is often described as ambient, due to its use of loops, drones, and other sound effects.

Figure 3: An example contains our instruction to LLMs and the generated descriptive context. We use green to highlight entity description prompt/ generation result and blue to highlight triplet description prompt/ generation result.

### 3.1 Extract Descriptive Context from LLMs

Recent studies have highlighted the remarkable ability of LLMs to contextualize structural data and transform it into context-rich segments (Xiang et al., 2022; Kim et al., 2022a). Here we borrow their insights and extract descriptive context from LLMs to address the limitations of the existing KGC corpus we mentioned in Section 1.

In particular, we focus on two commonly employed types of descriptions prevalent in prior methodologies: entity description (ED) (Yao et al., 2019; Chen et al., 2022a) and triplet description (TD) (Sun et al., 2020). Entity description refers to the definition and description of individual entities, while triplet description refers to a textual segment that reflects the specific relationship between two entities within a triplet. Given triplets of a knowledge graph  $t_i \in T$ , we first curate prompt  $p_i$  for the  $i^{th}$  triplet by filling the pre-defined template:

$$p_i = \text{Template}(h_i, r_i, t_i), \quad (1)$$

where  $h_i, r_i, t_i$  are the head entity, relation, and tail entity of the  $i^{th}$  triplet. Then, we use  $p_i$  as the input to prompt the LLM to generate the descriptive context  $c_i$  for each triplet:

$$c_i = \text{LLM}(p_i), \quad (2)$$

### 3.2 Generating Path

Without loss of generalization, we consider different generating paths to instruct the LLMs to generate textual information and conduct an ablation study in Section 4.3. All the generating paths we adopt are as follows:

$T \rightarrow (ED, TD)$  generates both entity description and triplet description at one time. As Figure 3 shows, this is the context generating path we use in the main experiment.

$T \rightarrow ED$  curates prompt to instruct the LLM to generate the entity description only.

$T \rightarrow TD$  curates prompt to instruct the LLM to generate the triplet description only.

$T \rightarrow RA$  prompts the LLM to generate rationale rather than descriptive context.

$T \rightarrow ED \rightarrow TD$  produces entity description and triplet description in a two-step way. The final descriptive context is obtained by concatenating the two segments of text.

We also give further details and examples of our prompt in Appendix F.

### 3.3 Multi-task Learning with Descriptive Context

Different PLM-based KGC models adopt diverse loss functions and pipeline architectures (Yao et al., 2019; Chen et al., 2022a; Xie et al., 2022; Chen et al., 2023a). **To ensure the compatibility of our Contextualization Distillation to be applied in various PLM-based KGC methods**, we design a multi-task learning framework for these models to learn from both the KGC task and auxiliary descriptive context-based tasks. For the auxiliary tasks, we design *reconstruction* (Section 3.3.1) and *contextualization* (Section 3.3.2) for discriminative and generative KGC models respectively.

#### 3.3.1 Reconstruction

The reconstruction task aims to train the model to restore the corrupted descriptive contexts. For the discriminative KGC models, we follow the implementation of Kenton and Toutanova (2019) and use masked language modeling (MLM). Previous studies have validated that **such auxiliary self-supervised tasks in the domain-specific corpus can benefit downstream applications** (Han et al., 2021; Wang et al., 2021b).

To be specific, MLM randomly identifies 15% of the tokens within the descriptive context. Among these tokens, 80% are tactically concealed with the special token " $\langle Mask \rangle$ ", 10% are seamlessly substituted with random tokens, while the remaining 10% keep unchanged. For each selected token, the objective of MLM is to restore the original content at that particular position, achieved through the cross-entropy loss. The aforementioned process can be formally expressed as follows:

$$c'_i = \text{MLM}(c_i), \quad (3)$$

$$\mathcal{L}_{rec} = \frac{1}{N} \sum_{i=1}^N \ell(f(c'_i), c_i) \quad (4)$$

The final loss of discriminative KGC models is the combination of the KGC loss<sup>1</sup> and the proposed reconstruction loss:

$$\mathcal{L}_{dis} = \mathcal{L}_{kgc} + \alpha \cdot \mathcal{L}_{rec}, \quad (5)$$

where  $\alpha$  is a hyper-parameter to control the ratios between the two losses.

### 3.3.2 Contextualization

The objective of contextualization is to instruct the model in generating the descriptive context  $c_i$  when provided with the original triplet  $t_i = h, r, t$ . Compared with reconstruction, **contextualization demands a more nuanced and intricate ability from PLM**. It necessitates the PLM to precisely grasp the meaning of both entities involved and the inherent relationship that binds them together, to generate fluent and accurate descriptions.

Specifically, we concatenate head, relation and tail with a special token “< Sep >” as input:

$$I_i = \text{Con}(h_i, \langle \text{Sep} \rangle, r_i, \langle \text{Sep} \rangle, t_i) \quad (6)$$

Then, we input them into the generative PLM and train the model to generate descriptive context  $c_i$  using the cross-entropy loss:

$$\mathcal{L}_{con} = \frac{1}{N} \sum_{i=1}^N \ell(f(I_i), c_i) \quad (7)$$

The final loss of generative KGC models is the combination of the KGC loss<sup>2</sup> and the proposed contextualization loss:

$$\mathcal{L}_{gen} = \mathcal{L}_{kgc} + \alpha \cdot \mathcal{L}_{con} \quad (8)$$

For generative KGC models, it is also applicable to apply reconstruction as the auxiliary task. We have done an ablation study in Section 4.5 to examine the effectiveness of each auxiliary task on generative KGC models.

## 4 Experiment

In this section, we apply our Contextualization Distillation across a range of PLM-based KGC baselines. We compare our enhanced model with our approach against the vanilla models using several KGC datasets. Additionally, we do further analysis of each component in our contextualized distillation and make our method more explainable by conducting case studies.

<sup>1</sup>We give the illustration of the discriminative KGC models we used in Appendix B.1

<sup>2</sup>We give the illustration of the generative KGC models we used in Appendix B.2

## 4.1 Experimental Settings

**Datasets** We use WN18RR (Dettmers et al., 2018) and FB15k-237N (Lv et al., 2022) in our experiment. WN18RR serves as an enhanced version of its respective counterparts, WN18 (Bordes et al., 2013). The improvements involve the removal of all inverse relations to prevent potential data leakage. For FB15K-237N, it’s a refine version of FB15k (Bordes et al., 2013), by eliminating concatenated relations stemming from Freebase mediator nodes (Akrami et al., 2020) to avoid Cartesian production relation issues.

**Baselines** we adopt several PLM-based KGC models as baselines and apply the proposed Contextualization Distillation to them. **KG-BERT** (Yao et al., 2019) is the first to suggest utilizing PLMs for the KGC task. we also consider **CSProm-KG** (Chen et al., 2023a), which combines PLMs with traditional Knowledge Graph Embedding (KGE) models, achieving a balance between efficiency and performance in KGC. In addition to these discriminative models, we also harness generative KGC models. **GenKGC** (Xie et al., 2022) is the first to accomplish KGC in a sequence-to-sequence manner, with a fine-tuned BART (Lewis et al., 2020) as its backbone. Following them, **KG-S2S** (Chen et al., 2022a) adopt soft prompt tuning and lead to a new SOTA performance among the generative KGC models.

**Implementation details** All our experiments are conducted on a single GPU (RTX A6000), with CUDA version 11.1. We use PaLM2-540B (Anil et al., 2023) as the large language model to distill descriptive context. We tune the Contextualization Distillation hyper-parameter  $\alpha \in \{0.1, 0.5, 1.0\}$ . We follow the hyper-parameter settings in the original papers to reproduce each baseline’s result. For all datasets, we follow the previous works (Chen et al., 2022a, 2023a) and report Mean Reciprocal Rank (MRR), Hits@1, Hits@3 and Hits@10. More details about our experiment implementation and dataset statistics are shown in Appendix C.

## 4.2 Main Result

Table 2 displays the results of our experiments on WN18RR and FB15k-237N. We observe that our Contextualization Distillation consistently enhances the performance of all baseline methods, regardless of whether they are based on generative or discriminative models. This unwavering

improvement demonstrates **the robust generalization and compatibility of our approach across various PLMs-based KGC methods.**

Additionally, some baselines we choose to implement our Contextualization Distillation also utilize context information. For example, both KG-BERT and CSProm-KG adopt entity descriptions to enhance entity embedding representation. Nevertheless, our approach manages to deliver additional improvements to these context-based baselines. Among them, it is worth noting that the application of our approach to KG-BERT achieves an overall 31.7% enhancement in MRR. All these findings lead us to the conclusion that **Contextualization Distillation is not only compatible with context-based KGC models but also capable of further enhancing their performance.**

### 4.3 Ablation Study on Generating Path

We investigate the efficacy of different context types in the distillation process by employing various generative paths. As illustrated in Table 3, we initially explore the impact of entity description and triplet description when utilized separately as auxiliary corpora ( $T \rightarrow ED$  and  $T \rightarrow TD$ ). The experimental findings underscore the critical roles played by both entity description and triplet description as distillation corpora, leading to noticeable enhancements in the performance of smaller KGC models. Furthermore, we ascertain that

Paths	FN15k-237N		
	H@1	H@3	H@10
-	18.7	27.3	33.7
$T \rightarrow ED$	20.0	28.9	34.5
$T \rightarrow TD$	20.1	29.0	34.6
$T \rightarrow RA$	19.4	28.2	34.2
$T \rightarrow ED \rightarrow TD$	19.8	28.6	34.5
$T \rightarrow (ED, TD)$	<b>20.4</b>	<b>29.3</b>	<b>34.9</b>

Table 3: Ablation study results in GenKGC with different generating paths to distill corpus from LLMs. We conduct the experiment using FB15k-237N. We add the vanilla GenKGC in the first row for comparison.

our method’s generating path  $T \rightarrow (ED, TD)$ , which utilizes these two corpora, achieves more improvements by endowing the models with a more comprehensive and richer source of information.

To gain a comprehensive understanding of the effectiveness of our Contextualization Distillation, we also explored other alternative generative paths. While rationale distillation has demonstrated its potential in various NLP tasks (Hsieh et al., 2023; Shridhar et al., 2023), our investigation delves into the  $T \rightarrow RA$  path, wherein we instruct the LLM to generate rationales for each training sample. Although the model utilizing rationale distillation exhibits improved performance compared to the vanilla one, it falls short when compared with our Contextualization Distillation incorporating entity

descriptions and triplet descriptions. One plausible explanation for this disparity lies in the intrinsic nature of rationales, which tend to be intricate and structurally complex. This complexity can pose a greater challenge for smaller models to fully comprehend, in contrast to the more straightforward descriptive text utilized in our approach.

$T \rightarrow ED \rightarrow TD$  borrows the insight from Chain-of-CoT (CoT) (Wei et al., 2022) that generates the content step by step. Interestingly, our findings indicate that this multi-step generative path also yields suboptimal performance when compared to the single-step generative path. This discrepancy can be attributed to the text incoherence resulting from the concatenation of three segments of descriptions. In light of the insights gained from these observations, we summarize our distillation guidance for KGC as follows: **smaller models can benefit more from comprehensive, descriptive and coherent content generated by LLMs.**

#### 4.4 Ablation Study on Descriptive Context

	H@1	H@3	H@10
GenKGC	18.7	27.3	33.7
GenKGC			
w/ Contextualization	19.2	27.9	34.0
w/ Wikipedia			
GenKGC-CD	<b>20.4</b>	<b>29.3</b>	<b>34.9</b>

Table 4: Ablation study results in GenKGC with descriptive context generated by our method and collected by Zhong et al. (2015).

In this section, we replace the auxiliary corpus used in the auxiliary task with the Wikipedia corpus collected by (Zhong et al., 2015) to study the effectiveness of the distillation. As Table 4 shows, while the auxiliary task with Wikipedia corpus improves the model’s performance, the overall enhancement is not as significant as that brought by our Contextualization Distillation. This further demonstrates **the corpus generated by large language models effectively tackles the limitations of the preceding corpus for KGC, resulting in more pronounced improvements for the KGC model.**

#### 4.5 Ablation Study on Generative KGC Models

In this section, we compare the effectiveness of reconstruction and contextualization in generative

w/ Contextualization	-	<b>20.4</b>	<b>29.3</b>	<b>34.9</b>
KG-S2S	35.4	28.5	38.8	49.3
w/ Reconstruction	35.8	<b>29.3</b>	38.9	48.9
w/ Contextualization	<b>35.9</b>	28.9	<b>39.4</b>	<b>50.2</b>

Table 5: Ablation study results on GenKGC and KG-S2S with reconstruction and contextualization as the auxiliary task respectively. We conduct the experiment using FB15k-237N.

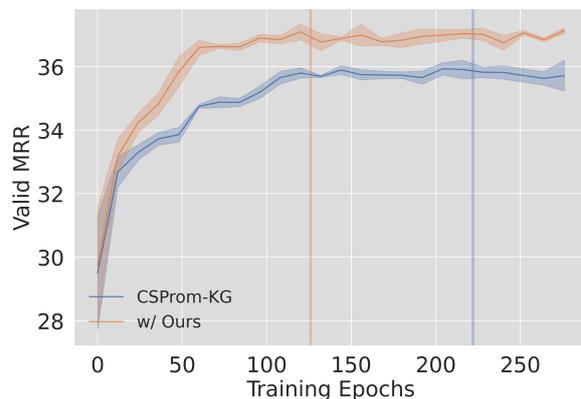

Figure 4: MRR scores on the validation set during the CSProm-KG training on FB15k-237N. We use thin bars to mark the epochs in which the models achieve the best performance in the validation set.

KGC models. For GenKGC and KG-S2S, we employ the pre-trained tasks of their respective backbone models (BART for GenKGC and T5 for KG-S2S) as the reconstruction objective. More details of our reconstruction implementation for generative KGC models can be found in Appendix D.

Table 5 presents the ablation study results on FB15k-237N. We find reconstruction is also effective in improving the performance of generative KGC models, showing that KGC models can consistently benefit from the descriptive context with different auxiliary tasks. Comparing the two auxiliary tasks, models with contextualization outperform those with reconstruction on almost every metric, except for Hits@1 in KG-S2S. This implies that **contextualization is a critical capability for generative KGC models to master for better KGC performance.** Generative models have benefited more from the training of converting structural triplets into descriptive context than simply restoring the corrupted corpus.

	from Wikipedia (Zhong et al., 2015)	Ours
Head	Ballard was a <b>novelist</b> .	J.G. Ballard (1930-2009) was an <b>English writer</b> . He was born in Shanghai, China, and his early experiences there shaped his writing. His novels often <b>explored themes of alienation, technology, and the future...</b>
Tail	Shanghai is a <b>2010 American mystery/thriller neo-noir film</b> directed by Mikael Håfström, starring John Cusack and Gong Li...	Shanghai is a <b>city in China</b> . It is one of the most populous cities in the world, and it is a major center of commerce and culture. Shanghai has a long history, and it has been <b>home to many different cultures over the centuries...</b>
Triplet	In 1984, J.G. Ballard <b>won broad, critical recognition</b> for the war novel Empire of the Sun, a <b>semi-autobiographical</b> story of the experiences of a British boy during the Japanese <b>occupation of Shanghai</b> .	Ballard <b>was born in</b> Shanghai in 1930. He lived there until he was eight years old, when his family moved to England. Ballard’s <b>early experiences</b> in Shanghai had a profound impact on his writing...

Table 6: Descriptive context of the triplet (*J.G. Ballard, place\_of\_birth, Shanghai*). The text in **green** represents positive content and the text in **red** represents negative content.

#### 4.6 Efficiency Analysis

The additional training cost brought by the auxiliary distillation tasks may pose a potential constraint on our approach. However, we also notice baseline models with our method coverage faster on the validation set. Figure 4 presents the validation MRR vs epoch numbers during the CSProm-KG training on FB15k-237N. It is obvious that CSProm-KG with Contextualization Distillation achieves a faster convergence and attains the best checkpoint earlier (at around 125 epochs) compared to the variant without our method (at around 220 epochs). This implies **auxiliary distillation loss can also expedite model learning in KGC**. This trade-off between batch processing time and training steps ultimately results in a training efficiency comparable to that of the vanilla models.

#### 4.7 Case Study

We conduct a comparative analysis between the description corpus collected from Wikipedia (Zhong et al., 2015) and those generated using our method to show the advantage of our Contextualization Distillation more straightforwardly. As presented in Table 6, entity descriptions generated by the LLM effectively address the limitations issue and static shortcomings, resulting in more informative and accurate content. Regarding the triplet description, although the “semi-autobiographical” used in Zhong et al. (2015) somewhat implies

Query	<i>(The Devil’s Double, genre, ?)</i>
Ground Truth	<i>Biographical film</i>
Baseline	<i>War film</i>
Ours	<i>Biographical film</i>
Our Context	The Devil’s Double is a <b>biographical film</b> that tells the story of Latif Yahia, a <b>young Iraqi man who was forced to impersonate Saddam Hussein’s son Uday Hussein...</b>

Table 7: Case study on FB15K-237N with KG-S2S. we also let the model generate a descriptive context for each test sample. The text in **bold** represents informative content in the generated descriptive context.

J.G. Ballard’s connection to Shanghai during his childhood, it still fails to express the semantics of “*place\_of\_birth*” clearly. In contrast, the descriptive context generated by our method provides a more elaborate and coherent contextualization of the “*place\_of\_birth*” between “*J.G. Ballard*” and “*Shanghai*”. These comparisons highlight the effectiveness of our method in addressing the previous corpus’ limitation.

Furthermore, We showcase how the auxiliary training with descriptive context enhances the baseline models. Table 7 presents the results of KG-S2S performance in a test sample of FB15k-237N, both with and without our contextualization distil-

lation. In this case, the vanilla KG-S2S wrongly predicts the genre of the film “*The Devil’s Double*” as “*War film*”, whereas the KG-S2S trained with our auxiliary task correctly labels it as “*Biographical film*”. Also, by making the model contextualize each triplet, we find the model with our method applied successfully captures many details about the movie, such as the genre and plot, and presents this information as fluent text. In summary, **the model not only acquires valuable insights about the triplets but also gains the ability to adeptly contextualize this information through our Contextualization Distillation.**

Due to the space limitation, we put further analysis about LLMs’ sizes in Appendix E.

## 5 Conclusion

In this work, we propose Contextualization Distillation, addressing the limitation of the existing KGC textual data by prompting LLMs to generate descriptive context. To ensure the versatility of our approach across various PLM-based KGC models, we have designed a multi-task learning framework. Within this framework, we incorporate two auxiliary tasks, reconstruction and contextualization, which aid in training smaller KGC models in the informative descriptive context. We conduct experiments on several mainstream KGC benchmarks and the results show that our Contextualization Distillation consistently enhances the baseline model’s performance. Furthermore, we conduct in-depth analyses to make the effect of our method more explainable, providing guidance on how to effectively leverage LLMs to improve KGC as well. In the future, we plan to adapt our method to other knowledge-driven tasks, such as entity linking and knowledge graph question answering.

## 6 Limitation

Due to limitations in computing resources, we evaluate our method on two KGC datasets, while disregarding scenarios such as temporal knowledge graph completion (Garcia-Duran et al., 2018), few-shot knowledge graph completion (Xiong et al., 2018) and commonsense knowledge graph completion (Li et al., 2022). In future research, we plan to investigate the effectiveness of our method in border scenarios.

## A Large Language Model Performance on KGC

We follow [Zhu et al. \(2023\)](#) to assess the performance of directly instructing LLMs to perform KGC and Table 8 gives an example of our input to LLMs. For PaLM, we utilize the API parameter “candidate\_count”, while for ChatGPT, we use “n” to obtain multiple candidates, enabling the calculation of Hit@1, Hit@3, and Hit@10 metrics. After obtaining the model’s outputs, we use the Sentence-BERT ([Reimers and Gurevych, 2019](#)) to guarantee each output result matches a corresponding entity in the dataset’s entity set.

Table 9 displays the additional experimental results for ChatGPT and PaLM2 across several KGC datasets. Although LLMs demonstrate promising performance in a series of NLP tasks [Liang et al. \(2022\)](#); [Yang et al. \(2023\)](#); ? with various reasoning strategies [Wei et al. \(2022\)](#); ?); ?); ?, they present a surprisingly poor performance in KGC with ICL. It is evident that the performance of ICL of LLM falls short of KG-S2S’s in every dataset. One potential explanation for this subpar performance can be attributed to the phenomenon of hallucination in LLMs ([Ji et al., 2023](#); [Yang et al., 2023](#)), leading to incorrect responses when the LLM encounters unfamiliar content. Additionally, ? exposes the ICL of LLMs’ limitation in learning a domain-specific entity across the whole dataset, which provides another perspective to explain ICL’s poor performance in KGC.

We also conducted an analysis of the influence of the number of demonstration samples. As Table 10 shows, we find while the number of demonstrations increases, the performance of LLMs shows a corresponding improvement. It appears that augmenting the number of demonstrations in the prompt could be a potential strategy for enhancing the capabilities of LLMs in KGC. Nonetheless, it’s essential to note that incorporating an excessive number of relevant samples as demonstrations faces practical challenges, primarily due to constraints related to input length and efficiency considerations.

Triplet	<i>(Stan Collymore, play_for, England national football team)</i>
Tail Prompt	Predict the tail entity [MASK] from the given (Keko (footballer, born 1973), plays for, [MASK]) by completing the sentence "what is the plays for of Keko (footballer, born 1973)? The answer is ". The answer is UE Figueres, so the [MASK] is UE Figueres. Predict the tail entity [MASK] from the given (Stan Collymore, plays for, [MASK]) by completing the sentence "what is the plays for of Stan Collymore? The answer is ". The answer is
Head Prompt	Predict the head entity [MASK] from the given ([MASK], plays for, UE Figueres) by completing the sentence "UE Figueres is the plays for of what? The answer is ". The answer is Keko (footballer, born 1973), so the [MASK] is Keko (footballer, born 1973). Predict the head entity [MASK] from the given ([MASK], plays for, England national football team) by completing the sentence "England national football team is the plays for of what? The answer is ". The answer is

## B Details of Various KGC Pipelines

### B.1 Discriminative KGC Pipelines

KG-BERT (Yao et al., 2019) is the first to propose utilizing PLMs for triplet modeling. It employs a special “[CLS]” token as the first token in input sequences. The head entity, relation, and tail entity are represented as separate sentences, with segments separated by [SEP] tokens. The input token representations are constructed by combining token, segment, and position embeddings. Tokens in the head and tail entity sentences share the same segment embedding, while the relation sentence has a different one. The input is fed into a BERT model, and the final hidden vector of the “[CLS]” token is used to compute triple scores. The scoring function for a triple (h, r, t) is calculated as  $s = f(h, r, t) = \text{sigmoid}(CWT)$ , where  $s$  is a 2-dimensional real vector  $s_{\tau_0}, s_{\tau_1} \in [0, 1]$  and  $CWT$  is the embedding of the “[CLS]” token. Cross-entropy loss is computed using the triple labels and scores for positive and negative triple sets:

$$\mathcal{L}_{kgc} = \sum_{\tau \in D^+ + D^-} (y_{\tau} \log(s_{\tau_0}) + (1 - y_{\tau}) \log(s_{\tau_1})), \quad (9)$$

where  $y_{\tau} \in \{0, 1\}$  is the label of that triplet. The negative triplet  $D^-$  is simply generated by replacing the head entity  $h$  or tail entity  $t$  in the original triplet  $(h, r, t) \in D^+$ .

CSProm-KG (Chen et al., 2023a) combines PLM and traditional KGC models together to utilize both textual and structural information. It first concatenates the entity description and relation description behind a sequence of conditional soft prompts as the input. The input is then fed into a PLM, denoted as  $P$ , where the model parameters are held constant. Subsequently, CSProm-KG extracts embeddings from the soft prompts, which serve as the representations for entities and relations. These representations are then supplied as input to another graph-based KGC model, labeled as  $G$ , to perform the final predictions. It also introduces a local adversarial regularization (LAR) method to enable the PLM  $P$  to distinguish the true entities from  $n$  textually similar entities  $t^l$ :

$$\mathcal{L}_l = \max(f(h, r, t), -\frac{1}{n} \sum_{i \in n} f(h, r, t_i^l) + \gamma, 0), \quad (10)$$

where  $\gamma$  is the margin hyper-parameter. Finally, CSProm-KG utilizes the standard cross entropy loss with label smoothing and LAR to optimize the whole pipeline:

$$\mathcal{L}_c = -(1 - \phi) \cdot \log p(t|h, r) - \frac{\phi}{|V|} \sum_{t' \in V/t} \log p(t' | h, r), \quad (11)$$

$$\mathcal{L}_{kgc} = \mathcal{L}_c + \beta \cdot \mathcal{L}_l, \quad (12)$$

where  $\phi$  is the label smoothing value and  $\beta$  is the LAR term weight.

### B.2 Generative KGC Pipelines

In GenKGC (Xie et al., 2022), entities and relations are represented as sequences of tokens, rather than unique embeddings, to connect with pre-trained language models. For the triples  $(e_i, r_j, e_k)$  with the tail entity  $e_k$  missing, descriptions of  $e_i$  and  $r_j$  are concatenated to form the input sequence, which is then used to generate the output sequence. BART is employed for model training and inference, and a relation-guided

demonstration approach is proposed for encoder training. This method leverages the fact that knowledge graphs often exhibit long-tailed distributions and constructs demonstration examples guided by the relation  $r_j$ . The final input sequence format is defined as:  $x = [< BOS >, demonstration(r_j), < SEP >, d_{e_i}, dr_j, < SEP >]$ , where  $d_{e_i}$  and  $dr_j$  are description of the head entity and relation respectively. And  $demonstration(r_j)$  means the demonstration examples with the relation  $r_j$ . Given the input, the target of GenKGC in the decoding stage is to correctly generate the missing entity  $y$ , which can be formulated as:

$$\mathcal{L}_{kgc} = -\log p(e_K|x) \quad (13)$$

Additionally, an entity-aware hierarchical decoding strategy has been proposed to improve the time efficiency.

Following them, KG-S2S (Chen et al., 2022a) adds the entity description in both the encoder and decoder ends, training the model to generate both the missing entity and its corresponding description. It also maintains a soft prompt embedding for each relation to facilitate the model to distinguish the relations with similar surface meanings. Given the query  $(e_i, r_j, e_k)$ , the input  $x$  and the label  $y$  to predict the tail entity  $e_k$  can be expressed as:

$$x = [< BOS >, P_{e1}, e_i, des_{e_i}, P_{e1}, < SEP >, P_{r1}, r_j, P_{r2}], \quad (14)$$

$$y = [< BOS > e_k, des_{e_k}], \quad (15)$$

where  $des_e$  represents the entity description and  $P$  here is the soft prompt embedding for entities or relations. Additionally, it adopts a sequence-to-sequence dropout strategy by randomly masking some content in the entity description to avoid model overfitting in the training stage:

$$x = RandomMask(x), \quad (16)$$

and the total loss can be expressed as:

$$\mathcal{L}_{kgc} = -\log p(y|x) \quad (17)$$

## C Additional Implementation Details

We show the detailed statistics of the KGC datasets we use in Table 11. Table 12 displays the hyper-parameters we adopt for each baseline model and dataset.

Dataset	# Entity	# Relation	# Train	# Valid	# Test
WN18RR	40,943	11	86,835	3,034	3,134
FB15k-237N	14,541	93	87,282	7,041	8,226

Table 11: Statistics of the Datasets.

model	dataset	batch size	learning rate	epoch	$\alpha$

## D Implementation Details of Reconstruction for Generative KGC Models

In the case of GenKGC, we adhere to the denoising pre-training methodology used in BART (Lewis et al., 2020). This approach commences by implementing a range of text corruption techniques, such as token masking, sentence permutation, document rotation, token deletion, and text infilling, to shuffle the integrity of the initial text. The primary objective of BART’s reconstruction task is to restore the original corpus from the corrupted text.

For KG-S2S, we follow the pre-training approach proposed by T5 (Raffel et al., 2020). This approach employs a BERT-style training objective and extends the concept of single token masking to encompass the replacement of text spans. In this process, we apply a 15% corruption ratio for each segment, randomly substituting a span of text with a designated special token “<extra\_id>”. Here we employ a span length of 3. The ultimate goal of T5’s reconstruction task is to accurately predict the content associated with these special tokens.

## E Analysis on LLMs’ Sizes

We conduct further analysis to validate the compatibility of our Contextualization Distillation with distillation models in various sizes. We choose 3 smaller language models, GPT2, T5-base and T5-3B, each possessing comparable parameter counts to the KGC models we use (T5-base, BERT-base and BART-base). Additionally, we incorporated a larger language model, vicuna-7B, into our analysis. As the first step, we follow the method in Section 3.1 and instruct all these models to generate descriptive contexts for the triplet “(J.G. Ballard| people, person, place\_of\_birth | Shanghai)”.

Model	Output
GPT2-base	relationship "people, person, place_of_birth". Please generate a paragraph to introduce "J.G.
T5-base	The first paragraph should be a single sentence, with the following:\n\n"I am a person, person, place_of_birth.
T5-3B	, person, place_of_birth   Shanghai) Contextualize: (J.G. Ballard
Vicuna-7B	J.G. Ballard was a British novelist, short king, and essayist, best known for his dystopian and post-apocalyptic fiction...
PaLM2-540B	J.G. Ballard (1930-2009) was an English writer. He was born in Shanghai, China, and his...

Table 13: Different models’ contextualization output for the given triplet.

As shown in Table 13, our observations reveal that the results produced by the three smaller language models (GPT-2, T5-base, and T5-3B) are subpar and irrelevant, indicating their incapacity to adhere to contextualization instructions effectively. By contrast, the context generated by Vicuna-7B is both fluent and informative, providing an accurate textual description of the entire triplet. So we conclude our first findings: **smaller language models, lacking the requisite capability to fully comprehend contextualization instructions and abstract triplets, are unsuitable as teacher models for our Contextualization Distillation.**

In the second step, we aim to investigate whether the context generated by smaller large language models would be beneficial for the KGC model. We follow exactly our method described in Section 3 and replace the PaLM2 with Vicuna-7B. We conducted an experiment in the FB15k-237N dataset with GenKGC as the KGC backbone model.

As depicted in Table 14, our Contextualization Distillation with Vicuna-7B remains effective in enhancing the KGC model, albeit not to the extent observed with CD utilizing PaLM2. This leads us to the conclusion that **Contextualization Distillation is also compatible with large language models with fewer parameters, even as small as 7B in size.** In the future, we will continue to explore the impact of different language model sizes (such as 13B and 30B) on our method.

	H@1	H@3	H@10
GenKGC	18.7	27.3	33.7
GenKGC-CD w/ Vicuna-7B	19.9	28.6	34.6
GenKGC-CD w/ PaLM2-540B	<b>20.4</b>	<b>29.3</b>	<b>34.9</b>

Table 14: Comparison between our method using Vicuna-7B and PaLM2-540B.

## F Additional Case Study

In this section, we provide detailed examples to illustrate the input and output of each generating path we adopt in the descriptive context/ rationale extraction stage. We present examples in Table 15, 16, 17, 18, 19.

Triplet	(J.G. Ballard, place_of_birth, Shanghai)
Prompt	Given a triplet (J.G. Ballard  people, person, place_of_birth   Shanghai), please generate a paragraph to introduce "J.G. Ballard" and "Shanghai" and reflect their relationship "people, person, place_of_birth".
Output	J.G. Ballard (1930-2009) was an English writer. He was born in Shanghai, China, and his early experiences there shaped his writing. His novels often explored themes of alienation, technology, and the future. Ballard's work has been praised for its originality and its insights into modern society. He is considered one of the most important writers of the 20th century. Shanghai is a city in China. It is one of the most populous cities in the world, and it is a major center of commerce and culture. Shanghai has a long history, and it has been home to many different cultures over the centuries. The city is known for its skyscrapers, its nightlife, and its vibrant atmosphere. J.G. Ballard was born in Shanghai in 1930. He lived there until he was eight years old, when his family moved to England. Ballard's early experiences in Shanghai had a profound impact on his writing. His novels often explore themes of alienation, technology, and the future. Ballard's work has been praised for its originality and its insights into modern society. He is considered one of the most important writers of the 20th century.

Table 15: Descriptive context obtained from the generating path  $T \rightarrow (ED, TD)$ .

Triplet	(J.G. Ballard, place_of_birth, Shanghai)
Prompt	Given a triplet (J.G. Ballard   people, person, place_of_birth   Shanghai), please generate a short paragraph to introduce "J.G. Ballard" and "people, person, place_of_birth". "J.G. Ballard" and "people, person, place_of_birth" must be concluded in the generated text.
Output	J.G. Ballard (1930-2009) was a British novelist, short story writer, and essayist. Born in Shanghai, China, he was raised there until the age of eight, when his family returned to England. Ballard's early experiences in China had a profound impact on his writing, and many of his novels and stories explore themes of alienation, isolation, and dystopia. He is considered one of the most important science fiction writers of the 20th century.

Table 16: Descriptive context obtained from the generating path  $T \rightarrow ED$ .

Triplet	(J.G. Ballard, place_of_birth, Shanghai)
Prompt	Given a triplet (J.G. Ballard   people, person, place_of_birth   J.G. Ballard), please generate a paragraph to reflect their relationship people, person, place_of_birth. "J.G. Ballard" and "Shanghai" must concluded in the generated text.
Output	J.G. Ballard was born in Shanghai, China on November 15, 1930. He was a British writer, best known for his science fiction novels and short stories. His work often explored themes of alienation, technology, and the human condition. Ballard's books have been translated into more than 30 languages and have sold over 15 million copies worldwide. He died in London on April 19, 2009.

Table 17: Descriptive context obtained from the generating path  $T \rightarrow TD$ .

Triplet	(J.G. Ballard, place_of_birth, Shanghai)
Prompt-Head	Given a triplet (J.G. Ballard   people, person, place_of_birth   Shanghai), please generate a short paragraph to introduce "J.G. Ballard"
Prompt-Tail	Given a triplet (J.G. Ballard   people, person, place_of_birth   Shanghai), please generate a short paragraph to introduce "Shanghai"
Prompt-Triplet	Given a triplet (J.G. Ballard   people, person, place_of_birth   Shanghai) and the description of the two entities J.G. Ballard: <Output-Head>Shanghai: <Output-Tail>please generate a short paragraph to reflect their relationship people, person, place_of_birth. "J.G. Ballard" and "Shanghai" must be concluded in the generated text.
Output-Head	J. G. Ballard was born in Shanghai and is a British writer. He is best known for his novels about science fiction and post-apocalyptic fiction. Some of his most famous works include "The Drowned World", "The Crystal World", and "Empire of the Sun".
Output-Tail	Shanghai is a metropolis on the east coast of China. It is the largest city in China and one of the most populous cities in the world. Shanghai is a major economic and cultural center, and is home to many skyscrapers and other landmarks. The city is also known for its nightlife and its vibrant street life. J.G. Ballard, the author of "Empire of the Sun", was born in Shanghai in 1930.
Output-Triplet	J. G. Ballard was born in Shanghai, China in 1930. He is a British writer best known for his novels about science fiction and post-apocalyptic fiction. Some of his most famous works include "The Drowned World", "The Crystal World", and "Empire of the Sun".

Table 18: Descriptive context obtained from the generating path  $T \rightarrow ED \rightarrow TD$ . <Output-Tail> and <Output-head> refer to the tail description and head description generated by the LLM in previous steps.

Triplet	(J.G. Ballard, place_of_birth, Shanghai)
Prompt-Tail	Given a triplet (J.G. Ballard   people, person, place_of_birth   [MASK]), please generate rationale to explain why [MASK] should be Shanghai
Prompt-Head	Given a triplet ([MASK]   people, person, place_of_birth   J.G. Ballard), please generate rationale at least 100 words to explain why [MASK] should be J.G. Ballard
Output-Tail	The rationale for [MASK] should be Shanghai is that:1. J.G. Ballard was born in Shanghai, China.2. Ballard’s father was a British engineer who worked in China.3. Ballard spent his early childhood in Shanghai.4. Ballard’s experiences in Shanghai influenced his writing.5. Ballard’s novels and short stories often feature themes of alienation, isolation, and dystopia.6. Ballard’s work has been praised for its originality, its insights into human nature, and its depiction of the future.In conclusion, the rationale for [MASK] should be Shanghai is that Ballard was born and raised there, and his experiences in Shanghai shaped his writing.
Output-Head	J.G. Ballard was born in Shanghai on 15 November 1930. His father was a British businessman and his mother was a Chinese woman. Ballard lived in Shanghai until the Japanese invasion in 1937, when he and his family were evacuated to England. Ballard’s experiences in Shanghai during the war had a profound impact on his writing, and many of his novels are set in dystopian cities that are reminiscent of Shanghai. Ballard’s work is often characterized by its bleak vision of the future, but it also contains a strong element of hope. Ballard believed that the future could be a place of beauty and wonder, but only if we are willing to confront the challenges that we face.

## Abstract

Recent developments in deep learning have led to great success in various natural language processing (NLP) tasks. However, these applications may involve data that contain sensitive information. Therefore, how to achieve good performance while also protecting the privacy of sensitive data is a crucial challenge in NLP. To preserve privacy, Differential Privacy (DP), which can prevent reconstruction attacks and protect against potential side knowledge, is becoming a de facto technique for private data analysis. In recent years, NLP in DP models (DP-NLP) has been studied from different perspectives, which deserves a comprehensive review. In this paper, we provide the first systematic review of recent advances in DP deep learning models in NLP. In particular, we first discuss some differences and additional challenges of DP-NLP compared with the standard DP deep learning. Then, we investigate some existing work on DP-NLP and present its recent developments from three aspects: gradient perturbation based methods, embedding vector perturbation based methods, and ensemble model based methods. We also discuss some challenges and future directions.

## 1 Introduction

The recent advances in deep neural networks have led to significant success in various tasks in Natural Language Processing (NLP), such as sentiment analysis, question answering, information retrieval, and text generation. However, such applications always involve data that contains sensitive information. For example, a model of aid typing on a keyboard which trained from language data might contain sensitive information such as passwords, text messages, and search queries. Moreover, language data can also identify a speaker explicitly by name or implicitly, for example, via a rare or unique phrase. Thus, one often encountered challenge in NLP is how to handle this sensitive information. To

overcome the challenge, privacy-preserving NLP has been intensively studied in recent years. One of the commonly used approaches is based on text anonymization (Pilán et al., 2022), which identifies sensitive attributes and then replaces these sensitive words with some other values. Another approach is injecting additional words into the original text without detecting sensitive entities in order to achieve text redaction (Sánchez and Batet, 2016). However, removing personally identifiable information or injecting additional words is often unsatisfactory, as it has been shown that an adversary can still infer an individual’s membership in the dataset with high probability via the summary statistics on the datasets (Narayanan and Shmatikov, 2008). Moreover, recent studies claim that deep neural networks for NLP tasks often tend to memorize their training data, which makes them vulnerable to leaking information about training data (Shokri et al., 2017; Carlini et al., 2021, 2019). One way that takes into account the limitations of existing approaches by preventing individual re-identification and protecting against any potential data reconstruction and side-knowledge attacks is designing Differentially Private (DP) algorithms. DP (Dwork et al., 2006) provides provable protection against identification and is resilient to arbitrary auxiliary information that might be available to attackers. Thanks to its formal guarantees, DP has become a de facto standard tool for private statistical data analysis.

Although there are numerous studies on DP machine learning and DP deep learning, such as (Abadi et al., 2016; Bu et al., 2019; Yu et al., 2019; Xiang et al., 2023; Xiao et al., 2023; Hu et al., 2023a,b), most of them mainly focus on either the continuous tabular data or image data, and less attention has been paid to adapting variants of DP algorithms to the context of NLP and the text domain. On the other side, while there are several surveys on DP and its applications, such as (Ji et al.,

2014; Dankar and Emam, 2013; Xiong et al., 2020; Wang et al., 2020b; Desfontaines and Pejó, 2020), none of them study its applications to the NLP domain. Recently, Klymenko et al. (2022) gave a brief introduction to applications of DP in NLP, but the reviewed work is not exhaustive, and it lacks a technical and systematic view of DP-NLP. Thus, to fill in this gap, in this paper, we provide the first technical overview of the recent developments and challenges of DP in language models.

Specifically, we give a survey on the most recent 70<sup>1</sup> papers on deep learning based approaches for NLP tasks under DP constraints. First, we show some specificities of DP-NLP compared with the general deep learning with DP. Then we discuss current results from three perspectives via the ways of adding randomness to ensure DP: the first one is gradient perturbation based methods which includes DP-SGD and DP-Adam; the second one is embedding vector perturbation based methods which includes DP auto-encoder; the last one is ensemble model based methods which includes PATE. For each type of approach, we also consider its applications to different NLP tasks. Finally, we present some potential challenges and future directions.

Due to space limits, in Appendix C, we give a preliminary introduction to DP to readers who are unfamiliar with DP.

## 2 Specificities of NLP with DP

We first discuss some specificities for DP-NLP compared with the standard DP deep learning. Generally speaking, there are two aspects: one is privacy notations, and another is privacy levels.

### 2.1 Variants of DP Notions in NLP

Recall that DP ensures data analysts or adversaries will get almost the same information if we change any single data sample in the training data, i.e., it treats all records as sensitive. However, such an assumption is quite stringent. On the one side, unlike image data, for text data, it is more common that only several instead of all attributes need to be protected. For example, for the sentence "My cell phone number is 1234567890", only the last token with the actual cell phone number needs to be protected. On the other side, canonical DP requires

that the log of the ratio between the distribution probabilities is always upper bounded by the privacy parameter  $\epsilon$  for any pair of neighboring data. However, such a requirement is also quite restrictive. For example, for the sentence "I will arrive at 2:00 pm", we want the adversary not to distinguish it from the sentence "I will arrive at 4:00 pm". However, DP also can ensure the adversary cannot distinguish it from the sentence "I will arrive at 100:00 pm", which is meaningless. Thus, for language data, besides the canonical DP, it is also reasonable to study its relaxations for some specific scenarios. Actually, this is quite different from the existing work on DP deep learning, which mainly focuses on standard DP definitions. In the following, we will discuss some commonly used relaxations of DP for language models.

**SDP.** As we mentioned above, in some scenarios, the sensitive information in text data is sparse, and we only need to protect some sensitive attributes instead of the whole sentence. Based on this, Shi et al. (2021) propose a new privacy notion, namely selective differential privacy (SDP), to provide privacy guarantees on the sensitive portion of the data to improve model utility. From the definition aspect, the main difference between SDP and DP is the definition of neighboring datasets. Informally, in SDP, two datasets are adjacent if they differ in at least one sensitive attribute. However, it is hard to define such neighboring datasets directly as there are some correlations between sensitive and non-sensitive attributes, indicating that we can still infer information on sensitive attributes (Kifer and Machanavajhala, 2011). To address the issue, Shi et al. (2021) leverage the Pufferfish framework in (Kifer and Machanavajhala, 2014).

**Metric DP.** To relax the requirement that the log probability ratio is uniformly bounded by  $\epsilon$  for all neighboring data pairs, Feyisetan et al. (2020) first adopt the Metric DP (or  $d_\chi$ -privacy) to the problem of private embedding, which is proposed by (Chatzikokolakis et al., 2013) for location data originally. In particular, a Metric DP mechanism could report a token in a privacy-preserving manner while giving a higher probability to tokens that are close to the current token, and a negligible probability to tokens in a completely different part of the vocabulary, where we will use some distance function  $d$  to measure the distance between two tokens.

<sup>1</sup>Note that we did not cover all related works, see the Limitations and Future Directions sections for the works that are not included in this paper.

**Definition 1.** For a data domain (vocabulary)  $\mathcal{X}$ , a randomized algorithm  $\mathcal{A} : \mathcal{X} \mapsto \mathcal{R}$  is called  $(\varepsilon, \delta)$ -Metric DP with distance function  $d$  if for any  $S, S' \in \mathcal{X}^l$  and  $T \subseteq \mathcal{R}$  we have

$$\Pr[\mathcal{A}(S) \in T] \leq e^{d(S,S')\varepsilon} \Pr[\mathcal{A}(S') \in T] + \delta.$$

From the above definition, we can see the probability ratio of observing any particular output  $y$  given two possible inputs  $S$  and  $S'$  is bounded by  $e^{\varepsilon d(S',S)}$  instead of  $e^\varepsilon$  in DP. Motivated by Metric DP and local DP, (Feyisetan et al., 2020) provides the Local Metric DP (LMDP) and uses it for private word embeddings (see Section 4 for details). Motivated by Utility-optimized LDP (ULDP) (Mura-kami and Kawamoto, 2019) rather than LDP, recently Yue et al. (2021) propose Utility-optimized Metric LDP (UMLDP). It exploits the fact that different inputs have different sensitivity levels to achieve higher utility. By assuming the input space, such as the set of tokens is split into sensitive and non-sensitive parts, UMLDP achieves a privacy guarantee equivalent to LDP for sensitive inputs.

## 2.2 Variants Levels of Privacy in NLP

When we consider using DP, the first question is what kind of information we aim to protect. In the previous studies on DP deep learning, we always wanted to protect the whole data sample. However, in the NLP domain, such one data sample could be either a word, a sentence, a paragraph, etc. If we ignore the concrete privacy level and directly apply the previous DP methods, we may have mediocre results. Thus, unlike the sample level privacy in DP deep learning, researchers in NLP consider different levels of privacy. Especially, they focus on the word level and sentence level, which aims to protect each word and sentence respectively (Meehan et al., 2022; Feyisetan et al., 2019).

In the federated learning setting, there is a central server and several users each of them has a local dataset, the sample level of DP may be insufficient. For example, in language modeling, each user may contribute many thousands of words to the training data, and each typed word makes its own contribution to the RNN’s training objective. In this case, just protecting each word is unsatisfactory, and it is still possible to re-identify users. Thus, besides the sample level, we also have the user level of privacy, which aims to protect users’ histories. After discussing some specificities of DP-NLP. In the following, we categorize its recent

studies into three classes based on their methods to ensure DP: gradient perturbation based methods, embedding vector perturbation based methods, and ensemble model based methods. See Tab. 1 for an overview.

## 3 Gradient Perturbation Based Methods

Generally speaking, a gradient perturbation method is based on adding noises to gradients of the loss during training the network to ensure DP. As the baseline and canonical algorithm for this type of approach, Differentially Private Stochastic Gradient Descent (DP-SGD) (Abadi et al., 2016) is a DP version of SGD. Its main idea is to use the noisy and clipped subsampled gradient  $g^t$  to approximate the whole gradient  $\nabla L(\theta^t, D)$ . In fact, besides SGD, we can use this idea for any optimizer, such as Adam (Kingma and Ba, 2015), whose private version DP-Adam is proposed and applied in BERT by (Anil et al., 2021). In the past few years, there has been a long list of work on DP-SGD from different perspectives, such as the subsampling strategy, faster clipping procedures, private clipping parameter tuning, and the selection of batch size. In the following, we will only discuss the previous work on using DP-SGD-based methods for variants of NLP tasks. See Appendix A for an introduction to DP-SGD.

### 3.1 DP Pre-trained Models

Recent developments in NLP have led to successful applications in large-scale language models with the appearance of transformer (Devlin et al., 2019). It combines the contextual information into language models with a more powerful ability of representation. These models are called pre-trained models, which train word embedding in large corpora targeting various tasks and gain the knowledge for downstream tasks (Peters et al., 2018). In this section, we review some papers that focus on pre-trained NLP models under DP constraints.

The workflow of BERT (Devlin et al., 2019) is pre-training the unlabeled text using some large corpora first. Then, the downstream tasks first initialize the model using the same parameters and fine-tune the parameters according to different tasks. Despite the benefits of powerful representation ability given by the pre-training process, it also has privacy issues since the model would memorize sensitive information such as words or phrases.

In order to solve this privacy leakage issue, there

are several studies on how to train BERT privately. [Hoory et al. \(2021\)](#) successfully trained a differentially private BERT model by modifying the WordPiece algorithm to satisfy DP, and conducted experiments on the problem of entity extraction tasks from medical text. They construct a tailored domain-specific DP-based trained vocabulary designed to generate a new domain-specific vocabulary while maintaining user privacy and then use the original DP-SGD in the training process. For the DP vocabulary part, they first construct a word histogram by dividing the text into a sequence of  $N$ -word tuples and then add Gaussian noise to the histogram to ensure  $(\epsilon, \delta)$ -DP. Finally, they clip the histogram with some threshold. For the training phase, they use the original DP-SGD to meet privacy guarantees. Besides, they also use the parallel training trick to make the training faster. Very recently, [Yin and Habernal \(2022\)](#) applied DP-BERT to the legal NLP domain. While DP-BERT can achieve good performance with privacy guarantees in language tasks. There are still two problems: a large gap between non-private accuracy and private accuracy, and computation inefficiency of clipping every sample gradient in DP-SGD. In order to mitigate these issues, [Anil et al. \(2021\)](#) later privatizes the Adam optimizer to improve the performance. Instead of adding noise and clipping every entry in every batch in DP-SGD, it selects a pre-defined number of samples randomly and sums the clipped gradients of these selected samples, then it updates average gradients with Gaussian noise adding the sum in each batch. Besides, it also uses an increasing batch size schedule instead of a fixed one. It finds that large batch size can improve accuracy, and the increasing batch size schedule can improve training efficiency. ([Senge et al., 2022](#)) recently studied five different typical NLP tasks with varying complexity using modern neural models based on BERT and XtremeDistil architectures. They showed that to achieve adequate performance, each task and privacy regime requires special treatment.

Besides BERT, [Ponomareva et al. \(2022\)](#) privately pre-train T5 ([Raffel et al., 2020](#)) via their proposed private tokenizer called DP-SentencePiece and DP-SGD. They show that DP-T5 does not suffer a large drop in pre-training utility, nor in training speed, and can still be fine-tuned to high accuracy on downstream tasks.

### 3.2 DP Fine-tuning

Besides training pre-trained models using DP algorithms, another direction is how to fine-tune pre-trained models privately. Here, the main difference is that we assume the pre-trained models, such as BERT have been trained with some public data, and our goal is to privately fine-tune targeting specific downstream tasks that involve sensitive data. It is noted that in this section, we also include some related work on training shallow neural networks in DP such as RNN or LSTM such as ([Li et al., 2022](#); [Amid et al., 2022](#)) as these methods can be directly applied to DP fine-tuning.

In this topic, the first direction is to investigate different tasks in the DP model and to compare its performance compared to the non-private one for studying the utility-privacy trade-off. [Yue et al. \(2022\)](#) consider the task of synthetic text generation and show that simply fine-tuning a pre-trained GPT-2 with the vanilla DP-SGD enables the model to generate useful synthetic text. [Mireshghallah et al. \(2022\)](#) recently extended to generating latent semantic parses in the DP model and then generating utterances based on the parses. [Carranza et al. \(2023\)](#) use DP-SGD to fine-tune a publicly pre-trained LLM on a query generation task. The resulting model can generate private synthetic queries representative of the original queries which can be freely shared for downstream non-private recommendation training procedures. Very recently, [Lee and Sogaard \(2023\)](#) adopted the DP-SGD to the meeting summarization task and showed that DP can improve performance when evaluated on unseen meeting types. [Aziz et al. \(2022\)](#) use GPT-2 and DP-SGD based methods to generate synthetic EHR data which can de-identify sensitive information for clinical text. [Wunderlich et al. \(2021\)](#) study the hierarchical text classification task, and they use DP-SGD to Bag of Words (BoW), CNNs and Transformer-based architectures. They find that Transformer-based models achieve better performance than CNN-based models in large datasets, while CNN-based models are superior to Transformer-based models in small datasets.

The second direction is to reduce the huge memory cost of storing individual gradients and decrease the added noise, which suffers notorious dimensional dependence in DP-SGD. Specifically, the studies in this direction always propose a general method for DP-SGD and then perform the method for different NLP tasks. [Yu](#)

et al. (2021) propose a variant of DP-SGD called the Reparametrized Gradient Perturbation (RGP) method. The framework of RGP parametrizes each weight matrix with two low-rank carrier matrices and a residual weight matrix, which will be used to approximate the original one. Such a way can reduce the memory cost for computing individual gradient matrices and can maintain the optimization process via forward/backward signals. Later, based on RGP, Yu et al. (2022) show that advanced parameter-efficient methods such as (Houlsby et al., 2019; Karimi Mahabadi et al., 2021) can lead to simpler and significantly improved algorithms for private fine-tuning. Instead of DP-SGD, Du and Mi (2021) propose a DP version of Forward-Propagation. Specifically, it clips representations followed by noise addition in the forward propagation stage.

Besides adapting the optimization method in vanilla DP-SGD, there are also some works on modifying the clipping operation or the fine-tuning method directly to save the memory cost. Li et al. (2021) propose a memory-saving technique that allows clipping in DP-SGD for fine-tuning to run without instantiating per-example gradients for any linear layer in the model. The technique enables private training Transformers with almost the same memory cost as non-private training at a modest run-time overhead. Dupuy et al. (2021) propose another variant of DP-SGD via micro-batch computations per GPU and noise decay and apply it to fine-tuning models. Specifically, they scale gradients in each micro-batch and set a decreasing noise multiplier with epoch. Then, they add scaled Gaussian noise to gradients. In this way, they can make the training faster and adapt it for GPU training. Bu et al. (2023) develop a novel Book-Keeping (BK) technique that implements existing DP optimizers, with a substantial improvement on the computational cost while also keeping almost the same accuracy as DP-SGD. Gupta et al. (2023) propose a novel language transformer finetuning strategy that introduces task-specific parameters in multiple transformer layers. They show that the method of combining RGP and their novel strategy is more suitable for low-resource applications. Bu et al. (2022) privatize the bias-term fine-tuning (BiTFiT) and show that DP-BiTFiT matches the state-of-the-art accuracy for DP algorithms and the efficiency of the standard BiTFiT (Zaken et al., 2022). Igamberdiev and Habernal (2022) apply

DP-Adam in Graph Convolutional Networks to perform the private fine-tuning for text classification. Specifically, they first split the graph into disconnected sub-graphs and then add noise to gradients.

Rather than reducing the memory cost, there are some papers considering developing variants of the DP-SGD method to improve performance. For example, Xia et al. (2023) propose a per-sample adaptive clipping algorithm, which is a new perspective and orthogonal to dynamic adaptive noise and coordinate clipping methods. Behnia et al. (2022) use the Edgeworth accountant (Wang et al., 2022) to compute the amount of noise that is required to be added to the gradients in SGD to guarantee a certain privacy budget, which is lower than the original DP-SGD. Li et al. (2022); Amid et al. (2022) propose new private optimization methods under the setting where there are some public and non-sensitive data.
