The Italian Conference on Computational Linguistics (CLiC-it) is the yearly conference organized by the *Associazione Italiana di Linguistica Computazionale* (Italian Association of Computational Linguistics, AILC). Its main goal is to promote and spread original and high-quality research on the diverse aspects concerning the automatic processing of natural language, both spoken and written. The eleventh edition of CLiC-it took place in Cagliari, from the 24th to the 26th of September 2025.

In line with previous editions, submissions to the conference could be of two types: regular papers, featuring original and unpublished contributions, and non-archival research communications, consisting of papers accepted in 2024 and 2025 by major publication venues, namely the major international Computational Linguistics (CL) conferences (workshops excluded) or international journals. Regular paper submissions were assigned to thirteen Senior Program Chairs based on the general area that covered the paper's topic. Paper assignments to reviewers were managed individually by the single Senior PCs, though resorting to a global pool of 151 available reviewers. We have received 138 submissions of regular papers, hitting once more the record number of submissions even compared to the previous edition in 2024, where regular papers submitted were 133. This confirms the vitality and growth of the Italian Computational Linguistics community. Along with regular papers, we also received 22 research communications. Among the regular submissions, 113 were accepted for presentation at the conference, resulting in a 81.8% acceptance rate, with respect to the 85.7% rate of CLiC-it 2024. Out of these, 55 were accepted as oral presentations and 58 as posters. After the author notification was sent, 4 papers were withdrawn by the authors themselves. As a result, the conference featured a total of 55 oral presentations and 54 posters. Finally, of the 22 research communications submitted – a clear sign of the vitality and quality of the research carried out within the community – 14 were included for poster presentation in a dedicated session. The selection was not based on an additional review process, but rather on the venue of publication. Even in this case, two research communications were withdrawn after the notification, hence 12 posters were presented at the conference.

The program also included two keynote talks, by **Karen Fort** (University of Lorraine) and **Edoardo Maria Ponti** (University of Edimburgh/NVIDIA):

- Karen Fort gave a talk titled "Large Language Models: the challenge of evaluation": *In the past five years or so, Natural Language Processing has witnessed a revolution. Not only have Large Language Models (LLM) submerged the domain, but they also invaded our societies: our systems now have real users and an impact on their lives. This dramatic change happened so fast that we -the research community- are still trying to catch up, especially concerning the evaluation of the real capabilities of these tools. In this presentation, I'll show what are the flaws of the present LLMs' evaluation and how ethics is a powerful leverage to improve it.*
- the talk by Edoardo Maria Ponti was titled "A Blueprint for Foundation Models with Adaptive Tokenization and Memory": *Foundation models (FMs) process information as a sequence of internal representations; however, the length of this sequence is fixed and entirely determined by tokenization. This essentially decouples representation granularity from information content, which exacerbates the deployment costs of FMs and narrows their "horizons" over long sequences. What if, instead, we could free FMs from tokenizers by modelling bytes directly, while making them faster than current tokenizer-bound FMs? To achieve this goal, I will show how to: 1) learn tokenization end-to-end, by dynamically pooling representations in internal layers and progressively learning abstractions from raw data; 2) compress the KV cache (memory) of Transformers adaptively during generation without loss of performance; 3) predict multiple bytes per time step in an efficient yet expressive way; 4) retrofit existing tokenizer-bound FMs into byte-level FMs through cross-tokenizer distillation.*

> *By blending these ingredients, we may soon witness the emergence of new, more efficient architectures for foundation models.*

One session of the conference was devoted to a discussion with **Paola Merlo**, conceived as a space for critical discussion on key areas of research in the fields of Computational Linguistics and Natural Language Processing, with a focus on both theoretical developments and applied scenarios within these disciplines. The discussion took place in an interview format. With the aim of promoting active and inclusive participation, a call for interest was launched, open to all interested participants - with a special focus on young researchers - to collect questions in advance to be addressed to Paola Merlo during the interview.

The conference was also preceded by a tutorial held by **Sandro Pezzelle** (University of Amsterdam) titled "*Language-and-vision models: From image-language alignment to storytelling and narration*". The tutorial aimed at providing an accessible yet in-depth overview of language-and-vision models, ranging from traditional modular pipelines to the latest end-to-end pre-trained systems (VLMs). The tutorial introduced foundational concepts and architectures, then focusing on recent approaches and evaluation challenges.

AILC also renewed its support to the **Emanuele Pianta Award** for the Best Master's Thesis defended at any Italian university between August 1st 2024 and July 31st 2025, and addressing a topic in computational linguistics or its applications. This year we received 9 candidate theses for the award. Of these, 2 were not further considered for evaluation due to incomplete submission. The candidate theses were evaluated by a jury composed of a current chair of CLiC-it, specifically Elisabetta Jezek was designated for this role, a co-chair of the past edition, i.e. Rachele Sprugnoli (University "Cattolica del Sacro Cuore" of Milan), and a further member of the AILC Board, i.e. Danilo Croce (University "Tor Vergata" of Rome). The winner was awarded by the members of the jury during the closing session of the conference.

We would like to thank all the **institutions** involved in the organization of the conference and the people of these institutions that worked with us for creating a successful event. For the logistic support, our thanks go to the Faculty of Economics, Law and Political Sciences of the University of Cagliari, that hosted the conference in the Sant'Ignazio Campus, and Valentina Deidda in particular, who kindly assisted us in all the technical and logistic aspects concerning the organization of the event. For the organizational and financial support, our thanks also go to the Department of Mathematics and Computer Science of the University of Cagliari, whose researchers were involved in the development and management of the website and whose students worked hard to help run things smoothly during the conference.

Our gratitude also goes to our **corporate supporters** for their generous provision of the financial resources and services that made this event possible: Aptus.AI, Talia, Aequa-tech, Almawave, Domyn, Elra, Logogramma, Prometeia, and Translated.

We express our deepest gratitude also to all Senior Program Chairs, all members of the Program Committee, and all participants, who contributed to the success of the event. Chairs and reviewers are named in the following pages.

Our final and special thanks go to **AILC**'s Board, whose members constantly supported us, giving guidance and invaluable assistance throughout the whole organization of the event, and to the whole AILC's association members that make this scientific event more interesting and richer every year.

## Declaration on Generative AI

During the preparation of this work, the authors used ChatGPT and Grammarly for grammar and spelling check. After using this tool, the authors reviewed and edited the content as needed and take full responsibility for the publication's content.

# Contemporary Voices in Ancient Tongue: Integrating Papal Encyclicals into the LiLa KB

Aurora Alagni[1,*,†], Federica Iurescia[1] and Eleonora Litta[1]

[1]Università Cattolica del Sacro Cuore, CIRCSE Research Centre, Largo Gemelli, 1, 20123 Milan, Italy

**Abstract**

This paper presents the integration of a new textual resource—the Papal Encyclicals corpus—into the LiLa: Linking Latin Knowledge Base. The inclusion of three recent Encyclicals authored by Pope Francis (*Lumen Fidei*, *Laudato si'*, and *Fratres omnes*) significantly enriches the LiLa Knowledge Base by extending its chronological coverage and introducing contemporary Latin vocabulary. The linking process involved automatic tokenisation, part-of-speech tagging, and lemmatisation using the LiLa Text Linker, followed by manual validation and disambiguation. The newly added lemmas fall into three categories: Latinized anthroponyms and toponyms, ethnic adjectives, and neologisms. These lexical additions reflect both a modernising trend in Vatican Latin and diverse morphological and semantic processes, including borrowing, calquing, and analogy-based reconstruction. The resource also opens avenues for analysing the stylistic and rhetorical features of Papal Encyclicals as a genre.

**Keywords**

Linked Open Data, Latin, textual resources

## 1. Introduction

### 1.1. LiLa

LiLa (Linking Latin) is a Linked Open Data (LOD) Knowledge Base (KB).[1] LiLa has been built to foster interoperability across textual and lexical resources for Latin [1]. The LiLa KB relies on two primary components:

- the Lemma Bank,[2] a collection currently comprising approximately 230,000 Latin lemmas (canonical citation forms of lexical items) published as LOD;[3]
- several language resources for Latin published as LOD and interconnected through the Lemma Bank, including corpora, lexica, and dictionaries.[4]

The LiLa KB employs several ontologies to represent both the data and metadata of the interlinked linguistic resources, such as POWLA for corpus data [2], OLiA for linguistic annotation [3], and Ontolex-Lemon for lexical data [4]. LiLa is an open-ended Knowledge Base: as new resources are integrated, the Lemma Bank is expanded. Lexical resources are linked to the Lemma Bank by connecting their lexical entries to their canonical forms. The single word occurrences (tokens) in textual resources are connected to the corresponding lemma in the LiLa Lemma Bank.

### 1.2. Papal Encyclicals

Among the textual resources in LiLa, a recent addition is the Papal Encyclicals corpus, which comprises pastoral letters dealing with Catholic doctrine written by Popes to Roman Catholic bishops.[5] In its first release, the corpus includes three encyclicals written by Pope Francis, namely *Lumen Fidei* (LF), *Laudato si'* (LS) and *Fratres omnes* (FO).[6] LF was published in 2013 and explores faith as a divine light illuminating human existence. LS was published in 2015 and advocates for a holistic response to ecological crises. FO was published in 2020, and pleads for universal fraternity and social friendship in the pursuit of a just and peaceful society. The source of the Latin text is their digital version on the Vatican site.[7] The integration of this resource enhances the coverage of the texts included in the LiLa Knowledge Base, extending both the chronological range and the diversity of textual

genres represented. Moreover, the addition of this corpus not only expands the Lemma Bank with new lemmas but also enables the study of lexical innovation strategies employed to express modern concepts in Latin.

# 2. Linking

## 2.1. Linking

The initial phase of the linking process involved the acquisition of plain-text versions of the three texts, retrieved from the official Vatican website. Collectively, these texts comprise 89,463 tokens, including punctuation and numerical elements associated with verse numbering and biblical references.

Tokenisation, sentence segmentation, part-of-speech (PoS) tagging, and lemmatisation were carried out automatically using the LiLa Text Linker—an NLP tool specifically designed for Latin. Table 1 displays the number of tokens per letter, excluding punctuation and numbering. Developed as part of the user-oriented services provided by LiLa [6], the Text Linker not only performs linguistic annotation but also establishes links between the annotated output and corresponding entries in the Lemma Bank. For PoS tagging and lemmatisation, the system relies on a UDPipe model trained on customised data. The linking procedure operates as follows: whenever the lemmatisation of a token yields a lemma–PoS pair that exactly matches a corresponding entry in the LiLa Lemma Bank, the system returns the URI of the matched lemma. These cases are referred to as 1:1 matches. In instances where the same lemma–PoS combination corresponds to multiple entries in LiLa, the system returns all relevant URIs, constituting 1:N matches. Conversely, when no entry in the Lemma Bank corresponds to the lemma–PoS pair produced during lemmatisation, the system returns no URI. These instances are classified as 1:0 matches. The output of this task is in Table 2.

Inevitably, the output of the lemmatisation process was not definitive. The accuracy of the 1:1 matches amount to around 97%. However, in certain cases, incorrect URIs were assigned.[8] One common source of error was the lemmatiser's assumption that any word beginning with a capital letter should be classified as a proper noun (PROPN). As a result, nouns occurring at the beginning of a sentence were sometimes misclassified, leading to erroneous matches when a proper noun homograph exists for a regular noun (e.g., *Amor*, the Roman god of love, versus *amor*, the common noun for 'love'). Another frequent error involved the lemmatisation of *quod*, which was uniformly tagged as a pronoun (PRON), despite its potential to function as a subordinating conjunction (SCONJ) or determiner (DET), depending on its syntactic role in the sentence. Similarly, *quam* was consistently tagged as a subordinating conjunction (SCONJ), although it could also serve as a pronoun (PRON) or a determiner (DET). Errors can arise for various reasons. As a result, the lemmatisation output was subjected to systematic manual review and correction by trained annotators, as well as disambiguation of 1:N matches.[9] Some of the one-to-zero matches also resulted from errors in lemmatisation or tokenisation. In particular, it was necessary in all instances to segment tokens containing enclitics, such as -*que*, -*ne*, and -*ue*, in order to enable accurate matching. For example, in tokens like *socialemque* 'and (something/someone) social', *eritne* 'will it be', *licetne* 'is it allowed', and *practicumue* 'or (something) practical', proper token splitting was required so that appropriate URIs could be assigned to both the first token (noun, verb, or adjective)

[8] Manual intervention was required in approximately 3% of the 1:1 matches subset.

[9] For an explanation of why 1:N matches regularly arise in the process of linking a textual resource to the LiLa LB, see the detailed report on how homography was handled during the integration of the LASLA corpus into the LiLa Knowledge Base [7, pp. 30–31].

and to the enclitic.

## 3. Papal Encyclicals in LiLa: Adding New Lemmas

Following the disambiguation process, several lemmas remain unlinked to LiLa, as they are not yet represented in the Knowledge Base. A thorough analysis of the 1:0 match types is necessary before considering their inclusion in the Lemma Bank. A subset of these unmatched lemmas corresponds to non-Latin words, which are not intended to be integrated into the Knowledge Base. These include: non-Latinized anthroponyms, such as *Nietzsche*, *Dostoevskij* (LF), *King*, and *Al-Tayyeb* (FO); words transliterated into the Latin alphabet from other languages, e.g., *emûnah* from Hebrew or *didachés* from Greek (LF); acronyms such as *DNA*, *OGM* (LS); and compound words joined by a hyphen or other special characters, such as *Deo-Amen* (LF) or *Rio+20* (LS).

In addition, a specific subset of the 1:0 matches—consisting of orthographic variants, dialectal forms, or alternative spellings of standardized forms—required targeted handling. In accordance with the OntoLex model used in LiLa, these cases have been incorporated as written representations (`ontolex:writtenRep`) of existing lemmas already present in the Lemma Bank [8, p. 69]. Specifically, these cases result from greater accuracy in transliteration from Hebrew (*Bethlehem*, LF; *Hillel*, FO), from the gemination of the sibilant in the toponym *Assisium* (FO; present in the Lemma Bank as *Asisium*), from the abandonment of a more Hellenising or archaic spelling of *Babilonia* (LS; listed in the Lemma Bank as *Babylonia*), and from a different graphical representation of the consonant cluster [ks] in *exstraneus* (FO; found in the Lemma Bank as *Extraneus*). These examples may reflect a modernising tendency in Latin spelling practices adopted by the Vatican, possibly aimed at aligning Latin orthography more closely with modern Italian spelling conventions (cf. *Assisi*, *Babilonia*, *Estraneo*). The same tendency will be noted again in later parts of the analysis.

The lemmas that have been added to the LiLa Knowledge Base, on the other hand, can be classified into three main categories.

The first category of lemmas added to the Lemma Bank includes Latinised anthroponyms and toponyms. Among the anthroponyms are *Desmondus*, *Martinus Luterus*, *Irenaeus* (FO), *Ludouicus* (LF), the patronymic *Aligherius* (LS), *Teresia*, and *Bonauentura* (LS, LF). These figures, cited in the Encyclicals, can play one of two roles: that of *auctoritas* or *exemplum*. In the case of Dante Alighieri, Saint Bonaventure, Saint Irenaeus, and Ludwig Wittgenstein, Pope Francis primarily refers to their words and works to support his arguments. For example, he cites Canto XXXIII of Dante's *Paradiso*, particularly the verse "l'amor che move il sole e l'altre stelle", to emphasise that "God's love is the fundamental moving force in all created things" (LS, 77).[10] Similarly, he references Wittgenstein's *Vermischte Bemerkungen*, where the philosopher discusses the "connection between faith and certainty" (LF, 27), and Irenaeus of Lyon's *Adversus haereses*, particularly the passage that uses the metaphor of melody to explain how different sounds can come from the same composer, just as each of us comes from the same Creator (FO, 58). By contrast, Desmond Tutu, Martin Luther King Jr., Mother Teresa of Calcutta, and Saint Thérèse of Lisieux serve as *exempla* to be emulated: for their acts of universal brotherhood despite religious differences, their faith in suffering, and their daily gestures of love and peace. As for toponyms, the category includes *Australia*, *Columbia*, *Corea*, *Croatia* (FO), and *Zelandia* (LS), all appearing in the genitive case following *episcopi*, as well as *Congus* (LS) and *Hiroshima* (FO), cited respectively as examples of the importance of preserving land and biodiversity, and of the moral imperative not to forget historical tragedies to which "we must never grow accustomed or inured" (FO, 248).

The second category consists of ethnic adjectives. Of the 15 instances found, 12 appear for the first time in the encyclical *Laudato si'*, two in *Fratres omnes*, and only one in *Lumen fidei*. From a derivational morphological perspective, these adjectives can be divided into three main types. The largest group (10 lemmas) consists of denominal adjectives derived from a toponym with the suffix *-ensis* (*Basileensis*, LS), including its extended form *-iensis* (*Canadiensis*, LS), a suffix typically used in Latin for forming ethnic adjectives [9, p. 439]. The second group includes *Apparitiopolitanus*, *Boliuianus*, *Paraguaianus* (LS), *Nazarethanus* (LS, FO), and *Bonaeropolitanus* (FO), formed with the equally canonical suffix *-anus* [9, p. 410]. A further distinction, intersecting with the previously discussed category of Latinized toponyms, concerns the nature of the geographical names from which these adjectives are derived. Some are adapted borrowings (**Basilea* from *Basileensis*), while others seem to be structural calques [10, pp. 118, 122], such as **Flumenianuarius* (from *Flumenianuariensis*, "of the city of Rio de Janeiro", LS). Some of these calques may undergo an additional morphological process, i.e. compounding with the Greek lexeme *polis*, resulting in forms like **Apparitiopolis* (from *Apparitiopolitanus*, "of the city of Aparecida", LS) and **Bonaeropolis* (from *Bonaeropolitanus*, "of the city of Buenos Aires", FO). Morphologically, the adjectives belong either to the second declension with two endings (first group) or to the first declension (second group), depending on the suffixation process. Semantically, the

[10] The text of this and other encyclicals is available in several languages at: https://www.vatican.va/content/francesco/it/encyclicals.index.html.

adjectives occur in different contexts: some appear in the genitive plural linked to *episcopi* (6); others refer to cities where documents, declarations, or environmental agreements were signed (4); two are characteristic attributes of female saints. *Bonaeropolitanus* refers to the positive influence of Jewish culture in Rio de Janeiro, while *Nazarethanus*, in both instances, occurs in the feminine form, dependent on *familia*.

The final category of new lemmas linked to the Lemma Bank consists of neologisms. The introduction of new lexical units into the inventory of a language can occur not only through internal resources and mechanisms, but also by drawing on elements from other languages, either through borrowing or calquing [11, p. 281]. In the present case, the linguistic influence is unidirectional, from Italian to Latin, which is unsurprising, given that Italian, although descended from Latin, is a living language with an active speaker community, unlike Latin. However, what is particularly noteworthy is that some of the Italian terms themselves are the result of interference from other languages. These layers of influence have contributed significantly to the enrichment of the Latin lexicon recorded in the LiLa Knowledge Base. Across the three encyclicals of Pope Francis under consideration, 234 neologisms have been identified, though they are not evenly distributed. In the first and shortest encyclical (see Table 1), *Lumen Fidei*, 32 neologisms appear for the first time. In the second, *Laudato si'*, 126 new formations are attested. Finally, in the third and longest encyclical, *Fratres omnes*, 76 neologisms are recorded.

Before proceeding with the analysis of this final category, a preliminary methodological clarification is required. In 1992, the *Libreria Editrice Vaticana* published the *Lexicon Recentis Latinitatis* (hereafter LRL), a lexicon that translates into Latin "many new words introduced by this era", generated "while preserving the norms of philology and the character of the Latin language".[11] This lexicon was fundamental for aligning word forms in the Encyclicals with the corresponding correct lemma. However, its application has also revealed the need for updates. Of the 234 lemmas analyzed, 145 are attested in the LRL. The remaining 89 were manually reconstructed by observing the word forms in their textual context. In some cases, reconstruction was straightforward; in others, it was not possible to determine the lemma with certainty. In these cases, the principle of analogy was applied. For instance, among the 36 neologisms formed with the suffix *-ismus*, half are found in the LRL. Of the remaining 18, only four appear in the nominative case. For the other 14, given the absence of modifying adjectives that could disambiguate gender (and therefore the case, which might otherwise suggest a nominative in *-ismum*), the lemmas were assigned masculine gender and classified as second-declension nouns with nominative in *-us*, based on analogy with the attested forms. For instance, the tokens *dynamismum* (LF, accusative) or *deconstructionismi* (FO, genitive), are entered into the KB as *dynamismus* and *deconstructionismus*, respectively. These reconstructions follow the model of lemmata such as *fatalismus* and *determinismus*, both attested in the LRL, or *anthropocentrismus* (LS), which is already found in the nominative form within the corpus. Another example involves nine lemmas pertaining to the semantic field of "Chemistry and Mineralogy" (see below). Among these, six such as *carbonium* (LS) and *fermentum* (FO) are present in the LRL as Latin equivalents of 'carbon' and 'enzyme' respectively, and are clearly neuter nouns of the second declension. One more, *dioxydum* (LS), appears in the nominative. By analogy, the word forms *cyanido* and *nitrogeni* were reconstructed as *cyanidum* and *nitrogenum* and added to the KB as neuter second-declension nouns. Moreover, the LRL further reflects a modernizing tendency in the lexical choices of the Latin used in the Encyclicals. A number of Italian terms that the LRL renders using periphrasis—in accordance with its assertion that "Latin is less suited (than Greek) to compounding words into one"[12]—reappear in the Encyclicals as single new lexical items. These are often modeled directly on Italian, incorporating morphological adaptations. For example, the Italian noun *totalitarismo* is translated in the LRL as "absolutum civitatis regimen", but appears in both *Lumen Fidei* and *Fratres omnes* as *totalitarismus*. Similarly, the adjective *mammifero*, which is translated in the LRL as "belua mammans", appears in *Laudato si'* as *mammiferum*, clearly modeled on the Italian form. Having established the necessary methodological premises, we can now proceed with an analysis of the neologisms. These may be classified into adjectives, nouns, and verbs.

As for adjectives, there are a total of 99. From a morphological perspective, 68 are first-class adjectives; 3 are first-class adjectives ending in *-ius* (*communitarius*, *consumptorius*, *fragmentarius*); 27 are second-class adjectives with two endings; 1 is a second-class adjective with a single ending (*globalizans*, present participle of **globalizo*). From a derivational standpoint, first-class adjectives are typically denominal, formed using the suffixes *-icus* (*atomicus*) and *-osus* (*gasiosus*), which are commonly employed in Latin for this type of morphological construction [9, p. 1125]. The nouns from which these adjectives are derived originate from Ancient Greek (*agnosticus*),[13] Classical Latin (*Prometheicus*), Medieval Latin

[11] Author's translation from Latin: "multa verba nova, quae haec aetas induxit" and "servatis normis disciplinae philologae et indole linguae Latinae" [12, p. 7].

[12] Author's translation from Latin: "linguam Latinam minus aptam esse (quam Graecam) ad componenda verba ita ut in unum coalescant" [12, p. 7].

[13] From this point on, only one example per source language or variety is cited. The list is not intended to be exhaustive; this editorial choice was made for space reasons. The linguistic analysis con-

(*inclusiuus*), Scientific Latin (*electricus*), Modern Latin (*aestheticus*), and Ecclesiastical Latin (*encyclicus*). They also result from interlinguistic influence between Italian and modern languages such as French (*acusticus*), English (*romanticus*), Czech (*roboticus*), German (*nazistus*). The second-class adjectives with two endings are formed either through suffixation with *-alis/-aris* (*structuralis*, *polaris*) or with *-bilis* (*renouabilis*). These are derived from nouns of various origins: Greek (*theologalis*), Classical Latin (*optionalis*), Medieval Latin (*interdisciplinaris*), Late Latin (*exsistentialis*), Scientific Latin (*molecularis*), Legal Latin (*solidalis*), and modern languages, such as English (*internationalis*). Remaining within the scope of derivation, it is particularly noteworthy that many of the neologisms exhibit prefixal or compositional structures prior to suffixation. These include prefixoids such as *inter-* (as in *interdisciplinaris*, *internationalis*), *multi-* (*multilateralis*, *multinationalis*, *multipolaris*), and *trans-* (*transgeneticus*, *transnationalis*). Other frequent compositional elements include bases such as *anthropo-* (*anthropocentricus*, *anthropologicus*), *auto-* (*autonomus*, *autotestimonialis*), and *techno-* (*technocraticus*, *technologicus*). Particularly prominent is the suffixoid *-logicus* (*methodologicus*, *oecologicus*, *technologicus*), which highlights how these adjectival neologisms respond to the growing need for terminology that addresses the study of the human being, its place within an increasingly interconnected world, the technologies it produces, and the discourse surrounding it.

As for new nouns, there are 131 in total. Morphologically, the majority belong to the second declension (64, of which 22 are neuter), followed, at a significant distance, by the third declension (33, of which 4 are neuter and 1 masculine), the first declension (32, with only 1 masculine noun, *asceta*), and finally, just 2 nouns belong to the fourth declension. Particularly interesting data emerge from the derivational morphological analysis of these nouns: 36 are denominal nouns formed with the suffix *-ismus*, which is used to create abstract nouns referring to religious, political, social, philosophical, literary, or artistic doctrines and movements (*dualismus*, *ascetismus*, *absolutismus*, *populismus*, *materialismus*, *romanticismus*), as well as attitudes, trends, collective or individual traits (*fanatismus*, *localismus*, *globalismus*), behaviors or actions (*fatalismus*), and even conditions or qualities, including moral or physical defects and harmful habits (*egoismus*, *narcissismus*). The high number of neologisms formed with this suffix clearly demonstrates not only the increasing need for its use but also its overuse in contemporary language.[14] There are also 11 nouns ending in *-tas*, all abstract and conveying a positive meaning, such as *actuositas*, *biodiversitas*, *solidarietas*, as well as nouns related to the sphere of the individual, such as *sacralitas*, *responsalitas*, *intimitas*, and *sexualitas*. Another noteworthy suffix is *-tio*, used to form deverbal nouns denoting actions, such as *dissentio*, *immigratio*, and *globalizatio*. Among the most common combining forms is *-logia* (from the Greek *logos*, and also the basis for the suffixoid *-logicus*, see above), which forms nouns such as *ideologia* and *oecologia*. Also worth noting is that, in the case of nouns as well, some of foreign origin have entered the Latin lexicon via Italian. Examples include *imanus* from Arabic (*imam*); three chemistry-related terms from French: *methanum*, *nitrogenum*, *dioxydum*; *mangrouia* from English; three terms with the combining form *gen-*, *genetica*, *genoma*, *genum*, from German. There are also nouns derived from Classical Latin (*uniuersalismus*), Late Latin (*reciprocitas*), Legal Latin (*solidalitas*), Medieval Latin (*represalia*), and Scientific Latin (*gasium*). Finally, particularly interesting from a derivational point of view are several structural calques from other languages: *tromocratia*, with its derivative *tromocratus*, from French *terrorisme* (from *terreur* + *-isme*); *autocinetum* or *autoraeda* from French *automobile*; *caeliscalpium* and *interrete* from English *skyscraper* and *internet*; and *ferriuia* from German *Eisenbahn*.

Finally, there are only four verbal neologisms. Of these, two belong to the first conjugation (*obstaculo*, *subordino*), one to the third conjugation (*interconecto*), while the remaining verb, *secumfert*, is classified as anomalous. This is due to its composition: it is formed by the enclitic attachment of the reflexive pronoun *se* to the preposition *cum*, followed by the verb *fero*, which itself is classified as an anomalous verb. From a derivational morphological perspective, three of these new verbs are the result of compounding, having been created by adding a prefix (*sub-*, *inter-*) or a prefixoid (*secum-*) to an already existing Latin verb. In contrast, *obstaculo* has undergone a derivational process, being a denominal verb derived from *obstaculum*, 'obstacle'.

From a semantic perspective, the classification of neologisms pertaining to the three parts of speech was conducted by mapping them to the 41 *domains*, defined as "spheres of activity or knowledge", established by BabelNet - a multilingual semantic network that integrates diverse resources, including WordNet, Wikipedia, the Italian WordNet and Wiktionary [13, p. 4560].[15] Across the three Encyclicals, and counting the occurrences of individual word forms, the neologisms most frequently attested (167 tokens) belong to the domain "Environment and meteorology", even though this domain comprises only nine lemmas. This result is unsurprising, consider-

ducted in this study is primarily based on the *Grande dizionario della lingua italiana*, available at https://www.gdli.it which served as the main reference for determining the historical and etymological origins of the lemmas.

[14] See, for example, the corresponding entry in the Treccani online dictionary at https://www.treccani.it/vocabolario/ismo/.

[15] For the process of identifying and refining domains, see *BabelDomains: Large-Scale Domain Labeling of Lexical Resources* [14].

ing that Pope Francis is widely regarded as one of the Popes most committed to environmental and climate-related issues. Notably, the adjective *ambitalis* alone appears 47 times. Ecology, represented through terms such as *oecologia*, *oecologicus*, and *oecosystema*, is a central theme of his pontificate. Throughout the texts, the Pope repeatedly reminds both global leaders and all people (*geosystema*) of their responsibility to protect and preserve biodiversity (*biodiuersitas*, *biosphaera*). This is followed by neologisms belonging to the domain "Philosophy, psychology and behavior" (58 lemmas, 159 tokens), "Culture, anthropology and society" (33 lemmas, 135 tokens), and "Politics, government and nobility" (21 lemmas, 103 tokens). As previously mentioned, philosophical reflection on the human condition is central to the Encyclicals, and is addressed from psychological (*actuositas*, *creatiuitas*, *egoismus*, *exsistentialis*, *infrahumanus*, *responsalitas*, *uulnerabilitas*), social (*communitarius*, *discriminatorius*, *ethicisticus*, *phyleticus*, *xenophobus*), and political (*absolutismus*, *demagogicus*, *nazistus*, *sinistrorsus*, *technocraticus*) angles. There is a noticeable drop in the number of occurrences for neologisms in the domain "Craft, engineering and technology" (8 lemmas, 39 tokens), which nevertheless reflect the idea of humanity as the primary agent of progress (*biotechnologia*, *nanotechnologia*, *technica*) and technological innovation (*roboticus*, *telegraphum*). At this point, and with the same number of occurrences (38) as those in the domain "Chemistry and mineralogy", appear the neologisms of the domain "Religion, mysticism and mythology" (22 lemmas). This is particularly significant, as one might have expected this to be among the most represented domains. The data instead confirm that the Encyclicals are not intended solely for Christian audiences, but are addressed to people of all faiths, promoting values intrinsic to the notion of humanity, not exclusively of Christianity. In fact, among the lemmas within this domain, only a few are explicitly tied to the Christian faith (*catechumenatus*, *christifidelis*, *christologicus*, *encyclicus*, *liturgia*, *trinitarius*), while others testify to the variety of world religions and belief systems (*agnosticus*, *ascetismus*, *dualismus*, *sacralitas*, *syncretismus*, *theologalis*). For the distribution of domains, see Figure 1 above.

The incorporation of new lemmas of modern and contemporary origin into the Lemma Bank, using the corpus of the three Encyclicals promulgated by Pope Francis between 2013 and 2020, has proven to be highly fruitful from both a quantitative and a qualitative standpoint. Undoubtedly, the efforts involved in the development and maintenance of a project such as LiLa—which was conceived as a network of interconnected language resources specifically for Latin—intersect with those of the Catholic Church, which continues to employ Latin as a universal language of communication. Both share a common goal: "to support the commitment to a greater knowledge and more competent use of Latin".[16]

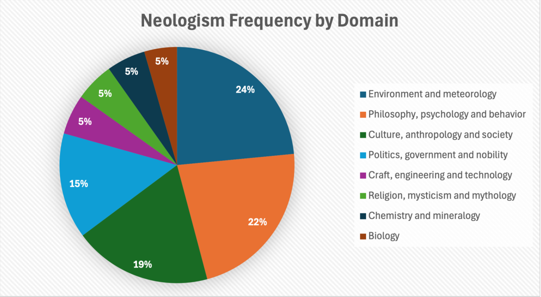

**Figure 1:** Distribution of neologism occurrences in Papal Encyclicals by Semantic Domain

## 4. Conclusions and Future Works

This paper has presented the integration of a new textual resource—the Papal Encyclicals corpus—into the LiLa Knowledge Base (KB). Although this is not the first instance of integrating a new corpus into LiLa—recent additions include Augustine of Hippo's *Confessiones*,[17] *de Ciuitate Dei*,[18] *de Trinitate*,[19] and Ovid's *Tristia* and *Epistulae ex Ponto* [15]—this first release of the Papal Encyclicals corpus is the result of a fine-grained manual revision of the automatic output. It constitutes a gold standard, whereas other textual resources linked to LiLa did not benefit from such an accurate manual revision - as in the case of the *Biblioteca Digitale di Testi Latini Tardoantichi*, where the considerably larger size of the corpus posed a limiting factor.[20] Furthermore, the inclusion of the Papal Encyclicals corpus is significant on a more fundamental level. A core assumption about Latin corpora is that they are static, since Latin is no longer a spoken language with native speakers. As a result, existing texts have been the subject of intense and ongoing scholarly investigation. For example, *Confessiones*, *de Ciuitate Dei* and *de Trinitate*, now linked to LiLa, have been studied for centuries from a variety of perspectives, ranging from psychological to strictly philological. Ovid's exilic writings have a long tradition of linguistic, historical and thematic analysis. In contrast, the Latin texts of Papal Encyclicals have not yet been the focus of consistent scholarly study. This means that the work presented in this paper is not built upon an

existing body of research, but is instead pioneering and foundational. It lays the groundwork for future studies and opens the door to a renewed consideration of Latin as a living language in specific, ongoing institutional contexts. Within the LiLa framework, the inclusion of a corpus that engages with contemporary concepts and referents significantly enriches the KB along several dimensions. First, the Lemma Bank has been expanded with new lexical items, enabling the study of linguistic strategies employed to create lemmas for concepts that did not exist in antiquity. This opens avenues for investigating the mechanisms of lexical innovation in Latin, particularly in the context of modern discourse. Second, the addition of the Encyclicals corpus offers a valuable opportunity to explore the distinctive linguistic and stylistic features of Papal Encyclicals as a genre. This resource allows for a more nuanced understanding of its rhetorical structures, specialised vocabulary, and register-specific phenomena. Third, the corpus contributes to extending the diachronic coverage of texts represented in the LiLa KB, facilitating longitudinal studies of Latin usage and lexical evolution across time. Future work will focus on expanding this initial integration to include the complete set of Latin Encyclicals authored by all Popes. This will support in-genre, cross-temporal comparisons, enabling scholars to trace linguistic trends and shifts within a consistent textual domain. Additionally, further analysis of unmatched lemmas and their potential inclusion will continue to refine the coverage and connectivity of the KB.

**Abstract**

This paper presents the manual annotation of ellipsis phenomena in a Latin treebank syntactically annotated following Universal Dependencies framework. Building on ongoing research in the field, it provides an overview of syntactic constructions that pose particular challenges for the annotation and reconstruction of ellipsis. By providing Latin examples, the work contributes to cross-linguistic comparisons and the broader understanding of ellipsis across languages. As a preliminary contribution, the paper offers insights into aspects that remain underspecified in current UD guidelines, suggesting directions for future refinement of annotation standards.

**Keywords**

Universal Dependencies, Ellipsis, Latin, Enhanced Dependencies, Treebank

## 1. Introduction

This work describes manual annotation of ellipsis in treebanks, which are syntactically annotated texts. The source data is a portion of UD_Latin-CIRCSE Treebank, a treebank manually annotated following Universal Dependencies (UD) framework.[1] At the time of writing, the treebank consists of three tragedies authored by Seneca (1st CE) – *Hercules Furens*, *Agamemnon*, *Oedipus* – and a treatise authored by Tacitus (1st-2nd CE) – *Germania*. Tacitus' *Germania*, being a prose work, was chosen for the present study to circumvent the stylistic challenges associated with tragic texts, particularly those arising from their diverse metrical structures. We relied on gold data as in the 15th UD release.[2] Nevertheless, the annotation did present several challenges and provided valuable insights to support ongoing research in the field of ellipsis in UD. Section 2 describes the state of the art in this field. Section 3 illustrates some examples of ellipsis and outlines the challenges encountered during the annotation. Section 4 concludes the paper and outlines potential avenues for future research.

## 2. State of the Art

Before delving into the core of the present work, this section provides a general introduction to UD (subsection 2.1), ellipsis (subsection 2.2), and the annotation of ellipsis in UD (subsection 2.3).

### 2.1. Universal Dependencies

Universal Dependencies is a framework for morphosyntactic annotation of different human languages [1]. The aim is to provide support for Natural Language Processing (NLP) researches and typologically oriented linguistic studies. In its most recent release, it includes 319 treebanks covering 179 languages.[3] UD offers two layers of annotation: basic syntactic annotation and enhanced syntactic annotation.[4] How they differ in the strategies adopted to annotate ellipsis, is the topic of subsection 2.3.

## 2.2. Ellipsis

Ellipsis refers to the omission of part of a sentence, indicating an asymmetry between a missing form and its meaning, which remains present even if not overtly expressed [2]. The meaning behind the omission is recoverable through an antecedent [3, p. 14],[5] which may be either explicitly attested in the text or inferred from world knowledge.

Being a phenomenon that operates at the intersection of different linguistic domains [4, p. 341], ellipsis has been the subject of numerous studies from various perspectives and theoretical frameworks. Concerning syntactic analysis, a substantial body of research has addressed the topic within a constituency-based approach ([5, 6, 7, 8], among others). In contrast, within the dependency framework, the amount of work on ellipsis is considerably smaller ([9, 10, 11], among others). This is mainly due to a fundamental difference: while constituency-based approaches allow for the existence of empty nodes in the syntactic structure, making it feasible to account for ellipsis, dependency-based approaches are less inclined to do so, and therefore tend to dismiss the treatment of ellipsis. This theoretical divergence is also reflected in the representation of ellipsis in treebanks. Ellipsis is explicitly addressed in the Penn Treebank (PTB) [12], which follows a constituency-based approach, as well as in the BulTreeBank [13], which is based on the Head-Driven Phrase Structure Grammar formalism [14]. As for dependency treebanks, the Prague Dependency Treebank (PDT) [15] handles ellipsis in a separate annotation layer,[6] whereas the Universal Dependencies framework accounts for ellipsis only marginally (see section 2.3 for further insights on ellipsis in UD). In the field of NLP and Large Language Models (LLMs), the challenges LLMs face in processing ellipsis reflect its inherent complexity [17], thereby underscoring the importance of gold-standard data in ellipsis research [18].

## 2.3. Ellipsis in UD

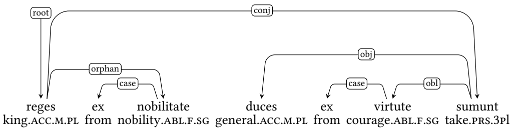
As mentioned in section 2.2, dependency-based treebanks are generally not inclined to introduce empty nodes into the syntactic structure. Currently, the most widely adopted and state-of-the-art framework for dependency treebanks is UD (see section 2.1), which handles ellipsis differently depending on the level of annotation—basic or enhanced.

Concerning the basic annotation, ellipsis is annotated using two different strategies:[7] (i) promotion and (ii) the `orphan` dependency relation (deprel). More specifically, promotion consists in elevating a dependent of the elided element to take on its syntactic role, effectively replacing the omitted node and assuming its function. This strategy follows a defined hierarchy.[8] By contrast, when promotion—and thus the preservation of the original syntactic function of the omitted element—would result in an unnatural syntactic structure, the `orphan` dependency relation is used instead. However, this dependency relation inevitably obscures the underlying syntactic structure, thereby entailing a loss of syntactic information.

It is therefore evident that UD does not directly address ellipsis in its basic annotation. Rather, ellipsis is concealed through the use of promotion, which—without targeted analysis—does not explicitly mark its presence, and is further obscured by the application of the `orphan` relation. While this relation enables ellipsis to be identified explicitly, it nonetheless obscures the syntactic representation of the sentence.[9]

In this work, we focus on examples of ellipsis annotated with the `orphan` deprel. Example 1 illustrates the basic annotation of such a sentence:

**Example 1 – Basic Annotation**
Tac., *Germ.* 7,1
*reges ex nobilitate duces ex uirtute sumunt*
They take their kings on the ground of birth, their generals on the basis of courage[10]



In this sentence, predicate ellipsis results in the promotion of the accusative *reges* ("kings") to the root position, leaving the dependent *ex nobilitate* ("on the ground of birth") orphaned.

This structure is illustrated in the basic dependency tree, where *reges* governs both *nobilitate* as `orphan` and *sumunt* ("they take") as a conjunct (`conj`).

Basic dependencies fall short of adequately representing implicit structures such as ellipsis. Instead, to thoroughly annotate elliptical constructions, a more suitable strategy within the UD framework is offered by enhanced

[5] In the literature, the term antecedent is typically used in a broad sense, not necessarily referring to an element that precedes the ellipsis. In fact, the element supplying the missing content may also follow the ellipsis, in which case the term postcedent would be more accurate. However, to remain consistent with established usage, we use the term antecedent in both cases.

[6] Refer to Mikulová [16] for further discussion of ellipsis in the PDT.

[7] https://universaldependencies.org/u/overview/specific-syntax.html#ellipsis

[8] https://universaldependencies.org/u/overview/specific-syntax.html#ellipsis-in-nominals

[9] For a proposal on explicitly marking ellipsis with a dedicated subtype, see https://unidive.lisn.upsaclay.fr/lib/exe/fetch.php?media=meetings:general_meetings:3rd_unidive_general_meeting:23_how_to_ellipsis_a_proposal_.pdf

[10] Latin translations are drawn by [19].

dependencies relations. At the current state of the art, enhanced dependencies for ellipsis involve the reconstruction of an empty node in the syntactic structure, along with the recovery of the relevant syntactic relations.[11] However, since enhanced annotation is "an optional addition to the basic representation",[12] the guidelines for annotating such cases remain underspecified.

## 3. Ellipsis in Tacitus' *Germania*

Given the current state of enhanced dependency annotation and the importance of gold-standard annotated data, we adopt the approach proposed by [20], which offers a consistent annotation scheme explicitly designed to address predicate ellipsis. The syntactic annotation of ellipsis in Tacitus' *Germania* was performed manually by a team of four annotators equipped with a background knowledge of Latin language and literature and expertise on syntactic annotation in the UD framework.[13]

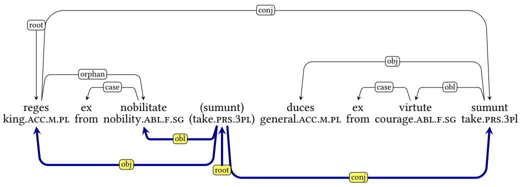
More specifically, in this work we focus on predicate ellipsis, presenting cases beyond this scope when they are relevant to illustrate annotation-related issues and decisions. We extend the enhanced annotation to cover primarily cases in which the basic annotation layer displays the `orphan` dependency relation, as well as, where applicable, cases in which predicate ellipsis is conveyed without being explicitly marked by means of `orphan`. There are 71 tokens out of 5,674 annotated with the deprel `orphan` in the basic layer.[14] They are distributed across 49 sentences out of a total of 299 sentences.[15] No specific pattern emerges regarding the distribution of elliptical constructions across the text.

In what follows, we report a few examples of reconstruction of predicate ellipsis (subsection 3.1), of the treatment of `orphan` deprel in cases of nominal ellipsis (subsection 3.2) and of ellipsis in copular constructions (subsection 3.3). We then illustrate cases of ellipsis in predicative (subsection 3.4) and comparative structures (subsection 3.5), providing examples of how we decide whether or not to intervene. Finally, we present an example of nested ellipsis (subsection 3.6).

### 3.1. Gapping

The main instance of predicate ellipsis found in the *Germania* is gapping. Gapping is a type of ellipsis in which a repeated verb is omitted from a coordinated clause, leaving behind only the contrasting elements [22]. Example 1a illustrates the enhanced annotation of the sentence presented in example 1:[16]

**Example 1a – Enhanced Annotation**
*reges ex nobilitate (sumunt) duces ex uirtute sumunt*



In the enhanced UD annotation, the elided verb *sumunt* is introduced as an empty node, explicitly marking the omitted predicate. Consequently, in the enhanced tree graph representation, the empty node becomes the root, governing *reges* as its direct object (`obj`) and *nobilitate* as an oblique dependent (`obl`). Finally, the empty node governs *sumunt* as `conj`.

### 3.2. Nominal Ellipsis

Example 2 illustrates an example of nominal ellipsis marked with the deprel `orphan` in the basic layer. The enhanced tree of this and of the following examples are detailed in the appendix A.

**Example 2**
Tac., *Germ.* 11,2
*nec dierum numerum ut nos sed noctium computant*
They count not by days as we do, but by nights

[11] For enhanced guidelines see: https://universaldependencies.org/v2/enhanced.html

[12] https://universaldependencies.org/v2/enhanced.html

[13] The annotators–three students from the graduate program in Linguistic Computing and one in Theoretical and Applied Linguistics–developed their expertise in syntactic annotation in the context of a dedicated training workgroup (approximately 30 hours) held at the CIRCSE research centre at the Università Cattolica del Sacro Cuore, Milano. In a first stage, the annotators practised on basic annotation layer by reannotating portions of gold standard texts from the CIRCSE treebank, both from poetry and prose. In this stage each dataset was annotated by all students. Their Inter Annotator Agreement (IAA), measured using Fleiss' Kappa coefficient, yielded an average score of 0.86 for edges and 0.85 for deprels. (Our script for calculating IAA on CoNLL-U files is available at https://github.com/johnnymoretti/CoNLL-U_Fleiss_Kappa). In a second stage, the annotators focussed on the advanced layer, by annotating ellipsis in Tacitus' *Germania.* Due to time constraints, in this stage each annotator was responsible for the annotation of a single portion of the text. The annotation of the single subsets were subsequently proof-checked by two expert annotators with advanced competence in Latin language and literature and expertise in the syntactic annotation of ellipsis. This process involved collaborative discussions during which the annotators presented the issues they encountered.

[14] Two tokens out of 71 are annotated with `orphan:missing` due to a lacuna in the *Opera Latina* corpus [21], which is the source text of the treebank.

[15] Two sentences (Tac., *Germ.* 2,3 and 37,4) stand out, as they present 4 and 6 tokens annotated as `orphan`, respectively, whereas the average distribution of `orphan` equals to 1.44 tokens per sentence.

[16] For gapping in Latin, see, e.g., [23, p. 585-586; 610-611].

This sentence illustrates a simple case of nominal ellipsis,[17] where the elided element is the noun *numerum* ("number") before *noctium* ("of nights"). In the basic UD dependency tree, the ellipsis is captured by the presence of the orphan relation assigned to the dependent *noctium*, directly governed by the main verb *computant* ("they count").

In the enhanced dependency graph, the elided noun *numerum* is introduced as an empty node to resolve the syntactic discontinuity. Thus, *noctium* is annotated as a dependent of the reconstructed empty node *numerum* via the nmod relation. This structure reproduces the expected syntactic structure and mirrors the dependencies found in the first clause *nec dierum numerum*, where the root *numerum* governs *dierum* as its nominal modifier nmod. Example 3 is a an instance of nominal ellipsis where a missing antecedent led to creation of an empty node, which could be semantically inferred, but still does not have an actual linguistic counterpart in the phrase:

**Example 3**
Tac., *Germ.* 15,1
*mos est ciuitatibus ultro ac uiritim conferre principibus uel armentorum uel frugum quod pro honore acceptum etiam necessitatibus subuenit*
It is the custom in their states to bestow upon the chief unasked and man by man some portion of one's cattle or crops: it is accepted as a compliment, but also serves his needs

In this sentence, the verb *conferre* ("to bestow") governs an argument in dative (*principibus*, "upon the chiefs") and semantically requires a direct object representing what is being bestowed. The coordinated genitives *armentorum* ("of cattle") and *frugum* ("of crops") function as modifiers of the verb, but not as arguments. They would imply a partitive relationship, and require an implicit head noun (e.g., *pars*, "a portion") to form a semantically complete direct object depending on *conferre*.

In the basic UD representation, this ellipsis is captured through the presence of an orphan, while *frugum* is a conjunct. The orphan label here marks the gap in the basic annotation: the genitive lacks a head noun, and the sentence lacks a direct object for *conferre*. This missing noun is both semantically necessary and syntactically expected, and this motivates its reconstruction. So, in the enhanced annotation, we reconstruct the argument expectations of *conferre* and introduce: a new empty nominal node functioning as the direct object of *conferre*; *armentorum* as nmod of the nominal empty node and *frugum* as its conjunct; the elimination of the orphan relation.

Crucially, we add an empty node without storing any lexical content, as there is no explicit antecedent to make reference to. Unlike more typical cases of predicate or comparative ellipsis (where the verb or noun is missing but recoverable from a parallel structure) here, no noun referring to e.g., "portion" appears in the clause, distinguishing this case from anaphoric ellipsis. Then, in the absence of an antecedent, the reconstructed node in our enhanced annotation is just empty, and not a copy of something else. So, the new reshaped phrase would appear like this: *conferre principibus uel armentorum uel frugum* _ , with the empty node occupying the last position.[18]

Example 4 features an instance of ellipsis of the subject which lacks an overt antecedent, requiring the reconstruction of an empty node not filled with any lexical or morphological information.

**Example 4**
Tac., *Germ.* 26,1
*faenus agitare et in usuras extendere ignotum ideoque magis seruatur quam si uetitum esset*
To exploit capital and to increase it by interest are unknown, and the principle is accordingly better observed than if there had been actual prohibition

The first clause describes the unfamiliarity of usury among the Germans. The second clause has the verb *seruatur* ("observed") as head: its implicit subject is understood as the negation of the previous clause, *faenus non agitare neque in usuras extendere* ("not to exploit capital and not to increase it"), whose negative meaning has to be inferred from *ignotum* ("are unknown").

Following the interpretation adopted by [19] in their translation, we reconstruct a single empty node for the omitted subject, representing this implied negative concept that may be paraphrased as a generic "principle". Hence, the reconstructed node is assigned the dependency relation nsubj:pass, under a nominal reading of the elided material. For reasons of accuracy, no lexical or morphological features are encoded, as no explicit antecedent is present in the text.

Example 3 and 4 serve to exemplify the procedure adopted in analogous cases: when no explicit antecedent is present in the text, the reconstructed node is left lexically and morphologically underspecified, and only the appropriate dependency relation is assigned. The absence of a textual antecedent is indicated in the MISC field of the CoNLL-U file by marking the source of interpretation as world knowledge (wk).

### 3.3. Copular Constructions

Example 5 illustrates a case of ellipsis of a copular construction. Such cases concern the omission of a predicate

[17] For nominal ellipsis in Latin, see, e.g., [24, p. 962].

[18] For a tentative recostruction of the elided part, see, e.g., [25, p. 41], who posits ellipsis of an indefinite pronoun, as head of *uel armentorum uel frugum*.

formed by the nominal component and a form of the verb *sum*.

**Example 5**
Tac., *Germ.* 27,2
*feminis lugere honestum est uiris meminisse*
Lamentation becomes women: men must remember

This sentence illustrates a case of nominal predicate ellipsis, involving the omission of both the copula *est* and the nominal component *honestum* ("convenient"). The structure is parallel, contrasting actions appropriate for women and man in mourning. In the first clause, the argument *feminis* ("for women") precedes the clausal subject *lugere* ("to mourn") of the nominal predicate; in the second, *uiris* ("for men") is followed by the infinitive *meminisse* ("to remember"), on which it depends, in basic annotation, via an `orphan` relation that marks the ellipsis of the predicate.

Hence, in the enhanced annotation, the ellipsis is resolved through the insertion of an empty node at the end of the second clause, mirroring the structure and the dependency relations of the first. In accordance with the proposal in [20], we reconstruct only the nominal part of the predicate, the head *honestum*, which carries the semantic content of the predicate and ensures cross-linguistic consistency.

## 3.4. Predicative Constructions

As mentioned in section 2.3, ellipsis is annotated only when it creates syntactic discontinuities, specifically, when the absence of a word leaves dependents orphaned. This is most visible in constructions like gapping (section 3.1), while in other structures, an elided predicate does not result in unattached dependents or broken syntactic structure, and therefore there are cases of elliptical constructions which are not annotated as `orphan` in UD (section 2.3). Example 6 is a case of predicative constructions involving coordinated or juxtaposed clauses:

**Example 6**
Tac., *Germ.* 13,1
*... scuto frameaque iuuenem ornant ... ante hoc domus pars uidentur, mox rei publicae*
... [they] equip the young man with shield and spear ... up to this point they seem a part of the household, next a part of the state

We focus on the final segment of the sentence: *ante hoc domus pars uidentur, mox rei publicae* ("up to this point they seem a part of the household, next a part of the state"). The first clause (*domus pars uidentur*) is a standard predicative construction consisting of a subject (understood as *illi* and referring to *iuuenem*), the verb *uidentur* ("they seem"), and the predicative nominal *domus pars.* In the second clause (*mox rei publicae*), both the verb *uidentur* and the predicative noun *pars* are absent. Nevertheless, they can be clearly inferred and the intended structure formed by the two clauses is parallel: *domus pars uidentur* ("they seem a part of the household") *rei publicae pars uidentur* ("they seem a part of the state").

However, despite the interpretative clarity, as both the verbal head and its nominal predicate are missing, this is a clear case of predicate ellipsis that is not marked in the basic UD annotation, since no dependent is left syntactically orphaned.

So, in the enhanced UD annotation, we insert two reconstructed nodes: the verb *uidentur* as the verbal head and the predicative nominal *pars*, which has *rei publicae* as a dependent. Therefore, in the enhanced tree graph representation the structure would include: a new verbal node *uidentur* connected to the first verb with the deprel `conj`; a new nominal node *pars* connected as `xcomp` to the reconstructed *uidentur*; the nominal phrase *rei publicae* dependent of pars as `nmod`.

## 3.5. Ellipsis in Comparative Constructions

Another significant case of ellipsis in the *Germania* occurs in comparative clauses.[19] The following case is one of this kind:

**Example 7**
Tac., *Germ.* 14,3
*nec arare terram aut exspectare annum tam facile persuaseris quam uocare hostem et uulnera mereri pigrum quin immo et iners uidetur sudore acquirere quod possis sanguine parare*
You will not so readily persuade them to plough the land and wait for the year's returns as to challenge the enemy and earn wounds: besides, it seems limp and slack to get with the sweating of your brow what you can gain with the shedding of your blood

In this sentence, the verb *persuaseris* ("you will persuade") governs the first clause of the comparative construction (with the two infinitive verbs *arare*, "to plough", and *expectare*, "to wait") but is not repeated in the second (verbs *uocare*, "to challenge", and *mereri*, "to earn"), despite clearly being the intended meaning. This omission might seem to be a candidate for ellipsis annotation. However, UD guidelines do not annotate such cases of comparative ellipsis for several theoretical and practical reasons, and we decide to do the same.

There is no `orphan` relation in the basic tree, so there is no ellipsis to resolve in the enhanced representation either. We see that there are no orphaned dependents in the second clause, as the infinitive verb *uocare* depends on *persuaseris* as `advcl:cmp` and *mereri* is its conjunct. Since all constituents are attached with appropriate

[19] For ellipsis in comparative construction in Latin, see, e.g., [23, p. 721].

heads, no orphan relation is needed. Being the sharing of the predicate a common phenomenon in comparative constructions, especially in Latin, we accept this syntactically and semantically recoverable pattern, and choose not to annotate it. So, even by doing nothing, here the clause remains structurally intact, and no dependents are left without a head, although *persuaseris* is intuitively present in both parts of the comparative construction.

### 3.6. Nested Ellipsis

Among the knotty sentences to annotate, example 8 stands out: exemplifying Tacitus' concise and condensed prose, it features a case of a nested ellipsis.

> **Example 8**
> Tac., *Germ.* 43,2
> *e quibus Marsigni et Buri sermone cultuque Suebos referunt Cotinos Gallica Osos Pannonica lingua coarguit non esse Germanos et quod tributa patiuntur*
> Among them the Marsigni and Buri in language and mode of life recall the Suebi: as for the Cotini and Osi, the Gallic tongue of the first and the Pannonian of the second prove them not to be Germans; so does their submission to tribute

The two clauses *Cotinos Gallica* and *Osos Pannonica lingua coarguit* are in asyndeton, with no subordinating connective present: indeed, in accordance with the guidelines, their relationship has been annotated with the label `conj`. The clause *Cotinos Gallica* shows a predicate ellipsis (*coarguit*) and instantiates an example of gapping (section 3.1): the use of a singular verb would otherwise be inexplicable.

What makes the situation more complex is that the reconstructed *coarguit* implies, even in this first clause, *non esse Germanos*. Therefore, another empty node (*Germanos*) has been reconstructed after *Cotinos*. In the enhanced UD annotation, the reconstructed *coarguit* thus takes on the role that *Gallica* played in the previous annotation; *Cotinos*, on the other hand, becomes the `nsubj` of the reconstructed `ccomp` *Germanos*.[20]

# 4. Conclusion

This work describes the challenges encountered during manual annotation of ellipsis in Tacitus' *Germania*. The treebank enhanced with this annotation will be included in the next UD release. Building on the proposal outlined in [20], it provides examples of ellipsis in Latin, thereby offering material for comparison on the treatment of ellipsis across languages. Unlike the approach taken in [20], where the reconstruction focussed exclusively on predicate ellipsis and did not attempt to recover omitted arguments, thus deliberately excluding cases of nominal ellipsis, the present study has highlighted the need to consider nominal ellipsis as well, as illustrated in Section 3.2. This opens the possibility of expanding the domain of reconstruction to include a broader range of omitted elements. Accordingly, this work offers insights into additional aspects that should be considered in the development of guidelines for ellipsis annotation within the UD framework, which remain currently underspecified.

For this work, we focussed on the description of the challenges and identified some directions for future works. First, a thorough examination of the position of the elided material shall pave the way for a study on the communicative reasons that may have guided the author in choosing an elliptical structure, such as topical focussing, among others. More research is needed to explore patterns of usage of elliptical constructions in the *Germania* and, more in general, in Tacitus' oeuvre. Second, a classification of the types of ellipsis encountered in Tacitus' *Germania* shall contribute to the ongoing discussion on ellipsis. The addition of other (Latin) treebanks enhanced with annotation focussing on ellipsis remains a desideratum, which will foster both research focussing on linguistic aspects of ellipsis and on stylistics. Such additions would, among other benefits, enable the training of NLP tools for ellipsis detection, thereby facilitating large-scale research into its frequency patterns and distribution across treebanks representing different genres and, for literary texts, across different authors.

# Low- vs High-level Lemmatization for Historical Languages. A Case study on Italian

Chiara Alzetta[1,*,†], Simonetta Montemagni[1,†]

[1]Istituto di Linguistica Computazionale "Antonio Zampolli", Consiglio Nazionale delle Ricerche, Pisa, Italy

## Abstract

Lemmatization remains a foundational yet challenging task in the processing of historical Italian texts, due to the complex interplay of orthographic, morphological, and diatopic variation. A crucial, yet often overlooked, aspect is the degree of normalization applied during lemmatization. A conservative approach preserves attested historical forms, ensuring greater linguistic fidelity but increasing data sparsity. Conversely, an abstract normalization strategy aligns historical variants with standardized contemporary lemmas, improving generalization but potentially introducing inaccurate mappings. In this paper, we present a comparative evaluation of conservative and normalized lemmatization strategies for historical Italian. To our knowledge, this is the first study to explicitly assess the impact of lemmatization strategies in the context of historical languages, particularly those that are morphologically rich. Our results indicate that high-level normalization offers a promising trade-off between precision and generalization.

## Keywords

Data-driven Lemmatization, Historical Italian, Universal Dependencies, Normalization

## 1. Introduction

Lemmatization is the task of identifying the canonical form, or *lemma*, of a given inflected wordform. While this mapping is often straightforward and based on well-established criteria, it can also involve a considerable degree of discretion, especially in the case of diachronic language data. In historical lexicography, lemma selection remains a well-known and unresolved challenge due to the high number of attested variant forms, many of which diverge significantly from the standard form. Choosing a specific lemma to serve as the headword — i.e. capable of effectively subsuming all its variants — is a widely debated issue. As Porter and Thompson [1] and Manolessou and Katsouda [2] have noted, it constitutes a genuine *dilemma*. In computational linguistics, by contrast, lemmatization criteria are rarely made explicit and are often taken for granted. While this may pose only minor issues in the lemmatization of contemporary language, it becomes a critical concern for historical language data. This paper investigates the role and impact of different lemma identification strategies in automatic lemmatization, with a focus on historical varieties.

Lemmatization is one of the fundamental tasks that facilitate downstream Natural Language Processing (NLP) applications and is particularly relevant for highly inflected languages. Traditionally, this task has been addressed using rule-based morphological analyzers and dictionary lookup. However, recent years have seen the rise of data-driven lemmatization approaches, where models learn to produce lemmas without relying on pre-defined linguistic rules and/or lexical resources. A key turning point in this methodological shift was the SIGMORPHON 2016 Shared Task, which reconceptualized lemmatization as a special case of morphological reinflection (Cotterell et al. [3]). This view paved the way for the current dominant approaches, based on neural models.

Within the data-driven paradigm, two main strategies have emerged. The generative character-level approach relies on encoder-decoder architectures that generate the lemma character by character, conditioned on the input form and its context (Qi et al. [4], Bergmanis and Goldwater [5]). In contrast, pattern-based models treat lemmatization as a supervised classification task (Straka [6]), where each class - derived from training data - corresponds to the edit operations that transform a specific wordform into its lemma. A comparative study on Estonian by Dorkin and Sirts [7] found that generative encoder-decoder models trained from scratch outperform both rule-based systems and pattern-based models fine-tuned from large pre-trained language models.

Among the most debated issues in lemmatization, particularly in data-driven models, there is the role of context and morphological information. Contextual information has been shown to be crucial for handling unseen and ambiguous words: see, among others, Bergmanis and Goldwater [5, 8] and McCarthy et al. [9]. The actual role of morphological information in performing contextual lemmatization was investigated by Toporkov and Agerri [10], who showed that fine-grained morphological information does not help to substantially improve

lemmatization (not even for highly inflected languages) and that using basic part-of-speech tags (UPOS) seems to be enough for comparable performance across languages.

Although much progress has been made on lemmatization for standard, resource-rich languages, the task remains challenging in the case of historical varieties, especially for morphologically complex languages like Italian. Historical Italian presents both orthographic and morphological variation, not only over time but often in the same period and even within the same text. These challenges include, among others: alternations between etymological and phonetic spellings (e.g., *haveva* vs. *aveva* '(it) had', *chupola* vs. *cupola* 'dome'); phonetic variation (e.g. *pulito* vs. *polito* 'clean', *eguale* vs. *uguale* 'equal'); morphologically distinct variants (e.g. *avria* vs. *avrebbe* '(it) would have'); cliticized finite verbal forms (*aveagli* '(it) had-to-him', *avevalo* '(it) had-it'). Additional challenges, also relevant to contemporary Italian, include the treatment of past participles (verbal vs. adjectival use) and derivative forms (the open issue is whether they represent an independent lemma or should be associated with the corresponding base form, e.g. the diminutive *angioletto* 'little angel' is an independent lemma or should be lemmatized as *angelo* 'angel').

A crucial but often neglected aspect of lemmatizing historical texts concerns the granularity and scope of the lemma list, as well as the criteria guiding lemma identification: in other words, the degree of normalization applied. This choice carries both theoretical and practical implications, influencing how linguistic variation is represented, how lexical continuity over time is interpreted, and how effectively the data can be searched, analyzed, or aligned across sources. Table 1 contrasts a conservative lemmatization approach - which preserves the graphical, phonological, and morpho-syntactic features of attested historical variants - with a more abstract normalization strategy that aligns such variants to a standardized contemporary (meta-)lemma. While the former offers greater linguistic precision and interpretability, it may lead to increased data sparsity. The latter, by contrast, reduces sparsity and facilitates generalization, though at the risk of introducing incorrect form–lemma associations.

The choice between these strategies is shaped by several practical factors, including the target application and the specific language involved. Linguistic analyses, for instance, may benefit from a conservative approach, whereas information retrieval systems and downstream NLP applications may perform better with normalized lemmas. Language-specific features also play a key role. As Manjavacas et al. [11] note, the highly heterogeneous nature of historical languages — marked by overlapping diachronic and diatopic variation and the absence of a stable standardized norm — makes it particularly challenging to carry out lemmatization and normalization simultaneously. In the case of diachronic Italian, a low-level lemmatization strategy was adopted by Favaro et al. [12, 13], deferring normalization to a later stage operating on lemma variants.

| wordform | Conservative Lemma | Normalized Lemma | POS |
|---|---|---|---|
| *brieve* | BRIEVE | BREVE | ADJ |
| *sanctissimo* | SANCTO | SANTO | ADJ |

| *guarentir* | GUARENTIRE | GARANTIRE | VERB |
| *surse* | SURGERE | SORGERE | VERB |

**Table 1**
Examples of conservative vs normalized lemmatization for historical Italian

In this paper, we present a comparative evaluation of these two lemmatization strategies for historical Italian, combining quantitative metrics with qualitative analysis. To our knowledge, this issue has not yet been explicitly addressed in the computational linguistics literature, where lemmatization choices are typically assumed rather than critically examined. We argue that this decision is especially relevant for morphologically rich languages, where different lemmatization strategies can have a substantial impact on both the performance and interpretability of downstream tasks.

The rest of the paper is organized as follows. In Section 2, the historical corpora selected as the basis of this study are described. Section 3 illustrates the strategy adopted for generating a version of these corpora with high-level normalized lemmatization. Section 4 describes the approach employed to train two models for lemmatizing Italian historical texts. Section 5 discusses the results obtained by the lemmatization models, focusing both on the results obtained in five-fold cross-validation experiments and against an external test set. Finally, Section 6 concludes the paper and presents some future prospects.

## 2. Data

For this study, we selected three corpora covering a wide timespan, going from the 14th to the 20th century, listed below:

- **UD-Italian Old** [14]: Italian-Old is a treebank containing Dante Alighieri's Comedy, based on the 1994 Petrocchi edition and sourced from the DanteSearch corpus [15]. The treebank includes lemmatization, morpho-syntactic, and syntactic

| Corpus | Sentences | Tokens |
|---|---:|---:|
| UD-Italian Old | 3,419 | 122,038 |
| GDLI-QC - GDLI Quotation Corpus | 1,500 | 36,624 |
| VGG - Voci della Grande Guerra | 4,945 | 108,208 |
| Total | 9,864 | 266,870 |

**Table 2**
Size of the used corpora of historical Italian

annotation. A partial manual revision was carried out to align morpho-syntactic annotation and lemmatization with the Universal Dependencies (UD) guidelines, with particular attention to proper nouns and fixed multiword expressions. For our experiments, we used version 2.15 of the treebank, released in November 2024;

- **VGG - Voci della Grande Guerra** [16]: VVG is a corpus of texts that were written in Italian in the period of World War I or shortly afterwards (most of them date back to the years 1915-1919). The corpus includes different textual genres, namely: discourses, reports, and diaries of politicians and military chiefs; letters written by men and women, soldiers and civilians; literary works of intellectuals, poets, and philosophers; writings of journalists and lawyers. The corpus is annotated at the morpho-syntactic level and lemmatized. Annotation was carried out with UDPipe [17] trained on IUDT [18]v2.0; a subset was then manually revised [19]. For this study, we used the gold portion of the corpus;
- **GDLI-QC - GDLI Quotation Corpus** [12]: GDLI-QC is a corpus derived from an authoritative historical Italian dictionary, namely the *Grande dizionario della lingua italiana* (GDLI) edited by Salvatore Battaglia. GDLI presents a huge collection of quotations covering the entire history of the Italian language, from which a subset has been extracted, representative of the most cited authors and covering a wide chronological span (from the 14th to the 20th century). GDLI-QC has been morpho-syntactically tagged and lemmatized with Stanza [4]: annotation was carried out automatically, with full manual revision.

All of these corpora follow a conservative lemmatization strategy. In terms of annotation, they are all natively annotated according to the Universal Dependencies (UD) scheme[1] (De Marneffe et al. [20]), which has become the *de facto* standard nowadays. Lemmatization has been manually revised for each corpus — albeit only partially for UD-Italian Old — to ensure linguistic accuracy and internal consistency. As such, these corpora can be considered gold-standard resources. Table 2 provides details on their size in terms of sentences and tokens.

For the comparative study of the two lemmatization strategies, a normalized counterpart of each corpus, featuring high-level linguistic annotation, was required. To generate the normalized versions of the three corpora, we identified two historical Italian lexicons adopting this lemmatization approach.

One such resource is the MIDIA lexicon, which was built starting from the balanced diachronic corpus of written Italian texts called MIDIA (D'Achille and Grossmann [21]), fully annotated with lemma and part-of-speech (POS) information. Covering the period from the early 13th to the first half of the 20th century, the corpus is organized into five chronological periods and seven textual genres, comprising approximately 7.5 million tokens drawn from about 800 texts. In MIDIA, lemmatization and POS tagging were automatically performed using a version of TreeTagger (Schmid [22]) adapted for historical Italian (Iacobini et al. [23]). To handle the linguistic variation typical of earlier stages of the language, the contemporary Italian lexicon embedded in TreeTagger was enriched with approximately 230,000 word forms, primarily dating from the 14th to the 16th centuries. This substantially expanded the original MIDIA lexicon. The version we used contains 70,083 unique lemmata, 571,779 distinct wordform–lemma pairs, and 584,041 unique wordform–lemma–POS triples. Notably, there is a high degree of overlap between the wordform–lemma pairs from the corpora under study and those in the MIDIA lexicon: 89.91% for UD-Italian Old, 86.65% for GDLI-QC, and 81.66% for VGG.

Another key reference resource identified for these purposes is the *Tesoro della Lingua Italiana delle Origini* (TLIO) (Beltrami [24]), a historical dictionary of old Italian based on all extant documentation from the earliest texts recognizable as Italian up to the end of the 14th century, which includes manual lemmatization.

To fully understand the type of lemmatization performed in these two resources, we report below the set of wordforms sharing the nominal lemma amministrazione 'administration' in the MIDIA and TLIO lexicons:

> **MIDIA**: *administratione, administrationi, administrazione, aministratione, amministratione, amministrationi, amministrazione, amministrazioni, nistrazione, strazione*
>
> **TLIO**: *adminestragione, administracion, administracione, administraciuni, administragione, administratione, administrationi, administrazione, aministracione, aministraciuni, aministragione, aministrascione, aministratione, amministracione, amministragione, amministragioni, amministratione, amministrazione, amministrazioni*

| PUN, SENT | PUNCT | Punctuation |
| CHE | PRON,SCONJ | |
| NUM | NUM | Numeral |
| WH | PRON,ADV,SCONJ | Interrogative |

**Table 3**
Mapping between MIDIA and UD part of speech tags

## 3. Lemma Normalization

To carry out lemma normalization, the first step consisted of converting the part of speech tags of the MIDIA lexicon to the UD annotation scheme. Table 3 details the correspondences between the two tagsets. The conversion was carried out automatically, and the ambiguous underspecified cases (e.g. CHE and WH tags) were then revised manually.

The normalization process of the selected corpora was carried out in three successive phases, relying on lexicon-based validation and correction. The objective was to verify and, where appropriate, normalize wordform-lemma (WL) pairs extracted from the selected historical corpora using the MIDIA and TLIO historical lexicons.

In the first phase, each WL pair was checked against the MIDIA lexicon. If the WL pair was found in MIDIA, the case was marked as `f1-match-found` and left unchanged. If the wordform was present in the MIDIA lexicon but was associated with a different lemma, or with both a different lemma and POS, the unmatching information was modified with the values appearing in MIDIA (case marked as `f1-modified-lemma` or `f1-modified-lemma+pos`). If the *wordform* was not found in MIDIA, the case was labeled `f1-form-missing` and passed as input to the second phase.

In the second normalization phase, the wordforms labelled as missing (i.e. `f1-form-missing`) in MIDIA during Phase 1 were re-analyzed. For these cases, we checked whether MIDIA contained the lemma matching any other form. If the POS in the corpus and MIDIA lexicon coincided, then we marked the case as correct using the label `f2-validated-lemma`. If the lemma was present in MIDIA with a different POS, the original POS from the corpus was preserved, and the case was labeled `f2-different-pos`. If no matching form or lemma was found in MIDIA, the case was labeled `f2-missing`.

The final phase addressed the remaining unresolved cases from Phase 2 — those labeled `f2-missing` and `f2-different-pos` — by consulting the TLIO lexicon. As a first step, we checked whether the triple (wordform, lemma, POS) was present in the lexicon. If so, we marked the case as validated (`f3-valid-lemma-F`), or modified the lemma to match the triple in TLIO (`f3-modified-lemma-F`). If the *lemma* appeared as a *wordform* in TLIO with the same POS, the lemma was changed to match the lemma reported in TLIO (`f3-modified-lemma-L`) or validated against the lexicon (`f3-valid-lemma-L`). If the *form* was present but associated with a different POS, the case was labeled `f3-different-lemma-pos`. If none of the above conditions applied, the case remained unresolved and was labeled `f3-missing`.

Table 4 exemplifies the cases treated in the different normalization steps, reporting the corpus annotation and how it was revised based on the evidence of the MIDIA / TLIO lexicons.

For each step described above, Table 5 reports the distribution of cases in the three normalization steps. For the three historical corpora, the number of matching WL pairs is very high: the lemmatization in the corpus and the lexicon coincided in more than 96% of the cases (with minor differences across the corpora). Cases normalized during one of the three phases amount to 3.56% in the UD-Italian Old, 3.02% in VGG, and 2.97% in GDLI-QC. A neglectable number of cases were not normalized, ranging from 0.09% in the UD-Italian Old, to 0.85% and 0.73% in VGG and GDLI-QC respectively.

## 4. Model Training

For the analysis of historical Italian texts, we trained the Stanza natural language processing neural pipeline [4], developed by the Stanford NLP Group. Stanza, following a generative character-level approach, offers a modular architecture with state-of-the-art models for tokenization, lemmatization, part-of-speech tagging, morphological analysis, dependency parsing, and named entity recognition. Built on a Python interface, it supports over 70 human languages and is trained on UD treebanks. In addition to its pre-trained models, Stanza allows users to train custom models from scratch using UD-formatted data. In this study, we specifically focused on the lemmatization component.

The lemmatization model was trained using the normalized versions of the selected historical corpora — UD-Italian Old, VGG, and GDLI-QC — as input data. To these, we added the contemporary Italian corpus ISDT (Italian

| Label | Corpus (wordform, lemma, POS) | Lexicon (wordform, lemma, POS) | Change Description |
|---|---|---|---|
| Phase 1, Lexicon: MIDIA | | | |
| f1-match-found | (proposta, proposta, NOUN) | (proposta, proposta, NOUN) | No changes are made; the triple matches the lexicon. |
| f1-modified-lemma | (altipiano, altopiano, NOUN) | (altipiano, altipiano, NOUN) | The lemma in the corpus is corrected to match the lexicon. |
| f1-modified-lemma+pos | (esuberanti, esuberare, VERB) | (esuberanti, esuberante, ADJ) | Both lemma and POS are corrected to align with the lexicon. |
| f1-form-missing | (prevvede, prevedere, VERB) | – | The form is missing from the lexicon and flagged for review. |
| Phase 2, Lexicon: MIDIA | | | |
| f2-validated-lemma | (com', come, ADV) | (come, come, ADV) | The corpus triple is validated despite form variation; lemma and POS match the lexicon. |
| f2-different-pos | (rassicurantissime, rassicurante, ADJ) | (rassicurante, rassicurare, VERB) | The same form appears in the lexicon with a different lemma and POS; the corpus POS is retained for further analysis. |
| f2-missing | (fidenti, fidente, ADJ) | – | The form and lemma are absent from the lexicon and marked as missing. |
| Phase 3, Lexicon: TLIO | | | |
| f3-valid-lemma-F | (accecamento, accecamento, NOUN) | (accecamento, accecamento, NOUN) | The triple is validated; it matches the lexicon entry. |
| f3-modified-lemma-F | (disolate, disolato, ADJ) | (disolate, desolato, ADJ) | The lemma is corrected to align with the TLIO lexicon. |
| f3-modified-lemma-L | (adirizar, adirizare, VERB) | (adirizare, addirizzare, VERB) | The triple is normalized using the lemma assigned to the variant in the lexicon. |
| f3-valid-lemma-L | (succian, succiare, VERB) | (succiare, succiare, VERB) | The triple is validated; the lemma is found in the lexicon with matching POS. |
| f3-different-lemma-pos | (ubbriachi, ubbriaco, ADJ) | (ubbriaco, ubriaco, NOUN) | Lemma and POS differ from the lexicon; no change is applied. |
| f3-missing | (addobbamenti, addobbamento, NOUN) | – | Both the form and lemma are missing from the lexicon; no change is made. |

**Table 4**
Normalization examples for each phase.

| Label | UD-Italian Old | GDLI-QC | VGG |
|---|---|---|---|
| f1-match-found | 117,586 (96.35%) | 35,270 (96.3%) | 104,071 (96.13%) |

| f1-modified-lemma+pos | 196 (0.16%) | 92 (0.25%) | 85 (0.08%) |
| f2-validated-lemma | 579 (0.47%) | 177 (0.48%) | 2,325 (2.15%) |
| f2-different-pos | 43 (0.04%) | 53 (0.14%) | 66 (0.06%) |
| f3-modified-lemma-L | 3 (0%) | 5 (0.01%) | 29 (0.03%) |
| f3-valid-lemma-L | 102 (0.08%) | 23 (0.06%) | 105 (0.1%) |
| f3-modified-lemma-F | 563 (0.46%) | 96 (0.26%) | 35 (0.03%) |
| f3-valid-lemma-F | 560 (0.46%) | 59 (0.16%) | 57 (0.05%) |
| f3-different-lemma-pos | 410 (0.34%) | 68 (0.19%) | 408 (0.38%) |
| f3-missing | 2062 (0.69%) | 266 (0.73%) | 924 (0.85%) |

**Table 5**
Distribution of cases across the three normalization steps for each source.

Stanford Dependency Treebank) (Bosco et al. [18]). For comparison purposes, we also trained a model using the original, non-normalized versions of the historical corpora. In the remainder of this paper, we refer to the model trained on normalized data as NORM_Lem, and to the one trained on unnormalized original data as ORIG_Lem.

To evaluate the performance of the NORM_Lem and ORIG_Lem models, we conducted two sets of experiments, each with a distinct objective. The first set was designed to assess the impact of low-level versus high-level normalization on lemmatization accuracy (Section 5.1). For this purpose, we performed 5-fold cross-validation: in each fold, the dataset was divided into a training set (containing 14,419 sentences, corresponding to the 80% of the full dataset), a validation set (4,806 sentences, 10%), and a test set (4,806 sentences, 10%). As detailed in Table 6, the internal composition of the validation and test sets was representative of the four different corpora used for training in similar proportions.

The second set of experiments aimed to evaluate the accuracy and robustness of the normalized lemmatization model on an external historical corpus (Section 5.2). In this case, the model was trained on the entire dataset and tested on a selection of sentences from the MIDIA corpus, which had been semi-automatically converted into the UD format. This evaluation allowed us to test

the generalizability of the NORM_Lem model beyond the data it was trained on.

# 5. Lemmatization Results

## 5.1. Low- vs High-level Normalization Results

The first set of experiments was conducted using 5-fold cross-validation. The NORM_Lem and the ORIG_Lem models were tested on the normalized and original versions of the treebanks respectively. Table 7 presents the accuracy scores for each fold, as well as for the entire DEV and TEST sets. In all cases, the NORM_Lem model consistently outperforms the ORIG_Lem model, both across individual folds and on average. A reduction in the number of incorrectly lemmatized tokens is observed for source corpora, with the most notable improvement in the UD-Italian Old corpus, where NORM_Lem yields a 0.38% decrease in lemmatization errors on both the DEV and TEST sets. An exception to this trend is GDLI-QC, for which both models show a slight drop in accuracy (−0.18 on both DEV and TEST). The VGG corpus is less affected by normalization, showing a reduction in lemmatization errors of 0.11%.

We also analysed the results by part-of-speech (POS). Table 8 reports the error rates in the TEST set. Aside from NUM (numerals), which is the worst-performing category with an increase of errors with the NORM_Lem model, the POS with the highest error rates (above 3%) are ADJ, VERB, and PROPN, followed by NOUN and PRON, with error rates of 2.37% and 1.87% respectively. All other POS categories show error rates below 1%. Errors involving ADJs and VERBs are mainly ascribable to the ambiguous use of past participles, which often alternate between verbal and adjectival function, a frequent source of lemmatization errors. As for NOUNs, the observed errors may also be linked to the treatment of derived forms, whose lemmatization may not always be consistent across treebank sources. Regarding NUM, the category with the highest error rate, we noted that most errors involve Roman numerals, often misinterpreted as PROPN.

| ORIG_Lem model |  |  |

## 5.2. Testing NORM_Lem with an External Historical Corpus

In the second set of experiments, we focused on the NORM_Lem model with the aim of evaluating its accuracy and robustness on an external historical corpus. The test set comprises a selection of sentences from the MIDIA corpus, for a total of 5,116 tokens. The sentences are acquired from ten different texts to ensure diversity in terms of genre and period of composition. In fact, the texts span a broad chronological range, from the early 14th century to the mid-19th century, thus offering a representative sample of linguistic variation across different evolution stages of the Italian language. In terms of genre distribution, the dataset includes three subsets of expository essays, three of scholarly or scientific texts, two of literary prose texts, and two of personal correspondence. This selection, which includes textual genres not represented in the training corpus, aims to evaluate the robustness of the NORM_Lem model in the face of stylistic, genre, and diachronic variation.

The overall lemmatization accuracy achieved by the NORM_Lem model on the external test set is 96.59%. While this score is slightly lower than the average accuracy obtained in the 5-fold cross-validation experiment described above, such a difference is expected given that the test set comprises previously unseen texts that partially differ both in genre and chronological coverage from the training data. The slight performance drop reflects the increased difficulty posed by domain shift, particularly with respect to historical variation (in this MIDIA sample there are periods which are not covered in the training corpus) and text type.

A closer analysis of the accuracy of lemmatization over time, shown in Figure 1, reveals that the performance remains relatively stable over the centuries, with significantly high values, ranging from 93.58% to 97.44%. The lowest accuracy is observed for the text dated 1505 by Leonardo Da Vinci (93.58%). However, this drop seems more related to the complexity and idiosyncrasies of the text's genre (i.e., technical and fragmentary scientific notes) rather than to its chronological distance. Excluding this outlier, lemmatization accuracy across the remaining texts shows limited variance, with most scores clustering around 96–97%, indicating the robustness of the model to diachronic variation.

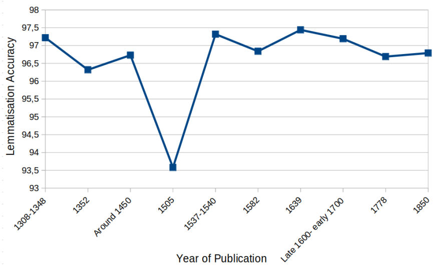

**Figure 1:** Lemmatization accuracy for different periods in the MIDIA test.

The genre-based evaluation further confirms this trend. The model performs best on personal correspondence and expository texts, achieving in both cases an accuracy of 96.94%, closely followed by literary prose (96.87%). Slightly lower accuracy is recorded for scientific texts (95.88%), very likely due to genre-specific linguistic characteristics, such as technical terminology, irregular syntax, and less standardized spelling. However, the performance remains consistently high across all genres, confirming the generalizability of the NORM_Lem model to different types of historical texts.

An analysis of lemmatization errors by part-of-speech (POS) on the external test set (Table 10) reveals patterns that are largely consistent with those observed in the five-fold evaluation, while also highlighting genre- and domain-specific challenges. As in the internal evaluation, ADJ, VERB, and PROPN remain among the POS with the highest error rates, recording values of 9.59%, 6.71%, and 6.80%, respectively, in the full test set. These results confirm the persistent difficulty posed by adjectives and verbs, often due to the ambiguous status of past participles that can function both as verbal and adjectival forms. Errors in the PROPN category remain notably high, particularly in scientific texts (21.43%). However, this result should be interpreted with caution, as it is influenced by the low frequency of proper nouns in these texts. Although the proportion of incorrectly lemmatized proper nouns appears substantial, the scientific subcorpus contains only 14 PROPN tokens in total. This small sample size limits their overall impact on the test set and may inflate the observed error rate due to sampling effects. ADV,

| POS | Expos. | Letters | Lit. Prose | Science | All Test |
|---|---|---|---|---|---|
| ADJ | 5.83 | 6.67 | 6.49 | 16.26 | 9.59 |
| ADP | 0.48 | 0 | 0.63 | 0 | 0.29 |

| **Global** | 3.06 | 3.06 | 3.13 | 4.12 | 3.41 |

**Table 9**
Percentage of erroneously lemmatized tokens by POS and by genre obtained by the NORM_Lem model against the MIDIA test set.

SCONJ, and DET also show minor fluctuations in accuracy, but their overall contribution to the global error rate remains limited. Errors in NOUN lemmatization reveal a range of recurrent challenges, including both lexical variation and morphological ambiguity. Several errors involve orthographic variants or archaic spellings that are typical of historical texts, such as *uppinione* lemmatized as UPPINIONE (instead of OPINIONE), or phonological or dialectal interference, e.g. *ariento* lemmatized as such instead of ARGENTO. Other errors highlight semantic or derivational mismatches, where the model fails to associate the inflected form with the appropriate lemma. For example, the wordform *diletti* is incorrectly lemmatized as DILETTARE (VERB) rather than DILETTO (NOUN). Finally, some errors involve mislemmatization due to homography or syntactic ambiguity, as seen, e.g., with *mostra* lemmatized as MOSTRARE, where the model incorrectly assumes a verbal or adjectival interpretation. Such cases may be tied to the POS-lemmatization interaction, where contextually ambiguous forms are resolved incorrectly, possibly due to inconsistent POS-tag/lemma alignments in training data.

Interestingly, NUM errors are less prominent in the external test set compared to the five-fold validation, likely due to the lower frequency of Roman numerals or a more predictable usage context. Other categories such as ADP, CCONJ, and AUX remain highly stable, with error rates below 1%, suggesting that closed-class words are generally well handled by the model, even in previously unseen texts.

Overall, the distribution of errors confirms the robustness of the NORM_Lem model across POS categories, while also emphasizing the influence of genre-specific lexical and morphological variation, particularly in scientific and early modern texts.

| Genre | Wrong | Correct |
|---|---|---|
| Letters | 0.25 | 0.75 |
| Lit.Prose | 0.30 | 0.70 |
| Science | 0.35 | 0.65 |
| Expositive | 0.35 | 0.65 |
| All | 0.32 | 0.68 |

**Table 10**
Percentage of wrong and correct lemma predictions by genre in Out-of-vocabular words.

Last but not least, we analyzed how the NORM_Lem model handles the challenge of Out-Of-Vocabulary (OOV) words — i.e., words not included in the pre-trained vocabulary — which typically lead to degraded model performance. The results reported in Table 10 are consistent with our previous observations: the highest percentage of incorrect predictions is found in Science and Expository texts (35%). This percentage decreases to 30% in Literary Prose and to 25% in Letters. We further examined the incorrect predictions by part of speech (POS), revealing that the most problematic categories are still NOUNs (30%), VERBs (27%), ADJECTIVEs (22%), and PROPER NOUNs (5%), which together account for 84% of the errors in OOV words. A closer inspection of individual cases suggests that there is still room for improvement: several errors are due to case mismatches, while others involve derivative formations.

## 6. Conclusion and Future Work

This paper has addressed the role and impact of different lemma definition strategies in automatic lemmatization, with a particular focus on historical language varieties. Specifically, we presented a comparative study of two lemmatization strategies for historical Italian: a conservative approach and a normalized one. The model trained on normalized data (NORM_Lem) was compared to a counterpart trained on unnormalized corpora, i.e. following a conservative lemmatization approach (ORIG_Lem). Both models were evaluated intrinsically via five-fold cross-validation. Results consistently favored the NORM_Lem model, which outperformed ORIG_Lem across all folds, achieving higher accuracy and reducing the number of incorrectly lemmatized tokens.

To further evaluate the effectiveness and generalization capacity of the NORM_Lem model, we tested it on an external dataset including textual genres and historical periods not represented in the training data. Although overall accuracy on this out-of-domain test set was slightly lower — due to domain and temporal variation — the model maintained strong generalization capabilities, with stable lemmatization accuracy across different historical periods. From a genre-specific perspective, lower accuracy was observed in scientific texts, where challenges such as domain-specific terminology and Latinized proper names were more prominent. A detailed POS-based error analysis confirmed that adjectives, verbs, and proper nouns remain problematic, often due e.g. to morphological ambiguity or derivational complexity. These findings align with previous observations on the limitations of character-based neural models in capturing morpho-syntactic regularities in low-frequency or irregular data, especially in historical language varieties.

Overall, our results provide empirical evidence that high-level normalized lemmatization improves the performance of data-driven models applied to morphologically rich and orthographically variable languages like historical Italian. In particular, high-level normalization emerges as a valuable preprocessing step for lemmatization tasks involving historical corpora. However, the trade-off between normalization and linguistic fidelity should be carefully considered, especially in philological or interpretative contexts where access to attested variants is essential.

Future work will explore hybrid approaches that combine normalization with variant-aware lemmatization strategies, potentially through multitask learning or post-lemmatization clustering techniques. Another promising direction involves assessing the impact of different lemmatization strategies on downstream tasks — such as information retrieval, syntactic parsing, or historical named entity recognition — in order to evaluate their broader utility within practical NLP pipelines.

## Acknowledgments

We gratefully acknowledge the support of the project *CHANGES – Cultural Heritage Innovation for Next-Gen Sustainable Society* (PE00000020), funded under the NRRP program of the Italian Ministry of University and Research (MUR) and financed by the European Union through NextGenerationEU. Furthermore, we express our sincere gratitude to the team who designed, developed, and currently maintains the MIDIA corpus, and, in particular, to Claudio Iacobini for his great support. Last but not least, we thank Felice Dell'Orletta and Alessio Miaschi for their precious suggestions in designing the experiments, and Elisa Guadagnini for her helpful comments on lemmatization criteria of historical Italian.

**Abstract**

Urban policy makers require comprehensive insights into transportation issues and demographic distributions to design equitable and efficient infrastructure. However, analyzing multi-modal data (numeric and visual) while accounting for diverse perspectives remains challenging. To address this, we propose PeRAG, a novel pipeline combining multi-modal perspective-oriented verbalization with Retrieval-Augmented Generation (RAG). Our approach first converts numeric transportation/demographic data and population heatmaps into natural language descriptions using LLaMA, incorporating multiple policy-relevant perspectives. These verbalizations are then fed into the RAG system to generate context-aware, perspective-driven responses for urban planners. We demonstrate the effectiveness of PeRAG in generating actionable insights for transportation policy, bridging the gap between raw data and decision-making. Our experiments highlight the pipeline's ability to handle heterogeneous data modalities while adapting to diverse stakeholder viewpoints, offering a scalable solution for smart city analytics.

**Keywords**

Multi-modal Verbalization, Retrieval-Augmented Generation (RAG), Perspective-Aware NLP, Large Language Models (LLMs), Urban Transportation Analytics

## 1. Introduction

Urban policy makers face significant challenges in designing equitable transportation systems due to the complex interplay of demographic shifts, infrastructure constraints, and socio-economic disparities [1]. Raw data (e.g., transit logs, census metrics, heatmaps) is often siloed, requiring labor-intensive integration to derive insights [2, 3]. While NLP and computer vision techniques have been applied to urban analytics, they typically treat data modalities independently, ignoring the need for cross-modal reasoning (e.g., correlating heatmap patterns with numeric poverty indices) [4]. This limits their utility for policy decisions requiring holistic, interpretable inputs.

In recent years, advances in machine learning and NLP have enabled new forms of automated data interpretation, particularly in multimodal settings where information spans both structured and unstructured modalities [5]. Urban environments provide a rich case for multimodal reasoning: data can include numerical variables (e.g., population size, number of transport lines), visual artifacts (e.g., heatmaps of population density), and geographical descriptors (e.g., district boundaries). Integrating and interpreting these different modalities coherently is essential for supporting informed decision-making.

One of the emerging challenges in this context is perspective-aware verbalization, the task of transforming multimodal data into textual descriptions that reflect different analytical or stakeholder viewpoints [6]. For instance, the same urban dataset can be verbalized from a demographics perspective ("This area has a high population of elderly residents") or a transportation accessibility perspective ("This zone has limited coverage of public transport lines despite high population density"). Generating such targeted descriptions from numeric and image data requires models that understand not only the input modalities but also the intended angle of interpretation [7]. This introduces both linguistic complexity—in choosing appropriate vocabulary, structure, and focus—and reasoning complexity—in determining what information is salient for a given perspective.

These challenges compound when integrated into retrieval-augmented generation (RAG) pipelines. Traditional RAG frameworks are typically designed for text-based retrieval from large knowledge bases; extending them to operate over generated textual representations of multimodal data introduces new issues: retrieval is

only as effective as the fidelity and perspective alignment of the verbalized input, and generation must remain factual, grounded, and contextually relevant [8]. Moreover, multimodal verbalizations are often more compact and abstract than traditional long-form documents, which poses difficulties in relevance ranking and context-aware generation.

In this work, we investigate the following core research questions:

1. How can multimodal data (numeric and visual) be verbalized in a perspective-aware manner to support policy-level interpretation?
2. What are the linguistic and functional trade-offs between zero-shot and few-shot verbalization approaches in this context?
3. Can a lightweight, locally-deployable RAG pipeline (PeRAG) effectively answer urban policy questions when built on top of such verbalizations?
4. How does the factuality and utility of such a system compare to general-purpose LLMs, especially in high-stakes policy scenarios?

To address these questions, we present PeRAG, a novel framework that combines multimodal data verbalization with a perspective-aware Retrieval-Augmented Generation pipeline. Our work is based on a custom dataset for the city of Turin, comprising over 7,000 examples across multiple years (2012–2019), including 31 features covering demographics, transportation, and traffic. We verbalize both numeric and heatmap data into English summaries across several perspectives (e.g., demographics-focused, transport lines-focused, temporal shifts), using *LLaMA-3.1-8B* for the verbalization of numeric data, and *LLaMA-3.2-11B-Vision* for the verbalization of heatmap data in zero-shot and few-shot settings. These verbalizations serve as the retrievable memory in a *Gemma-3-4B-IT*-powered RAG system, which supports question-answering on urban policy issues. All models are run locally to ensure data privacy and control.

Our key contributions are as follows:

- We introduce a multi-modal perspective-aware verbalization pipeline that generates textual summaries from numeric and image data for urban policy domains.
- We propose and implement PeRAG, a lightweight RAG-based QA framework grounded in multimodal verbalizations, optimized for locally-deployable urban analytics.
- We explore and analyze zero-shot vs. few-shot verbalization strategies in real-world settings, providing insight into generation fidelity and perspective alignment.
- We conduct human evaluation and qualitative analysis to assess factuality and relevance, and compare PeRAG outputs against general-purpose LLMs.

The rest of this paper is organized as follows: Section 2 reviews related work in multimodal NLP, verbalization, and RAG systems. Section 3 describes the methodology, including dataset details, verbalization techniques, and system architecture. Section 4 outlines our experimental setup. Section 5 presents results from verbalization and QA evaluations. Section 6 offers a detailed analysis and discussion. Section 7 concludes the paper and outlines directions for future work.

## 2. Related Work

Perspectivism in NLP is an emerging approach that emphasizes representing and reasoning with multiple, potentially divergent, viewpoints. Traditional NLP systems often adopt a mono-perspective stance, optimizing for a generalized “truth” or majority viewpoint. In contrast, recent work has called for more inclusive approaches that recognize and operationalize multiple coexisting viewpoints [9, 10].

In this context, Data Perspectivism [10] proposes that AI systems—especially in socially sensitive domains—should be capable of tailoring outputs to the values and expectations of distinct population segments. Though this paradigm has influenced tasks in Natural Language Understanding (NLU), its application in Natural Language Generation (NLG)—especially from heterogeneous data sources—is still under-explored. Our work addresses this gap by extending perspectivist reasoning to the generation of text from multimodal data, creating perspective-conditioned verbalizations that help communicate the same data through different analytical and social lenses.

Current multi-modal NLP approaches integrate structured and unstructured sources—such as tables, images, and text—but usually with the aim of generating a single canonical description (e.g., image captioning or data-to-text generation). What is largely missing is the ability to generate multiple alternative descriptions of the same input, each aligned with a distinct interpretive frame.

Our work situates itself uniquely at this intersection—producing diverse textual outputs from structured numeric and image-based urban data, each representing a different lens (e.g., accessibility for elderly residents, environmental concerns, transit network optimization). In this way, we operationalize perspectivism across modalities and offer diverse conditioned NLG from heterogeneous sources, a setting largely unexplored in current literature.

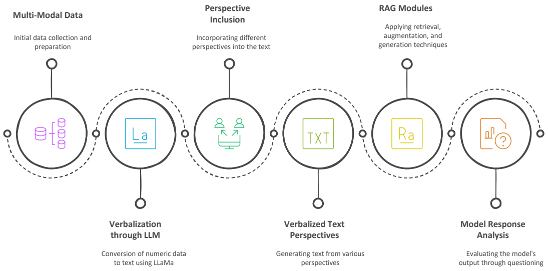
A major research avenue in knowledge-enhanced language modeling is Retrieval-Augmented Generation (RAG), in which a retriever module selects relevant textual passages from a knowledge base that are then fed into a generator to produce a grounded, informative response [8, 11]. This has been particularly effective in tasks like open-domain QA, summarization, and dialogue. Variants such as MuRAG [12] have explored incorporating multiple modalities into retrieval pipelines.

In our work, we adapt and extend the RAG architecture for perspective-aware generation by populating the retrieval index with natural language verbalizations that encode distinct viewpoints over the same input data. Unlike knowledge injection methods that incorporate triplet-based structured knowledge [13], we work purely with free-text verbalizations generated from multimodal data. The retriever retrieves relevant perspective-conditioned passages, and the generator uses them to compose contextually rich, stakeholder-specific responses. This results in a system—PeRAG (Perspective-aware RAG)—that enables context-sensitive generation not just based on topical relevance but on the interpretive stance encoded in the input text passages. To the best of our knowledge, PeRAG represents the first instantiation of RAG tailored for multi-perspective decision support in urban governance contexts.

Although LLMs such as ChatGPT and GPT-3 [14] have shown great success in general-purpose generation tasks, their application in decision-making processes has been limited by a lack of specificity and contextual adaptation [15]. Generic outputs are often insufficient in high-stakes domains like urban planning, where conflicting group needs (e.g., between commuters, the elderly, and environmentally conscious citizens) must be mediated through nuanced communication strategies. Efforts like BLOOM [16] have underlined the importance of transparent, representative training data, particularly for multilingual settings. However, our implementation is currently focused on English language generation, which remains dominant in LLM infrastructure and evaluation. By operating entirely in English while incorporating multi-perspective reasoning, our approach can generalize to multilingual contexts in future iterations but already demonstrates strong utility in data-rich governance scenarios [17].

# 3. Methodology

Our methodology introduces a novel pipeline that bridges heterogeneous urban data and perspective-aware natural language generation using a tailored Retrieval-Augmented Generation (RAG) architecture. The following subsections detail our approach to homogenizing structured inputs, dataset preparation, verbalization strategies, system design, and evaluation.



Multi-Modal Data
Initial data collection and preparation
Verbalization through LLM
Conversion of numeric data to text using LLaMa
Perspective Inclusion
Incorporating different perspectives into the text
Verbalized Text Perspectives
Generating text from various perspectives
RAG Modules
Applying retrieval, augmentation, and generation techniques

## 3.1. Homogenizing Heterogeneous Urban Data for RAG

Unlike conventional RAG systems that are designed to interface with a variety of knowledge representations—including tables, RDF triples, JSON schemas, and unstructured documents—our approach standardizes heterogeneous urban data into a unified format of unstructured textual narratives. This design choice fundamentally simplifies the retrieval mechanism and maximizes compatibility with LLM-based generation models. Rather than adapting the retriever to handle multiple data representations, we adopt a single retriever pipeline enabled by transforming structured data, including tables, geospatial indicators, and statistical measures, into natural language paragraphs. The resulting textual narratives are semantically enriched and explicitly crafted to reflect distinct analytical perspectives, ensuring that core domain-specific patterns are preserved while adapting the framing to match varied stakeholder viewpoints.

The homogenization approach offers several key advantages for urban policy applications. First, retrieval simplification is achieved through a unified representation that allows for a single dense retriever without requiring modality-specific modules, reducing system complexity and computational overhead. Second, our approach enables cross-modal comparability by facilitating reasoning across different data types, such as comparing demographics with transportation patterns through uniform verbal representations. Third, LLM compatibility is naturally reinforced by using natural language as both input and output, aligning with the intrinsic design of generative models and enabling seamless integration into query-response pipelines. Figure 1 outlines how PeRAG's components, multi-modal data, verbalization, perspective inclusion, RAG modules, and evaluation, integrate within the pipeline.

## 3.2. Dataset Description

The dataset comprises 7,019 urban data records covering Turin's geography, demography, and transportation systems from 2012 to 2019, offering a comprehensive longitudinal view of urban dynamics.

The data encompasses 3,850 census areas, which are portions of municipal territory organised in polygons, used by ISTAT[1] to divide the city into manageable, statistically meaningful areas. Demographic information about each census area is collected with respect to size and population distribution. Special attention is given to urban vulnerabilities, housing conditions, migration flows, and demographic changes in specific neighborhoods. Census areas can vary significantly in both size and demographic characteristics—they can be as small as a single street or encompass an entire residential block. For this reason, the census areas differ greatly from one another.

The census area is the smallest territorial unit used for analysis and is organized into 93 statistical zones. Statistical zones are aggregations of multiple census tracts and represent one of the intra-municipal territorial units into which the territory of the City of Turin is divided. In turn, the statistical zones are grouped into 9 districts - territorial subdivisions over which the local civil authority exercises its functions. This hierarchy of spatial units provides multiple levels of geographical granularity for analysis, enabling both fine-grained local insights and broader district-level policy evaluation. Additionally, the data for each census area is available for two reference years: 2012 and 2019, allowing for temporal comparisons across various dimensions. The dataset includes 31 structured features for each census-year tuple, systematically categorized into four primary domains.

Demographic information includes population density, gender distribution, age brackets, foreign residents, and the number of families, providing a comprehensive population profile. Additionally, the density of each demographic is calculated within a 500-meter buffer from the centroid of each census area. This approach accounts for the spatial distribution of density and makes the areas more comparable in terms of population concentration and access to services.

Public transport metrics include stop and line density, as well as connectivity indicators that measure how well each census area is linked to others in terms of accessibility and network coverage. Geographical identifiers encompass census codes, dimensions, statistical zones, district names, and boundaries that enable spatial analysis and policy targeting. Traffic and safety data document the number of accidents, vehicle involvement patterns, and the number of public transport incidents, supporting risk assessment and safety planning initiatives. This collection represents a significant expansion, enabling richer temporal and spatial analyses that capture urban evolution patterns and long-term policy impacts. The longitudinal scope allows for trend identification, seasonal pattern analysis, and evaluation of policy interventions over time.

The dataset was constructed by integrating multiple sources: all demographic data was obtained from the GeoPiemonte[2] portal, while public transport, traffic, and safety data were provided by Gruppo Torinese Trasporti (GTT)[3], which manages public transport services including urban, suburban, and extra urban routes, as well as tram and metro lines.

## 3.3. Perspective-Aware Verbalization of Urban Data

To enable retrieval over rich, interpretable textual data, we developed an Urban Data Verbalization System that translates structured urban records into fluent natural language narratives using large language models (LLMs). This system addresses the fundamental challenge of transforming quantitative urban data into qualitative insights that align with different stakeholder perspectives and analytical frameworks.

### 3.3.1. Verbalization

Our verbalization pipeline employs *LLaMA-3.1-8B* as the default model for processing numerical data and *LLaMA-3.2-11B-Vision* for processing heatmaps. The selection of these models allows us to maintain compatibility with other LLMs, ensuring both flexibility and reproducibility. We implement two primary verbalization strategies to balance generation quality with computational efficiency. Zero-shot verbalization allows the model to generate descriptions without specific examples, providing maximum creative freedom but potentially sacrificing consistency. Few-shot verbalization employs carefully curated single-shot examples that guide narrative style while preserving creative expression, resulting in more consistent and domain-appropriate outputs.

The system utilizes handcrafted prompts specifically designed to elicit structured yet non-hallucinatory summaries for each data record, ensuring factual accuracy while maintaining linguistic diversity. Two distinct prompt templates are employed: one for processing numerical tabular data using LLaMA-3.1-8B (see Table 6), and another for processing heatmap visualizations using LLaMA-3.2-11B-Vision (see Table 5). Complete prompt examples for both verbalization modalities are provided in Appendix C to ensure reproducibility. In both LLaMA configurations, generation control is achieved through carefully tuned parameters, including temperature set to 0.6 for optimal creativity balance, top-5 sampling at 0.9 for response diversity, repetition penalty of 1.2 to ensure

[1] National Institute of Statistics: https://www.istat.it/

[2] https://geoportale.igr.piemonte.it/cms/

[3] https://www.gtt.to.it/cms/

coherence, and the maximum token length is set to 512 for the 8B version and 1024 for the 11B-Vision version to support concise yet informative descriptions.

Each structured record is transformed into multiple narrative versions conditioned on distinct stakeholder perspectives. These include accessibility-oriented planning focusing on mobility and inclusion, safety and equity perspectives highlighting transportation risks and distribution fairness, and demographic inclusion addressing the needs of diverse populations. This multi-perspective approach ensures that verbalizations transcend generic summaries and address the specific analytical needs of different urban stakeholders. Table 3, presented in Appendix A, provides an example of this type of verbalization, illustrating both a general narrative and its corresponding multi-perspective version.

#### 3.3.2. Quality Assessment and Validation

Unlike conventional LLM-generated general texts, which often suffer from loss of specificity, repetitiveness, or context ignorance, our perspective-aware narratives emphasize trends, deficiencies, and socio-geographic factors of particular interest to diverse urban stakeholders. The annotation protocol involved a systematic evaluation across four key dimensions: (1) contextual relevance whether the verbalization appropriately captures the urban context and stakeholder perspective, (2) information accuracy alignment between the verbalized content and source data, (3) coverage of information aspects completeness of perspective-specific elements in the verbalization, and (4) data factuality dealing with absence of hallucinations or fabricated information. Three expert annotators, including two postdoctoral researchers and one NLP researcher, independently evaluated a random sample of generated narratives for each dimension. Given the exploratory nature of this novel task and time constraints, a focused evaluation was conducted on a carefully selected subset of examples, with annotation disputes resolved through collaborative discussion among the research team. Their comprehensive assessment confirmed the validity, relevance, and framing alignment of perspective-aware verbalizations, providing empirical support for their use in downstream RAG generation tasks.

To mitigate potential ambiguities introduced during the natural language verbalization process, our approach incorporates several safeguards. First, the verbalization prompts explicitly instruct models to use exact numerical values without modification or approximation, preventing quantitative distortions. Second, the prompts restrict models from drawing conclusions, making assumptions, or interpreting data significance, thereby reducing interpretive ambiguity. Third, during the annotation process, evaluators specifically assessed verbalizations for information accuracy and data factuality, identifying instances where ambiguous phrasing might misrepresent the underlying data. Additionally, the multi-perspective approach inherently reduces ambiguity by providing explicit analytical framing, rather than generating generic descriptions that could be interpreted in multiple ways.

### 3.4. Perspective-Aware RAG (PeRAG)

PeRAG extends the traditional RAG paradigm to handle structured urban data through its verbalized form, creating a novel architecture specifically designed for perspective-aware policy support. The system integrates retrieval and generation components that work synergistically to provide contextually relevant and factually grounded responses to complex urban planning queries.

#### 3.4.1. Retrieval Module

The retrieval module employs the *all-mpnet-base-v2* sentence transformer for dense vector encoding, chosen for its superior performance on semantic similarity tasks and computational efficiency. Text chunking is implemented using a token-based approach with a chunk size set to 500 tokens and an overlap of 50 tokens to ensure semantic continuity across chunk boundaries. This strategy ensures that semantically related content remains within the same retrievable segment, preserving coherence and relevance across retrieval operations.

The retrieval mechanism operates through cosine similarity-based semantic ranking with configurable top-k retrieval, defaulting to 5 results to balance comprehensiveness with computational efficiency. The system maintains comprehensive provenance metadata for complete traceability, enabling users and analysts to verify the source of retrieved information and ensuring accountability in policy-relevant applications.

#### 3.4.2. Generation Module

The generation module utilizes *Gemma-3-4B-IT* as the default model while supporting any causal decoder-based large language model to ensure adaptability across different computational environments. The module processes user queries alongside retrieved perspective-aligned narratives using carefully engineered prompts that structure the input format as query plus perspective narratives.

Generation parameters are optimized for policy applications, with a temperature of 0.7 balancing creativity and factuality, and a 512-token limit ensuring brevity without sacrificing informational depth. The system demonstrates robust capability in responding to complex urban planning questions, supporting district-wise comparisons, demographic-transport correlations, safety and infrastructure assessments, and trend identification over temporal dimensions.

### 3.5. Implementation and System Efficiency

The full system is implemented in Python, leveraging PyTorch and Hugging Face Transformers for deep learning and natural language processing tasks, alongside SentenceTransformers for semantic retrieval capabilities. The implementation includes comprehensive batch processing capabilities with integrated performance monitoring to ensure scalable operation across large datasets. GPU acceleration with automatic device detection optimizes computational efficiency while maintaining compatibility across different hardware configurations.

The system architecture incorporates detailed logging for each transformation step, enabling comprehensive debugging and performance analysis. Key operational features include support for batch verbalization, which processes multiple records simultaneously; real-time querying capabilities for interactive policy analysis; and modular model swapping, allowing for easy adaptation to different language models or domain-specific requirements. This implementation approach ensures both research reproducibility and practical deployment feasibility for real-world urban policy applications. The source code for our PeRAG system, along with the various verbalization configurations, is publicly available at the following link[4]

## 4. Experimentation

Our experimental evaluation is designed to assess the effectiveness of perspective-aware verbalization and the overall performance of the PeRAG system in supporting urban policy decision-making. We conduct experiments across two primary dimensions: verbalization quality assessment and end-to-end system performance evaluation. All experiments are performed on locally deployed models to ensure data privacy and reproducibility, using NVIDIA GPUs for computational acceleration.

The experimental framework evaluates our system against several key research questions established in the introduction: the effectiveness of perspective-aware verbalization compared to general approaches, the comparative performance of zero-shot versus few-shot verbalization strategies, the utility of PeRAG for urban policy question answering, and the factuality and relevance of system outputs compared to general-purpose large language models.

### 4.1. Verbalization Evaluation Protocol

We conduct a systematic comparison between general verbalization, i.e., template-based approach, and perspective-aware verbalization approaches using our Turin dataset. General verbalization employs standard data-to-text generation without specific perspective conditioning, while perspective-aware verbalization generates targeted descriptions aligned with specific stakeholder viewpoints, including demographics-focused, transportation infrastructure-focused, temporal analysis, and deficiency assessment perspectives.

A random sample of 200 data records is selected for detailed verbalization analysis, ensuring representation across different districts, time periods, and demographic profiles. Our multi-modal dataset is processed through both zero-shot and few-shot verbalization strategies for each perspective type, generating a comprehensive corpus of verbalized descriptions for comparative evaluation.

For the verbalization quality assessment, two authors jointly annotated three representative examples in a structured meeting format, with any disagreements resolved through immediate discussion. While the limited sample size ($n = 3$) precluded formal inter-annotator agreement (IAA) calculation using Cohen or Fleiss' Kappa, the collaborative annotation process ensured consistency in evaluation criteria application. Future work will expand the annotation sample size to enable robust inter-annotator reliability metrics.

### 4.2. System Performance Evaluation

We develop a comprehensive set of 25 urban policy-oriented questions that span different complexity levels and analytical requirements. The question set includes factual queries about specific demographic or transportation metrics, comparative questions requiring cross-district or temporal analysis, analytical questions demanding trend identification and causal reasoning, and policy-oriented questions seeking recommendations based on data insights.

Questions are categorized by type (factual, comparative, analytical, policy-oriented), complexity level (simple, moderate, complex), and required perspective alignment (demographics, infrastructure, temporal, deficiency-focused). This categorization enables a systematic assessment of system performance across different query types and complexity levels.

System performance is evaluated against multiple baseline approaches to assess the contribution of our perspective-aware framework. These baselines involve querying general-purpose LLMs without access to urban-specific data. For this purpose, we use the *Gemini 2.0 Flash* and *GPT-4o Mini* models. Additionally, we evaluate RAG systems using general (non-perspective-aware) verbalizations under both zero-shot and few-shot configurations. Each baseline is tested using the same set of questions and evaluation criteria to ensure a fair and consistent comparison.

[4] Code and dataset are available at https://github.com/MasterHoracio/CLiC-it-HARMONIA.git.

### 4.3. Evaluation Metrics

In order to evaluate the performance of our proposed perspective-aware framework, as well as all the baseline approaches, we employ the Retrieval Augmented Generation Assessment (RAGAS) framework, specifically designed for reference-free evaluation of RAG pipelines [18]. This framework defines three main metrics. The first, *faithfulness*, measures whether the answer accurately reflects information that can be directly inferred from the given context. The second, *answer relevance*, evaluates whether the answer directly and appropriately responds to the given question, without being incomplete or redundant. Finally, the third metric, *context relevance*, assesses how well the context includes only the necessary information to answer the question, avoiding redundancy. For a detailed explanation, we refer the reader to the following paper [18].

## 5. Results

Table 1 presents the evaluation results for the different configurations considered. The first section of the table (rows 2 and 3) shows the results obtained by directly querying the LLMs without providing any additional context. It is important to note that the *faithfulness* and *context relevance* metrics could not be computed in this case, as both require access to the retrieved context. Nevertheless, the *answer relevance* scores reveal low performance for both models. This can be attributed to the fact that most of the responses were of the type *"I cannot answer the question due to lack of necessary data"*. Specifically, GPT-4o responded this way in 21 out of 25 cases, while Gemini 2.0 did so in 18 out of 25. Overall, Gemini demonstrated marginally better performance in this setting.

Additionally, Table 1 also compares the performance of general verbalizations using zero-shot and few-shot configurations. These results are shown in the second section of the table (rows 4 and 5). As can be observed, the *answer relevance* scores are higher than those obtained by the previously evaluated LLMs, which can be attributed to the incorporation of relevant information retrieved by the retrieval module. When comparing the general verbalization settings, we observe that the few-shot configuration outperforms the zero-shot setting across all three evaluation metrics, with an average improvement of 6%. This gain is likely due to the higher quality and greater level of detail present in the verbalizations generated under the few-shot configuration.

Finally, we present the evaluation results of our proposed PeRAG system. As shown, it achieves the highest scores across all three evaluation metrics, with an average improvement of 20% compared to the best-performing general verbalization configuration. Overall, the highest metric score was obtained in *faithfulness*, indicating that the responses generated by the PeRAG system effectively leverage information inferred from the provided context. On the other hand, the lowest score—both for PeRAG and previous configurations—was observed in the *context relevance* metric. This may be attributed to the diversity of information retrieved by the retriever module, which stems from the chunk partitioning strategy used. In particular, this strategy incorporated independent general and multi-perspective verbalizations for each district, zone, or census area.

**Table 1**
Evaluation results for the considered reference-free metrics. Reported values correspond to the average over the 25 evaluation questions. The prefixes ZS and FS indicate the *zero-shot* and *few-shot* configurations of the general verbalization.

| Approach | Faithfulness | Answer R. | Context R. |
|---|---|---|---|
| GPT-4o | - | 0.134 | - |
| Gemini 2.0 | - | 0.163 | - |
| ZS-RAG | 0.685 | 0.582 | 0.166 |
| FS-RAG | 0.725 | 0.595 | 0.184 |
| PeRAG | **0.793** | **0.626** | **0.272** |

## 6. Analysis

To gain deeper insight into the performance of our proposed PeRAG pipeline, this section presents a quantitative and qualitative analysis of the generated responses. In particular, we conduct a comparative evaluation of the answers produced by the RAG system using the different types of verbalizations. For this analysis, we randomly sample three questions from our set of 25, focusing on the *demographic* and *transportation* perspectives. The selection of three questions for detailed BERTScore analysis was determined by several practical constraints. First, generating reference factual answers for comparative evaluation requires extensive manual verification against the original Turin dataset, which is a time-intensive process involving careful cross-referencing of multiple data sources and temporal dimensions. Second, as this represents an initial exploration of a novel task combining multi-modal verbalization with perspective-aware RAG, we prioritized depth over breadth in the qualitative analysis to thoroughly examine the mechanisms underlying performance differences between general and perspective-aware verbalizations. Third, the computational overhead of generating responses across all verbalization configurations and computing detailed semantic similarity metrics scales considerably with the number of questions analyzed. The three selected questions were chosen to represent different complexity levels and analytical requirements.

For each of these questions, we generate a reference factual answer by manually extracting and synthesizing the relevant information directly from the original Turin dataset. The reference answer generation process involves several systematic steps: (1) identifying the specific data fields and temporal dimensions required to answer each question, (2) querying the structured dataset to retrieve exact numerical values for the relevant census areas, statistical zones, or districts, (3) performing necessary aggregations or comparisons across the 2012-2019 timeframe where temporal analysis is required, and (4) formulating a concise factual response that accurately reflects the quantitative findings without interpretive bias. For instance, for questions involving demographic trends, reference answers include precise population counts, percentage changes, and specific demographic categories affected, all derived directly from the census data. This manual reference generation process, while labor-intensive, provides ground-truth answers that serve as reliable baselines for evaluating the factual accuracy and completeness of system-generated responses through semantic similarity metrics. We use the BERTScore metric [19], a widely adopted measure of semantic similarity between a generated text and a reference [20]. Finally, we present a discussion highlighting the strengths and weaknesses of the PeRAG pipeline compared to general verbalizations.

Table 2 presents the BERTScore evaluation results for the three randomly selected questions. The first section of the table (rows 2 and 3) reports the results for the general verbalizations, where the *few-shot* configuration achieves the highest scores across all BERTScore metrics. These outcomes are consistent with the trends observed in the reference-free evaluation metrics. The second section of the table shows the results for our PeRAG pipeline, which consistently achieves the best performance across all three metrics, further reinforcing the findings obtained through the reference-free evaluation.

We acknowledge that the BERTScore analysis based on three questions represents a preliminary assessment of semantic similarity performance, and the limited sample size constrains the statistical generalizability of these findings. The selection was necessitated by the substantial manual effort required for reference answer generation and verification against the multi-dimensional Turin dataset. Each reference answer requires careful extraction and synthesis of information across multiple data fields, temporal dimensions, and geographical units, followed by independent verification by domain experts. While these three questions provide initial evidence of PeRAG's superior semantic alignment with ground truth data, we recognize that broader systematic analysis is essential for robust conclusions. Future work will implement automated reference generation procedures and expand the evaluation to cover the complete 25-question set, enabling more comprehensive statistical analysis of semantic similarity performance across different question types, complexity levels, and analytical perspectives. Additionally, we plan to incorporate multiple semantic similarity metrics beyond BERTScore to provide a more comprehensive assessment of response quality and factual alignment.

**Table 2**
Evaluation results based on BERTScore. The columns report the macro-average recall, precision, and $F_1$ score across the three randomly selected questions. The prefixes ZS and FS indicate the *zero-shot* and *few-shot* configurations of the general verbalization.

| Approach | Recall | Precision | $F_1$ |
|---|---|---|---|
| ZS-RAG | 0.818 | 0.831 | 0.821 |
| FS-RAG | 0.837 | 0.852 | 0.846 |
| PeRAG | **0.851** | **0.873** | **0.862** |

An important consideration in our verbalization approach is the management of potential linguistic ambiguities that could impact downstream RAG performance. Our analysis of generated verbalizations reveals that perspective-aware conditioning significantly reduces interpretive ambiguity compared to general verbalization approaches. For instance, when describing transportation infrastructure, general verbalizations might use ambiguous terms like ‘adequate coverage’ or ‘reasonable accessibility’, whereas perspective-aware verbalizations provide specific contextual framing, such as ‘limited accessibility for elderly residents due to sparse stop density in residential areas’. This specificity not only reduces ambiguity but also enhances retrieval precision, as queries can be matched more accurately to relevant perspective-conditioned content. However, we acknowledge that some residual ambiguity remains inherent to natural language representation, particularly in cases where numerical thresholds are verbalized using qualitative descriptors (e.g., ‘high density’ vs. specific population counts). Future work will explore hybrid approaches that preserve exact numerical values alongside natural language descriptions to further minimize interpretive ambiguity.

To compare the outputs generated by our different configurations, Table 4 (included in Appendix B) presents a comparison between the response produced by our PeRAG pipeline and the one generated using the *few-shot* configuration of the general verbalization. This configuration was selected due to its strong performance in both the reference-free metrics and the BERTScore. Additionally, both responses are contrasted with a reference answer constructed from factual information. The question used in this analysis was selected from the set of three randomly chosen questions.

As shown in Table 4, the selected question involves a temporal comparison of demographic characteristics from 2012 to 2019. According to the reference answer, a population decrease is observed across most demographic groups, including males, females, minors, foreigners, and working-age citizens. In contrast, the only group that experienced population growth during this period was senior citizens.

When comparing these findings to the output generated by the PeRAG pipeline, we observe that it successfully identified the overall downward trend across multiple demographic groups, highlighting that the reduction was not evenly distributed. This aligns with the factual data presented in the reference answer. Moreover, PeRAG accurately captured the groups that experienced decline—such as the working-age population, minors, and foreigners—and correctly identified an increase in the senior population, consistent with the reference.

However, the PeRAG response emphasized the working-age population as the most affected category, whereas the reference answer pointed to foreigners. This discrepancy may be attributed to the nature of the multi-perspective verbalizations, which were generated at the level of census areas, statistical zones, and districts. Consequently, when retrieving information using the retriever module (configured with $k = 5$), it may not have captured a fully comprehensive view across all nine districts. This limitation has been corroborated by analyzing the retrieved chunks, where recalculating the values based on the retrieved verbalizations indeed showed that the working-age group experienced the largest decline.

Finally, Table 4 also includes the output of the general verbalization under the *few-shot* configuration. As shown, the response generated by the RAG system fails to clearly identify the downward trends across the different demographic groups as well as the upward trend for seniors. These results are consistent with those observed in the reference-free evaluation metrics. Moreover, although the response is factually correct, it does not address the perspective implied by the question, highlighting the importance of incorporating perspective-aware verbalizations. Similar to the PeRAG pipeline, the retrieved chunks in this configuration also exhibit limitations, indicating a potential area for improvement in future work.

## 7. Conclusion

This research demonstrates that multimodal urban data can be effectively verbalized through perspective-aware approaches to support policy-level interpretation, with our framework successfully processing over 7,000 examples across multiple analytical perspectives (RQ1). The comparative analysis reveals that few-shot verbalization strategies provide superior generation fidelity and perspective alignment compared to zero-shot approaches, despite increased computational overhead (RQ2). PeRAG, our lightweight locally-deployable RAG pipeline, effectively answers urban policy questions by leveraging these multimodal verbalizations as retrievable memory, ensuring data privacy while maintaining system responsiveness (RQ3). Human evaluation confirms that PeRAG exhibits superior factuality and utility compared to general-purpose LLMs in high-stakes policy scenarios, with domain-specific grounding providing enhanced accuracy and contextual relevance (RQ4). The framework establishes a reproducible methodology for transforming complex urban datasets into actionable policy insights, demonstrating that specialized, domain-grounded AI systems outperform general-purpose alternatives in critical decision-making contexts.

**Limitations** The various perspectives explored in this research, such as demographic, population, transportation, gender, and age, were derived from the dataset used in our evaluation. However, these perspectives do not incorporate public opinion. As ongoing work, we are expanding these perspectives through a research survey aimed at integrating viewpoints that reflect public opinion of citizens and stakeholders of Turin. The annotation protocol, while systematic, was applied to a limited sample size due to the exploratory nature of this novel task. The collaborative annotation approach, though ensuring consistency, does not provide quantitative measures of IAA. Future iterations of this work will implement larger-scale annotation studies with multiple independent annotators and IAA metrics to strengthen the evaluation framework. Additionally, we are working at enriching the evaluation framework. We plan to complement the reference-free evaluation metrics applied [21] by incorporating task-based evaluation protocols and comprehensive human evaluation strategies to better assess the practical utility of perspective-aware verbalizations in real-world urban planning contexts.

**Table 3**
PeRAG Verbalization Example: Multi-Perspective Data Transformation

| Input/Perspective | Verbalization Output |
|---|---|
| **Numeric Input** | `year=2018; sez_cens=2535; stat_zone=75; area=145065.42; pop=192; perc_pop=2.69566E-05; perc_f=0.546875; per_immigrants=0.21875; perc_immigrants_F=0.135416667; perc_minor=0.130208333; perc_senior=0.223958333; n_stops=5; n_lines_stopping=5; perc_stops=0.026041667; perc_stops_per_line_stopping=1; perc_length_stopping=0.000167865` |
| **General Verbalization** | In 2018, census section 2535 in statistical zone 75 covered an area of 145,065.42 units, with a population of 192. The population percentage was approximately 0.0027%, of which 54.7% were female. Immigrants comprised 21.9% of the population, with 13.5% being female immigrants. Minors accounted for 13.0%, seniors 22.4%. There were 5 stops and 5 lines stopping, with stops representing 2.6% coverage, 100% stop-to-line ratio, and 0.017% length coverage. |
| **Demographics Perspective** | In 2018, census section 2535 in statistical zone 75 had a population of 192 individuals. Females accounted for 54.7% of the population. Immigrants represented 21.9% of residents, with female immigrants making up 13.5%. Children under 18 years old comprised 13.5% of the population, while seniors accounted for 22.4%. |
| **Population Perspective** | The total population of census section 2535 was 192, representing approximately 0.0027% of the overall population. The area covered by this section was 145,065.42 units, indicating a low population density given the large area size. |
| **Geographical Perspective** | Census section 2535 covers a substantial area of 145,065.42 units within statistical zone 75. Despite its size, the population remains small at 192 individuals. |
| **Transport Infrastructure** | Within census section 2535, there are 5 stops served by 5 lines. Stops cover 2.6% of the area, with an equal number of stops per line. The total length covered by stops corresponds to 0.017% of the area. |
| **Immigration Perspective** | Immigrants make up 21.9% of the population in census section 2535, with female immigrants comprising 13.5%. This suggests a significant immigrant presence within the local population. |
| **Age Group Perspective** | Minors account for 13.5% of the population in census section 2535, while seniors make up 22.4%, indicating a population with a notable proportion of older adults. |
| **Gender Distribution** | Females represent 54.7% of the population in census section 2535, showing a slightly higher female population compared to males. |

# A. Verbalization Examples

# B. Example of Output Response

# C. Verbalization Prompt Examples

To ensure reproducibility and transparency of our verbalization approach, we provide the complete prompt templates used for both numerical data (see Table 6) and heatmap verbalization (see Table 5).

## C.1. Heatmap Verbalization Prompt (LLaMA-3.2-11B-Vision)

The following prompt template is used for generating narratives from population density heatmaps and other visual data representations:

## C.2. Numerical Data Verbalization Prompt (LLaMA-3.1-8B)

The following prompt template is used for generating narratives from structured numerical urban data:

**Table 4**
Example of an output response to a randomly selected question, illustrating the outputs produced by the different verbalization configurations.

| | |
|---|---|
| **Question** | From 2012 to 2019 the population in Turin has decreased. Considering all the census, does this decrease affect all the demographics? Which category is more affected and which one is less affected? |
| **Reference Answer** | Between 2012 and 2019, the population of Turin declined by 4.32%, and this trend affected most demographic groups. Both male and female populations decreased at nearly the same rate (4.34% and 4.31% respectively), indicating no significant gender disparity. The number of minors saw a notable decline of 5.96%, while the foreign (legally registered) population experienced the most significant drop, decreasing by 6.48%, together with the number of working-age citizens (6.28%). In contrast, the senior population was the only group to increase, growing by 2.05% |
| **PeRAG Output** | Analyzing the demographic shifts across Turin's statistical zones between 2012 and 2019, it is evident that the overall population declined during this period. However, the decrease was not evenly distributed across all demographic categories. The working-age population (19–64) experienced the most significant contraction, suggesting a notable loss of economic contributors. This trend was consistently observed across various districts. In contrast, the number of seniors slightly increased, indicating a growing aging population. The number of minors also declined, though to a lesser extent than the working-age group. Meanwhile, the foreign-born population registered a visible decline as well, potentially due to migration dynamics. In summary, while most demographic segments were negatively affected, the working-age group was the most impacted, whereas the senior population was the least affected, showing a modest increase. |
| **FS-RAG Output** | Analyzing the provided census data reveals a complex picture regarding demographic shifts between 2012 and 2019 in Turin's districts. While a precise overall population decrease for the entire city isn't evident from this dataset, several districts demonstrate notable changes. District 5 (specifically areas like Basse di Stura and Le Vallette) shows a consistent population size—around 41 residents in 2019, mirroring 2012—with minimal fluctuation within the 500-meter radius. Conversely, District 1 exhibits a clear increase in population size between the two years. In 2012, Census Area 799 (Politecnico) held 52 residents, expanding to 1,478 within a 500-meter radius. Similarly, Census Area 3209 (Politecnico) grew from 212 residents to 2,784. Looking at specific categories, the *minor* population appears significantly impacted by this growth, increasing dramatically in District 1 (from 32 to 423) compared to a smaller change in District 5. Seniors also show increased numbers in District 1 (47 to 652) while remaining largely stable in District 5. The foreign national population experienced a relative increase in District 1 (2 to 104) compared to a slight increase in District 5 (13 to 20). Therefore, while certain districts remained static, the overall trend indicates that the *minor* population is experiencing the most pronounced demographic shift, particularly within District 1, driven by expansion of the area analyzed. |

**Table 5**
Prompt template used for map-to-text narrative generation

```
<|begin_of_text|><|start_header_id|>system<|end_header_id|>
You are an expert urban data analyst. Your task is to generate clear and precise narratives based
 on census and transport data for the city of Turin.
<|start_header_id|>user<|end_header_id|>

Generate a comprehensive narrative that analyzes and compares the {field_description.lower()}
across the statistical zones of Turin, based on the provided comparison maps.
The image displays comparison data for the years 2012 and 2019.
<|image|>
Your narrative must:
- Be concise, informative, and clearly highlight key patterns and trends in the
 {field_description.lower()}, considering both temporal changes
 (between 2012 and 2019) and within-year variations, where relevant.
- Provide a Top-summary for each of the following:
    - The most common patterns observed across zones.
    - Zones with the highest increases in values from 2012 to 2019
    (i.e., where 2019 value > 2012 value).
    - Zones with the largest decreases in values from 2012 to 2019
    (i.e., where 2019 value < 2012 value).
- Use the exact numerical values provided for each statistical zone—do not round, estimate, or
omit any data.
- Refrain from interpreting, inferring causes, or comparing with any external datasets or years
outside of 2012 and 2019.
Below are the statistical zones with their respective values for the selected field in 2012 and
2019:
{values}
Generated Narrative: <|eot_id|><|start_header_id|>assistant<|end_header_id|>
```

Prompt template used for numeric-to-text narrative generation

```
<|begin_of_text|><|start_header_id|>system<|end_header_id|>
You are an expert urban data analyst. Convert census and transport data into clear narratives.
<|start_header_id|>user<|end_header_id|>

Generate a comprehensive, single-paragraph narrative about an urban area based on the following
numeric data.
The narrative must:
- Be concise, informative, cover all key aspects of the urban landscape, and limit to a single
 paragraph.
- Include and reflect the exact values as given in the Numeric Facts, without modification or
 approximation.
- Focus solely on describing the attributes defined in Field Descriptions, matching each field
 with its corresponding value.
- Avoid drawing conclusions, making assumptions, or interpreting the significance of the data.
- Avoid comparing the data to other entries, past values, or the example provided.
Unique Identifier: {row_context}
Field Descriptions: {field_description}

# Beyond Raw Text: Knowledge-Augmented Italian Relation Extraction with Large Language Models

Gianmaria Balducci[1,2,*,†], Elisabetta Fersini[1,*,†] and Enza Messina[1,*,†]

[1] *Università Degli studi di Milano-Bicocca), Viale Sarca 336, Milano, 20125, Italia*
[2] *P.M.I. Reboot S.r.l., Viale Lunigiana 40, Milano, 20125, Italia*

**Abstract**

Relation extraction (RE) is a fundamental NLP task that identifies semantic relationships between entities in text, serving as the foundation for applications such as knowledge graph completion and question answering. In real-world deployments, organizations frequently encounter low-resource scenarios where labeled training data is scarce, making effective RE particularly challenging. Existing approaches often rely on external knowledge sources to augment training data, but such resources can be noisy, incomplete, or misleading for model learning. To address this limitation, we propose an approach that leverages the reasoning capabilities of Large Language Models (LLMs) to generate reliable background knowledge for RE tasks on Italian texts.

**Keywords**

Relation Extraction, LLMs, Reasoning, Low resources, Italian

## 1. Introduction

Relation extraction (RE) is a fundamental task in natural language processing that aims to identify and classify relationships between subject and object entities mentioned in text [1]. Formally, given an input sentence $X_i = \{x_1, x_2, \ldots, s, \ldots, o, \ldots, x_n\}$ containing $n$ tokens, where $s$ and $o$ represent head and tail entities respectively, RE systems predict a relation label $Y_i \in \mathcal{Y}$ from a predefined set of relationships (e.g., `founded_by`, `born_in`, and `Work_For`). This capability underlies many critical NLP applications, including knowledge graph completion and question answering systems [2]. Most past approaches focus on adapting standard-scale language models (SLMs) such as BERT[3] to downstream RE tasks [4]. Recent advances in RE have been driven by deep neural networks, with large pre-trained language models achieving state-of-the-art performance. However, despite these advances, several fundamental challenges persist in real-world deployment scenarios. The primary limitation stems from the long-tail distribution of relations in natural datasets. While frequent relations benefit from abundant training examples, the majority of relations suffer from severe data scarcity. This creates a significant bottleneck since deep learning approaches require substantial labeled corpora resources that are often unavailable in low-resource settings [5]. Moreover, while prompt-tuned SLMs and instruction-tuned LLMs have shown remarkable success across various NLP tasks, they exhibit a tendency to memorize rather than truly understand training data [6]. This limitation becomes particularly problematic for semantically complex tasks like RE, which require deep domain-specific knowledge and robust generalization capabilities. To address these limitations and further enhance the effectiveness of RE models, we propose a pipeline based on exploiting the LLMs' reasoning capabilities. The hypothesis is that extending each sample of a given dataset using the knowledge extracted by querying the LLM with specific clarification prompts helps the models trained on these samples, along with clarifications, to understand the task better. We train several models on an Italian dataset, CoNLL04 Italian, translated from the CoNLL04 dataset [7]. Experimental results demonstrate that incorporating LLM-generated background knowledge significantly improves RE performance, particularly in low-resource settings. Subsequently, we conduct an analysis on the contribution that different outlooks that compose the knowledge give to the model's prediction capabilities.

## 2. Related Work

In the current landscape dominated by Large Language Models (LLMs), Relation Extraction (RE) continues to play a pivotal role. Despite the impressive capabilities of LLMs, they often struggle to fully preserve and accurately interpret implicit relational knowledge—particularly in long-tail scenarios, where entity relations may be subtle or infrequent. These limitations highlight the contin-

ued relevance of RE methods, which explicitly model relationships between entities and thereby enhance LLM performance. Moreover, RE techniques are especially valuable in dynamic domains characterized by the constant emergence of new entities and relation types. Their adaptability makes them well-suited for scalable knowledge extraction from unstructured textual data, fueling ongoing research and development in this area. Recent advances in deep neural networks (DNNs) and pretrained language models (PLMs) have substantially boosted RE performance. Several studies [8, 9] approach RE as a pipeline process: first identifying entities within text, then determining the relationships between identified entity pairs. Earlier RE systems [10, 11] typically relied on external Named Entity Recognition (NER) tools for entity detection, followed by the use of supervised classifiers with hand-engineered features to predict relations. In contrast, more recent approaches assume that entity mentions are pre-identified, focusing solely on relation classification [12, 13]. However, pipeline architectures are prone to error propagation—errors in entity recognition can adversely affect the accuracy of relation classification. Relation Extraction and Classification can be tackled as a generation task: REBEL [14] uses an autoregressive model that outputs each triplet present in the input text. To this end, it employs BART-large [15] as the base model for the seq2seq approach. The Italian LLM ecosystem has recently seen notable expansion, with several new models released or announced that are specifically tailored for the Italian language. Among these is **LLaMAntino-3-ANITA** [16], a fine-tuned version of Meta's LLaMA-3 (8B) [17], adapted through Supervised Fine-Tuning (SFT) and Direct Preference Optimization (DPO) to align with user preferences and reduce biases. Another significant contribution is **Fauno** [18], developed by Sapienza University as the first open-source Italian conversational LLM (7B, with a 13B version forthcoming), trained on a blend of synthetic and technical corpora. **Minerva 7B** [19], created by Sapienza NLP in collaboration with FAIR, CINECA, and Italy's National Recovery and Resilience Plan (PNRR), is trained from scratch on 2.5 trillion tokens (50% Italian), and further enhanced through instruction tuning and safety layers. **Velvet** [20], developed by Almawave, is a family of multilingual LLMs that includes Italian and is built on a proprietary architecture. This wave of Italian LLMs—from academic research efforts to industry-grade solutions—reflects a growing commitment to developing robust, safe, and effective native Italian models. These advances also contribute to improvements in downstream tasks, including RE. For instance, [21] propose an Italian Open Information Extraction framework that leverages LLMs for Open Named Entity Recognition, Open Relation Extraction, and joint tasks via prompt-based instructions. Similarly, [22] combine LLMs with fine-tuned models to extract relations from Italian literary texts. Their approach involves using an LLM to preprocess the text into natural language triples, thereby simplifying the RE task for the fine-tuned model. Existing RE methods also tend to exploit additional knowledge to assist model reasoning. For example, [23] proposes a knowledge-attention encoder that incorporates prior knowledge from external lexical resources like FrameNet and Thesaurus.com into deep neural networks for the relation extraction task. [24] uses enriched sentence-level representations by introducing both structured knowledge from external knowledge graphs and semantic knowledge from the corpus. However, external knowledge can be misleading and vague; external resources don't consider the context and the domain of entities and relations, leading models to misinterpret the meaning of the sentence.

Despite these advances, the potential of Italian LLMs to support and improve downstream RE remains largely underexplored. Given their demonstrated utility, further investigation into their integration with RE workflows is both timely and necessary.

## 3. Dataset

In this research the proposed approach is evaluated on an Italian translated version of CoNLL04 [7]. The CoNLL04 is a benchmark dataset used for relation extraction tasks. It contains 1,441 sentences, each of which has at least one relation. The sentences are annotated with information about entities and their corresponding relation types [25]. It comprises news articles from The Wall Street Journal and the Associated Press. It encompasses annotations for both entity and relation types, making it versatile for various NLP tasks. The dataset includes relations among entities like people, organizations, locations, and other miscellaneous entities. Relation types are five: *Live_In, Located_In, OrgBased_In, Kill, Work_for.* Relations included: Person-Location, Organization-Person, Person-Person, etc.

**Table 1**
CoNLL04 benchmark statistics. Every sample is a sentence.

| | sentences | entities | relations |
|---|---|---|---|
| train | 922 | 3377 | 1283 |
| validation | 231 | 893 | 343 |
| test | 288 | 1079 | 422 |
| total | 1441 | 5349 | 2048 |

This work employ a sophisticated hybrid approach for translating the ConLL04 English relation extraction dataset to Italian while preserving the crucial token-level annotations required for named entity recognition and relation extraction tasks. The translation process operates in three main phases: first, the com-

**Table 2**
CoNLL04 becnhamrk relation types statistics

| relation type | train | validation | test |
|---|---|---|---|
| Live_In | 330 | 91 | 100 |
| Located_In | 247 | 65 | 94 |
| OrgBased_In | 271 | 76 | 105 |
| Kill | 179 | 42 | 47 |
| Work_for | 256 | 65 | 76 |

plete English sentence is translated to Italian using X-ALMA [26], built upon ALMA-R by expanding support from 6 to 50 languages. It utilizes a plug-and-play architecture with language-specific modules, complemented by a carefully designed training recipe. In particular, a 8-bit quantized version due to resource limit constraints is used from the offical repository on Huggingface at *https://huggingface.co/mradermacher/X-ALMA-13B-Group2-GGUF.* The translator model generates fluent Italian text but disrupts the original token alignments. Second, to address the critical challenge of maintaining entity boundaries and types across languages—where direct token-to-token mapping fails due to morphological differences, word order changes, and varying translation lengths, the system employs OpenAI's GPT-4o-mini model [27] to perform intelligent entity alignment by analyzing both the original English tokens and their Italian counterparts, then identifying which specific Italian tokens correspond to each English entity based on semantic understanding rather than positional heuristics. Finally, the system reconstructs the annotated dataset by mapping the spans of the identified Italian entity back to token indices. This step has the main goal to preserve entity types and relation labels while handling edge cases through fallback mechanisms that include proportional mapping and fuzzy string matching when exact alignment fails. This ensures that the resulting Italian dataset maintains the structural integrity necessary for training and evaluating relation extraction models. The comprehensive error handling and multi-stage validation process addresses the inherent complexities of cross-lingual annotation transfer in structured NLP datasets. In each split of the dataset, some translated sentences are removed due to the impossibility of maintaining relation labels. This case is represented by a few sentences that are not well translated, in which one or more entities that were in the relationship label are missing.

Table 1 and Table 3, show the small reduction of sentences (from 1441 to 1407) and consequently of the number of relations and entities. However, in the translation process, entity types and relation types distribution are maintained 2, 4.

**Table 3**

# 4. Method

## 4.1. Background

This work considers an LLM as a reliable Knowledge Base (KB). Large Language Models (LLMs) offer significant advantages over external knowledge bases like Wikidata for relation extraction tasks, particularly in their superior ability to interpret sentence semantics and contextual nuances. Unlike Wikidata, which provides static, predefined relations between entities in a structured format, LLMs possess deep contextual understanding that enables them to capture implicit relationships, resolve ambiguities, and interpret complex linguistic phenomena such as metaphors, negations, and conditional statements that traditional knowledge bases cannot handle. LLMs excel at understanding how the same entity pair can express different relations depending on syntactic structure, discourse context, and pragmatic implications—for instance, distinguishing between "CEO of Apple" and "former CEO of Apple" or interpreting temporal and causal relationships that emerge from sentence composition rather than explicit statement. Furthermore, LLMs can handle novel entity combinations and emerging relationships that may not yet exist in manually curated databases, while their training on vast text corpora allows them to recognize subtle linguistic cues and contextual modifiers that determine relation validity and type. This semantic depth proves particularly valuable for relation extraction in domains with complex, evolving terminology or when dealing with informal text where relationships are expressed through natural language patterns rather than formal declarations, making LLMs more robust and adaptable for real-world text analysis scenarios where meaning emerges from the intricate interplay of syntax, semantics, and context. Given a sentence $s = \{w_1, w_2, \ldots, w_n\}$ consisting of $n$ tokens, and

La sua posizione implica che rappresenta il PS e partecipa attivamente nel processo politico...".

**k = t + f + r**

**Figure 1:** Overview of proposed approach. Starting from the input sentence, the method augment the input with NER predictions and knowledge extracted from Phi4. Subsequently, a supervised fine-tuning with LoRA strategy is performed. LLMs learn to generate the target with a specific notation.

a set of entities $E = \{e_1, e_2, \ldots, e_k\}$ where each entity $e_i$ is defined by its span $(start_i, end_i)$ and type $t_i \in \mathcal{T}$, the relation extraction task aims to identify and classify semantic relationships between entity pairs. Formally, let $\mathcal{R}$ be the set of all possible relation types, including a special *no-relation* type $\emptyset \in \mathcal{R}$. For each ordered pair of entities $(e_i, e_j)$ where $i \neq j$, the relation extraction task seeks to determine the relation type $r_{ij} \in \mathcal{R}$ that holds between $e_i$ (head entity) and $e_j$ (tail entity) within the context of sentence $s$.

## 4.2. NER predictions

This step involves in the extension of the input space using state-of-the-art Named Entity Recognition (NER) Italian models. NER is formulated as a sequence labeling task where each token in the input sequence is assigned a label that indicates its role in entity identification and classification. Given an input sentence $s = \{w_1, w_2, \ldots, w_n\}$ consisting of $n$ tokens, the NER task aims to produce a corresponding label sequence $y = \{y_1, y_2, \ldots, y_n\}$ where each label $y_i \in \mathcal{L}$ encodes both the entity type and the token's position within the entity span. In particular, for each of input sentences of the dataset, this work construct a set of NER predictions $E$ comprising annotations from three state-of-the-art multilingual and Italian-specific named entity recognition models. The prediction ensemble includes: (1) `span-marker-multilingual-cased-multinerd`, [28] a SpanMarker model fine-tuned on the MultiNERD. (2) `bert-italian-cased-ner` [29], a cased BERT model specifically trained for Italian NER on the WikiNER Italian dataset plus manually annotated Wikipedia paragraphs, capable of recognizing four entity classes (Per, Loc, Org, Misc); and (3) `DeepMount00/universal_ner_ita`, an Italian adaptation of GLiNER [30] (Generalist Model for Named Entity Recognition using Bidirectional Transformer) that leverages natural language descriptions to identify arbitrary entity types. Entity types for GLiNER are *"persona", "città", "nazione", "organizzazione", "data", "luogo", "evento", "prodotto"* (*"person", "city", "nation", "organisation", "date", "location", "event", "product"*). Each model processes the tokenized Italian sentences independently, with predictions aligned to the original token boundaries. The resulting prediction set $E$ composed of all the token-level predictions obtained from cited models provides diverse perspectives on entity recognition.

## 4.3. Knowledge Extraction

Given the extended input (s, $E$) the aim of this step is to further extend the input, extracting knowledge $\mathbf{k}$ from LLM. $\mathbf{k}$ is composed by three different outlooks that are concatenated together to compose the semantic interpretation of a single dataset sample. In particular for a given sentence $s_i \in S$ where S represent the entire corpus of a dataset, $k_i = t_i \oplus f_i \oplus r_i$ where $t$ is the **Entities outlook**, $f$ is the **Sentence outlook** and $r$ is the **Relations outlook**.

- For the Entities outlook we ask to the LLM: "Spiega brevemente il significato dei soggetti principali menzionati per comprendere la frase: {s}" ("Briefly explain the meaning of the main subjects mentioned in order to understand the sentence: {s}").
- Sentence outlook is obtained by asking "Spiegami molto brevemente la frase con il contesto necessario: {s}" ("Explain the sentence to me very briefly, providing the necessary context: {s}").
- Relation outlook is obtained asking "Basandoti sul testo e sulle predizioni di entità: Spiega brevemente le relazioni tra le entità menzionate nel testo. Testo: {s} Predizioni NER {$E$}" ("Based on the text and entity predictions: Briefly explain the relationships between the entities mentioned in the text. Text: {s} NER predictions {$E$}")

The model used to extract the Italian knowledge is Phi-4 [31] a 14B parameter state-of-the-art open model, due to the high quality and advanced multilingual reasoning capabilities, even though the small size. In this settings we are able to concatenate the sentence with NER predictions $E$ and knowledge **k** in order to represent the **enriched input** space <**s** , **E, k** > for a given sentence $s \in S$. Given this input space we employ a parameter-efficient fine-tuning strategy using Low-Rank Adaptation (LoRA) [32] within the PEFT framework [33] for supervised fine-tuning (SFT) of several Italian LLMs.

### 4.4. Target representation

Relations triplets are composed of a head entity, a tail entity, and a predicate indicating the semantic relationship between a subject entity and the object entity:

*"Hideo Kojima ha acquistato una nuova casa a Tokyo." ("Hideo Kojima has purchased a new home in Tokyo.")*

The semantic relationship according to CoNLL04 annotation can be (Hideo Kojima, Vive_A, Tokio). Inspired by REBEL triplets linearization [14], we try to minimize the number of tokens in the generation stream in order to decode the output tokens efficiently. A relation triplet is represented by this notation:

**Head Entity -> Tail Entity (Relation type)** (1)

Multiple relations are separated by the semicolon character "**;**".

In this work relation extraction is treated as a generation task where the aim is to learn the conditional probability distribution given the input X = <s, E, k> :

$$P(Y|X) = P(y| < s, E, k >) \tag{2}$$

A few Italian LLM's are fine-tuned using LoRA strategy in order to learn to generate the target representation 1. We fine-tune also mREBEL$_{32}$ [34], a multilingual version of REBEL [14]. All models are fine-tuned for 10 epochs. At the end of each epoch, models are evaluated on the validation set, best model on the evaluation set is saved. Translation process, Knowledge extraction step, and training step are executed on the same machine with a NVIDIA GeForce RTX 3090 with 24GB of memory and AMD Ryzen 9 5900X 12-Core Processor.

## 5. Results

In this section, we present the experimental results of our supervised fine-tuning approach on the Italian ConLL04 dataset. We evaluate multiple Italian large language models under different input configurations to assess the effectiveness of our generative relation extraction framework. We conduct experiments using three configurations:

- **Enriched**: Complete input including sentence, entity predictions, and background knowledge $\langle s, E, k\rangle$
- **Raw**: Input containing only the source sentence $\langle s\rangle$
- **Enriched-Raw**: Model fine-tuned on enriched input but evaluated using only raw sentence input at inference time

The enriched-raw configuration allows us to investigate the implicit knowledge distillation effects, where reasoning capabilities from the enriched training data transfer to simpler inference scenarios.

### 5.1. Main Results

Table 5 presents the performance comparison across different Italian language models and input configurations. Following standard practice in relation extraction, we report both micro and macro F1 scores, with macro F1 serving as the primary evaluation metric for state-of-the-art comparisons.

### 5.2. Performance Analysis

LLaMAntino-3 demonstrates superior performance when trained and evaluated on enriched input, achieving 70.6% macro F1 score. This represents a significant improvement over both Minerva-7B (59.6%) and Velvet-14B

**Table 5**
Performance comparison of supervised fine-tuned Italian LLMs on relation extraction. Input configurations: (enriched) includes entity predictions and background knowledge; (raw) uses only sentence text; (enriched-raw) represents models trained on enriched data but evaluated with raw input only.

| Model Configuration | F1 Micro | F1 Macro |
|---|---|---|
| mREBEL (enriched) | 62.7 | 63.9 |
| mREBEL (raw) | 58.1 | 59.6 |
| mREBEL (enriched-raw) | 49.7 | 49.12 |
| Minerva-7B (enriched) | 57.2 | 59.6 |
| Minerva-7B (raw) | 55.6 | 57.9 |
| Minerva-7B (enriched-raw) | 48.9 | 51.0 |
| Velvet-14B (enriched) | 56.9 | 60.2 |
| Velvet-14B (raw) | 63.0 | 65.2 |
| Velvet-14B (enriched-raw) | 42.6 | 46.4 |
| LLaMAntino-3 (enriched) | **68.5** | **70.6** |
| LLaMAntino-3 (raw) | 58.4 | 62.1 |
| LLaMAntino-3 (enriched-raw) | 61.1 | 64.9 |

(60.2%), despite LLaMAntino-3 being a smaller 8B parameter model. The results indicate that model architecture and training methodology are more critical factors than pure parameter count for this task. The strong performance of mREBEL demonstrates that sequence-to-sequence models, which were previously state-of-the-art for this task, can achieve comparable results to large language models (LLMs). Additionally, mREBEL benefits from enriched input. However, Velvet-14B exhibits the opposite behavior, performing better with raw input (65.2%) than with enriched input (60.2%). This suggests the model may be overfitting to the auxiliary information provided in the enriched input. Comparing LLaMAntino-3 configurations reveals the substantial benefit of enriched input during training. The model trained on enriched data (70.6% macro F1) significantly outperforms the same model trained solely on raw sentences (62.1% macro F1). This demonstrates the value of incorporating entity predictions and background knowledge in the training process. The enriched-raw configuration yields particularly interesting results, achieving 64.9% macro F1 despite using only raw sentence input at inference time. This performance exceeds that of the model trained exclusively on raw input (62.1% macro F1), suggesting an interesting implicit knowledge distillation during training. The model appears to internalize reasoning patterns from the enriched training data, enabling improved performance even when auxiliary information is unavailable at inference time. Table 5.2 shows label-wise performances where the underlying capability of LLaMAantino3-8B to predict well the "Kill" relation, which is the least represented in the training set. These results validate our approach of treating relation extraction as a conditional text generation task and demonstrate the effectiveness of supervised fine-tuning on Italian language models for this domain. Error analysis and Ablation study, presented in this section are perfromed on the best model LLaMAntino-3.

**Table 6**
Label wise performances of best model LLaMAantino3-8B (encriched)

| relation type | precision | recall | f1 |
|---|---|---|---|
| Vive_a | 69.9 | 61.05 | 65.17 |
| OrgLocata_In | 71.95 | 63.44 | 67.42 |
| Situato_In | 60.63 | 60.63 | 60.63 |
| Lavora_Per | 62.5 | 80.0 | 70.17 |
| Ha_ucciso | 86.0 | 93.4 | 89.58 |

## 5.3. Error Analysis

Error analysis reveals two primary failure modes in the LLaMAntino-3 model's relation extraction performance: **spurious relation generation** (41 instances) and **missed relation detection** (37 instances). The model demonstrates a tendency toward over-generation, particularly struggling with complex sentences containing multiple entities where it produces semantically plausible but factually incorrect relations. Geographic relations (*Situato_In*) show the highest error rates, followed by organizational affiliations (*OrgLocata_In*). Two representative error patterns illustrate these challenges: **Over-generation example**: In the sentence "*Nikita Chruščëv, infuriato, ordinò alle navi dell'Unione Sovietica di ignorare il blocco navale del Presidente Kennedy durante la crisi dei missili cubani*", the model incorrectly generated four identical *Kill* relations between Khrushchev and Kennedy, while missing the correct *Vive_A* relation between Khrushchev and the Soviet Union. This demonstrates the model's tendency to infer dramatic but incorrect relations from contextual conflict scenarios. **Under-detection example**: For the sentence "*MILANO, Italia (AP)*" (Milan, Italy (AP)), the model correctly identified organizational relations for the Associated Press but failed to extract the fundamental *Situato_In* relation between Milan and Italy, suggesting difficulty with implicit geographic knowledge in simple locative constructions. **Out-of-domain hallucination example**: In the sentence "*King venne ucciso il 4 aprile del 1968 a Memphis, nel Tennessee*", the model correctly identified the *Situato_In* relation between Memphis and Tennessee, but additionally generated correct (but counted as wrong) *Evento* relations involving the date "4 aprile del 1968" with Memphis. The *Evento* relation type does not exist in the defined schema, demonstrating the model's tendency to create novel relation categories when encountering temporal-spatial contexts. These patterns indicate that while the generative approach successfully captures complex relational semantics, it requires improved calibration mechanisms, particularly for handling entity-dense contexts and fundamental geographic relations.

# 6. Ablation Study

Table 7 presents the performance impact of removing each knowledge component individually. The baseline enriched model achieves 70.6% macro F1, serving as our reference point for measuring component contributions.

**Table 7**
Ablation study results showing the impact of removing individual knowledge outlook components from the enriched input. Each configuration excludes one specific knowledge type while maintaining entity predictions and the base sentence.

| Model Configuration | F1 Micro | F1 Macro |
|---|---|---|
| LLaMAntino-3 (enriched) | **68.5** | **70.6** |
| LLaMAntino-3<br>without Entity Outlook | 60.1 | 62.6 |
| LLaMAntino-3<br>without Sentence Outlook | 49.0 | 50.6 |
| LLaMAntino-3<br>without Relation Outlook | 63.1 | 65.7 |

The ablation results reveal distinct contribution patterns for each knowledge component: Removing **sentence contextualization** causes the most severe performance degradation, with macro F1 dropping by 20.0 percentage points (70.6% → 50.6%). This dramatic decline indicates that contextual sentence understanding is fundamental to relation extraction performance. The sentence outlook provides essential discourse-level information that enables the model to disambiguate entity relationships within specific contextual frameworks. Excluding **entity explanations** results in an 8.0 percentage point decrease (70.6% → 62.6%), demonstrating the importance of explicit entity semantics. Entity-focused knowledge helps the model understand the nature and characteristics of mentioned entities, facilitating more accurate relation inference. Removing **relation-specific** explanations leads to a 4.9 percentage point reduction (70.6% → 65.7%), showing the smallest but still meaningful impact. While relation outlook provides valuable relational reasoning guidance, the model appears capable of inferring relations from entity and sentence context when this component is absent. The ablation study reveals a clear hierarchy of knowledge component importance: **Sentence Context > Entity Semantics > Relation Guidance**. This hierarchy suggests that: **Contextual understanding** is paramount for relation extraction, as sentences provide the situational framework within which entities interact **Entity semantics** serve as the foundation for identifying potential relation participants and their characteristics **Explicit relational reasoning** provides incremental benefits but is less critical when strong contextual and entity understanding exists. These findings highlight the differential contribution of each component to the overall system performance. The results also suggest potential optimization strategies, where computational resources could be prioritized toward generating high-quality sentence and entity explanations when resource constraints exist.

# 7. Conclusion

This work presents an effective approach for Italian relation extraction that leverages Large Language Models as reliable knowledge sources to enhance model performance in low-resource scenarios. Our method systematically augments training data with three complementary knowledge components: entity explanations, sentence contextualization, and relation-specific guidance, extracted using Phi-4's reasoning capabilities. The experimental results on the Italian CoNLL04 dataset demonstrate the effectiveness of our approach, with LLaMAntino-3 achieving 70.6% macro F1 when trained on enriched input, representing significant improvements over baseline configurations. The ablation study reveals a clear hierarchy of component importance: sentence context (20.0% performance drop when removed) $>$ entity semantics (8.0% drop) $>$ relation guidance (4.9% drop), highlighting the critical role of contextual understanding in relation extraction. Particularly noteworthy is the implicit knowledge distillation effect observed in the enriched-raw configuration for LLaMAntino-3, trained on enriched data but evaluated with raw input, still outperforms the same model trained exclusively on raw sentences (64.9% vs 62.1% macro F1). This suggests that some reasoning patterns from the enriched training data are internalized by the smallest model.
**Limitations:** An important limitation is that this approach relies heavily on the choice of LLM from which the knowledge is extracted. It would be interesting to investigate the contribution to the task of several LLM that can be used as knowledge-based. Furthermore the results of SFT depend on the well-formatted prompt used in the training phase. **A promising direction** for future work involves explicit knowledge distillation from enriched input $\langle s, E, k\rangle$ to raw input $\langle s\rangle$. This could be achieved by minimizing the Jensen-Shannon divergence or Kullback-Leibler divergence between the output distributions of models trained on enriched versus raw inputs. Such an approach would enable the deployment of lightweight models that maintain the reasoning capabilities learned from enriched training while operating solely on raw text at inference time, making the system more practical for real-world applications where auxiliary information may not be readily available. The work contributes to the

growing body of research on Italian NLP by providing both a translated benchmark dataset and demonstrating effective strategies for leveraging LLM reasoning in structured prediction tasks. Our findings suggest that carefully designed knowledge augmentation can significantly improve relation extraction performance, particularly in scenarios where training data is limited.

# When Figures Speak with Irony: Investigating the Role of Rhetorical Figures in Irony Generation with LLMs

Pier Felice Balestrucci[1,†], Michael Oliverio[1,*,†], Soda Marem Lo[1], Luca Anselma[1], Valerio Basile[1], Alessandro Mazzei[1] and Viviana Patti[1]

[1]Computer Science Department, University of Turin, Italy

**Abstract**

Irony poses a persistent challenge for computational models because it depends on context, implicit meaning, and pragmatic cues. This study investigates the ability of Large Language Models (LLMs) to generate ironic content by focusing on rhetorical figures—pragmatic devices that may shape and signal ironic intent. Using two datasets, TWITTIRÒ-UD and the Italian subset of MultiPICo, we fine-tune multilingual LLMs for rhetorical figure classification and evaluate their capacity to generate ironic Italian texts. Our work addresses two main questions: (1) how accurately LLMs can classify rhetorical figures in ironic Italian texts, and (2) whether such training supports the generation of irony that reflects human-like rhetorical usage. Human evaluation shows that LLMs achieve fair agreement with annotators in rhetorical figure classification, indicating a partial but promising alignment with human judgment. By leveraging rhetorical figures as a bridge between irony detection and generation, our results suggest that such training improves the stylistic control and interpretability of LLM-generated ironic language.

**Keywords**

Rhetorical Figures, Irony Generation, Large Language Models

## 1. Introduction

Irony is a complex linguistic phenomenon that involves expressing a meaning that contrasts with the literal interpretation of an utterance [1]. As a rhetorical figure, it is activated through multiple linguistic devices and pragmatic features to subvert literal meaning. Although irony is a pervasive and deeply rooted aspect of human communication, its computational modeling remains a complex and unresolved challenge.

Large Language Models (LLMs), especially when instruction-tuned, have shown remarkable progress in understanding pragmatic phenomena [2, 3]. However, their ability to leverage pragmatic features for the detection and generation of ironic content remains largely underexplored. One promising direction for addressing this challenge is to analyze the linguistic strategies through which irony is commonly expressed. Specifically, Karoui et al. [4] defined eight categories of irony, characterized by pragmatic features used to express meaning incongruence and grounded in rhetorical figures. Following their categorization of irony, this study investigates the capacity of LLMs to analyze and generate ironic texts in Italian when rhetorical figures are taken into account as cues for ironic intent. Thus, we focus on how they contribute to the expression of irony.

Indeed, irony can be also activated through the interaction with rhetorical figures, either amplifying their intended effects, as in the case of paradox, or subverting them entirely, as occurs with hyperbole. This interplay contributes to the richness and rhetorical complexity of ironic expressions [5].

In this work, we draw on two complementary datasets: TWITTIRÒ-UD, a corpus of ironic Italian tweets annotated using the rhetorical figure annotation scheme introduced by Karoui et al. [4], and MultiPICo, a multilingual collection of social media post–reply pairs annotated for irony by annotators with diverse sociodemographic characteristics, in which each reply is annotated with a binary label indicating whether it is ironic with respect to the corresponding post. By integrating fine-tuning and reasoning-enhanced prompting, we aim to evaluate both the classification and generative capabilities of LLMs in this domain for Italian.

Our study is structured around the following research questions (RQ):

- **RQ1:** To what extent can LLMs accurately classify rhetorical figures in ironic Italian texts?
- **RQ2:** Does fine-tuning LLMs on rhetorical figure classification lead to the generation of more

human-like ironic replies, in terms of rhetorical devices?

To address these questions, we fine-tune a set of multilingual open-weight LLMs on rhetorical figure classification and assess their performance. We then enrich the Italian subset of MultiPICo with automatic annotations and conduct a human evaluation to validate a small sample extracted from that corpus. Finally, we use the best-performing fine-tuned model to generate new replies to ironic posts in MultiPICo and carry out a linguistic analysis of the model-generated replies, comparing them with human-written ones.

This work contributes to (i) advancing the research into rhetorical figure classification using LLMs, by proving the effectiveness of Chain-of-Thought fine-tuning strategy; (ii) improving the interpretability of LLMs in pragmatic text generation, showing that rhetorical figure-aware models tend to create sentences stylistically more similar to human-written texts.[1]

## 2. Related Works

**Rhetorical Figure Classification** There are mainly two approaches to the automatic detection and classification of rhetorical figures in natural language: ontology-based methods and machine learning techniques [6, 7]. These approaches have shown effectiveness in supporting tasks such as sentiment analysis and intent classification [8, 9]. Several studies focus on their relationship with irony [10, 11], particularly in the context of irony detection. In this vein, Karoui et al. [4], drawing on well-established linguistic theories that explore the interplay between irony and rhetorical figures—such as oxymoron, paradox, false assertion, and analogy—propose an annotation schema for classifying these categories of irony in social media texts. Their work focuses on French, English, and Italian, highlighting the relevance of irony categories and markers for a linguistically informed approach to irony detection.

**Irony Generation** Irony generation remains a relatively underexplored area in Natural Language Generation. especially when compared to the growing literature on humor, puns, and sarcasm [12, 13]. Recent work has begun to model sarcasm through linguistic features such as valence reversal and contextual incongruity [14, 15], yet irony is still rarely addressed directly.

Among the more recent studies on irony generation, Balestrucci et al. [16] propose an approach that leverages LLMs to generate ironic text. The authors demonstrate that LLMs are capable of learning to produce ironic content, and explore the possibility of linking irony generation to the socio-demographic characteristics of user profiles—such as generational groups—with the goal of generating personalized ironic content tailored to different age groups.

## 3. Datasets

**TWITTIRÒ-UD** A collection of ironic Italian tweets annotated according to the Universal Dependencies framework. TWITTIRÒ-UD was created by enriching a resource originally developed for the fine-grained annotation of irony [17]. The original corpus consists of $1,424$ tweets, with a total of $28,387$ tokens [18]. Each tweet in the corpus has been annotated with the corresponding rhetorical figure used to convey irony, such as OXYMORON PARADOX, HYPERBOLE, or EUPHEMISM. The treebank includes both the fine-grained annotation for ironic tweets introduced in Karoui et al. [4] and the morphological and syntactic information encoded in the UD format.[2] Figure 1 shows the distribution of rhetorical figures in the corpus.

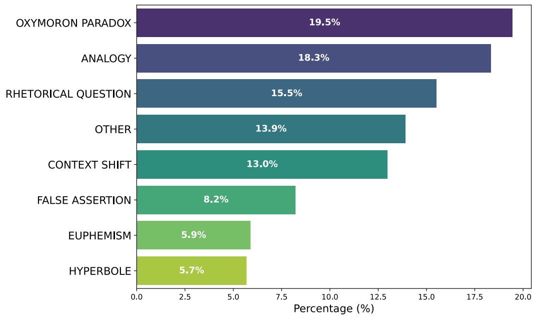

**Figure 1:** Distribution of rhetorical figures in the TWITTIRÒ corpus.

**MultiPICo** The dataset consists of disaggregated multilingual posts and replies from social media, each annotated to indicate whether the reply is ironic given the post. The corpus includes $18,778$ post–reply pairs, collected from Reddit ($8,956$) and Twitter ($9,822$), and covers 9 different languages. A total of 506 annotators, with different sociodemographic information, carried out the annotations, producing $94,342$ individual labels (an average of 5.02 per conversation). Each annotation is accompanied by sociodemographic metadata about the annotator, including gender, age, ethnicity, student status, and employment status. For the Italian subset of the

**Table 1**
Rhetorical figures used to convey irony. Reproduced from Karoui et al. [4].

| Rhetorical Figure | Description |
|---|---|
| ANALOGY | Covers analogy, simile, and metaphor. Involves similarity between two things that have different ontological concepts or domains, on which a comparison may be based |
| HYPERBOLE | Make a strong impression or emphasize a point |
| EUPHEMISM | Reduce the facts of an expression or an idea considered unpleasant in order to soften the reality |
| RHETORICAL QUESTION | Ask a question in order to make a point rather than to elicit an answer |
| CONTEXT SHIFT | A sudden change of the topic/frame, use of exaggerated politeness in a situation where this is inappropriate, etc. |
| FALSE ASSERTION | A proposition, fact or an assertion fails to make sense against the reality |
| OXYMORON PARADOX | Equivalent to “False Assertion” except that the contradiction is explicit |
| OTHER | Humor or situational irony. |

corpus, 24 annotators provided 4, 790 annotations on 1, 000 post–reply pairs [19].[3]

## 4. Methodology

To assess the ability of LLMs to analyze ironic Italian texts and classify rhetorical figures, we adopted the annotation scheme proposed by Karoui et al. [4], which defines a set of rhetorical figures commonly used to convey irony (summarized in Table 1).

We selected several open-weight multilingual LLMs trained on Italian data and fine-tuned them on the TWITTIRÒ dataset for the task of rhetorical figure classification. Models' performances were evaluated against two baselines: (i) a random classifier and (ii) a prompting-based approach. The best-performing model was then used to enrich the ironic Italian subset of the MultiPICo dataset—aggregated by majority vote—with rhetorical figure annotations. To validate the model's predictions, we conducted a human evaluation on a small subset of the annotated data.

Finally, to address the second research question, we focused on ironic post–reply pairs in Italian from MultiPICo, again selected via majority vote, and compared the distribution of rhetorical figures across three types of replies: (i) automatically generated by an LLM fine-tuned to recognize rhetorical figures, (ii) replies generated by the same model out-of-the-box, and (iii) written by humans. In addition to comparing the distributions, we conducted a linguistic analysis of these replies. A representative sample of the generated content was manually annotated to support this evaluation.

## 5. Rhetorical Figure Classification

In this section, we evaluate a set of LLMs for rhetorical figure classification. We fine-tune several open-weight, mid-sized LLMs using two different approaches on the original TWITTIRÒ-UD split (see Table 2). To highlight the impact of fine-tuning on rhetorical figure classification, we compare the performance of the fine-tuned models against two baselines: a random classifier and a zero-shot prompting approach. Our experiments involve five multilingual LLMs: Qwen2.5-7B-Instruct[4] (referred to as Qwen2.5-7B), Llama-3.1-8B-Instruct[5] (Llama-3.1-8B), Ministral-8B-Instruct-2410[6] (Ministral-8B), LLaMAntino-3-ANITA-8B-Inst-DPO-ITA[7] (LLaMAntino-3-8B), and Minerva-7B-instruct-v1.0 (Minerva-7B).[8]

**Table 2**
Data split statistics for the TWITTIRÒ-UD dataset.

| | Train | Dev | Test |
|---|---|---|---|
| #Tweets | 1, 138 | 144 | 142 |
| Avg. Tokens | 20.77 | 20.80 | 20.96 |

Fine-tuning was performed using two different prompt strategies, described below, both relying on Low-Rank Adaptation (LoRA) [20].

**Instruction Fine-Tuning** In this approach, which we refer to as FT, we trained all the models (training details are available in Appendix A), using the following instruction:

> Given the ironic sentence (INPUT), identify and return the rhetorical figure

[3] https://huggingface.co/datasets/Multilingual-Perspectivist-NLU/MultiPICo

[4] https://huggingface.co/Qwen/Qwen2.5-7B-Instruct

[5] https://huggingface.co/meta-llama/Llama-3.1-8B-Instruct

[6] https://huggingface.co/mistralai/Ministral-8B-Instruct-2410

[7] https://huggingface.co/swap-uniba/LLaMAntino-3-ANITA-8B-Inst-DPO-ITA

[8] https://huggingface.co/sapienzanlp/Minerva-7B-instruct-v1.0

> it exemplifies in (OUTPUT).

**Instruction CoT Fine-Tuning** To explore an alternative, we apply a Chain-of-Thought fine-tuning strategy (referred to as CoT-FT), which guides the model to generate an explanation before predicting the rhetorical figure [3]. For example:

> **Instruction**: Given the ironic sentence (INPUT), identify and return the rhetorical figure it exemplifies in (OUTPUT).
>
> *Explain your reasoning first, and then answer with the rhetorical figure.*
> **Input**: @user se continui sarò costretto a darti l'oscar (*@user if you keep going, I'll be forced to give you an Oscar.*)
> **Output**: The sentence draws a comparison between different domains to create irony through similarity. That's why it is an example of ANALOGY.

## 5.1. Model Evaluation

For the evaluation, we use the test split of TWITTIRÒ-UD. Each LLM is run three times per input using a temperature of 0.1. We report the results as the weighted average of Precision, Recall, and F1-Score, in order to account for the distribution of the rhetorical figures in the dataset.

**Table 3**
Model performance: weighted averages of precision, recall, and F1-score across three runs per model. FT and CoT-FT indicate Fine-Tuning and Chain-of-Thought Fine-Tuning, respectively.

| | Model | Precision | Recall | F1 |
|---|---|---|---|---|
| FT | Qwen2.5-7B | 0.346 | 0.359 | 0.350 |
| | Llama-3.1-8B | 0.370 | 0.394 | 0.378 |
| | LLaMAntino-3-8B | 0.373 | 0.399 | 0.379 |
| | Ministral-8B | 0.371 | 0.371 | 0.366 |
| | Minerva-7B | 0.382 | 0.399 | 0.388 |
| CoT-FT | Qwen2.5-7B | 0.350 | 0.352 | 0.349 |
| | Llama-3.1-8B | 0.378 | 0.406 | 0.384 |
| | LLaMAntino-3-8B | 0.382 | 0.397 | 0.385 |
| | Ministral-8B | **0.393** | **0.408** | **0.396** |
| | Minerva-7B | 0.367 | 0.385 | 0.372 |
| Baseline | Random | 0.138 | 0.122 | 0.125 |
| | Zero-Shot | 0.213 | 0.218 | 0.185 |

Table 3 reports the evaluation results. The baselines used are: (i) a random classifier (Random), which assigns one of the eight possible labels uniformly at random to each input, and (ii) a zero-shot prompting approach. For the latter, we selected the best-performing model overall (Ministral-8B CoT-FT) in its non–fine-tuned version, and included the full list of rhetorical figures as candidate outputs in the prompt.

The random baseline serves as a reference point to assess the task's intrinsic difficulty: with eight possible classes, achieving high performance by chance is highly unlikely. The zero-shot results, instead, lead to two relevant observations: (i) LLMs exhibit some prior knowledge of rhetorical figures and their usage, as evidenced by their better performance compared to random guessing; and (ii) fine-tuning on the TWITTIRÒ dataset yields a considerable improvement in classification performance.

Among the fine-tuned models (FT), Italian-developed models generally outperform multilingual ones, with Minerva-7B achieving the best results in this setting, followed by LLaMAntino-3-8B.

When reasoning capabilities are introduced through Chain-of-Thought fine-tuning, performance improves consistently for most models—with the notable exception of Minerva-7B. This might be due to the fact that Minerva-7B is trained on nearly 2.5 trillion tokens—1.14 trillion of which are in Italian, which could make it less effective at generalizing reasoning when prompted in English. This behavior is evident in the outputs, where it often mixes Italian and English, producing labels such as EUFEMISMO instead of EUPHEMISM.

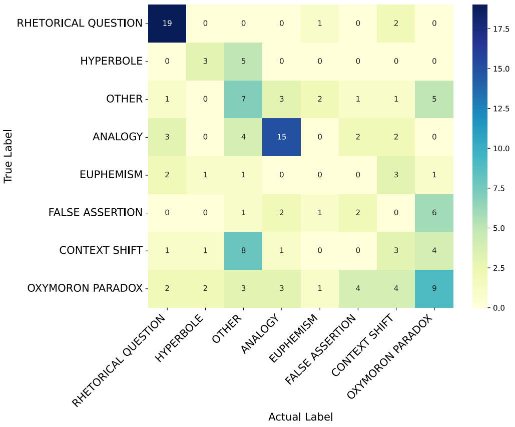

**Figure 2:** Confusion matrix from the third generation run of Ministral-8B with CoT-FT.

Figure 2 shows the confusion matrix for the third run of the best-performing model, Ministral-8B with CoT-FT. We observe that some rhetorical figures are easier for the model to recognize than others. In particular, the model performs well on RHETORICAL QUESTION (19 out of 22 correctly predicted) and ANALOGY (15 out of 26), which are among the most represented figures in the TWITTIRÒ dataset.

In contrast, the model struggles with several other categories—especially EUPHEMISM, for which it made no correct predictions (0 out of 8). These results highlight a substantial margin for improvement in this task and suggest the need for further investigation into the model's behavior and the characteristics of under-represented or more challenging rhetorical categories.

## 6. MultiPICo Enrichment

This section focuses on enriching the Italian MultiPICo with annotations of rhetorical figures. To this end, we employ the best-performing rhetorical figure classification model (see Table 3), Ministral-8B with CoT-FT, to classify rhetorical figures in the Italian post-reply pairs. As mentioned in Section 3, MultiPICo consists of both ironic and non-ironic post-reply pairs. Therefore, we extract only the ironic pairs from the dataset, using a majority vote approach to determine whether a post-reply pair is ironic, given the disaggregated nature of MultiPICo, resulting in a subset of 278 ironic post-reply pairs.

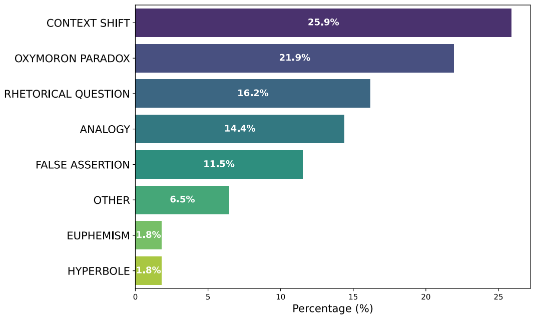

**Figure 3:** Distribution of rhetorical figures extracted from the Italian MultiPICo corpus.

We then use our model to classify the rhetorical figures in this subset. As shown in Figure 3, the most frequently extracted rhetorical figures in the post–reply pairs are CONTEXT SHIFT (25.9%) and OXYMORON PARADOX (21.9%), while the least frequent are EUPHEMISM and HYPERBOLE (1.8% each). This distribution closely resembles that of TWITTIRÒ, and the high frequency of CONTEXT SHIFT may be attributed to the nature of post–reply interactions, where replies often reframe or shift the meaning of the corresponding posts. Given the difficulty in classifying some rhetorical figures, as highlighted in Table 2, we carry out a human evaluation in Section 6.1 to assess the quality of the model predictions.

### 6.1. Human Evaluation

Following the annotation guidelines in Karoui et al. [4], two authors of this paper—both expert in computational linguistics—manually annotated a subset of 20 out of the 278 ironic post-reply pairs. The annotators were tasked to specify the rhetorical figures used to express irony in the reply given the corresponding post, selecting one or more labels from those reported in Table 1.

The annotators achieved an average Cohen's $\kappa$ score [21] of 0.63 on a subset of 20 post–reply pairs, a value comparable to that reported by Karoui et al. [4] for the same task (0.60), indicating substantial agreement. Krippendorff's $\alpha$ [22] was also computed, yielding a score of 0.60, which confirms a similarly substantial level of inter-annotator reliability.

We then compared the human annotations with the predictions produced by our automatic model. The resulting Krippendorff's $\alpha$ was 0.21, corresponding to a *fair* level of agreement.

To better understand this result, we examined the 14 out of 20 pairs where both annotators assigned the same label. In 3 of these cases, the model's prediction matched the human annotation exactly.

For example, for the post: *Due si candidano in quanto "ci vuole una donna" nel #Pd: #Schlein e #DeMicheli. Una sola domanda: perché?"* (Two women are running for office in the Democratic Party because 'we need a woman': Schlein and DeMicheli. One question: why?") the reply: *@USER Perché per un canguro è ancora presto."* (Because for a kangaroo it's still too early.") was labeled as CONTEXT SHIFT by both annotators and the model. The label was assigned due to the sudden change in topic, introducing an unexpected element (the kangaroo) that breaks coherence and signals irony.

In the remaining 11 cases where the model's prediction did not match humans' annotations, the model frequently labeled replies as OXYMORON PARADOX when annotators had chosen OTHER—this occurred in 6 out of the 11 pairs.

Consider the following example: *"Salvini ripropone il ponte sullo stretto di Messina, opera imprescindibile per lo sviluppo economico. Condivido e rilancio: contestualmente realizzerei anche il tunnel sottomarino Civitavecchia - Cagliari. Dai non facciamo come al solito la figura dei barboni, pensiamo in grande" ("Salvini reintroduces the Strait of Messina bridge proposal, a crucial infrastructure for economic development. I agree and raise: let's also build the Civitavecchia–Cagliari submarine tunnel. Let's not be our usual broke selves—let's think big!")* with the reply: *"Si può proporre il ponte Palermo–Cagliari già che ci siamo… una spesa unica… compri uno, paghi tre… no com'è la storia?" ("We might as well propose a Palermo–Cagliari bridge while we're at it… one payment for three projects… or how does it go again?")*

Here, the model likely interpreted the absurdity of the reply as a rhetorical figure of type OXYMORON PARADOX, whereas human annotators labeled it as a case of sarcasm, and thus as OTHER.

An illustrative example of the remaining cases is the following: *"Lo scrivo per tanti idioti che rispondono ai Twitter come le pecore. Sono un Sovranista, non sono vaccinato, non pagherò la multa e la mia Libertà non è in svendita." ("I write this for all the idiots who respond to tweets like sheep. I'm a sovereignist, I'm unvaccinated, I won't pay the fine, and my freedom is not for sale.")* with the reply: *"Lo scrivo per te … non bere più" ("I write this for you… stop drinking.")*

In this case, the model assigned the label ANALOGY, possibly misled by the introductory phrase in the post, failing to capture the sarcastic tone of the reply. This example suggests that prompt design could be improved to better guide the model's focus toward the reply and its pragmatic intent.

This evaluation highlights the LLM's ability to produce overall reasonable outputs. Although its performance is not particularly high, it can still serve as a useful tool for silver annotation, thanks to the reasoning and explanations it provides.

## 7. Irony Generation

Inspired by previous work on irony generation [16], we investigated whether a model trained to classify rhetorical figures would also be capable of employing them during generation—producing ironic outputs comparable to those written by humans in terms of rhetorical figures. To explore this hypothesis, we considered the 278 post–reply pairs selected in Section 6, using the posts as input to the best-performing model for rhetorical figure classification. The model was prompted to generate an ironic reply for each post, which was then compared to the original human-written reply. As a baseline, we used the same model in its non–fine-tuned version, applying the same prompting strategy. To illustrate this process, we provide the following example:

> **Instruction**: Ti viene fornito in input (INPUT) un post estratto da conversazioni sui social media. Fornisci in output (OUTPUT) una risposta ironica in italiano. (*You are given as input (INPUT) a post extracted from social media conversations. Provide as output (OUTPUT) an ironic reply in Italian.*)
>
> **Input**: Consigli su workout in casa in questo periodo di palestre chiuse? (*Any tips for home workouts during this period of gym closures?*)
>
> **Output**: Ah, certo! Prova a fare squat con il divano, push-up con il tavolino e flessioni con il gatto! (*Oh, sure! Try doing squats with the couch, push-ups using the coffee table, and some presses with the cat!)*

**Table 4**
Distribution of rhetorical figures in human and model-generated ironic replies (rep.) from MultiPICo. CoT-FT refers to the fine-tuned model; Baseline to the non-fine-tuned version.

| | **Human rep.** | **Model rep.** | |
|---|---|---|---|
| | | CoT-FT | Baseline |
| ANALOGY | 40 | 58 | 41 |
| HYPERBOLE | 5 | 3 | 2 |
| EUPHEMISM | 5 | 9 | 6 |
| RHETORICAL QUESTION | 45 | 34 | 64 |
| OXYMORON PARADOX | 61 | 67 | 51 |
| CONTEXT SHIFT | 72 | 62 | 52 |
| FALSE ASSERTION | 32 | 35 | 34 |
| OTHER | 18 | 10 | 28 |

Table 4 presents the distribution of rhetorical figures in the ironic replies generated by humans, the fine-tuned model, and the baseline model, all classified by Ministral-8B with CoT-FT. Overall, the differences across distributions are not substantial, but some trends are worth noting.

The fine-tuned model produces slightly more ANALOGY and EUPHEMISM compared to humans, which may reflect the influence of the TWITTIRÒ training data, where these categories are relatively well represented. Conversely, CONTEXT SHIFT appears underrepresented in the model outputs compared to human replies, which could be due to either the complexity of capturing discourse-level phenomena.

Interestingly, the baseline model shows a notable increase in the use of RHETORICAL QUESTION and OTHER, suggesting a more generic or less targeted use of rhetorical strategies when the model is not fine-tuned. This may indicate that zero-shot generation leads to a reliance on broadly applicable or ambiguous rhetorical patterns, as already seen in Balestrucci et al. [16].

To better understand these patterns and assess the reliability of the automatic classification, we conducted a human evaluation on a subset of 20 model-generated replies from both systems.

Specifically, the same two annotators from Section 6.1 independently labeled the rhetorical figures predicted by the models. Inter-annotator agreement was substantial, with a Cohen's $\kappa$ of 0.68 and a Krippendorff's $\alpha$ of 0.65. In contrast, the Krippendorff's $\alpha$ between the annotators and the classifier was 0.26, confirming all the previous results.

### 7.1. Linguistic Analysis

Following the approach proposed by Balestrucci et al. [16], we also conducted a linguistic analysis focusing on specific stylistic markers—namely, average token length, type-token ratio (TTR), and the use of interjections and negations—across human-written replies and model-generated outputs.

**Table 5**
Linguistic analysis for human-written posts, human-written replies, fine-tuned model generations (CoT-FT), and baseline generations (Baseline): average number of tokens (Tokens), type/token ratio (TTR), and average occurrences of interjections (Interjections) and negations (Negations).

| | **Human** | | **Model Replies** | |
|---|---|---|---|---|
| | Post | Reply | CoT-FT | Baseline |
| Tokens | 30.586 | 12.471 | 20.173 | 22.399 |
| TTR | 0.924 | 0.956 | 0.938 | 0.935 |
| Interjections | 0.594 | 0.273 | 0.381 | 0.507 |
| Negations | 0.050 | 0.072 | 0.410 | 0.982 |

Table 5 reports a linguistic analysis of human-written replies compared to those generated by the fine-tuned and baseline models. The comparison includes the average number of tokens, type-token ratio (TTR), and the average occurrences of interjections and negations.

Human replies tend to be shorter (12.47 tokens on average) than those generated by both the fine-tuned model (20.17) and the baseline (22.40), suggesting that human-written irony is often more concise. The type-token ratio remains high across all outputs, indicating a generally rich lexical variety. Notably, the TTR of the fine-tuned model (0.938) is slightly higher than that of the baseline (0.935), and closer to the human replies (0.956), suggesting that fine-tuning may help preserve or recover some degree of lexical diversity.

Regarding stylistic markers, human replies make limited use of interjections (0.273 per reply), while both models tend to use them more frequently—especially the baseline (0.507), possibly as a compensatory strategy to signal irony more explicitly. A similar trend is observed for negations: while human replies contain very few (0.072), model generations show a noticeable increase—particularly in the baseline output (0.982). This may indicate a tendency of the baseline model to overuse negative constructions, possibly due to a lack of fine control over tone and pragmatics in ironic generation.

Overall, these findings suggest that while model outputs differ in length and surface features from human replies, the fine-tuning on rhetorical figure classification task helps reduce some of the stylistic drift, bringing the generations closer to human-like patterns in terms of lexical variation and use of pragmatic markers.

## 8. Conclusions

Our study explored the extent to which rhetorical figures can serve as a bridge between the detection and generation of ironic content in Italian. We showed that fine-tuning LLMs on rhetorical figure classification enables models to identify key linguistic devices involved in irony with reasonable accuracy. The best results were obtained using a CoT strategy, which guided models to provide explanations before predicting the rhetorical category. While the models performed well on frequently represented figures such as `ANALOGY` and `RHETORICAL QUESTION`, they struggled with more subtle or under-represented categories like `EUPHEMISM`, suggesting that further refinement and data augmentation may be needed.

For the irony generation task, we observed that models fine-tuned on rhetorical figure classification produced ironic replies that more closely resembled human outputs in terms of rhetorical devices and stylistic markers. Although the overall distribution of rhetorical figures remained similar across models, the fine-tuned version demonstrated a more balanced use of devices, reducing the over-reliance on rhetorical questions and interjections observed in the baseline. This suggests that rhetorical figure awareness acquired through classification can positively influence generation, even in the absence of explicit training on ironic text generation.

Manual evaluation confirmed the model's ability to generate plausible annotations and replies, albeit with fair agreement compared to human annotators. Nonetheless, the consistency and interpretability of its outputs highlight its potential as a tool for silver annotation—particularly valuable in low-resource settings. Finally, our linguistic analysis showed that the fine-tuned model better preserved lexical diversity and pragmatic subtlety than its non-fine-tuned counterpart, indicating that rhetorical figure classification fine-tuning may also serve as a form of stylistic control. Taken together, these findings point to the value of leveraging rhetorical figures to enhance both the interpretability and expressiveness of LLMs in pragmatic language generation.

As future work, we plan to extend this study to other languages, such as French and English, with the goal of comparing the capacity of LLMs to classify rhetorical figures and generate ironic content across different linguistic contexts.

Moreover, a key research direction we intend to pursue concerns the perspectivist nature of the MultiPICo dataset. In particular, we aim to explore whether rhetorical figures function as shared cues in the perception of irony across different sociodemographic groups, thereby pointing to the existence of rhetorical devices that act as universal markers of ironic intent.

## 9. Limitations

Despite the promising results, this work presents several limitations that call for further investigation.

First, the rhetorical figure classification task was trained and evaluated on a relatively small dataset (TWITTIRÒ-UD), which may hinder the generalizability of the models—particularly for under-represented categories such as EUPHEMISM and HYPERBOLE. While fine-tuning contributes to improved performance, the models still struggle with these categories, likely due to data sparsity and the intrinsic ambiguity of certain rhetorical devices.

Second, the human evaluation was conducted on a relatively limited subset, which reduces the statistical robustness of the agreement scores. Although the results align with previous studies and provide qualitative insights into model behavior, a larger annotation effort would be needed to draw more conclusive findings—especially when distinguishing between closely related rhetorical categories. However, large-scale human annotation remains time-consuming and costly.

Finally, this study did not include a direct comparison with models explicitly fine-tuned for irony generation. Such a comparison would be necessary to better assess the specific contribution of rhetorical figure classification to the generation of ironic content, and to determine whether the observed improvements are attributable to rhetorical awareness or other factors.

# A. Experimental Setup

This appendix reports the hyperparameter configuration used during model fine-tuning. All experiments were performed using LoRA. Training was conducted using the `transformers` and `peft` libraries. The table below summarizes the main parameters used in the `TrainingArguments` class and in the LoRA configuration.

**Table 6**
Configuration of hyperparameters used in the LoRA-based fine-tuning process.

| Parameter | Value |
|---|---|
| **LoRA configuration** | |
| LoRA rank ($r$) | 64 |
| LoRA alpha | 16 |
| Dropout probability | 0.1 |
| **TrainingArguments** | |
| Number of training epochs | 5 |
| Enable fp16 training | `False` |
| Enable bf16 training | `True` |
| Batch size per GPU for training | 1 |
| Batch size per GPU for evaluation | 1 |
| Gradient accumulation steps | 1 |
| Maximum gradient norm | 0.3 |
| Initial learning rate | 2e−4 |
| Weight decay | 0.001 |
| Optimizer | `adamw_torch` |
| Learning rate schedule | `cosine` |
| Warmup ratio | 0.03 |

**Abstract**

In this work we introduce the automatically generated dataset in BLiMP-IT, a novel benchmark for evaluating Italian language models based on minimal pairs (i.e. sentence pairs that differ only in a critical morphosyntactic aspect). Drawing inspiration from the success of BLiMP for English, BLiMP-IT combines and adapts several existing resources—including COnVERSA, AcCompl-it, and BLiMP—to construct a high-quality evaluation dataset for Italian. We present an automatic methodology for generating the evaluation's items by leveraging a large Italian corpus for lexicon extraction, POS tagging, and animacy annotations. Our approach not only ensures coverage of diverse morphosyntactic phenomena (e.g., agreement and inflection, verb class, non-local dependencies) but also scales the creation of minimal pairs to automatically expand the items for the evaluation benchmark. BLiMP-IT demonstrates that an automated pipeline for generating minimal pairs to evaluate LMs is both feasible and effective, ensuring comprehensive coverage of diverse morphosyntactic phenomena in Italian while reducing reliance on manual annotation.

## 1. Introduction

The development of benchmarks and datasets for the linguistic evaluation of Language Models (LMs) in a specific language is essential for a systematic assessment of their ability to handle its morphosyntactic structures. Given cross-linguistic variation in inflectional morphology, syntactic configurations, agreement mechanisms, and word order flexibility, language models often exhibit differential performance depending on the structural properties of the target language. A dedicated evaluation framework allows for rigorous analysis of morphosyntactic accuracy, including the handling of inflectional paradigms, syntactic dependencies, agreement constraints, and constituent ordering, providing a comprehensive assessment of a model's grammatical competence. In linguistic theory acceptability judgments have been often defined as the main empirical method used to access human linguistic competence and language acquisition [1, 2]. This methodology has also been proved to be a classical and reliable tool for assessing the linguistic capabilities of LMs across various linguistic phenomena [3, 4, 5, 6]. A common methodology is the employment of minimal pairs, couples of sentences differing minimally in their structure, with one being grammatically acceptable and the other one being unacceptable. An effective LM should assign higher probabilities to grammatically acceptable sentences than to their unacceptable counterparts. Alternatively, it can be evaluated by presenting a series of sentences—both grammatical and ungrammatical—and requiring the model to perform a binary acceptability classification. While benchmarks such as BLiMP have provided valuable insights for English, the lack of analogous resources for Italian poses a challenge for multilingual NLP and for an effective and comprehensive evaluation of these models. We address this gap by introducing BLiMP-IT [1], a benchmark specifically designed for Italian. Our contributions are twofold:

- **Resource Adaptation and Assembly:** We construct BLiMP-IT by integrating and adapting existing Italian and English datasets and benchmarks for the linguistic evaluation of LMs, within a minimal pairs' framework.
- **Automatic Minimal Pair Generation:** We develop an automated pipeline for generating minimal pairs by extracting a detailed lexicon from a large Italian corpus, tagging it with linguistic information (e.g., POS, UPOS, animacy), and systematically mapping various linguistic phenomena to unique sequence tags, to produce both grammatical and ungrammatical sentence pairs (i.e. minimal pairs) [2].

In this work, we focus on the automatic pipeline component of the BLiMP-IT resource, providing a comprehensive description of its operational workflow.

## 2. Related work

Large Language Models (LLMs) have sparked an ongoing debate about whether they develop genuine linguistic competence or rely primarily on spurious statistical generalizations [7, 8]. This fundamental question is complicated by LLMs' opacity in processing language patterns and their tendency to conflate world knowledge with morphosyntactic competence [9]. While some interpret LLMs' performance with complex grammatical configurations as evidence against the Poverty of Stimulus hypothesis [10], critics note that such results depend on dramatically oversized training data compared to child language acquisition [11]. Moreover, higher performance on increasingly specific tasks does not always correspond to genuine gains in linguistic understanding [12], suggesting that standard performance metrics may inadequately capture linguistic competence [1]. Within this context, developing linguistically informed benchmarks has become crucial for evaluating model performance and the nature of their competence [13]. The evaluation of language models via acceptability judgments and minimal pairs has a long-standing history in theoretical and computational linguistics. Recent benchmarks such as BLiMP [14] and CLiMP [15] have demonstrated the value of this approach, while recent shared tasks have highlighted how small-sized training regimes (10-100M tokens) can achieve relatively good results on various linguistic benchmarks including BLiMP and CoLA [16, 14]. However, the most performant architectures that show improvement with additional training often yield diminishing returns in psycholinguistic terms [17]. Recent work capitalizing on the BabyLM Challenge in English [18] and similar tasks in Italian [19] has stressed the importance of adopting appropriate linguistic benchmarks to meaningfully challenge the Poverty of Stimulus hypothesis. For Italian specifically, resources like Laccolith [20] and AcCompl-it [21] have targeted acceptability judgments through binary and rating-based methods. However, there remains a need for a comprehensive Italian benchmark that harnesses the minimal pairs framework, a gap that BLiMP-IT aims to fill.

## 3. BLiMP-IT Dataset Construction

### 3.1. Minimal Pairs Framework

The minimal pairs framework adopted in BLiMP-IT centers on constructing sentence pairs that differ only in a critical grammatical feature. One sentence in the pair is grammatically acceptable, while the other violates a specific morphosyntactic rule. This approach builds on previous work in linguistic evaluation, notably the BLiMP benchmark for English (e.g., [14]) and provides a fine-grained measure of a language model's sensitivity to subtle grammatical contrasts. Minimal pairs serve as a fine-grained diagnostic tool: by presenting a model with two sentences that are identical except for one grammatical feature, researchers can assess whether the model is sensitive to the relevant linguistic distinction. For example, in the case of subject-verb agreement, a model should consistently assign higher probability or acceptability to the correct agreement form (e.g., "La ragazza mangia la mela" vs. "La ragazza mangiano la mela") [3]. This controlled setup eliminates confounding variables and allows precise measurement of model performance on particular phenomena. To ensure interpretability and reproducibility, BLiMP-IT constructs minimal pairs based on abstract tag templates that encode both grammatical and ungrammatical structures. These templates are manually designed and systematically mapped to lexical entries drawn from a linguistically annotated corpus. The use of tag-based generation not only facilitates large-scale pair creation but also guarantees that the only difference between the sentences in a pair is the grammatical target under investigation. The minimal pairs are organized around four major categories of morphosyntactic phenomena: Agreement and Inflection, Verb Class and Argument Structure, Pronouns, and Non-local Dependencies. Each pair is associated with a specific sub-phenomenon (e.g., determiner-noun agreement, reflexive clitic placement, long-distance wh-dependencies), enabling detailed evaluation across diverse syntactic domains. In design-

[2] The automatically generated resources, as well as a flowchart describing the process, can be accessed at https://nets-lab.github.io/blimpit-generation/. Please note that these data are provisional and subject to ongoing generation and refinement.

[3] "The girl eats the apple" vs. *"The girl eat the apple"

ing these pairs, particular attention was paid to structural symmetry, lexical consistency, and plausibility. Sentences were constructed to be semantically neutral where possible, to avoid introducing biases unrelated to the grammatical phenomenon. This was especially important for more complex structures, such as those involving coordination or wh-movement, where maintaining interpretability across grammatical and ungrammatical variants can be challenging. Finally, minimal pair evaluation supports both probabilistic scoring (e.g., comparing log-likelihoods assigned by a language model) and binary classification tasks, such as acceptability judgments. This flexibility allows BLiMP-IT to be used with a wide range of language models and evaluation metrics, aligning with the goals of interpretability and cross-model comparability.

### 3.2. BLiMP-IT: Integrated Resources

BLiMP-IT encompasses 78 morphosyntactic phenomena, which are categorized into four main groups: Agreement and Inflection (including phenomena such as noun-determiner and subject-verb agreement), Verb Class and Argument Structure (addressing issues like auxiliary selection and $\theta$-role assignment), Pronouns (focusing on clitics, reflexives, and person agreement), and Non-local Dependencies (encompassing long-distance dependencies and island effects).

The dataset is constructed by integrating multiple existing Italian linguistic resources (and English resources in the case of BLiMP) while also incorporating newly created minimal pairs. Our sources include:

- COnVERSA: A battery designed for assessing grammaticality through minimal pairs [22].
- AcCompl-it: An evaluation campaign component focused on acceptability and complexity judgments [21].
- BLiMP: a test set for evaluating the grammatical knowledge of English LLMs, featuring 67 minimal pair paradigms across 12 categories [14].
- New phenomena: a set of new linguistic phenomena such as ATB [23] and parasitic gaps (inspired by [24]).

The adaptation process involved selecting phenomena that are central to Italian grammar (e.g., noun-determiner agreement, subject-verb agreement, verb argument structure, clitic usage, and non-local dependencies) and reformulating the examples to align with the minimal pairs methodology. For instance, items from English BLiMP, if compatible with and relevant for Italian morphosyntax, were carefully translated and restructured to account for Italian-specific syntactic and morphological features.

## 4. BLiMP-IT: automated generation

### 4.1. Corpus Creation for Lexicon Extraction

A fundamental component of our automatic generation pipeline is the creation of a large high-quality Italian dataset, initially developed to take part to the BabyLM challenge [25], which consists of approximately 3 million tokens sourced from diverse resources and serves as the foundation for lexicon extraction. It is divided into five sections: child-directed speech (CHILDES Italian section), child movie subtitles (from OpenSubtitles), child songs (from the Zecchino D'Oro repository), telephone conversations (VoLIP corpus, [26], and fairy tales (from copyright-expired sources). After a cleaning process that removed metalinguistic annotations and children's productions, the corpus contains 2,431,038 tokens with an overall Type-Token Ratio (TTR) of 0.03. The distribution of tokens across sections is as follows: CHILDES (346,155 tokens, TTR = 0.03), SUBTITLES (700,729 tokens, TTR = 0.05), CONVERSATIONS (58,039 tokens, TTR = 0.11), SONGS (222,572 tokens, TTR = 0.08), and FAIRY TALES (1,287,826 tokens, TTR = 0.05). Statistical analysis of the corpus ensures sufficient lexical diversity and coverage of the linguistic phenomena under investigation.

### 4.2. Lexicon Extraction and Linguistic Tagging

We extract a lexicon from the corpus that captures key linguistic attributes for each word. First, we annotate words with both POS and UPOS tags using state-of-the-art taggers (spaCy). In addition, we manually labeled nouns with animacy information to address semantic nuances. This lexicon forms the basis for selecting appropriate words when generating minimal pairs.

### 4.3. The pipeline for minimal pairs generation

Our automatic minimal pair generation process follows a structured and modular pipeline designed to produce large-scale, linguistically controlled sentence pairs. This section details each stage of the pipeline, emphasizing both the design rationale and the implementation steps.

- **Resource loading:** The process begins with the loading of two key components: (i) a lexicon extracted from the Italian corpus, enriched with linguistic annotations such as part-of-speech (POS), universal POS (UPOS), animacy, and morphological features; and (ii) a set of tag sequences, each defining the structure of a sentence in terms of syntactic categories. These tag sequences are constructed in minimal pairs, where each pair consists of a grammatical and an ungrammatical variant. The ungrammatical variant introduces a targeted morphosyntactic violation (e.g., a mismatched subject-verb agreement or incorrect determiner-noun concord), ensuring that the only difference between the two sequences is the critical grammatical contrast under investigation. This design supports a controlled evaluation of model sensitivity to specific phenomena.

- **Tag Matching and Word Selection:** Once the tag templates are loaded, the system proceeds to match each tag in a sequence with a suitable word from the lexicon. Word selection is guided by the required grammatical features encoded in the tag (e.g., number, gender, animacy, tense). To prevent repetition and encourage lexical diversity, a tracking mechanism records previously selected tokens and prioritizes less frequently used words when possible. Special handling is applied to verbs, which require agreement features to be matched precisely with their subject counterparts. The system identifies verb roots and selects appropriate inflected forms based on number and person. Additionally, animacy plays a role in selecting nouns and pronouns, especially in structures where semantic compatibility influences grammaticality (e.g., reflexive pronouns or clitic constructions). If a matching lexical item cannot be found for a given tag within the constraints, the system either retries with an alternative lexeme or skips the current sequence to maintain sentence well-formedness and overall dataset quality.

- **Sentence Construction:** With the tag-to-word mappings established, the system constructs sentence pairs by linearizing the selected tokens according to their tag sequence order. Minimal surface normalization is performed at this stage, including the insertion of appropriate punctuation, handling of elisions and contractions, and capitalization of the sentence-initial token. Each sentence is generated in parallel with its minimal counterpart, ensuring that both share identical lexical items and structure, differing only in the targeted morphosyntactic element. This parallelism ensures the interpretability and diagnostic value of each pair.

- **Iterative Generation and Quality Control:** To ensure dataset diversity and minimize redundancy, the pipeline includes a control mechanism to detect and filter out duplicate or near-duplicate sentence pairs. Duplicates are identified not only by surface form but also by underlying tag structure, preventing syntactically redundant examples from being overrepresented. The generation process is iterative: multiple passes are performed over the tag templates and lexicon, dynamically adjusting word choices based on availability and prior usage. When generation fails (e.g., no valid word found for a required combination), the system logs the instance and skips the pair to avoid compromising the grammatical precision of the dataset. Internally, each generated (good-sentence, bad-sentence) tuple is stored in a Python set and tested for membership in O(1) time: any exact surface-form repeat is skipped. To prevent an endless loop when unique pairs run out, the loop also caps the total number of attempts (e.g., 10× the target) and logs a warning if it cannot reach the requested count.

- **Quality check:** We employ a human-in-the-loop strategy, where a team of linguistic experts meticulously reviews the generated minimal pairs to ensure grammatical accuracy and naturalness. Each pair is independently rated by at least two reviewers and any doubts trigger a discussion session to reach consensus and to establish if the pair must be removed. Experts also log error types and provide targeted feedback on problematic tag sequences or lexicon entries.Their expertise not only enhances the overall quality of our evaluation tool but also ensures inter-rater reliability, fostering consistency and objectivity in the assessment process.

## 4.4. Methodological challenges

While the automatic generation pipeline described above enables scalable creation of minimal pairs, its implementation also revealed several methodological challenges that required careful consideration. First, the process of animacy annotation introduced a bottleneck due to the need for manual labeling. Although part-of-speech (POS) and universal POS (UPOS) tags could be obtained using existing NLP tools such as spaCy, the classification of nouns and pronouns based on animacy required human intervention. This task is particularly sensitive in Italian, where animacy can influence grammaticality judgments, especially in constructions involving clitics, reflexives, or subject-verb agreement. Ensuring consistent annotation across the lexicon was essential to preserve the validity of minimal pairs involving semantically conditioned structures. Second, the construction of sequence tags—representing grammatical and ungrammatical syntactic structures—proved complex. Tag sequences must encode subtle contrasts in grammaticality while remaining compatible with the lexicon and word selection rules. Designing these templates required extensive linguistic knowledge and iterative refinement. In some cases, identifying minimal but meaningful structural contrasts demanded revisiting the theoretical underpinnings of the targeted phenomenon. Another critical challenge was matching lexical items to abstract tag templates. While the lexicon provides detailed linguistic annotations, finding appropriate word combinations that meet all morphological and syntactic constraints was nontrivial. This was especially true for verbs, where selecting appropriate inflected forms (e.g., singular/plural, tense, auxiliary selection) required tracking agreement features and root compatibility. Additionally, ensuring lexical diversity while avoiding repetitive or unnatural constructions added further complexity to word selection. The generation process also involved quality control mechanisms to filter out low-quality or duplicate pairs. Despite automated checks, certain errors—such as overly rigid or implausible sentences—could only be caught through manual review. This underscores the continued importance of human-in-the-loop validation, particularly for capturing edge cases that automatic systems may overlook. Finally, the reliance on a corpus of child-directed speech and simplified texts (developed for the BabyLM Challenge) had implications for lexical diversity. While the corpus offered controlled and well-annotated input data, its domain-specific nature may limit coverage of more formal or idiomatic constructions. Addressing this limitation requires expanding the source corpus in future iterations to include a broader range of registers and genres.

## 5. Results

Our pipeline successfully generated 2,899 minimal pairs covering 18 phenomena—spanning agreement, non-local dependencies, and other key categories—from the 78 phenomena included in BLiMP-IT. We are actively working to expand this coverage to include all 78 phenomena. Following the methodology proposed for English in [18], early findings from employing BLiMP-IT to assess models that replicate the constraints children face while learning language show that strong performance on standard evaluation metrics doesn't translate to equally strong results on minimal pair tests, and these models fail to capture the linguistic patterns typical of children [19]. These initial findings indicate that children's language learning follows expected linguistic principles, while large language models demonstrate inconsistent behavior. Specifically, preliminary results [4] reveal that although training different language models (GPT-2, BERT, ad hoc RNN) on approximately 10 million tokens increases overall accuracy (rising from 40% to 79%), its performance on certain BLiMP-IT components actually worsens (dropping from 61% to 52%). The models' reliability in distinguishing correct from incorrect language forms decreases from 44% to 32%, falling short of human benchmarks (around 86% accuracy and 72% consistency observed in seven-year-old children). We are still in the process of testing and evaluating different models on our automatically-generated minimal pairs.

## 6. Discussion

BLiMP-IT represents a significant step forward in the evaluation of Italian language models by providing a benchmark that combines manually curated linguistic phenomena with an innovative pipeline for automatic minimal pair generation. Through the integration of diverse resources and a structured methodology, our approach ensures both linguistic relevance and scalability. One of the strengths of our approach lies in the combination of curated content and automation. While the manual adaptation of resources such as COnVERSA and AcCompl-it guarantees that the dataset reflects core aspects of Italian grammar, the automated generation pipeline makes it possible to scale the number of minimal pairs efficiently and consistently. This dual strategy enables us to address a broader range of morphosyntactic phenomena while maintaining control over the

[4] Forthcoming in Proceedings of GLOW 47

grammatical integrity of the examples. Moreover, by implementing a human-in-the-loop quality control process, we ensure that automatically generated sentence pairs remain grammatically accurate and linguistically natural. Linguistic experts systematically validate the outputs, which strengthens the internal consistency of the dataset and enhances its reliability for downstream evaluation tasks. This step is crucial given the complexity of Italian syntax and morphology, where subtle changes in word form or word order can significantly affect acceptability. Another key contribution of BLiMP-IT is its focus on minimal pairs as an evaluation methodology. This approach provides a fine-grained tool for testing specific grammatical contrasts, such as subject-verb agreement or clitic placement, that are often underrepresented in broader benchmarks. By isolating individual linguistic features, BLiMP-IT allows researchers to probe the syntactic sensitivity of language models in a controlled and interpretable way. The breadth of phenomena included in BLiMP-IT, spanning from local agreement patterns to long-distance dependencies, also makes it a valuable diagnostic resource. In particular, the inclusion of lesser-tested constructions such as parasitic gaps or ATB (Across-The-Board) movement contributes to a more comprehensive picture of a model's grammatical competence. This is especially important in the context of evaluating transformer-based models, which may succeed in surface-level generalizations but struggle with deeper syntactic dependencies. Furthermore, the design of BLiMP-IT allows for ongoing extension and refinement. Since the core generation pipeline is modular, it can be expanded to incorporate additional phenomena as more linguistic data becomes available. The current focus on 18 phenomena, though already substantial, represents only a subset of the 78 phenomena identified in the full benchmark framework. Ongoing work is directed toward increasing this coverage while maintaining the same level of quality control. Finally, by grounding our dataset in a linguistically annotated corpus developed for the BabyLM Challenge, we ensure that our lexical and syntactic inputs are well-attested and systematically organized. Although this corpus primarily reflects child-directed language, it still provides sufficient lexical and morphosyntactic variety to generate a diverse and representative set of sentence pairs. The detailed analysis of type-token ratios across subdomains (e.g., fairy tales, songs, subtitles) confirms that the source material supports the goals of minimal pair generation in a linguistically meaningful way.

## 7. Conclusions

We have presented BLiMP-IT, a novel evaluation benchmark for Italian language models that integrates curated linguistic resources with an automated pipeline for minimal pair generation. This hybrid methodology allows us to systematically and efficiently generate sentence pairs that test key morphosyntactic competencies—such as agreement, inflection, verb argument structure, and non-local dependencies—across 78 targeted phenomena. Our approach ensures scalability while maintaining high linguistic quality through expert validation. The contribution of BLiMP-IT is twofold: first, it addresses the significant gap in Italian-specific evaluation datasets for language models, and second, it proposes a generalizable, language-agnostic framework for benchmark construction. These features make BLiMP-IT a valuable tool not only for evaluating existing LMs, but also for supporting their training and fine-tuning—particularly in low-resource or developmentally plausible settings, such as those promoted by the BabyLM challenge. The automatic generation pipeline opens the door for large-scale, consistent, and reusable evaluation items, minimizing the reliance on manual crafting, which is both time-consuming and difficult to scale. This makes it feasible to evaluate a wide range of grammatical contrasts in a way that is both linguistically informed and computationally practical. Looking forward, we aim to expand coverage to all 78 phenomena, increase the lexical and syntactic diversity of the generated items, and incorporate more advanced linguistic annotations, such as semantic roles and animacy, using semi-supervised or model-assisted techniques. Additionally, we plan to develop a fully language-independent version of the pipeline, enabling researchers to create similar benchmarks for other morphologically rich languages. By combining linguistic depth with computational scalability, BLiMP-IT sets a new standard for targeted evaluation of linguistic competence in Italian language models and offers a blueprint for multilingual benchmarking in the future.

## 8. Limitations

As discussed in Section 4.4, several methodological challenges were encountered during the design of the automatic generation pipeline. In addition to those, our current setup faces broader limitations that affect the dataset's generalizability and scalability. Most notably, the underlying corpus was originally developed for the BabyLM Challenge and, as such, is largely composed of texts classified as 'child-directed speech'. This focus limits the diversity of the lexicon used for minimal pair creation and may not fully represent the broader spectrum of language registers. In future work, we plan to extend our dataset to incorporate a wider range of text sources, thereby enriching the lexicon and enhancing representativeness. Additionally, our current pipeline relies on manual processes for animacy annotation and the construction of sequence tags. This dependency on manual efforts introduces potential inconsistencies and limits scalability. We aim to transition to a fully automated approach in subsequent iterations, which will improve both the reliability and efficiency of our pipeline.

**Abstract**

This paper investigates how Large Language Models (LLMs) represent the affective experiences of individuals with disabilities on social media. We simulate posts using LLMs and compare them to authentic user-generated content in English, collected from disability-related subreddits, focusing on sentiment, emotion, and indicators of depression. Our analysis reveals that LLMs tend to produce overly positive and idealized portrayals, often failing to capture the complexity and nuance of disabled individuals' emotional expressions. These misrepresentations underscore broader concerns about the limitations of LLMs in authentically reflecting the lived experiences of marginalized communities.

**Keywords**

Large Language Models, Representation, Disability, Bias

## 1. Introduction

Recent studies have shown that computational models of language, trained on real-world data, reflect and amplify harmful societal biases, often disproportionately affecting marginalized communities [1, 2, *inter alia*]. This can lead to psychological harm, unhappiness, and, in some cases, suicide attempts [3]. The increasing use of Large Language Models (LLMs) has exacerbated the risks related to this issue, potentially spreading these representational harms further [4]. In response, researchers have proposed methods to mitigate these biases. For example, recent LLMs have incorporated de-biasing techniques and AI guards (e.g., Inan et al. [5]) that block offensive questions and adjust responses to be non-toxic and positive. However, recent work on studying the depiction of personas from marginalized groups of LLMs indicates that many biases are concealed even in texts containing words with a positive sentiment, which can still offend their sensitivities and lead to pernicious positive portrayals [6]. Moreover, in the specific case of disability, excessive positivity can be counterproductive to inclusion: some members of the disability community express dissatisfaction when they are portrayed in an excessively and pathetically positive and optimistic manner: according to them, this form of optimism reinforces what is known as "inspiration porn" [3, 7, 8] which has the negative consequence of dehumanizing individuals with disabilities, leading society to praise their efforts rather than working toward tangible solutions that alleviate the often strenuous challenges they face in survival through accessible political and social policies.

In this paper, we thus examine how current LLMs portray individuals with disabilities[1] from an affective perspective. Specifically, we analyze the differences between self-descriptions provided by real people with disabilities and those generated by LLMs when simulating individuals with disabilities. Our focus is on assessing the sentiment, emotional tone, and levels of depression in these descriptions, with the aim of understanding how authentically LLMs represent the emotional experiences of people with disabilities and identify differences and patterns in the affective portrayal of disability in AI-generated content.

Our work aims to deepen discussions on how LLMs should authentically represent disability, a topic that has received comparatively less attention in NLP literature [3], despite the frequent discrimination faced by disabled individuals [9, 10]. Specifically, we address the following Research Question (RQ):

> Can LLMs authentically represent the affective experiences of people with disabilities on social media?

Answering the above RQ, we offer the following contributions:

CLiC-it 2025: Eleventh Italian Conference on Computational Linguistics, September 24 — 26, 2025, Cagliari, Italy

[1] In this paper, we primarily use people-first language (e.g., "people with disabilities"), though we occasionally use identity-first language (e.g., "disabled people", "non-disabled people") based on sentence structure. We recognize that preferences for people-first or identity-first language vary among individuals. we intend not to offend or diminish anyone's perspective.

**C1.** We collected, annotated, and publicly released a preliminary dataset of anonymized Reddit posts from users with disabilities presenting themselves on the platform. Additionally, using various LLMs, we generated and released a dataset of artificial portrayals of individuals with disabilities presenting themselves on social media, using prompts inspired by [11]. Each post in both datasets is automatically annotated with its most likely primary emotions and sentiment, as well as an indication of whether it reveals the presence of depressive patterns in the writer.

**C2.** We compared web-collected posts with those generated by LLMs to study how models represent individuals with disabilities from an affective point of view, identifying differences between real-world and AI-generated portrayals.

Our findings emphasize the need to expand research on stereotypes to address both negative ones and positive idealizations, as both can harm marginalized groups. Furthermore, the analysis of the dataset on people with disabilities reveals significant challenges they frequently face, often associated with negative emotions or depressive symptoms, a fact already observed in literature [12]. Experiments also show that LLMs tend to minimize these aspects when portraying people with disability and substitute them with a more socially desirable narrative.[2]

## 2. Related Work

**LLMs and Fairness.** Recent advancements in LLMs have transformed text processing and generation, increasingly shaping social interactions. However, these models can perpetuate harmful stereotypes and biases [4], inheriting issues from uncurated internet data, such as misrepresentations, derogatory language, and biased associations [13, 6, 14, 1, 2]. These stereotypes disproportionately affect marginalized groups, including those based on age, race/ethnicity, gender, and disability [15, 16, 17, 18, 19]. As awareness of these misrepresentations grows, research has focused on bias and stereotypes evaluation, mitigation methods, and datasets to address them [4]. However, despite 1.3 billion people living with disabilities [20], there is limited research on stereotypes regarding disability representation in LLMs [21, 22]. Furthermore, existing datasets like BBQ [23], HolisticBias [19], and PANDA [24] address disability representation partially, lacking a comprehensive range of impairments and analysis.

**Bias against people with disabilities.** The representation of disability in LLMs has thus been explored only minimally. Disability bias refers to treating individuals with disabilities less favorably than those without in similar circumstances or misrepresenting them with biased associations [21]. Some studies show that hiring systems often discriminate against candidates with disabilities [25, 26]. In particular, Glazko et al. [26] highlights that even GPT-4 shows bias in suggesting job candidates. Venkit et al. [21] and Hutchinson et al. [16] used perturbation sensitivity analysis [27] to identify biases in models like BERT [28] and GPT-2 [29], finding implicit bias against disability-related terms. [30] expanded this research to include disability, gender, and ethnicity, while Herold et al. [31] found BERT frames disabilities mainly in medical terms. Recent work by Li et al. [32] suggests newer models like GPT-3.5 and GPT-4 offer less biased portrayals of disabilities.

**LLM-based portrayals and human simulation.** A related research trend is human simulation, where LLMs are assessed on their ability to replicate human behavior, a concept introduced by the Turing Experiment [33]. This is applied to simulate behavior in various social and political settings [34, 35] and to identify stereotypes [11, 6]. Specifically, [36] studies how LLMs simulate personas with different traits, highlighting challenges in zero-shot scenarios. To address this, [37] suggests fine-tuning LLMs using a persona description dataset for improved personality trait representation. Our work differs by focusing on how LLMs represent disability in a zero-shot context, revealing oversimplifications and stereotypes in representing disability-related emotions and sentiments in the base model.

## 3. Methods

### 3.1. A dataset of LLMs-generated portrayas of people with disabilities

Using a set of prompts inspired by Kambhatla et al. [11] and Cheng et al. [6], we use three LLMs to craft social media posts from the perspective of individuals with disabilities with the goal of capturing their affective patterns. In particular, we employ Mixtral-8B (Mixtral-8x7B Instruct, quantized to 4 bits using GPTQ [38] due to hardware limitations), GPT-4o-mini, and Gemini-1.5F (the Flash variant). For the latter two models, we utilized their paid APIs. The models are used with the temperature set to 1.0 to guarantee the variability and randomness of the responses generated.

Each prompt asks the models to introduce themselves as an individual with a disability and share experiences related to disability or general life experiences such as ex-

[2] The code and the dataset are available at: https://github.com/marcobombieri/LLM-disability-representation

| *[PERSON]* | *[ACTIVITY]* |
|---|---|
| **P1**: *a person with a disability* | **A1**: *sharing experiences related to your disability* |
| **P2**: *a person with autism* | **A2**: *sharing the emotions you felt today* |
| **P3**: *a person with blindness* | **A3**: *sharing the thoughts you had today* |
| **P4**: *a person with deafness* | **A4**: *sharing the activities you did today* |
| **P5**: *a person with cerebral palsy* | **A5**: *asking the community a question or suggestion* |
| **P6**: *a person with depression* | **A6**: *commenting on today's events* |

**Table 1**
Possible values for *[PERSON]* and *[ACTIVITY]* in our prompt template: *"Imagine you are [PERSON]. Write a social media post introducing yourself and [ACTIVITY]."*

pressions of emotions, feelings, or thoughts, descriptions of daily activities, questions for the community, requests for suggestions, or commentary on current events, i.e., the typical activities a user can do on a social media platform [39]. We opted to keep the prompts as general as possible following the motivations discussed in [6], since more detailed prompts may direct the model toward a specific topic and introduce further stereotypes. In more detail, all the prompts follow the template:

> *"Imagine you are [PERSON]. Write a post on social media introducing yourself and [ACTIVITY]."*

where *[PERSON]* and *[ACTIVITY]* can be one of those defined in Table 1.

The combination of P1-P6 with A1-A6 aims to generate posts from the perspective of individuals with different types of disabilities or impairments. Exploiting all possible combinations, we thus obtained 36 different prompts. Each prompt is submitted 10 times to take into account the output variability of the models, thus obtaining, for each LLM, a collection of 360 posts of artificial portrayals of people with disabilities. We call LLMD$_{\text{GPT}}$, LLMD$_{\text{GEM}}$, and LLMD$_{\text{MIX}}$ the datasets containing the posts generated by GPT-4o-mini, Gemini-1.5F, and Mixtral-8B, respectively. In this preliminary work, we narrow our focus to the disabilities examined in similar studies, such as [26], resulting in six alternative options (P1–P6) for *[PERSON]*.

## 3.2. A dataset of people with disabilities' self-descriptions

In addition to the datasets described in Section 3.1, we collected posts from six disability-related subreddits. We began with the general subreddit `r/disability`[3], which offers diverse discussions on disability-related topics and ranks among the top 2% by size. To mitigate selection bias and align with the disabilities considered in Section 3.1, we added five focused subreddits: `r/blind`[4], `r/autism`[5], `r/depression`[6], `r/deaf`[7], and `r/celebralpalsy`[8]. These subreddits aim to foster community and exchange among disabled individuals. We included posts published until 2024 containing textual content, excluding empty posts or those with only links, images, or videos. Using Mixtral-8B and the below prompt, we filtered for first-person posts from users self-identifying as disabled, excluding content from caregivers, professionals, or others:

> *You are a text classifier operating on social media posts. You must classify posts into two disjoint classes, "1" or "2". Your answer must be in the format: "predictedClass;explanation," where "predictedClass" can be "1" or "2," and "explanation" briefly describes why you have chosen that class. Separate "predictedClass" from "explanation" with the string ";". Do not add other text. A post belongs to class "1" if: (the author of the post writes about himself/herself in the first person) AND ( the author of the post explicitly mentions his/her own disability/illness). A post belongs to class "2" otherwise. Follow the post you have to analyze:*
> {word}

From the filtered results, we randomly sampled 450 posts from `r/disability` and 220 from each of the disability-specific subreddits. Three annotators then manually reviewed all these posts, removing those wrongly annotated as relevant by the LLM. The final dataset, REDD, includes 352 posts from `r/disability`, 165 from `r/blind`, 174 from `r/autism`, 204 from `r/depression`, 171 from `r/deaf`, and 183 from `r/cerebralpalsy`.[9] To ensure annotation quality, 50

**Table 2**
Summarization of datasets collected in this paper, together with the number of posts they contain and the average number of tokens per post.

posts were independently labeled by three annotators, achieving a Fleiss' Kappa of $0.875$, indicating very high agreement [40]. Table 2 summarizes the obtained datasets and their sizes that are in line with state-of-the-art studies [6].

### 3.3. Comparison metrics

To address our research question, we aim to perform a pairwise comparison of the previously described datasets, i.e., the LLM-generated portraits (Section 3.1) and human descriptions from Reddit users (Section 3.2) using metrics descriptive of the affects of an individual. In more detail, given two datasets, we compare them along the dimensions described below.

**Sentiment.** The predominant *sentiment* of each post $p$ is computed using VADER [41], which assigns a sentiment score $S(p) \in [-1, +1]$. Following VADER indications, a post is classified as positive if $S(p) > 0.05$, negative if $S(p) < -0.05$, and neutral otherwise. For a dataset $P = [p_1, \dots, p_N]$ of $N$ posts, we compute the number of positive, negative, and neutral posts:

$$\begin{aligned} N_{\text{positive}} &= \left|\{p_i \mid S(p_i) > 0.05\}\right|, \\ N_{\text{negative}} &= \left|\{p_i \mid S(p_i) < -0.05\}\right|, \\ N_{\text{neutral}} &= \left|\{p_i \mid -0.05 <= S(p_i) <= 0.05\}\right|. \end{aligned}$$

We then compute the relative frequency of sentiment-loaded posts:[10]

$$P_{\text{positive}} = \frac{N_{\text{positive}}}{N},\ P_{\text{negative}} = \frac{N_{\text{negative}}}{N}.$$

**Emotions.** The distribution of *emotions* emerging from a dataset using the NRC Word-Emotion Association Lexicon (EmoLex) [42], namely *anger*, *fear*, *anticipation*, *trust*, *surprise*, *sadness*, *joy* and *disgust*. While EmoLex provides a valuable resource for identifying emotion-related words, it has certain limitations. Specifically, it is based solely on word-level counts from the lexicon. It does not account for contextual factors such as negations, word dependencies, or the broader semantic structure of the text. Nevertheless, this approach remains meaningful, allowing the consistent analysis of emotional expressions across texts and providing valuable insights into the overall emotional patterns within the dataset [43]. Let $P = \{p_1, p_2, \dots, p_N\}$ represent the dataset with its set of $N$ posts. For each post $p_i$, we calculate the number of words associated with each emotion $e \in E$, denoted by $w_{e,p_i}$, where $w_{e,p_i}$ is the number of words in post $p_i$ that are associated with emotion $e$. If a word is linked to multiple emotions, all associated emotions are considered. The proportion $\rho_{e,p_i}$ of words in post $p_i$ associated with emotion $e$ is given by:

$$\rho_{e,p_i} = \frac{w_{e,p_i}}{w_{p_i}}$$

where $w_{p_i}$ is the total number of words in post $p_i$ that are linked to any emotion. At the dataset level, the average proportion of each emotion across all posts is computed as:

$$\bar{\rho}_e = \frac{1}{N}\sum_{i=1}^{N} \rho_{e,p_i}.$$

**Depression.** The indication of the presence of *depression* as determined by the best-performing model from the Shared Task on *Detecting Signs of Depression from Social Media Text* at LT-EDI-ACL2022 [44].

Let $p_{i,l}$ denote the predicted depression label for a given post $p_i$, where:

$$p_{i,l} \in \left\{ \begin{array}{l} l_1 = \textit{no depression}, \\ l_2 = \textit{moderate depression}, \\ l_3 = \textit{severe depression} \end{array} \right\}.$$

To analyze the distribution of labels across the dataset,

compile a dataset of posts by people with disabilities to support our analysis; the LLM (78% accuracy) was used solely to assist filtering.

[10] Posts with scores between $-0.05$ and $0.05$ are considered neutral. Since REDD is the only dataset containing neutral posts — and only two such posts — we chose to focus the following analysis exclusively on positive and negative posts.

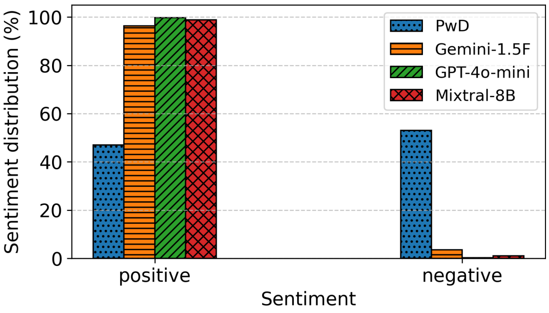

**Figure 1:** Comparison of sentiment between posts from people with disabilities (PwD) on Reddit (REDD Dataset) and posts generated by Gemini-1.5F (LLMD$_{\text{GEM}}$ Dataset), GPT-4o-mini (LLMD$_{\text{GPT}}$ Dataset), and Mixtral-8B (LLMD$_{\text{MIX}}$ Dataset).

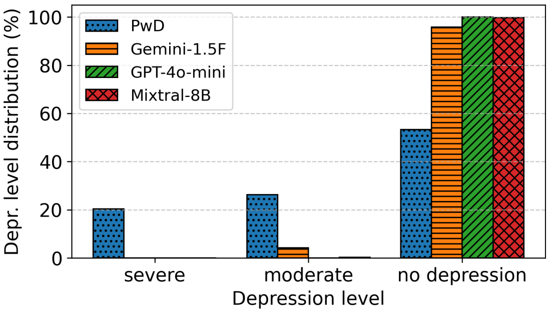

**Figure 2:** Comparison of depression levels between posts from people with disabilities (PwD) on Reddit (REDD Dataset) and posts generated by Gemini-1.5F (LLMD$_{\text{GEM}}$ Dataset), GPT-4o-mini (LLMD$_{\text{GPT}}$ Dataset), and Mixtral-8B (LLMD$_{\text{MIX}}$ Dataset).

we define the proportion of each label $l \in \{l_1, l_2, l_3\}$ as:

$$P(l) = \frac{N_l}{N},$$

where $N$ represents the total number of posts in the dataset, and $N_l$ is the number of posts $p_{i,l}$ assigned to label $l$.

Sentiment, emotion, and depression analyses offer quantitative insights into emotional tone and mental health indicators. These analyses enable affective comparisons with LLM-generated texts and provide a preliminary valuable clues about how LLMs represent individuals with disabilities.

In our setting, to address our RQ, we perform sentiment, emotion, and depression analysis on LLMD$_{\text{GEM}}$, LLMD$_{\text{GPT}}$, LLMD$_{\text{MIX}}$, and REDD, comparing the first three datasets generated by the LLMs with the data from people with disabilities (REDD).

## 4. Results and Discussions

Figures 1, 2, and 3 illustrate the differences between the posts in REDD and those LLM-generated, i.e., those collected in LLMD$_{\text{GPT}}$, LLMD$_{\text{MIX}}$, and LLMD$_{\text{GEM}}$, in terms of sentiment, depression level, and emotion, respectively.

Figure 1 shows that the three LLMs overwhelmingly generate posts with positive sentiment, ranging from $99.72\%$ for GPT-4o-mini (LLMD$_{\text{GPT}}$ dataset) to $96.39\%$ for Gemini-1.5F (LLMD$_{\text{GEM}}$ dataset). In contrast, actual Reddit posts (REDD dataset) present a starkly different picture, with $53.06\%$ of posts exhibiting negative sentiment. This discrepancy suggests that LLMs systematically underrepresent the negative emotional tone often present in real discussions about disability. The tendency to default to positivity may create an artificial and potentially misleading portrayal of lived experiences.

Figure 2 further reinforces this pattern, as GPT-4o-mini exhibits no signs of depression, and Mixtral-8B has only one post classified as "moderate depression" in the LLMD$_{\text{MIX}}$ dataset. Gemini-1.5F shows slightly higher rates, with $4.17\%$ of posts categorized as "moderate depression" and $95.83\%$ as "not depression". Notably, the few instances of moderate depression detected in LLM-generated content occur only when the models explicitly attempt to portray individuals with depression—and even then, at very the very low rates indicated above. These results contrast sharply with the Reddit dataset, where $20.42\%$ of posts are labeled as "severe depression" and $26.26\%$ as "moderate depression". In the collected dataset, posts exhibiting symptoms of depression are present across all the subreddits. The substantial under-representation of depressive expressions in LLM-generated content suggests that these models fail to capture the full emotional depth of real-life disability narratives. By filtering out or minimizing negative expressions, LLMs risk misrepresenting the struggles and challenges discussed in real-world communities, substituting them with a more palatable narrative that aligns with a non-disabled, socially desirable perspective.

Figure 3 further highlights these discrepancies, showing that Reddit posts contain significantly more negative emotions, such as anger, disgust, fear, and sadness, while LLM-generated posts emphasize positive emotions, including joy, trust, surprise, and anticipation. This overrepresentation of positivity suggests that LLMs adopt an overly optimistic and sanitized perspective on disability, potentially reinforcing harmful biases related to inspiration porn. The lack of emotional diversity in LLM-generated content may contribute to an inaccurate or even dismissive portrayal of the emotional realities experienced by people with disabilities.

Overall, these preliminary findings suggest that LLMs fail to authentically replicate the emotional tone of real experiences of social media disabled users. Instead, they

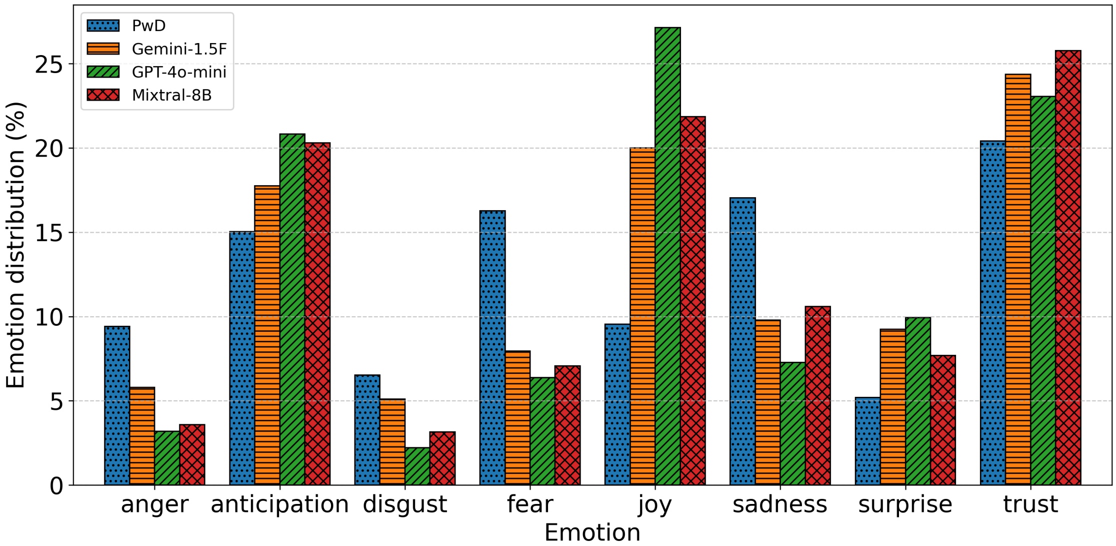

**Figure 3:** Comparison of emotions between posts from people with disabilities (PwD) on Reddit (REDD Dataset) and posts generated by GEMINI-1.5F (LLMD$_{GEM}$ Dataset), GPT-4O-MINI (LLMD$_{GPT}$ Dataset) and MIXTRAL-8B (LLMD$_{MIX}$ Dataset).

appear to spread a positivity bias, which may impact how disability is represented in AI-generated discourse.

To complement our quantitative metrics, we conduct a preliminary qualitative analysis of both LLM-generated and real posts, examining their structure and recurring themes. LLMs tend to frame disability through consistently positive lenses, emphasizing inclusion, accessibility, and triumph over adversity, with frequent use of words like *advocacy*, *inclusion*, *grateful*, *excited*, and *proud*. Follow an excerpt of a post generated by GPT-4O-MINI when representing a blind person:

> *I'm a **proud** member of the blind community. [...] One of my biggest passions is sharing my experiences and **advocating** for **accessibility** and **inclusion**. [...] I also want to highlight the **amazing** community I've found among fellow visually impaired individuals. We share stories, support one another, and **inspire** each other every day [...].*

In contrast, real posts by people with disabilities more often reference health, educational or financial struggles, using terms such as *pain*, *unemployed*, *bad*, and *anxiety*, **worse**, reflecting a broader emotional range and lived complexity.

Follow an excerpt of a post from `r/blind`:

> *I was born blind. Always been this way. From the time I was in high school, I began to have really **bad insecurities** about my blindness. [...] Growing up, **I hated** every blind person I went to school with. []. By the time I got to high school, **it just got worse and worse**. [...]*

In future research, we will expand this preliminary analysis with an in-depth qualitative and qualitative thematic analysis of posts.

**Answer to RQ.** The results reveal that the LLMs' affective descriptions of disability significantly differ from those expressed by real people with disabilities. LLM-generated texts largely emphasize positive sentiments and emotions, minimizing or entirely omitting the negative feelings that individuals with disabilities often experience. This tendency risks fostering a form of toxic positivity that overlooks the complex emotional landscape of disability, as highlighted by [45]. The analysis of REDD's posts, however, paints a starkly dangerous picture, where individuals with disabilities frequently express negative emotions such as anger, sadness, and fear. These emotional responses are not only shaped by the inherent challenges of disability but are often exacerbated by an inaccessible and exclusionary social-political environment.

## 5. Conclusions

In this paper, we investigated how LLMs represent disability from an affective point of view by comparing AI-generated portrayals with social media posts authored by individuals with disabilities. By leveraging a dataset of Reddit posts and artificial portrayals generated by LLMs, we analyzed the emotional tone, sentiment, and depressive patterns of these texts. Our work contributes not only to a publicly available dataset but also to insights into the fundamental differences in how LLMs and real individuals describe disability, highlighting significant oversimplifications. Most specifically, through our experiments, we found that LLMs frequently idealize disability-related affective experiences, producing overly optimistic portrayals that ignore the complex realities and challenges faced by individuals with disability. In stark contrast, posts written by real individuals often convey more nuanced emotions, including negative feelings stemming from the intersection of their disabilities with inaccessible and non-inclusive societal systems.

This disconnect highlights the risk of toxic positivity, where overly optimistic portrayals diminish the real challenges faced by disabled individuals. Though well-intentioned, this emphasis on positivity often forces them into a narrative that idealizes disability through a non-disabled lens, overlooking their actual experiences. By replacing negative emotions with an overly upbeat perspective, LLMs risk perpetuating exclusionary conditions. Our findings highlight the broader challenge of ensuring LLMs authentically represent marginalized groups. While addressing negative stereotypes in AI is crucial, our study calls for a more nuanced approach that reflects the diverse realities of marginalized groups without reductive idealizations. This paper raises a critical question: should LLMs represent affective experiences in an exclusively optimistic, "good vibes only" manner, or should they strive for more authentic, emotionally complex portrayals that better reflect real human experiences?

In future work, we plan to test additional prompts and simulate a broader range of social media scenarios. We also plan to expand the collection of posts by including a wider range of subreddits, social media platforms, and languages. This will help capture a more diverse set of experiences from individuals with disabilities. We also aim to include a broader spectrum of disabilities and analyze how their representation varies across different categories. Additionally, we will enhance this study with thematic analysis methods to examine discourses related to disabilities in real and LLM-generated posts, identifying keywords that distinguish the two corpora—those written by disabled individuals and those generated by LLMs. A qualitative analysis will further complement this approach. Finally, comparing how LLMs portray individuals with disabilities versus the general population, following the methodology in [6], will offer deeper insights into these dynamics and help address the risk of oversimplification or misrepresentation.

## Limitations

This paper is a preliminary work and thus has some limitations. First, we focused on a subset of disabilities to simplify the analysis. While this does not fully capture the complexity of the subject, it aligns with the approach taken in similar studies [26]. Second, we use lexicon-based tools to estimate emotions and sentiments, which may not always capture contextual nuances, potentially affecting the accuracy of the analysis. This methodology is, however, also employed in authoritative studies to ensure the method remains explainable and reproducible [6]. Furthermore, although we assume individuals who mention being disabled are indeed disabled, some may be bots or people pretending to be disabled. Finally, these findings are specific to the versions of the models and the dates on which they were tested (especially those accessed via API). As LLMs are updated and their guardrails evolve, these results may change.

## Ethical and societal implications

This paper has a positive impact by shedding light on how disability is represented in zero-shot LLMs, emphasizing crucial ethical considerations. Current debiasing and representation models focus on “category” rather than “individual,” leading to potentially generalized, insensitive, or inappropriate responses. A model aiming to be inclusive must understand the personal experience of the individual represented. These models often fail to capture pain, suffering, and depression, substituting them with overly positive language. While optimism may be suitable in some cases, neglecting suffering flattens a key human experience. A “only good vibes” approach risks marginalizing those experiencing hardships, not just people with disabilities but anyone going through difficult times, exposing to the risk of inspiration porn. Therefore, these models must reflect the complexity of human emotions authentically and respectfully to foster genuine understanding, inclusion, and support. While addressing such personal topics may unintentionally cause misunderstandings, our intention is to promote constructive dialogue between technologists and humanists for more inclusive AI systems.

## Abstract

The ability to recognize and interpret causal relations is fundamental for building robust intelligent systems. Recent research has focused on developing benchmarks and tasks to evaluate the inferential and causal reasoning capabilities of LLMs, such as the Pairwise Causal Discovery (PCD) task. However, most of these resources are limited to English. In this paper, we present Expli**CITA**, a translation of the English ExpliCa dataset [1], which is the first publicly available dataset for joint temporal-causal reasoning in Italian, enabling evaluation of LLMs on Italian PCD. We conduct an extensive empirical study across 20 Italian and multilingual models of varying sizes and training strategies, combining a perplexity-based evaluation of causal reasoning competence with multiple-choice prompting tasks in both zero-shot and few-shot settings. Our results show that all tested models, including the GPT family, struggle with the Expli**CITA** PCD task, more so than with the original English ExpliCa, in both evaluation scenarios. Moreover, native Italian models do not outperform fine-tuned multilingual alternatives. Consistent with prior findings, we observe that the linguistic competence of models, measured using perplexity-based metrics, is higher than their respective performances, measured via accuracy on prompting results; however, this gap tends to narrow with increasing model size. Finally, a per-class performance analysis reveals that models handle causal relations relatively better than temporal ones.

LLMs, Causal Reasoning, Language Resources, Evaluation, Benchmarking

## 1. Introduction

Recognizing *causal relations* is a core human cognitive skill. Causal understanding is in fact fundamental to intelligent reasoning [2]. Thus, a strong AI system should be capable of performing causal reasoning.

The past few years have in fact seen a vigorous debate about the extent to which large language models (LLMs) are actually capable of genuine inference, beyond mere pattern matching [3, 4, 5]. Among the inferences a model should be able to perform lies the causal one. Therefore, several benchmarks targeting causality have emerged recently [6, 7, 8].

A popular evaluation paradigm for causal reasoning is Pairwise Causal Discovery (PCD), which aims to detect pairwise causal relations from observational data. In a PCD task a model must determine if a causal link exists between two events, along with the direction of causality [9, 10]. A common way to frame this task is to give two sentences as input to the model (i.e., *"Martina has less chances of getting the flu"* and *"Martina has been vaccinated against the flu"*), and to ask the model if the first sentence is a consequence of the first with a yes/no question (in this case, groundtruth: *"yes"*) [1, 10].

Temporality plays a crucial role in the context of causality, as every causal relation inherently implies a temporal one: If an event A causes an event B, A must necessarily occur (or begin to occur) before B. Conversely, the presence of a temporal relation between two events does not necessarily imply a causal link. For this reason, we extended the PCD task to include the identification of temporal relations, to explicitly disentangle the interplay between causality and temporal sequencing.

To address this issue, in previous works we introduced the ExpliCa (**Expli**cit **Ca**usality) benchmark [1], offering a more controlled experimental setup that jointly addresses temporal and causal reasoning. ExpliCa presents pairs of sentences, each describing a distinct event, without any surface-level linguistic cues for temporal and causal relation, except for a *connective* that explicitly encodes both the type of relation (i.e., causal and temporal), and the order between the two events. For example, in [1], we asked the models to choose which of four connectives (*so*, *because*, *then*, and *after*) best represents the relation between the sentences *"Martina has less chances of getting the flu"* and *"Martina has been vaccinated against the flu"* (in this case, groundtruth: *"because".*)

Despite these progresses, resources for joint temporal-causal reasoning are still lacking, especially

in languages other than English. At the same time, a rich ecosystem of LLMs pre-trained on, or adapted to, languages other than English, including Italian, is rapidly emerging.

To partially fill this gap, we introduce **ExpliCITA** (**Explic**it **C**ausality in **ITA**lian). ExpliCITA is an Italian adaptation of ExpliCa and we believe it is the first benchmark dedicated to joint temporal and causal reasoning in Italian.

We also leverage the evaluation framework for ExpliCa to conduct the first large-scale evaluation of Italian language models on causal reasoning. The framework allows us to test both **competence** (what the model "knows" about the probability distribution of linguistic events) via perplexity, and **performance** (how it applies that "knowledge") via prompting [11, 12]. Specifically, the prompting task is formulated as a multiple-choice task, where models have to select the appropriate connective in a cloze-style prompt. We explore different generation settings: greedy decoding and the Outlines framework [13], under both zero- and few-shot regimes. Our evaluation includes a total 20 models across a spectrum of several sizes and training approaches: i.) seven native Italian models trained from scratch, ii.) four multilingual models fine-tuned on Italian, iii.) three open-weights multilingual models, iv.) an open-weight reasoning-specialized LLM, and v.) five commercial systems from the GPT family.

We make both the data and code available on GitHub to replicate our experiments.[1]

Our contribution is twofold:

- we present ExpliCITA, the first dataset for joint temporal-causal reasoning in Italian;
- we deliver an extensive empirical study across 20 Italian and multilingual models, following a robust evaluation framework combining an evaluation via perplexity with multiple-choice prompting in several settings. This allows us to highlight strengths, weaknesses, and performance variation across model types and sizes.

The remainder of the paper is organized as follows: Section 2 reviews related work; Section 3 introduces the ExpliCITA dataset; Section 4 details the experimental setup; and Section 5 presents and discusses the results.

## 2. Related Works

The study of causality and its linguistic expressions has recently regained momentum, particularly in the context of evaluating the reasoning capabilities of large language models (LLMs). In this domain, many evaluation datasets focus on presenting a contextual scenario to test causal inference [14, 6, 15, 16, 17, 18], while others challenge NLP systems to identify causal relations directly on the text [19, 16, 20], also along with temporal ones [21, 22, 23, 24, 25]. **ExpliCITA** stems from ExpliCa [1], a dataset developed to evaluate the ability of LLMs to detect explicit causal and temporal relations between events. In ExpliCa, relations are annotated via crowdsourcing and are signaled exclusively through a connective linking a pair of sentences, carefully stripped of any additional contextual or lexical cues. This controlled setup minimizes the influence of surrounding context and enables a more focused assessment of the model's reasoning on explicit relational cues.

Due to its design, ExpliCITA shares its structure with other datasets that frame implicit causal relations in a sentence-pair format, where each sentence expresses an individual event. Notable among these are the COPA dataset [26], the e-CARE dataset [27], and tasks from the BIG-Bench benchmark [28], which also test models on explicit causal reasoning. COPA and e-CARE were both incorporated into the original ExpliCa dataset.

While resources for English are abundant, the availability of non-English datasets for causal reasoning remains limited. Nevertheless, contributions exist for Spanish [29], German [30], Arabic [31], and Persian [32]. Among multilingual efforts, MECI [20] stands out as a resource where causal relations are annotated across several language editions of Wikipedia.

Causal reasoning, and related tasks such as Pairwise Causal Discovery (PCD), belongs to a broader class of inference-based tasks in natural language understanding. These tasks aim to evaluate a model's ability to derive implicit information from textual input, whether through logical entailment, causal attribution, or commonsense associations. Within this wider inference landscape, Natural Language Inference (NLI) benchmarks like XNLI [33] test models on cross-lingual entailment across 15 languages, while datasets such as X-CSQA [34] focus on cross-lingual commonsense reasoning in a question-answering format.

In the Italian context[35], the first dataset for textual entailment was introduced during the EVALITA 2009 evaluation campaign, comprising 800 sentence pairs derived from Wikipedia revision histories [36]. More recently, the HellaSwag-it dataset, an adaptation of the original HellaSwag dataset [37], was developed to test commonsense inference by asking models to choose the most plausible ending to a given scenario. Additionally, for causal reasoning, the COPA dataset was translated into Italian (and other languages) as part of the XCOPA project [38]. Both XCOPA-it and HellaSwag-it were integrated into ItaEval [39], a benchmark for evaluating LLMs on Italian commonsense and factual reasoning. ItaEval was featured in the 2024 Italian NLP evaluation

[1] https://github.com/Unipisa/ExpliCITA

campaign, CALAMITA [40], which included a wide range of datasets to test commonsense and factual knowledge. Among them, Gita [41] is particularly relevant here: it focuses on physical commonsense in Italian, presenting pairs of plausible and implausible stories composed of sentence sequences. To the best of our knowledge, ExpliCITA is the first dataset specifically dedicated to evaluating explicit causal and temporal reasoning in a controlled setting for the Italian language.

## 3. The ExpliCITA Dataset

The ExpliCITA Dataset is a direct translation of ExpliCa [1]. The original dataset was designed as a benchmark for evaluating explicit causal reasoning in LLMs, with a particular focus on distinguishing causal relations from temporal ones, using the PCD task. A thorough description of the dataset and its properties is reported in [1]. In the following, we highlight some of its key aspects.

Approximately a third of the items in ExpliCa are based on other existing datasets [42, 28, 27]. The remaining two thirds are manually crafted. In total, 600 items are in the dataset. Each item of the dataset comprises a sentence pair S1 and S2, where each sentence describes an event.

The dataset has two key dimensions, namely the *type of relation* and the *order of presentation.* As for the type of relation, the items were selected by authors to be equally divided into three main subsets: i.) CAUSAL, where the relationship is causal, and possibly of temporal precedence; ii.) TEMPORAL, where the relation is only of temporal precedence, without causality; iii.) UNRELATED, that includes thematically related sentences that are neither causally nor temporally related. Potential biases in lexical elements are controlled for using Mutual Information between lexical elements of the sentence pairs. This is done to avoid having very different lexemes in the UNRELATED group with respect to the other groups. The differences in the association strengths between lexemes in the three groups are not statistically significant.

As for the order of presentation, it can be either ICONIC (in short form *Ic*), if the sequence of events expressed in the two sentences matches their chronological and/or logical-causal order (e.g., "S1 then S2"), or ANTI-ICONIC (in short form, *A-Ic*), if the sequence of events expressed in the two sentences is inverted compared to their chronological and/or logical-causal order (e.g., the effect is mentioned before the cause: "S2 because S1"). Note that, for each sentence pair, the dataset includes both the Iconic and Anti-Iconic order for a total of $600 \times 2 = 1,200$ items.

The type of relation and the order of presentation are expressed via one out of four *connectives*, that act as linguistic cues to explicitly signal the nature of the relationship. In the English version of the dataset, the connectives are: *so* (Causal, Iconic), *because* (Causal, Anti-Iconic), *then* (Temporal, Iconic), and *after* (Temporal, Anti-Iconic).

A defining feature of the dataset is that **the connective is the sole linguistic cue** indicating the semantic relation between sentence pairs. To ensure a controlled and challenging evaluation of causal reasoning, the dataset excludes any additional explicit marker, such as causal verbs, and removes anaphoric references by avoiding personal pronouns. This design compels models to rely exclusively on event semantics and the connective itself, without support from broader contextual cues.

The dataset was then annotated via crowdsourcing by English native speakers. Specifically, annotators were asked to rate the acceptability of a sentence pair linked by one of the connectives. Each sentence pair, in both orders, with all possible connectives ($600 \times 2 \times 4 = 4800$ total items) was rated by 15 participants. For each sentence pair in both orders of presentation, the connective with the highest acceptability rating was considered as the ground truth. Note that the ground truth based on human ratings do not overlap perfectly with the original distinction in CAUSAL, TEMPORAL, and UNRELATED groups made by authors when building the sentence pairs.

To build ExpliCITA from ExpliCa, we followed a semi-automatic translation procedure. First, we used ChatGPT via the web interface[2] to translate each sentence from the 600 pairs independently. Then, each sentence was manually evaluated to address errors in the automatic translation. Errors ranged from mistakes in gender assignment (e.g., "*Luca è stata [...]*") to completely missing idiomatic expressions (e.g., "Marco ran the red light", translated as "*Marco ha corso la luce rossa*" instead of "*Marco è passato col rosso*"). A significant number of translations needed manual verification. For ExpliCITA, we used the following four connectives:

***Quindi*** - Indicates a causal relation in the iconic order. The event in S1 causes the event in S2.

***Perché*** - Indicates a causal relation in the anti-iconic order. The event in S1 is caused by the event in S2.

***E poi*** - Indicates a temporal relation in the iconic order. The event in S1 temporally precedes the event in S2.

***Dopo che*** - Indicates a temporal relation in the anti-iconic order. The event in S1 follows the event in S2.

The choice of multi-token expression for the temporal connectives is due to the fact that no sufficiently frequent single word in Italian conveys the proper meaning.

ExpliCITA includes each sentence pair in both orders of presentation. Thus, the number of data points is $600 \times 2 = 1,200$. We consider as our ground truth the results of the crowdsourcing experiment for ExpliCa [1]. In

| Group<br>Connective | CAUSAL | TEMPORAL | UNRELATED | Total |
|---|---|---|---|---|
| ***Quindi*** (Caus., Ic) | 181 | 15 | 66 | 262 |
| ***Perché*** (Caus., A-Ic) | 183 | 33 | 72 | 288 |
| ***E poi*** (Temp., Ic) | 17 | 207 | 180 | 404 |
| ***Dopo che*** (Temp., A-Ic) | 19 | 145 | 82 | 246 |

**Table 1**
Distribution of connectives across groups in ExpliCITA.

Table 1 we report statistics on the dataset. We consider both the original division in the three groups (CAUSAL, TEMPORAL, UNRELATED) and the numerosity of each connective, both in the three groups and globally.

## 4. Experimental Setting

The goal of our experiments is to test LLMs on the PCD task of the ExpliCITA dataset from two perspectives. On the one hand, we want to assess the linguistic **competence** of the model: the fact that it encodes some linguistic knowledge about causal and temporal relations. We do so by leveraging a **perplexity-based evaluation**. On the other hand, we want to address the actual **performance** of the model on the dataset. We do so via a **prompt-based evaluation** in which the model has to solve our PCD task, by identifying the correct connective for a sentence pair. Our main goal is to evaluate Italian LLMs on Italian data. In addition to native Italian LLMs, we also consider other model classes. Specifically, we account for i.) Italian fine-tuned models, i.e. open-weights models fine-tuned on Italian, ii.) open-weights multilingual models, iii.) open-weights reasoning models, and iv.) closed commercial models. All tested models are listed in Section 4.1.

**Perplexity-Based Evaluation.** This experiment is an exact replica of the one conducted in [1]. For each sentence pair in the dataset (i.e., in both orders of presentation), we derive one sentence for each connective, in the form "`S1 {{ connective }} S2`". We obtain $1,200 \times 4 = 4,800$ sentences in total. For each of them, we compute a model's perplexity (PPL) over the whole sentence. We then rank the four sentences based on PPL, and consider the one with the lowest value as the "model connective choice". Finally, we compute the accuracy of the model choices against the ground truth. We call this metric **Accuracy on Perplexity Score (APS)**.

**Prompt-Based Evaluation.** For the prompt-based evaluation, we asked the models to identify the correct connective to use between S1 and S2. We chose to focus on a standard multiple-choice task, as it is one of the most widely used formats for evaluating LLMs, and replicates one of the prompting experiments in [1]. In the task, the model is presented with S1 and S2 and a list of choices, each representing a connective. The task is to provide the correct choice. We experiment in both zero-shot and few-shot scenarios. For the few-shot, the models saw one example for each connective, for a total of four examples. To avoid biases in the choices, both the order of options to choose from and the position of the correct answer is randomized. Note however that all models saw the same exact prompt for any item in the dataset. We use accuracy as our main metric. To distinguish from APS, we refer to values obtained via prompting as **Accuracy on Prompt Execution (APX)**.

The template for the prompt is shown in Appendix A. We used the Jinja template syntax.[3] The prompt is not a direct translation but it is heavily inspired to the one used in [1]. First, we provide the models with the description and format of the task; for the few-shot scenario, we provide the examples; then, we give clear instructions for how to complete the task; finally, we describe the task. Since we use both pre-trained only and instruction fine-tuned models, we used a template that would enable also pre-trained only models to answer. Note that we did not implement specific templating strategies (e.g., chat formatting, special tokens, etc.) for any model, and we fed all the models with exactly the same prompt.

The only exception was GPT, which was prompted using the chat format, as required by the model's API. However, the content of the prompt was the same as the one used for all other models, without the addition of any custom system messages, special tokens, or instruction-specific formatting.

We used a markdown-like syntax to highlight the sections of the prompt. We acknowledge that not formatting the prompt for each model may hinder performances in some cases. However, we argue that this ensure a more fair evaluation. The only exception was made for the reasoning model, for which we also include the `<think>` token at the end of the prompt, to ensure that the Chain-of-thought is started.

We used a greedy decoding strategy for all experiments, that is we always sample the next most likely token at each generation step. We let each model generate a maximum of 20 tokens in their response. For the reasoning model, we let it generate a maximum of 10,000 tokens. All models, with the exception of GPT variants, where used in their HuggingFace implementation.[4]

A notable issue with unconstrained text generation is that less performing models may yield text that do not conform to the standard asked for in the prompt. This remains true also for cases, like ours, where the expected answer can be the direct continuation of the prompt, rather than the answer to a question or the turn in a

[3] https://jinja.palletsprojects.com
[4] huggingface.co

conversation. To alleviate this issue, we proceeded in two ways. First, we implemented a post-processing strategy based on a set of regular expressions to parse each model response and extract one answer. The regexes were designed to extract one and only one option from the generated text. In cases where multiple answers or no answer were detected, it was counted as a mistake for the model. In Section 5, we report the results of the model after this post-processing. Some models consistently failed to provide appropriate answers in this setting.

Second, we employed **Outlines** [13],[5] a Python library built to provide structured text generation with LLMs (e.g., with type constraints, following regular expressions, or providing json-formatted outputs). In the case of multiple choices, it uses masking on the output probabilities to restrict the model outputs to a set of valid completions [13]. In our case, the possible completions are the "A", "B", "C", and "D" options for the tasks. This approach has become quite popular in the literature and has been adopted in several recent studies on generative LLMs [12]. Note that Outlines was not used for the GPT variants and one of the open-weights tested models, namely Gemma3. In fact, all GPT models consistently yielded properly formatted outputs, making an additional evaluation redundant (recall that the next-token prediction is performed in a greedy fashion) and economically costly. Moreover, a known bug in the current Outlines and HuggingFace implementations prevents all Gemma3 models to be run through Outlines at this stage.

### 4.1. Tested Models

We chose to experiment on a variety of models and model classes, to gain a broader and clearer picture of the problem. Our main goal was to evaluate native Italian LLMs on the PCD task. Thus, we considered the following native Italian model families/variants:

**Minerva** [43]. We considered all model sizes of the Minerva family (from 350M to 7B), including both the Instruction fine-tuned and pre-trained only ones.

**Velvet** [44]. We experimented with both available models, namely Velvet-2B and Velvet-14B.

We highlight that we were not able to ran experiments on the Italia-9B model due to issues with its loading via the HuggingFace library.

We also chose to experiment with non-native Italian models for a clear and fair comparison. These can be distinguished into four classes:

**Italian Fine-Tuned models:** This class includes `LLaMAntino-2-chat-7b-hf-UltraChat-ITA` [45], `LLaMAntino-3-ANITA-8B-Inst-DPO-ITA` [46] and `cerbero-7b` variants [47]. They are respectively fine tuned versions of LLaMA-2, LLaMA-3 and Mistral.

**Open LLMs:** We also evaluated the performances of strong contenders in the Open LLM space. To do so, we selected Meta's LLaMA-3.1-8B [48] and two versions of Google's Gemma3 [49], namely the 4B and 12B ones.

**Reasoning LLMs:** We also tested one reasoning model, namely `DeepSeek-R1-Distill-Llama-8B` [50], a distilled version of DeepSeek-R1 using LLaMA-3.1-8B. This allows us to explore how reasoning impact performances on our PCD task.

**Commercial models:** Finally, we tested the GPT-4x family as representative of commercial closed-source models. We evaluated both `gpt-4o` and `gpt-4o-mini` [51], and all the GPT-4.1 variants (`gpt-4.1`, `gpt-4.1-mini`, and `gpt-4.1-nano`) [52].

Depending on its size, each model required a time between 0.5 and 1 GPU hours to complete its run, that includes both the zero-shot and few-shot experiments, each consisting of: i.) generation with greedy decoding; ii.) generation with Outlines; and iii.) PPL scores computation. The `DeepSeek-R1-Distill-Llama-8B` model required around 10 GPU hours in total, due to its much higher demand for test-time compute. Experiments with the GPT-4x family were conducted using the official OpenAI Batch API.[6] The code for replicating the experiments is available on GitHub.

## 5. Results and Discussion

In this Section we present and discuss the results. We first look at the overall results based on Accuracy of models on the PCD task of ExpliCITA, in terms of both i.) linguistic competence with APS, and ii.) performance with APX in zero- and few- shot experiments, with and without Outlines. Then, we present additional results by considering two aspects. On the one hand, we look at the distribution of answers for each model, to highlight possible biases and failures in providing an answer. On the other hand, we look at per-class performances, to understand whether the tested LLMs show biases in modelling specific aspects of temporal and causal reasoning.

### 5.1. Overall Results

Our main findings for the evaluation of LLMs on ExpliCITA are summarised in Figure 1. The Figure shows the Accuracy of all tested models, in all scenarios. We divide the plot by model family, and sort each family by the model size.

[5] https://github.com/dottxt-ai/outlines

[6] https://platform.openai.com/docs/guides/batch

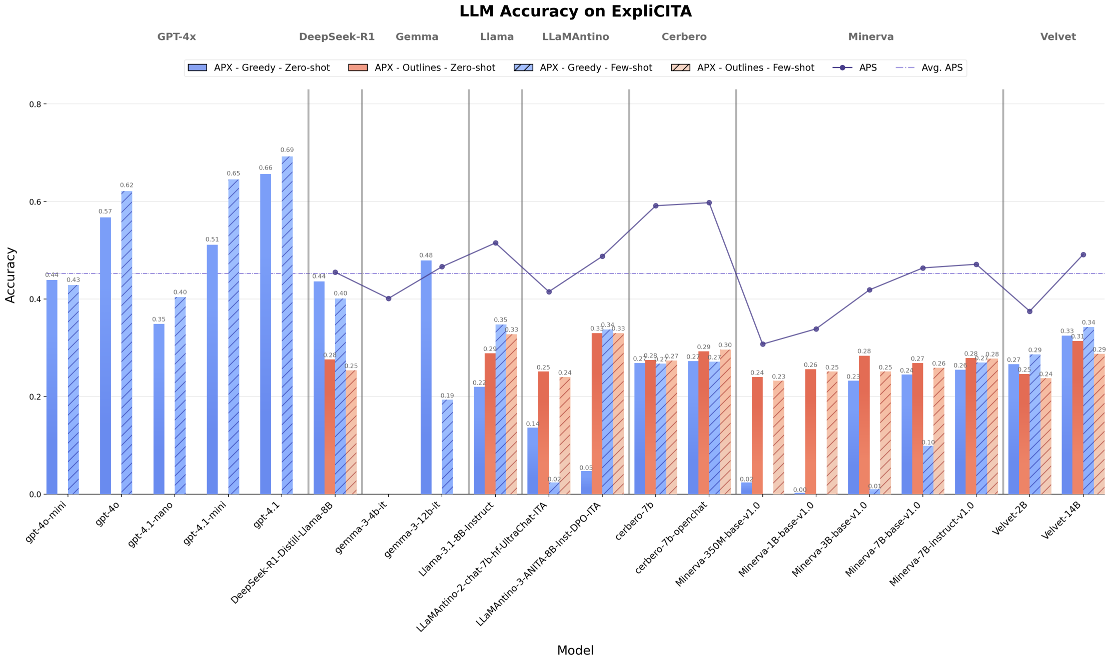

**Figure 1:** APS and APX scores for LLMs on ExpliCITA, grouped by model family and ordered by size.

The results are in line with the experiments reported for ExpliCa [1]. We highlight several interesting aspects in the following.

**Overall performance.** As for the raw performances, all models except the GPT-4x family show rather poor or at least somewhat brittle performances. The only models capable of approaching GPT-level performances are DeepSeek-R1 and Gemma3-12B. However, this is achieved either with the inclusion of reasoning for DeepSeek, or only in a specific setting for Gemma.

**Zero- vs Few-Shot.** As for the difference in zero-shot and few-shot settings, the GPT-4x family is again the only one where there is a clear and consistent trend, in this case in favour of the few-shot setting. In other cases, the few-shot examples are not always beneficial: for some models (e.g., Gemma3-12B, LLaMAntino-2 and Minerva-3B) it appears to be detrimental, while for other it is ineffective. However, for Minerva-7B we observe that while for the pre-trained variant the examples are detrimental, this is not true for the instruction-tuned one. This is possibly due to the instruction-tuning dataset of the model.

**Impact of Outlines.** It appears to be beneficial mostly for cases where zero- or few-shot performances are quite low (e.g., below 0.1). In other cases, the use of Outlines seems less influential. Nevertheless, the same accuracy may be obtained from a significantly different distribution of answers, as will be discussed in the following Sections.

**Model sizes.** As shown in [1], we observe that the size of the model is relevant for its downstream performances. In the open-weights model classes, the two best performing models are Gemma3 and Velvet, respectively in the 12B and 14B variants. Both also display above average APS scores. However, it is also interesting to note that while Gemma3-4B was not able to solve the task at all, the 2B variant of Velvet was consistent in its performance, which closely match those of some larger models.

**Competence vs. Performance.** It is important to notice that APS is always better than APX, with the sole exception of the `Gemma-3-12B` model. This further corroborates some of the findings in [1]: while models' internal representations and probability distribution encode, at least to some extent, knowledge about causal and temporal relations, this knowledge is not fully accessed via prompting. This is also in line with other research [11]. Moreover, it was shown in [1] that the gap between APS and APX shrinks with the size of the model. Given the wide array of tested open-weights model, we can further corroborate this hypothesis by looking at Figure 2. We can clearly see that the rate of improvement in APX as models grow in size (red trendline) is higher than their respective rate of improvements in APS (blue trendline) on the task.

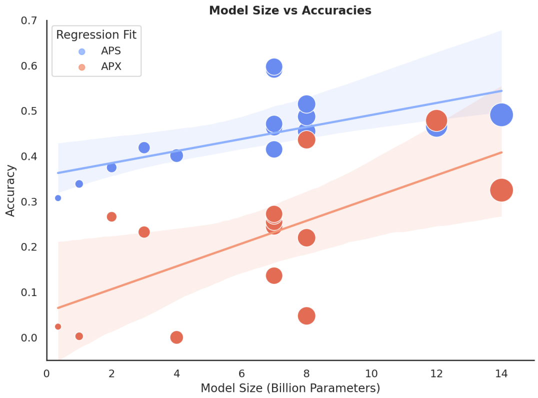

**Figure 2:** Difference between APS and APX across models of varying sizes.

We also highlight the following relevant findings associated to specific model classes:

**Italian Models are weak; Native Italian pre-training is not beneficial.** Native Italian models do not show relevant improvements with respect to fine-tuned alternatives, neither at the same size, nor at larger sizes. The Velvet family appears to provide relatively solid results at all scales; in contrast, smaller models in the Minerva family appear to be less robust on ExpliCITA. The fine-tuned Italian models display similar, if not better, performances than native ones. This could lead us to question whether it's truly necessary to train LLMs from scratch on Italian data. Results suggest that, albeit limited to this case study, it is not.

**GPTs struggle.** On ExpliCa, the GPT model family displayed performances that couldn't reach 0.8 Accuracy [1]. Changing the language of the dataset and the prompt highlight a stark contrast: the drop in performances for the same model is around .20 points, and even newer models cannot reach a 70% accuracy. Considering the fact that the task has remained exactly the same, and that GPT "speaks" fluent Italian, this may be indication that current LLMs are still limited in terms of actual causal reasoning, and still reliant on their internal probabilistic representations of texts.

**Test-time compute is beneficial.** We observed that the performances of the distilled DeepSeek-R1 drastically improve when it is allowed to use its "reasoning" abilities. This is particularly interesting, as it somewhat contrasts with the expectation that the task not require particular forms of reasoning, which may be instead required when modelling phenomena such as *implicit* causal relations. This issue will be further addressed in future works. We also note that while answers were provided in Italian, the chain-of-thought enclosed in the <think> tokens is almost exclusively in English.

## 5.2. Additional Analyses

Besides evaluating the accuracy of models on ExpliCITA, we also consider two other aspects that allow us to further understand the behaviour of the tested models in our setting.

**Distribution of Answers.** First, we explore how models actually answered to the multiple-choice task. The distribution of answers with greedy decoding and with outlines in the zero-shot setting is shown in Figure 3. We leave out the visualization of the few-shot setting due to space limitations, but they are very similar in nature.

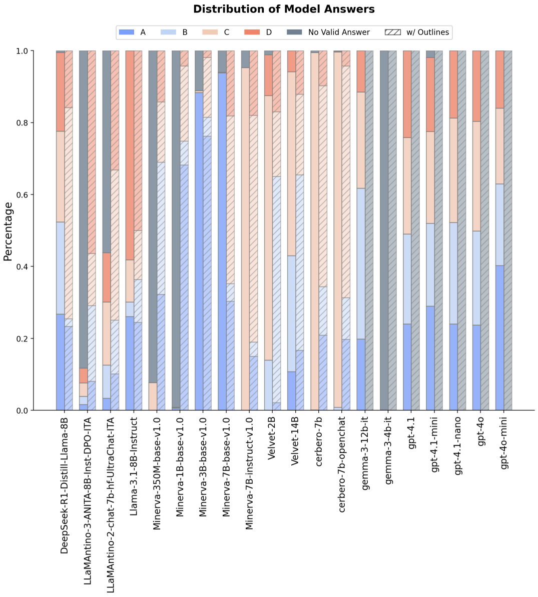

**Figure 3:** Model answer distribution in zero-shot multiple-choice tasks using greedy decoding and prompting via outlines.

We observe that some models consistently fail to provide an adequate answer, thus drastically lowering their performances. For example, it is possible that when ANITA actually answered it did so correctly, but it was able to answer on a very small fraction of the questions. Moreover, although we applied post-processing to the model responses (see Sec. 4), we still observed persistent failure modes, primarily due to the model's inability to follow the expected output format. Such behaviors can be broadly described as faithful hallucinations caused by instructional inconsistency [53], in which the model's output is not properly aligned with the user's request. These failures often consisted in limitations in the number of requested output tokens, which the models were unable to respect, unintended rewriting of the input question, or, more generally, a lack of adherence to the structure and intent of the prompt.

We also observe that several models have a strong preference for a specific answer, which is often either "A" or "C". This is in line with research on biases in multiple choice tasks [54]. This is corroborated by the fact that, even with Outlines, these models still tend to prefer a specific answer over the others.

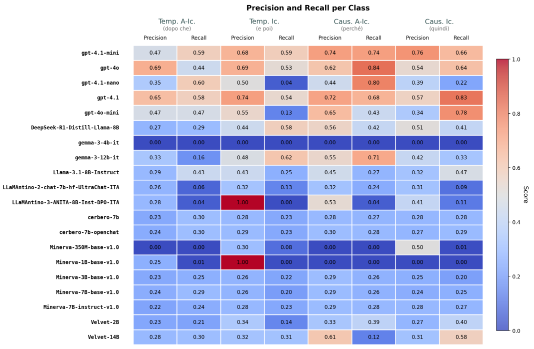

**Figure 4:** Per-class Precision and Recall for each model in the zero-shot setting.

**Per-class Performances.** Finally, Figure 4 shows the Precision and Recall performances of each model, divided by class. Again, we look at the zero-shot scenario and leave out the few-shot one due to space limitations. By looking at the plot, three main observations can be made. First, the GPT-4x models are the most consistent across classes, with only a few notable exceptions for the smallest models. Second, we observe that some of the models display a relatively strong bias towards a single or a pair of answers. Finally, if we zoom out and look at the bigger picture, we see that models have a slight preference towards causal relationships. The less biased models are the two biggest ones, namely gpt-4.1 and gpt-4o. This may further suggest that at smaller scales models rely more on distributional properties of words (e.g., causal connectives often imply a temporal relationship as well, but not vice versa) and are more sensitive to frequency effects linked to word combinations frequently encountered during training. In Italian, in fact, causal connectives such as *"perché"* or *"quindi"* are often used in syntactic constructions where the premise is explicitly connected to the consequence via one of these two connectives. The construction "`S1 connective S2`" is therefore typical for causal relationships.

In contrast, there is greater variability in how temporal sequential relationships can be expressed in Italian. These can be conveyed through temporal conjunctions such as *"e poi"* or *"dopo che"*, as well as through adverbs and adverbial expressions such as *"precedentemente"* ("previously"), *"successivamente"* ("subsequently"), or *"poco fa"* ("a short while ago"). Equally frequent are cases in which temporal relations are conveyed solely through verb tense agreement between the two clauses, for instance, through a past–present combination to express anteriority between S1 and S2. Compared to causal relationships, the temporal dimension is thus more susceptible to variability, both in terms of the range of constructions available to express the same temporal relation in Italian, and in terms of the diversity of contexts in which the same temporal adverb might occur.

Indeed, while causality pertains to a subset of verbs and situational contexts, temporal information, whether implicit or explicit, is present in all events expressed by a verb. This variability affects the generalization capabilities of the models, especially the smaller ones. In fact, larger models seem better able to properly evaluate the context and identify the correct relationship between events.

## 6. Conclusions and Future Works

In this paper, we presented the ExpliCITA dataset, the Italian translation of ExpliCa [1]. The dataset is designed to evaluate explicit temporal and causal reasoning in LLMs. We also replicated part of the experiments made on ExpliCa with several LLMs, including i.) natively-trained Italian models, ii.) multilingual models fine-tuned on Italian, iii.) multilingual open-weights models, iv.) a multilingual reasoning open open-weights model, and v.) closed-weights commercial models from OpenAI.

Our findings can be summarized as follows. First, consistently with [1], we observe two key facts. On the one hand, all tested models, including GPT, struggle to solve the task, in Italian more so than in English, both in the zero- and few-shot setting. We also see that this struggle is also due to their inability to reliably provide the answers required by the task, which is only partially alleviated by using the decoding method of Outlines. On the other hand, we observe that linguistic competence of models, measured with the APS, is consistently better than the respective performance when prompted. However, we see that this gap between APS and prompted accuracy tends to reduce with the model size.

Second, we observe that native Italian models are no better than the fine-tuned alternatives when it comes to the ExpliCITA PCD task.

Third, we see that leveraging test-time compute appears to be beneficial for the task, possibly suggesting that the reasoning training is important to boost the ability to recognize semantic relations between events, even when these are linguistically expressed. We plan to conduct a more systematic investigation of the effects of both chain-of-thought reasoning and Outlines across different models and languages. This will include an in-depth error analysis aimed at understanding when and why such prompting strategies are effective, and whether their benefits depend on the structure of the prompt, the language used for reasoning (e.g., English vs. Italian), or the intrinsic capabilities of the models themselves.

Finally, we observe a slight improvement in managing the causal aspect of the relationship rather than the temporal one, highlighted by the per-class performances.

In the future, we plan to systematically compare the results obtained without chat-specific templating to those obtained by prompting each model using its native chat format. This will help better isolate the impact of instruction tuning and formatting on model performance. Furthermore, although a direct comparison with traditional NLP systems was beyond the scope of this work, future research could explore whether LLMs provide a competitive advantage in explicit causal reasoning (i.e., without task-specific training) compared to lightweight, specialized models. Finally, as part of future work, we plan to experiment with implicit causality as well. We also aim to further explore the impact of reasoning and test-time-compute on the performance of models on both explicit and implicit causal relations.

## Acknowledgments

# A. Prompt template

An example of the ExpliCITA PCD task, framed as a multiple-choice prompting task, is provided in the box below.

Multiple-choice Prompt

```
# Compito di scelta multipla

## Descrizione del Compito
Ti sara' fornito un compito. Avrai a disposizione due frasi, Frase 1
e Frase 2, e una lista di parole connettivo. Il tuo compito e' quello
di scegliere dalla lista di parole connettivo la parola piu'
appropriata per collegare le due frasi in maniera logica e coerente.
La parola scelta dovrebbe essere grammaticalmente e contestualmente
corretta. Per scegliere la parola devi scrivere la lettera
corrispondente alla parola scelta nel campo risposta.

## Formato del Compito
Frase 1: [Frase 1]
Frase 2: [Frase 2]

Opzioni:
A. [parola A]
B. [parola B]
C. [parola C]
D. [parola D]

Risposta: [Lettera dell'opzione corrispondente alla parola corretta]

{% if examples %}
## Esempi
{% for example in examples %}
### Esempio
Frase 1: {{ example.S1 }}
Frase 2: {{ example.S2 }}

Opzioni:
A. {{ example.option_A }}
B. {{ example.option_B }}
C. {{ example.option_C }}
D. {{ example.option_D }}

Risposta: {{ example.correct_answer }}
{% endfor %}
{% endif %}

## Istruzioni del Compito
1. Leggi attentamente la Frase 1 e la Frase 2;
2. Esamina l'elenco delle parole fornite;
3. Seleziona l'opzione corrispondente alla parola che meglio collega
le due frasi, nell'ordine in cui ti sono fornite, in maniera logica
e coerente. ATTENZIONE: scrivi nel campo "Risposta" **SOLO** la
lettera dell'opzione (A, B, C, o D) corrispondente alla parola che
meglio collega le due frasi nel campo risposta, ad esempio
"Risposta: C".

## Compito:
Frase 1: {{ sentence_a }}
Frase 2: {{ sentence_b }}

Opzioni:
{{ options }}

Risposta:
```

After using these tool(s)/service(s), the author(s) reviewed and edited the content as needed and take(s) full responsibility for the publication's content.

# Sparse Autoencoders Find Partially Interpretable Features in Italian Small Language Models

Alessandro Bondielli[1,2,*], Lucia Passaro[1,2] and Alessandro Lenci[2]

[1]*Department of Computer Science, University of Pisa*

[2]*CoLing Lab, Department of Philology, Literature and Linguistics, University of Pisa*

## Abstract

Sparse Autoencoders (SAEs) have become a popular technique to identify interpretable concepts in Language Models. They have been successfully applied to several models of varying sizes, including both open and commercial ones, and have become one of the main avenues for interpretability research. A number of approaches have been proposed to extract latents from the model, as well as automatically provide natural language explanations for the concepts they supposedly represent. Despite these advances, little attention has been given to applying SAEs to Italian language models. This may be due to several factors: i) the small number of Italian models; ii) the costs associated with leveraging SAEs, which includes the training itself, as well as the necessity to parse and assign an interpretation to a very large number of features.

In this work, we present an initial step toward addressing this gap. We train a SAE on the residual stream of the `Minerva-1B-base-v1.0` model, for which we release the weights; we leverage an automated interpretability pipeline based on LLMs to evaluate both the quality of the latents, and provide explanations for some of them. We show that, albeit the approach shows several limitations, we find some concepts in the weights of the model.

## Keywords

Mechanistic Interpretability, Sparse Autoencoders, Large Langauge Models, Italian,

## 1. Introduction

The rise of Large Language Models (LLMs) have profoundly affected the landscape of Natural Language Processing (NLP). These models have demonstrated remarkable capabilities in many tasks, often achieving near-human performances and saturating benchmarks as soon as they are released. Nevertheless, many questions remain about their internal workings: Whether and how they perform some form of reasoning [1], and to what extent their grasp of concepts through natural language approximates human conceptual understanding.

The aim of **Mechanistic Interpretability** (MechInterp) is to address this pressing issue by attempting to reverse-engineer the learned representations and algorithms within their neural networks [2]. A promising technique within MechInterp is the use of sparse dictionary learning methods like Sparse Autoencoders (SAEs) [3]. The idea behind SAEs is similar to that of standard autoencoder. Autoencoders are unsupervised models that learn two functions: an encoding function, that projects the input data from an $n$ dimensional space into a $k$ != $n$ dimensional space; a decoding function, that should reconstruct the $k$-dimensional data back into the original $n$-dimensional one. Autoencoders are typically used for dimensionality reduction, i.e., $k << n$. In the case of SAEs, instead, $k >> n$: the model is trained to project the input space into a much higher-dimensional (and thus sparser) one, and then project it back into the original dimensional space. In our context, SAEs are trained to reconstruct the internal activations of a language model's residual stream by projecting them into a higher-dimensional latent space, while being constrained to use only a small number of "features" from a learned dictionary. This *sparsity* constraint encourages the SAE to learn a set of *monosemantic* features, also referred to as *latents*, that is, features each corresponding to a single, hopefully more interpretable concept [4]. This is in contrast with a *polysemantic* representation, which is typical of standard dense neural networks [5, 6], in which several concepts are superimposed in the same activation patterns. SAEs allow to decompose model activations into a set of near-orthogonal, i.e., largely disentangled features that should be semantically coherent.

Recent work has demonstrated the effectiveness of SAEs in uncovering meaningful features within both toy models [7] and large-scale commercial LMs, revealing representations for concepts ranging from concrete objects to abstract ideas [8, 9, 10]. As noted in [9], several distinctive features have been identified in Claude-3.5-Sonnet – most notably, one corresponding to the "Golden Gate Bridge." SAEs have also been applied successfully to smaller, English-centric models in the 1 to 10 Billion

parameter range [11]. This class of models is becoming more and more relevant, as research on Small Language Models (SLMs) [12] and Baby Language Models (BabyLMs) [13, 14], that mitigate the costs of training and serving LLMs while attempting to retain most of their abilities, is a very active endeavour particularly in the open-source/open-weights community.

Two key limitations remain for the applicability of SAEs to achieve interpretability. First, the computational cost of training a SAE. Given their nature, the internal layer of a SAE has to be a number of times larger than the size of residual stream, and thus the context window, of the target LM. The number of parameters of a SAE scales with a factor of the context size of the model, multiplied by the number of *hookpoints* in the models where activations are collected (e.g., after every transformer block/layer). Thus, the larger the target LM, the bigger and the more computationally expensive the SAE.

Second, and most importantly, SAEs output a large number of features, that have then to be interpreted in some way. While the literature has not reached a consensus on what is the best practice, a popular method to address this is to leverage another LLM to provide explanations for the features based on examples of which tokens (and respective contexts) they fired on. For example, if the feature $f_i$ fired on 10 tokens, the explainer model is fed with these tokens, their contexts and the request to find a common property among them. In most works, commercial LLMs with hundred of billions of parameters are successfully used for this task [9, 10]. However, researchers have also shown that smaller and cheaper LMs can be leveraged effectively as well [15].

The vast majority of efforts regarding the use of SAEs for interpretability has been done on English-centric LMs[9, 10, 11]. In addition to this, several efforts have been made in the direction of finding universal features that apply across models and languages [16, 17]. However, models primarily trained on languages other than English have received less attention.

In this work, we aim to provide an early evaluation on the feasibility of using SAEs to interpret models trained to be natively Italian. In the interest of maintaining a limited computational cost, we chose to use the `Minerva-1B-base-v1.0` from the Minerva model family [18]. We trained a SAE on the residual stream of every layer of the model using an Italian split of mC4 [19]. Then, we collected feature activations for the Italian dump of Wikipedia [20], and attempt to explain them and score explanations automatically using an LLM, following [15].

Our contributions are the following:

- We **train and release a Sparse Autoencoder on `Minerva-1B-base-v1.0`**. We make the Autoencoder weights available to the research community via HuggingFace.[1]
- We collect feature activations from a relatively large collection of Italian data, and provide a **quantitative and qualitative evaluation on the explanations using an auto-interpretability pipeline**. We show that SAE are promising for finding concepts in Italian SLMs, but auto-interpretability pipelines shows several limitations for Italian.
- We report on the **challenges and lessons learned on training and using SAEs**, especially in computationally constrained settings.

This paper is organised as follows: In Section 2 we detail the training procedure of the SAE; Section 3 provides an overview of the auto-interpretability pipeline we employ; in Section 4 we present and discuss the obtained results; finally, Section 5 draws some conclusions and highlights future works.

## 2. SAE Training

In the following, we detail the data and procedure used to train the SAE on the `Minerva-1B-base-v1.0` SLM.

We trained the SAE on the residual stream of the model, with hookpoints on the outputs of each attention block. For our experiments we used the Sparsify library from EleutherAI,[2] which is built to roughly follow the training recipe presented in [10] for a GPT-4 SAE. It trains a $k$-Sparse Autoencoder [21]. The autoencoder uses a TopK activation function that allows for direct control over the number of active latents. Specifically, it only keeps the $k$ largest latents and assign zero to the rest. Authors in [10] argue that this eliminates the need for the L1 penalty, which biases activations toward zero and is only a rough proxy for L0, and supports any activation function. They also show that it outperforms ReLU autoencoders in sparsity-reconstruction tradeoffs and enhances monosemanticity as small activations are clamped to zero.

**Recipe.** A full breakdown of the most relevant parameters selected for training is presented in Table 1. The parameters were chosen following recipes for similar sized models, e.g. [11]. The expansion factor controls the size of the hidden layer, and is a multiplier over the model context size. In our case, an expansion factor of 32 yields a hidden layer of size $2,048 \times 32 = 65,536$ parameters.

[1] https://huggingface.co/alessandrobondielli/sae-Minerva-1B-32x The model can be used with the Sparsify and Delphi libraries for interpretabilty.

| Parameter | Value |
|---|---|
| Activation | TopK |
| Expansion Factor | 32 |
| k | 32 |
| Multi TopK | False |
| Transcode | False |
| Batch Size | 16 |
| Loss Function | Fraction of Variance Unexplained (FVU) |
| Optimizer | Signum |

**Table 1**
Parameters for the SAE training.

**Data.** As for the training data, we chose to use mC4 [22]. Specifically, we consider the "tiny" split of the `clean_mc4_it` dataset [19]. It includes 6 Billion tokens (4 Billion words). The choice of the dataset was made on the basis that it is relatively large, especially for the Italian language, and it includes a variety of different texts. The data was not included in the training set for `Minerva-1B-base-v1.0`. We chose to use 6 Billion tokens following recent literature on training SAEs for similar-sized models [11].

**Setup.** We trained our model on a single Nvidia A100 with 80 GB VRAM. A full training run required 200 GPU hours, which roughly equates to 8 days. The final model, that we call **`sae-Minerva-1B-32x`**, occupies around 40 GB of disk space including hookpoints to all layers. The final model is available on HuggingFace[3] and can be loaded and used with Sparsify.

## 3. Auto-Interpretation of Features

For finding and explaining latents of the SAE models, we use the auto interpretability pipeline proposed in [15]. It is implemented via the Delphi library from EleutherAI.[4] The library includes tools for generating and scoring text explanations for SAE.

The auto intepretability pipeline has three main steps:

1. Activations are collected from a text dataset.
2. An *Explainer* LLM is shown activating contexts and is asked to provide interpretations in natural language for them.
3. A *Scorer* LLM is tasked to distinguish between activating and non activating contexts of a feature, as a binary classifier. This is achieved by asking the model, given several sequences and an intepretation, whether each of the sequences activates the SAE latent with that interpretation.

In the following we detail our implementation of the pipeline.

**Collecting Activations.** As for the text dataset, we chose to use 20 Million tokens from the Italian subset of the November 2023 Wikipedia dump [20] available on HuggingFace.[5] The choice of Wikipedia as our test dataset rather than a sample of the SAE training data (`clean_mc4_it`) was made with the purpose of increasing the probability of finding concepts specific to the Italian language and culture, that could have been left out from a relatively small sample of a web-based dataset. We created equal-sized batches from the texts, shuffled them, and then collected their token-level activations. We collected the activations at three hookpoints, namely at layers 2, 8 and 14. We did so with the aim of understanding whether there is any difference in the features found near the beginning, middle, or near the end of the residual stream. In the following we use the hookpoint notation to refer to layers, namely `Layer.`$x$.

**Generating Explanations.** As for the explanation generation step, we followed the same procedure as [15]. We showed the Explainer LLM 40 examples of the activating tokens and their contexts. We used a context length of 32 tokens. The activating token can be in any of the 32 positions, but is highlighted as `"« token »"`. We show an example of explanation generation in Figure 1.

To limit the computational cost, we attempted to generate explanations only for a sample of 2,000 latents selected from the pool of 65k. Latents with less than 40 examples were skipped. We used the number of latents with enough examples at each hookpoint in the residual stream to highlight their differences.

The chosen model to generate explanations is `Meta-Llama-3.1-8B-Instruct-AWQ-INT4`,[6] a quantized version of `Meta-Llama-3.1-8B-Instruct` [23]. We prompted the model both in English and Italian. For the English prompt, we used the one provided in [15] for the zero-shot experiment. The Italian version is a direct translation of the English prompt. The translation was made semi-automatically: first, the prompts were translated with Gemini-2.5 Pro.[7] Then, the translated prompt was manually revised to ensure its quality.[8]

**Scoring Explanations.** Finally, we scored the explanations. We employed a binary classification method. For each explanation, the model was shown five examples of sentences, where each had equal probability of being associated with the latent. The model was then asked

to decide, for each example, whether it corresponded to the explanation, and output a list of of decisions. If the output did not match a list of decision, it was assigned `None`. The output was then compared with the ground truth provided by the activations. The model for scoring was the same one used to generate explanations. As for the prompt and its translation in Italian, we followed the same translation procedure as well. We evaluated the quality of explanations with accuracy. Specifically, we considered a **per-sample accuracy** (i.e., how many out of the five examples the scorer model got right) and the average accuracy across across latents for the same hookpoint.

We acknowledge that our choice of using a multilingual, relatively small, and quantized LLMs for generating and scoring explanations is far from ideal, and it is not an adequate substitute neither for human evaluation nor for more performing LLMs. The choice of a multilingual model rather than an Italian-only one was made due to the current lack of such models with open weights, high performances and capability to follow instructions. This choice led also to prompting the model both in English and Italian; this was done to assess its explanation/scoring capabilities both in its "native" language, albeit on data from another language, and on Italian, in order to limit potential biases in the interpretation of results from using only one or the other language. As for the choice of a medium-sized quantized model, this was made in the interest of limiting the computational costs of our experiments, i.e., both in terms of the memory footprint of the model, and of the overall GPU hours. Using larger (including non-quantized variants) models would have drastically increased both the need of resources and overall time of the experiments. Nonetheless, we argue that our choice represents a lower-cost alternative to using much larger and costlier models, that could prove especially useful to provide some early insights into the quality of the latents found by the SAE, and of the model being interpreted.

Authors in [15] estimate a cost in the order of hundreds or thousand of dollars for explaining and scoring 100k latents with larger or commercial models; our experiments, in contrast, can be easily replicated on a single GPU. In our case, generating and scoring explanations for 2,000 latents at three different hookpoints, in two different languages, took 0.5 GPU hours each on a single Nvidia A100, for a grand total of 3 GPU hours. Given the size of the model used, the experiments could be also replicated on much less performing hardware as well, provided a trade-off on GPU hours.

# 4. Results and Discussion

In the following, we present our results. First, we show a quantitative evaluation of the extracted latents, and the performances of the generation and scoring pipeline, both with Italian and English prompts. To explore the results in greater depth, we also perform a qualitative evaluation. We consider explanations that received highest scores by the scorer model. We use the results to discuss the feasibility of the proposed approach on Italian SLM, as well as potential shortcomings.

## 4.1. Quantitative Evaluation

The core of our quantitative analysis is based on the results we obtained using the Delphi library, with the configuration presented in Section 3.

**Quality of the Latents.** To evaluate the quality of the latents obtained via the SAE encoding, several metrics can be used. Recall that we collected latent activations using 20 Million tokens from the Italian subset of Wikipedia. Note also that here we are not yet using prompts, so we do not distinguish between Italian and English.

Table 2 provide several common metrics used to evaluate the quality of the extracted latents at each hookpoint. First, we look at fraction of alive latents. A latent is considered alive if at least one input token in the dataset made it fire. With the exception of Layer.8, the other two have much smaller fractions of alive latents than it is typical for SAEs (see for examples results reported in

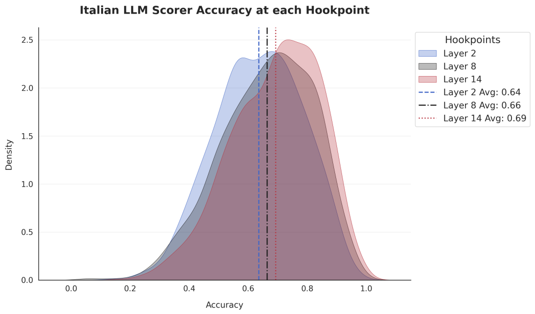

**Figure 2:** Accuracy distribution with Italian prompts.

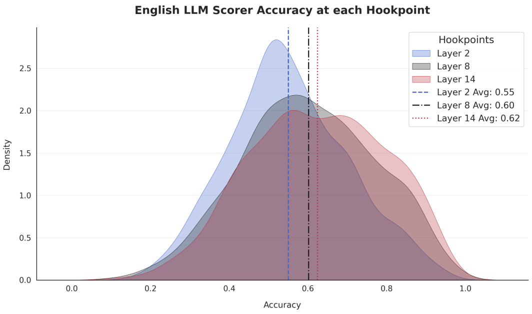

**Figure 3:** Accuracy distribution with English prompts.

| Metric | Layer.2 | Layer.8 | Layer.14 |
|---|---|---|---|
| Fraction of latents alive (%) | 72.02 | **95.16** | 84.65 |
| Latents fired >1% of the time (%) | 0.27 | **0.45** | 0.38 |
| Latents fired >10% of the time (%) | **0.06** | 0.00 | 0.01 |
| Weak single-token latents (%) | **9.93** | 2.20 | 2.77 |
| Strong single-token latents (%) | **12.40** | 0.55 | 0.47 |

**Table 2**
Latent activity statistics across selected layers

[10] and [11]). This may be the results of several factors. On the SAE side, we could hypothesize an overcomplete latent space for the evaluation data, i.e. a too broad latent space for encoding the evaluation data. Recall in fact that we used mC4 to train the SAE, and evaluated it on Wikipedia, which may present less variety in terms of texts.

On the Language Model side, we could hypothesize that the latent space of the analyzed model is very anisotropic at both earliest and latest layers, while more isotropic near the middle of the stack. This however is in direct contrast with works such as [24], and thus requires a more in-depth analysis, that we leave to future works. Another interesting aspect to consider are weak and strong single-token latents, that is latents that fire on a specific token only. Weak ones are those for which the token in question makes many other latents fire; strong ones are cases where the token preferentially activates the specific latent. We observe that `Layer.2` is heavily biased towards single token latents. This may indicate that earliest layers sill leverage the embedding representation quite strongly. Finally, we see that latents that fired either more than one or 10% of the times are less and less as we move towards the residual stream. These latents may be used to store single-token concepts of words such as function ones.

**Quality of the Explanations.** To evaluate the quality of explanations, we consider the results of the explanation generation and scoring pipeline. Specifically, for each latent, we compute the accuracy at distinguishing between sequences that activate and do not activate the latent. Figures 2 and 3 show respectively the distribution of Accuracy for the scorer model using Italian and English prompts for each hookpoint in the residual stream.

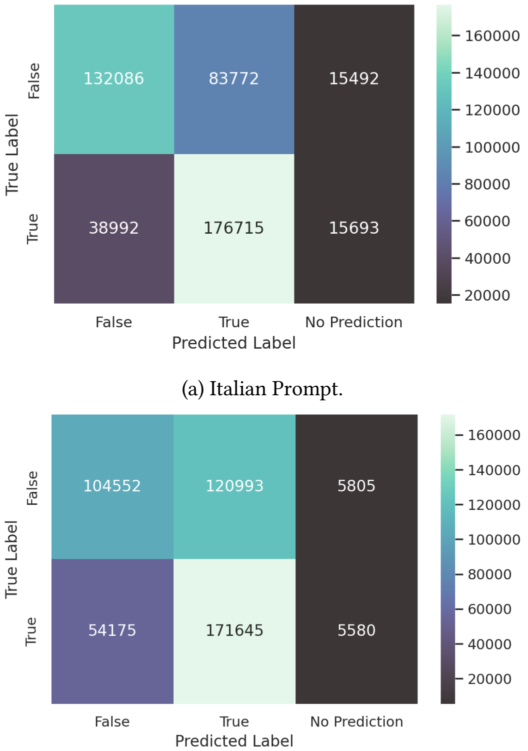
We observe that, in both cases, there are significant differences both in distribution and averages for the three hookpoints. We also observe that explanations for latents extracted from later layers seem to be easier to score correctly for the scorer model. This may indicate that **concepts identified in later layers are, on average, more easily interpretable by an LLM**. The accuracy scores obtained using the Italian prompt are generally higher than those for the English one, with average scores ranging from 0.64 to 0.69; the English ones, in contrast, range from 0.55 to 0.62. However, these results in isolation cannot be taken as a direct indication that explanations in Italian are better than English ones. It may as well be the result of poorer and broader explanations provided by the Explainer model.

We also plot the aggregate confusion matrices over all the predictions of both prompts. The confusion matrices are shown in Figure 4. While the model prompted in Italian seem to fare better in all metrics except for True Positives, we also see that the number of times the model was not able to follow instructions and provide a prediction with the Italian prompt is three times higher than with the English one. This may be further indication that the Explainer/Scorer model used struggles with Italian.

## 4.2. Qualitative Evaluation

To dig deeper into the quality of the explanations, we directly looked at them and provide examples of seemingly good and bad explanations. Specifically, we sampleed from the 50 explanations that received highest scores by the Scorer, both in English and Italian.

As for the Italian explanations, we immediately observed that a large fractions of them suffer from *Degenerate Repetition* [25]: The model starts to generate the same token or sequence of tokens over and over. On



(a) Italian Prompt.

(b) English Prompt.

**Figure 4:** Confusion Matrices for the Scorer model on both the Italian and English prompt.

the contrary, English ones does not suffer from this issue. However, if we look at the quality of explanations, aside from repetitions, we observe that at least some of the Italian ones are quite relevant to the examples, and while sometimes slightly missing the mark, they highlight some interesting aspects of the tokens that fire the latent.

Among these, we can clearly see that `Layer.2` is mostly represented by single token latents: the token "ale" as part of "*federale*" (federal), in several contexts, or the token "*letto*", as both a noun (bed) and a verb (read). `Layer.14` latents on the other had appear to represent more abstract concepts. For example, we see latents firing on the final number of a year date, and a very interesting latent firing on the concept of *competition* (see Fig. **??**). `Layer.8` explanations are generally more confusing and less interesting. Examples are reported in Figure 5 with the relative explanation, cut to avoid showing repetitions.

As for the English explanations on the other hand, we observed that most of them actually miss the mark. In fact, they often provide an explanation related to the contexts, rather than the firing tokens. This may be due to the fact that, while it is specified in the prompt, we use Italian texts as examples but instructions and expected outputs are in English. Neverhteless, we observe an interesting trend: most explanations, at all layers, that actually focus on the firing tokens refer to functional aspects of the text, including punctuation marks, special characters, and functional words. For example, Latent 1818 of `Layer.14` is explained as "Prepositions and conjunctions used to connect words or phrases in Italian text, such as "*a*", "*di*", "*nel*", "*in*", "*su*", "*da*", "*al*", "*nei*", "*all*", "*sulle*", "*col*" [...]". This is in contrast with what we observed for Italian explanations.

## 4.3. Discussion of Key Findings

In the following, we highlight some of the key aspects that emerged from the experiments.

**SAEs can find partially interpretable features in Italian Small Language Models.** First, we observe that using a SAE we are able to extract features that somewhat align to interpretable concepts, despite some limitations that we can mostly attribute to the quality of the training data, both for the original model and the SAE, and to the limitations of the auto-interpretability pipeline (see below). It is possible that leveraging a dataset more attuned with the Italian culture would yield better results in finding relevant latents.

**Different behaviours in the residual stream.** We observed some relevant differences in the quality and types of latents that are properly identified in various points of the residual stream. In general, we observed that latents obtained from earlier in the stream are more relevant to single tokens and grammatical aspects of the language, while latents in later points of the stream show a slight tendency towards more abstract conceptualizations.

**Auto-interpretability is promising, but currently shows limitations for Italian.** Auto-interpretability pipelines are definitely a promising approach for simplifying and reducing the costs of finding explanations for latents of SAEs. Our experiment suggest in fact that this is a low-cost alternative that is nonetheless able to deliver some interesting results. Nevertheless, we observed two main limitations that we can argue are actually two sides of the same coin. On the one side, the Explainer model showed some limitations in understanding the task and providing coherent texts for the explanations, while the Scorer model performed quite poorly in the binary classificationt task. This is especially true in the case of language mixing, i.e. when the model is prompted in its "main" language, i.e. English, but has to work on another

**Figure 5:** Examples of explanations for latents in Italian.

language, in this case Italian. On the other side, the size of the model used in our experiments could severely limit its performances.

Thus, both issues could be solved either by leveraging a stronger Italian-centric model as the Explainer/Score, or by using a generally larger and better performing model. However, as for the first solution, there are currently no models on par with English ones in the 7-15B parameters range, wich whould allow for reducing the cost. As for the second solution, this would dramatically increase the costs, both computational and monetary.

## 5. Conclusions and Future Works

In this paper, we have shown that SAEs can partly uncover interpretable concepts in Italian Small Language Models. Specifically, we did so by training a SAE model on the residual stream of the `Minerva-1B-base-v1.0` SLM, and then applying an auto-interpretability pipeline to generate explanations for its latents.

Our findings suggest that SAE can be used to this end, and that it exist a hierarchical representation within the model, with earlier layers showing more token-centric features and later layers more abstract concepts. As for the auto-interpretability pipeline, while promising for its low cost, underscored the need for better language-specific tools for Italian.

Moving forward, we aim to explore several avenues. First, we plan to scale our experiments in two directions: on the one hand, we aim to train SAEs on larger Italian models, e.g. larger variants of Minerva as well as others; on the other hand, we observe that we need to improve the models used for auto-interpretability, in order obtain more reliable explanations. This could be achieved both by scaling them up substantially, and by tuning Italian-speaking models to the specific tasks of latent explanation and scoring. Second, we plan to leverage SAE and auto interpretability to address potential differences of representations in models pre-trained specifically on Italian data, e.g. Minerva and Velvet [26], and multilingual models that received only fine-tuning in Italian, like the LLaMAntino variants [27] and Cerbero [28]. Finally, we plan to explore the larger latent space to attempt to uncover features linked specifically to Italian-centric concepts, in addition to properties of the Italian Language.

This work is an early first step in exploring interpretability research using Sparse Autoencoders for non-English-centric Language Models. Albeit limited in scope, we are optimistic that it may provide a relevant foundation for this yet under explored research area, both in terms of approach and the release of open models for the community.

## Limitations

Our initial effort to interpret Italian SLMs using Sparse Autoencoders has several limitations. The choice of the smaller `Minerva-1B-base-v1.0` model, driven by computational constraints, means our findings might not generalize to larger Italian models. The SAE's training data, while substantial for Italian, might not fully capture all linguistic nuances, potentially affecting the quality of learned features. Additionally, using different data to train and evaluate the SAE, while arguably not problematic in principle, may have introduced some unwanted biases.

A key limitation stems from our cost-effective auto-interpretability pipeline, which relies on a relatively small, quantized multilingual LLM. This model struggled with generating coherent Italian explanations, often repeating itself, and performed poorly in scoring when mixing languages. This highlights the strong dependence of explanation quality on the explainer/scorer model's capabilities, and the current lack of robust, affordable, Italian-specific tools.

Finally, our analysis was based on a sample of 2000 latents across only three layers, not the entire SAE latent space. While insightful, this limited scope and subjective qualitative assessment means we cannot yet claim a comprehensive understanding of the model's internal workings.

## Acknowledgments

**Explainer Prompt (Eng)**

```
You are a meticulous AI researcher
      conducting an important
      investigation into patterns found
      in the Italian language. Your
      task is to analyze text and
      provide an explanation that
      thoroughly encapsulates possible
      patterns found in it.

Guidelines:
You will be given a list of text
      examples in Italian on which
      special words are selected and
      between delimiters like <<this>>.
      If a sequence of consecutive
      tokens all are important, the
      entire sequence of tokens will be
      contained between delimiters <<
      just like this>>. How important
      each token is for the behavior is
      listed after each example in
      parentheses.

- Try to produce a concise final
      description. Simply describe the
      text latents that are common in
      the examples, and what patterns
      you found.
- If the examples are uninformative,
      you don't need to mention them.
      Don't focus on giving examples of
      important tokens, but try to
      summarize the patterns found in
      the examples.
- Do not mention the marker tokens
      (<< >>) in your explanation.
- Do not make lists of possible
      explanations. Keep your
      explanations short and concise.
- The last line of your response must
      be the formatted explanation,
      using [EXPLANATION]:

{{ prompt }}
```

**Explainer Prompt (Ita)**

```
Sei un meticoloso ricercatore di
      intelligenza artificiale che
      conduce un'importante indagine
      sugli schemi presenti nella
      lingua italiana. Il tuo compito e
      ' analizzare il testo e fornire
      una spiegazione che racchiuda in
      modo esauriente i possibili
      schemi in esso riscontrati.

Linee guida:
Ti verra' fornito un elenco di esempi
      di testo in italiano in cui
      parole speciali sono selezionate
      e inserite tra delimitatori come
      <<questo>>. Se una sequenza di
      token consecutivi e' tutta
      importante, l'intera sequenza di
      token sara' contenuta tra
      delimitatori <<proprio come
      questo>>. L'importanza di ciascun
      token per il comportamento e'
      elencata dopo ogni esempio tra
      parentesi.

- Cerca di produrre una descrizione
      finale concisa. Descrivi
      semplicemente gli elementi
      latenti del testo comuni negli
      esempi e gli schemi che hai
      trovato.
- Se gli esempi non sono informativi,
      non e' necessario menzionarli.
      Non concentrarti sul fornire
      esempi di token importanti, ma
      cerca di riassumere gli schemi
      trovati negli esempi.
- Non menzionare i token marcatori
      (<< >>) nella tua spiegazione.
- Non creare elenchi di possibili
      spiegazioni. Mantieni le tue
      spiegazioni brevi e concise.
- L'ultima riga della tua risposta
      deve essere la spiegazione
      formattata, usando [SPIEGAZIONE]:

{{ prompt }}
```

## Abstract

Low back pain represents a leading source of disability worldwide and poses a significant challenge for evidence-based clinical decision support. In contexts where Italian-language resources for diversified therapeutic pathways are lacking, we have assembled a novel, annotated dataset comprising up to three pre-treatment documents per patient (MRI report, X-ray report, and patient visit notes), alongside demographic information (age and sex). The cohort consists of 176 patient records, stratified into three therapeutic groups: 50 conservative, 92 regenerative, and 34 surgical.

The primary aim is to investigate whether the collected dataset can be harnessed to predict which of the three treatment modalities is most appropriate. To this end, six document-combination scenarios were defined, evaluating each single-report modality as well as all possible pairings. For each scenario, two modeling strategies were contrasted: a traditional Support Vector Machine classifier leveraging TF–IDF features based on unigrams, bigrams, and trigrams, and a fine-tuned Italian BERT model adapted to our corpus.

Experimental results indicate that classic n-gram–based approaches achieve the highest performance (macro–$F_1$ up to 71.3%). The BERT model, while outperforming the baseline, encounters limitations in this low-resource scenario.These findings suggest that the present dataset has the potential to catalyze the development of Italian-language clinical decision support systems that account for the distinct signatures of treatment pathways.

## Keywords

Italian Medical Corpus, Decision Support Systems, Clinical Natural Language Processing, Treatment Prediction, NLP in healthcare

## 1. Introduction

Low back pain (LBP) represents one of the most prevalent medical conditions globally, significantly impacting both individual well-being and healthcare systems [1, 2]. It is a considerable health problem in all developed countries and is most commonly treated in primary healthcare settings. LBP is usually defined as pain, muscle tension, or stiffness localized below the costal margin and above the inferior gluteal folds, with or without leg pain. Up to 84% of the general population will experience an episode of LBP during its lifetime, and recurrence rates are high [3].

Despite extensive research and clinical experience, determining optimal treatment strategies remains challenging due to the diverse range of available therapeutic interventions. LBP management has been extensively studied considering the aforementioned impacts on the individual patient and the community. However, there is still a gap between this information and its applications in clinical practice, particularly in the area of detailing conservative (non-invasive) management. As surgeries and interventional therapies are not recommended in most patients with acute LBP, it is important for primary care physicians (PCPs) to know the details of non-invasive treatment.

The complexity of treatment selection is compounded

by the need to consider multiple patient-specific factors, including clinical presentation, radiological findings, and demographic characteristics.

Electronic health records (EHRs) provide a rich source of clinical data that can inform LBP treatment decisions, particularly through unstructured texts such as imaging reports (e.g., Magnetic Resonance Imaging (MRI) and X-rays) and physician notes [4, 5]. Recent advancements in natural language processing (NLP) have demonstrated significant potential in extracting meaningful clinical insights from these texts, thereby supporting data-driven, informed, and personalized decision-making in healthcare [6]. This progress has been supported by large-scale English-language datasets, such as MIMIC-CXR [7] and MIMIC-IV-Note [8], which provide radiology reports related to central and lower body axial regions. However, the development of NLP-based clinical decision support systems for LBP is significantly limited by the lack of annotated datasets, especially in languages other than English. Building language-specific datasets is critical to promoting equitable access to AI-driven healthcare innovations [9, 10] adapted to different healthcare contexts, like the Italian one.

The primary objective of this work is to develop and release a novel dataset of manually annotated Italian clinical notes for low back pain management, created in close collaboration with medical experts. This resource addresses a significant gap in biomedical NLP for the Italian language, where publicly available annotated datasets are extremely limited.

To demonstrate the potential of this dataset as a valuable tool for the BioNLP community, we conduct a set of preliminary analyses focused on the task of automated treatment recommendation. Specifically, we compare the performance of traditional machine learning methods (i.e., Support Vector Machines) and Transformer models [11] like BERT [12], with the goal of exploring how this resource can support physicians decisions.

This work thus provides two main contributions:

- The release of a new annotated dataset of Italian clinical notes for LBP treatment, offering the BioNLP community a much-needed resource for conducting research in biomedical language processing in Italian.
- A preliminary comparative study designed to evaluate the dataset's capacity to support different NLP techniques and modeling strategies, thereby validating its role as a foundation for further investigation in clinical decision support and related tasks.

## 2. Dataset

**Data Acquisition** This study is based on a retrospective analysis of anonymized clinical records collected during routine care for patients with LBP enrolled at the spine clinic of the *Fondazione Policlinico Campus Bio-Medico* in Rome. The dataset represents a pilot collection curated through a rigorous manual selection process carried out in collaboration with board-certified orthopaedic specialists. All records were obtained prior to any therapeutic intervention and reflect real-world clinical decisions made during standard care.

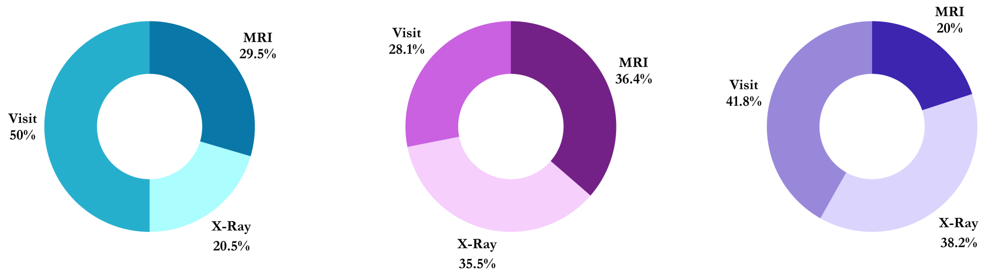
Each case was annotated by the attending physician responsible for the patient's care, linking each patient to a treatment label reflecting the therapeutic decision. Consequently, no additional annotation was necessary. For each patient, we selected the corresponding pre-treatment documents, thus creating a realistic decision-support scenario in which models are trained to predict treatment strategies based solely on clinical text available prior to intervention.

**Dataset Composition** The dataset reflects the real-world distribution of therapeutic strategies typically employed in orthopedic practice, clustering into three patient groups:

- **Conservative.** Patients managed non-invasively through physiotherapy, pharmacological pain control, and rehabilitative interventions designed to restore muscular strength and joint mobility;
- **Regenerative.** Patients treated with minimally invasive biologic therapies, including growth-factor injections, stem-cell preparations, or platelet-rich plasma, aimed at promoting tissue regeneration and functional recovery;
- **Surgical.** Patients who underwent operative procedures, such as spinal stabilization, to address severe pathology or persistent symptoms unresponsive to conservative care.

The dataset includes a total of **176** patients, distributed as follows: 50 conservative, 92 regenerative, and 34 surgical cases. This imbalanced distribution mirrors actual clinical practice, where non-invasive approaches are generally preferred over surgical interventions when clinically appropriate.

Each record consists of textual data from three primary clinical sources: radiological reports (MRI and X-ray) and consultation notes. MRI reports describe spinal anatomy and pathology; X-ray reports focus on vertebral alignment and bone structure; consultation notes provide narrative summaries written by orthopedic specialists during outpatient visits. Demographic variables, including age and sex, are also available for each patient.



(a) Conservative (b) Regenerative (c) Surgical

**Figure 1:** Percentage distribution of MRI, X-ray, and clinical visit reports across treatment categories.

| Treatment Class | MRI | | X-ray | | Clinical Visit | |
|---|---|---|---|---|---|---|
| | Chars | Tokens | Chars | Tokens | Chars | Tokens |
| Surgical | 1520.36 | 348.82 | 492.81 | 115.19 | 676.57 | 176.74 |
| Regenerative | 968.84 | 220.53 | 486.06 | 105.95 | 603.18 | 151.06 |
| Conservative | 1058.73 | 239.65 | 452.78 | 99.67 | 523.02 | 135.36 |

**Table 1**
Average length (in characters and tokens) of medical text across different treatment classes and note types.

An example of these reports is provided in Appendix A. Overall, the corpus is a multi-source, domain-specific collection that integrates radiologic descriptions with unstructured clinical narratives of varying information density.

The detailed composition of our dataset reveals varying distributions of textual data across treatment categories. Specifically, Figure 1 illustrates the percentage distribution of MRI, X-ray, and clinical visit reports across the three groups, while Table 1 presents the average report lengths for each category. Notably, X-ray reports and clinical visit notes exhibit similar average lengths across the treatment categories, while MRI reports show a marked difference, with surgical patients having significantly longer reports. This suggests that MRI documentation may be particularly relevant in distinguishing surgical from non-surgical cases in clinical practice [13, 14]. However, this hypothesis should be interpreted with caution, given the relatively small and imbalanced nature of the dataset, which may affect the generalizability of such findings.

## 3. Methods

The classification of clinical reports for LBP treatment poses specific challenges due to the linguistic complexity and domain-specific nature of medical documentation. These texts often feature highly specialized terminology, diverse narrative styles, and intricate links between diagnoses and recommended therapies. To address these challenges and to assess the suitability of our dataset, we adopted a modeling strategy that integrates both traditional machine learning techniques and modern deep learning approaches.

Our aim was to evaluate whether the combination of unstructured text and demographic data provides sufficient signal for a multiclass classification task focused on LBP treatment decisions. The classification task involves assigning each case to one of the three treatment classes, reflecting typical therapeutic pathways for LBP.

To explore how different modeling paradigms handle the specificities of the Italian medical language and the integration of heterogeneous inputs, we implemented and compared two approaches: a Support Vector Machine (SVM) with TF–IDF vectorization, and a BERT-based model fine-tuned on our dataset.

We chose these two models to contrast a strong classical method with a state-of-the-art contextual model. A linear-kernel SVM remains highly effective for text classification, especially on small or imbalanced clinical datasets where lexical cues often suffice [15]. In contrast, BERT [12] uses Transformer architectures [11] to capture deep contextual and semantic relationships, making it better suited for narrative clinical notes where meaning depends heavily on context.

***SVM Approach*** We developed a multiclass classification pipeline based on a SVM with a linear kernel, leveraging traditional NLP techniques to process clinical text and predict the appropriate treatment category. The pipeline begins with standard text pre-processing steps, including tokenization, stop-word removal, and lemmatization, aimed at normalizing the clinical narratives and reducing linguistic variability [16]. For feature representation strategy, we applied Term Frequency–Inverse Document Frequency (TF–IDF) vectorization using a combination of unigrams, bigrams, and trigrams. This n-gram approach enables the model to capture both individual medical terms and short multi-word expressions that frequently occur in clinical language. The TF–IDF transformation converts the unstructured reports into structured numerical representations by emphasizing terms that are particularly informative within the context of the corpus. To incorporate demographic information, patient age and sex were appended to the TF–IDF feature vectors, allowing the SVM to integrate both textual and structured data in the classification process.

***BERT Approach*** We developed a multiclass classification pipeline based on the ***bert-base-italian-xxl-uncased model*** on Hugging Face made by Bavarian State Library[1], fine-tuned on our dataset to capture the semantic complexity of Italian clinical narratives. Each instance is constructed by concatenating one or more clinical free-text reports with patient age and sex, forming a single input sequence. No additional feature engineering is required, as the transformer architecture learns deep, context-aware representations of the sequence through self-attention mechanisms. The embedding of the [CLS] token is passed to a classification head that outputs the predicted treatment category via a softmax activation.

# 4. Experiments

To explore the capabilities of our dataset, we conducted a series of experiments examining how varying combinations of clinical documents and different feature-extraction techniques affect system performance. Through this systematic analysis, we identified the optimal configuration for deploying our LBP treatment-planning decision support system in the Italian healthcare setting, as illustrated in Figure 2.

## 4.1. Classification Approach

- **SVM (TF–IDF N-grams):** We implemented an SVM Classifier and evaluated three n-gram configurations with TF-IDF vectorization to extract features from Italian-language LBP clinical reports: unigrams (1-gram), bigrams (2-gram), and trigrams (3-gram). This multilevel approach enabled us to capture both individual medical terms and significant multi-word expressions commonly found in diagnostic-related documentation. The n-gram analysis proved especially effective at uncovering language-specific LBP diagnostic patterns and treatment indicators in Italian medical terminology.
- **BERT:** Rather than relying on manual feature engineering, we fine-tuned a pre-trained Italian BERT model to obtain contextualized token representations. Thanks to its multi-head self-attention mechanism, BERT inherently models the sequential dependencies among tokens, such that the order of concatenated documents (e.g., X-ray → MRI vs. MRI → X-ray) can influence prediction performance. For this BERT approach, we therefore applied the full document-combination analysis described in Section 4.2 to evaluate how different report sequences affect model accuracy [17, 12].

## 4.2. Document Combination Analysis

To assess the impact of our Italian LBP dataset on model performance, we systematically explored the following eight input configurations, and, for each paired setup, evaluated all possible document orders:

- **Single Document Decision Support:**
  - MRI reports
  - X-ray reports
  - Clinical visit notes
- **Paired Document Decision Support:**
  - MRI reports with clinical visit notes
  - X-ray reports with MRI reports
  - X-ray reports with clinical visit notes
- **Comprehensive Decision Support:**
  - Integration of all three document types

Patient demographic (age and sex) are appended as additional input information at the end of the selected (concatenation of) documents.

**Patient Cohort:** As this study reflects the real-world clinical scenario, not every patient in the registry possesses the full set of imaging and clinical documents. For

[1] Model available at *https://huggingface.co/dbmdz/bert-base-italian-xxl-uncased*.

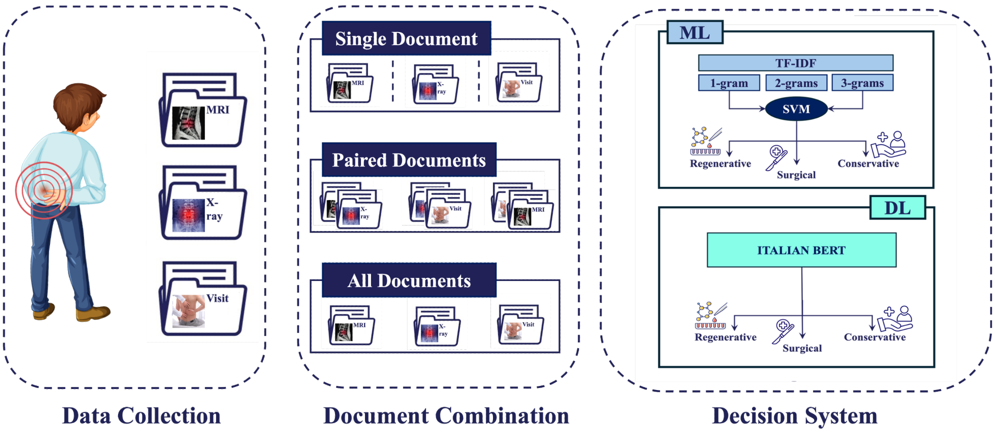


**Figure 2:** Overview of the LBP decision support system pipeline, from initial data collection through document combination strategies to the final treatment recommendation based on NLP and machine learning techniques.

**Table 2**
Performance of SVM models with different n-gram settings. $F_1$-Score is reported as mean ± standard deviation. The results are compared with the baseline.

| Document(s) | # of samples | # Train | # Test | SVM 1-gram (%) | SVM 2-grams (%) | SVM 3-grams (%) | Baseline (%) |
|---|---|---|---|---|---|---|---|
| MRI | 125 | 100 | 25 | $27.54 \pm 0.45$ | $29.71 \pm 4.54$ | $29.71 \pm 4.54$ | $30.22 \pm 0.82$ |
| X-ray | 125 | 100 | 25 | $60.24 \pm 7.36$ | $54.20 \pm 12.58$ | $53.97 \pm 10.65$ | $28.52 \pm 1.17$ |
| Visit | 135 | 108 | 27 | $62.31 \pm 8.94$ | $67.99 \pm 5.18$ | $69.75 \pm 6.18$ | $25.84 \pm 2.49$ |
| MRI+Visit | 168 | 134 | 34 | $65.04 \pm 6.30$ | $68.74 \pm 7.40$ | $70.27 \pm 8.24$ | $22.94 \pm 0.45$ |
| X-ray+MRI | 142 | 113 | 29 | $50.15 \pm 3.47$ | $47.81 \pm 6.04$ | $45.34 \pm 4.14$ | $26.30 \pm 1.02$ |
| X-ray+Visit | 170 | 136 | 34 | $68.42 \pm 8.04$ | $68.18 \pm 4.41$ | $69.55 \pm 5.95$ | $22.56 \pm 1.08$ |
| X-ray+MRI+Visit | 176 | 140 | 36 | $68.31 \pm 5.57$ | $\mathbf{71.34 \pm 6.05}$ | $68.83 \pm 8.14$ | $22.88 \pm 0.32$ |

each input configuration we therefore retain all patients who have at least one of the documents in that specific combination (e.g., any patient with an X-ray *or* an MRI is included in the X-ray+MRI setting). This choice maximizes cohort size while mirroring typical clinical availability, where documentation completeness varies across healthcare facilities.

This structured evaluation aimed to identify the most informative combination of clinical documents for LBP treatment prediction. We focused particularly on configurations that balance predictive performance with clinical availability, acknowledging that healthcare facilities may have varying access to different types of diagnostic documentation. The analysis of document combinations proved especially relevant in LBP cases, where the diagnostic value of imaging studies may vary based on specific pathology presentations and resource availability.

## 4.3. Evaluation Protocol

We performed 5-fold cross-validation for each configuration, maintaining consistent patient splits across all models to ensure a fair and comparable evaluation. Class distributions were preserved within each folad to retain the original class balance across splits. Model performance was evaluated using the macro-averaged $F_1$-score, which is particularly appropriate for imbalanced classes. All models were compared against a baseline classifier that always predicts the majority class within each fold. Results are reported as the mean ± standard deviation across the five folds.

## 4.4. Training Configuration Details

To ensure reproducibility and provide clarity on our modeling setup, we report below all the key hyperparameters and implementation choices for both the BERT-based and the SVM-based experiments. All hyperparameters reported were left at their default values in the respective libraries, with no manual tuning.

**Table 3**
$F_1$-Scores, reported as mean ± standard deviation, of BERT models and majority-class baseline on different document combinations.

| Document(s) | # of samples | # Train | # Test | BERT (%) | Baseline (%) |
|---|---|---|---|---|---|
| MRI | 125 | 100 | 25 | 31.93 ± 10.55 % | 30.22 ± 0.82 % |
| X-ray | 125 | 100 | 25 | 36.66 ± 10.32 % | 28.52 ± 1.17 % |
| Visit | 135 | 108 | 27 | 52.84 ± 13.95 % | 25.84 ± 2.49 % |
| MRI+X-ray | 142 | 113 | 29 | 52.21 ± 7.54 % | 26.30 ± 1.02 % |
| X-ray+MRI | 142 | 113 | 29 | 46.39 ± 5.84 % | 26.30 ± 1.02 % |
| MRI+Visit | 168 | 134 | 34 | 51.89 ± 15.59 % | 22.94 ± 0.45 % |
| Visit+MRI | 168 | 134 | 34 | 48.60 ± 2.98 % | 22.94 ± 0.45 % |
| X-ray+Visit | 170 | 136 | 34 | 53.51 ± 7.95 % | 22.56 ± 1.08 % |
| Visit+X-ray | 170 | 136 | 34 | **55.24 ± 9.37 %** | 22.56 ± 1.08 % |
| MRI+X-ray+Visit | 176 | 140 | 36 | 49.65 ± 8.56 % | 22.88 ± 0.32 % |
| MRI+Visit+X-ray | 176 | 140 | 36 | 51.54 ± 10.94 % | 22.88 ± 0.32 % |
| X-ray+MRI+Visit | 176 | 140 | 36 | 44.12 ± 8.40 % | 22.88 ± 0.32 % |
| X-ray+Visit+MRI | 176 | 140 | 36 | 47.76 ± 7.67 % | 22.88 ± 0.32 % |
| Visit+MRI+X-ray | 176 | 140 | 36 | 47.67 ± 12.25 % | 22.88 ± 0.32 % |
| Visit+X-ray+MRI | 176 | 140 | 36 | 49.78 ± 13.25 % | 22.88 ± 0.32 % |

- **BERT** We use BERT's fast tokenizer to preprocess the input, applying truncation and padding to a fixed length.
  - Max sequence length: 512 tokens
  - Batch size: 16
  - Number of epochs: 6
  - Learning rate: $5 \times 10^{-5}$
  - Optimizer: AdamW
- **SVM**
  - Vectorization: TF–IDF with n-gram range $[1, N]$, $N \in \{1, 2, 3\}$
  - Classifier: `LinearSVC` with $C = 1.0$, class weights = inverse sample frequency

# 5. Results

Tables 2 and 3 present the results of our preliminary experiments using SVMs with *n*-gram features and a BERT-based model on various combinations of clinical documents. These results should be interpreted not as evidence of a finalized decision support system, but as an initial validation of the dataset's utility in supporting automatic classification tasks in the context of LBP treatment. To provide a meaningful reference point for model performance, we include the results of a simple majority class predictor, which assigns all test instances to the most frequent class observed in the training set for each fold. This baseline yields macro-averaged $F_1$-scores in the range of 22–30%, establishing a minimal threshold that highlights the added value of learning-based approaches. Our analysis emphasizes comparative insights across different input configurations and modeling strategies.

## 5.1. Classification Approach

**SVM with TF-IDF N-grams** Table 2 compares the macro-$F_1$ performance obtained with unigram, bigram, and trigram TF-IDF vectors. The bigram configuration attains the highest score, **71.34 ± 6.05%**, improving upon unigrams (68.31 ± 5.57%) and trigrams (68.83 ± 8.14%) while exceeding the majority-class baseline of 22% by almost 50 percentage points. The advantage of bigrams is most pronounced when the full set of reports (Visit, X-ray, and MRI) is concatenated, indicating that short multi–word expressions such as *"discopatia lombare"* encapsulate diagnostic nuance that unigrams cannot capture. In contrast, for single-source inputs the benefit is attenuated: unigrams remain preferable for isolated X-ray reports (60.24% vs 54.20%), suggesting that imaging lexicons are adequately represented by individual tokens.

**BERT** Table 3 shows the fine-tuned `bert-base-italian-xxl-uncased` model results. The model reaches a maximum macro-$F_1$ of 55.24 ± 9.37% when the clinical visit note precedes the X-ray report (Visit→X-ray), again outperforming the baseline but trailing the best bigram SVM combination by roughly 16 percentage points. Performance varies with document order: reversing the sequence (X-ray→Visit) lowers the score to 53.51 ± 7.95%, and the inclusion of MRI text frequently degrades results. These fluctuations confirm the order sensitivity anticipated in Section 4.1

and underscore that, under the limited data regime of this study, contextual embeddings do not yet capitalise on MRI radiological terminology as efficiently as lexical features.

### 5.2. Document Combination Analysis

**SVM** Consistent with the experimental design of Section 4.2, eight input configurations were evaluated using the *n*-gram representation. Among single documents, the clinical visit note achieves the highest macro-$F_1$ (69.75 ± 6.18% for the trigram representation), whereas the MRI report is the *only* configuration that underperforms the majority-class baseline, reaching just 29.71 ± 4.54%. Pairing X-ray with the visit note yields a substantial gain to 68.18 ± 4.41%, and adding MRI further increases performance to the overall peak of **71.34 ± 6.05%** for the bigram representation. By contrast, the combination X-ray+MRI, which excludes the narrative Visit note, attains only 47.81 ± 6.04% macro-$F_1$. This sharp drop, together with the sub-baseline score of the MRI alone, underscores how indispensable free-text clinical observations are for differentiating low-back pain treatments. Beyond classification performance, we also sought to enhance the interpretability of the best-performing model (SVM with TF–IDF bigrams on all reports) through qualitative analysis of its learned features. Each weight reflects the discriminative power of a lexical bigram for a given treatment class. In Appendix B, we present the most informative medical expressions associated with each class, emphasizing how specific terms are strongly linked to particular treatment decisions.

**BERT** The document-level ranking mirrors that of the SVM but at lower absolute values. The sequence Visit→X-ray tops the list (55.24 ± 9.37%), followed by X-ray→Visit (53.51± 7.95%) and MRI→X-ray (52.21 ± 7.54%). Configurations that concatenate all three reports might exceed the 512-token limit and achieve no more than 51%. Despite these constraints, every BERT variant surpasses the baseline, confirming that contextual representations contain useful decision cues even when suboptimal ordering or length truncation is necessary.

## 6. Discussion

Our comparative evaluation of traditional machine learning and transformer-based approaches for classifying LBP treatments yields several key insights into how NLP models behave across different types of clinical documentation.

In particular, SVM models leveraging TF–IDF representations consistently outperformed BERT-based models across multiple experimental settings, especially when applied to radiological reports (MRI and X-Ray). These reports are typically concise, standardized, and lexically redundant, making them well-suited to models that exploit explicit lexical features. SVMs, in particular, benefit from frequent term patterns and domain-specific collocations captured through n-gram vectorization.

In contrast, BERT showed stronger performance on less structured, semantically dense documents such as clinical visit notes. These notes are written in natural language, often include temporal and referential elements, and require a deeper semantic understanding to accurately interpret. Despite being the least represented document type across all treatment classes, visit notes boosted performance when used alone or in combination with other sources. This indicates their high semantic informativeness and BERT's ability to leverage contextual cues and long-range dependencies.

For a sample of each report type, see Appendix A.

Interestingly, although BERT underperformed compared to SVM in nearly all configurations, its strengths became more evident when visit notes were incorporated into multidocument setups. The best-performing configuration among all SVM experiments was the integration of all three document types. This reinforces the idea that each source contributes distinct and valuable information: X-rays provide succinct structural summaries, MRIs add detailed anatomical insights (especially relevant for surgical decision-making), and visit notes contribute clinical reasoning and narrative depth. The integration of these heterogeneous data sources allows the model to capture a more comprehensive clinical picture, ultimately improving classification accuracy.

BERT was consistently outperformed by SVM across nearly all configurations. A likely explanation lies in the underrepresentation of visit notes within the dataset. Although visit notes are semantically rich, their greatest impact on classification performance becomes evident when they are combined with radiological sources. One of the most notable findings from this dataset is that the integration of all three document types yielded the best-performing configuration in all SVM experiments. This outcome underscores the complementary nature of the information encoded in these documents: X-rays provide concise structural descriptions, MRIs offer detailed anatomical insights (especially valuable for surgical planning), and visit notes contribute clinical reasoning and contextual narrative. The fusion of these heterogeneous inputs enables the model to capture multiple dimensions of the clinical scenario, ultimately leading to improved classification accuracy.

It should be noted that, given the real-world nature of this dataset, not all document combinations are directly comparable due to the differing numbers of available documents across treatment categories. While this variability accurately reflects actual clinical practice, caution is warranted in interpreting comparative model performances, particularly when smaller document subsets may limit the generalizability of results.

### 6.1. Clinical Implications

Although MRI is routinely regarded as the most informative examination for surgical planning in low-back pain, its impact in our study was limited by availability: surgical cases accounted for only 34 of 176 patients and contained proportionally fewer MRI reports than the other treatment groups. This scarcity translated into weak stand-alone performance - an SVM trained on MRI text alone fell below the majority-class baseline (macro-$F_1$ 29.7 ± 4.5 %) and, even when coupled with X-ray, remained inferior to the X-ray + visit-note configuration. Clinically, these results indicate that the proposed decision-support tool already offers actionable triage guidance in contexts where MRI access is delayed, while underscoring the need to enrich the dataset with additional surgical MRIs, through prospective collection, to reduce the risk of under-referral for patients who would ultimately benefit from operative management.

## 7. Conclusions

The results of this study underscore the clinical relevance and future potential of our curated dataset as a foundation for developing NLP-based decision support tools in the context of low back pain. By aligning structured radiology reports with semantically rich clinical narratives and treatment labels drawn from real-world care trajectories, the dataset captures a heterogeneous and realistic cross-section of diagnostic information, reflective of everyday clinical reasoning.

Despite its limited size, the dataset reveals meaningful interactions between document types and model performance. Notably, while magnetic resonance imaging is routinely regarded as the most informative modality for surgical planning, its impact in our study was constrained by availability: only 34 out of 176 patients were classified under the surgical group, and this subset contained proportionally fewer MRI reports than the others. This imbalance translated into weak stand-alone performance.

These results suggest that the proposed dataset already supports the development of decision-support tools capable of offering actionable triage guidance, even in contexts where MRI access is limited or delayed. At the same time, the findings highlight a clear direction for future dataset enrichment: increasing the number of surgical MRIs, either through prospective data collection or active-learning-guided sampling, will be essential to reduce the risk of under-referral for patients who may ultimately require surgical intervention.

In future works, we will explore other models capable of handling longer input sequences, such as recent large language models, allowing us to include the full content of all three documents (MRI, X-ray, and visit notes) without truncation.

We further plan to expand the dataset through the collection of additional clinical cases. Once validated, the extended corpus will be released to foster reproducibility and enable further research. We will also perform systematic hyperparameter optimization on the extended dataset to further improve model performance.

# A. Sample Reports

We present three representative reports that illustrate distinct documentation styles: the MRI and X-ray findings are conveyed with technical details, whereas the clinical evaluation is presented as a concise narrative.

The imaging reports describe features such as lumbar disc degeneration, spondylolisthesis, and preserved vertebral alignment. In contrast, the consult note summarizes patient history, describes symptoms, and reports physical examination findings, before referencing the imaging results. Thus, the narrative note provides clinical context, while the radiological reports contribute detailed anatomical and pathological descriptions.

# B. SVM's Lexical Feature Analysis

To improve the interpretability of our best-performing SVM classifier, trained with TF–IDF bigrams on the full set of clinical documents, we analyzed the feature weights learned by the model from the top-performing fold of the 5-fold cross-validation. These weights indicate the contribution of each lexical bigram to treatment classification, highlighting expressions with clear clinical significance.

We manually prioritized domain-specific expressions (e.g., anatomical or pathological descriptors)from the top 50 lexical features (unigrams and brigrams) ranked by coefficient value for each treatment class, over generic tokens (e.g., grado, presenza), which, despite their assigned weights, lack standalone diagnostic value. The most informative medically relevant features identified by the model for each treatment class—Conservative, Regenerative, and Surgical—are reported in Table 5, along with their associated weights and frequencies in the training and test sets. Importantly, the selected inspected features exhibit meaningful clinical relevance, effectively capturing diagnostic and pathological indicators that inform therapeutic decision-making.

Specifically, conservative treatment is associated with clinically less invasive descriptors such as *sostanzial-*

**Table 5**
Medical lexical features with the highest SVM weights per treatment class. The symbol '-' indicates the absence of the feature for the given class.

*mente conservati* and *degenerazioni artrosiche*. Regenerative treatments, meanwhile, are characterized by medically pertinent terms like *muri somatici* and *proiezioni dinamiche*. Finally, surgical treatment features expressions indicative of more severe pathology, including *spondilolistesi* and *stenosi*, both frequently occurring in the training data and receiving high positive weights (0.698 and 0.688, respectively).

Notably, our analysis highlighted polarity inversion phenomena, whereby certain clinically relevant terms (e.g., *spondilolistesi*, *ernia*) showed positive weights in one treatment class and negative weights in another. This underlines the context-sensitive nature of their clinical interpretation.

Furthermore, it is worth emphasizing that feature frequency alone does not fully explain clinical importance: even relatively infrequent terms can receive high model weights if they demonstrate strong discriminative power. For example, antero listesi appeared only 11 times in the training set yet emerged as one of the top-ranked surgical features, confirming the model's capability to identify clinically informative lexical indicators.

# MakeItSample: a Python Library for Generating Typological Language Samples Based on the Diversity Value Metric

Luca Brigada Villa

*Dipartimento di Studi Umanistici, Università di Pavia, Piazza del Lino, 2 - 27100 - Pavia, Italy*

**Abstract**

This paper presents makeitsample, a Python library for generating typological language samples based on the diversity value (DV) metric. The library handles the construction of hierarchical language family trees from a list of CSV, the calculation of diversity values for each node in the trees, and the selection of languages based on their weight within the tree. The library aims to ease the process of creating typological language samples by providing an automated, scalable, and reproducible solution.

**Keywords**

typology, sampling, diversity value, language family tree, typological databases

## 1. Introduction

Linguistic typology is the study of structural patterns and variation across the world's languages [1, 2]. Since there are over 7,000 known languages [3], full coverage of linguistic diversity in typological studies is unfeasible. Instead, researchers rely on language samples — subsets of languages selected to represent the world's linguistic diversity as accurately as possible [4, 5]. However, the way these samples are constructed greatly impacts the validity of typological generalizations, as biased sampling can distort conclusions about universal tendencies and linguistic variation [6].

Several sampling strategies have been developed to improve representativeness in typological studies. Random sampling is a straightforward method, but it risks including many closely related languages, reducing genealogical and areal diversity [5, 7]. Stratified sampling mitigates this issue by ensuring balanced representation across language families and geographic regions [8], yet defining appropriate strata remains a challenge. For instance, genealogical classification varies between databases such as Glottolog [3] and Ethnologue [9], leading to inconsistencies in sampling.

Another approach is diversity-based sampling, which prioritizes structurally diverse languages rather than simply ensuring equal representation across language families or regions [6]. This method focuses on maximizing linguistic variation within a sample, making it particularly useful for detecting cross-linguistic patterns [10]. While promising, current implementations of diversity-based sampling often lack computational automation and clear reproducibility, limiting their practical application.

Despite efforts to refine sampling methods, typological research remains susceptible to several biases [11]:

- Bibliographic bias: since typological studies rely on existing descriptions, well-documented languages are favored over lesser-described or endangered languages [12]. In addition to this, the quality of the descriptions may affect the results of the typological analysis, as some grammars may have been written with a specific theoretical framework in mind, or been written in the past and not updated to reflect current linguistic theories.
- Genetic bias: samples may be unbalanced due to the overrepresentation of some language families, leading to an underestimation of linguistic diversity [4, 7].
- Areal bias: some geographic regions (e.g., Europe) are disproportionately represented in typological databases compared to highly diverse but under-documented areas such as New Guinea and the Amazon [13, 14].
- Typological bias: this bias occurs when a sample contains a disproportionate number of languages with similar typological features, leading to overgeneralizations about linguistic universals [6]. For example, if a sample contains a large number of SVO languages, it may lead researchers to conclude that SVO is the most common word order across languages or that a feature associated with this order (e.g. adjective-noun order) is the most common across languages, even if this is not the case. This bias can also occur when researchers focus on a specific typological feature (e.g., case marking) and select languages that exhibit that feature.
- Cultural bias: this bias occurs when language samples underrepresent the world's cultural and

CEUR Workshop Proceedings ceur-ws.org ISSN 1613-0073
published 2025-11-30

linguistic diversity. It relates to the idea of linguistic relativity—the notion that language can influence how people think and perceive the world [15, 16]. While early theories assumed a strong, deterministic link, more recent research treats the connection between language and thought as testable. For instance, Lucy [17] showed that speakers of languages with obligatory number marking perceive and categorize objects differently than speakers of classifier languages, illustrating how grammatical structures can reflect cultural patterns.

These biases can skew typological conclusions, reinforcing the need for an automated sampling pipeline that accounts for linguistic diversity in a principled manner.

To address one of these biases, this paper presents a Python library to ease the process of generating typological language samples. The library, called `makeitsample`[1], is designed to automate the sampling process and provide a principled and scalable solution to generating language samples for typological studies. The library implements a sampling method based on the diversity value (DV) metric [18, 19, 11] and comes with a command-line interface. The library is designed to:

- Construct a set of hierarchical language family trees from a set of CSV files.
- Compute diversity values (DVs) for each language family and subgroup, ensuring that more structurally diverse families contribute proportionally to the final sample.
- Select languages based on the weights of the groups and families they belong, propagating the selection algorithm from higher-level families down to subgroups, ensuring a genealogically and typologically balanced sample.

By integrating computational methods with linguistic typology, this library provides an automated, scalable, and genealogical bias-aware solution to sampling. The paper is structured as follows: Section 2 describes the methodology behind the DV metric and the sampling algorithm. Section 3 details the implementation of the package, describing the libraries it relies on and the modules of the library. Finally, Section 4 discusses the potential applications of `makeitsample` and concludes the paper.

# 2. Methodology

In this section, I describe the methodology behind the diversity value (DV) metric and the sampling algorithm. I first introduce the family tree representation used to model genetic relationships between languages (Section 2.1). Then, I explain how DVs are calculated for each language family and subgroup (Section 2.2). Finally, I detail the sampling algorithm that selects languages based on their weight within the tree (Section 2.3).

## 2.1. The Family Tree Representation

A family tree is a hierarchical structure that represents the genetic relationships between languages. Each node in the tree corresponds to a language family or subgroup, while edges indicate parent-child relationships. The hierarchical structure allows us to visualize the genealogical relationships between languages, with higher-level nodes representing broader families and lower-level nodes representing more specific subgroups or individual languages. This way of representing language families traces back to Schleicher's works [20, 21], where he proposed a tree-like structure to illustrate the relationships between languages. This representation has been widely adopted in historical linguistics and typology, as it provides a clear and intuitive way to visualize the genetic relationships between languages. The idea behind the family tree is to represent the evolution of languages over time, with branches representing the divergence of languages from their common ancestors. Each language family can be thought of as a trunk, with subgroups and individual languages branching out from it. The length of the branches can be interpreted as a measure of the time since the languages diverged from their common ancestor, with longer branches indicating greater divergence. The tree is rooted at the top-level family, with subgroups branching out from their respective parent nodes. This representation allows us to model the genealogical relationships between languages and determine their relative weights within the tree.

As an example, consider the Indo-European language family, which, according to Ethnologue [9], is divided into eight subgroups: Albanian, Armenian, Baltic, Celtic, Germanic, Greek, Indo-Iranian, and Italic. These subgroups are further divided into smaller subgroups and individual languages, forming a hierarchical structure that captures the genetic relationships between Indo-European languages as in Figure 1.

The family tree representation allows us to model the genetic relationships between languages and see which families and groups are more structurally diverse. This information is crucial for calculating diversity values and selecting languages for the final sample.

[1] Available at https://pypi.org/project/makeitsample/. `makeitsample` is open source and licensed under the MIT license. The source code is available at https://github.com/unipv-larl/makeitsample.

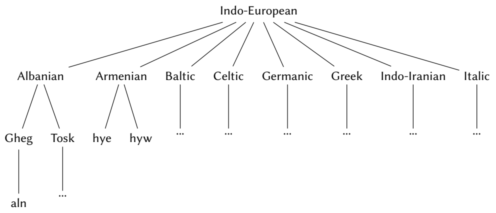

**Figure 1:** Sample of the tree of the Indo-European family. This representation does not take into account the temporal aspect of the tree, i.e. the length of the branches is not proportional to the time since the languages diverged from their common ancestor.

## 2.2. Calculating the Diversity Value (DV)

The diversity value (DV) metric quantifies the structural diversity of a language family or subgroup based on the topological properties of its family tree. This metric was first introduced by Rijkhoff and Bakker [18] and later refined by Bakker [11] as a way to maximize the typological diversity of languages in a sample. The calculation involves the following steps:

1. Breadth-First Search (BFS): starting from a given node for which we want to calculate the DV (henceforth "root"), perform a BFS to determine the level of each node in the tree. The level of a node is the number of edges from the root to that node.
2. Level Counts: calculate the number of nodes at each level. This helps in understanding the distribution of nodes across different levels of the tree.
3. Contributions Calculation: for each level, calculate the contributions to the DV. The contribution of a level is determined by the number of nodes at that level and their distance from the starting node. The contributions are accumulated as we move from the root to the leaves of the tree. The contribution $C_i$ of level $i$ can be calculated as:

$$C_i = C_{i-1} + (N_i - N_{i-1}) \times \frac{L - (i-1)}{L}$$

where $C_{i-1}$ is the contribution of the level upwards (setting to 0 the contribution of the root level) $N_i$ is the number of nodes at level $i$, $N_{i-1}$ is the number of nodes at the level above, and $L$ is the maximum number of levels in the forest. If we are calculating the DV for the root of the family tree, then $L$ is the maximum number of levels in any tree in the forest. If we are calculating the DV for a subgroup, then $L$ is the maximum number of levels in the sibling trees of the tree rooted at the subgroup (including the subgroup tree).

Sometimes, family trees are shaped like the left side tree in Figure 2 in which a branch of the tree stops at a certain level without reaching the bottom of the tree (see the group 1 branch in Figure 2). If we apply the previous formula, we would get a negative factor while calculating the contribution of the bottom level, since $N_i$ would be lower than $N_{i-1}$. To avoid this, we add a number of pseudo-nodes to the tree (x nodes in Figure 2), so that the number of nodes at each level is always greater than or equal to the number of nodes at the level above. This is done by adding a number of pseudo-nodes equal to the difference between the number of nodes at the level above and the number of nodes at the current level. The pseudo-nodes are not included in the final sample, but they are necessary to ensure that the contributions are calculated correctly. The pseudo-nodes are added only to the levels that are not the last level of the tree. This way, we can ensure that the contributions are always positive and that the DV is calculated correctly.
4. Mean of Contributions: the DV is the mean of the contributions calculated in the previous step. This average value represents the structural diversity of the language family or subgroup. The DV can be expressed as:

$$DV = \frac{1}{D} \sum_{i=1}^{D} C_i$$

where $D$ is the depth of the tree rooted at the node for which we are calculating the DV, and $C_i$ is the contribution of level $i$.
For language isolates, the DV is set arbitrarily to 1 (as suggested by Rijkhoff and Bakker [19]), in order to avoid assigning a value of 0 to these languages and to ensure that they get the chance to be selected in the sampling algorithm.

By following these steps, we can compute the DV for any node in the family tree (except for nodes representing languages which are not structurally diverse in the tree). The DV metric provides a principled way to quantify the typological diversity of languages and guide the selection process in the sampling algorithm.

As a matter of example, let us consider the example forest in Figure 2 and let us suppose that we want to calculate the DV of the family 1. The first step is to define $L$, i.e. the maximum number of levels under the root node in the forest. In this case, $L = 3$. Then, we proceed to calculate the contributions of each level. For the first level, i.e. the one including group 1 and group 2, we have $N_1 = 2$ and $N_0 = 1$. $C_0$ is set to 0, so we have:

$$C_1 = 0 + (2-1) \times \frac{3-(1-1)}{3} = 0 + (1 \times 1) = 1.$$

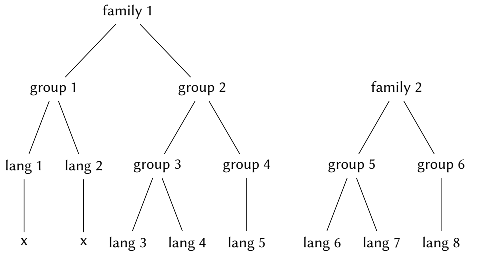

**Figure 2:** An example forest of language families.

For the second level, i.e. the one including lang 1, lang 2, group 3 and group 4, we have $N_2 = 4$ and $N_1 = 2$, so:

$$C_2 = 1 + (4 - 2) \times \frac{3 - (2 - 1)}{3} = 1 + (2 \times \frac{2}{3}) = \frac{7}{3}.$$

For the third level, i.e. the one including the two pseudo-nodes, lang 3, lang 4 and lang 5, we have $N_3 = 5$ and $N_2 = 4$, so:

$$C_3 = \frac{7}{3} + (5 - 4) \times \frac{3 - (3 - 1)}{3} = \frac{7}{3} + (1 \times \frac{1}{3}) = \frac{8}{3}.$$

Finally, we can calculate the DV as:

$$DV = \frac{1}{3}\left(1 + \frac{7}{3} + \frac{8}{3}\right) = \frac{1}{3} \times 6 = 2.$$

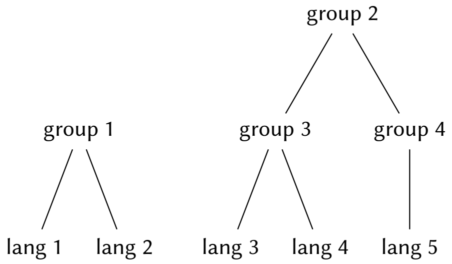

**Figure 3:** The forest obtained considering the sibling trees of group 1. The pseudo-nodes are not needed here since all the leaves are at the same level.

This algorithm can be applied to any node in the family tree. If we want to calculate the DV of a subgroup, we can simply set $L$ to the maximum number of levels in the sibling trees of the tree rooted at the subgroup (including the subgroup tree). For example, if we want to calculate the DV of group 1, we can set $L = 2$ (since the maximum number of levels in the sibling trees is 2). Then, we can calculate the contributions as before, without considering the pseudo-nodes. The full calculation of the DV of this node and all the other nodes in the forest is not shown here for the sake of brevity, but it can be found in Appendix A.

### 2.3. The Sampling Algorithm

The sampling algorithm aims to select the most diverse set of languages from the family trees, ensuring that the final sample is representative of the world's linguistic diversity. Let us suppose that we need a sample of size $N$. If $N$ is higher than the total number of languages in the family tree, we start by selecting at least a language from each family. If there is still a number of languages to be selected, we distribute this number among the families according to their DVs. The distribution is randomic but weighted by the DVs of the families. This ensures that more structurally diverse families contribute proportionally more to the final sample. If the sample size $N$ is smaller than the total number of families, we select the families randomly, but weighted by their DVs and select a language from each selected family.

If the sample is not complete, we proceed selecting other languages. At this stage, each selected family has at least one language included in the sample. The remaining languages are then allocated to the subgroups of each family, continuing down to the individual language level. This allocation is done randomly but weighted by the diversity values of the nodes, as shown in Figure 4.

When each subgroup has been assigned a number of languages, we select the languages randomly from the subgroups.

## 3. Implementation

In this section, I describe the implementation of `makeitsample`, outlining the dependencies it utilizes (section 3.1), and the two modules of the library: `language_family_tree` (Section 3.2) and `forest` (Section 3.3). I also provide an overview of the command-line interface (Section 3.4) and the structure of the input data (Section 3.4.1).

### 3.1. Libraries

The modules rely mainly on two libraries: `pandas` [22, 23] for data manipulation and `networkx` [24] for graph representation and algorithms. The `pandas` library is used to read the input data and construct the family tree. The `networkx` library is used to represent the family tree as a graph and perform graph-based operations such as BFS traversal and DV calculation.

### 3.2. The `language_family_tree` Module

The `language_family_tree` module is responsible for constructing the family trees from the input data. It reads the CSV files and creates a hierarchical structure representing the genetic relationships between languages. It

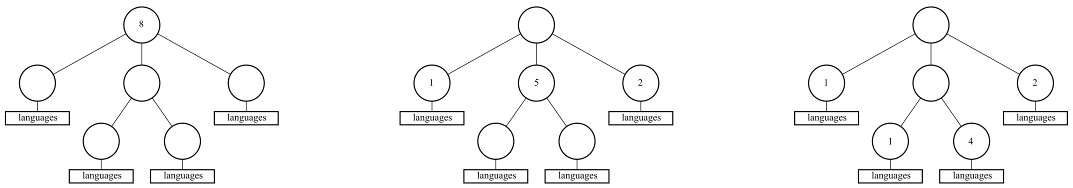

**Figure 4:** Illustration of the allocation to the subgroups. If we have to select 8 languages from this family tree (step 1), we start by selecting 1 language from each branch and distribute the remaining 5 languages among the branches (step 2). If we reach the bottom of the tree, we select the languages from the branch, otherwise we repeat the process (step 3).

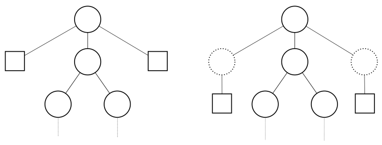

**Figure 5:** Example of the tree structure before and after adding a node. Circles represent subgroups and families, while squares represent languages.

consists of a class called `LanguageFamilyTree` inherited from the `networkx.DiGraph` class. This class represents the family tree as a directed graph, where each node corresponds to a language family, subgroup or language, and edges represent parent-child relationships. The class provides methods for building the tree from a CSV input (formatted as described in Section 3.4.1), for exporting the tree to a JSON or CSV file, for converting it to a dictionary, for calculating the diversity values of the nodes and for selecting a certain number of languages from the tree according to the sampling algorithm described in Section 2.3.

When importing the data, a function of `LanguageFamilyTree` refines the structure of the tree in order to avoid structures that would make impossible to be processed by the sampling algorithm. This occurs when a subgroup contains both languages and other subgroups as children. To address this, an additional level is introduced in the tree to separate the languages from the subgroups. This is achieved by creating new nodes that become parents to each language and children to the node that was previously their parent, as shown in Figure 5. This ensures the structure remains a tree, allowing the sampling algorithm to function correctly.

## 3.3. The `forest` Module

The `forest` module is responsible for managing multiple family trees and performing operations on them. It consists of a class called `Forest` that inherits from the `list` class. This class represents a collection of family trees and provides methods for reading a set of CSV files representing family trees from a directory, adding new `LanguageFamilyTree` objects to the forest, exporting the forest to a set of JSON or CSV files, calculating the diversity values of the trees in the forest, and selecting languages from the forest according to the sampling algorithm.

## 3.4. Command-Line Interface

The command-line interface (CLI) of `makeitsample` is designed to be user-friendly and allows users to easily run the sampling pipeline from the command line. To run the pipeline, users can use the following command:

```
makeitsample [-h] [-n N] [-i INPUT] [-o OUTPUT] [-f {csv,json}] [-s SAMPLENAME] [-r RANDOM_SEED]
```

where `N` is the sample size, `INPUT` is the input directory containing the CSV files, `OUTPUT` is the output directory where the sample will be saved, `f` is the output format (`csv` or `json`), `SAMPLENAME` is the name of the sample file, and `RANDOM_SEED` is the random seed for reproducibility.

### 3.4.1. Structure of the Input Data

In order to run `makeitsample`, the input data must be in a CSV format (as in the example in Table 1 in Appendix B). The CSV files (one for each language family) should contain:

- `id`: a column for the unique identifier of the language (e.g., ISO code), of the family or the group;
- `name`: a column storing the name of the language, of the family or the group;

- `parent_id`: a column storing the `id` of the parent node in the family;
- `type`: a column storing the type of the node (the only allowed values for this column are `family`, `group` or `language`).

The user can also add other columns with additional information about the languages, families or groups. `makeitsample` will ignore these columns when constructing the family tree, but they will be included in the output file.

## 4. Conclusions

In this paper, I presented `makeitsample`, a Python package that aims to ease the generation of typological language samples based on the diversity value (DV) metric. I presented the modules of the library and the command-line interface, which allow to construct a set of hierarchical language family trees, to calculate diversity values for each node, and to select languages based on their weight within the tree. By automating the sampling process and accounting for linguistic diversity, the library and the command-line interface provide a principled and scalable solution to generating language samples for typological studies helping researchers create more representative samples and reduce genealogical biases in their analyses.

The library is designed to be flexible and extensible, allowing researchers to adapt it to their specific needs and incorporate additional sampling strategies or metrics. Although user-friendly, the library is still in its early stages and requires some knowledge of Python to be used effectively or at least some familiarity with the command line. This might be a limitation for some users, and the plan is to create a web interface to make it more accessible to a wider audience.

## A. Full Calculation of the DV for the Example in Figure 2

### tree 1

#### family 1

$DV = 2$ (full calculation in Section 2.2)

#### group 1

$L = 2$ (maximum number of levels in the sibling trees of the tree rooted at group 1)

Node count:

- $N_0 = 1$ (number of nodes at level 0)
- $N_1 = 2$ (number of nodes at level 1)

Calculating the contributions:

- $C_0 = 0$ (contribution of the root level)
- $C_1 = 0 + (2-1) \times \frac{2-(1-1)}{2} = 0 + (1 \times 1) = 1$

$DV = 1$

#### group 2

$L = 2$ (sibling of group 1)

Node count:

- $N_0 = 1$ (number of nodes at level 0)
- $N_1 = 2$ (number of nodes at level 1)
- $N_2 = 3$ (number of nodes at level 2)

Calculating the contributions:

- $C_0 = 0$ (contribution of the root level)
- $C_1 = 0 + (2-1) \times \frac{2-(1-1)}{2} = 0 + (1 \times 1) = 1$
- $C_2 = 1 + (3-2) \times \frac{2-(2-1)}{2} = 1 + (1 \times \frac{1}{2}) = \frac{3}{2}$

$DV = \frac{1}{2}\left(1 + \frac{3}{2}\right) = \frac{5}{4} = 1.25$

#### group 3

$L = 1$ (maximum number of levels in the sibling trees of the tree rooted at group 3)

Node count:

- $N_0 = 1$ (number of nodes at level 0)
- $N_1 = 2$ (number of nodes at level 1)

Calculating the contributions:

- $C_0 = 0$ (contribution of the root level)
- $C_1 = 0 + (2-1) \times \frac{2-(1-1)}{2} = 0 + (1 \times 1) = 1$

$DV = 1$

#### group 4

$L = 1$ (sibling of group 3)

Node count:

- $N_0 = 1$ (number of nodes at level 0)
- $N_1 = 1$ (number of nodes at level 1)

It behaves like a language isolate, so we set $DV = 1$.

### tree 2

#### family 2

$L = 3$ (sibling of family 1)

Node count:

- $N_0 = 1$ (number of nodes at level 0)
- $N_1 = 2$ (number of nodes at level 1)
- $N_2 = 3$ (number of nodes at level 2)

Calculating the contributions:

- $C_0 = 0$ (contribution of the root level)
- $C_1 = 0 + (2-1) \times \frac{3-(1-1)}{3} = 0 + (1 \times 1) = 1$
- $C_2 = 1 + (3-2) \times \frac{3-(2-1)}{3} = 1 + (1 \times \frac{1}{3}) = \frac{4}{3}$

$DV = \frac{1}{2}\left(1 + \frac{4}{3}\right) = \frac{1}{2} \times \frac{7}{3} = \frac{7}{6} = 1.167$

**group 5**

$L = 1$ (maximum number of levels in the sibling trees of the tree rooted at group 5)

Node count:

- $N_0 = 1$ (number of nodes at level 0)
- $N_1 = 2$ (number of nodes at level 1)

Calculating the contributions:

- $C_0 = 0$ (contribution of the root level)
- $C_1 = 0 + (2 - 1) \times \frac{1-(1-1)}{1} = 0 + (1 \times 1) = 1$

$DV = 1$

**group 6**

$L = 1$ (sibling of group 5)

Node count:

- $N_0 = 1$ (number of nodes at level 0)
- $N_1 = 1$ (number of nodes at level 1)

It behaves like a language isolate, so we set $DV = 1$.

## B. Example of input CSV file

| id | name | parent_id | place | type |
|---|---|---|---|---|
| Afro-Asiatic | Afro-Asiatic | - | - | family |
| 36 | Berber | Afro-Asiatic | - | group |
| 1793 | Awjila-Sokna | 1063 | - | group |
| 1063 | Eastern | 36 | - | group |

# The OuLiBench Benchmark: Formal Constraints as a Lens into LLM Linguistic Competence

Silvio Calderaro[1], Alessio Miaschi[2] and Felice Dell'Orletta[2]

[1]*Università di Pisa*

[2]*ItaliaNLP Lab, Istituto di Linguistica Computazionale "A. Zampolli" (CNR-ILC), Pisa*

## Abstract

Recent progress in Large Language Models (LLMs) has led to impressive capabilities in Natural Language Generation (NLG). However, standard evaluation benchmarks often focus on surface-level performance and are predominantly English-centric, limiting insights into models' deeper linguistic competences, especially in other languages. In this paper, we introduce OuLiBench, a novel benchmark inspired by the literary movement OuLiPo, designed to evaluate LLMs' ability to generate Italian text under explicit linguistic constraints, ranging from morpho-syntactic requirements to creative and structural challenges. Our goal is to assess the extent to which LLMs can understand and manipulate language when guided by specific, sometimes artificial constraints. We evaluate a range of state-of-the-art models in both zero- and few-shot settings, comparing performance across constraint types and difficulty levels. Our results highlight significant variability across models and tasks, shedding light on the limits of controllable text generation and offering a new lens for probing LLMs' generative and linguistic competence beyond traditional benchmarks.

## Keywords

Large Language Models, Benchmark, Evaluation, Controllable Text Generation

## 1. Introduction and Background

The recent and rapid advancements in Large Language Models (LLMs) development has profoundly reshaped the landscape of Natural Language Processing (NLP) [1, 2, 3, 4]. These models exhibit remarkable proficiency across a wide range of tasks, particularly excelling in the generation of coherent and contextually appropriate text. They demonstrate a sophisticated grasp of complex linguistic structures with high accuracy. Such capabilities have been extensively evaluated through a variety of benchmarks, many of which are aggregated on platforms like the Open LLM Leaderboard [5] to facilitate cross-model comparisons.

However, despite the value of these benchmarks as reference frameworks, a significant gap remains in the comprehensive assessment of LLMs' intrinsic linguistic competencies, independently of specific task formulations and with a cross-cutting perspective [6, 7]. Standard evaluation metrics often emphasize surface-level features (e.g., n-gram overlap using BLEU or ROUGE), which may fail to capture deep semantic understanding or robust syntactic flexibility.

Another critical issue, often underestimated in current evaluation methodologies, is the overwhelming predominance of benchmarks developed and validated primarily for the English language [8]. This bias significantly limits the accurate assessment of multilingual systems or models tailored for other languages, such as Italian. Moreover, it impedes the identification and study of culturally specific linguistic phenomena, which are inherently tied to the socio-cultural characteristics of individual linguistic communities.

Concurrently, Controllable Text Generation (CTG) is emerging as a pivotal research area within the LLM domain [9, 10, 11, 12, 13]. CTG focuses on developing and analyzing techniques that guide text generation to conform to explicit constraints, such as style (e.g., formal vs. informal), emotional tone, desired length, structural complexity (e.g., number of subordinate clauses), and predefined semantic content. By leveraging strategies such as prompt conditioning, targeted fine-tuning on annotated datasets, and the implementation of dedicated control mechanisms, CTG research aims to produce generative systems capable of generating outputs that precisely satisfy specified criteria. Intrinsically, this field not only provides methodologies for evaluations better aligned with practical and real-world communicative needs but also emphasizes the models' ability to manipulate language in response to explicit conditions.

This focus on controlled generation naturally raises the question of how far such control can be extended, particularly when constraints become highly specific or even deliberately artificial, designed not merely to produce functional output but to probe the very limits of linguis-

tic manipulation and computational creativity. In this regard, there exists a compelling parallel with the principles of the literary group OuLiPo (Ouvroir de Littérature Potentielle), which has long explored the generative potential of formal constraints. By imposing stringent rules on literary creation, OuLiPo demonstrates how limitations can paradoxically unlock new expressive forms and reveal deeper structural properties of language. We hypothesize that such intricate, often playful linguistic challenges, when adapted as evaluation tasks, can yield valuable insights into the degree of fine-grained control an LLM can exert and its implicit understanding of linguistic structure, moving beyond mere fluency to assess true generative competence.

Building on these insights, in this paper we introduce OuLiBench, a novel benchmark, and present an extensive evaluation of LLMs' ability to generate Italian text under targeted linguistic constraints, ranging from morpho-syntactic to stylistic-formal phenomena.

By prompting language models to generate sentences that adhere to specific linguistic constraints (e.g., "Generate a sentence with exactly five words" or "Generate a sentence without the letter 'e'") and, where applicable, evaluating their ability to reflect on these constraints or on properties of the generated text, we aim to address the following research questions: i) To what extent can LLMs produce text that satisfies explicit linguistic constraints defined in OuLiBench, including quantitative, structural, and creative constraints? ii) What differences emerge among various LLMs in their ability to meet complex linguistic constraints, and which types of constraints pose the greatest challenges? iii) How does the nature of the constraint (e.g., syntactic vs. creative) affect the quality and coherence of the generated text?

**Contributions**. Our main contributions are:

- We propose a framework, based on the OuliBench benchmark, for evaluating the linguistic abilities of state-of-the-art Italian LLMs when generating text.
- We conduct extensive evaluations across different open- and closed-source models and linguistic constraints.
- We evaluated models' abilities across several configurations, testing their performance in zero- and few-shot settings.

## 2. Our Approach

We systematically evaluate the ability of several LLMs to generate Italian sentences under a range of explicitly defined linguistic constraints. These constraints are formalized as a set of properties $P = p_1, p_2, ..., p_n$, where each property $p_i$ corresponds to a specific quantitative, morpho-syntactic or creative linguistic phenomenon. The goal is to assess to what extent models can control these properties during text generation, and how robustly they generalize across different types of constraints.

For each property $p_i$, we define a corresponding set of possible target values $V_p = v_{p1}, v_{p2}, ..., v_{pn}$. We prompt the models to generate a fixed number of sentences conditioned on each value $v_{pi}$ using a consistent prompt format. For example, for the property "number of words" a representative prompt would be:

> *Genera 50 frasi composte esattamente da 5 parole ciascuna, escludi dal conto la punteggiatura e gli spazi. [transl. Generate 50 sentences consisting of exactly 5 words each, excluding punctuation and spaces from the count.]*

Considering the difficulty that LLMs show in meeting strict numerical specifications, such as generating sentences with an exact length in terms of words or characters, we intentionally structured the evaluation around increasing values of each property. This approach allows us to examine whether the models are sensitive to the relative ordering and magnitude of constraints, even when exact conformity is difficult to achieve. The underlying hypothesis is that although a model may not reliably produce a sentence with exactly 5 words, it may still exhibit a monotonic tendency, generating progressively longer sentences as the required number increases.

For syntactic constraints, such as those related to the syntactic order of the elements (e.g. SVO, SOV, VSO), the analysis focused on the model's ability to adapt the syntactic structure of the sentence to predetermined patterns. Here, the aim is to assess the structural flexibility of the model and its ability to model the output according to specific grammatical configurations. Finally, concerning OuLiPo-inspired linguistic constraints, such as lipograms (texts that deliberately omit a particular letter) and tautograms (texts in which all words start with the same letter), the evaluation was structured around specific letters of the alphabet, testing the model's ability to inhibit or concentrate the use of certain letters within the generated sentences. This allows us to examine the controllability of the models in more creative and stylistic contexts, where the constraints are not numerical but qualitative and symbolic.

The linguistic constraints span both formal properties (e.g. sentence length in words or characters, permutations of sentence elements in the context of linguistic typology) and creative phenomena (e.g., lipograms, tautograms, acrostics), enabling a comprehensive evaluation of controllability across structural and stylistic dimensions. In all cases, the evaluation assesses whether the generated sentence not only satisfies the target constraint but also maintains syntactic correctness, semantic coherence, and linguistic appropriateness in Italian.

# 3. OuLiBench

To address the need for more granular evaluation tools for the Italian language, we developed **OuLiBench**. This novel benchmark is specifically designed to thoroughly analyze the capability of LLMs to generate text while adhering to a diverse and progressively complex set of explicit linguistic constraints, thereby moving beyond assessments based on mere surface-level fluency.

## 3.1. Conceptual Framework and Task Taxonomy

The conceptual foundation of OuLiBench integrates principles from **Controllable Text Generation (CTG)** [10], which focuses on guided generation according to predefined attributes, with the creative, constraint-based methodologies of the **OuLiPo (Ouvroir de Littérature Potentielle)** literary group. Founded in 1960 by writer Raymond Queneau and mathematician François Le Lionnais, OuLiPo emerged as a revolutionary literary movement that sought to explore the potential of literature through the systematic application of formal constraints. In their Premier Manifeste (First Manifesto) [14] of 1961, Le Lionnais articulated the group's foundational philosophy Littérature potentielle, defining littérature potentielle as "the search for new structures and patterns that can be used" to create literary works. The group used the restrictions of literary forms to spark creativity, developing techniques such as lipograms (texts excluding specific letters), tautograms, anagrams and palindromes. This approach demonstrated that systematic limitations could paradoxically expand rather than restrict creative possibilities, generating what the group termed "potential literature". OuLiBench adapts these philosophies into a suite of computationally evaluable tasks, entirely formulated and contextualized for the Italian language.

OuliBench is organized according to a taxonomy that reflects different levels and types of linguistic control:

1. **Quantitative Constraints:** This category assesses the precision of dimensional control over the textual output. Tasks require models to generate sentences adhering to an **exact word count** or an **exact character count** (net of punctuation and spaces). These constraints challenge models to balance numerical restrictions with semantic coherence and grammatical correctness.
2. **Syntactic Constraints:** These tasks evaluate the models' competence in manipulating fundamental Italian grammatical structures. They include **verbal diathesis control** (requiring generation in active, passive, or reflexive/medium voice) and **constituent order permutations** (Subject-Verb-Object), testing flexibility in generating canonical and non-canonical sentence structures.
3. **Stylistic-Formal (OuLiPo-inspired) Constraints:** Representing the most elaborate challenges, this category implements OuLiPian *contraintes*. It includes tasks such as the **Lipogram** (omission of specific letters), **Inverse Lipogram** (mandatory inclusion of specific letters), **Tautogram** (all words starting with the same letter), **Anagram** (at both word and phrasal levels), **Palindrome** (symmetrical text), and **Acrostic** (initial letters of words forming a target word). These tasks demand advanced linguistic planning and sophisticated sub-lexical and structural manipulation.

For each task, specific prompts were formulated in Italian. Table 1 provides a comprehensive overview of the tasks included in OuLiBench, as well as the prompts used for generating the sentences.

# 4. Experimental Setting

We evaluate a pool of Italian LLMs by testing their ability to follow the linguistic constraints defined in OuliBench. We conduct our experiments in both zero-shot and few-shot settings. In the zero-shot condition, the model receives only the instruction formulated in natural language. In the few-shot configuration, the prompt is augmented with five, ten, and fifteen exemplar sentences corresponding to the same constraint. This setup is intended to investigate whether LLMs improve in constraint-following behaviour when exposed to in-context demonstrations. In the following, we describe the set of tested models and the evaluation strategy adopted to assess the extent to which generated outputs satisfy the defined constraints.

## 4.1. Models

The landscape of Italian large language models (LLMs) is evolving rapidly, with notable differences in development strategies. Some models have been pre-trained from scratch with intrinsic emphasis on the Italian language, while others have been fine-tuned for Italian starting from well-established architectures. For this study, we selected models with comparable parameter scales: Minerva-7B-instruct-v1.0 (SapienzaNLP) [15], Velvet-14B (Almawave) [16], Maestrale-chat-v0.4-beta (mii-llm) [17], and LLaMAntino-3-ANITA-8B-Inst-DPO-ITA (SWAP-UNIBA) [18]. The first group includes three models pre-trained from scratch. Minerva-7B-instruct-v1.0 is a 7-billion-parameter Transformer pre-trained

| Category | Task Name | Constraint Description | Example Target Sentence (Italian) |
|---|---|---|---|
| Quantitative | Length by Words | Generate Italian sentences with an exact word count. | "Il gatto dorme sul divano." (5 words) |
| | Length by Characters | Generate Italian sentences with an exact character count (no punct/space). | "Mangio la pizza" (13 chars) |
| Syntactic | Diathesis Control | Generate Italian sentences in specified voice (active, passive, reflexive). | "La lettera è scritta da Marco." (passiva) |
| | Word Order Permutations | Generate Italian sentences using specific SVO permutations (SOV, VSO, etc.). | "Mangia la mela Luca" (VOS) |
| Stylistic-Formal (OuLiPo-inspired) | Lipogram | Generate Italian text excluding a specific letter. | "Oggi vado in montagna" (without 'e') |
| | Inverse Lipogram | Generate Italian sentences where a specific letter appears min. once for each words. | "Questo esercizio contiene molte esse." ( 'e') |
| | Tautogram | Generate Italian text where all words start with the same letter. | "Maria mangia mele morbide" ('m') |
| | Word Anagram | Generate a valid Italian anagram for a given Italian word. | "Noce" → "Ceno" |
| | Phrasal Anagram | Reorder sentence letters into a new meaningful Italian sentence. | "Amo Roma" → "Moro ama" |
| | Palindrome | Generate Italian text reading the same forwards and backwards. | "Aceto nell'enoteca" |
| | Acrostic | Generate Italian text where initial word letters form a target word. | "Viva V.E.R.D.I." |

**Table 1**
OuLiBench Task Summary (Evaluated on Italian).

on 2.5 trillion tokens, balancing Italian, English, and code, and later refined through supervised fine-tuning (SFT) and direct preference optimization (DPO). Velvet-14B is a dense 14-billion-parameter Transformer trained from scratch on the Leonardo HPC system using 4 trillion multilingual tokens, approximately 23% of which are in Italian, achieving competitive scores on Italian-language benchmarks. These models integrate Italian language knowledge from the earliest stages of training. The second group is based on existing architectures. LLaMAntino-3-ANITA-8B-Inst-DPO-ITA is derived from Meta-LLaMA-3-8B-Instruct and specializes in Italian through super-fine-tuning (QLoRA SFT) on mixed datasets and DPO optimization. Maestrale-chat-v0.4-beta, based on Mistral-7B, underwent continued pre-training on an Italian corpus and "Occiglot," followed by conversational SFT and DPO alignment aimed at improving factuality and mathematical reasoning. Although these models build upon pre-trained foundations, they have invested significantly in adapting and optimizing for the specific characteristics of the Italian language. To achieve a comprehensive and diversified evaluation of LLM capabilities across the tasks proposed by the benchmark, it was essential to extend the comparison to include larger proprietary models that currently represent the state of the art in the field. This strategic choice enabled assessment of the selected Italian open-source models in relation to the highest standards achieved by global research and development. Specifically, the comparison included Claude Sonnet 4 [19], DeepSeek [20], Gemini 2.5 Flash, and GPT-4o mini [2].

## 4.2. Prompting Optimization

The effectiveness of text generation using advanced Language Models is critically dependent on the calibration and formulation of prompts. Our research has systematically analyzed the interaction between prompt structure and output quality for each model, defining optimized strategies to maximize compliance with experimental requirements. Generally, precision in criteria definition was found to be critical: for text length control, making explicit the exclusion of non-linguistic elements (such as punctuation and spaces) significantly improved the precision of some models (Maestrale and Anita). Similarly, for the handling of verbal diathesis in particular middle (or reflexive) diathesis, explicit formulations reduced interpretive ambiguities, increasing the adherence of outputs. In the context of OuLiPo constraints, whenever possible we avoided specific terminology in the prompt (Lipograms, Inverse Lipograms, Tautograms, and Palindromes), describing the task directly and using quotation marks to highlight restricted letters.

A crucial aspect of our methodology was the implementation of few-shot learning, exploring its configurations with 0, 5, 10 and 15 examples. The tasks that employed few-shot were: quantitative constraints, diathesis, Lipograms, Palindromes. The examples were collected from the Italian Universal Dependency dataset, a corpus consisting of 34,383 sentences derived from the main Italian treebanks included in the Universal Dependencies project, including ISDT[21] VIT[22], PARTUT[23], PoSTWITTA[24] and TWITTIRO [25].

During few-shot experimentation, it emerged that the Minerva and Velvet models tended to slavishly reproduce the examples provided in the prompt, generating outputs identical or nearly identical to the initial examples, regardless of the variation required by the task. This behavior compromised the evaluability of the outputs, as it did not allow verification of the model's ability to generalize or adapt to the specific constraint. Consequently, these models were excluded from the tables related to few-shot configurations.

### 4.3. Evaluation Strategy

The assessment of model performance within OuLiBench employs an integrated approach, combining quantitative metrics for formal adherence with qualitative analyses for more nuanced aspects of generation.

The primary quantitative metrics are:

- **Success Rate (SR):** Calculated as the percentage of generated outputs that *perfectly* satisfy the linguistic constraint imposed by the specific task. This metric provides a direct measure of the model's precision.
- **Spearman's Rank Correlation Coefficient ($\rho$):** Used to determine the models' sensitivity to incremental or decremental variations in constraints (e.g., whether models produce longer sentences when requested to increase word count), even when exact adherence is not achieved. This metric was only computed for the evaluation of the quantitative constraints.

To apply these metrics, particularly for SR on constraints involving specific lexical or syntactic features, model outputs were pre-processed and analyzed, partly with the support of linguistic analysis tools. In particular, we employed ProfilingUD [26], a tool that allows the extraction of more than 130 properties representative of the linguistic structure underlying a sentence and derived from raw, morpho-syntactic and syntactic levels of annotation based on the UD formalism. ProfilingUD was specifically applied to the sentences generated by the tested models to extract linguistic features used to evaluate model performance (e.g. sentence length, in terms of tokens or characters, diathesis control, etc.).

The qualitative analysis was carried out manually on the responses that had passed the automatic evaluation, meaning those that met the formal constraints required by the task. The aim was to examine more closely the linguistic quality of the sentences produced, considering three main aspects: grammatical correctness, semantic coherence, and linguistic appropriateness. These criteria were not applied according to a strict hierarchy, although semantic coherence often played a central role, as it is crucial for the comprehensibility and meaning of the sentence. In the presence of particularly strong constraints, such as in the case of tautograms or anagrams, the evaluation was conducted with greater flexibility. The rigidity of the structure required by these constraints can compromise the naturalness of the sentences, making it necessary to allow some tolerance in assessing the other qualitative aspects.

## 5. Results

The results obtained from the application of the OuLiBench benchmark highlight substantial differences among the tested models, both in terms of absolute capabilities and sensitivity to various types of linguistic constraints. The analysis was conducted considering both quantitative metrics (**Success Rate** and **Spearman's correlation**) and qualitative evaluations of semantic coherence and grammatical correctness.

### 5.1. Overall Performance

Table 2 reports the results obtained by the Italian open-source models, which highlight a significant variability in models' linguistic control capabilities. **LLaMAntino-3-ANITA-8B-Inst-DPO-ITA (Anita) stands out as the best-performing Italian model, achieving an average SR of 53% in the zero-shot setting**, clearly outperforming the others. Velvet-14B reaches an average of 29%, while Maestrale-chat-v0.4-beta and Minerva-7B-instruct-v1.0 show more limited performance, with 19% and 12% respectively.

To better contextualize these results, Table 3 reports the performance of larger proprietary models, which can be considered as an upper bound relative to the Italian ones. Within this group, **Gemini 2.5 Flash** achieves the highest performance with an overall average of 70%, followed by **GPT-4o mini** (66%) and **DeepSeek R1** (65%). **Claude Sonnet 4**, while competitive across several tasks, records an overall average of 61.5%.

### 5.2. Analysis by Constraint Categories

#### 5.2.1. Quantitative Constraints

Length control tasks proved to be the most challenging for all tested models. In word-count control, Gemini performed best (34%), followed by DeepSeek (30%) and GPT-4o mini (17%), while Claude obtained the worst performance (9%). Among open-source models, Anita achieved 27% in zero-shot, significantly outperforming Maestrale (9%), Velvet (5%), and Minerva (3%). Spearman correlations were consistently high for proprietary models (94%–100%), thus indicating strong ordinal sensitivity despite difficulties in precise control.

Character-count control was even more demanding: Gemini led (14%), trailed by GPT-4o mini (13%), DeepSeek (05%) while Claude struggled severely (0.03%). Anita remained competitive (15%) among open-source models,

| Task | Anita | | | | Maestrale | | | | Minerva | | | | Velvet | | | | Task Avg |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | 0 | 5 | 10 | 15 | 0 | 5 | 10 | 15 | 0 | 5 | 10 | 15 | 0 | 5 | 10 | 15 | |
| Word Length | **.27/.90** | .25/.95 | .24/.95 | .13/.93 | .09/.88 | .06/.64 | .04/.68 | *.02/.89* | .03/## | - | - | - | .05/.66 | - | - | - | **.11/.75** |

**Table 3**
Performance of the closed-source models on OuliBench both in zero- and few-shot configurations (SR/$\rho$). **Best** and *worst* results for each property and metric are in **bold** and *italic*, respectively. ## indicates non-significant correlations.

whereas Velvet (1%) and Maestrale (0.06%) showed major limitations. Minerva failed entirely (0).

### 5.2.2. Syntactic Constraints

Diathesis control revealed in general a clear advantage for proprietary models: DeepSeek and Anita achieved near-perfect scores (100% and 99%, respectively), followed by GPT-4o mini (97%) and Gemini (99%). Claude trailed slightly (89%), while Italian open-source models—Minerva (72%), Velvet (67%), and Maestrale (59%)—struggled more.

Constituent order permutations highlighted a stark divide: GPT-4o mini excelled (99%), with DeepSeek (100%), Gemini (95%), and Claude (86%) close behind. Open-source models performed uniformly worse: Anita and Velvet (both 16%), Maestrale (12%), and Minerva (8%), suggesting architectural limitations in complex syntactic manipulation.

### 5.2.3. Stylistic-Formal Constraints

This category showed the widest performance gaps. For lipograms, GPT-4o mini achieved the best results (89%), ahead of DeepSeek (79%), Claude (77%), and Gemini (73%). Anita remained competitive (59%), while other open-source models obtained significantly lower scores: Velvet (47%), Maestrale (32%), and Minerva (28%).

Tautograms revealed polarizing results: Claude led (0.99), followed by GPT-4o mini (98%), Gemini (94%), and DeepSeek (91%). Among open-source models, Anita (0.73) vastly outperformed Maestrale (55%), with Velvet (8%) and Minerva (0.07%) failing critically.

Word anagrams exhibited extreme variability: GPT-4o mini scored perfectly (1.0), while Anita surprised with 92%, surpassing DeepSeek (76%), Gemini (58%), and Claude (54%). Other open-source models failed completely: Maestrale (18%), Velvet (10%), and Minerva (0).

Palindromes were universally the hardest task. Claude led (74%), with GPT-4o mini (26%), Gemini (20%), and DeepSeek (18%) far behind. Anita achieved 54% in zero-shot, while all other open-source models scored zero.

## 5.3. Effects of Few-Shot Learning

The few-shot learning analysis reveals non-uniform patterns across models and tasks. **Anita** shows a general degradation of performance with an increase in examples (from 53% in zero-shot to 26-40% in few-shot configurations), particularly evident in quantitative tasks where word control decreases from 27% to 13% with 15 examples, and voice control degrades from 99% to 90%. This trend suggests possible contextual overfitting phenomena.

**Maestrale**, on the other hand, exhibits a pattern of gradual improvement (from 19% in zero-shot to 35% with 15 examples), with clear benefits in quantitative tasks: character control improves from 0.006 to 0.03, and voice

**Table 4**
Example outputs for selected tasks across four Italian LLMs.

| Model | Lipogram (no ’e’) | Permutation (VSO) | Tautogram (letter ’m’) |
|---|---|---|---|
| **Anita** | *“Un topo salta sopra un muro alto.”*<br>*Eng. "A mouse jumps over a high wall."*<br>Correct lipogram | *“Suona Giulia il pianoforte.”*<br>*Eng. "Giulia plays the piano."*<br>Correct | *“Molti mangiano molta minestra.”*<br>*Eng. "Many people eat a lot of soup."*<br>Correct |
| **Maestrale** | *“I gatti miagolano sonnacchiosi”*<br>*Eng. "Cats meow sleepily"*<br>Correct lipogram | *“Mangia Luca una mela rossa”*<br>*Eng. "Luca eats a red apple"*<br>Correct permutation | *“Mosse machiavelliane macchiano magnanimi mandarini.”*<br>*Eng " Machiavellian moves tarnish magnanimous mandarins."*<br>Respects the constraint but the sentence sounds contrived |
| **Velvet** | *“Il bosco era fitto e misterioso.”*<br>*Eng. "The forest was dense and mysterious."*<br>Violates the constraint with the letter ’e’ | *“Luca studia matematica.”*<br>*Eng. "Luca studies math.*<br>Does not respect the constraint | *“Meraviglioso momento musicale regalato dall’artista magistrale della serata.”*<br>*Eng. "A wonderful musical moment provided by the masterful artist of the evening."*<br>Does not respect the constraint in the whole sentence |
| **Minerva** | *“Io non voglio andare al mare oggi.”*<br>*Eng. "I don’t want to go to the beach today."*<br>Violates the constraint with the letter ’e’ | *“Mangio un panino al salame per pranzo.”*<br>*Eng. "I eat a salami sandwich for lunch."*<br>The subject is implied, so the sentence does not respect the correct order | *“Marito mio, mia moglie.”*<br>*Eng. "My husband, my wife."*<br>Constraint satisfied, slightly artificial |

control reaches perfection (1.0) with 5 and 15 examples. A slight improvement from 0.32 to 0.37 with 5 examples is also observed in lipograms, indicating more robust in-context learning capabilities.

It is noteworthy that **Minerva** and **Velvet** systematically tend to reproduce the few-shot examples almost verbatim, particularly in quantitative tasks and lipograms. This behavior made their outputs effectively unassessable in few-shot settings. A plausible explanation is that the high complexity of the tasks, combined with the explicit presence of in-context examples, may lead these models to default to copying strategies rather than genuine generalization. This tendency ultimately compromises output quality and originality, suggesting limitations in their ability to adapt constraints creatively beyond provided exemplars.

## 6. Discussion

The OuLiBench results provide valuable insights into the linguistic competence of Large Language Models (LLMs), particularly in their ability to generate text under various formal constraints. One of the most striking findings is the performance gap between tasks involving quantitative constraints and those requiring more structural or stylistic control. This disparity suggests that while LLMs exhibit a robust implicit grasp of linguistic structure, they struggle with fine-grained numerical control, a limitation likely rooted in the statistical nature of transformer architectures.

Comparing open-source and closed-source models, the latter generally outperform the former, particularly in tasks involving stylistic-formal constraints. However, this advantage is not consistent across all task types. Notably, even closed-source models, despite their overall superiority, struggle with specific tasks such as palindromes, which require strict character-level control. Similarly, tasks involving quantitative constraints pose significant challenges for both model categories, as they demand precise control over features like length or repetition, capabilities that are difficult to enforce within transformer-based architectures relying on statistical patterns rather than explicit rule-based mechanisms. These limitations further corroborate the value of OuLiBench as a benchmark for evaluating LLMs’ ability to generate text while adhering to complex and diverse constraints. Finally, models from both categories perform well on syntactic constraints, suggesting that such structural aspects are relatively well captured by current architectures.

Focusing instead on smaller open-source models, we noticed that their linguistic production frequently suffered, primarily in stylistic-formal tasks, from an inability to generate truly well-structured sentences in Italian, often producing ungrammatical or semantically incoherent outputs. This degradation of linguistic quality under complex constraints highlights the trade-off between adherence to the constraint and maintenance of basic linguistic competence. A particularly notable pattern emerged in the palindrome tasks: smaller models frequently abandoned Italian and began generating sentences in English. This involuntary code-switching suggests a tendency to revert to the predominant language in the training data when the task deviates from standard generation patterns.

From a more qualitative point of view, the generated outputs of the models reveal systematic behavioral patterns, particularly evident in smaller models but also observable in larger ones. A recurring phenomenon is the tendency for thematic and lexical repetition with superficial word order variations across most tasks, suggesting limitations in creative diversification under constraints.

In the specific case of anagrammatic tasks, Anita and Velvet showed a simplified resolution strategy, limiting themselves to swapping word order within phrases rather than performing true letter-level permutations (as shown in the examples below). This behavior indicates a superficial understanding of the anagrammatic constraint and the adoption of simplified heuristics.

**Examples from Anita:**

> *Original:* “Tre gatti in casa fanno rumore strepito”
> *Anagram:* “Strepito in casa fanno gatti tre rumore”
> *English:* “Three cats in the house make noise and uproar” → “Uproar in the house make cats three noise”
>
> *Original:* “Tre per cento in banca stanno”
> *Anagram:* “Stanno in banca trecento per”
> *English:* “Three percent are in the bank” → “Are in the bank threehundred percent”

**Examples from Velvet:**

> *Original:* “Il sole splende.”
> *Anagram:* “Splende il sole.”
> *English:* “The sun shines.” → “Shines the sun.”
>
> *Original:* “La luna brilla.”
> *Anagram:* “Brilla la luna.”
> *English:* “The moon shines.” → “Shines the moon.”
>
> *Original:* “Il gatto mangia.”
> *Anagram:* “Mangia il gatto.”
> *English:* “The cat eats.” → “Eats the cat.”

In summary, these results highlight **the difficulty of models in reflecting and producing according to meta-linguistic principles**, a fundamental feature of human linguistic creativity, thus highlighting **the limitations of multi-objective planning mechanisms with respect to controllability and performance in complex linguistic tasks**.

## 7. Conclusion and Future Works

In this study, we presented OuLiBench, a novel benchmark designed to rigorously assess the linguistic capabilities of Large Language Models (LLMs) through the generation of Italian texts governed by explicit formal constraints. Drawing inspiration from the Oulipo literary tradition, our benchmark diverges from conventional evaluation methodologies that typically emphasize task performance on downstream applications. Instead, OuLiBench centers its evaluation on the model’s proficiency in adhering to a diverse array of linguistic constraints, encompassing structural, quantitative, syntactic, and stylistic dimensions. This shift of focus allows for a more nuanced understanding of a model’s fine-grained control over language generation processes. Our empirical evaluation involved both open-source and commercial LLMs tested in zero-shot and few-shot scenarios. The results revealed substantial variability in their ability to meet the prescribed constraints. Quantitative constraints, such as specific letter counts or palindromic structures, posed significant difficulties across the board, underscoring persistent limitations in current architectures for handling sub-lexical control. Conversely, syntactic and stylistic constraints were more successfully navigated by larger models, suggesting that model scale and complexity contribute positively to managing higher-level linguistic features. Notably, Italian-focused LLMs, including Anita, demonstrated competitive performance, highlighting the benefits of dedicated linguistic resources and targeted training on specific languages, which can partially offset the advantages conferred by sheer model size. These findings emphasize the persistent challenges in controllable text generation, especially under intersecting and mutually interacting constraints and demand simultaneous fulfillment without compromising linguistic naturalness and coherence. The results indicate a pressing need for innovative generation frameworks capable of embedding meta-linguistic reasoning and constraint-aware planning mechanisms throughout the text production pipeline. Looking forward, OuLiBench lays the groundwork for several promising directions in computational linguistics and AI research. Extending the benchmark to other languages would facilitate cross-linguistic investigations into the controllability of multilingual LLMs, while the integration of multimodal or pragmatic constraints could broaden the scope of evaluation beyond purely textual parameters. Additionally, developing refined qualitative and creativity-focused metrics will be critical to advancing our understanding of deep linguistic competence, ultimately guiding the design of next-generation models with enhanced flexibility, expressiveness, and adherence to formal language structures. Ultimately, OuLiBench not only enriches the evaluation toolkit for Italian NLP but also serves as a conceptual bridge between computational linguistics and literary formalism, pushing the boundaries of what LLMs can achieve under constraint.

## Acknowledgments

This work has been supported by the FAIR - Future AI Research (PE00000013) project under the NRRP MUR program funded by the NextGenerationEU. Partial support was also received by the project *"Understanding and Enhancing Preference Alignment in Large Language Models Through Controlled Text Generation"* (IsCc8_ALIGNLLM), funded by CINECA under the ISCRA initiative, for the availability of HPC resources and support.

# BES4RAG: A Framework for Embedding Model Selection in Retrieval-Augmented Generation

Lorenzo Canale[1,*,†], Stefano Scotta[1,*,†], Alberto Messina[1,*] and Laura Farinetti[2]

[1] *RAI - Centro Ricerche, Innovazione Tecnologica e Sperimentazione, Via Giovanni Carlo Cavalli 6, 10138, Turin, Italy*

[2] *Politecnico di Torino, Corso Duca degli Abruzzi 24, 10129, Turin, Italy*

## Abstract

Embedding model selection is a crucial step in optimizing Retrieval-Augmented Generation (RAG) systems. In this paper, we introduce **BES4RAG**, a framework designed to evaluate embedding models based on question-answering accuracy rather than standard retrieval metrics. BES4RAG automates dataset processing, automatic question generation, passage indexing, retrieval, and answer evaluation to determine the optimal embedding model for specific datasets. Experimental results on three diverse datasets confirm that embedding choice significantly affects performance, varies across datasets, and can enable smaller LLMs to outperform larger ones when paired with the right embeddings. Additionally, since a key component of this framework is automatic question generation, we found that its performance closely aligns with manually crafted questions, as evidenced by the Pearson correlation between the two.

## Keywords

Embedding Model Selection, Automatic Question Generation, Evaluation Framework, Retrieval-Augmented Generation (RAG),

## 1. Introduction

Retrieval-Augmented Generation (RAG) has emerged as a powerful approach for improving the factual accuracy and contextual relevance of Large Language Models (LLMs) by incorporating external knowledge sources [1]. A crucial component of a RAG system is the embedding model, which converts textual data into vector representations for retrieval [2, 3, 4, 5]. Standard retrieval metrics like Recall@k, Mean Reciprocal Rank (MRR), Normalized Discounted Cumulative Gain (NDCG), Mean Average Precision (MAP), and Precision at some cutoff (Precision@k) are commonly used to evaluate embeddings [6], but they do not always reflect how well retrieved passages enhance answer quality. Additionally, these metrics require knowing the source document of key answer components, yet this information is not always easily accessible.

In this work, we introduce **BES4RAG**, a framework designed to address these limitations by focusing on evaluating embedding models based on their impact on question-answering accuracy, rather than relying solely on traditional retrieval metrics.

BES4RAG implements a fully automated pipeline that processes datasets, generates multiple-choice questions (MCQs) using an LLM, indexes passages using different embedding models, retrieves relevant documents, and evaluates the accuracy of generated answers. By comparing retrieval-augmented responses across different embeddings and LLM configurations, BES4RAG enables practitioners to identify the best embedding model for their specific dataset and use case.

We used BES4RAG to conduct a series of experiments on three diverse types of datasets: news articles, TV program transcripts, and movie-related data — including both scripts and additional metadata — each with varying lengths and characteristics, addressing three key research questions.

**RQ1** **Are optimal embedding choices dataset-dependent?** We demonstrate that different datasets yield significantly different optimal embeddings, reinforcing the importance of dataset-specific selection.

**RQ2** **Can small LLMs outperform larger models when paired with the right embeddings?** Our findings suggest that embedding quality can play a more significant role than LLM size, highlighting the necessity of embedding optimization.

**RQ3** **Do results from automatically generated questions correlate with those from manually created ones?** We validate that automated question evaluation is a reliable proxy for human-generated assessments, confirming the robustness of BES4RAG's methodology.

In summary, our results emphasize the importance of evaluating embedding models based on their impact on question-answering accuracy, with a methodology that minimizes user effort through the automatic generation of questions.

## 2. Related Work

The Massive Text Embedding Benchmark (MTEB) provides a valuable overview of the performance of hundreds of embedding models across a variety of tasks and datasets [7]. However, it also presents some limitations. Even when models are evaluated on multiple datasets for a given task, these datasets rarely match the specific characteristics — such as language, document length, or corpus size — of the data a user might use to build a RAG system. Additionally, for retrieval tasks, the evaluation metrics adopted by MTEB may not be fully appropriate in scenarios where the same information is spread across multiple documents. In such cases, the ranking of individual documents becomes less meaningful, as the relevant information is redundantly present in several of them.

For these reasons, *new evaluation methods are emerging in the literature that incorporate Large Language Models (LLMs)* [8]. For example, in [9], the capabilities of ChatGPT and Llama2 are leveraged to evaluate embedding models in the context of RAG. Instead of relying solely on retrieval metrics, ChatGPT is used to rank the relevance and usefulness of the context retrieved by different embedding models. In [10], the authors propose a clustering-based approach to analyze the behavior of *embedding models within RAG systems*. By grouping models into families based on their retrieval characteristics, the study reveals that top-k retrieval similarity can show high variance across different model families, especially at lower values of $k$. This highlights how seemingly similar models may behave quite differently in practice, reinforcing the importance of dataset-specific and task-aware embedding evaluation. More recent work has further emphasized the importance of considering embedding performance specifically within RAG pipelines. Sakar and Emekci, in [11], show that balancing context quality with similarity-based ranking is crucial, along with understanding trade-offs related to token usage, runtime, and hardware constraints. Their findings highlight the role of contextual compression filters in improving hardware efficiency and reducing token consumption, despite their effect on similarity scores. Similarly, in [12] COCOM is introduced, a context compression method that reduces long input contexts to a small set of compact embeddings. This approach significantly accelerates generation time by mitigating the overhead introduced by lengthy contextual inputs, which directly impacts user latency.

In parallel, the *automatic generation of questions using LLMs* has gained attention, especially in educational and evaluation contexts. In [13] it is presented a system that allows users to specify a question type (e.g., reading, speaking, or listening) and a base text, from which the system automatically generates questions accordingly. A more structured approach with PFQS (Planning First, Question Second) is proposed in [14], in which Llama 2 generates an answer plan that is then used to produce relevant questions. While these methods demonstrate the potential of LLMs for generating educational content, the systematic use of automatically generated questions for evaluating embedding performance in RAG systems remains underexplored and merits further investigation.

## 3. BES4RAG: A Framework for Selecting Embeddings in RAG.

**BES4RAG** (Benchmarking Embeddings for Selection in RAG) is a modular framework written in Python code and designed to assess embedding models *end-to-end* by evaluating their performance in the full RAG pipeline, rather than relying solely on pre-retrieval metrics.

BES4RAG differs from conventional evaluation methods by integrating automated question generation and response evaluation within the RAG loop. This enables a direct comparison of how different embeddings affect the final output quality, making the framework suitable for real-world, task-specific deployment.

The framework, depicted in Figure 1, is publicly available on GitHub.[1] In the following sections, we describe the individual pipeline modules.

### 3.1. Data Preprocessing: File Conversion and Organization

The preprocessing phase is handled by a module that ingests a variety of input formats—namely JSON, TXT, and PDF files—and converts them into plain text for downstream processing. This module also creates a `file_mapping.json` file, which records the correspondence between the original input and the resulting text files. Optionally, a brief textual description can be associated with each input document. This description can be generated automatically based on the original filename or derived from the content using a large language model (LLM); alternatively, the user can manually specify it. This step ensures that the dataset is normalized, forming the foundation for consistent question generation and passage segmentation in later stages.

[1] https://github.com/RaiCRITS/BES4RAG

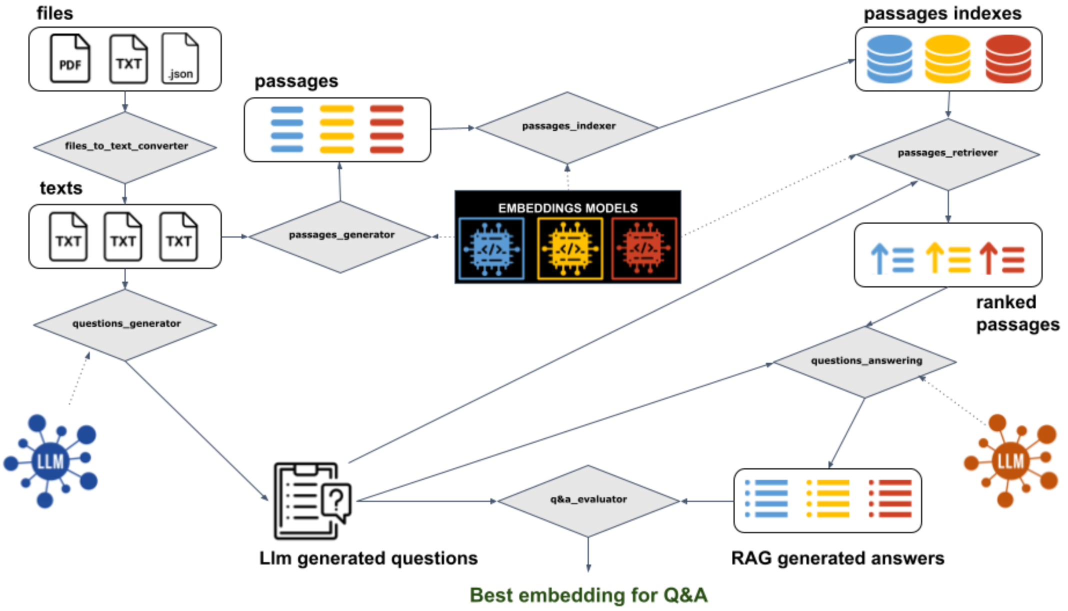

**Figure 1:** BES4RAG framework pipeline. The schema shows the whole pipeline starting (top left) from the documents which are converted into text files and then split into passages, see Section 3.1. The embedding of the passages are then computed and stored in indexes (top right), see Section 3.4. The text files are then sampled and given to an LLM appropriately prompted to automatically generate multiple-choice questions (bottom left), see Section 3.2. For each of these questions and for each embedding model, we rank the passages based on their similarity to the question (center right), see Section 3.5. The generated questions are then prompted to an LLM with the top $k$ retrieved passages for all the embedding models and different values of $k$, collecting the answers given (bottom right), see Section 3.6. Lastly, comparing the answers given by the LLM in the previous phase with the correct ones, generated alongside the questions, it is possible to evaluate which embedding model performs best for the particular dataset considered (bottom), see Section 3.7.

## 3.2. Automatic Questions Generation

A central component of BES4RAG is the automatic generation of MCQs from the input text. Using a LLM, the `questions_generator` module selects random text segments from the normalized dataset and formulates MCQs based on a customizable prompt template. The standard prompt used for question generation is in Figure 2. The questions are stored in JSON format.

## 3.3. Text Segmentation

Once the dataset is converted into text files, it is segmented into passages suitable for indexing. The `passages_generator` module performs this task by applying a specified tokenizer to the input text. A key consideration in this process is that the segmentation into passages is determined by the embedding model being used since the tokenizers have a maximum token length. By default, the framework uses the maximum token length supported. However, it is possible to specify a smaller token length.

## 3.4. Passages Indexing

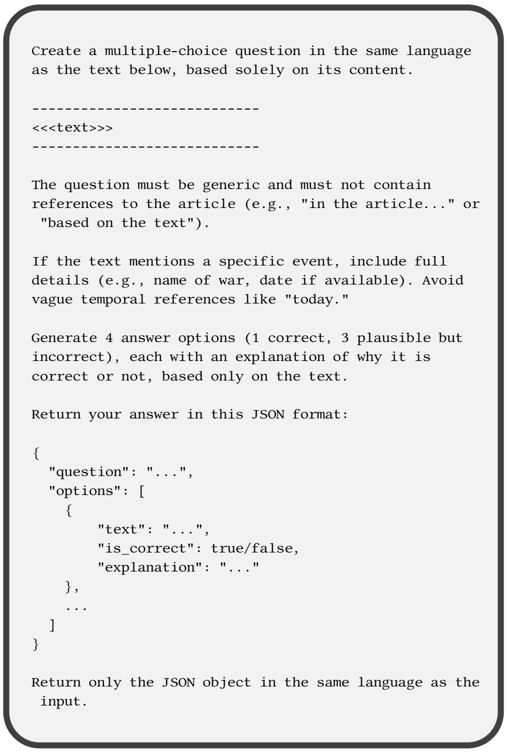
The segmented passages are embedded using one or more embedding models via the `indexer` module. This module computes and stores vector representations of the passages.

## 3.5. Passages Retrieval

Given a set of questions and indexed embeddings, the `passages_retriever` module ranks the passages based on similarity, typically using cosine similarity, though other similarity metrics can be employed depending on the embedding model. The retrieved passages are then stored, organized by embedding model, allowing for flexible experimentation with different top-$k$ retrieval sizes.

## 3.6. Question Answering

Using the retrieved passages and corresponding questions, the `questions_answering` module evaluates how well an LLM can answer each question in a RAG



```
Create a multiple-choice question in the same language
as the text below, based solely on its content.

---------------------------
<<<text>>>
---------------------------

The question must be generic and must not contain
references to the article (e.g., "in the article..." or
 "based on the text").

If the text mentions a specific event, include full
details (e.g., name of war, date if available). Avoid
vague temporal references like "today."

Generate 4 answer options (1 correct, 3 plausible but
incorrect), each with an explanation of why it is
correct or not, based only on the text.

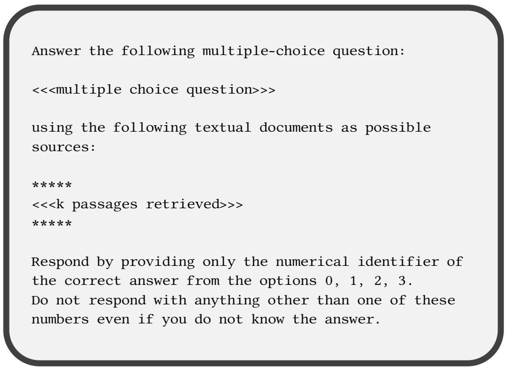
Return your answer in this JSON format:

{
  "question": "...",
  "options": [
    {
        "text": "...",
        "is_correct": true/false,
        "explanation": "..."
    },
    ...
  ]
}

Return only the JSON object in the same language as the
 input.
```

**Figure 2:** Prompt used for automatic question generation.

setup. For each value of $k$ (with default values of $k = 0, 1, 2, 3, 4, 5, 10$), the module combines the top-$k$ retrieved passages with the question prompt and queries an LLM to generate an answer. The prompt used for let the LLM answer the questions is in Figure 3. The results are stored in structured JSON files, organized by embedding and LLM configuration.



```
Answer the following multiple-choice question:

<<<multiple choice question>>>

using the following textual documents as possible
sources:

*****
<<<k passages retrieved>>>
*****

Respond by providing only the numerical identifier of
the correct answer from the options 0, 1, 2, 3.
Do not respond with anything other than one of these
numbers even if you do not know the answer.
```

**Figure 3:** Prompt used for question answering.

### 3.7. Evaluation

The final module, `q&a_evaluator`, assesses the performance of the RAG system across different embeddings by computing the answer accuracy over all questions. For each embedding model and retrieval configuration (e.g., varying $k$), the module calculates accuracy and generates a plot to visualize performance. This plot is crucial for identifying the embedding model that leads to the best overall performance in the specific domain or dataset under analysis. Additionally, it helps determine the optimal value of $k$ for the considered task. This evaluation also enables a comparison between free and open-source embedding models and their proprietary counterparts, providing insights into the trade-offs between computational cost and accuracy.

## 4. Experimental Setup

In this section, we describe the experimental setup used to evaluate the performance of the proposed system. We first provide an overview of the datasets used, followed by details about the embedding models and LLMs employed in the pipeline. Finally, we explain the evaluation metric adopted to measure the system's performance in answering questions.

### 4.1. Datasets

We evaluate our system on three distinct datasets, each representing a different domain and content type. These datasets were selected to test the system's versatility and ability to generalize across varying text types, from news articles to transcripts of TV programs and movie scripts.

- **RaiNews:** This dataset consists of approximately 16,000 news articles, from the RaiNews portal, covering a wide range of topics from current events. The articles are typically short and serve as concise textual documents, ideal for testing the system's ability to retrieve and generate answers from concise content.
- **Medicina33:** This dataset includes roughly 159 full transcripts from the *Medicina 33* TV program. This Italian television program focuses on medical topics, with discussions featuring experts in the field of medicine. The transcripts are longer with respect to the news, making them suitable for testing the system's handling of more complex, specialized content.
- **Movies:** This dataset comprises approximately 2,000 movie scripts, metadata, and reviews. It includes both short and long documents, providing a diverse set of examples ranging from concise

**Table 1**
Embedding models adopted for all three datasets

| Type | Model |
|---|---|
| *ColBERT* | antoinelouis/colbert-xm |
| *openai* | text-embedding-3-large |
| *openai* | text-embedding-3-large (512 token limit) |
| *Sentence Transformers* | intfloat/multilingual-e5-large |
| *Sentence Transformers* | sentence-transformers/all-MiniLM-L6-v2 |
| *Sentence Transformers* | dunzhanq/stella_en_1.5B_v5 |

summaries to lengthy dialogues. This dataset is intended to evaluate the system's performance on text with a narrative structure and its ability to handle various types of content, such as reviews and scripts.

The RaiNews and Medicina33 datasets are in Italian, while the Movies dataset is in English.

## 4.2. Embedding Models

In our experiments, we distinguish between three main families of embedding models: ColBERT, OpenAI embeddings, and Sentence Transformers.

The *ColBERT* model, described in [15], is a state-of-the-art method for efficient and effective passage retrieval. ColBERT uses a bi-level representation of text, allowing for a more compact and computationally efficient representation of passages. The antoinelouis/colbert-xm[2] model, based on this framework, is a multilingual variant, providing advantages in multilingual tasks by capturing semantic meaning in multiple languages simultaneously.

*Openai* offers a range of powerful models for generating embeddings from text, including the text-embedding-3-large[3] model. The main disadvantage of these models is that they are proprietary, and the vector representation is available only through a paid API.

The *Sentence Transformers* family includes several models optimized for sentence-level embeddings.

- intfloat/multilingual-e5-large[4][16]: A multilingual model capable of generating high-quality embeddings for text in multiple languages.

- sentence-transformers/all-MiniLM-L6-v2[5] [17]: A smaller, faster variant of the BERT model, providing efficient sentence embeddings while maintaining a high degree of accuracy for various NLP tasks.

- dunzhanq/stella_en_1.5B_v5[6] [18]: A large-scale transformer model fine-tuned for English sentence-level tasks, designed to provide powerful embeddings for more complex textual data.

*Remark* 1. We selected primarily multilingual embedding models since our experiment involves two datasets in Italian and one in English (see Section 4.1), to reduce potential mismatches between dataset languages and model training data. This choice ensures broader language coverage and more robust cross-lingual representations. However, BES4RAG does not aim to recommend a specific model a priori, but rather to evaluate a user-defined set of models and identify the best-performing one for the dataset considered.

To compare the embeddings produced by these models, the most common *similarity measure* is cosine similarity, which computes the cosine of the angle between two vectors, capturing their relative orientation in the embedding space. Cosine similarity is used for all models in our setup except for those in the *ColBERT* family. For the latter, such as antoinelouis/colbert-xm, we instead use the *MaxSim* function, a more specialized similarity measure designed for passage retrieval that works by first computing the similarity between each individual query token and each document token using a similarity metric like cosine similarity; it then takes the maximum of these token-level similarities as the final relevance score between the query and the document.

Finally, for all datasets, the maximum token limits for embeddings were applied to split the textual data into passages, except for the OpenAI model text-embedding-3-large (512 token limit), which is the same model as text-embedding-3-large but with maximum tokens length limited to 512. The decision of considering also this case was made based on the observation that increasing the size of passages, although possible with this model, does not necessarily improve the quality of the retrieved information. This will become clear when observing the results in Section 5.

### 4.3. Large Language Models

In our experimental setup, we employed two distinct families of LLMs for the generation of questions and answering, respectively. For question generation, `GPT-4o`[7] model was adopted through the OpenAI API. For answering, we adopted two variants of the LLaMA 3.1 series developed by Meta: the 70-billion parameter model `meta-llama/Llama-3.1-70B-Instruct`[8] and the smaller 8-billion parameter version `meta-llama/Llama-3.1-8B-Instruct`[9].

To ensure consistency and reduce stochastic variation across outputs, a temperature of 0 was used during inference for all models. Additionally, for answer generation tasks, the maximum output length was restricted to a single token, since the expected answer is always a discrete value in the set $\{0, 1, 2, 3\}$, in accordance with the prompt specification described in Section 3.6.

### 4.4. Evaluation Metric

Unlike to what is done in [9], we do not aim to evaluate the performance of our embedding models using a LLM as an external judge. In other words, we do not rely on the LLM to assess the quality of the retrieved passages or to rate their relevance. Instead, we consider the end goal of the pipeline: whether the final multiple-choice answer produced by the RAG system is correct.

To this end, we introduce a simple yet informative metric that we refer to as *Question Answering Accuracy* — or simply *accuracy* in the remainder of this paper. For each question, the system selects an answer option based on the response generated by the LLM, using the passages retrieved by the embedding model. The accuracy is computed as the proportion of questions for which the selected answer matches the correct one, as defined in the ground truth. This metric directly reflects the effectiveness of the entire RAG pipeline in producing correct answers, integrating both retrieval and generation performance.

*Remark* 2. Theoretically, the pipeline could be adapted to incorporate standard retrieval metrics such as those mentioned in Section 1, by changing the question generation module so that questions are generated from individual passages rather than from full documents. However, we adopt the *Question Answering Accuracy* metric for its direct alignment with the end goal of the RAG pipeline: selecting the embedding that enables correct answers. While we acknowledge its binary nature and the lack of granularity in capturing partial understanding or passage quality, we consider this trade-off acceptable for an automated evaluation setup. More expressive metrics often require detailed annotations that are not always available.

## 5. Results and Discussion

### RQ1: Optimal embedding choices vary across datasets

As observed in Figure 4, the accuracy of the `Llama 3.1 70B` model on automatically generated questions exhibits variations not only with the number of retrieved documents, but also with respect to the choice of embedding model. The ranking of the embedding models varies across datasets, as demonstrated by the different performance patterns observed in the first and subsequent positions. This variation highlights the dataset-specific characteristics that influence the efficacy of embedding models, further emphasizing the utility of the proposed framework for selecting the optimal embeddings for each dataset, rather than relying on a one-size-fits-all approach.

### RQ2: Small LLMs can outperform bigger LLMs with the right embedding

In some cases, the choice of the embedding model may be even more critical than selecting the most powerful LLM within a RAG system. This hypothesis is supported by experimenting BES4RAG using two different LLMs framework on the same dataset and with the same embedding models. As shown in Figure 5, these experiments demonstrate that using a more effective embedding model with a smaller LLM can lead to better performance than relying on a more powerful LLM combined with weaker embedding models. In particular, LLama 3.1 8B, when paired with antoinelouis/colbert-xm, intfloat/multilingual-e5-large, or text-embedding-3-large, outperforms the larger LLama 3.1 70B when the latter is combined with sentence-transformers/all-MiniLM-L6-v2 or dunzhanq/stella_en_1.5B_v5, at least for lower values of $k$. Indeed, for higher values of $k$, the performance of the smaller LLM deteriorates, likely due to the increased prompt length exceeding its optimal processing capacity. These experiments highlight the importance of carefully evaluating the choice of the embedding model, especially when considering the use of smaller LLMs. In fact, selecting an effective embedding model can enable the adoption of smaller language models, thus reducing computational requirements and leading to more cost-effective and resource-efficient solutions.

**Figure 4:** Accuracy comparison of LLama 3.1 70B on automatically generated questions from different datasets depending on the embedding models and the number of retrieved documents used to answer the questions (x-axis). The legend (the same for the three plots), with shortened names for the models in Section 4.2, is displayed only in (b) to not compromise the readability of the plots.

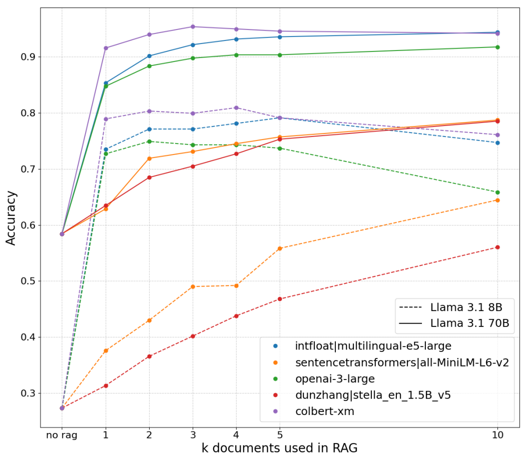

**Figure 5:** Accuracy comparison between Llama 3.1 8B and Llama 3.1 70B on automatically generated questions from the Rainews dataset depending on the embedding models (the ones in Section 4.2, here with shortened names) and the number of retrieved documents used to answer the questions (x-axis).

## RQ3: Automatically generated and user-generated questions

To assess whether evaluation using automatically generated questions provides results consistent with human-authored ones, we relied on a manually curated set of 1,414 questions created by approximately eighty students enrolled in an undergraduate database course. These students were instructed to formulate meaningful and unambiguous multiple-choice questions based on the movies scripts, plots and metadata.

**Table 2**
Pearson correlation between accuracy matrices obtained from manual and automatic questions for the *Movies* dataset, using different normalization strategies.

| Normalization Strategy | Pearson Correlation (r) |
|---|---|
| None (raw scores) | 0.78 |
| Min-max per row | 0.80 |
| Min-max over full matrix | 0.90 |

We then compared the accuracy scores obtained using these human-authored questions with the automatically generated ones for the *Movies* dataset. Specifically, for each embedding model and for each value of $k$ in the top-$k$ retrieval, we computed the accuracy of the final answers returned by the RAG pipeline. This yielded two matrices of scores: one for manual questions and one for automatically generated questions, where rows correspond to different embedding models and columns to different $k$ values.

We then calculated the Pearson correlation coefficient between the corresponding entries of these two matrices to quantify the alignment between the two evaluation modes. As shown in Table 2, the raw accuracy values already exhibit a strong correlation ($r = 0.78$). When applying min-max normalization per row (i.e., within each embedding), the correlation improves slightly ($r = 0.80$), indicating that the relative behavior of each model across different $k$ remains consistent. Finally, full matrix-wise normalization further increases the correlation to $r = 0.90$, suggesting a strong structural similarity between the two evaluation matrices. These findings support the use of automatically generated questions as a viable proxy for manual evaluation.

*Remark* 3. In addition to the quantitative correlation analysis, we manually inspected a random sample of both human and automatically generated questions to assess their coherence and correctness. The review confirmed a high level of quality in both sets. The automatically generated questions typically referred to more specific and localized portions of the source text. Anyway, the strong correlation observed between the two evaluation modes further supports the use of automatically generated questions as a reliable and efficient benchmark for assessing embedding model performance.

## 6. Conclusion and Future Work

In this work, we presented BES4RAG, a modular framework for the evaluation of embedding models in retrieval-augmented generation (RAG) pipelines. The framework provides a comprehensive approach by focusing on end-to-end evaluation, incorporating automatic question generation, passage segmentation, and answer evaluation. Unlike traditional methods, which rely on pre-retrieval metrics, BES4RAG integrates task-specific performance assessments, allowing for a more accurate comparison of embedding models based on their impact on the final output.

BES4RAG is also versatile, making it suitable for a variety of use cases, including datasets that represent subsets of larger corpora. A prime example would be transcribed multimedia archives, where smaller portions of the dataset can be used to effectively represent the entire collection.

Although BES4RAG demonstrates strong performance and general applicability across diverse datasets, it is not without limitations. One notable limit lies in its reliance on automatically generated MCQs, which, although efficient and scalable, may not always be adequate in highly domain-specific contexts, i.e. in technical or expert-driven fields where factual precision or nuanced phrasing is critical. Furthermore, the binary nature of the evaluation metric is easily interpretable, but it can fail to capture partial understanding, near-miss responses, or the contextual relevance of the retrieved passages. This trade-off between simplicity and expressiveness, while intentional for automation and reproducibility, highlights the need for complementary metrics or qualitative assessments in more complex scenarios.

Looking ahead, avenues for future work include the following:

- Investigating whether using two different LLMs for question generation and retrieval provides better performance or if using the same LLM for both tasks yields comparable results.
- Exploring alternative methods for question generation that consider larger portions of documents.
- Introducing new metrics to assess questions without options, potentially linking detailed answers back to one of the predefined options, offering more flexibility in evaluating the question-answer generation process.
- Integrate within the pipeline some element that returns statistical significance measures of the results obtained, such as paired tests to assess whether differences between embedding models are statistically significant. Moreover, regarding the evaluation of LLM's answers it could be interesting to analyze the token-level probability distribution to assess how embeddings affect the confidence of LLM predictions.
- Study the scalability of the proposed approach on significantly larger datasets, evaluating both its performance and reliability under increased data volume, as well as the computational time and resource requirements of the entire pipeline.

**Abstract**

This paper explores the impact of ecologically and cognitively plausible data on the training of language models. It builds on prior work [1, 2] integrating child-directed speech, curriculum learning and instruction tuning to train Italian BabyLMs. To evaluate our BabyLMs, we compare their performance (trained on fewer than 100M words using various techniques) with that of native Italian Large Language Models using the Invalsi-ITA [3] benchmark, designed to evaluate Italian students on text comprehension and linguistic abilities. The goal is to assess whether cognitively motivated training approaches (Curriculum Learning based on Child-Directed speech and child-friendly data), which are crucial for meaningful comparison between human learners and computational systems [4], yield greater efficiency than standard methods.

**Keywords**

Italian BabyLM, Invalsi-ITA benchmark, LM Evaluation, Text Comprehension, Italian Grammar

## 1. Introduction

Even though Language Models (LMs) have taken research in linguistics and cognitive science by storm, their meaningful application in these fields still faces significant challenges. In order for LMs to be useful and informative for understanding language and cognition, several plausibility criteria must be met [5, 6, 7]. Among them, the most important are the amount of input received during training and the number of trainable parameters. A growing body of empirical evidence shows that beyond a certain model size and amount of training data, the probability distributions generated by LMs diverge from human-like patterns and become poor predictors of psycholinguistic measures, such as eye-tracking data [8, 9]. In contrast, smaller models trained on a limited amount of data appear to align more closely with human reading strategies. This observation is consistent with findings from the BabyLM Challenge, which demonstrate that models trained on child-directed speech and capped at 100 million words can achieve strong syntactic competence [10, 11]. In addition to model size and training data volume, other plausibility criteria should be considered. These include the quality of the input (such as child-directed speech) and the manner in which it is presented, for instance through Curriculum Learning (CL). Moreover, the standard language modeling objective differs substantially from the discursive and interactive exchanges children engage in with adults and peers [4]. In short, approximating child language learning conditions requires attention to multiple dimensions.

This study aims at investigating the impact of such dimensions on LMs' development of linguistic skills. Specifically, we examine the effectiveness of training Italian BabyLMs using child-directed speech, curriculum learning, and instruction tuning—techniques inspired by human language acquisition to the purpose of assessing whether these cognitively grounded methods lead to improved performance compared to conventional training approaches, particularly when working with limited data. To this end, we evaluate our BabyLMs against native Italian Large Language Models using the Invalsi-ITA benchmark, which is focused on text comprehension and linguistic knowledge.

The paper is structured as follows: first, an overview of related works is provided in Section 2. Section 3 is dedicated to the description of the models' evaluation. The models are presented in Section 3.1, whilst in Sections 3.2 and 3.3 the Invalsi-ITA benchmark, used for the evaluation, and the procedure followed to assess the models' abilities are described. The results of the evaluation are detailed in Section 3.4 and discussed in Section 3.5. Finally, some conclusions are drawn in Section 4.

## 2. Related Works

Two lines of research are particularly relevant to our goals, as they represent two sides of the same coin: the first focuses on the quality and quantity of training data necessary for BabyLMs to develop linguistic abilities; the second concerns the evaluation of BabyLMs through the creation or adaptation of benchmarks originally designed to assess the linguistic competence of human speakers.

Regarding the first aspect, several studies have explored training models on datasets that are comparable—both in size and in linguistic nature—to the input typically received by children during early development (e.g., [12, 13, 14]). These works show that while a large volume of data is essential for achieving strong performance on standard Natural Language Understanding tasks, a significantly smaller amount is sufficient for acquiring core syntactic knowledge. In addition to data quantity and quality, the importance of curriculum learning strategies and model architecture optimization has also been highlighted [10].

On the evaluation front, several benchmarks have been developed over the years (e.g., [15, 16, 17]). While these benchmarks are effective tools for comparing models against each other, they are not well-suited for comparing models to human language abilities, especially those of children. Although some studies have directly addressed this gap (e.g., [18]), they have not yet produced large-scale, standardized benchmarks for this purpose.

For the Italian language, to the best of our knowledge, only two benchmarks currently enable both model-to-model and model-to-human comparisons. The first is BaBIEs [1], a benchmark derived from the adaptation of four standardized tests originally designed to assess the semantic and syntactic competence of Italian-speaking children. The second is Invalsi-ITA [3, 19], described in Section 3.2, which aims to evaluate text comprehension and linguistic abilities in Italian students from primary through high school.

In this study, we employ the Invalsi-ITA benchmark to evaluate various Bambi models, a series of Italian BabyLMs which differ from one another in terms of i.) the amount of training data, ii.) the type of training data and learning strategies adopted, and iii.) instruction tuning (cf. Section 3.1). This benchmark is particularly well-suited to our analysis, as it allows us to observe improvements or declines across school grades and to isolate which of the above three variables may be influencing such trends in performance.

## 3. Evaluating Text Comprehension and Grammatical Knowledge with Invalsi-ITA

### 3.1. Models

The **Bambi** model is based on a lightweight GPT-2-style decoder architecture, with approximately 136 million parameters (Table 1). It is trained on a dataset composed of **transcripts of child-directed speech and multimedia content designed for children** [2]. So far, the dataset is organized into three tiers of increasing linguistic complexity, corresponding to the age ranges 0–6, 6–12, and 12–18. An additional tier is currently in progress. For the Bambi baseline model, all three tiers are used in a fully shuffled format. In contrast, the **Bambi_CL** (Curriculum Learning) model is trained on the tiers sequentially, progressing from the simplest to the most complex. Based on both the base and CL models, **Instruction Tuning** (IT) variants are implemented (Table 2). The IT training dataset comprises the following resources:

- `teelinsan/camoscio_cleaned`: a translated version [20] of the Stanford Alpaca dataset [21], which consists of LM-generated instruction-response pairs based on a seed set of human-written prompts [22]. The dataset contains approximately 50,000 items.
- `massimilianowosz/gsm8k-it` : a translated version of GSM8K [23], a dataset of 8.500 grade school-level math word problems.
- `Mattimax/DATA-AI_Conversation_ITA` : a dataset of Italian-language conversations, comprising 10,000 items [24].

For comparison purposes, the same architecture was trained on a traditional dataset of equivalent size, using a random subset of **mC4** [25], a corpus derived from the public Common Crawl web scrape and used to train standard LMs.

It is important to note that BabyLMs typically operate with limited input and output context windows, both to maintain model compactness and to respect cognitive plausibility constraints. In particular, the training data for the first and second developmental tiers avoid excessively long sequences. However, to enable evaluation on the Invalsi-ITA benchmark, the models were trained with a context window of 6,144 tokens, the minimum required to avoid truncating benchmark items. Crucially, our dataset remains untouched. The BabyLMs are compared against five other models (Tables 1 and 2). **Minerva-3B** is the model trained on the least amount of data, despite not being the smallest in size. It is followed by **Minerva-7B** and **Minerva 7B-it**, which rank second in terms of data volume [26]. Next is **Velvet-2B**, trained on approximately 3

| Architecture | Vocabulary Size | Layers x Heads | Hidden Size | Trainable Parameters |
|---|---|---|---|---|
| Bambi | 30,000 | 12x12 | 768 | 135,856,128 |
| Minerva-3B | 32,768 | 32x32 | 2,560 | 2,894,236,160 |
| Minerva-7B | 51,200 | 32x32 | 4,096 | 7,399,018,496 |
| Velvet-2B | 126,976 | 28x32 | 2,048 | 2,223,097,856 |

trillion tokens [1], and finally **Cerbero-7B**, for which the amount of training data has not been disclosed by the developers [27]. These models were chosen because their training corpora are predominantly in Italian.

## 3.2. Invalsi-ITA

**Invalsi-ITA** [3] is a benchmark derived from the adaptation of an established battery of assessments aimed at gauging educational proficiency throughout Italy.

The INVALSI (*Istituto nazionale per la valutazione del sistema educativo di istruzione e di formazione* 'National Institute for the Evaluation of the Education and Training System') tests have been administered to Italian students since the 2005/2006 school year. These tests are designed to monitor the students' competence of Italian language and Mathematics throughout their educational path. Increasingly complex tests are administered during primary school (grades 2 and 5), middle school (grades 6 and 8) and high school (grades 10 and 13).

Invalsi-ITA focuses on the Italian language. It originally included 1,264 questions, classified by [3] into: i.) multiple choice; ii.) binary (e.g., TRUE/FALSE); iii.) open-ended; iv.) other. The authors of the benchmark excluded categories (iii.) and (iv.) retaining only multiple choice (87.47%) and binary (14.33%) questions, for a total of 1,117 questions. The benchmark assesses two main kinds of competence: **text comprehension** and **linguistic knowledge**. Text comprehension items (930/1,117, 83.26% of the total) require students to read a text and answer related questions (e.g., *Le prime tre righe del racconto parlano della vita di Polipetto nel suo ambiente. Quale frase spiega in poche parole come viveva Polipetto?* 'The first three lines of the story talk about Polipetto's life in his environment. Which sentence briefly explains how Polipetto lived?'), while language items (187/1,117, 16.74% of the total) assess knowledge of specific grammatical rules (e.g., *Indica in quale frase la parola "pietra" è usata in senso figurato, cioè non indica la pietra vera e propria.* 'Indicate in which sentence the word "stone" is used figuratively, that is, it does not refer to an actual stone.').

| **Total** | 151 | 327 | 67 | 311 | 228 | 33 |

**Table 3**
Internal structure of the Invalsi-ITA benchmark.

Table 3 summarizes the macro-areas covered by the questions in each grade (for more details, see [3, 19]).[2] Evaluating language models brings to the fore important questions about data contamination. The Bambi model was trained on a dataset specifically built and curated by the authors, ensuring it is free from contamination. For other models, verification is more challenging. Minerva models stand out for their transparency in this regard, and it appears safe to assume they were not exposed to the benchmark data. Cerbero-7B was released prior to the benchmark (2023 vs. 2024), so contamination also seems unlikely. Velvet-2B is more recent and its training dataset has not been made publicly available, making it difficult to assess potential overlap.

## 3.3. Method

The items are presented to the models in a zero-shot setting. Each item consists of a *text* (when present), a *question* that includes the list of multiple-choice options, and the *answer*, often represented only by the letter corresponding to the correct choice. Prompts and expected outputs are formatted using the following template (originally in Italian; a translation is provided here for clarity).

**Prompt:**

> Read the text and answer the question:
> `{text}`
> `{question}`

**Completions:**

- La risposta corretta è A: `{answer_a}`
- La risposta corretta è B: `{answer_b}`
- La risposta corretta è C: `{answer_c}`
- La risposta corretta è D: `{answer_d}`

A likelihood-based method was used to select the model's responses. Each model was presented with the prompt and the set of possible completions. The selected answer corresponds to the prompt–completion pair with the highest likelihood.

## 3.4. Results

Figure 1 shows the accuracy obtained by all models in each grade, considering both the text comprehension and the linguistic items. The accuracy values for each model in each grade are reported in Table 4 (Appendix 4).

A similar accuracy pattern emerges across grades 2 to 10 (Figure 1,). Cerbero-7B consistently achieves the highest accuracy, although its performance gradually declines over the grades. Minerva-7B and Minerva-7B-it follow with slightly lower scores, showing peaks in grades 2 and 6, a pattern also observed in Velvet-2B. In contrast, Minerva-3B aligns more closely with the Bambi models, which display the lowest accuracy throughout these grades.

A different pattern emerges in grade 13: Bambi, Bambi_it, and Bambi_mc4_it achieve the highest accuracy, alongside Velvet-2B. Slightly lower scores are obtained by the Minerva models, with Minerva-7B-it still leading this group. Notably, Cerbero-7B's performance drops significantly in this final grade. Focusing on the Bambi family, the strongest performances are overall exhibited by Bambi, Bambi_it, Bambi_CL_it, and Bambi_mc4_it.

Let us now turn to the accuracy the models achieved in the text comprehension items, displayed in Figure 2. The accuracy values are reported in Table 5 (Appendix A). The figure shows that the accuracy values and patterns observed for the comprehension items largely reflect those found in the overall analysis. Cerbero-7B consistently

[2] Due to the limited number of items within each linguistic macro-area, we opted to group all linguistic items together for the analysis. As a result, only comprehension and language items are discussed in Section 3.4.

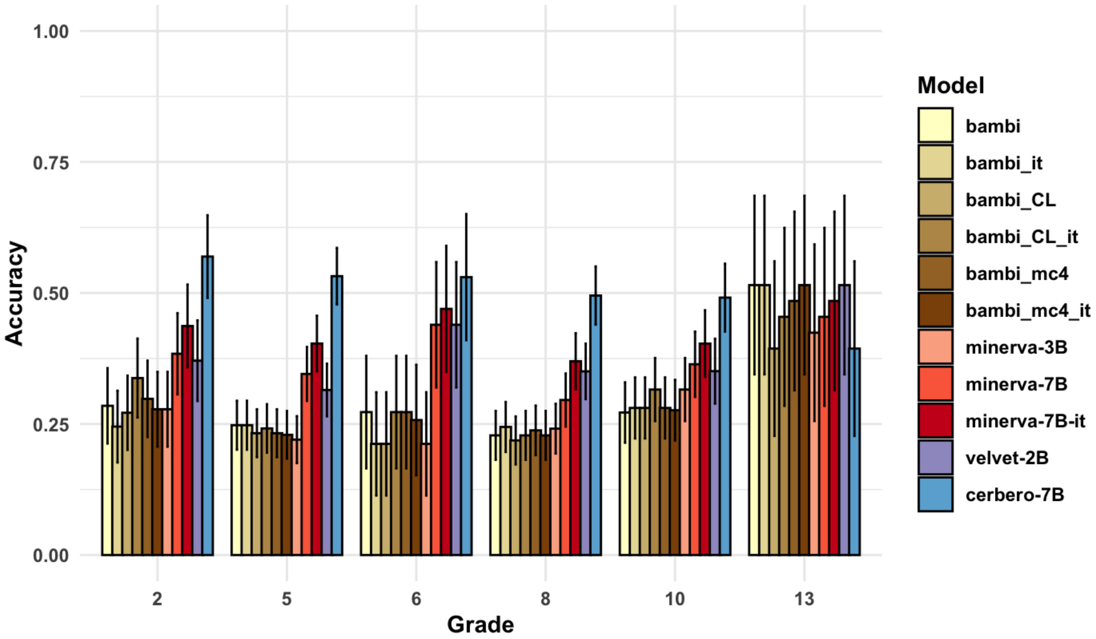

**Figure 1:** Accuracy reached by each model, for each grade, considering both the comprehension and the linguistic items. Error bars represent 95% confidence intervals.

achieves the highest accuracy across grades 2 to 10 (with all values above 0.50, though gradually declining), while a marked drop is observed in grade 13. Across grades 2 to 10, the Minerva models attain the second-highest accuracy, with Minerva-7B-it performing best within the family, closely followed by Minerva-7B. As in the overall analysis, the Bambi models perform poorly from grades 2 to 10 but improve significantly in grade 13: Bambi, Bambi_it, and Bambi_mc4_it all exceed 0.50 accuracy in this grade. The same pattern is observed for Velvet-2B.

A different trend is observed when considering only the accuracy achieved with respect to language items, displayed in Figure 3. The accuracy values are reported in Table 6 (Appendix A). Cerbero-7B, Velvet-2B, and Minerva-3B perform overall worse with respect to items specifically targeting grammatical knowledge than they do in text comprehension items. Minerva-7B and Minerva-7B-it, on the contrary, achieve similar accuracies in both tasks, and perform better in this task in grades 2 and 6. As for Bambi models, they differ from each other regarding the accuracy they achieve. In grade 2, only Bambi, Bambi_mc4, and Bambi_mc4_it achieve the highest accuracy (0.50) of all grades, whereas the others do not provide any correct answer in this grade. In grade 5 the same three Bambi models perform slightly better than Minerva-3B and Velvet-2B. In grade 6 Bambi_CL and Bambi_CL_it reach a peak in accuracy exceeding 0.50, followed by Bambi_mc4_it. Overall, grades 2 and 6 appear to be easier for some models, but challenging for others. Grade 13 is challenging for all models, as none of them provide a correct response.

Finally, let us take a look at the accuracy achieved by the models in the two kinds of questions that compose the Invalsi-ITA benchmark, i.e., multiple choice and binary (a summary of the accuracy values achieved for binary and multiple choice questions is reported in Table 7, given in Appendix A). The accuracies achieved for the binary questions are displayed in Figure 4.

For binary questions, accuracy generally hovers around or slightly above the expected chance level (0.5). Most models tend to perform better at the lower (grade 2) and upper (grade 13) ends of the evaluation spectrum, with a noticeable dip in performance across intermediate grades (5–10). Among the best-performing models, Bambi_CL_it and Cerbero-7B achieve the highest accuracy at grade 2 (0.70 and 0.65, respectively). Minerva-7B-it and Cerbero-7B show relatively stable performance across grade levels, with only minor fluctuations. Notably, Bambi_CL_it performs comparably to larger models.

Multiple choice questions (Figure 5) appear to be more challenging for all models. Given the four-alternative

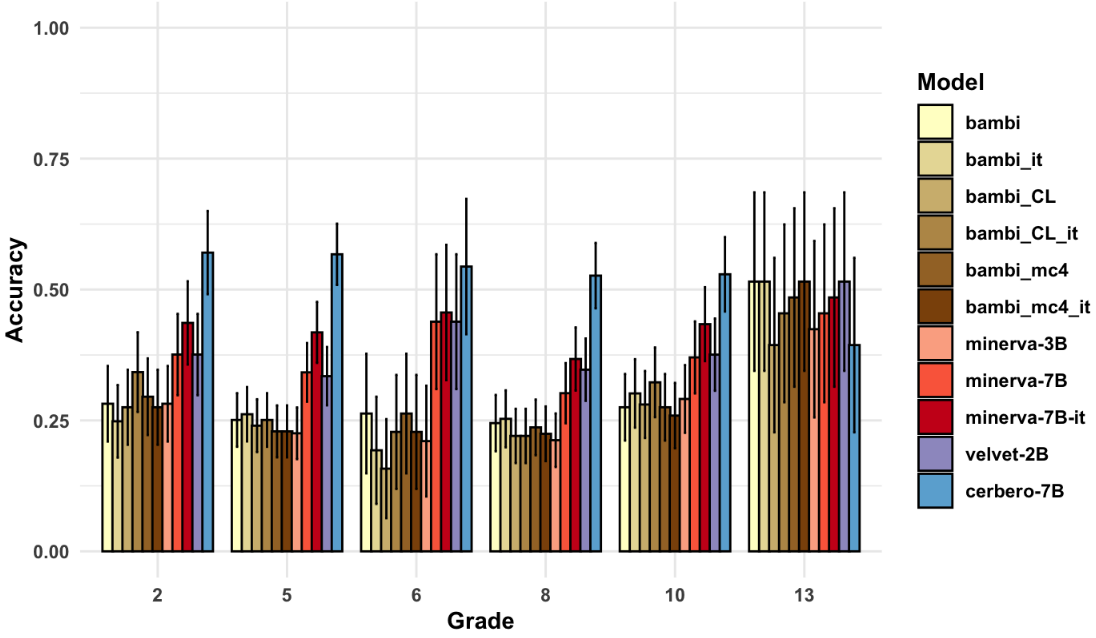

**Figure 2:** Accuracy reached by each model, for each grade, considering the text comprehension along with 95% confidence intervals (shown as error bars).

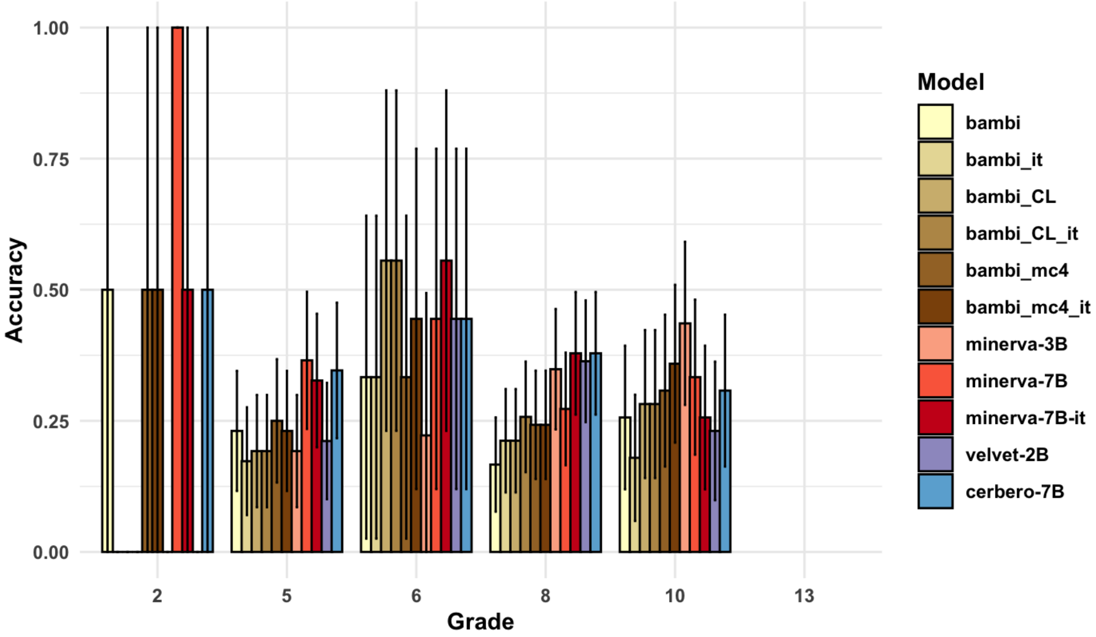

**Figure 3:** Accuracy reached by each model, for each grade, considering the language items along with 95% confidence intervals (shown as error bars).

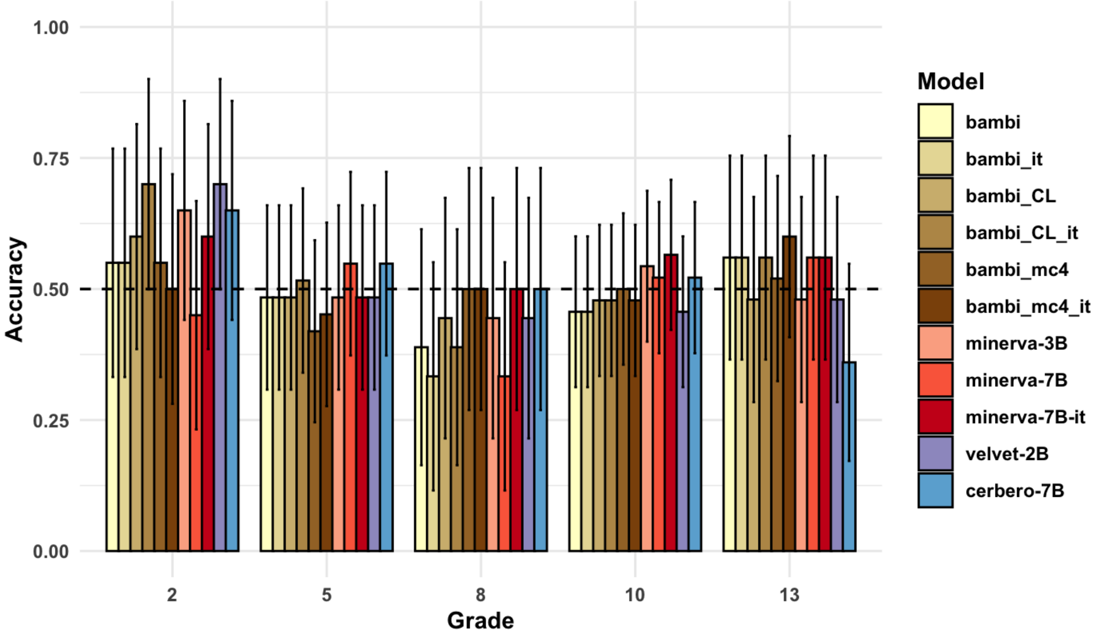

**Figure 4:** Accuracy achieved by all models in all grades with respect to binary questions along with 95% confidence intervals (shown as error bars). The dashed line represents the expected performance under random chance.

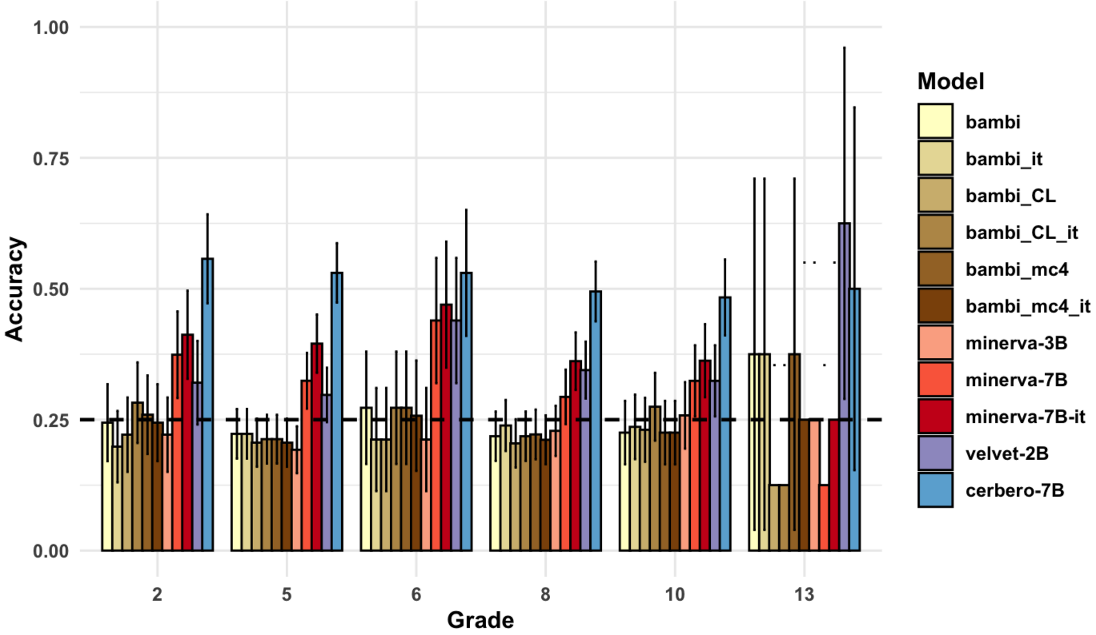

**Figure 5:** Accuracy achieved by all models in all grades with respect to multiple choice questions, along with 95% confidence intervals (shown as error bars). The dashed line represents the expected performance under random chance.

format, chance accuracy is approximately 0.25, and most models perform only marginally above this baseline. Still, some models demonstrate steady improvement across grade levels, particularly Velvet-2B and Cerbero-7B. The latter stands out as the most consistent and accurate performer in this task, achieving scores in the range 0.53 to 0.56 across several grades and peaking at 0.625 in grade 13. Bambi models, on the contrary, seem to find this kind of questions more challenging, particularly considering grades 2 to 10. However, Bambi, Bambi_CL_it, and Bambi_mc4 exceed the above-chance level in various grades. In particular, the performance of Bambi, Bambi_it, and Bambi_mc4 peaks at grade 13, reaching an accuracy around 0.40.

## 3.5. Discussion

The Invalsi-ITA benchmark appears to be challenging for all the models under investigation, as none of them exceed an accuracy value of 0.60. It should be kept in mind, however, that Invalsi tests are also challenging for Italian students [3]. [3].

The larger models, i.e., Cerbero-7B, Minerva-7B and Minerva-7B-it, perform overall better in this benchmark, especially when they are instruction-tuned. The reason may lie in the nature of Invalsi-ITA. This benchmark consists indeed of text comprehension items and language items, which specifically address normative grammatical rules, instead of the models' linguistic competence *tout-court.* Naturally, models which are exposed to a larger amount of training data and, even more importantly, to a large amount of *written* data, may be facilitated in these kinds of tasks, either because they have been exposed to the actual texts used in the benchmark, or because they are more used to this kind of linguistic input.

Nonetheless, Bambi models exhibit a great improvement in grade 13 with respect to the text comprehension items, and some of them perform comparably to larger models with respect to language items (e.g, in grades 2 and 6). These results suggest that compact models, despite lacking comprehensive world knowledge, can develop robust grammatical knowledge at early stages of training. Furthermore, considering binary questions, most of them, particularly Bambi_CL_it, Bambi_mc4 and Bambi_mc4_it, perform comparably to larger models in specific grades despite their compact size and training constraints, suggesting the potential benefits of a combination of oral and written training data.

Turning to curriculum learning and instruction tuning, a closer examination of the different Bambi models indicates that each strategy contributes modest gains, particularly in early grades. However, models that combine both strategies, such as Bambi_CL_it, show more consistent improvements, especially compared to IT-only variants. This is particularly evident in the case of the language items. The pattern implies that CL may enhance a model's capacity for subsequent learning, making IT more effective. This finding aligns with insights from human developmental learning, where structured progression lays the groundwork for improved adaptability and generalization over time [4].

These results give rise to some puzzling observations that merit closer examination. For instance, when comparing the Bambi models with their mc4-trained counterparts, substantial differences appear only in grades 2 (although this grade includes only two items) and 6 of the language items. This prompts the question of whether using ecologically plausible data is as crucial as often assumed, or if standard training corpora, such as mc4, can produce comparable results. In fact, the Bambi_mc4 models perform comparably to other Bambi models in many settings, indicating that the choice of data alone does not yeld substantial difference. However, they do not clearly outperform the Bambi models either: they achieve their best relative result in grade 5 of the language items, but in all other grades and tasks they perform worse or at best match the level of at least one of the Bambi variants. This pattern suggests that while web training data can approximate the results of carefully curated child-directed speech to some extent, it does not consistently provide an advantage, highlighting the need for a deeper analysis of the interactions between data quality, structure, and curriculum learning.

Another notable result is the unexpected jump in performance for the Bambi_CL models in grade 6 with respect to the language items. One possible explanation lies in the CL learning strategy: although the total number of tokens processed by these models over multiple epochs approaches the lifetime exposure of an 18-year-old adolescent, the absolute size of the Bambi dataset more closely reflects the typical linguistic input of a child aged six to eight. This alignment may account for the relatively strong results in grade 6, which corresponds to the final portion of the training curriculum. However, this interpretation does not readily explain another surprising outcome: in the text comprehension task for grade 13, the Bambi and Bambi_mc4 models outperform not only Bambi_CL and Bambi_CL_it, but also larger models like Minerva and Cerbero-7B. This could be an artifact of the limited number of items in this grade, but it highlights an area where further investigation is warranted to understand how data composition, curriculum

[3] Unfortunately, the benchmark does not provide student-level data. However, the paper describing the original resource [3] includes a bar plot illustrating the performance gap, which highlights the challenges faced by Italian students.

[4] We acknowledge the importance of cross-linguistic validation. To this end, we have submitted a related study to the third BabyLM Challenge [28], which is currently under review. Preliminary results on English show a similar trend.

pacing, and task type interact in shaping model behavior.

Taken together, these findings highlight several key insights. First, larger model size alone does not guarantee superior performance: smaller models can be competitive in specific cases, particularly in structurally simpler tasks. Second, apparently, training strategies such as CL and IT yeld effective improvements only under specific evaluation conditions. Finally, the performance gap between BabyLM and LLM remains substantial, particularly in tasks requiring semantic depth understanding or world knowledge. Closing this gap without compromising cognitive and linguistic plausibility remains a key challenge. Future work will need to explore new training strategies. and evaluation frameworks to address it.

## 4. Conclusion

In this work, we presented an evaluation of six Bambi model variants alongside five larger models, using the Invalsi-ITA benchmark, which assesses text comprehension and linguistic abilities.

This evaluation revealed that larger models are facilitated in the text comprehension task, because either they have already encountered the texts used in the benchmark or they are more used to this kind of linguistic input. Nonetheless, smaller but more cognitively plausible models appear to be facilitated in the learning and generalization processes, as highlighted by their improvement in higher grades considering both text comprehension and language items.

**Abstract**

The Natural Language Processing (NLP) community has recently begun to engage with endangered languages and dialects which encode culturally different perspectives and local knowledge. Regardless of the usefulness and applicability of NLP tools for such languages, creating resources for dialects increases our knowledge of them, encourages the community to study them further, and supports the preservation of an important heritage. As part of this endeavour, we are focussing on Sicilian, a dialect spoken in Sicily, with a rich cultural history. Sicilian preservation is crucial to maintaining Southern Italy's linguistic diversity. In this paper, we present the first release of a novel treebank called SICILIAN3BANK. On the one hand, to improve the usability of this resource and provide access to non-Sicilian speakers, all sentences are linked to their translation into Italian, resulting in a 1:1 parallel resource. On the other hand, by applying the Universal Dependencies format, a widely used standard for the annotation of treebanks, we pave the way for data-driven cross-linguistic research. We hope that this work can serve as a basis for further linguistic research and computational applications for the Sicilian dialect.

## 1. Introduction

Recent developments in generative Artificial Intelligence (genAI) have increasingly highlighted the importance of taking more into account a larger variety of the languages spoken in the world. Developing tools and resources to deal with a language has meaningful effects, among which the most important is an improvement of the awareness of the underlying cultural heritage, an aspect that can be crucial for the achievement of better performances by Large Language Models (LLMs) in several tasks.

According to [1], the world's living languages can be categorised into 500 institutional languages and a further 6,500 local vernaculars, or oral languages. While institutional languages feature standardised orthographies and widespread literacy, the local languages include ancestral languages, with an unbroken history of oral transmission, and languages in danger of disappearing. Most Natural Language Processing (NLP) tools and resources developed until now are almost only for institutional languages, since only in the very last years the NLP community has begun to engage with local and endangered languages. Therefore the challenges to address are still many.

In this paper, we focus on the first steps of developing a resource for one of the most spoken Italian dialects, which is featured in a long tradition of studies in linguistics, but not considered enough in NLP until now.[1] The aim of this study goes beyond introducing a specific novel resource and consists of starting a discussion on the challenges that can be encountered when NLP meets a dialect or a language without a standardised orthography and reference grammar.[2] Starting this discussion may be especially relevant in the context of the CLiC-it conference, since Italy is characterised by a one-of-a-kind linguistic diversity in the European landscape, where diatopic variation implicitly encodes local knowledge, cultural traditions, artistic expressions, and the history of its speakers [3]. With respect to high-resource lan-

[2] In linguistics, the distinction between a language and a dialect is not always clear-cut and is often influenced by political and sociocultural factors rather than purely linguistic ones. A dialect is typically considered a regional or social variety of a language, but varieties such as Sicilian, which may lack official status or standardisation, are often labelled as dialects despite possessing many characteristics of a distinct language. For this reason, we use the terms language and dialect interchangeably when referring to Sicilian, to reflect its complex sociopolitical status.

CEUR Workshop Proceedings ceur-ws.org ISSN 1613-0073
published 2025-11-30

guages, which have extensive amounts of digital data and resources available, Italian dialects are under-resourced, lacking sufficient digital representation and support.

The language observed in our study is Sicilian, as the title *arbuli sunnu* suggests, literally 'trees (they) are', showing a common predicate-initial structure. Sicilian is a vernacular language with local functions that include intergenerational knowledge transmission. The resource presented comprises diachronic and diatopic variants, enabling the analysis of linguistic changes in certain phenomena along these axes. In addition, it features orthographic variability due to the non-standardised transfer from oral to written form.

In order to make the resource accessible to a bigger audience, we provide the Italian translation in a 1:1 alignment setting. We decided to translate into Italian rather than English to underline the importance of mitigating the over-reliance towards English [4].

It is beyond the scope of this article to cover all the challenges associated with developing a treebank[3] for Sicilian; we focused mainly on the phenomena that have a major impact at (morpho-)syntactic level. By showing some of the major challenges in the treebank annotation, we hope to pave the way for the future development of an expanded resource and the discussion about the involved phenomena.

The paper is organised as follows: the next section (Sec. 2) presents an overview of related work, followed by Sec. 3, which describes the data collection and annotation process for the first release of the Sicilian3bank, including the translation of Sicilian sentences into Italian to create a parallel corpus. In Sec. 4 we show the parallel architecture of the treebank and the annotation methodology we followed. This section also highlights the challenges we faced developing a treebank for Sicilian. Finally, the last section (Sec. 5) is about conclusions and future work.

# 2. Related Work

This section provides a brief introduction to the Universal Dependencies (UD) formalism and existing parallel treebanks in UD, followed by a discussion on language variation in NLP, with a focus on dialects and, eventually, on Sicilian.

## 2.1. Universal Dependencies and Parallel Treebanks

UD [5] is a framework for annotating morphology and syntax consistently across languages. In recent decades, UD has become the *de facto* standard for treebanks. As its name suggests, UD represents syntax using dependency trees, instead of constituency trees. This is because dependency trees are perceived as better suited to represent free or flexible word order languages [6]. Furthermore, models using dependency representations have achieved promising results in many NLP tasks (e.g. in machine translation and information extraction) [6, p. 3].

UD comprises treebanks in more than 100 languages, including low-resource languages (see sec. 2.2 for a definition), e.g. Irish, Faroese, Uyghur. Among the UD treebanks, there are also parallel treebanks, i.e. treebanks that have been translated into other languages and subsequently annotated. The biggest effort in this respect has been done for the PUD treebank [7], which consists of 1,000 sentences in 18 languages (the majority originally in English). Translators were asked to opt for the translation which is fluent but also sharing the most grammatical features of the original. Another example of parallel treebanks in UD is ParTUT [8], which contains sentences from different domains in English, Italian and French. In ParTUT, the alignment is not 1:1 for all the sentences [9], though the texts coming from a more formal register, i.e. those from the JRC-Acquis corpus [10], are almost all aligned 1:1.

The 1:1 alignment has been considered as especially helpful in learning contexts, and has been therefore applied in the case of the English Second Language (ESL) [11] or VALICO-UD [12] treebanks, resources which include learner texts in English and Italian, respectively. We decided to follow their example for Sicilian3bank, as it might be used for language learning.

## 2.2. Language Variation in NLP

It is possible to distinguish two main groups of languages based on the availability of resources: high-resource languages and low-resource languages [4]. The former are languages (excluding sign languages) that have a large collection of machine-readable texts or, at the very least, a solid foundation upon which to build corpora, treebanks, and similar linguistic resources [4]. These include English, Mandarin Chinese, Arabic, and French, as well as Portuguese, Italian, Dutch, Standard Arabic, and Czech to a somewhat lesser but still significant extent [4]. Many languages, particularly local varieties and dialects, are at risk of disappearing in a relatively short time due to the lack of attention and resources they receive.

In the European context, standard languages exhibit notable diatopic variation [3]. Failing to prioritise research on language variations in the field of NLP would mean losing not only the languages as systems of communication, but also the identities, social values, and heritage of the societies they represent. It is not only a matter of increasing efforts towards these languages, but of doing so with an appropriate approach [3]. A shared

[3] A treebank is a corpus enriched with (morpho-)syntactic annotations.

goal should be established, knowledge must be made accessible to all, and subsequently disseminated beyond the community itself through engagement initiatives and the promotion of active participation. In addressing low-resource and endangered languages a novel approach would be applied based on respect, cultural awareness, and sensitivity to the wishes of their speakers.

## 2.3. Dialects in NLP

Focussing now specifically on dialects, it is important to note that their marginalisation is not a phenomenon exclusive to the field of NLP. A negative connotation of dialects is often rooted in complex historical, social, and political dynamics. For example in Italy, regional varieties, dialects, and other non-standard linguistic forms often coexist with the standard language in a situation known as *dilalia* [13], where there is not a rigid compartmentalisation of the languages, as it happens in *diglossia*, but still Italian is preferred in formal and high-prestige domains, and dialects in informal, everyday, or familial interactions. The significant linguistic loss experienced by Sicilian and other Italian dialects can also be attributed to the Fascist dictatorship, which aimed to achieve linguistic unification by suppressing regional language varieties and all that was perceived as foreign. Furthermore, the Italian language was instrumental in constructing national unity, serving as a symbol of collective identity at the expense of non-standard varieties, which were increasingly marginalised in both institutional and public domains [3].

One notable effort to address dialects and local languages is the MaiBaam project, a multi-dialectal Bavarian UD treebank [14]. It represents the first UD treebank for the Bavarian language, a West German dialect spoken in southern Germany, Austria, and northern Italy (South Tyrol). The major challenges encountered by the MaiBaam project authors, which are common issues within this field, are the difficulty to collect texts and find native-speaking annotators. While we are facing the former challenge, we did not encounter the latter, as the majority of our team members are native speakers of Sicilian. Nevertheless, there remains the necessity for a strong linguistic knowledge of the dialect being worked on—a requirement that is uncommon, given that dialects are rarely studied actively but are instead acquired through everyday use. The solution adopted by the MaiBaam group to adress this issue is making their work publicly available, which enables them to engage with the population and collect contributions from the community.[4] The Bavarian dialect is also represented for tasks such as Named Entity Recognition (NER) and Dialect Identification (DID), thanks to BarNER, a medium-sized corpus collecting Wikipedia and tweets data [15]. The authors in [16] show how such resources can be effectively utilised in NLP.

A similar initiative is the COSER-UD treebank [17], the first syntactically annotated corpus of spoken peninsular rural Spanish distributed within the UD framework [18]. The treebank addresses features such as word-order flexibility, ellipses, disfluencies, and colloquial expressions, critical for accurately representing morphosyntactic variation in oral communication.[5] By focussing on rural dialects beyond urban linguistic norms, COSER-UD enhances the diversity of linguistic data available to NLP and supports sociolinguistic preservation of under-represented varieties. The COSER-UD resource has supported the development of tasks such as Part-of-Speech (PoS) tagging, where models adapted to rural speech have been evaluated against a gold-standard dataset of over 13,000 sentences. Furthermore, the dataset has been used to test automatic speech recognition tools on dialectal Spanish audio [19].

Another noteworthy project is the East Cretan Treebank [20]. It was built from audio material of folkloric narratives collected from radio broadcasts, which were transcribed and annotated according to the UD framework. The treebank annotates dialect-specific features, such as euphonics and voicing phenomena, which are represented using dedicated tags and treated as distinct tokens in the annotated data. The East Cretan Treebank has been used for two main NLP tasks: PoS tagging and dependency parsing. Both tasks were addressed via fine-tuning of the Greek BERT model, using either exclusively the Eastern Cretan corpus data or in combination with data from the GUD, a treebank for Standard Modern Greek [21].

Focussing on Italian dialects, a treebank for Ligurian [22] is available in the UD repository which is the first-ever digital corpus of that language, comprising 316 sentences and 6,928 tokens. Like Sicilian, Ligurian is a minority variety within the Italian linguistic landscape and faces many challenges due to its low-resourced status. The project shares similar goals with ours, aiming to promote research and NLP development for endangered dialects, with a focus on supporting language preservation. The study also addresses orthographic aspects of the Genoese variety of the Ligurian dialect. The treebank was used for parsing experiments, and despite the performance of the parser is lower than those trained on high-resourced languages, the results obtained are in line with or superior to other small-scale corpora, confirming annotation consistency.

[4] Apart from sharing our resource, we mitigated this also during the annotation process by making it the most objective as possible by using shared resources.

[5] Additional information can be found at https://github.com/UniversalDependencies/UD_Spanish-COSER.

The UD repository also includes a small Neapolitan treebank that contains only 20 sentences, corresponding to 197 tokens and 199 syntactic words[6].

As far as Sicilian is concerned, a particularly interesting project is the one carried out by Arba Sicula[7] [23], which presents the first neural machine translator for the Sicilian dialect based on a deep-learning transformer model fed with Sicilian sentences augmented using back-translation [24] to cope with the lack of resources. The results were evaluated using the BLEU score metric and yielded scores of 35.0 for English>Sicilian and 36.8 for Sicilian>English. The project was later expanded into a multilingual translation system by incorporating Italian, using techniques such as transfer learning.

## 2.4. Studying Sicilian

When approaching the creation of a treebank for a dialect, one must come to terms with the absence of an orthographic standard and norms to regulate its development. Sicilian, as well as other dialects, exhibits great variability, especially at the diachronic and diatopic levels. To deal with these critical issues, we adopted a combined approach, drawing on different grammars and dictionaries of Sicilian and comparing them. In general, the grammars proved to be very useful to explain several phenomena and guide their representation in Sicilian3bank. However, for a few especially challenging issues, those for which we found a discordance of opinions reported in the grammars, we provided solutions based on our intuition of native speakers and consulting a linguist expert on Sicilian. We carefully discussed them and kept track of our motivations in the annotation guidelines.

For the purpose of lexical consultation and to handle different word forms, some online tools were used, such as *Wikizziunariu*[8], *Glosbe*[9], *Napizia-Chiù dâ Palora* [10], *Salviamo il siciliano*[11], plus social posts and blogs, demonstrating the importance of leveraging every available resource for dialectal language research and preservation. In addition, we consulted *Nuovo vocabolario siciliano-italiano* by Antonio Traina [25], selected for its breadth and accuracy, and various other dictionaries [26, 27, 28].

Several grammars from various time periods were also consulted [29, 30, 31, 32, 33, 34, 35, 36, 37], in order to gain a comprehensive understanding of the language also on diachronic aspect. Consulting these works revealed significant variability in the treatment of linguistic phenomena. On the one hand, some grammars document some phenomena in detail, while in others they are completely absent. On the other hand, some phenomena are mentioned in all grammars but treated differently. It was therefore necessary to make a choice based on a critical comparison of the sources and data available to us. It should be noted that, as it is common in the development of resources from scratch, some decisions were taken based on the limited set of examples currently included in the treebank. In future extensions of the resource, new comparisons with additional instances of the same or similar phenomena may prompt a revision of certain annotation choices.

# 3. Data Collection and Translation

In the development of a treebank, the first step to be addressed is the collection of texts to be later annotated. When the objective is a parallel treebank, texts must be made available in at least two languages. For the development of the first release of the Sicilian3bank[12] we collected a group of open source texts available on the web (sec. 3.1), and we applied to these texts a semi-automatic procedure to obtain their Italian version (sec. 3.2).

## 3.1. Data Collection

The first of the challenges we encountered was finding suitable texts and sources for building the treebank. We constrained our search to literature, but we do not exclude to include other genres in future enlargement of the resource, e.g. including the Sicilian pages of Wikipedia.[13] We started our search based on the criterion of contemporaneity, that is, we sought texts modern and reflecting language use consistent with present-day Sicilian. A useful source has been Panzaredda website.[14] From this source, we retrieved two of the three texts of our corpus: *U cuntu di Purpu*[15] and *Amara Sapi - Capìtulu Unu, U Zuccu*[16]. These texts do not indicate the geographic origin of the authors or the dialectal variety, which prevents us from declaring with certainty the provenance of these texts. However, based on a lexical analysis of the terms used, it is likely that the first text comes from the Agrigento area and the second from the Catania area. The third text is a collection of 18 diatopic variants[17] of

the legend of *Colapisci*, a very well-known folktale in Sicily, narrating the story of a merman.

In the CoNLL-U file of Sicilian3bank, a comment line has been added at the beginning of each text, containing information regarding the text's diatopic variant and publication year. In the specific case of *Colapisci*, this information is provided at the beginning of each story.

## 3.2. Creating the Parallel Sicilian3bank

In this section, we present the challenges of LLMs in translating the selected texts from Sicilian into Italian, and the translation principles we applied for manually correcting the automatic translations.

### 3.2.1. GenAI for Automatic Sicilian>Italian Translation

To translate the Sicilian texts into Italian, we exploited LLMs to obtain a first version, which was then manually revised by Sicilian native speakers.[18] We decided not to use machine translation-specific systems, because they usually do not cover dialects, and when they do, e.g. Google translate, their performance is low, as verified at a first qualitative check on our texts. We preferred to use general-purpose LLMs, as this might be the start of a more systematic study on LLMs abilities with translation of low-resource languages. The machine translated versions were produced in three different settings, giving the whole text in the prompt and asking for the translation, giving a sentence at a time with the whole text as context and giving each sentence in isolation.[19] These three versions have been produced for each of the three LLMs tested, i.e. Mistral 3 Small, LLaMA 3.3 70B and GPT-4o models. These models were accessed using GPT@JRC, a tool that enables the use of genAI models in a safe and AI-Act compliant environment [2], and using standard settings (e.g. temperature 0.7). Despite the three texts having different lengths (from less than 2k to more than 5k tokens), this did not influence the translation quality, though only qualitatively evaluated, especially in the setting asking for the translation of the whole text together, which is the one producing the best translations. This means that the degradation of performance reported in the literature about LLMs [38] (using automatic metrics such as BLEU) is not visible with our qualitative evaluation. In particular, reviewing the translations, it was observed that the best translations were generated by Mistral for the texts *Amara Sapi* and *U Cuntu di Purpu*, whereas for *Colapisci*, the most satisfactory version was the one produced by GPT-4o.[20]

We considered subjective qualitative evaluations of the overall quality of the translation, focussing on the relationship between fidelity to the original text and fluency of the translated text. Notably, despite not being specifically trained on dialect data, the LLMs demonstrated a remarkable ability to generate meaningful translations, producing a fluent and largely accurate output in both cases.[21] However, some inaccuracies regarded: (i) Untranslated or roughly translated terms—nouns in particular are the most difficult to translate and required manual corrections and lexical consultations; (ii) Cultural and linguistic nuances not correctly identified and translated; (iii) Inconsistencies in subject-verb agreement, especially in translations produced by Mistral, and the use of verb tense, which impaired temporal coherence; (iv) Omitted content—a few cases were observed where the models failed to translate parts of the text, producing incomplete results and requiring manual intervention.

### 3.2.2. Translation Choices

We created fluent translations into Italian, opting for the variant that has the most grammatical features of the original, when possible, as in the PUD treebank [7]. Nevertheless, fully rendering the meaning of certain expressions in the translation has been challenging. We have indeed encountered words that did not have an equivalent in Italian, or had one or more meanings. For example, in *U cuntu di Purpu*, the nickname of the main character, 'Purpu'[22], literally means 'octopus', but it is commonly used also to offensively indicate homosexual people. Nowadays, in the translation literature, it is commonly agreed that proper names are not translated, unless they carry a meaning or the target audience requires it. A thoroughly studied case is the translation of names in Harry Potter [39, 40], where localisation seems to be the most adopted technique. Since our primary aim is not translation, we decided to opt for a one-size-fits-all strategy instead of localisation, which involves an ad hoc solution for each different case: proper names were not translated, even when they carried meaning. However, in the document with the whole translated text, provided in the resource repository[23], we added footnotes provid-

collected tales contained Italian sentences, particularly in explanations of details or cross-references to similar versions. These sections were not included in the corpus.

[18] The first authors of this paper.

[19] We are aware that giving the whole text as a context per sentence is not efficient considering computation costs, but we tried this setting as we had only three texts.

[20] It must be noted that safety filters were triggered in some cases, especially in the short story *U Cuntu di Purpu*, as it is mentioned a dead body. This hindered the possibility for a full comparisons of the models and settings.

[21] Qualitatively better than translations obtained using Arba Sicula translator or Google Translate (Sicilian>English).

[22] See https://it.wiktionary.org/wiki/purpu for the translation of the term and this Quora thread https://it.quora.com/Perché-in-Sicilia-gli-omosessuali-vengono-chiamati-purpi for a discussion of its common use.

[23] Available here: https://github.com/ElisaDiNuovo/Sicilian3bank.

ing translation and further explanation where necessary. Other examples of proper names we met in the texts included in the Sicilian3bank—which are known in the translation literature as challenging since rich in social, geographical, or cultural references—are 'Liotru' (from *U Cuntu di Purpu*), literally translatable as 'elephant', but also bearing a reference to the city of Catania, that any Sicilian reader would also recognise; 'Zuccarata' (from *Amara Sapi*), which is not only an affectionate epithet used to describe a person, but also the name of a traditional dessert typical of the region.

A different approach was taken with the toponyms that had a direct equivalent in Italian, which were indeed translated, e.g. *Missina*, *Turri di Faru*, and *Napuli* (from the text *Colapisci*), rendered respectively as Messina, Torre Faro, and Napoli. Finally, fictional toponyms, such as *Cirasitu*, found in the text *Amara Sapi*, was Italianised as *Cirasito*, however the Italian reader would lose the reference to cherries.

## 4. Sicilian3bank in UD

In this section, we describe the annotation process and the challenges we faced in applying the UD format to our collection of texts described in Sec. 3. All the annotation choices are documented in the annotation guidelines, provided in the resource repository.

### 4.1. Parsing Sicilian in UD

There is no annotated resource or treebank in UD format for the Sicilian dialect. Based on the supposed similarity of Sicilian with Italian and the availability of UD treebanks for this latter, we decided to create a first draft of the Sicilian annotated data using the models for Italian, expecting to find a significant amount of errors in the output to be manually corrected. We selected the models trained on ISDT [41] and POSTWITA [42] treebanks, which are the biggest resources for Italian available in the UD repository, and we have a performance evaluation of these models in non standard Italian texts (i.e. [12]). A preliminary comparison of the outputs generated by UDPipe[24] trained on them showed that the model based on ISDT outperforms that based on POSTWITA in dealing with Sicilian data. We started therefore the manual check and correction of the output of UDPipe trained on ISDT, feeding it with gold sentence segmentation.[25]

The three first authors, all native Sicilian speakers skilled in linguistics and computational linguistics, carried out this manual revision of the automatic annotation leading to the first version of the Sicilian3bank. The tool used for the correction was Arborator [43].[26] Each of the three texts was annotated by one annotator. The annotation was reviewed by a second annotator. Problematic phenomena were discussed by the three annotators together, and specific cases also with the rest of the authors.[27] In Table 2 in Appendix A we report an example of the CoNLL-U file for a Sicilian sentence of the treebank, featuring a comment line with the Sicilian text, and the aligned Italian translation.

When it comes to this parallel dataset composed of the translations into Italian of the Sicilian sentences (described in Sec. 3), the same parsing approach has been applied, thus creating the Sicilian-Italian parallel treebank. Nevertheless, considering that our main focus is on the Sicilian dialect, we decided to concentrate our current efforts on the creation of the parallel data (translation into Italian) and the manual correction of the annotation of the Sicilian data, carefully checking them both, and planning instead the manual check of the annotation of the Italian parallel data of the Sicilian3bank as a future work. This is further justified as automatic parsers for Italian are considered good enough, although some marginal phenomena still are consistently wrongly annotated [44, 12]. The next section is therefore focused on the analysis based on the Sicilian data only.

### 4.2. A Quantitative Analysis of the Sicilian Data

After the manual check and correction, the Sicilian resource annotated in CoNLL-U format consists of a total of 505 sentences and 11,709 tokens (Table 1). Each annotated sentence of each of the three texts presented in Sec. 3.1 includes a comment text line that reports the sentence in Sicilian dialect followed by a comment text line containing the translation into Italian. Following this, the UD annotation of the sentence is provided organised in the ten columns typical of this format (Table 2).

| Text | Number of sentences | Number of tokens |
|---|---:|---:|
| *Amara Sapi* | 246 | 4723 |
| *Colapisci* | 179 | 5092 |
| *U cuntu di Purpu* | 80 | 1894 |
| Total | 505 | 11709 |

**Table 1**
The distribution of sentences and tokens in the Sicilian data of the Sicilian3bank.

[24] Available here: https://lindat.mff.cuni.cz/services/udpipe/.

[25] For sentence segmentation we followed the VALICO-UD project, which does not split sentences on colons and treats direct speech as single segment.

[26] We noticed that Arborator (https://arborator.ilpga.fr) allowed to split tokens only into two, so in case of verb + double clitic we had to further tokenise manually.

[27] To further ensure annotation quality, an inter-annotator agreement score (Krippendorff's kappa) will be computed for future releases of the treebank.

A comparison of the annotation provided by UDPipe with the manually corrected data enables us to evaluate the transfer domain abilities of the parsing models when applied on the Sicilian data. In Table 3 in Appendix A, we report the scores (precision, recall and F1 for UPOS, LAS and UAS) obtained by UDPipe models trained on ISDT and on PoSTWITA. These results confirm that the model based on ISDT outperforms the other one, but it must be observed that it may depend at least in part on the fact that the output of UDPipe trained on ISDT was the base for the manual correction. The table shows that the best performance based on ISDT can be referred to *Colapisci* (LAS F1 72.87) while the worst to *Amara Sapi* (LAS F1 59.80). An in-depth investigation of these results is beyond the scope of this paper, but will be addressed in our future work. However, we can qualitatively observe that the performance of the two models differs for some phenomena. For example, the model trained on PoSTWITA was more robust in annotating verbs containing double clitic pronouns.

## 4.3. Challenges in Dealing with the Sicilian Dialect

The approach used for the generation of the annotated data, based on models available for Italian, has clearly brought out some characteristics and phenomena that differentiate Sicilian from Italian. It is in dealing with these phenomena that the parser has produced more annotation errors, and it is on them that the work of manual correction was mostly concentrated.

This section presents some choices we had to make to deal with some features of the Sicilian texts considered. In particular, we focus on tokenisation (articulated prepositions), lemmatisation (orthographic variations of some pronouns reflecting suprasegmental traits), and syntactic (focussing here on the reduplication phenomenon) choices.

### 4.3.1. Tokenisation Issues

A particularly relevant phenomenon that emerged during the annotation is that represented by articulated prepositions, for which there has been, over time, a process of grammaticalisation that has determined their evolution. Generally, many prepositions that in Italian occur in a unified form have undergone a transformation in Sicilian, first passing through a disjunct form (Example 1)[28], until arriving at forms with elision (Example 2)[29] [34, 31] and, in more recent times, with contraction (Example 3)[30], although the disjunct form is still present, at least in some areas [33].

**la** DET **lu** ***the***
manu NOUN manu *hand*

Contracted articulated prepositions—graphically marked by the circumflex accent [29, 30, 32]—were split into two different tokens, as shown in Example 3. In this way we show, for each articulated preposition, the morphology attached to it, even in those cases in which it is not apparently visible, as it is nevertheless part of its evolution and can be described by formal rules. A different choice, such as not splitting it into two tokens, would have highlighted the grammaticalisation of this particular phenomenon by not splitting it into two tokens. However, this choice might necessitate the creation of a specific UPOS, which would hinder cross-language comparisons.

Similarly the forms *nta* and *ntâ* differ as the former is a simple preposition, equivalent to *in* of Italian, while the latter is the articulated preposition. Depending on the gender and number of the article, it can be rendered as *ntô* (masculine singular), *ntê* (plural, both masculine and feminine).

It is worth noting in this regard that the Italian preposition *in* can be rendered in Sicilian in various ways, such as *in*, *ni*, *nni*, *nta* [29]. The same is true for the Italian simple preposition *da*, which in Sicilian occurs in the forms *di*, *ni* and *nni* [29]. These different forms are reflected also in the corresponding articulated prepositions

[28] English translation: *This Piscicola was one from Faro.*
[29] English translation: *[...] were embalmed just as they emerged from the sea.*
[30] English translation: *He wiped away his tears with his hand.*

(e.g. the Italian preposition *nello*, such as *ntô*, *nô* and *nnô*). Please see Sec. 4.3.2, for our lemmatisation choices for these variants.

The complete scheme of the articulated prepositions system in Sicilian is presented in Table 4 in Appendix A.

### 4.3.2. Lemmatisation Issues

Concerning lemmatisation, as Sicilian does not have a unified orthography—although recent efforts try to standardise this [32]—in the texts considered there are different variants for the same forms, which try to render different pronunciations. For example, in the considered texts there is no consistency in the transcription of the Sicilian word meaning 'no one', *nuddu*, which is pronounced reproducing a long voiced retroflex stop, but it is transcribed sometimes as *nuddu*, other times as *nuḍḍu*, stressing the retroflex pronunciation. Other variants of the same word are *nuddru*, *nuddhu*. Since our aim is not focused on phonetics, we lemmatised these occurrences without any pronunciation marks, i.e. *nuddu*, and decided not to uniform the orthographic rendering (i.e. the form) of this word and similar cases, e.g. *ci*/*cci* and *ni*/*nni*, as shown in Examples 4a-4b and 5a-5b, respectively.

(4a) # text = **ci** succidìu accussì LEMMA **ci**
# translation = **gli** successe questo (*this happened **to him***)

(4b) # text = chi **cci** jemu a fari? LEMMA **ci**
# translation = che **ci** andiamo a fare? (*what are we going to do **there**?*)

(5a) # text = **ni** chiamavanu "l'Armali" LEMMA **ni**
# translation = **ci** chiamavano "gli Animali" (*they called **us** "the animals"*)

(5b) # text = Chi **nni** putìa sapiri iu? LEMMA **ni**
# translation = Che **ne** potevo sapere io? (*How could I know **about that**?*)

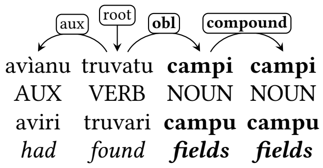
We applied the same principle to shortened oral variants of words, e.g. *diri* ('to say') or *riri*, both of which are abbreviated forms of *diciri*. All such variants have been lemmatised using the extended lemma, such as *diciri* in Example 8).

To summarise, the main aim of lemmatisation is to reduce the sparseness of forms and their variants by reducing them to a common lemma, regardless of the causes of this sparseness. Therefore, we have applied the same strategy used in other resources where sparsity is determined, for example, by the writing style of the users (or by errors due to the writing device they use), as in PoSTWITA[42], to the lemmatisation of Sicilian3bank.

### 4.3.3. Syntax Issues

One of the cases in which we had to take a decision about a syntactic phenomenon is reduplication, a typical and widespread phenomenon in the Sicilian dialect [45], which consists in the repetition of a word, resulting in a shift or extension of meaning within the sentence. It is a phenomenon still highly productive in contemporary Sicilian, as shown by Amenta through the analysis of a corpus from the *Atlante Linguistico della Sicilia* [46], where these forms exhibit neither diachronic nor diastratic variation, thereby confirming the ongoing vitality of this linguistic process. This phenomenon can involve the reduplication of a verb to form an adjective or a noun; a noun to form an adjective or an adverb; and other PoS [47]. This last pattern, the most frequent in our texts, reveals several semantic implications, but frequently is used as a locational nominal modifier. In order to highlight the compound nature of this phenomenon (in [45, p. 350], it is clearly stated that it is not possible to interpose any words between the two elements of the reduplicated construct), we use the relation *compound* and the relation *obl*, in line with UD guidelines, as shown in Example 6[31]. In addition we added *LOC=adv* in the last column of the CoNLL-U file, as it is done in VALICO-UD, to indicate that there is an adverbial locution.

(6) # text = avìanu truvato **campi campi**
# translation = avevano trovato **tra i campi**



| avìanu | truvatu | **campi** | **campi** |
|---|---|---|---|
| AUX | VERB | NOUN | NOUN |
| aviri | truvari | **campu** | **campu** |
| *had* | *found* | ***fields*** | ***fields*** |

## 4.4. A Cross-Linguistic Analysis Example

In Sicilian, modal verbs—like the auxiliaries *essiri* ('to be') and *aviri* ('to have')—can serve two main functions: they may appear independently with their own lexical meaning, or they may function as support verbs, combining with an infinitive (without a preposition) to convey specific modal values, such as: (i) ability/possibility → *putiri* ('can'); (ii) will/desire → *vuliri* ('want'); (iii) obligation/necessity → *duviri* ('must') or *aviri a* ('have to').

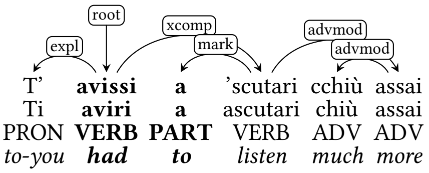
In modern Sicilian, particularly in spoken usage, the periphrastic construction *aviri a* + infinitive is commonly employed to express modal meanings, especially obligation, replacing the older verb *duvìri* found in Old Sicilian [30] (see Example 7)[32]. Within this construction, the tense of *aviri* plays a central role in conveying modal values, whether epistemic or deontic. When *aviri* appears in the past remote, its perfective aspect confers an epistemic meaning, indicating certainty about the event's occurrence in the past. In contrast, when *aviri* is used in the present or imperfect—both imperfective tenses—the construction can express either an epistemic sense of probability or a deontic sense of obligation or necessity.

[31] English translation: *[...] they had found among the fields.*

[32] English translation: *I should listen to you much more often.*

In some cases, especially with the present indicative or imperfect subjunctive, an exhortative function may also emerge [48].

(7) # text = T'**avissi a** 'scutari cchiù assai
# translation = ti **dovrei** ascoltare molto di più

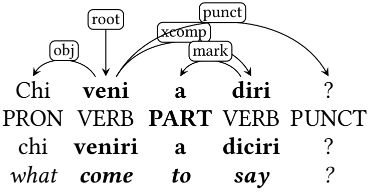


root
expl
xcomp
mark
advmod
advmod
T' avissi a 'scutari cchiù assai
Ti aviri a ascutari chiù assai
PRON VERB PART VERB ADV ADV
to-you had to listen much more

The annotation in UD of such resource allows for drawing a parallel with other languages. For example, with the English *have to* construction, which is similarly used to express obligation and certainty [49, p. 210]. In the English UD treebanks *to* is consistently annotated as a particle when used in this way (see Example 9a in Appendix A). We therefore decided to treat the element *a*, which is usually tagged as a preposition in our corpus, as a particle in this specific construction. However, in Italian *avere da* can be used with the same meaning (see Example 9b in Appendix A), but *da* is not annotated as particle. This might be due to historical reasons, a different function of *da* in Italian than of *to* in English, or to highlight a less grammaticalised relation.

Another periphrastic construction found in the treebank texts is *veniri + a + diciri* (literal translation into Italian *venire a dire*), which can have the meaning of the Italian verb *significare* ('to mean'). In such cases, we treated it in the same way as the previous one, as shown in Example 8[33].

(8) # text = Chi **veni a diri**?
# translation = Che **significa**?



## 5. Conclusion and Future Work

We can create a world that sustains its languages [50]. Among the concrete actions we can perform to achieve this goal, there is the possibility of speaking and studying the original languages of our places.

This paper describes and discusses the issues involved in the development of the first release of the Sicilian3Bank. Many are the challenges we have encountered in dealing with a language which has never been treated before and which is in addition a dialect, which carries with it an uninterrupted history of oral transmission but does not have a standardised form of transcription or unified treatment of phenomena in grammars.

The project we present here is intended therefore solely as a preliminary foundation and proposal, which nonetheless requires substantial further work and numerous improvements. First, the inclusion of more texts and perform inter-annotator agreement, to verify guidelines soundness. Second, the corpus enrichment introducing Italian glosses in the MISC column of the CoNLL-U file. In the current version, each sentence is accompanied by a fluent Italian translation in a comment line, we propose the inclusion of a literal word-for-word translation from Sicilian into Italian. Although this form of translation may result in grammatically incorrect or unnatural Italian, it would provide an almost word-by-word parallel aligned resource that mirrors the syntactic structure of the original Sicilian sentences and would facilitate syntactic calque studies. Third, a future objective would be to manually validate the automatic annotation generated with UDPipe for the aligned Italian resource as well. This step is needed to give to the Italian parallel dataset the same quality we are currently providing for the Sicilian annotated data. Fourth, another interesting enhancement might be to systematically include graphic accents on all verb lemmas, to help reading them, and including in MISC column of the CoNLL-U file the International Phonetic Alphabet transcription. This idea is motivated by the desire to turn the resource not only into a syntactic dataset but also into a tool to support language learning, scientific studies and preservation of Sicilian. Finally, an aspect we would like to improve in the future concerns the translation of proper nouns. As already discussed, we encountered several challenges in translating these elements, which ultimately led us to the decision not to translate the proper nouns found in the texts at this stage. The focus of this work is the development of a Sicilian treebank, and although a deeper engagement with translation would certainly have added valuable insights, it would have diverted attention from the project's primary objective. We therefore plan to revisit this aspect in a later phase of the project.

## Acknowledgment

We would like to express our gratitude to Giuseppe Domenico Muscianisi, PhD, from the University of Parma, for very kindly sharing with us his expertise, which was instrumental in resolving several of our questions and improving our knowledge about the literature on the Sicilian dialect.
A special thanks goes to the JRC internal reviewers and to the CLiC-it 2025 anonymous reviewers for their precious comments.

## Abstract

Natural language processing (NLP) has made significant improvements in recent years, primarily driven by the latest advancements in deep learning technologies and the increasing availability of large-scale linguistic resources. Nevertheless, such advancements have mostly benefited high-resource languages, leaving many minority and underrepresented languages at the margins of computational linguistics research. Sardinian, the native language of the island of Sardinia, exemplifies this disparity. Indeed, despite its cultural and linguistic value, there is a lack of proper resources, annotated corpora, and NLP tools. This work proposes a Part-of-Speech tagging system for Sardinian characterized by methods consistent with its morphological specificity. The system integrates a BERT-based token classifier capable of assigning a grammatical category to each input word in a sentence. The classifier was trained on a balanced, manually-annotated corpus, and its performance was evaluated using standard machine-learning-oriented performance metrics (Accuracy, F1-score, Recall, and Precision). Experiments show that pre-trained architectures such as BERT remain effective even for languages with limited data availability.

## Keywords

Low-resource languages, Part-of-speech tagging, Language models.

## 1. Introduction

Recent scientific advances in language models (LMs) and natural language processing (NLP) have contributed to the development of sophisticated technologies for generating, analyzing, and interpreting the world's major languages. In such a context, large language models (LLMs), such as GPT-4 [1], Llama-3 [2], and Phi-4 [3], have shown strong proficiency across a wide range of language-related tasks [4], including tasks such as sentiment analysis [5, 6], text classification [7, 8], text summarization, and part-of-speech (PoS) tagging [9].

However, despite their increasing effectiveness, LLMs still present limitations in performing several NLP tasks [10]. In particular, they struggle when the task concerns minority and/or low-resource languages, which often exhibit distinctive linguistic features that make them a subject of special interest for linguists. However, linguists rarely have access to automated tools and resources that facilitate in-depth studies, as these minority and/or low-resource languages are often underrepresented in the digital domain and thus inadequately, or even entirely, unknown to most models. Indeed, in this scenario, tools that support linguistic analysis, such as PoS taggers, remain scarce or nonexistent, limiting the ability of linguists to study the features of such tools at scale. More specifically, PoS tagging aims to assign a grammatical label to every word in a sentence to facilitate the study of its grammatical structure. This task is crucial for analyzing the multifaceted nature of a given language.

Sardinian, a Romance language spoken primarily on the island of Sardinia (Italy), stands out as a notable case study of low-resource language. Indeed, its rich morphological structure and its classification as an endangered language have attracted increasing attention in linguistic preservation and digital humanities [11]. In this direction, the present work describes the creation and the evaluation of an automatic Sardinian PoS tagging model. The methodology relies on fine-tuning a BERT-based language model [12] using a corpus manually annotated by linguists specializing in Sardinian. The experimental phase includes the analysis of the hyperparameters and the monitoring of machine-learning-oriented performance metrics. The proposed approach provides a foundational methodology that can be adapted to develop similar tools for other low-resource languages.

The remainder of this paper is structured as follows: Section 2 describes the state of the art; Section 3 provides a mathematical formulation of the problem and a description of the proposed approach; Section 4 illustrates the results; and finally, Section 5 concludes the work.

## 2. Related Work

This section provides an overview of the state of the art in PoS tagging for low-resource languages, followed by a description of the work carried out for the Sardinian language in the context of NLP. The PoS tagger is an NLP tool that assigns a grammatical label to each word in a sentence, thus enabling the identification of the function of each word in that sentence. This tool facilitates syntactic analysis and provides fundamental support for developing any low-resource language, including Sardinian, by automating linguistic analysis in contexts where structured linguistic resources are lacking.

In recent years, numerous approaches have been extensively investigated, with the aim of developing automatic tagging systems or augmenting training corpora to enable high-accuracy, high-efficiency grammatical annotation at the sentence level. In the context of low-resource languages, where typically scarce data is publicly available, data from more widely known languages similar to the target language is usually employed; one approach following this direction involves the use of Hidden Markov Models (HMMs), in which the PoS tagging task is modelled as a sequence-to-sequence problem [13, 14]. HMMs are first trained on a language with large amounts of annotated data, followed by a model that transfers the learned information to the target language of interest. Different approaches that fill the gap in labeled data are based on adopting unsupervised learning techniques to group words within sentences, annotate them, and then assign a label [15, 16]. Moreover, the problem of PoS tagging is sometimes interpreted as a classification problem. For example, several works proposed to first train fully-connected neural networks (FNNs) and long short-term memory (LSTM) models on annotations projected into English and, subsequently, adapt them to the tags of the target low-resource language [17, 18, 19].

The aforementioned works build upon resources from other languages to create the PoS taggers; alternative methods focus on optimizing the limited availability of data for the target language to achieve equally good results. An example is provided by a model that utilizes translations of parts of the Bible to train PoS taggers by aggregating tags from multiple annotated languages and spreading them through word alignment within the text [20]. Furthermore, different deep learning models have been evaluated to build a PoS tagger for the Albanian language [21], which is a low-resource language as well.

To the best of our knowledge, no prior studies describe a PoS tagger for the Sardinian language. Recent work has introduced a linguistic resource designed to identify semantic relationships between Sardinian words through manual mapping of existing WordNet entries to Sardinian word meanings [22]. However, this resource does not include any tools for automatic linguistic annotation.

## 3. Methodology

This section describes the methodology followed to build and evaluate the PoS tagger for the Sardinian language. The section is organized as follows: first, the problem is formulated mathematically; subsequently, an overview of the entire methodology is provided; then, an analysis of the data used to build the PoS tagger is conducted; finally, the fine-tuning technique employed is presented.

### 3.1. Problem Formulation

Mathematically, let $\mathbf{s} \in \mathcal{S}$ be a sentence belonging to a set of sentences; then $\mathbf{s}$ can be identified as a vector whose entries represent the words included in the sentence $\mathbf{s} = [w_1, \ldots, w_m]$, with $m \in \mathbb{N}^+$. Therefore, a PoS tagger can be defined as a function $f$ expressed as:

$$\begin{aligned} f : \mathcal{S} &\longrightarrow \mathcal{T} \\ \mathbf{s} &\longmapsto f(\mathbf{s}) = \mathbf{t} = [t_1, \ldots, t_m] \end{aligned}$$

where $t_j \in \mathcal{U}$ identifies the tag, i.e., a grammatical label, of the $j$-th word and is chosen from a specific tagset $\mathcal{U}$, and $\mathcal{T}$ is the set of vectors whose entries contain the tag of each word in a sentence.

In this work, from an application point of view, the problem of estimating the function $f$ defined above is interpreted as a classification problem, and therefore, it is solved by training a specific classifier. Given a dataset $\mathbf{D} = \{\mathbf{s}, \mathbf{t} | \mathbf{s} \in \mathcal{S}, \mathbf{t} \in \mathcal{T}\}$ that includes sentences and their respective tags, the objective is to optimize the parameters of a classifier so that it accurately assigns the correct grammatical tag to each word in a sentence.

### 3.2. Methodology Overview

Figure 1 illustrates the workflow followed to develop the Sardinian PoS tagger proposed in this study.

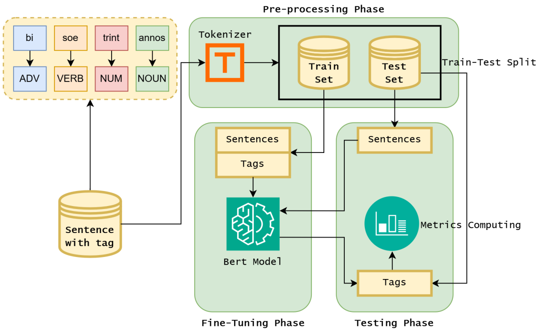

**Figure 1:** Workflow of the Sardinian PoS tagger.

The process consists of three main steps. In the first phase (*pre-processing*), the available tagged data is transformed and formatted adequately for use in the subsequent steps. Once transformed, the data is split into two parts: one part is used for training the model, and the other for evaluating it. In the second step (*fine-tuning*), the model learns to accurately assign grammatical tags to each word in a sentence based on the training data. Finally, in the third step (*testing*), the fine-tuned model automatically annotates the test data, and standard machine learning metrics are computed to evaluate how well it has learned to assign tags to each word.

Let us note that, as mentioned in the previous section, tags must be chosen from a specific set $\mathcal{U}$. In this work, two different state-of-the-art tag sets will be considered, i.e., the *Universal Tags* [23] (denoted as `tag`), and the tagset, conceived for the Italian language, adopted in the work of Palmero Aprosio & Moretti [24] (denoted as `fineTag`). The latter tagset is compliant with the *EAGLES* standards [25] and also more fine-grained than the former. Consequently, the pipeline depicted in Figure 1 is executed for each tagset separately.

## 3.3. Data Pre-Processing

In the context of minority languages, particularly the Sardinian language, it is challenging to find or utilize data that enables the training of specific models. In our scenario, to the best of our knowledge, the only available dataset for the Sardinian language that allows us to address a PoS tagging task is proposed by Mura et al. [26]. The dataset consists of $1,472$ sentences in which each word is annotated with both tag sets described in the previous section. The sentences were extracted from transcripts of interviews conducted with 21 native Sardinian emigrants, each speaking a different variety of Sardinian, as part of the *Mannigos* project [27].

Figure 2 illustrates the distribution of the number of words per sentence in the dataset. It is worth pointing out that the term *word* in this context refers to any part of the sentence, including punctuation. It can be observed that most sentences contain a limited number of words, with a significant portion not exceeding 100 words. Another key aspect is the distribution of tags within the dataset. Ensuring a balanced representation of grammatical categories allows the model to effectively learn each tag from the two defined tag sets. Figure 3 illustrates this distribution and highlights the overall balance level. Even though the dataset appears to be heavily imbalanced due to the natural linguistic structures that are common in any language, it is noteworthy that *all* tag labels in the considered tag sets are represented in the dataset.

The development of the PoS tagger in this work is based on fine-tuning the BERT language model. This choice requires a careful data pre-processing phase,

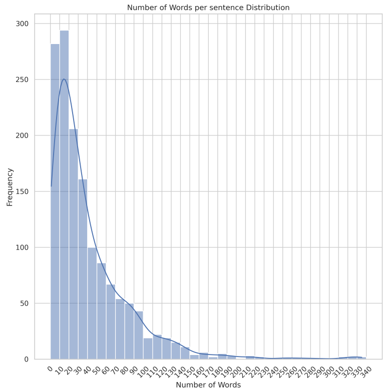

**Figure 2:** Distribution of the number of words per sentence.

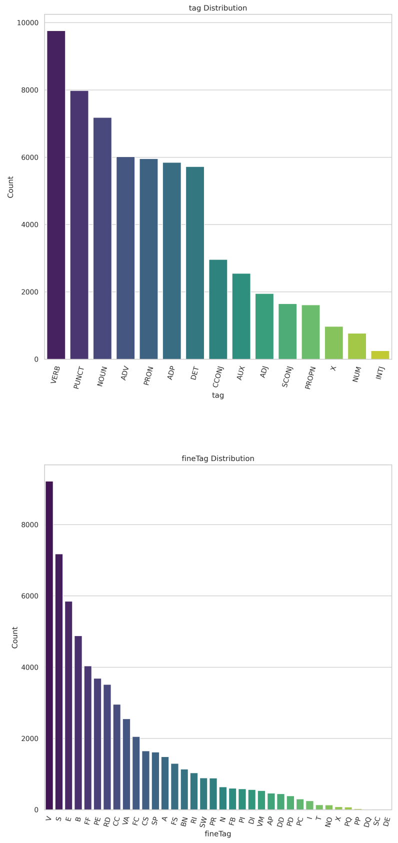

**Figure 3:** Distribution of labels from the `tag` (above) and the `fineTag` (below) sets in the dataset used in this study.

**Table 1**
Size of train and test sets for the two considered tagsets.

| Tagset | Train set size | Test set size |
|---|---|---|
| `tag` [23] | 1,172 | 293 |
| `fineTag` [24] | 1,177 | 295 |

where the text is appropriately tokenized (i.e., divided into smaller units called tokens, which may consist of words, sub-words, or characters). For consistency, this process was performed using the BERT tokenizer, which employs the *WordPiece* technique. This latter breaks unknown words into more common sub-word units, ensuring that each token aligns with an entry in the BERT vocabulary. Finally, each token is transformed into a numerical identifier that BERT can process. To streamline processing, each sentence was standardized to a length of 512 tokens by appending padding tokens as needed.

Following tokenization, the dataset was divided into two train sets and two test sets, one for each tagset, selecting 80% of the sentences for the first set and 20% for the second. These pre-processing steps, along with the removal of sentences containing missing or incorrect tags, led to the data splits described in Table 1.

## 3.4. Model Fine-Tuning

The next step is to choose the appropriate model for the fine-tuning phase. As a result of extensive, preliminary empirical evaluations, the pre-trained BERT model in its *large-cased* version was selected [12]. In more detail, BERT is a deep learning model based on the Transformer architecture developed by Google. Its special feature is its ability to process context bidirectionally, i.e., by simultaneously considering both the context to the left and the right of a word, significantly improving performance in the context of this work. It should be noted that, in this study, BERT was implemented for token classification, and the same architecture is used for both tagsets. For token classification, BERT follows this structure:

- *Input Embedding*: Each token is transformed into a vector representation that combines *token embeddings*, i.e., the token representation, *segment embeddings*, i.e., the sentence the token belongs to, and *positional embeddings*, the position of the token in the sentence.
- *Transformer Layers*: The network comprises 24 layers of this type, each using multi-head attention mechanisms to model the relationships between tokens.
- *Output Layer*: BERT returns a probability distribution over all possible classes for each token. The final output is a sequence of logits, with one prediction for each token.
- *Token Alignment*: Since some tokens are split into sub-tokens, it is necessary to realign the predictions to assign a single label to the original word.

Even though the BERT model is multilingual, it does not recognize minority languages like Sardinian. However, the pre-trained BERT model has learned the morphosyntactic behaviors of languages similar to Sardinian, such as Italian or Spanish. Consequently, a fine-tuning phase in which the BERT model identifies the primary characteristics of the Sardinian language can lead to a high-performance PoS tagger for the Sardinian language.

Given that the PoS tagging problem can be interpreted as a classification problem, the tuning phase of a token classification model can be interpreted as a supervised training phase, in which the model sees which tags are assigned to each part of speech. In this phase, it is therefore essential to choose the appropriate loss function to minimize during the tuning phase and the hyperparameters to be input to the trainer to allow optimal learning. As for the former, the Cross-Entropy Loss function was chosen, which, with the padding approach, takes the form:

$$\mathcal{L} = -\frac{1}{\sum_{i=1}^{N} m_i} \sum_{i=1}^{N} m_i \cdot \log(p_{i,y_i}) \tag{1}$$

where:

- $N$ is the total number of tokens;
- $m_i \in \{0, 1\}$ is the mask that is 1 if the token $i$ is valid (not padding), 0 otherwise;
- $y_i \in \mathcal{U}$ is the true class of the token $i$;
- $p_{i,y_i}$ is the probability the model predicts for the correct class $y_i$.

Note that the same loss function was used for models trained on both the `tag` and `fineTag` sets.

Figure 4 shows the evolution of training loss, validation loss, and validation F1 score over epochs for both models during the tuning phase. These graphs were instrumental in determining the optimal number of fine-tuning epochs and in choosing other hyperparameters. Although all three metrics were considered, particular attention was paid to the validation F1 score, as it most directly reflects the model's ability to generalize on the classification task.

**Table 2**
Hyperparameters used for fine-tuning the BERT model.

| Hyperparameter | `tag` set | `fineTag` set |
|---|---|---|
| **Batch Size** | 16 | 16 |
| **Epochs** | 30 | 40 |
| **Weight Decay** | 0.01 | 0.01 |
| **Learning Rate** | 2e-5 | 2e-5 |
| **Optimizer** | *AdamW* | *AdamW* |

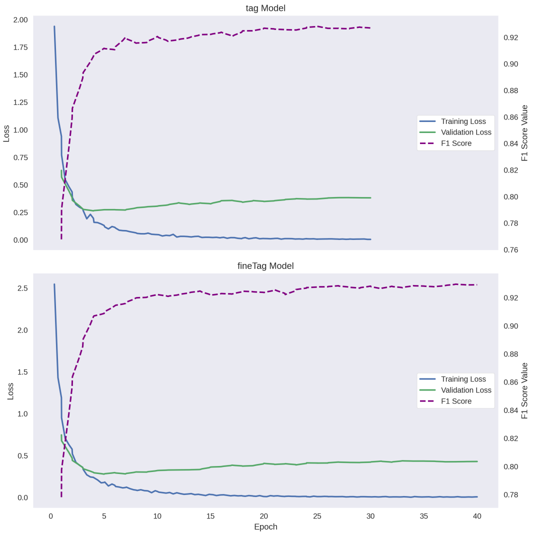

**Figure 4:** Train loss, validation loss, and validation F1 score over epochs tracked during fine-tuning.

All experiments were conducted on an NVIDIA RTX A6000 GPU with 48GB of vRAM.

### 3.5. Model Testing

Several metrics were used to evaluate model performance. Given the classification nature, the four performance metrics used in this study are Accuracy, Recall, Precision, and F1 score. Note that the last three metrics mentioned were calculated in their macro version, considering the presence of more than two classes to be evaluated.

These metrics allow us to assess how accurately the PoS tagging models classify the various words in the sentence. In particular, they allow us to analyze both the model's ability to identify all relevant classes (Recall) and its accuracy in avoiding false assignments (Precision), providing an overall measure of the balance between these two properties (F1 score). The following formulas define the metrics in detail.

$$\text{Accuracy} = \frac{\sum_{i=1}^{N} m_i \cdot \mathbb{1}(y_i = \hat{y}_i)}{\sum_{i=1}^{N} m_i}$$

$$\text{Precision}_{\text{macro}} = \frac{1}{C} \sum_{c=0}^{C-1} \frac{TP_c}{TP_c + FP_c}$$

$$\text{Recall}_{\text{macro}} = \frac{1}{C} \sum_{c=0}^{C-1} \frac{TP_c}{TP_c + FN_c}$$

$$\text{F1}_{\text{macro}} = \frac{1}{C} \sum_{c=0}^{C-1} \frac{2 \cdot \text{Precision}_c \cdot \text{Recall}_c}{\text{Precision}_c + \text{Recall}_c}$$

**Table 3**
Evaluation of the fine-tuned models for the two tagsets.

| Metric | `tag` set | `fineTag` set |
|---|---|---|
| Accuracy | 0.9418 | 0.9362 |
| Precision$_{\text{Macro}}$ | 0.9250 | 0.9274 |
| Recall$_{\text{Macro}}$ | 0.9347 | 0.9308 |
| F1$_{\text{Macro}}$ | 0.9298 | 0.9291 |

with:

- $TP_c = \sum_{i=1}^{N} m_i \cdot \mathbb{1}(y_i = c) \cdot \mathbb{1}(\hat{y}_i = c)$;
- $FP_c = \sum_{i=1}^{N} m_i \cdot \mathbb{1}(y_i \neq c) \cdot \mathbb{1}(\hat{y}_i = c)$;
- $FN_c = \sum_{i=1}^{N} m_i \cdot \mathbb{1}(y_i = c) \cdot \mathbb{1}(\hat{y}_i \neq c)$.

in which $N$, $m_i$, and $y_i$ are the same as defined in Formula 1; while $\hat{y}_i$ is the tag predicted by the model, $C$ is the size of the set $\mathcal{U}$ (i.e. the number of all possible tags), and $\mathbb{1}(A)$ is the indicator function, equal to 1 if condition $A$ is true, 0 otherwise.

It is important to note that all metrics introduced vary within a range between 0 and 1, with values closer to 1 indicating better performance.

## 4. Experimental Results

This section is organized into two main parts. In the first part, we present the quantitative analysis of the models, reporting and comparing their performance on the test sets. These results allow us to evaluate the overall effectiveness of each model in a rigorous and reproducible manner. The second part is dedicated to a brief qualitative analysis, in which we examine selected examples unobserved during the fine-tuning and testing phases. This analysis aims to illustrate the models' predictions in practice, thus complementing the information obtained from the quantitative evaluation.

### 4.1. Quantitative Analysis

Table 3 shows the performance of the two fine-tuned BERT-based models on the test sets[1]. The first model, fine-tuned on the coarser-granularity tagset (`tag`), achieves an accuracy of 0.9418 and a macro F1 score of 0.9298, with recall and precision scores of 0.9347 and 0.9250, respectively. The second model, fine-tuned on the more detailed tagset (`fineTag`), produces slightly lower but still good results, with an accuracy of 0.9362, a macro F1 of 0.9291,

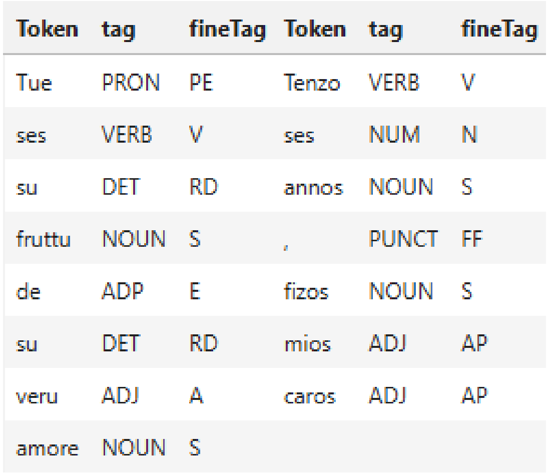
[1] While per-tag evaluation metrics could in principle offer additional insights, given also the large size of the tagset, we chose to focus on overall metrics to maintain a clear and coherent narrative aligned with the primary research questions. We consider a detailed per-tag analysis an important direction for future work, particularly in application-specific settings where tag-level behavior is critical.

a recall of 0.9308, and a precision of 0.9274. These results indicate that both models generalize to the test data well. It is important to note that high performance is still achieved even in the `fineTag` setting, which involves a classification task with 36 PoS classes (the `tag` set included 15 PoS classes). This observation highlights the robustness of the fine-tuned models, demonstrating their ability to handle more complex and fine-grained label distributions without substantial performance loss. Notably, these results are achieved despite the linguistic variability within the dataset, which includes multiple Sardinian language varieties with differing morphological features. Nevertheless, the models successfully capture the core structural patterns of each variety, demonstrating strong generalization across intra-language variation.

### 4.2. Qualitative Analysis

In addition to quantitative evaluation, we conducted a qualitative analysis to gain a deeper understanding of the behavior of the two fine-tuned PoS taggers in real-world scenarios. This section presents two illustrative examples, shown in Figure 5, where we compare the results of the two PoS taggers on sentences that are not part of the dataset but are completely external. These examples allow us to examine how the models handle both simple and ambiguous linguistic structures and to evaluate their ability to assign the correct PoS tags in context. The model outputs are easily readable and clearly aligned with each token in the sentence, making it straightforward to assess the tagging quality and spot possible inconsistencies visually.

One notable aspect is the accurate tagging of simpler elements, such as punctuation marks, which both models consistently identify. More interestingly, the models also demonstrate a strong ability to disambiguate words based on context. For instance, both sentences in Figure 5 include the word *ses*, which in Sardinian can function either as a numeral (meaning "six") or as a verb (a form of the verb to be). Despite the ambiguity, both models correctly assign different PoS tags to *ses* depending on their usage in each sentence, showing that they have learned to exploit contextual cues to resolve such lexical ambiguity. This suggests that the models are not merely memorizing patterns, but rather capturing meaningful linguistic distinctions across a morphologically rich and internally diverse language.



| Token | tag | fineTag | Token | tag | fineTag |
|---|---|---|---|---|---|
| Tue | PRON | PE | Tenzo | VERB | V |
| ses | VERB | V | ses | NUM | N |

| amore | NOUN | S | | | |

**Figure 5:** Example output of the two PoS taggers on external sentences. Each row corresponds to a token, with associated tags produced by the two models: the *tag* column shows the output of the model fine-tuned on the *Universal Tagset* tagset, while the *fineTag* column displays the output of the model fine-tuned on the more fine-grained tagset of [24].

## 5. Conclusions

This work has introduced an automatic PoS tagging model for Sardinian, a minority and morphologically complex language, using a BERT fine-tuning approach. Starting from a heterogeneous, manually annotated corpus composed of sentences taken from interviews with native speakers of different varieties of Sardinian, we implemented and tested two distinct models, each trained on a different set of grammatical classes, from [23] and [24] respectively. The results obtained, both in terms of quantitative and qualitative analyses, highlighted the effectiveness and robustness of the proposed model, which is capable of generalizing even in the presence of language variability. This contribution is part of a broader effort to promote and preserve low-resource languages, offering methodologies that can be replicated and extended to other similar linguistic contexts [28].

Looking ahead, this work can be extended in several directions. On the one hand, it will be possible to further refine the models by expanding the corpus, integrating parallel resources (e.g., annotated translations), or using semi-supervised learning techniques or transfer learning from other languages. A particularly relevant aspect that will need to be addressed concerns the transparency, understandability, and interpretability of the models, an issue not explored in this study but increasingly important across many application domains where intelligent methods support human activity, such as medicine [29, 30], finance [31, 32, 33], safety [34], data analysis [35], and industry [36, 37, 38], to name a few. Furthermore, it will be essential to annotate the dataset with explicit information about Sardinian varieties and assess the PoS taggers' performance across these varieties, in order to better understand their generalization capabilities and potential linguistic biases. Finally, an important development could be the creation of an accessible user interface that would make the PoS tagger usable by linguists, scholars, and citizens not experts in computer science. Such a tool could be integrated into digital platforms for teaching, documentation, and linguistic research on Sardinian, contributing to greater digitization and visibility of the language.

# A Hypothesis-Driven Framework for Detecting Lexical Semantic Change

Pierluigi Cassotti[1], Nina Tahmasebi[1]

[1]University of Gothenburg, Department of Philosophy, Linguistics and Theory of Science, Gothenburg, Sweden

**Abstract**

This paper introduces a hypothesis-driven framework aimed at detecting lexical semantic change, addressing the limitations of current computational methods that struggle with the dynamic and contextually modulated nature of word meanings. Traditional approaches, such as Word Sense Disambiguation (WSD), fail to capture the fluidity of senses, whereas Word Sense Induction (WSI), while more flexible, lacks the precision necessary to align with predefined semantic structures. Our approach systematically combines expert-defined sense hypotheses with advanced computational techniques, including generative models, encoding and prototyping methods, and targeted semantic analysis. Using words historically significant in scientific contexts—such as theory, gene, and force—we demonstrate the effectiveness of our method in tracing fine semantic changes and metaphorical extensions over time, highlighting its advantages over naive computational strategies.

**Keywords**

lexical semantic change, lexical semantics, diachronic, historical linguistics

## 1. Introduction

Polysemy, the phenomenon where a single word carries multiple meanings, has long intrigued researchers. Often, words reach a polysemic state, through a process of semantic change in which the (set of) senses of a word has been altered. Dictionaries serve as vital resources in this field, cataloging the various senses of words. However, they are not all-encompassing and the granularity of the recorded senses varies across dictionaries, reflecting the approaches of lexicographers, who are often categorized as "lumpers" or "splitters." Lumpers favor broader, more encompassing definitions, while splitters distinguish senses with subtle nuances.

This variability ties into contextual modulation [1], where a word's core meaning remains stable but shifts slightly depending on its context. Such shifts become more pronounced over time, as word meanings evolve in response to cultural and social changes. For instance, the Oxford English Dictionary [2] defines "phone" simply as a “telephone apparatus,” a broad enough definition to encompass its evolution from landline phones to public telephone booths to modern smartphones.

This dynamic nature of meaning poses significant challenges for computational modeling. Traditional approaches like Word Sense Disambiguation (WSD) [3] struggle because they assume fixed meanings, ignoring the fluid continuity of senses. In contrast, Word Sense Induction (WSI) is better suited, as it derives sense structures directly from data. However, WSI's open-ended nature makes it challenging to align derived senses with a predefined ground truth, especially when attempting to track meaning changes across centuries of a language's history.

Current computational models often fail to align with ground truth sense representations unless explicitly guided. One way to address this is by starting with predefined search hypotheses, which can simplify the modeling process and provide a clearer framework for tracking meaning shifts over time.

By establishing research hypotheses, we can predefine the organization and structure of word senses, guiding computational models toward a predetermined ground truth. However, this remains challenging with standard technologies, which require models capable of adapting to meaning representations without relying on specific senses.

In this paper, we present our hypothesis-driven theoretical framework for detecting meaning change (Section 3). We also demonstrate a practical implementation of this framework using recently developed computational models (Section 2). Furthermore, we provide a concrete example by comparing our approach to naive WSI methods (Section 4), highlighting the advantages of the hypothesis-driven approach.

## 2. Related Work

Detecting changes in word meaning typically involves two stages: first, representing the meaning of words in individual time periods, and second, verifying whether a change in meaning has occurred over time.

## 2.1. Representation of Word Meanings

Representing word meanings in historical texts poses unique challenges for computational models [4]. These models must understand historical contexts, avoid reliance on lexicographic resources that may omit new or obsolete senses, and ideally capture subtle temporal shifts within a word's meaning, rather than just the addition or removal of senses. For example, the word "horse" once referred to the primary mode of transportation but no longer holds that role in our daily lives today.

To address these challenges, approaches to representing word meanings often use a greater degree of freedom that allow for nuanced representations. Models for word meaning representation can be viewed on a continuum. At one end, Word Sense Disambiguation (WSD) models assign all instances of a word's meaning to a single sense, offering limited flexibility. At the other end, contextualized models [5] treat each instance as a unique entity, providing greater freedom but often encoding extraneous information, such as syntactic or morphological variations, which may not be relevant for tracking meaning change. WSD-based models, while precise, are often too rigid to capture subtle variations within a sense.

In recent years, research has focused on developing balanced solutions—models that are nearly as flexible as contextualized approaches but prioritize semantic characteristics over other linguistic aspects. This enables more effective modeling of contextual modulation.

One such model is XL-LEXEME [6], a bi-encoder based on SBERT [7] with a Siamese architecture and an XLM-R [8] backbone. XL-LEXEME has been trained on the Word-in-Context (WiC) [9] task to predict whether a target word has the same meaning in two given sentences (1 for the same meaning, 0 for different meanings). This is done by generating two XL-LEXEME vector representations of the word's meaning in each sentence by aggregating subword embeddings from the entire sentence. These vectors are compared using cosine similarity, and a contrastive loss function encourages higher similarity for matching meanings and lower similarity otherwise.

However, XL-LEXEME's output—cosine similarity scores between sentence pairs—lacks the interpretability needed to fully understand the processes underlying meaning change.

Recently, we have seen novel methods for modeling meaning, namely *definition generation*, where for a given target word in context, the method generates a dictionary-like definition [10, 11]. Such definition generation models produce definitions that capture the intended word meaning but may deviate from ground-truth definitions for three main reasons. First, like humans, models may express the same concept using different words, requiring mappings to the underlying sense. Second, errors such as hallucinations can compromise performance. Third, a model may generate a definition that reflects *contextual modulation.* While this is not rewarded in the evaluation of the models (where generated definitions are evaluated against dictionary definitions), it is often a desirable outcome when we want to study meaning change.

Another way to use the potential of large language models (LLMs) is by using them as computational annotators. This involves prompting instructed LLMs to interpret the meaning of a word (by solving the WiC task) in a zero-shot setting, without requiring task-specific training. For example, in [12], we compared GPT-4 with contextualized models like BERT and XL-LEXEME on tasks such as Word-in-Context (WiC), Word Sense Induction (WSI), and Lexical Semantic Change Detection (LSCD). The results demonstrate that XL-LEXEME and zero-shot GPT-4 perform comparably across all tasks, despite GPT-4 having significantly more parameters (1,000 times larger) and higher computational costs.

## 2.2. Detection of changes

The process for detecting changes in word meaning over time *typically* follows a standard pipeline, c.f. [13]:

1. Collect the occurrences of a word $w$ over time, denoted as $U_1, U_2, \ldots, U_T$, where $U_k$ represents the instances in which the word $w$ appears at time $k$.
2. Encode the uses of the word into vectors, resulting in the sequence $V_1, V_2, \ldots, V_T$, where $V_k$ represents the vectors encoding the uses of the word $w$ at time $k$.
3. Select a metric $m$ for comparing the vectors, chosen from the following options [14]:
    - **Average Pairwise Distance (APD)**: Computes and averages distances between all pairs of vectors from two time points.
    - **Prototype Distance (PRT)**: Calculates the distance between centroids (prototypes) of two time points.
    - **Cluster-based Jensen-Shannon Distance (JSD)**: Clusters data irrespective of time, computes the frequency of senses for each time period separately, treats them as probability distributions, and calculates the distance between two time points via Jensen-Shannon distance of the probability distributions.
4. Compare the vectors using the metric $m$ according to a specific strategy, e.g.
    a) Comparison with the first period: $(V_1, V_2), (V_1, V_3), \ldots, (V_1, V_T)$
    b) Comparison with the last period: $(V_1, V_T), (V_2, V_T), \ldots, (V_{T-1}, V_T)$

c) Comparison with the previous period: $(V_1, V_2), (V_2, V_3), \ldots, (V_{T-1}, V_T)$

d) Comparison within a window of size $k$: $(V_i, (V_{i-k}, V_{i+k})), (V_{i+k}, (V_i, V_{i+2k})), \ldots$

To tailor the pipeline to specific computational models, certain modifications can be introduced. For definition generation, an additional step can be inserted after step (1). First, generate definitions for each instance of word use. Then, in step 2, encode these definitions into vectors instead of the word uses themselves. For large language models (LLMs) as computational annotators, LLMs provide a semantic distance value for pairs of word uses directly. In this case, steps (1) and (2) are bypassed, and the Average Pairwise Distance (APD) is used to compute the average distances between pairs of time points.

### 2.3. Historical Word Usage Generation

The study of lexical semantic change requires large-scale, diachronic sense-annotated corpora, yet such resources are scarce due to the time, expertise, and cost involved in annotating historical texts. To overcome this barrier, Janus [15], a generative model fine-tuned on the Llama 3 8B architecture using 1,191,851 example sentences from the Oxford English Dictionary (OED), was developed. Janus generates historically accurate and sense-specific word usages for any given *word*, its *sense definition*, and a *target year* from 1700 onward. This capability enables the creation of extensive datasets for tasks such as word sense disambiguation and detecting semantic shifts over time.

Janus produces sentences that reflect the intended meaning of a word in a specific historical context. Its performance was compared to baseline models, including GPT-3.5, GPT-4o, and Llama 3 Instruct variants, across three key metrics: (i) context variability, which measures the diversity of generated sentences to ensure varied expressions of the same sense; (ii) temporal accuracy, which assesses how well the language aligns with the specified historical period (e.g., avoiding "airplane" before 1903); and (iii) semantic accuracy, which evaluates how closely the generated sentences match the provided sense definition. Janus outperforms baselines in context variability and temporal accuracy, producing diverse sentences with a root mean squared error (RMSE) of 54.75 years for historical alignment (in line with the baseline). Qualitative analysis highlights Janus's ability to emulate temporal linguistic shifts, such as the declining use of archaic pronouns like "thee" and the evolving meaning of "awful" from impressive to negative.

## 3. Hypothesis-Driven LSCD

To investigate the historical evolution of word senses, we propose a hypothesis-driven methodology. For instance, a research hypothesis might posit that the word **gene** began to be used metaphorically shortly after its establishment in the biological sciences during the 1950s, reflecting its profound influence on modern thought. Our goal is to trace the evolution of **gene** across the 20th century and identify its earliest occurrences in various senses, a task traditionally performed by experts manually examining thousands of concordances.

A conventional word sense disambiguation (WSD) system, often based on resources like WordNet [16], is limited in this context. WordNet, for example, provides only a single definition for **gene**:

> *(genetics) a segment of DNA that is involved in producing a polypeptide chain; it can include regions preceding and following the coding DNA as well as introns between the exons; it is considered a unit of heredity.*

Instead, OED contains a second sense:

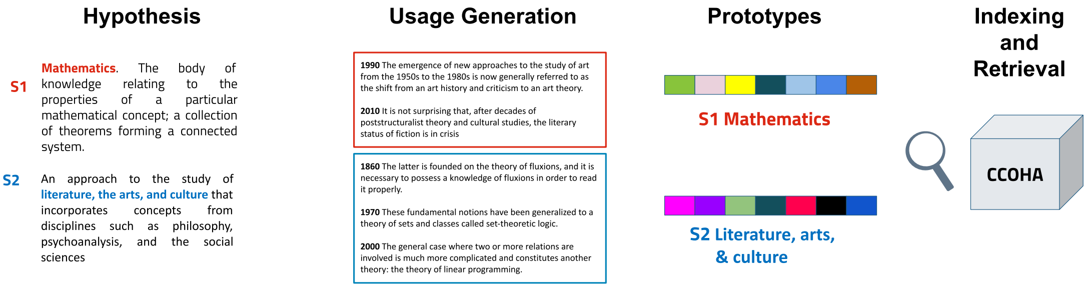
> *In figurative and extended use, esp. with reference to qualities regarded as deeply ingrained or (often humorously) as inherited. Often in plural.*

Such systems struggle with historical texts due to (i) their incompatibility with archaic language and (ii) their incomplete coverage of senses, particularly metaphorical or emerging uses. Large language model (LLM)-based models, on the other hand, offer improved sense identification but are computationally expensive and environmentally unsustainable for analyzing thousands of word occurrences in large historical corpora.

### 3.1. Our Approach

We propose a scalable, hypothesis-driven framework comprising three components: an encoder $C$, a prototyper $P$, and a comparison function $F$. This framework systematically analyzes word sense evolution by combining expert-defined sense definitions with computational techniques.

1. **Definition of Senses**: Let $S = \{s_1, s_2, \ldots, s_N\}$ represent a set of $N$ sense definitions for the target word (e.g., *gene*), crafted to align with the research hypotheses. For each sense $s_i$, we use a generative model (e.g., Janus) to produce a collection of synthetic examples, $E_i = \{e_{i_1}, e_{i_2}, \ldots, e_{i_m}\}$, representing the word's usage in that sense across the target time period.



**Mathematics**. The body of knowledge relating to the properties of a particular mathematical concept; a collection of theorems forming a connected system.

An approach to the study of **literature, the arts, and culture** that incorporates concepts from disciplines such as philosophy, psychoanalysis, and the social sciences

**1990** The emergence of new approaches to the study of art from the 1950s to the 1980s is now generally referred to as the shift from an art history and criticism to an art theory.

**2010** It is not surprising that, after decades of poststructuralist theory and cultural studies, the literary status of fiction is in crisis

**1860** The latter is founded on the theory of fluxions, and it is necessary to possess a knowledge of fluxions in order to read it properly.

**1970** These fundamental notions have been generalized to a theory of sets and classes called set-theoretic logic.

**2000** The general case where two or more relations are involved is much more complicated and constitutes another theory: the theory of linear programming.

**Figure 1:** The computational pipeline: (1) synthetic usages are generated using Janus; (2) their XL-LEXEME embeddings are average into prototypes; (3) the prototypes are used to retrieve sentences that are most similar to each prototype. Once relevant corpus data is retrieved, we apply the traditional LSC framework to them.

2. **Prototype Generation**: For each sense $s_i$, the encoder $C$ transforms the synthetic examples $E_i$ into a set of vector representations $V_i = \{C(e_{i_1}), C(e_{i_2}), \ldots, C(e_{i_m})\}$, where $C$ : text $\rightarrow \mathbb{R}^d$ maps text to a $d$-dimensional vector space. The prototyper $P$ aggregates these vectors into a single prototype vector $p_i = P(V_i)$, which encapsulates the semantic characteristics of sense $s_i$.
3. **Corpus Analysis**: Let $U = \{u_1, u_2, \ldots, u_K\}$ denote the set of actual occurrences of the target word in the historical corpus. Each occurrence $u_j$ is encoded into a vector $v_j = C(u_j)$. The comparison function $F : \mathbb{R}^d \times \mathbb{R}^d \rightarrow \mathbb{R}$ measures the similarity between each corpus vector $v_j$ and each prototype vector $p_i$. For each sense $s_i$ and time period $t$, we **identify the most relevant corpus occurrences** by ranking $F(v_j, p_i)$.
4. **Analysis and Interpretation** This approach enables experts to examine the highest-ranked sentences for each sense and time period, facilitating the identification of when a particular sense, such as a metaphorical use of *gene*, first emerged. By leveraging encoded representations and prototype-based comparisons, our method provides a scalable and systematic alternative to manual concordance analysis, while maintaining interpretability for domain experts.

# 4. Use case

In this section, we outline a comprehensive pipeline for analyzing semantic shifts in three words relevant to the history of science: *theory*, *gene*, and *force*. Our approach combines exploratory analysis using traditional Lexical Semantic Change Detection (LSCD) methods (outlined in Section 2.2) with targeted, hypothesis-driven investigations based on our novel framework.[1]

For our analysis, we sourced historical data from the Clean Corpus of Historical American English (CCOHA) [17]. To generate usage embedding representations, we utilized XL-LEXEME because of its role as the state-of-the-art model for LSCD. Sense clusters were induced from these embeddings using agglomerative clustering with a distance threshold of 0.5.

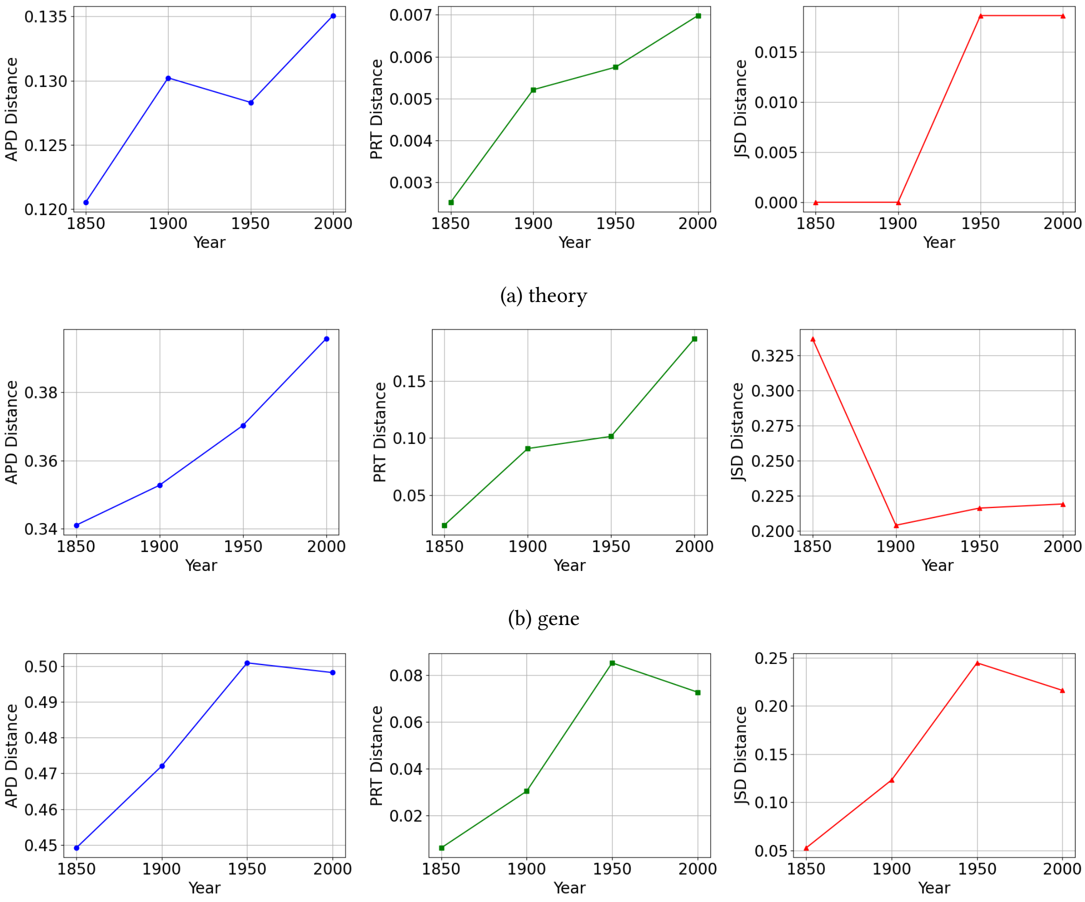
To assign semantic content to clusters and monitor semantic change, we employ LLama-Dictionary to generate context-specific definitions by selecting one representative instance for each cluster. Additionally, we use Janus to create synthetic usage examples based on predefined hypotheses and sense definitions. These examples are used to construct prototype vectors and enabling hypothesis-driven queries of the corpus.

## 4.1. LSCD Metrics

To evaluate lexical semantic change, we employed three distinct metrics—APD, PRT, and JSD—to quantify shifts in the meanings of the words *theory*, *gene*, and *force* over time, as depicted in Figure 2. These metrics were applied to vector representations generated by XL-LEXEME. For each word, we calculated the three metrics with respect to the first time point (e.g., $\langle V_1, V_t \rangle$).

**APD** The APD metric computes the average cosine distance between all pairs of vectors representing word uses from two time periods. Figure 2(a–c) illustrates that APD values for *theory* show moderate fluctuations, indicating subtle shifts in usage, while *gene* exhibits a sharp increase in APD around the 1900s, reflecting the emergence of its biological sense. Similarly, *force* displays

[1] This pipeline and these results were presented first in a keynote for the workshop Large Language Models for the History, Philosophy, and Sociology of Science.



(a) theory

(b) gene

(c) force

**Figure 2:** Semantic Change Over Time for *theory* (a), *theory* (b), and *theory* (c) using APD, PRT, and Jensen-Shannon Distance (JSD). Each subplot illustrates how the meaning of a word shifts across historical time points.

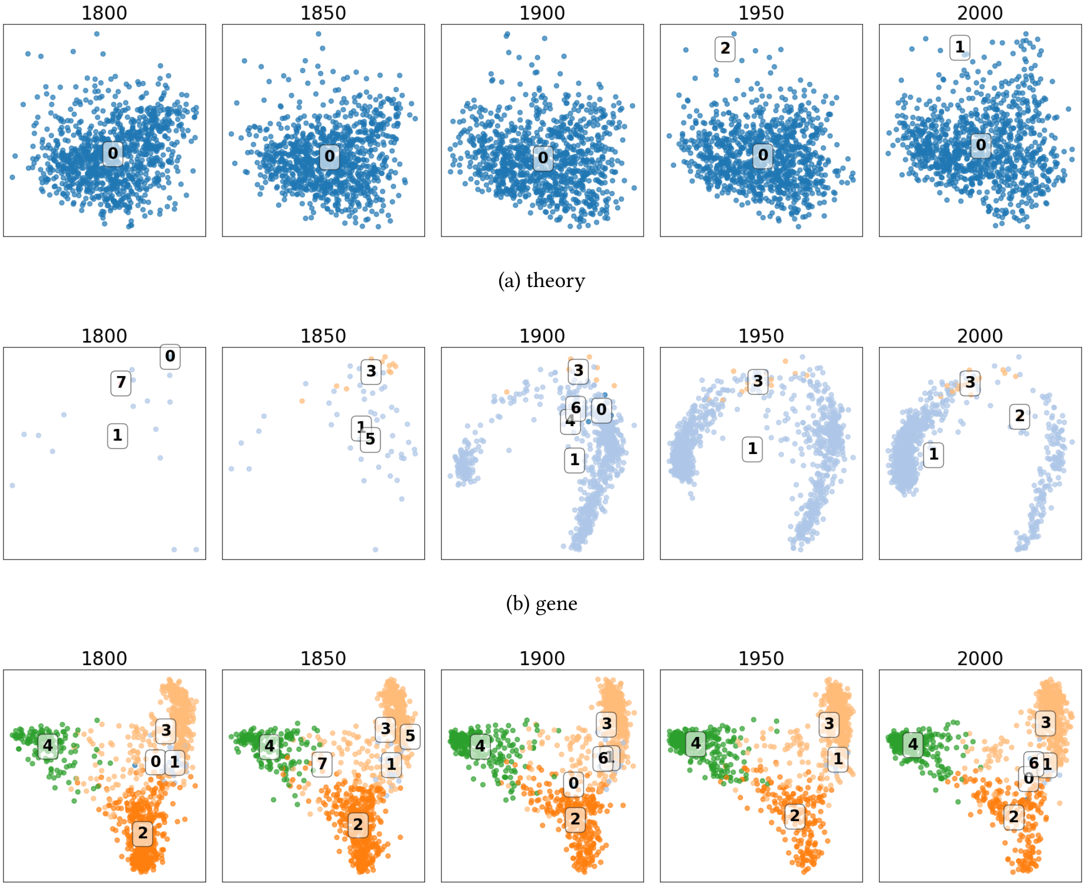
varying APD trends, with peaks corresponding to the 1950s.

**PRT** The PRT metric measures the cosine distance between centroid vectors (prototypes) of word uses at different time points. For each word, prototypes were generated by averaging the XL-LEXEME embeddings for all occurrences within a time period. Figure 2(a–c) shows that PRT distances for *gene* increase significantly post-1950, while for *theory* and *force*, PRT reveals more stable transitions.

**JSD** The JSD metric involves clustering word use embeddings (using agglomerative clustering with a distance threshold of 0.5, as shown in Figure **??**) and treating the frequency of senses as probability distributions. JSD then quantifies semantic change by computing the distance between distributions of two time periods. Figure 2(a–c) indicates that JSD captures pronounced shifts for *gene* and *force*, while for *theory* values remain relatively low. This is because only one cluster is mainly present across all time points for *theory*, with two small clusters appearing only in the final two periods.

## 4.2. Labeling Clusters with Definitions

We employed LLama-Dictionary to generate context-specific definitions for the words *force*, *theory*, and *gene*. For each word, sense clusters were induced in Section 4. A representative instance from each cluster was selected, and LLama-Dictionary generated a definition reflecting the word's meaning in that context. These definitions, presented in Table 1, provide a structured representation



(a) theory

(b) gene

(c) force

**Figure 3:** PCA Visualization of semantic clusters for the words *theory*, *gene*, and *force*, derived from CCOHA data. Each cluster represents distinct semantic interpretations or senses.

of the senses for each word.

For the word *force*, Table 1 lists seven distinct senses, ranging from physical influences (e.g., *an influence tending to change the motion of a body*) to military contexts (e.g., *a military unit engaged in a particular operation or mission*) and coercive actions (e.g., *to cause (something) to perform an action against its will or inclinations*). These definitions highlight the word's polysemy, capturing both concrete and abstract uses across historical contexts.

The word *theory* has three identified senses in Table 1: a speculative belief (*a belief that is based on speculation rather than adequate evidence*), a fashion-related sense (*a fashion theory, a style of fashion design*), and a narrative account (*a narrative account of a phenomenon, event or chain of events*). These definitions reflect the word's evolution from abstract intellectual constructs to more specific, domain-related meanings.

For *gene*, Table 1 identifies seven senses, including its modern biological meaning (e.g., *a distinct sequence of nucleotides forming part of a chromosome*) and clusters containing instances with OCR errors (e.g., *to go* or *a set of generations*).

## 4.3. Hypotesis-Driven Investigation

In our hypothesis-driven investigation, we conducted an in-depth semantic analysis of the lexical items *theory*, *force*, and *gene*. In particular, we selected word sense definitions from the OED that do not appear to emerge through the traditional pipeline. For theory, which appeared to have only one dominant sense in previous analyses, we identified two sub-senses: one relating to the arts and another to mathematics. For force, we chose the specific sense associated with physics, while for gene,

| Word | Cluster Definition |
|---|---|
| **Force** | **0** A body of water or air moving under the influence of a force; **1** To cause (something) to perform an action against its will or inclination; **2** An influence tending to change the motion of a body or produce motion or stress in a stationary body; **3** To put out a runner by requiring him to run; **4** A military unit engaged in a particular operation or mission; **5** To advance or mature by natural or inevitable progression; **6** To cause (a result) by the exertion of force; **7** An army. |
| **Theory** | **0** A belief that is based on speculation rather than adequate evidence as to its truth; **1** A fashion theory, a style of fashion design; **2** A narrative account of a phenomenon, event or chain of events. |
| **Gene** | **0** To go; **1** A distinct sequence of nucleotides forming part of a chromosome, the order of which determines the order of monomers in a polypeptide or nucleic acid molecule which a cell (or virus) may synthesize; **2** A unit of heredity which is transferred from a parent to offspring and is held to determine some characteristic of the offspring; **3** A set of genetic instructions; **4** A set or class; **5** A name, especially a shortened name; **6** A set of people descended from a common ancestor; **7** A set of generations. |

**Table 1**
Definitions of semantic clusters for the words *force*, *theory*, and *gene*. For each cluster, one representative instance was selected, and LLama-Dictionary was used to produce a context-specific definition reflecting the word's meaning in that instance.

we focused on the metaphorical sense referring to inherited traits. Table 2 illustrates representative sentences from historical periods for each targeted sense, along with corresponding similarity scores.

For *theory*, we identified clear semantic distinctions between its mathematical and arts-related conceptualizations. The mathematical sense consistently emphasizes structured systems of knowledge or deduction, notably stable across historical contexts with high similarity scores (ranging from 0.9632 in 1850 to 0.9835 in 1950). Conversely, the artistic sense of *theory* reflects broader cultural and philosophical applications, maintaining moderate similarity scores (around 0.96) but allowing variations tied to aesthetics and criticism.

The physical sense of *force* remains remarkably stable and contextually consistent, as evidenced by similarity scores consistently exceeding 0.96 across time periods.

Applying the same methodology to *gene*, specifically focusing on its metaphorical sense, clarified the earlier observed anomaly. Early instances from the 1800s were OCR errors (e.g., "genie rose," "genie really"). Genuine metaphorical usage of "gene" emerged gradually, with similarity values steadily increasing until the metaphorical sense became clearly established around the 2000s.

The hypothesis-driven investigation provides significant precision and interpretability advantages over the traditional lexical semantic change detection pipeline. By explicitly defining and targeting specific subsenses, such as distinguishing between the mathematical and artistic senses of *theory*, identifying the metaphorical usage of *gene*, and isolating the physical meaning of *force*, our method captures semantic differences that previously remained hidden within broader senses. Moreover, by directly analyzing real corpus sentences from the CCOHA dataset, experts gain improved control over the interpretation and validation of results.

## 5. Conclusion

In this work, we introduced a hypothesis-driven framework for detecting lexical semantic change. By integrating expert-defined sense definitions with SOTA computational models like XL-LEXEME and Janus, our framework systematically traces the evolution of word meanings across historical corpora. Starting with a word and its senses (or only the ones that we want to study), we utilize the strength of LLMs to allow for easy investigation into relevant corpus data. The method is not limited in terms of data it can be applied to, thus the user can choose the data of interest, and limit to the relevant senses. We envision that the researcher can also define senses of interest, rather than using those listed in dictionaries, for example by adding connotational information. This would allow for the investigation of when word sense e.g., became more positive in meaning.

The proposed hypothesis-driven framework offers a robust methodology for accurately detecting and analyzing lexical semantic changes in historical texts. By integrating predefined hypotheses, generative language models, and vector encoding techniques, our approach not only results interpretable for domain experts but also systematically scales to large historical corpora. The case studies on words like "theory," "gene," and "force" illustrate the framework's capability to reveal significant shifts in meaning, particularly those reflective of cultural and scientific developments.

# Balancing Translation Quality and Environmental Impact: Comparing Large and Small Language Models

Antonio Castaldo[1,2,†], Petra Giommarelli[1,2,†] and Johanna Monti[2]

[1]University of Pisa, Largo Bruno Pontecorvo, 3, 56127 Pisa, Italy
[2]University of Naples L'Orientale, Via Chiatamone, 61/62, 80121 Naples, Italy

**Abstract**

Large Language Models (LLMs) have demonstrated remarkable performance in machine translation (MT), specifically concerning high-resource European languages. However, their extensive computational requirements raise sustainability concerns. This paper investigates the potential of smaller, fine-tuned language models as a more sustainable alternative for MT tasks. We conduct a comparative analysis of model performance in terms of translation quality and $CO_2$eq emissions, and examine the key errors associated with using smaller models. Furthermore, we propose a novel metric that balances translation quality against environmental impact, aiming to inform more sustainable model selection in MT research and practice.

**Keywords**

machine translation, large language models, sustainability

## 1. Introduction

MT has been a core topic in natural language processing (NLP) for several decades, evolving from rule-based systems to statistical methods, and more recently to neural machine translation (NMT) and transformer-based models. The emergence of LLMs has significantly advanced the state-of-the-art in MT, demonstrating remarkable performance on various NLP tasks [1].

Their ability to generate fluent, context-aware translations in different domains has positioned LLMs at the forefront of MT research [2]. Their ability to model context, semantics, and discourse phenomena makes them highly attractive for both academic and industrial translation applications.

However, this performance comes at a significant environmental cost. Training and deploying LLMs consumes enormous computational resources, leading to considerable carbon emissions and infrastructure demands [3, 4]. These challenges have prompted the exploration of more sustainable alternatives.

This paper investigates whether smaller language models can serve as efficient and environmentally sustainable valid alternatives to LLMs in MT. Specifically, we will fine-tune the Gemma-3-4B[5] model on a parallel English-Italian (EN-IT) parallel corpus, and evaluate its performance, with human and automatic evaluation, against larger models. This setup allows us to assess the real-world viability of small models for machine translation when fine-tuned for specific language pairs and domains.

We conduct a comprehensive analysis of model performance, in terms of translation quality and $CO_2$eq emissions, validating our results with a human evaluation of the key errors associated with each model. Finally, we introduce a metric called Carbon-Adjusted Quality Score (CAQS), designed to facilitate sustainable model selection, that quantifies the trade-off between translation quality and sustainability.

## 2. Background

### 2.1. LLMs and Translation

LLMs have achieved state-of-the-art results in MT, by leveraging extensive pretraining on multilingual corpora, enabling them to deliver remarkable performance across a wide range of domains and language pairs [6]. In contrast to NMT systems, which rely primarily on parallel corpora, LLMs are pretrained on massive web-scale monolingual and multilingual datasets. This enables them to generate high-quality translations even in domains where parallel data is limited [7].

Notably, GPT-based models excel at producing contextually accurate translations, effectively capturing discourse relations and maintaining sentence-level coherence. They consistently outperform encoder-decoder architectures such as Transformer-big and M2M100, particularly in zero-shot and few-shot settings [8].

Moreover, LLMs support document-level translation by leveraging discourse-aware context windows, which enable the maintenance of lexical cohesion and consistent

resolution of anaphoric references across sentences [9]. This capability results in more fluent translations, making LLMs increasingly favored in professional translation settings.

The adoption of LLMs, however, requires substantial computational resources and infrastructure, which may not be feasible for all organizations or languages. Beyond these practical limitations, the widespread adoption of LLMs also raises significant concerns about their environmental sustainability.

### 2.2. LLMs Sustainability

While Large Language Models (LLMs) have enabled remarkable progress in NLP, their growing environmental footprint raises important sustainability concerns. Training large-scale models such as GPT-3, with hundreds of billions of parameters, can consume up to 1.3 GWh of electricity, comparable to the yearly energy usage of more than 100 US homes [10]. This results in hundreds of tons of $CO_2$ emissions, depending on the carbon intensity of the power grid.

In addition to training, the inference phase of LLMs also significantly contributes to their overall carbon footprint, particularly in large-scale deployments. While the energy cost of a single inference is lower than that of training, the cumulative emissions can become substantial depending on usage patterns. For example, serving a single ChatGPT prompt may emit over 4g of $CO_2$eq, more than 20 times the emissions of a typical web search [11].

The same study emphasizes that total environmental impact depends on a combination of factors: model size, batch size, and hardware type. The latter reflects the impact of producing high-performance GPUs, which involves substantial embodied carbon emissions. Although these emissions occur at production time, they contribute to the model's overall environmental cost throughout its operational lifetime.

### 2.3. Small Language Models

Recent research has emphasized the growing feasibility and importance of SLMs as efficient alternatives to LLMs in constrained environments [12, 13]. SLMs, typically ranging from hundreds of millions to a few billion parameters, are substantially more resource-efficient and accessible, especially when tailored to specific tasks.

SLMs benefit from architectural simplifications, such as compact tokenizers and reduced model width and depth, which are optimized to preserve key capabilities while minimizing parameter overhead [14]. Small models, like Gemma [15] and PanGu-$\pi$-1.5B Pro model with only a few billion parameters have recently outperformed much larger models on several benchmarks due to optimizations in model architecture and training strategy [14].

Moreover, recent studies show that even highly complex capabilities like multi-step reasoning, previously thought to emerge only in models over 100B parameters, can be acquired by SLMs through targeted fine-tuning and distillation. Distilling chain-of-thought reasoning abilities, for instance, from GPT-3.5 into FlanT5 variants (250M to 3B) resulted in significant performance improvements on math reasoning tasks without the need for full retraining of the model's weights [16].

A comprehensive survey of SLMs underscores the value of model compression techniques such as pruning, quantization, and knowledge distillation. These enable the deployment of efficient models on mobile and edge devices while maintaining competitive accuracy for many tasks [17]. The adoption of SLMs is particularly promising for democratizing NLP, enabling smaller institutions and low-resource languages to benefit from modern AI without the environmental or infrastructural burden of LLMs.

In this study, we evaluate whether SLMs, when combined with modern fine-tuning strategies and lightweight architectures, could offer a pragmatic and sustainable path forward for machine translation and other NLP applications.

## 3. Fine-tuning a SLM

To demonstrate the effectiveness of using SLMs as sustainable alternatives to larger, more resource-intensive models in machine translation, we compare two state-of-the-art models: GPT-4o-mini [18] and an open-source model, Gemma-3-4B [15], which is significantly smaller than its OpenAI counterpart.

We fine-tune Gemma-3-4B on a carefully curated subset of the OpenSubtitles corpus, obtained from the Opus Corpus [19]. We evaluate both models on a held-out test set of 400 segments for the English–Italian (EN-IT) language pair and present our findings.

### 3.1. Dataset Curation

For our experiments, we focused on the EN–IT subset of the OpenSubtitles corpus, made available through the Opus Corpus repository. While OpenSubtitles is a rich resource for dialogue-based translation data, it also contains a considerable amount of noise due to its automatic extraction and alignment process. Therefore, careful curation was necessary to ensure the quality and relevance of the dataset.

We began by removing duplicate entries and any empty lines. Following this, we applied the `langdetect` [20] tool to verify the language of each sentence. This step was essential, as web-crawled corpora, although intended to be language-specific, occasionally contain segments in other languages. Sentences detected to be in languages outside our target pair, and that could not be classified with a high confidence score, were filtered out.

Finally, we applied COMET-QE [21], a quality estimation model, to score the remaining sentence pairs. Using these scores, we selected the top 100,000 highest-quality translations for use in our fine-tuning experiments. The strategy of mining large datasets and selecting top-k sentence pairs based on quality metrics for fine-tuning helps to further filter out noisy segments and ensures that the limited available data contribute maximally to model training [22]. This approach is consistent with our goal of reducing computational costs. By carefully curating a smaller but higher-quality dataset, we limit energy consumption and the associated environmental costs, while maximizing translation performance.

**Table 1**
Corpus size after each curation step.

| Step | Pairs Remaining |
|---|---:|
| Original Dataset | 50,000,000 |
| Training Set | 100,000 |
| Test Set | 400 |

## 3.2. Training

The Gemma-3-4B model was fine-tuned for three epochs using Low-Rank Adaptation (LoRA) [23], a fine-tuning technique which injects small trainable matrices in the model's weights. The adoption of LoRA for fine-tuning has shown strong empirical results in machine translation [24, 25], enhancing efficiency, while reducing training time and computational costs. As demonstrated in experiments conducted by [26], fine-tuning with LoRA obtained the same improvements in terms of BLEU score [27], while drastically reducing training time and modifying only a small number of trainable parameters, with respect to supervised fine-tuning involving all parameters of the original network. In our case, we train effectively 0.42% of the trainable parameters, corresponding to the LoRA adapter matrices injected in Gemma-3-4B.

Our fine-tuning pipeline was implemented using the Hugging Face Transformers library [28], leveraging its integration with the PEFT library. For the LoRA configuration, we set the rank (`r`) to 16 and the scaling factor (`alpha`) to 16, with a dropout rate of 0.05 to improve generalization. The training was carried out on a single NVIDIA A100 GPU using mixed-precision (fp16) computation. We used the `CodeCarbon`[1] library to monitor the environmental impact of our training process.

CodeCarbon is a Python library that estimates carbon emissions by tracking the energy consumption of computing resources (CPU, GPU, RAM) during code execution and combining this data with the carbon intensity of the electricity grid based on geographic location.

The fine-tuning session consumed approximately **0.65 kWh**, resulting in an estimated **162 g $CO_2$eq** under an average EU grid intensity of 250 g$CO_2$/kWh.

## 3.3. Gemma-3 Evaluation

We conduct our evaluation on a held-out test set of 400 segments from the same corpus, ensuring no overlap with the training data. Table 2 reports the evaluation of EN–IT translation performance for Gemma-3-4B before and after LoRA fine-tuning, using BLEU [27], chrF [29], and COMET [30] as quality metrics. Our fine-tuned Gemma-3-4B model, with only 0.42% of additional trainable parameters, shows a notable improvement over the base version, achieving a +4 point gain in BLEU, a modest increase in chrF, and a +1 point gain in COMET. These results place our model on par with GPT-4o in COMET and above GPT-4o-mini in all three metrics.

In addition to performance, we also measure the environmental impact of inference using the CodeCarbon library. The estimated carbon emissions per inference for the fine-tuned model are approximately 0.028g $CO_2$eq, twice that of the base model, but significantly lower than GPT-4o models, each exceeding 0.42g per inference as estimated in a relevant study [31].

Our evaluation demonstrates that fine-tuning Gemma-3-4B with LoRA leads to competitive performance gains with low additional environmental cost.

# 4. Quality-Sustainability Trade-Off

In our second experiment, to further assess the viability of trading off quality for sustainability with the use of SLMs, we extend our evaluation on a set of multilingual LMs, of different parameter sizes. We select the models for our evaluation based on state-of-the-art performance and usage in the research community. We benchmark each model on the same held-out EN–IT test set, using BLEU, chrF and COMET, and log the $CO_2$eq emissions per inference using the CodeCarbon framework. Importantly, we emphasize in our approach that a sustainable model choice should not be based on its parameter size alone, but actual carbon emissions.

As shown in Table 3, we highlight that the relationship between model size and emissions is **non-linear**. For instance, Qwen-3B [32], despite its relatively small size, exhibits disproportionately high emissions. This can be attributed to its reasoning behavior during inference,

[1] https://mlco2.github.io/codecarbon/index.html

**Table 2**
Evaluation of EN–IT translation performance for Gemma-3-4B before and after LoRA fine-tuning. Metrics include BLEU, chrF, and WMT22 COMET-DA. We also report estimated $CO_2$eq emissions per inference.

| Model | BLEU | chrF | COMET | $CO_2$eq (g) |
|---|---|---|---|---|
| Gemma-3-4B (Base) | 46.0 | 69.0 | 93.0 | 0.014 |
| Gemma-3-4B (Ours) | 50.0 | 72.0 | **94.0** | 0.028 |
| GPT-4o-mini | 49.0 | 71.0 | 92.0 | *>0.42* |
| GPT-4o | 52.0 | 73.0 | **94.0** | *>0.42* |

which results in extended reasoning outputs before generating a final answer. This behavior increases inference latency and environmental cost.

Similarly, the assumption that larger models necessarily produces more carbon emissions does not always hold. This is the case for models developed with a Mixture-of-Experts (MoE) architectures. In these models, only a subset of the total parameters is activated during inference. As a result, MoE models like Mixtral, although large in aggregate size, can have lower or comparable emissions to smaller, densely activated models. This decoupling of parameter size and runtime efficiency highlights the need for measuring more empirical results, such as $CO_2$eq emissions.

Therefore, we introduce a **Carbon-Adjusted Quality Score** (CAQS) metric as a measure of model cost-effectiveness, and we calculate it on each corpus translation generated by the models evaluated in our study. Our CAQS score penalizes each gram of carbon emissions exponentially, while ensuring that low-quality models are not rewarded more than high-quality ones, regardless of their efficiency. We define the CAQS metric as follows.

$$\text{CAQS} = \text{avg}(\text{METRICS}) \times \exp(-\lambda \times \text{CO}_2\text{eq}) \quad (1)$$

Here, $\lambda$ is a sensitivity parameter that controls the strength of the carbon penalty and can be adjusted according to the user's desired trade-off between quality and sustainability. The exponential penalty function reflects the urgent need for sustainable AI, where a single increase in emissions becomes increasingly problematic. In our experiment, we use $\lambda = 2$ and provide ranking for interpretability.

Table 3 shows that Gemma-3-4B and Magistral-Small [33] rank first according to our metric, while larger and slighly superior models, like Llama-3.3-70B [34], are strongly penalised due to their high emissions. Similarly, we find that low-quality models, like Phi-2 [35] and Llama-3.2-1B are not exceedingly rewarded.

We emphasize the need for sustainable model choices in both industrial and academic settings, and recommend the adoption of a standardized approach: measuring $CO_2$eq emission using CodeCarbon or similar tools on a representative sample of the target corpus, then calculating a carbon-adjusted score that considers both translation quality and sustainability.

## 5. Error Analysis

To complement the quantitative results and better understand the practical implications of the quality-sustainability trade-off, we conduct a manual error analysis on the translations generated by four representative models: our fine-tuned version of Gemma-3-4B, and the baseline instruction-tuned Gemma-3-27B, Llama-3.2-3B and Llama-3.3-70B.

**Annotation Process.** We conducted our error analysis following the MQM framework [36], with two annotators who were native speakers of the target language, proficient in English, and with expertise in translation studies. The annotators applied a set of MQM categories: accuracy, fluency, style, locale conventions, and verity, along with their respective subcategories. Errors were rated using four severity levels: trivial, minor, major, and critical, corresponding to weights of 0, 1, 5, and 25, respectively.

After annotating 10% of the dataset, inter-annotator agreement (IAA) was calculated to ensure the reliability of the annotations. The initial agreement, measured with Cohen's Kappa, was equal to $K = 0.28$, due to disagreements primarily on the severity levels to assign, rather than the identification of the error categories themselves. Following a collaborative resolution process, we refined the annotation guidelines and calculated agreement on the final annotations, reaching a Cohen's Kappa equal to $K = 0.53$. The annotators proceeded separately and annotated the translations generated by two models each.

**Annotation Results.** The results, displayed in Table 4 indicate that Gemma-3-27B, the largest model in the Gemma family, produced the fewest overall errors, with only one major error and 8 minor ones. In the context of our study, minor errors were defined as those that do not significantly alter the meaning expressed by the source text. Interestingly, we find that Gemma-3-4B demonstrates comparable performance to the much

**Table 3**
Comparison of translation quality and $CO_2eq$ emissions per inference for various multilingual models on the EN–IT test set. Models are sorted and ranked by CAQS, where higher CAQS values indicate better effciency.

| Model | Params (B) | BLEU | chrF | COMET | $CO_2$eq (g) | CAQS | Rank |
|---|---|---|---|---|---|---|---|
| Gemma-3-4B | 4.0 | 50.0 | 72.0 | 94.0 | 0.028 | 68.08 | **1** |
| Magistral-Small | 7.0 | 48.6 | 70.2 | 92.7 | 0.053 | 63.41 | 2 |
| Llama-3.2-3B | 3.0 | 37.4 | 62.6 | 90.0 | 0.019 | 60.97 | 3 |
| Gemma-3-27B | 27.0 | 49.3 | 72.8 | 93.9 | 0.112 | 57.42 | 4 |
| Llama-3.3-70B | 70.0 | 49.5 | 71.3 | 93.6 | 0.115 | 56.78 | 5 |
| Llama-3.2-1B | 1.0 | 19.8 | 46.0 | 76.5 | 0.005 | 46.96 | 6 |
| Phi-2 | 2.7 | 6.8 | 32.1 | 49.5 | 0.015 | 28.60 | 7 |
| Qwen-3B | 3.0 | 40.3 | 65.2 | 92.4 | 0.503 | 24.12 | 8 |

**Table 4**
Error severity distribution across models. The final score represents the weighted sum of all errors.

| Model | Critical | Major | Minor | Score |
|---|---|---|---|---|
| Gemma-3-27B | 0 | 1 | 8 | 13 |
| Llama-3.3-70B | 0 | 3 | 29 | 44 |
| Gemma-3-4B | 0 | 4 | 29 | 49 |
| Llama-3.2-3B | 1 | 28 | 56 | 221 |

larger and environmentally demanding model, Llama-3.3-70B. In terms of weighted scores, both models show similar results, with very few major errors and a comparable number of minor ones. The smallest Llama checkpoint presents a very high number of both major and minor errors, when compared to the Gemma-3-4B model. The findings may suggest that Llama-3's architecture is suboptimal for translation tasks across model sizes, given that Gemma-3-4B matches the performance of its largest checkpoint. However, the results should be interpreted with caution, as our evaluation was limited to a small test set and a single language pair.

In terms of error category distribution increasing parameter size leads to an overall performance improvement, as seen in Table 5. This trend is particularly evident within the Gemma models, where the jump from 4B to 27B parameters results in a significant drop in errors across all categories. In contrast, Llama-3.2 models exhibit a less linear improvement, suggesting diminishing returns from scaling model size. This observation, however, is limited by the fact that only the smallest Gemma model was LoRA-adapted, while the LLaMA models were evaluated in their original form. A more rigorous comparison, involving both original and adapted versions across model sizes, is left for future work.

When comparing Gemma-3-4B and Llama-3.3-70B, we find that most of the errors in the Gemma model are concentrated in surface-level issues, especially in spelling diacritics. These errors, however, do not compromise the overall understandability of the output. In contrast, Llama-3.3-70B displays fewer fluency issues but a higher number of style-related errors, including two rated as major. These style errors typically result in translations that sounds unnatural or awkward for a target-language speaker, thereby reducing the overall quality of the translation.

## 6. Conclusions

In this study, we investigated the potential of SLMs as sustainable alternatives to LLMs, for MT tasks focusing on the EN-IT language pair. Our results demonstrate that parameter-efficient fine-tuning of SLMs can achieve competitive translation quality while dramatically reducing environmental impact. The fine-tuned Gemma-3-4B model achieved performance comparable to GPT-4o and outperformed GPT-4o-mini across all metrics, while consuming approximately 15 times less energy per inference.

We complement these results with a MQM human evaluation across a set of representative models, confirming that Gemma-3-4B performed comparably to the much larger Llama-3.3-70B, producing only minor fluency and spelling errors.

We also highlighted that the relationship between model size and carbon emissions is non-linear and highly dependent on architectural choices, emphasizing the need for accurate measurements of carbon emissions.

Given the non-linear relation between model size and environmental impact, we introduced the CAQS, a novel metric specifically designed to facilitate sustainable model selection by integrating translation quality and carbon emissions. CAQS includes a sensitivity parameter that allows users to adjust how strongly quality is penalized by the model's carbon footprint. According to this metric, Gemma-3-4B and Magistral-Small emerged as the most efficient models in our study, offering optimal trade-offs between sustainability and translation quality.

**Table 5**
MQM error category breakdown per 100 segments for each model.

| Model | Accuracy | Fluency | Style | Others | Total |
|---|---|---|---|---|---|
| Gemma-3-4B | 10 | 17 | 6 | 0 | 33 |
| Gemma-3-27B | 7 | 1 | 1 | 0 | 9 |
| Llama-3.2-3B | 40 | 16 | 29 | 0 | 85 |
| Llama-3.3-70B | 8 | 9 | 15 | 0 | 32 |

# 7. Limitations

In light of practical constraints related to time and resources, the main limitations of our study lie in the relatively small sample of segments and the domain-specific nature of the OpenSubtitles corpus, used for both training and inference. For this reason, we highlight that our evaluation results may not be reproducible in other domains.

As our evaluation focuses on a relatively high-resource language pair (EN-IT), our findings may not be applicable for distant or low-resource pairs. Finally, our carbon emission measurements are specific to the computational infrastructure used (NVIDIA A100 GPUs, EU electricity grid). Results may differ when deploying models on different hardware configurations, cloud providers, or geographical regions.

# On the Impact of Hate Speech Synthetic Data on Model Fairness

Camilla Casula[1], Sara Tonelli[1]

[1]Fondazione Bruno Kessler, Trento, Italy

**Abstract**

Although attention has been devoted to the issue of online hate speech, some phenomena, such as ableism or ageism, are scarcely represented by existing datasets and case studies. This can lead to hate speech detection systems that do not perform well on underrepresented identity groups. Given the unprecedented capabilities of LLMs in producing high-quality data, we investigate the possibility of augmenting existing data with generative language models, reducing target imbalance. We experiment with augmenting 1,000 posts from the Measuring Hate Speech corpus, an English dataset annotated with target identity information, adding around 30,000 synthetic examples using both simple data augmentation methods and different types of generative models, comparing autoregressive and sequence-to-sequence approaches. We focus our evaluation on the performance of models on different identity groups, finding that performance can differ greatly for different targets and "simpler" data augmentation approaches can improve classification better than state-of-the-art language models.

hate speech detection, synthetic data, model fairness, hate speech target

## 1. Introduction

Generic hate speech detection models can nowadays achieve high performance on benchmark datasets, especially for high-resource languages [1]. However, these models can still present a number of issues and weaknesses. In particular, the creation and maintenance of corpora for this task can be problematic due to the relative scarcity of hateful data online [2], the negative psychological impact on annotators [3], dataset decay and therefore reproducibility of results [4], and more.

Hate speech detection models have also been found to often have a tendency to over-rely on specific identity terms, in particular minority group mentions and other identity-related terms [5, 6, 7]. Another issue with existing datasets and systems for this task is related to the representation of identity groups that are targets of hate, which is rather unbalanced. For example, misogyny has been covered in several datasets [8, 9], while other phenomena have received much less attention, such as religious hate [10] or hate against LGBTQIA+ people [11, 12, 13]. Furthermore, phenomena such as ageism and ableism have only been marginally addressed, as shown in the survey by Yu et al. [14]. This disparity affects in turn system fairness, because offenses against less-represented targets will be classified with a lower accuracy, further impacting communities that are already marginalized [15]. By *fairness*, in this work we mean group fairness, which implies independence between model classification outputs and sensitive attributes [16].

A potential solution that has been proposed for many of the issues with hate speech detection data is the creation of synthetic data [17]. Indeed, recent research has shown it to be a promising solution [18, 19, 20, 21], albeit with mixed results [22, 23]. However, no in-depth analysis of the effects of data augmentation (DA) for less represented hate speech targets has been carried out, while it could be beneficial not only to make systems more accurate and robust, but also *fairer*, with comparable performance on hate speech targeting different demographic groups [16]. Another aspect we investigate in this work is a comparison between recent generative language models and more traditional approaches to data augmentation with regards to hate speech detection, since increasing the amount of training data with synthetic examples has been successfully exploited well before the advent of generative large language models, and can lead to improvements although these methods have a much lower computational cost [24].

In this work, we therefore address the following research questions:

**(Q1)** What is the impact of data augmentation on model performance for specific target identities?

**(Q2)** Can information about identity groups in the generation process help the creation of better and more representative synthetic examples?

**(Q3)** Can certain data augmentation setups enhance the performance of models on underrepresented targets, therefore improving their fairness by reducing differences in performance across different identity groups?

We aim at answering these questions through a set of experiments in which we focus on the performance of

*CLiC-it 2025: Eleventh Italian Conference on Computational Linguistics, September 24 — 26, 2025, Cagliari, Italy*

ccasula@fbk.eu (C. Casula); satonelli@fbk.eu (S. Tonelli)

models by target identity. In addition, we introduce two novel elements compared to previous work on generative DA: *(i)* we experiment with setups in which we exploit target identity information during generation, attempting to increase the relative representation of scarcely represented targets, with the aim of positively impacting model fairness, and *(ii)* we experiment with instruction-finetuned large language models (LLMs), which have recently been shown to be able to improve downstream task performance [25]. We also further investigate potential fairness-related weaknesses of models using the HateCheck test suite [7] combined with a manual analysis of generated examples.

## 2. Background

The field of hateful content detection has gained a large amount of traction in recent years, with increased effort from the research community in establishing common guidelines and benchmarks (e.g. Basile et al. [26], Zampieri et al. [27]) across different languages and targets of hate [28, 29, 11, 30].

A potential way that has been proposed to mitigate some of the issues with hate speech datasets, such as data scarcity [2] and negative psychological impact on annotators [3], is data augmentation, which could also benefit the performance of hate speech detection systems. Data augmentation refers to a family of approaches aimed at increasing the diversity of training data without collecting new samples [31]. While DA is widely used to make models more robust across many machine learning applications, it has not been as frequently adopted or researched in NLP [32, 33] until recently, with LLMs that are capable of generating realistic text [34, 35].

DA for the detection of hate speech has recently been explored using generative LLMs: Juuti et al. [36] use GPT-2 [37] to augment toxic language data in extremely low-resource scenarios. Similarly, Wullach et al. [18] and D'Sa et al. [19] successfully augment toxic language datasets using GPT-2. Fanton et al. [38] combine GPT-2 and human validation to create counter-narratives that cover multiple hate targets. More recently, Ocampo et al. [39] have applied data augmentation to increase the number of instances for the minority class in implicit and subtle examples of hate speech. Casula and Tonelli [22] show that generative data augmentation for hate speech detection using GPT-2 is in some cases challenged by a simple oversampling baseline, while Casula et al. [23] analyse the qualitative differences between original and paraphrased hate speech data. Finally, Hartvigsen et al. [20] use manually curated (through a human-in-the-loop process) prompts to generate implicitly hateful sequences with GPT-3 [40].

To our knowledge, no dedicated analyses have been carried out on the impact data augmentation can have on the performance of models for specific targets of hate, or into the exploitation of target identity information to potentially improve fully automated data augmentation processes.

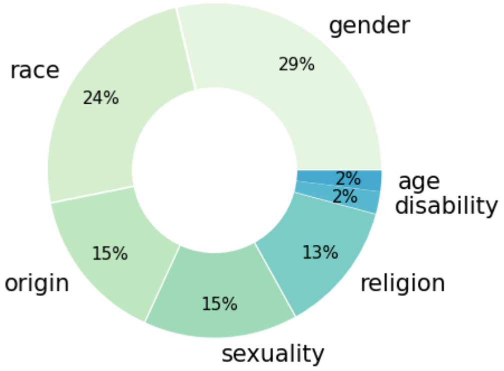

**Figure 1:** Identity group distribution in the MHS corpus.

## 3. Data

For our experiments, we use the Measuring Hate Speech (MHS) Corpus [41, 42], a dataset consisting of social media posts in English from three social media platforms (Reddit, Twitter, and YouTube). While the corpus is meant to capture different levels of hatefulness on a scale, it also includes binary hate speech labels for benchmarking purposes, which we use in our experiments.

The MHS corpus features labels regarding the binary identification of pre-specified identity groups and subgroups in texts. Importantly, this annotation is present regardless of hatefulness, resulting in target annotations even for posts containing supportive or counter-speech. In the MHS dataset [1] we find annotations for seven target identity groups: *race*, *religion*, *origin*, *gender*, *sexuality*, *age*, and *disability*. Their distribution in the data can be seen in Figure 1, which shows how the most widely studied targets of hate speech, *race* and *gender*, are also the most widely represented in the MHS corpus.

Given that the MHS corpus uses disaggregated annotations, we aggregate them so that each example has a unique label and set of targets. First, we consider each example to be about or targeting all the identity groups identified by at least half of the annotators who annotated it. Since the hatespeech label in the dataset can assume three values (0: *non hateful*, 1: *unclear*, 2: *hateful*), we binarize these by averaging all the annotations for

[1] https://huggingface.co/datasets/ucberkeley-dlab/measuring-hate-speech

a given post, mapping it to *hateful* if the average score is higher than 1 and to *non hateful* if it is lower.[2] After this process, we are left with 35,243 annotated posts, of which 9,046 are annotated as containing hate speech.

# 4. Methodology

For our experiments, we compare different generation strategies to train hate speech detection models of different sizes, aiming at assessing the impact of data augmentation based on language models on specific target identities. In order to do this, we evaluate both decoder-only and encoder-decoder models, experimenting also with their instruction-tuned counterparts. Additionally, we experiment with the inclusion of target identity information in the prompts, with the assumption that this information might lead to more varied and representative generated texts. We then use two different methods of exploiting existing information and data to generate new sequences: finetuning and few-shot prompting.

## 4.1. Generative Models

While most of the work on generation-based data augmentation for this task focuses on decoder-only Transformer models [22], other works have shown encoder-decoder Transformers to be potentially effective as well [43]. Since no work has been carried out on comparing decoder-only with encoder-decoder models for this type of data augmentation, we experiment with both. Then, based on work showing how instruction-tuning can improve generalization to unseen tasks [25, 44], we aim at experimenting also with instruction-finetuned models.

To favor reproducibility, we choose to only use openly available models for our experiments. We employ Llama 3.1 8B in its base and *Instruct* versions [45], OPT in its base and IML (instruction-tuned) versions [46] and T5 in its base and FLAN (instruction-tuned) versions [47, 44]. We use the 1.3B parameter version of OPT and OPT-IML and the Large version of T5 and Flan-T5 (770M), aiming at capturing in our analyses the effects of this kind of methodology with different model sizes.

## 4.2. Target Identity Information

In addition to performing DA with different types of models and techniques, we investigate for the first time the possibility of including target identity information both when finetuning models and when prompting them, with the hypothesis that the inclusion of this kind of information might help in generating more varied data with regards to identity group mentions for both hateful and non-hateful messages. By generating target-specific examples also for the non-hateful class, we ideally aim at implicitly contrasting identity term bias. In order to do this, we encode target identity information into the prompts given to the models in various ways.

## 4.3. Finetuning vs Few-Shot Prompting

A large number of works on data augmentation based on generative models rely on finetuning a model on a small set of gold data, and then generating new data with the finetuned model, encoding the label information within the text sequences in some form (e.g. Anaby-Tavor et al. [34], Kumar et al. [35]). Other works use few-shot demonstration-based prompting, in which the pretrained model is prompted with one or more sequences similar to what the model is expected to generate, with no finetuning (e.g. Hartvigsen et al. [20], Azam et al. [43], Ashida and Komachi [48]). We experiment with both strategies.

**Finetuning (FT)** For finetuning, we follow an approach similar to that of Anaby-Tavor et al. [34], in which a generative LLM is finetuned on annotated sequences that are concatenated with labels. At generation time, the desired label information is fed into the model, and the model is expected to generate a sequence belonging to the specified class. We discuss the details of the formatting of the label information in Section 4.4.

This method has the upside of theoretically being more likely to generate examples that are closer to the original distribution of the data to be augmented. However, this can also be a downside, if the desired effect is increasing the variety of the data. In addition, finetuning is more computationally expensive than few-shot prompting.

For models finetuned with target identity information, given that each sequence can be associated with more than one target (in cases of intersectional hate speech for instance), a different label-encoding sequence will be used to include all target identities represented in that post. An example of prompt to produce a a post about *gender* that is hateful is *Write a hateful social media post about gender.*

**Few-shot prompting (FS)** Following the large amount of works focusing on few-shot demonstration-based instructions, especially with instruction-finetuned models [49, 44], we also experiment with demonstration-based prompting, in which the models are shown 3 examples belonging to the desired label (and target identity, if available), and then asked to produce a new one.

With models exploiting target identity information for few-shot prompting, we associate the desired label and

[2] While we are aware this does not exploit the most novel and interesting features of the MHS dataset, the exploration of annotator (dis)agreement with regards to data augmentation is beyond the scope of this work, and is left for future research.

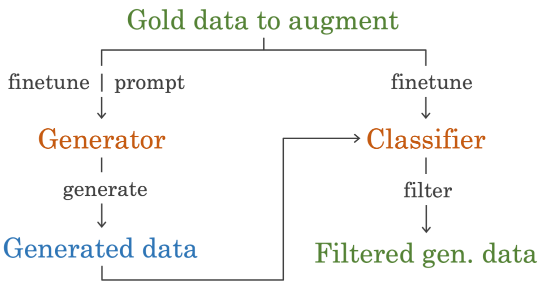

**Figure 2:** Generative DA pipeline.

target with 3 sequences. For instance, if the model is expected to generate a non-hateful post about gender, we select 3 sequences that are annotated in the gold data as non-hateful and about gender.

**Filtering** In both cases, following previous work, we perform an additional filtering step after generating, in order to try and filter out synthetic examples that are assigned an incorrect label, since label assignment is not always reliable with this type of DA [35]. The filtering step consists in feeding the generated sequences into a classifier trained on the initial non-augmented data, and only preserving sequences that are predicted by the classifier as belonging to the same label that was prompted to the generative model at generation time. An overview of the data augmentation pipeline we use is shown in Figure 2.

### 4.4. Prompting and Formatting

We aim at using the same type of prompting layout across experiments. We choose to use prompting sequences in natural language, given that they have been found to lead to generally more realistic generated examples for this purpose [22]. In order to find prompts in natural language that could be leveraged by our models, we consulted the FLAN corpus [25], which is part of the finetuning data of both FLAN-T5 and OPT-IML. Among the instruction templates, we find one of the CommonGen templates [50] to fit with our aims: '*Write a sentence about the following things: [concepts], [target]*'. We reformulate it to obtain a prompting sequence that reflects our application, and can be exploited by instruction-finetuned models: *Write a [∅/ hateful] social media post [∅/ about t]*, where $t$ is a target identity category.

## 5. Experimental Setup

For all experiments, we simulate a setup in which we have a small amount of gold data available prior to augmentation, following previous work on data augmentation in which data scarcity is simulated to assess the effectiveness of data augmentation [34, 22]. We randomly select 1,000 examples, as we deem it a realistically small dataset size for a hate speech detection corpus on the small end of the spectrum, after looking at the hate speech dataset review by Vidgen and Derczynski [17].

Our goal is to create a larger dataset out of the starting 1,000 examples. Given that the 'natural' size of the Measuring HS dataset is 35k examples, we aim for 30k new annotated examples to use in augmentation, which will result in a 31k example dataset for each setup. We generate $\sim$ 3x the examples we need, based on the findings of Wullach et al. [18], setting the total number of generated examples for each setup to 100,000. For each setup, we prompt models to generate 50k for each label, ideally mitigating label imbalance.

Given that our focus is on different targets of hate, we aim at increasing the percentage of posts targeting or about scarcely represented minorities, ideally in order to make systems fairer, so we augment each target identity category equally. For models that rely on target identity information, out of the 50k to generate for each label, we generate 1/7 for each target (7,140 sequences).

Once we generate 100,000 examples, we feed them into a DeBERTa-v3 Large classifier [51] finetuned on the initial 1,000 gold examples, and we only preserve the examples for which the classifier label assignment matches the desired label that was in the model input at generation time. If less than 15k generated sequences pass filtering, we preserve the examples that did pass filtering, and proceed with the rest of the pipeline.

We mainly test the quality of the synthetic data extrinsically, i.e., we test its usefulness when it is used for training models, using the performance of models trained on the synthetically augmented data as a proxy for the quality of the synthetic data itself. To do this, we use synthetic data in addition to the initial available gold data for training classifiers aimed at detecting the presence of hate speech. The reasoning behind this choice is that better-quality synthetic data should lead to better performance of models trained on data augmented with it, as that is ultimately the purpose of the data in our case. Further details about our implementations, including hyperparameters and random seeds for reproducibility, are reported in Appendix B.

**Baselines** We implement three baselines using DeBERTa: *i)* the classifier finetuned on the starting 1k gold examples; *ii)* the same classifier finetuned on an oversampled version of the training data (repeating the initial 1k sequences until we get to 31k, the size of the augmented setups), which has been found effective even in cross-dataset scenarios [22]; and *(iii)* as a stronger baseline, we also compare all of our models with models trained on

**Table 1**
DeBERTa results (macro-F1 and hate-class F1) with generative DA, averaged over 5 runs $^{\pm stdev}$, overall and by target (*Ge*nder, *Ra*ce, *Or*igin, *Se*xuality, *Re*ligion, *Di*sability, and *Ag*e). n(h) = number of hateful synthetic examples preserved after filtering. *FT* stands for *fine-tuning*, while *FS* stands for *few-shot*. The *Tar* columns refers to the presence of target information in the fine-tuning or the prompting of the model.

data augmented using Easy Data Augmentation (EDA) [52]. EDA consists of four operations: synonym replacement, random insertion, random swap, and random deletion of tokens. Similarly to our other setups, we produce 30k new sequences with EDA, of which 7,500 with each operation, on the initial 1,000 examples in each fold. We then also experiment with the mixture of EDA and generative DA, in which instead of augmenting the initial gold data with 30k synthetic sequences obtained with EDA or generative DA, we randomly select 15k examples of each and concatenate them.

## 6. Results and Discussion

In this section we report the results of our experiments, averaged across 5 data folds using different random seeds. The performance of our baselines and models trained on generation-augmented data in terms of macro-averaged F1 score and hateful class F1 (*h-F1*)both globally and by target identity group is reported in Table 1. All models are tested on a held-out portion of the gold data from the MHS corpus.

Considering simply the *no augmentation* baseline, it is clear that performance can vary greatly across target groups, with up to 27% hate-F1 differences between them. In particular, the model appears to struggle with posts about *origin* (Or), *religion* (Re), and *age* (Ag), while, although underrepresented compared to other target groups, posts about *disability* (Di) tend to be classified more accurately on average. This suggests that performance might also be influenced by factors other than the representation of targets in the dataset, such as how broad a target category is or how much variation there is within it. For instance, *origin* can include any type of discrimination based on geographical origin, potentially making it harder to generalize for, and *religion* as a category encompasses any type of religious discourse, in spite of each religion being targeted through specific offense types [10]. This makes classification challenging, especially for systems that rely primarily on lexical features.

Most of the models trained on generation-augmented data outperform the *no augmentation* baseline across targets, with different improvements based on target identity group (*origin*, *religion*, and *age* in particular). Strikingly, however, EDA performs better than all generation-based DA configurations, regardless of prompting type or access to target information, for all targets but *age*.

We hypothesize EDA is effective because small perturbations can make models more robust, especially with regard to the *hateful* class, while generative models do increase performance, but they are also more likely to inject noise.

The impact of finetuning vs. few-shot prompting seems model-dependent, with differences across models also regarding the impact of target information. Interestingly, the amount of synthetic examples labeled as *hateful* that pass filtering does not appear to be linked with better performances of models trained on synthetic data.

## 7. Qualitative Analysis

In this section, we look into the synthetically generated texts and the models trained on them from a qualitative point of view. First we carry out a manual annotation on the generated texts. Then, we turn to the HateCheck test suite [7], which includes examples aimed at exploring the weaknesses of hate speech models, especially their out-of-distribution generalization, again focusing on performance by target. HateCheck targets are in some cases more specific than those present in our dataset, thus providing a complementary view on our models' performance.

### 7.1. Manual Annotation

A total of 1,120 generated texts filtered with DeBERTa were annotated by two annotators with a background in linguistics and experience in hate speech research. For each combination of finetuning/prompting/target presence for each model, they annotated 70 examples, evenly distributed across labels and, where available, targets. The examples were annotated according to *label correctness*, *target category correctness* (where available), and *realism.*

**Table 2**
Generated texts labeled as correct by human annotators in terms of labels, target categories, and realism. N/A refers to cases in which all of the generated texts were nonsensical (0% realistic), with impossible assignment of labels or categories.

For the examples generated *without access to target information*, the *target* dimension was not annotated. Consider for example the following sentence, generated giving 'age' as target information: *'F*ckin white men are trashy like a muthaf*cker'*. In this case, Label would be '*hateful*', Realism would be '*Yes*' but Target would be '*No*', because the target identity category of the generated example is 'race' and not 'age'.

Inter-annotator agreement was calculated using Krippendorff's alpha on 10% of the manually analyzed data (112 examples). The annotators showed moderate agreement with regards to label correctness ($\alpha$ = 0.76), while the scores were higher for category correctness ($\alpha$ = 0.83) and realism ($\alpha$ = 0.82).

The results of the manual analysis are reported in Table 2. In most cases, the addition of target information results in more realistic texts and, in general, more accurate label assignment. However, this is not directly associated with improved model performance from augmented data. In addition, the rate of realistic texts and the accuracy of the identity categories are still somewhat low compared to the correctness of label assignment, showing that the generative models we tested might have difficulties dealing with more than one type of constraint/instruction. Indeed, while few-shot (FS) approaches sometimes lead

**Table 3**
DeBERTa results on HateCheck (hate-class $F_1$) by target identity, averaged over 5 runs $^{\pm stdev}$. *p.* is an abbreviation for *people*, while *disab* stands for *people with disabilities*. *FT* stands for *fine-tuning*, while *FS* stands for *few-shot*. The *Tar* columns refers to the presence of target information in the fine-tuning or the prompting of the model.

to more realistic generated sequences, this often entails lower label or category correctness and vice versa.

## 7.2. HateCheck

We perform a second qualitative analysis using the HateCheck test suite [7], a collection of functional testing examples that enable targeted diagnostic insights of hate speech detection models. All HateCheck test cases mention a specific target identity, to allow the exploration of unintended biases against different target groups. However, the target groups used in HateCheck do not fully overlap with the target identity groups in the MHS corpus (Figure 1). The target identities in HateCheck are: women (which would fall under *gender* in MHS), trans people (*gender* in MHS), gay people (*sexuality* in MHS), black people (*race* in MHS), disabled people (*disability* in MHS), Muslims (*religion* in MHS) and immigrants (*origin* in MHS). The *age* category is present in MHS corpus and entirely missing in HateCheck.

We report in Table 3 the results obtained by the models trained on augmented data on HateCheck in terms of hate-class $F_1$ score, divided by target identity group according to the identity categories used in HateCheck. Overall, we can notice significant improvements over the *no augmentation* baseline across different setups and target identities, although these improvements are variable, and again overshadowed by Easy Data Augmentation, resulting in more evenly distributed scores across all targets.

Interestingly, however, even overlapping targets between the MHS dataset and HateCheck show different improvements across generative DA setups. For instance, the HateCheck target *people with disabilities* apparently benefits from the inclusion of target information more than the *Disability* category in the MHS corpus, suggesting that the inclusion of identity group information could affect performances differently in and out of domain.

Furthermore, HateCheck test instances are manually created starting from templates that include specific mentions of identity-group terms, which could lead to sentences that are very different from 'real' examples that could be found on social media. For instance, one of the hateful templates used in HateCheck is '*I hate [IDENTITY]*', in which *[IDENTITY]* is substituted with *women*, *disabled people*, and so on for all of the targets reported above. This can result in somewhat stereotypical examples, while hateful posts in the MHS corpus often contain slurs and offensive terms instead of more neutral names to refer to people belonging to a certain identity group.

## 8. Conclusions

We have investigated the impact of data augmentation with generative models on specific targets of hate, experimenting with instruction-finetuned models and the addition of target information when generating new sequences. Overall, it appears that DA methods have different types of impact on different targets, but they can improve performance even for scarcely represented identity categories (Q1). However, we observed that generative data augmentation alone is not as strong as simpler methods such as EDA.

Through a qualitative analysis, we also emphasized the fact that including target information when generating synthetic examples can facilitate the creation of examples that are more realistic and exhibit more correct label assignments (Q2), although further work could investigate why these characteristics do not directly correlate with downstream task performance.

Overall, our analysis shows that there is potential in data augmentation with regards to model group fairness (Q3), implying independence between model classification output and sensitive attributes [16]. However, although potentially useful, this type of DA can still lead to unpredictable results, and it is not guaranteed to always improve the performance of models across all identity groups with regards to hate speech. We plan to further explore this research direction in the future, considering also intersectionality and more specific targets (e.g. groups such as *trans women* rather than the *gender* category). In addition, we worked on English data because of the availability of the Measuring Hate Speech corpus, which was large enough to perform our DA experiments and presented the kind of fine-grained target annotation required in our study. However, we are aware that DA would benefit more classification with lower-resourced languages, so we plan to work on different languages in the future.

In summary, we show that data augmentation with generative language models can be beneficial, even when using only openly available models. However, given their high computational costs, alternatives like EDA could be considered if limited resources are available, because they can still yield performance improvements compared to a low-resource setting. Again, there seems to be no one-fits-all solution or approach to generation or data augmentation in this kind of scenario.

We acknowledge that data augmentation techniques may be used also for malicious purposes, for example to create thousands of hateful examples with the goal of hurting the same groups that we want to support. Because of this, we provide all the necessary details for the reproduction of our results, but we do not plan to openly release the code or to upload the generated data produced by our experiments, especially in order to avoid it being crawled and ending up in the training data of LLMs in the future. We are, however, open to sharing the data with other researchers who might be interested.

## A. Prompting Examples

Below are examples the sequences and prompts used for training and prompting our models.

**FT-target** *Write a (hateful) social media post about {target}: {text}*

**FT-no target** *Write a (hateful) social media post: {text}*

**FS-target** *Write a (hateful) social media post about {target}: {text}* [...]
*Write a (hateful) social media post about {target}: {text}*

**FS-no target** *Write a (hateful) social media post: {text}*
[...]
*Write a (hateful) social media post: {text}*

The values used for ‘target’ are the identity group names in the MHS dataset, reported in Sec. 3.

## B. Hyperparameters and Reproducibility

For all of our experiments, we employ the HuggingFace Python library. All the hyperparameters we use that are not specified in this section are the default ones from their `TrainingArguments` class. The classifiers we use as baselines and for filtering are trained on 5 epochs.

We finetune all generative models with batch 16 and $LR = 1e - 3$. For generation, we set *top-p*=0.9 and min and max lengths of generated sequences to 5 and 150 tokens respectively. Finally, we avoid repeating 4-grams. All the classifiers that are trained on augmented data are trained for 3 epochs with batch size 16 and LR $5e - 6$. In this case, at the end of training, we preserve the model from the epoch with the lowest evaluation cross-entropy loss.

The random seeds we used for shuffling, subsampling the gold data, and initializing both generative and classification models are 522, 97, 709, 16, and 42. These were chosen randomly. Finetuning of all classifiers and generative models, including baselines and models trained on augmented data, took 70 hours, of which 55 on a Nvidia V100 GPU and 15 on a Nvidia A40. Inference time for generating all of the sequences (a total of 8 million generated texts) took $\sim$400 hours total.

## Abstract

This paper introduces a retrieval-based text classification framework tailored for language corpora in the domain of gas pipe damage description analysis, with a specific focus on determining patch applicability. Due to the scarcity of free-text damage descriptions in this domain, we construct a synthetic binary classification dataset, referred to as *CoRe-S*. This dataset consists of 11,904 damage descriptions generated from structured attributes, where each instance is labeled as either *Patchable* (True) or *Unpatchable* (False). The *CoRe-S* dataset presents two primary challenges: (i) a class imbalance, where positive cases are the minority, and (ii) frequent use of domain-specific terminology, which results in low lexical diversity across descriptions. To quantify this lack of variation, we introduce the *Corpus Pairwise Diversity* statistic, which measures the degree of lexical dissimilarity between documents in a corpus.

We adopt a training-free, retrieval-based text classification approach and demonstrate that *Sentence-BERT-NLI* is the most effective encoder under low-diversity conditions, as it excels at capturing subtle lexical and semantic differences between otherwise similar documents. To address the class imbalance, we apply random undersampling, which outperforms other under-sampling strategies in our experiments. Our results show that the proposed retrieval-based classifier significantly outperforms other training-free text classification methods—whether zero-shot, few-shot, or similarity-based—achieving an improvement of approximately 35.2% in macro F1-score over the second-best method.

Our code is publicly available at: https://github.com/links-ads/core-unimodal-retrieval-for-classification.

## Keywords

Gas pipe damage description analysis, Training-free text classification, Low lexical diversity, Low lexical diversity

## 1. Introduction

Text classification is the task of assigning predefined labels to a given text and has been applied to a wide range of domains, including sentiment analysis [1], emotion recognition [2], news classification [3], and spam detection [4]. Early approaches typically decomposed the task into two stages: feature extraction using neural models such as Recurrent Neural Networks (RNNs) [5, 6] or Convolutional Neural Networks (CNNs) [7], followed by feeding the extracted features into a classifier [8] to predict labels. With the emergence of transformer architectures [9], Large Pretrained Models (LPMs) such as BERT [10] and GPT [11] have become the foundation for modern NLP systems. Trained on massive textual corpora, these models demonstrate strong generalization capabilities across various downstream tasks, often without requiring additional task-specific training data. In this work, we address the task of text classification over gas pipe damage descriptions, with the objective of determining whether a patch is applicable (*True*) or not (*False*). Due to the limited availability of free-text damage reports in this domain, we construct a synthetic

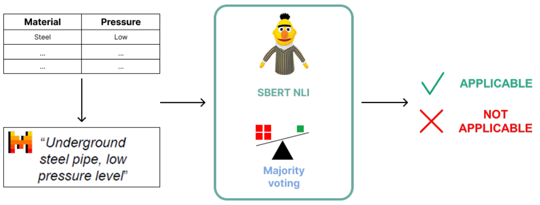

**Figure 1:** Overview of our classification framework. Starting with a tabular dataset, we use the Mistral-7B language model to generate textual descriptions. For a given input query, we retrieve the most similar labeled descriptions using embedding similarity. The final label is determined through a majority voting mechanism.

binary classification dataset, referred to as **CoRe-S**. This dataset comprises 11,904 damage descriptions generated from structured attributes such as pipe material, lesion type, and pipe exposure. This setting poses two main challenges: (i) a class imbalance, where positive cases are the minority; and (ii) low lexical diversity, as descriptions tend to be highly similar across classes, relying heavily on domain-specific terminology and recurring linguistic patterns. Consequently, texts from different categories may be lexically indistinguishable, complicating classification based on surface-level features.

To quantify this lexical variability, we introduce a novel statistic, **Corpus Pairwise Diversity**, which measures the degree of lexical dissimilarity between documents within a corpus. When applied to our dataset, this statistic produces significantly lower values compared to generalist corpora such as *20NewsGroups* [12], which are characterized by a broader vocabulary and greater topical diversity.

For the classification task, we employ a training-free, retrieval-based framework, depicted in Figure 1, that leverages PLMs, consisting of a document encoder and a similarity-based classifier. Given the low corpus diversity and frequent repetition of domain-specific terms—regardless of class—conventional semantic search models may underperform in this setting, as they often fail to capture fine-grained linguistic distinctions. For instance, two descriptions may differ only in a subtle feature such as pressure level, which can determine whether a leak is patchable.

This observation motivates the hypothesis that encoders focusing on logical inference, rather than relying solely on surface-level semantic similarity, are better suited for classification in such contexts. Accordingly, we employ the Sentence-BERT model pre-trained on Natural Language Inference (NLI), a task that requires determining whether a hypothesis can be logically inferred, contradicted, or is neutral with respect to a given premise. We adopt *SBERT-NLI* [13], which effectively captures subtle lexical and semantic differences between near-identical documents. To mitigate the effects of class imbalance, we apply random undersampling to the retrieval corpus, which achieves superior performance compared to alternative imbalance-handling strategies in our experiments. Experimental results demonstrate that our text classification model consistently outperforms state-of-the-art training-free approaches, including zero-shot, few-shot, and similarity-based methods.

The main contributions of this work are as follows:

- We introduce **CoRe-S**, a novel dataset in the domain of gas pipe damage descriptions, which, to the best of our knowledge, is the first dataset developed in this domain.
- We introduce a novel statistic, **Corpus Pairwise Diversity**, to quantify the lexical dissimilarity between documents within a corpus.
- We demonstrate that in low-diversity settings, a Natural Language Inference–pretrained encoder, specifically *SBERT-NLI*, outperforms standard semantic similarity models by effectively capturing subtle distinctions between documents belonging to different classes.

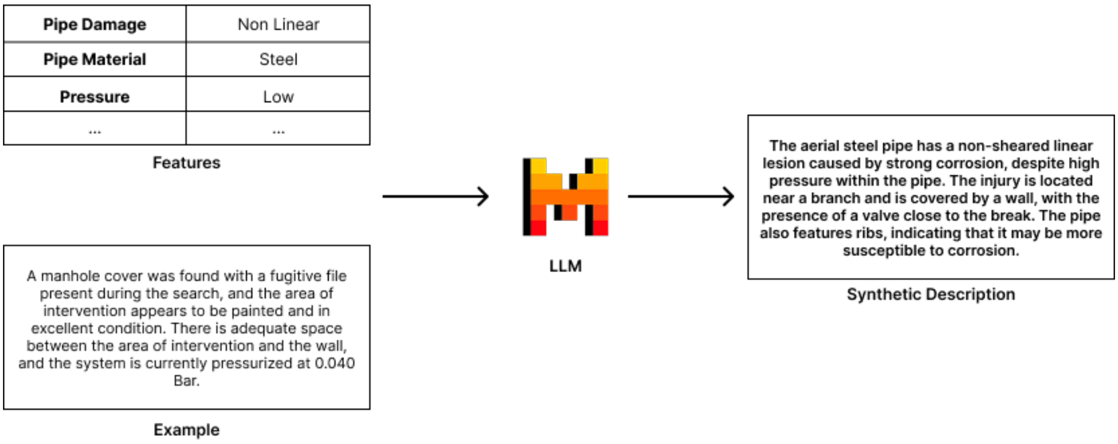
## 2. Background on Training-Free Text Classification

With the advent of transformer architectures equipped with attention mechanisms [9], a new wave of Large-scale Pretrained Models (LPMs) has emerged. These models are trained on vast textual corpora such as BooksCorpus (800M words) [14] and Common Crawl [15]. Modern PLMs are predominantly based on either the BERT [10] or GPT [11] architectures. BERT utilizes a transformer encoder to produce dense contextual representations of input text, making it well-suited for language understanding tasks. In contrast, GPT adopts a decoder-only architecture originally designed for generative applications, though it has also shown strong performance in classification tasks [16, 17]. Both architectural families exhibit strong transfer learning capabilities, enabling effective adaptation to a variety of downstream tasks, and paving the way for training-free approaches to text classification.

BERT-based approaches leverage embeddings to compare semantic similarity between pieces of text. Depending on the nature of the task, these methods can be broadly categorized into: (i) *zero-shot methods*, which compare the input text directly with class labels or their representative keywords [18, 19, 13]; and (ii) *retrieval-based methods*, which perform semantic search over a database containing auxiliary knowledge [20, 21].

Schopf et al. [22] presented, for the first group of methods (zero-shot), two different approaches. The first one consists of representing each document as the average of its paragraph embeddings. Similarly, each label is represented as the average embedding of a set of predefined keywords associated with that label. Classification is then performed by computing the similarity between the document and label embeddings, assigning the label with the highest similarity score. The second approach, instead, implements a zero-shot entailment technique. Each input document is paired with a hypothesis representing a candidate label, and the model predicts whether the hypothesis is entailed by the input.

GPT-based approaches, on the other hand, leverage the full potential of natural language processing and the generative capabilities embedded in the models. These methods are typically applied in either: (i) a *zero-shot* fashion, where predictions are made without any labeled



| Pipe Damage | Non Linear |
|---|---|
| Pipe Material | Steel |
| Pressure | Low |
| ... | ... |

A manhole cover was found with a fugitive file present during the search, and the area of intervention appears to be painted and in excellent condition. There is adequate space between the area of intervention and the wall, and the system is currently pressurized at 0.040 Bar.

The aerial steel pipe has a non-sheared linear lesion caused by strong corrosion, despite high pressure within the pipe. The injury is located near a branch and is covered by a wall, with the presence of a valve close to the break. The pipe also features ribs, indicating that it may be more susceptible to corrosion.

**Figure 2:** Illustration of the text generation process using the Mistral-7B model. Tabular data are transformed into natural language descriptions, based on the characteristics represented by the features and the style provided by the example description.

**Table 1**
Description of pipe-related variables and their possible values.

| Variable Name | Description | Possible Values |
|---|---|---|
| `pipe_damage` | Type of damage affecting the pipe. | Galvanised fittings, Steel, Bitumen-coated steel, Polyethylene-coated steel, Cast iron, Polyethylene |
| `pipe_material` | Components or structural elements of the pipe. | Non-sheared linear lesion, Hole, Cluster of holes, Sheared linear lesion, Visible axial deformation, Thread, Elbow, Sleeve, Tee, Nipples, Ball valve |
| `corrosion` | Indicates whether the pipe is affected by corrosion. | True, False |
| `mecc_charac` | Indicates whether the pipe retains mechanical integrity despite corrosion. | True, False |
| `pressure` | Pressure level inside the pipe. | High, Low |
| `wall` | Whether there is a gap larger than 1 cm between the pipe and the wall. | True, False |
| `wall_more` | If a wall is present, indicates whether it can be broken or removed. | True, False |
| `valve` | Presence of a valve near the damaged area. | True, False |
| `ribs` | Presence of structural ribs on the pipe. | True, False |
| `coated_tube` | Indicates whether the pipe is coated. | True, False |
| `welds` | Presence of welds on the pipe. | True, False |

examples [16]; or (ii) *in-context learning*, where the model generates textual outputs (e.g., label words) conditioned on a prompt that usually includes a few annotated examples for downstream tasks [23, 24].

In this paper, we present a BERT-based, retrieval-enhanced approach to tackle two central challenges in the classification of gas pipe damage descriptions: low lexical diversity and class imbalance.

## 3. CoRe-S Dataset

In current pipe repair operations, data is typically collected through structured questionnaires completed after the intervention. These forms use categorical and boolean fields to document the conditions surrounding the fault and the type of repair performed.

In this work, we propose a simplified data collection approach based on free-text fault descriptions. We also introduce a novel use case for these descriptions: supporting technicians in determining whether a fault is patchable or requires replacement of the damaged pipe segment.

To explore this idea and assess its feasibility, we construct a synthetic dataset by transforming existing structured tabular data—originally collected in the field—into natural language descriptions.

The original tabular dataset comprises 11,904 pipe repair interventions. Each intervention is described using 11 categorical or boolean features—listed in Table 1—which capture the condition of the pipe at the time of the damage. Additionally, each record is labeled as Patchable (`True`) or Not Patchable (`False`), depending on whether the intervention involved a successful patch or required replacement of the pipe segment. Among all interventions, only 126 examples (1.06%) are labeled as successful patches, while the remaining 11,778 (98.94%) represent replacements.

We generate the textual descriptions using the large language model (LLM) *Mistral-7B Instruct v0.3*[1].

Figure 2 illustrates through an example the pipeline used to generate the dataset, where a prompt—shown in Figure 3—combines (i) a randomly selected example from a curated set of 36 real technician-written descriptions and (ii) a structured template filled with the most informative features extracted from the tabular dataset, enabling the LLM to produce realistic and domain-specific textual representations of pipe failures.

Specifically, for each entry in the original tabular dataset $\mathbf{x}_i \in \mathbb{R}^F$, we extract the relevant feature values and insert them into the template prompt, together with the example used to guide the writing style.

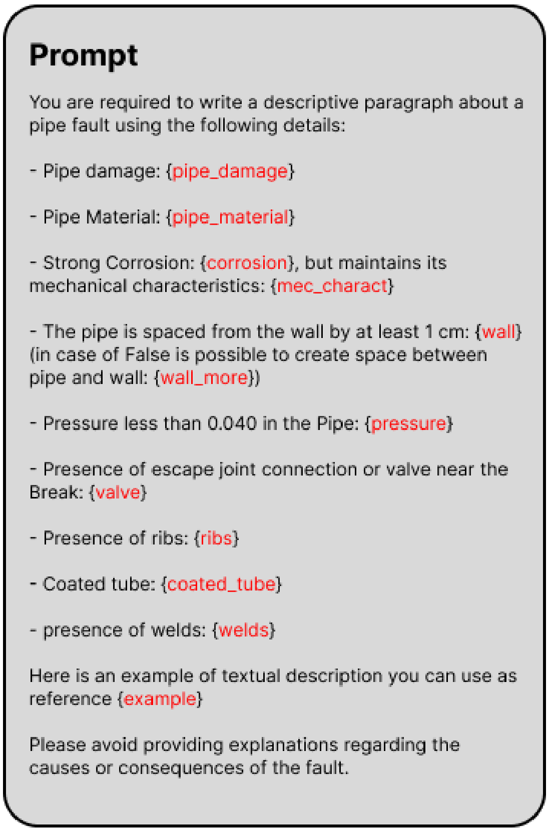
The label $y_i \in True,$ *False* indicates whether the intervention was resolved via patching ($y_i =$ *True*) or required pipe replacement ($y_i =$ *False*), and is directly inherited from the original dataset.

The resulting **CoRe-S** dataset consists of pairs $(t_i, y_i)$, where $t_i$ is the synthetic textual description generated from the structured features of intervention $i$, and $y_i$ is the corresponding repair label.

To ensure the quality and reliability of the generated descriptions, we perform a human review process to: (i) verify stylistic consistency with real examples written by technicians, and (ii) randomly assess the semantic alignment between each description $t_i$ and the original feature vector $\mathbf{x}_i$.

## 4. Corpus Pairwise Diversity Statistic

This section introduces the formal definition of the **Corpus Pairwise Diversity** statistic, which serves as a foundational element for both the design and evaluation of our retrieval-based classifier. By measuring the average dissimilarity between the vocabularies of document pairs, this statistic informs downstream components that rely on accurate estimations of inter-document similarity.



**Prompt**

You are required to write a descriptive paragraph about a pipe fault using the following details:

- Pipe damage: {pipe_damage}

- Pipe Material: {pipe_material}

- Strong Corrosion: {corrosion}, but maintains its mechanical characteristics: {mec_charact}

- The pipe is spaced from the wall by at least 1 cm: {wall} (in case of False is possible to create space between pipe and wall: {wall_more})

- Pressure less than 0.040 in the Pipe: {pressure}

- Presence of escape joint connection or valve near the Break: {valve}

- Presence of ribs: {ribs}

- Coated tube: {coated_tube}

- presence of welds: {welds}

Here is an example of textual description you can use as reference {example}

Please avoid providing explanations regarding the causes or consequences of the fault.

**Figure 3:** Prompt template used for converting tabular data representing pipe damage into textual descriptions. The prompt is composed of: (1) the features relevant for generating the content, and (2) an example description written by a specialist to guide the style.

### 4.1. Definition

Let $D = \{d_1, \ldots, d_N\}$ be a corpus of $N$ documents, where each document $d_i$ is represented as the set of its unique terms. The *Jaccard distance* between two documents $d_i$ and $d_j$ is

$$\delta_J(d_i, d_j) = 1 - \frac{|d_i \cap d_j|}{|d_i \cup d_j|} \in [0, 1].$$

We then define the *Corpus Pairwise Diversity* statistic as

$$CPD(D) = \frac{1}{\binom{N}{2}} \sum_{1 \le i < j \le N} \delta_J(d_i, d_j).$$

By construction, $CPD(D) \in [0, 1]$; low values indicate high overall similarity, and high values indicate high overall dissimilarity among documents. It is *non-negative*, symmetric, and unaffected by the order of the set $D$.

**Figure 4:** Overview of our classification pipeline. Given an input query $Q$, we retrieve the top-$k$ most similar labeled descriptions based on embedding similarity. The final label is assigned using a majority voting mechanism over the retrieved top-$k$ documents.

**Table 2**
Pairwise lexical diversity ($CPD$) measured across various text classification datasets. Here, $|D|$ indicates the number of documents, and $|V|$ represents the vocabulary size.

| Dataset | $\|D\|$ | $\|V\|$ | $CPD(D)$ |
|---|---|---|---|
| 20NewsGroups | 10,998 | 85,551 | 0.99 |
| Yahoo! Answers | 1,375,428 | 739,655 | 0.99 |
| CoRe-S | 11,903 | 2283 | 0.69 |

Moreover, it is also *invariant to document length and term frequency*, even when vocabulary sizes differ substantially.

## 4.2. Empirical Analysis

To better understand the behaviour of the $CPD$ statistic, we compute it across multiple corpora. Table 2 shows that datasets like *20NewsGroups* and *Yahoo! Answers* generally obtain higher diversity scores $CPD(D)$, indicating increased textual heterogeneity and more extensive vocabularies. In contrast, the *CoRe-S* dataset exhibits lower diversity, which can be attributed to its specialized terminology and repetitive textual patterns. This is likely a consequence of the constrained set of attributes used during the generation process (see Section 3), which restricts variability in term usage. As a result, it becomes challenging to distinguish between damage descriptions across different categories.

# 5. Retrieval-based Classifier

We adopt a zero-shot learning approach, depicted in Figure 4 built around a retrieval-based pipeline. The strategy involves retrieving the top-k most similar labeled textual descriptions based on embedding similarity and, using a majority voting mechanism across these top-k retrieved instances, determine the final label assigned to the input.

## 5.1. Formal Description

Let $D \subseteq X^*$ be the set of all documents, where $X$ is a finite alphabet of symbols. The dataset $D$ is partitioned into two subsets: the *query set* $Q \subseteq D$ and the *corpus* $C \subseteq D$. For each query $q \in Q$, the system retrieves relevant documents from the *corpus* $C$, which contains descriptions of past pipe failures, each labeled as *patchable* (true) or *not patchable* (false). Let $e : X^* \to \mathbb{R}^n$ be an *encoding function* that maps a document into an $n$-dimensional embedding space using a pre-trained model and let $s : \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}$ be a *similarity function* that measures the closeness between two embedded documents $q \in Q$ and $c \in C$, the *retrieval process* is defined as:

$$\mathrm{Re}_{s,k,C}(q) = \underset{N \subseteq C : |N| = k}{\arg\max} \sum_{c \in N} s(e(q), e(c)) \quad (1)$$

where $C$ is the corpus, $k$ is the number of top retrieved documents, $s(e(q), e(d))$ is the similarity score between the query document$q$ and the corpus document $c$. We denote the resulting top-$k$ retrieved documents for a given query $q$ as:

$$N^*_{q,k} = \mathrm{Re}_{s,k,M}(q) \quad (2)$$

Finally, the system produces its final prediction by applying *majority voting* over the labels of the documents in $N^*_{q,k}$:

$$\hat{y}_q = \mathrm{MajorityVote}\left(\{\mathrm{label}(d) \mid d \in N^*_{q,k}\}\right) \quad (3)$$

## 5.2. Encoder and Similarity Metrics Selection

For our training-free classification pipeline, we explore several pre-trained encoders to generate high-quality semantic embeddings for both queries and corpus documents. All selected encoders are transformer-based models chosen for their zero-shot capabilities, strong performance on general-purpose semantic similarity benchmarks, and availability through the `sentence-transformers` library, which facilitates seamless integration into our pipeline. Specifically, we test `all-mpnet-base-v2`[2], a sentence-transformer model based on MPNet [19], fine-tuned on over 1 billion sentence pairs for semantic similarity tasks. We also include `multi-qa-mpnet-base`[3], a variant of MPNet fine-tuned on multiple question-answering datasets—including Natural Questions, TriviaQA, and SQuAD—to better handle question-style inputs [25]. Finally, we use `bert-base-nli-mean-tokens`[4], a BERT-based encoder trained on the SNLI and MultiNLI datasets for natural language inference (NLI) [13].

We evaluate two popular similarity metrics for comparing document embeddings: the *dot product*, which captures the directional similarity between embeddings and the *Euclidean distance* ($\ell_2$), which measures the straight-line distance between vectors in the embedding space.

## 5.3. Corpus Under-sampling Techniques

To address class imbalance in our dataset, we use several under-sampling strategies that reduce the number of documents in the corpus set of the majority class. We test different algorithms: Random Under-sampling, Near Miss with its 3 different versions and the Edited Nearest Neighborhood.

### 5.3.1. Random Under-sampling

It is a simple technique that randomly removes examples from the majority classes until the desired class distribution is reached.

### 5.3.2. NearMiss

The algorithm consists of preserving samples from the majority class that are most relevant for the classification task, based on the evaluations of distances between samples from the majority and minority classes. There are different versions of the same algorithm:

- **NearMiss-1** selects majority class samples with the smallest average distance to the closest samples of the minority class.
- **NearMiss-2** selects majority class samples with the smallest average distance to the farthest samples of the minority class.
- **NearMiss-3** first selects a subset of minority samples and retains their nearest neighbors among the majority. Then, it keeps the majority class samples with the largest average distance to their selected neighbors.

### 5.3.3. Edited Nearest Neighbors (ENN)

The `EditedNearestNeighbors` (ENN) technique uses a K-Nearest Neighbors (KNN) approach to filter out noisy or ambiguous samples from the majority class. The procedure involves training a KNN classifier on the entire corpus, then for each instance in the majority class, identifying its $k$ nearest neighbors and remove the instance if any or most of its neighbors belong to a different class.

# 6. Experiments

## 6.1. Experimental Details

Experiments are conducted using an NVIDIA GeForce RTX 2080 Ti GPU. Model performance is primarily evaluated using the F1-Macro score to ensure a balanced assessment across classes. Additionally, all results are obtained through 5-fold cross-validation, which involves changing the split of the corpus and query set in each fold to ensure robust evaluation. For the main results, we also report the Recall-Macro and Precision-Macro scores.

## 6.2. Results

### 6.2.1. Comparison with Zero-Shot Classification Methods

We compare our zero-training retrieval-based classification approach with several zero-shot and few-shot classification baselines.

The **Baseline approach**[22] represents each document as the average of its paragraph embeddings. Similarly, each label is represented as the average embedding of a set of predefined keywords associated with that label. Classification is performed by computing the similarity between the document and label embeddings, assigning the label with the highest similarity score. We evaluate this method using two different encoders: `all-MiniLM-L6-v2` and `all-mpnet-base-v2`.

We also implement a **zero-shot entailment technique**[22], using pre-trained models such as `DistilBERT`, `BART-large`, and `DeBERTa`. Each input document is paired with a hypothesis representing a candidate label, and the model predicts whether the hypothesis is entailed by the input.

**Table 3**
Main results across CoRe Synthetic dataset.

| Method | Precision *(macro)* | Recall *(macro)* | F1 *(macro)* |
|---|---|---|---|
| Baseline-mean | 0.517 | 0.506 | 0.508 |
| 0SHOT-NLI | 0.497 | 0.500 | 0.497 |
| LLM – 0SHOT | 0.514 | 0.736 | 0.466 |
| LLM – FEWSHOT | 0.517 | **0.756** | 0.501 |
| OURS | 0.704 | 0.672 | **0.687** |

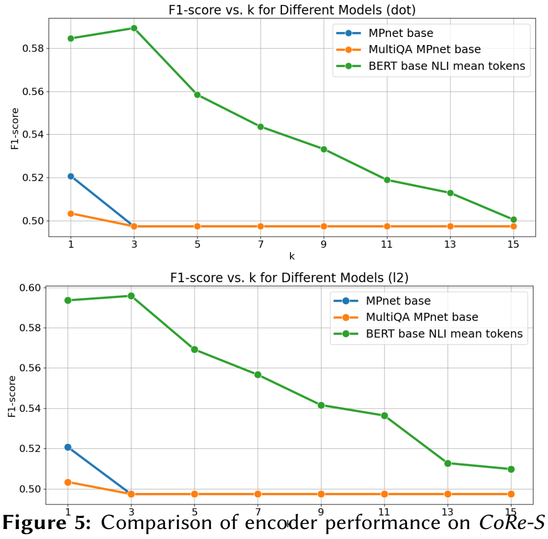

**Figure 5:** Comparison of encoder performance on *CoRe-S* datasets using different similarity metrics for various values of $k$.

Additionally, we evaluate **large language models (LLMs)** through zero-shot and few-shot prompting. In the zero-shot setting, the prompt includes only a description of the task and candidate labels. For the few-shot setting, we extend the prompt by adding two randomly selected labeled examples (one per class) drawn from the training set. These examples are excluded from the test set.

Table 3 presents the best results obtained by each method. Our retrieval-based approach achieves the highest performance overall, reaching a macro-F1 of 0.687.

### 6.2.2. Ablation Study

**Similarity Metric Selection** In our zero-shot pipeline, we evaluate two most used similarity metrics: the **dot product** and the **Euclidean distance** ($\ell_2$). Figure 5 illustrates the performance of our retrieval-classification strategy under both similarity functions. Both metrics are tested across all selected encoders to determine which yields better retrieval quality for classification. Our experiments reveal that the $\ell_2$ distance consistently outperforms the dot product: it better captures fine-grained semantic dissimilarity by measuring absolute geometric distance in embedding space. Consequently, all the other results in this work are reported using $\ell_2$ similarity.

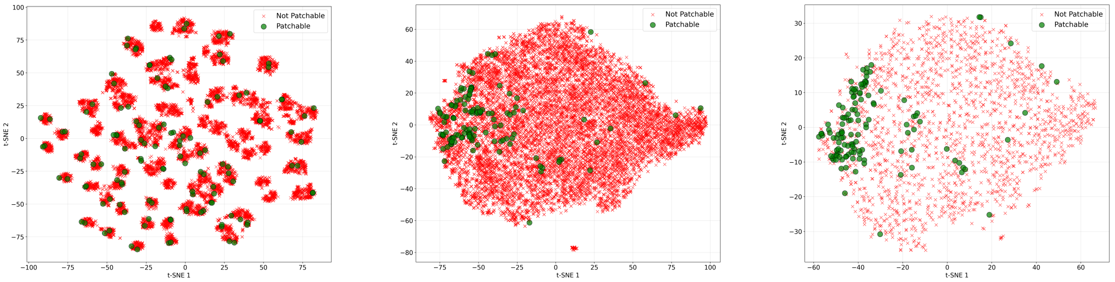
**Encoder Selection** Figure 5 shows macro-F1 performance for values of $k$ ranging from 1 to 15, using both dot-product and Euclidean ($\ell_2$) similarity on the *CoRe-S* dataset. Across all values of $k$, SBERT consistently outperforms MPNet and QA-MPNet, achieving peak performance at $k = 3$ with Euclidean similarity. This indicates that NLI-pretraining enables SBERT to better capture logical relations relevant to the task.

This performance advantage becomes more evident when considering the linguistic challenges posed by the *CoRe-S* dataset: it contains a high degree of lexical overlap between sentence pairs, where distinctions often hinge on subtle cues such as *adjectives and negation* (e.g., “low vs. high pressure” or “no corrosion”). These subtle differences are critical in determining whether a leak is patchable or non-patchable. General-purpose encoders can be misled by shared technical terms like *pressure* or *pipe*, which can dominate similarity computations without truly capturing the underlying logical relationship.

To further illustrate this, Figure 6(a) and Figure 6(b) show t-SNE visualizations of the document embeddings produced by MPNet and SBERT-NLI, respectively. In Figure 6(b), embeddings corresponding to the same label—especially the green points representing the positive class—tend to be more tightly clustered. In contrast, Figure 6(a) reveals that MPNet’s embeddings are more dispersed, with red points (False label) forming scattered clusters across the space. The SBERT-NLI plot also exhibits a prominent macro-cluster containing both true and false labels, but with a clearer organization and denser neighborhood structures, particularly among positively labeled instances. This spatial coherence further supports the claim that entailment-based encoders are better equipped to model subtle semantic nuances crucial for this task.

**Corpus Under-sampling** Figure 7 shows how different sampling strategies impact performance on the *CoRe-S* dataset across values of $k$ from 1 to 15. The results reported in the figure represent the best outcomes obtained across the tested hyperparameter configurations.

When no under-sampling is applied, macro-F1 peaks at $k = 7$ (0.609), but then declines as if additional neighbors introduce semantic noise. In contrast, applying under-sampling leads to higher macro-F1 scores across all values of $k$. Notably, random under-sampling achieves the best overall performance, improving from 0.601 at $k = 1$ to



(a) MPNet

(b) SBERT NLI

(c) SBERT NLI + Undersampling

**Figure 6:** t-SNE visualizations of embeddings produced by: (a) the MPNet encoder, (b) SBERT NLI, and (c) SBERT NLI with random undersampling. Clearer cluster separation is observed between the labels `true` (patchable) and `false` (not patchable).

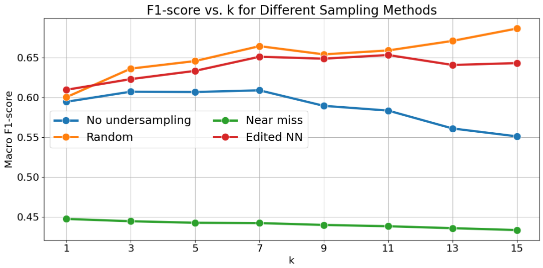


**Figure 7:** Comparison of our retrieval-for-classification approach with different undersampling strategies on *CoRe-S* datasets using $\ell_2$ similarity for various values of $k$.

a peak of 0.687 at $k = 15$. This suggests that random under-sampling effectively balances the class distribution in the corpus, enabling the model to achieve stronger generalization and more robust performance.

The use of near-miss under-sampling, on the other hand, significantly degrades performance. Although the edited nearest neighbor (edited nn) strategy performs better than using no under-sampling at all, it still falls short of the results achieved with random under-sampling. This may be because these strategies remove fewer training examples and may not sufficiently rebalance the corpus. In fact, the high similarity in textual descriptions with label patchable or non-patchable can lead to very close embeddings and as a result, these strategies might remove fewer examples. Random under-sampling instead operates solely based on a class ratio threshold, resulting in a more pronounced reduction and a more effective rebalancing of the corpus. The best performance is achieved with a reduced corpus of 962 training samples and the full set of 5,952 query instances.

Figure 6(c) illustrates a t-SNE representation of the document embeddings produced by the best encoder, SBERT-NLI, after applying random under-sampling to the corpus. As previously shown, SBERT-NLI naturally clusters green points (true labels) and red points (false labels) near each other, reflecting its ability to capture fine-grained semantic distinctions. After under-sampling, however, the red points are pushed further away from the green points, creating clearer separations between classes. This enhanced separation corresponds to improved macro-F1 performance, demonstrating how under-sampling helps the model better distinguish between patchable and non-patchable instances by reducing class imbalance and mitigating semantic noise.

### 6.2.3. Cross-Corpus Encoder Selection with Varying Lexical Diversity

To further explore the influence of corpus lexical diversity on model performance, we expand our evaluation beyond *CoRe-S* to include two additional text classification datasets: *20NewsGroups* and *Yahoo Answers*, both of which demonstrate higher lexical variability, as shown in Section 4 using our proposed *Corpus Pairwise Diversity* statistic.

We compare the performance of three document encoders within the same retrieval-based classification framework: SBERT-NLI, MPNet and QA-MPNet. For evaluation, each dataset's test set is evenly split into two subsets: one half is used as the retrieval corpus and the other half as the query set, where classification performance is measured.

Table 4 reports the best F1 scores achieved by each encoder on the respective datasets. The results reveal a clear interaction between corpus lexical diversity and encoder effectiveness. On the low-diversity *CoRe-S* dataset, SBERT-NLI achieves the highest F1 score, supporting our hypothesis that NLI-pretrained models are better suited for distinguishing fine-grained linguistic nuances between similar documents. In contrast, on the higher-diversity datasets *20NewsGroups* and *Yahoo Answers*, MPNet consistently outperforms the other encoders. In these settings, MPNet's enhanced ability to capture broad semantic content makes it more effective at handling lexical variation.

**Table 4**
Best F1 scores obtained with each encoder across datasets, using the same retrieval-based classification framework.

| Dataset | Model | F1 Score |
|---|---|---|
| 20NewsGroup | MPNet | **0.752** |
| | SBERT-NLI | 0.555 |
| | QA-MPNet | 0.744 |
| Yahoo Answers | MPNet | **0.638** |
| | SBERT-NLI | 0.505 |
| | QA-MPNet | 0.618 |
| CoRe-S | MPNet | 0.521 |
| | SBERT-NLI | **0.609** |
| | QA-MPNet | 0.503 |

## 7. Limitations

A key limitation of this study is the reliance on synthetic data. While synthetic fault descriptions are necessary due to the lack of large-scale real-world technician-written reports, they may not fully capture the noise, variation, and contextual complexity present in actual field documentation. This may affect the generalizability of the findings when applied to real-world scenarios. Future work should explore the collection and use of authentic, technician-authored data to validate and refine the proposed method.

## 8. Conclusion

In this paper, we address the task of classifying gas pipe damage descriptions. Starting from a set of damage features and real examples, we generate a new dataset called *CoRe-S*, the first of its kind in this domain. This dataset exhibits low lexical diversity, characterized by a restricted and repetitive vocabulary, along with severe class imbalance. To quantify lexical diversity within a corpus, we propose the *Corpus Pairwise Diversity* statistic.

To overcome these challenges, we design a training-free retrieval-based text classifier that leverages SBERT-NLI to handle low lexical diversity, combined with undersampling techniques to mitigate class imbalance. Experimental results demonstrate that our method outperforms other training-free approaches, including zero-shot, few-shot, and similarity-based methods. Additional experiments suggest that natural language inference pretrained text encoders are particularly effective in low-diversity scenarios where subtle differences between texts of different labels must be captured.

Future work may involve a more extensive comparison of text encoder effectiveness across various text classification datasets exhibiting different levels of lexical diversity.

# Knowledge-Grounded Detection of Factual Hallucinations in Large Language Models

Cristian Ceccarelli, Alessandro Raganato and Marco Viviani*

University of Milano-Bicocca (DISCo – IKR3 Lab), Edificio U14 (ABACUS), Viale Sarca, 336 – 20126 Milan, Italy

**Abstract**

Large Language Models (LLMs) have achieved remarkable success in various Natural Language Processing (NLP) tasks, yet they remain prone to generating factually incorrect content, known as hallucinations. In this context, this work focuses on factuality hallucinations, offering a comprehensive review of existing detection methods and an empirical evaluation of their effectiveness. In particular, we investigate the role of external knowledge integration by testing hallucination detection approaches that leverage evidence retrieved from a real-world Web search engine. Our experimental analysis compares this knowledge-enhanced strategy with alternative approaches, including uncertainty-based and black-box methods, across multiple benchmark datasets. The results indicate that, while external knowledge generally improves factuality detection, the quality and precision of the retrieval process critically affect performance. Our findings underscore the importance of grounding LLM outputs in verifiable external sources and point to future directions for improving retrieval-augmented hallucination detection systems.

**Keywords**

Natural Language Processing (NLP), Large Language Models (LLMs), Hallucinations, Retrieval-Augmented Generation (RAG)

## 1. Introduction

In recent years, the rapid advancements in technology and the growing availability of data have fostered the emergence of *Large Language Models* (LLMs). These models, based on the Transformer architecture, exploit attention mechanisms to analyze relationships between textual elements and effectively capture contextual meaning [1]. This capability allows LLMs to excel in natural language generation and a wide range of *Natural Language Processing* (NLP) tasks, including text summarization, machine translation, and conversational AI. Due to their impressive ability to understand, interpret, and generate human-like language, LLMs have become indispensable tools in fields such as education, research, and healthcare.

However, despite their capabilities and the significant technological advancements they represent, LLMs still face some challenges. A particularly critical issue is their tendency to generate the so-called *hallucinations*, which are outputs that are plausible but incorrect, under different perspectives [2]. The prevalence of such hallucinated outputs is particularly concerning given the increasing integration of LLMs into sensitive domains. The generation of incorrect content can undermine trust in AI systems, limit their practical applicability, and contribute to the spread of misinformation [3], especially in critical areas such as journalism, medicine, and scientific research, where factual accuracy is paramount. As such, hallucinations represent a major challenge in the deployment of LLMs. Addressing this issue requires a deeper understanding of its underlying causes and the development of robust detection and mitigation strategies to ensure the reliability and safety of these technologies in real-world applications [4].

In this context, we investigate how incorporating *external knowledge* can improve the effectiveness of hallucination detection in LLMs. Specifically, we explore the integration of *Retrieval-Augmented Generation* (RAG) frameworks [5] into existing detection pipelines, with the aim of enhancing their ability to identify hallucinated content by accessing verifiable information. Therefore, in this work, we develop an automated knowledge retrieval system that leverages the Google Search API to collect relevant external evidence, which is then integrated through RAG into two distinct hallucination detection methods: $(i)$ a *few-shot prompting* approach, where an LLM is explicitly instructed to assess the factuality of a given statement, and $(ii)$ SelfCheckGPT [6], a state-of-the-art hallucination detection method based on response sampling, which evaluates whether a generated output contains hallucinated content. Finally, the impact of knowledge integration on the effectiveness of hallucination detection approaches is assessed by conducting a comparative evaluation. Specifically, the performance of each approach is measured both with and without the incorporation of external knowledge, using established benchmark datasets for hallucination detection.

# 2. Background and Related Work

Within the context of LLMs, the term "hallucination" refers to the generation of content that is either nonsensical or unfaithful to the source content. In the literature, hallucinations are typically categorized into two main types: *factuality hallucinations* and *faithfulness hallucinations* [2]. The remainder of the section therefore provides background on the two distinct concepts, before considering the literature that directly addresses the problem.

## 2.1. Factuality Hallucinations

This category of hallucination encompasses all content that contradicts established real-world knowledge. It constitutes the primary focus of this study, as it is directly associated with the presence and potential dissemination of misinformation. Factuality hallucinations can be further classified based on the verifiability of the generated content against reliable sources, depending on whether they are characterized by:

- *Factual inconsistency*, which refers to cases in which the output contradicts verifiable information from reliable sources, thereby generating incorrect content;
- *Factual fabrication*, which occurs when the generated output cannot be verified against any reliable source, indicating the generation of unverifiable or entirely invented content.

## 2.2. Faithfulness Hallucinations

Faithfulness hallucinations arise when the generated content is inconsistent with the input or contextual information provided by the user. This category can be further subdivided into three types, depending on whether they are characterized by:

- *Instruction inconsistency*, which occurs when the output deviates from the explicit instructions given by the user;
- *Context inconsistency*, where the generated content is misaligned with the contextual information supplied by the user;
- *Logical inconsistency*, which is typically observed in reasoning tasks and is characterized by contradictions or errors in the reasoning steps of the model.

## 2.3. Related Work

In recent years, numerous studies have investigated the issue of hallucinations in LLMs, proposing a variety of detection approaches based on different methodological strategies to identify and mitigate this phenomenon. These approaches can be broadly classified into the following categories:

- *Uncertainty estimation-based*: Studies suggest that outputs produced with high model uncertainty are more prone to hallucinations [7]. Accordingly, these methods estimate the LLM's uncertainty by analyzing its internal states to infer the likelihood of hallucinated content. A key advantage of these techniques is their independence from external knowledge; however, they require access to the model's internal representations, which may not be feasible in all settings, especially with proprietary models;
- *Knowledge retrieval-based*: These approaches leverage external knowledge sources—such as online encyclopedias or structured databases—to verify the factuality of LLM-generated content. While generally reliable and adaptable across domains, these methods often incur high computational costs due to the retrieval and processing of external information;
- *Zero-resource and black-box*: These techniques detect hallucinations by analyzing output consistency and model behavior across multiple generations, without relying on external knowledge or internal model access. Although these methods are broadly applicable to any LLM, they may be less effective in scenarios involving queries with multiple plausible answers or ambiguous interpretations.

Belonging to the first category, the work described in [8] argues that when an LLM generates hallucinated content, it implicitly encodes a degree of uncertainty within its internal representations. Based on this assumption, the authors introduce SAPLMA, a method that aims to determine the factuality of a generated statement by analyzing the internal states of the model to estimate its uncertainty. Since it is not yet fully understood which internal layers best capture information relevant to factuality, the authors investigate multiple variants of the approach by extracting hidden states from different layers of the model, such as intermediate or final layers. These representations are then passed to a shallow neural classifier, which outputs the probability that the statement is true or false. Despite the good results, the optimal layer from which to extract internal states remains unclear and appears to be dependent on the specific LLM employed. Furthermore, the evaluation was conducted on isolated statements classified as true or false, rather than on complete model responses generated in relation to specific user inputs, thereby limiting the assessment of the method's effectiveness in realistic interaction scenarios.

The approach presented in [9], which belongs to the second category of approaches, introduces FActScore, a method based on comparison with a reliable external knowledge source. The procedure begins by decomposing the content generated by the LLM into atomic facts, defined as concise and discrete statements. These atomic facts are then manually verified by human annotators, who assess their factuality using English Wikipedia as the reference source. Each atomic fact is labeled as supported or unsupported depending on whether it is supported by the knowledge base. The overall factuality score of the content is computed as the proportion of atomic facts that are supported by reliable knowledge. While this method offers a structured and interpretable evaluation of factual accuracy, it presents notable limitations. Specifically, it has been validated exclusively in biographical texts, domains characterized by objective and easily verifiable information.

Finally, belonging to the third category of methods, in [6] the authors propose SelfCheckGPT, a hallucination detection method that leverages stochastic sampling of multiple responses generated by an LLM from the same input prompt. The underlying assumption of this approach is that, when an LLM possesses reliable knowledge about a given topic, its responses will exhibit a high degree of consistency; conversely, a lack of knowledge will lead to greater variability among responses. To evaluate the consistency of these sampled outputs, the authors introduce five distinct variants of SelfCheckGPT: SelfCheckGPT with BERTScore, which performs semantic similarity comparisons between responses; SelfCheckGPT with *Question Answering* (QA), which generates questions from the original answer and uses the sampled responses to answer them; SelfCheckGPT with *Natural Language Inference* (NLI), which applies an NLI model to determine whether responses entail or contradict one another; SelfCheckGPT with $n$-grams, which estimates token-level probabilities; and SelfCheckGPT with LLM prompt, which relies on prompting an LLM to judge the consistency of the sampled outputs. However, the evaluation of this approach was conducted on a limited dataset comprising 238 Wikipedia-style articles synthetically generated by an LLM, with factuality assessed manually at the sentence level. While this setting provides initial insights, the scope of the study remains narrow and could be extended to include more diverse and conceptually complex content.

In light of the primary limitations identified in the literature for existing hallucination detection approaches, this study proposes a fully automated methodology that completely eliminates the need for human involvement in the knowledge retrieval process. Manual retrieval is often labor-intensive and time-consuming; by contrast, the proposed approach leverages an automated pipeline for sourcing and integrating external knowledge, thereby significantly reducing both time and operational costs. Furthermore, the effectiveness of the method is validated through experiments conducted on three established benchmark datasets for hallucination detection, each encompassing a variety of domains. This ensures a broader evaluation scope and demonstrates the robustness of the method across diverse contexts.

# 3. Methodology

This section details the methodologies employed for the development of the automatic knowledge retrieval system, alongside the strategies utilized for integrating the retrieved knowledge into both: $(i)$ the few-shot prompting approach, and $(ii)$ the SelfCheckGPT framework.

## 3.1. Knowledge Retrieval System

The knowledge retrieval system is built entirely upon a customized Google Search engine, accessed via the Google Search API. In particular, the retrieval process is organized into the following steps:

- A query is submitted to the search engine;
- The search engine communicates with the Web through the API and returns a list of query-relevant URLs;
- The content of the first URL is parsed to extract the main body text from the HTML;
- The retrieved textual content is then encoded using an embedding model, and its vector representation is stored in a vector database, allowing for efficient retrieval and integration with the LLM.

Figure 1 illustrates the pipeline for the knowledge retrieval process.

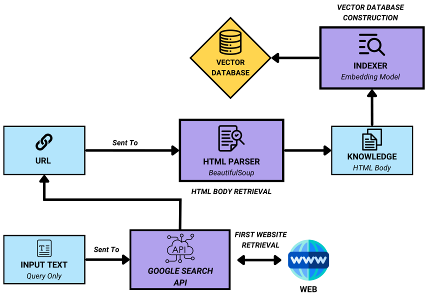

**Figure 1:** Pipeline of the knowledge retrieval process.

## 3.2. Few-Shot Prompting with Knowledge

Few-shot prompting is a technique in which an LLM is presented with a limited number of task-specific examples to guide its behavior and enhance its ability to perform a given task. However, the model's responses in this setting are based solely on the knowledge acquired during the pre-training phase. To enhance its performance and expand its informational basis, the framework integrates external knowledge retrieved through the automated retrieval system. This additional context is provided to the model during inference, enabling more accurate and informed task execution. Specifically, the process is structured into the following steps:

- The user's query is encoded using the embedding model;
- The resulting embedding is used to retrieve relevant information from the vectorized knowledge base;
- The retrieved knowledge is incorporated into the prompt, together with a set of examples and the question–answer pair to be assessed;
- The LLM evaluates the factuality of the answer by leveraging both its internal knowledge and the external information, classifying the response as either factual (*true*) or hallucinated (*false*).

Figure 2 illustrates the pipeline of the few-shot prompting approach enhanced through the integration of specialized external knowledge.

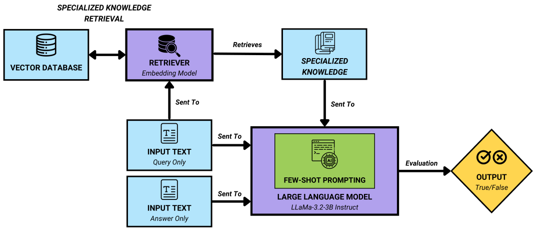

**Figure 2:** Pipeline of the few-shot prompting approach enhanced with the specialized knowledge.

### 3.3. SelfCheckGPT with Knowledge

The knowledge was also integrated into the SelfCheckGPT framework to improve the quality of the sampled responses. The underlying assumption is that providing the LLM with relevant external information will lead to the generation of more accurate and reliable responses. As a result, when these samples are compared with the target response using one of the SelfCheckGPT variants, it becomes easier to assess whether the target response is hallucinated. The process is structured according to the following steps:

- The user's query is encoded using the embedding model;
- The resulting embedding is used to retrieve relevant information from the vectorized knowledge base;
- Based on the user's query and the retrieved knowledge, the model is prompted to generate $N$ responses to the same query;
- The response under evaluation is segmented into individual sentences, which are then compared with the $N$ sampled responses using one of the SelfCheckGPT variants;
- SelfCheckGPT assigns a hallucination score to the evaluated response by averaging the sentence-level scores, resulting in a value between 0 and 1, where 0 indicates a hallucinated response and 1 denotes a factual one. This score is subsequently transformed into a binary classification (true/false) using a threshold function.

Figure 3 illustrates the pipeline of the SelfCheckGPT framework enhanced through the integration of external knowledge.

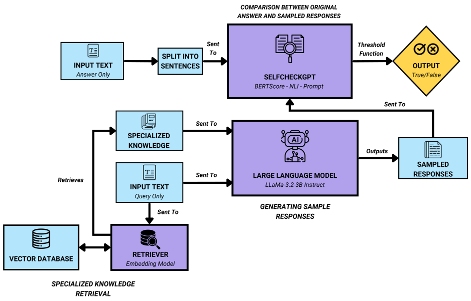

**Figure 3:** Pipeline of the SelfCheckGPT framework enhanced with the specialized knowledge.

## 4. Experimental Evaluation

This section presents the experimental setup employed to conduct the experiments, describes the datasets and the metric used for performance evaluation, and provides an analysis of the results obtained.

### 4.1. Experimental Setup

All experiments were carried out on the Google Colab platform,[1] utilizing a Tesla T4 GPU. The LLM employed for the few-shot prompting approach, response sampling, and the LLM-prompt variant of SelfCheckGPT was

[1] https://colab.research.google.com/

Llama-3.2-3B-Instruct, accessed using the Transformers library of Hugging Face.[2] For both approaches, the model selected for generating semantic embeddings and as a retriever was jina-embeddings-v3.[3] The retrieved knowledge was segmented into chunks of 256 characters with an overlap of 25 characters to preserve semantic coherence across segments. The retriever was configured to return the top 5 most relevant documents according to similarity to the input query.

The few-shot prompting approach was evaluated by providing the model with 1, 5, and 10 examples. To generate the response, the LLM was set to a temperature value equal to 0.001. Figure 4 presents the prompt structure provided to the LLM to classify a given text as either factual or hallucinated.

**Prompt for Few-Shot Prompting with Knowledge**

```
I want you to act as a response judge.
Given a user query, a knowledge, and a response by an LLM, your objective is to determine if the response is an hallucination or not.
In the context of NLP, an "hallucination" refers to a phenomenon where the LLM generates text that is incorrect, nonsensical, or not real. Based on your knowledge, on the knowledge provided, and on the definition of hallucination provided, analyze the user query and the response of the LLM, and answer the following question: is the response factual or not?
BE CAREFUL: sometimes the knowledge may be empty or not useful, in which case you have to respond based only on your knowledge.
Answer True if you consider the response factual, False otherwise.
You don't have to provide any explanation.
### EXAMPLE 1
User query: [USER QUERY]
Knowledge: [KNOWLEDGE]
LLM response: [LLM RESPONSE]
Answer: [ANSWER]
...
### EXAMPLE N
User query: [USER QUERY]
Knowledge: [KNOWLEDGE]
LLM response: [LLM RESPONSE]
Answer: [ANSWER]
### LLM TURN
User query: [USER QUERY]
Knowledge: [KNOWLEDGE]
LLM response: [LLM RESPONSE]
Answer:
```

**Figure 4:** Prompt submitted to the LLM for few-shot prompting with knowledge.

For the implementation of SelfCheckGPT, the variants employed for evaluation purposes are BERTScore, NLI, and LLM prompt (see Section 2.3). In accordance with the original SelfCheckGPT configuration, 5 responses per query were sampled using a temperature setting of 1.0 and a maximum output length of 128 tokens. Figure 5 illustrates the prompt provided to the LLM for the generation of these sampled responses.

**Prompt for Generating Sampled Responses with Knowledge**

```
Based on your knowledge and on the context provided, answer the following question giving as much detail as you can.
Question: [QUESTION]
Context: [KNOWLEDGE]
Answer:
```

**Figure 5:** Prompt submitted to the LLM for generating the sampled response using the retrieved knowledge.

## 4.2. Datasets and Evaluation Metric

For the experimental evaluation, three benchmark datasets for hallucination detection were selected. Each dataset includes a *user query*, the corresponding LLM-generated *response*, and a *binary label* indicating whether the response is factually accurate. The datasets employed are *FactAlign* [10], *FactBench* [11], and FELM [12], all of which are described in detail in the following.

**FactAlign.** This dataset was created to improve the factual accuracy of LLM-generated long-form responses [10]. For each query, a corresponding answer was generated and then segmented into individual sentences. Each sentence was further broken down into atomic facts, which were verified against a Wikipedia-based reference corpus. A sentence was considered factual only if all its atomic facts were supported by this reference. An answer received a factual label if at least 75% of its sentences met this criterion, yielding a binary label (i.e., *true* or *false*). The version used in this work, retrieved from Hugging Face, contains a total of 2 562 instances.[4] Of these, 1 307 were labeled as factual (true) and 1 255 as non-factual (false). Each instance includes a user prompt, the corresponding response generated by an LLM, and a binary factuality label indicating the truthfulness of the response. For evaluation, only those instances where the user query was a question—i.e., ending with a question mark—were selected. This filtering criterion was adopted

[2] https://huggingface.co/meta-llama/Llama-3.2-3B-Instruct
[3] https://huggingface.co/jinaai/jina-embeddings-v3

[4] https://huggingface.co/datasets/chaoweihuang/factalign-gemma2-f1_0.75

to facilitate more effective knowledge retrieval through the Google Search API and to simplify both the factuality classification task performed by the LLM and the generation of sampled responses within the SelfCheckGPT framework. Following this filtering step, a random sample of 100 questions was selected. This limitation was imposed by constraints on computational resources and time, which required a balance between the number of examples and processing efficiency. Furthermore, to ensure comparability and consistency across the methods and each variant, a fixed random seed was used to guarantee the reproducibility of the 100 instances across all experiments.

**FactBench.** This dataset was specifically developed to evaluate FactCheck-GPT, a multi-step framework designed for the detection and correction of factual errors in responses generated by LLMs [11]. FactBench was constructed by integrating three distinct benchmark datasets aimed at hallucination detection:

- *Knowledge-based FacTool*: Created to assess the performance of the FacTool framework, which evaluates the factual consistency of LLM-generated responses through external knowledge retrieval [13]. This dataset was constructed by selecting 50 prompts from FactPrompts and fact-checking datasets such as TruthfulQA [14]. For each prompt, responses were generated using ChatGPT and subsequently annotated by human evaluators with binary labels indicating factual correctness;
- *FELM-WK*: Subset of the FELM dataset that will be detailed in the next paragraph;
- *HaluEval*: This benchmark dataset for hallucination detection was constructed by initially considering 52 000 prompts, followed by a filtering procedure aimed at selecting those most likely to elicit hallucinated responses from a LLM. Specifically, each prompt was submitted to ChatGPT three times, and the average semantic similarity among the generated responses was calculated. The 5 000 prompts with the lowest semantic similarity scores were retained to ensure the dataset included only the most challenging queries. The selected prompts were then resubmitted to ChatGPT to obtain a second set of responses, which were manually annotated as either true or false based on their factual accuracy [15].

FactBench was made publicly available by the authors on GitHub and comprises a total of 4 835 examples, of which 3 838 are labeled as true and 995 as false.[5] Each instance includes a user query, the corresponding response generated by an LLM, and a binary factuality label. For evaluation purposes, only the entries corresponding to user queries in the form of questions were retained. Due to computational constraints, a subset of 100 observations was selected. To mitigate the effects of class imbalance, an equal number of true and false instances (50 each) were randomly sampled. A fixed random seed was applied to ensure reproducibility and consistency across all experimental configurations.

**FELM.** FELM is a multi-domain benchmark dataset designed for the evaluation of hallucination detection in LLMs, encompassing five distinct domains, each posing specific challenges for the models under analysis [12]. The domains are defined as follows:

- *World knowledge*: Includes questions related to general cultural and factual knowledge;
- *Science and technology*: Comprises statements related to scientific facts or citations across disciplines such as physics and biology;
- *Reasoning*: Contains prompts that require multi-step logical reasoning to produce a correct response;
- *Recommendation and writing*: Involves open questions requiring the model to provide suggestions or generate creative or structured written content;
- *Math*: Encompasses problems that necessitate both logical reasoning and mathematical skills to arrive at correct answers.

FELM was constructed by aggregating prompts from diverse sources, which were then submitted to ChatGPT operating in a zero-shot configuration. The resulting responses were segmented into sentences, each of which was subsequently evaluated by a team of experts. The factual accuracy of each sentence was assessed based on comparison with reliable sources, and sentences were annotated as either true or false accordingly. A response was labeled as true only if all its sentences were assessed as accurate; otherwise, it was classified as false. The FELM dataset was obtained from Hugging Face and comprises a total of 847 instances.[6] Each instance includes a user prompt, the corresponding response generated by the LLM, and a factuality label. Of these examples, 566 are labeled as factual, while 281 are labeled as non-factual. For evaluation, only the *World knowledge* and *Science and technology* domains were considered, as the remaining presented substantial limitations for the knowledge retrieval approach (*e.g.*, mathematical prompts such as *"What is the value of the expression 1! + 2! + 3! + ... +*

[5] https://github.com/yuxiaw/Factcheck-GPT/blob/main/Factbench.jsonl

[6] https://huggingface.co/datasets/hkust-nlp/felm

*10!*"). As in the previous datasets, only prompts formulated as questions were retained. To mitigate class imbalance and accommodate computational constraints, a balanced subset of 100 samples—comprising 50 factual and 50 non-factual instances—was randomly selected. A fixed random seed was applied to ensure consistency across experiments.

**Evaluation metric.** Since all the datasets employed in the evaluation are balanced, *Accuracy* was adopted as the primary performance metric. It is defined as follows:

$$\mathit{Accuracy} = \frac{TP + TN}{TP + FP + TN + FN}$$

where *TP* denotes factual responses correctly classified as factual, *TN* represents hallucinated responses correctly identified as hallucinations, *FP* corresponds to hallucinated responses incorrectly classified as factual, and *FN* refers to factual responses mistakenly classified as hallucinations.

### 4.3. Results and Discussion

To evaluate the impact of knowledge integration, the performance of both SelfCheckGPT and the few-shot prompting approach was evaluated in two configurations: with and without the inclusion of external knowledge. A summary of the comparative results is presented in Table 1. The notation W/O and W denotes whether the evaluated variant operates without or with integrated knowledge, respectively. For each variant and dataset, the version (with or without knowledge) that achieves the highest performance is underlined; if both versions perform equally, no underlining is applied.

| Models | Variant | FactAlign | | FactBench | | FELM | |
|---|---|---|---|---|---|---|---|
| | | W/O | W | W/O | W | W/O | W |
| *SelfCheckGPT* | *BERTScore* | 59.0 | 61.0 | 61.0 | 60.0 | 56.0 | 59.0 |
| | *NLI* | 67.0 | 67.0 | 64.0 | 69.0 | 67.0 | 71.0 |
| | *LLM Prompt* | 62.0 | 65.0 | 57.0 | 63.0 | 69.0 | 68.0 |
| *Few-Shot Prompting* | *One-shot* | 50.0 | 54.0 | 62.0 | 62.0 | 62.0 | 63.0 |
| | *Five-shot* | 57.0 | 55.0 | 53.0 | 64.0 | 56.0 | 59.0 |
| | *Ten-shot* | 55.0 | 59.0 | 59.0 | 65.0 | 59.0 | 62.0 |

**Table 1**
Comparison between methods with and without integrated knowledge, to evaluate its impact on their performance.

As shown in Table 1, the SelfCheckGPT framework consistently outperforms the few-shot prompting approach across all evaluated conditions. This result aligns with expectations, given that SelfCheckGPT is specifically designed for hallucination detection, whereas few-shot prompting is a more general-purpose methodology. Among the SelfCheckGPT variants, the NLI-based method demonstrates the highest overall effectiveness and efficiency, surpassing the LLM prompting variant across all three benchmark datasets. With regard to few-shot prompting, the ten-shot configuration achieves the best performance, followed by the five-shot and one-shot variants, respectively. This trend is consistent with the hypothesis that providing a greater number of examples enables the LLM to better internalize the task structure, thereby improving generalization and overall accuracy.

In this regard, the strategy for selecting examples in the few-shot prompting approach could be improved. In the current evaluation, examples were randomly sampled from the datasets, which may result in class imbalance among the examples shown to the LLM, potentially affecting performance. Ensuring a balanced representation of classes in the selected examples would therefore be crucial for enhancing the robustness of the analysis in the few-shot prompting setting.

Regarding the impact of knowledge integration, on the FactAlign dataset, the only method that underperforms when incorporating external knowledge is few-shot prompting with five examples; all other tested methods either match or surpass the performance of their counterparts without knowledge. A similar trend is observed on FactBench, where all approaches that leverage retrieved knowledge perform at least as well as, and often better than, those without knowledge integration. Finally, in the FELM dataset, incorporating external knowledge generally leads to performance improvements across methods, with the sole exception of SelfCheckGPT using the LLM Prompt, where performance declines by one percentage point after knowledge integration. Overall, these analyses suggest that integrating external knowledge generally enhances the performance of the evaluated approaches across all datasets, with only a few exceptions where a slight decrease in performance was observed.

These performance declines may be attributed to limitations in the knowledge retrieval process. Specifically, only the first retrieved URL is considered—typically the most popular, but not necessarily the most informative. Additionally, the retrieval system occasionally fails to access relevant content due to Web restrictions, such as anti-bot mechanisms or CAPTCHA protections, which hinder the acquisition of valuable external knowledge. Nevertheless, on average, approaches augmented with external knowledge outperform their non-augmented counterparts. This suggests that further improvements in the retrieval process could improve the overall effectiveness of these methods and lead to even greater performance gains.

## 5. Conclusions and Perspectives

In this study, we introduced a fully automated knowledge retrieval framework that leverages a custom search engine interfacing with the Web via the Google Search API to extract relevant external information. The retrieved knowledge was subsequently integrated into two distinct methodologies: (i) *few-shot prompting*, which consists of providing a set of examples to guide task execution, and (ii) *SelfCheckGPT*, a hallucination detection framework that generates and compares multiple responses from an LLM to identify factual inconsistencies. The enhanced versions of both approaches, incorporating retrieved knowledge, were evaluated on three benchmark datasets for hallucination detection—FactAlign, FactBench, and FELM—spanning a diverse range of domains. The experimental results indicate that SelfCheckGPT consistently outperforms the few-shot prompting approach, demonstrating strong performance across all three benchmark datasets. Among its variants, the NLI configuration emerges as the most effective and computationally efficient. Moreover, the integration of external knowledge generally enhances the performance of the evaluated approaches compared to their counterparts without such integration. Nonetheless, the observed improvements could be further amplified by refining the knowledge retrieval process in future work. Specifically, challenges such as CAPTCHA mechanisms or site access restrictions that limit automated retrieval should be addressed. Additionally, the quality of the queries submitted to the search engine could be improved by leveraging LLMs to generate more precise and contextually rich queries, thereby yielding more informative results. Moreover, expanding the number of retrieved Web sources may lead to more comprehensive and accurate knowledge; for instance, retrieving the top five results could increase the relevance and diversity of the retrieved information. Finally, future researches may also focus on further refining the knowledge integration process by leveraging more advanced and sophisticated RAG techniques [5]. Enhancing integration within frameworks such as SelfCheckGPT, which has already demonstrated promising results in hallucination detection, holds significant potential. These advancements could support the development of a reliable, scalable, and efficient multi-domain hallucination detection system.

# Benchmarking Historical Phase Recognition from Text and Events

Fabio Celli[1,*], Marco Rovera[2]

[1]Maggioli Research, Santarcangelo di Romagna, Italy
[2]Fondazione Bruno Kessler, Trento, Italy

**Abstract**

This paper presents preliminary studies on a benchmark for the Historical Phase Recognition task. This task explores the application of computational linguistics to the study of long-term historical dynamics. We compare the utility of Event Tagging and BERT embeddings for classifying the phases of secular cycles defined by the the Structural-Demographic Theory. We explore this task both as five-class classification (crisis, growth, population immiseration, elite overproduction, State stess) and binary classification (rise, decline), on the basis of human- and LLM-annotated labels. Our findings reveal that Event Tagging, when aligned with human annotations, yields good performance in multi-class classification, but not in binary classification. Conversely, using BERT to extract features directly from text yields better performances with LLM-generated labels, in particular on the binary classification task. We also report higher inter-annotator agreement between LLMs compared to humans when labeling historical phases.

**Keywords**

Historical Phase Recognition, Cultural Analytics, Structural Demographic Theory, Large Language Models,

## 1. Introduction and Motivation

Historical Phase Recognition is a novel task that aims at the classification of phases of past societies according to existing theoretical frameworks. This task, based on the idea that history is a complex adaptive system [1] like language [2], can be useful for exploring and comparing societal adaptation processes in their long-term trends [3], to find replicable patterns. Societies have historical and structural dimensions [4] and evolve through dynamics that create cycles [5], following irreversible developmental paths that eventually cause them to break down [6] or recover. Crucially, much of historical information is expressed in natural language [7], and it is available from open sources like Wikipedia [8, 9], hence computational linguistics tasks such as event detection [10] can offer a great contribution to this line of research.

A theoretical framework in this area that has proven to be suitable for computational analysis is the Structural-Demographic Theory (SDT) [11]. By integrating this theory with data modeling techniques, researchers were able to make remarkably accurate predictions about the global crises that unfolded in the 2020s [12]. This predictive power underscores the value of SDT as a tool for analyzing complex socio-political dynamics within historical datasets [13]. Specifically, the SDT posits that historical cycles are characterized by five distinct phases:

- 0. Crisis (widespread conflict that results in a restructuring of the socio-political order);
- 1. Growth (a new order creates social cohesion, triggering high productivity and increasing competition for social status);
- 2. Population immiseration (increased competition for status and resources leads to rising inequality);
- 3. Elite overproduction (inequalities lead to radical factionalism and frustrated individuals who may become agents of instability) and
- 4. State stress (the rising instability brings fiscal distress and both lead the State towards potential crises with widespread conflicts, restarting the cycle).

SDT has proven to be a valuable framework for understanding a diverse array of historical occurrences. For instance, it has been applied to analyze the underlying causes of the French Revolution, the elite rivalries that fueled the American Civil War [14], and the factors contributing to the collapse of the Qing Dynasty [15]. Furthermore, SDT is also employed to analyze contemporary historical events, ranging from the Egyptian revolution of 2011 [16] to the political instability experienced in the US in 2021 [17].

Previous work in Historical Phase Recognition [18] released the Chronos dataset, annotated by humans, and demonstrated that systems can learn models with performance above chance, although far from perfect. Recent research in the field reports that LLMs can reach human performance in Historical Phase labeling and report that the intra-annotator agreement of LLMs is consistent [19].

CEUR Workshop Proceedings ceur-ws.org ISSN 1613-0073
published 2025-11-30

Still there is no benchmark in Historical Phase Recognition, and there are research questions about this task that remain unanswered, for instance:

- (RQ1) Can Event Tagging provide a generalization that helps Historical Phase Recognition?
- (RQ2) Can LLMs-as-annotators reach a higher consensus than humans in SDT labeling?
- (RQ3) Which kind of label is easier to model, the one made by humans or by LLMs?
- (RQ4) Is it easier to perform Historical Phase Recognition as 5-class or as a binary classification task?

To answer RQ1 we use EventNet-ITA, a Frame Parser[1] trained on a large Italian corpus, annotated with semantic frames of events[2]. This tool provides a fast and effective method for extracting Event Frames in Italian, achieving a performance of 0.9 F1-score for Frame Identification and 0.72 for Frame Element Identification on the original dataset [20]. To answer RQ2 we employ GPT4 [21] and Llama 3.1-400b [22] as annotators, producing a new SDT annotation on data. To answer RQ3 we adopt a perspectivist approach [23], running the classification task on different label sets and even on combination of labels. Lastly, to answer RQ4, we aggregate phases 1 and 2 under the label "rise" and phases 3, 4, and 0 under the label "decline," and then perform a binary classification task.

The paper is structured as follows: In Section 2 we describe how we created a benchmark from the Chronos dataset to promote the reproducibility of future experiments. In Section 3 we describe our experimental design, with annotation guidelines, prompts, analysis of labels and the results of the classification experiments. Finally, in Section 4, we draw our conclusion.

## 2. Data

Previous work on the Historical Phase Recognition task made a huge effort to produce annotated data [18], but the results of the previous classifications are not fully replicable. Hence we decided to develop a benchmark with fixed training and test sets out of the Chronos dataset.

The Chronos dataset, built upon the Seshat historical databank [24] and augmented with Wikipedia content, provides time-series data, in Italian and English, of historical events for 366 polities across 18 sampling zones, spanning from neolithic to the 2010s CE. Each row in the dataset represents an historical decade of a polity in a sampling zone. Textual descriptions of the selected events that happened in the decade include information about wars, reforms, rulers, population, elites, disasters, alliances, socio-economic context, famines, protests, elite changes, and religions. Descriptions are summarized to an average of 400 characters per decade, with source references when available. Each entry includes a timestamp, historical age, sampling zone, world region, and a standardized Polity ID encoding origin, name, societal type, and periodization. The dataset contains more than 9000 rows, but most of them have no textual description, especially those in remote times. Moreover, there are duplicates, as some polities expanded over more than one sampling zone, and were sampled more than once. The dataset also contains a flag to indicate whether the historical information reported is recorded or supposed. Using these information we created a benchmark.

### 2.1. Annotation and Agreement

First, we extracted event tags from the historical descriptions in Italian with EventNet-ITA. Then we removed duplicates and selected the rows with tags, text and recorded information. We obtained 1422 rows with data spanning from antiquity to 2010s. The data included also the original SDT labels, annotated by human hand following the points in these guidelines:

1. Read the textual description to identify key events: wars, reforms, rulers, population, elites, disasters, epidemics, alliances or treaties, socio-economic context, famines or financial stress, protests or movements, religions.
2. Use polity identifiers to find the start and end points of cultures. The end of a culture represents a crisis period.
3. Starting from the beginning of a culture, initially assign the sequence of labels of a standard secular cycle model: 1,1,2,2,3,3,4,4,4,0 and then evaluate whether to keep or change the labels in each decade. It is possible to have longer or shorter cycles. There can be only one label 0 (crisis) per cycle. A polity can have one or more cycles.
4. Having in mind the key events in the textual description, select one of the following labels to describe the decade: 1=growth. A society is generally poor when it experiences renewal or change followed by demographic (but not always territorial or economic) growth. Reforms, alliances, wars won or similar events are potential indicators of this phase. 2=impoverishment of the population. Potential economic and/or territorial expansion slows while demography continues to expand. The elite takes much of the wealth and defines the status symbols. Stability and external attacks are potential indicators of this phase. 3=Overproduction of the elites. The wealthy seek to translate their wealth into positions of authority and prestige. The population becomes poor.

[1] https://huggingface.co/mrovera/eventnet-ita
[2] https://huggingface.co/datasets/mrovera/eventnet-ita

Movements, protests, and wars are potential indicators of this phase. 4=State stress. The elites want to institutionalize their advantages in the form of low taxes and privileges that lead the state into fiscal difficulties. Wars, protests and changes in the elite are potential indicators of this phase. 0=Crisis. a triggering event such as a war, revolt, famine or disaster that the state is unable to manage leads to a new configuration of society. Emigration of elites, subjugation to other societies, civil wars or profound reforms are potential indicators of this phase.

5. Use the progressive order of the phases if no textual description is available for the decade.
6. Make sure there is a progressive order of the labels (e.g. phase 3 must follow phase 2). All labels can be repeated in the following decade except the crisis phase, which conventionally lasts one decade.

The annotation in the Chronos dataset was validated with three human annotators, who independently labeled a sample of 93 examples from the data. The initial agreement was low (Fleiss' $k$ 0.206) because a single disagreement has an exponential impact on the rest of the sequence, but after a training session and the use of a standard pattern to start with (the sequence of secular cycle labels 1,1,2,2,3,3,4,4,4,0), the agreement between humans raised to Fleiss' $k$ 0.455.

In order to answer RQ3 (whether it is easier to predict labels annotated by humans or LLMs) we produced new labels using GPT4 (1.8 trillion parameters) and Llama 3.1 (405 billion parameters) with the prompt reported in Figure 1 and temperature of 0.5. We provided the input data in chunks containing sequential decades of one or two polities per run. Despite the prompt explicitly required to assume that the sequence of labels follows a standard secular cycle model like the one used by humans (1,1,2,2,3,3,4,4,4,0), sometimes the LLMs produced as output unordered labels.

In order to create a benchmark, we split the data into training (1222 instances) and test set (200 instances). The labels have comparable distributions in the training and test set, as reported in Figure 2. While human and LLM labels approximate a log-normal distribution, the averaged labels approximate a normal distribution. This is because averaging labels with big misalignments (such as label "1" and label "4") tend to produce more labels "2", which became a wastebasket label.

We computed the inter annotator agreement over all 1422 examples and pairs of annotators, greatly expanding the experiments presented in literature. We evaluated results with $k$ statistics and Krippendorf's $\alpha$ [25]. Although pairs that mix human and LLM annotations have an agreement comparable to previous results, here GPT4

Act as an expert historian and consider the Structural Demographic Theory (SDT). Given a set of descriptions of historical decades for different polities, label each description with one of the following secular cycle phases (sdtphase):
0=crisis (in this phase may happen societal collapse patterns, power transitions, conflicts, administrative or social structure changes, and external influences. Look for signs of civil wars, military coups, environmental factors, population movements, reform of tax systems, trade network disruptions, class conflicts, and foreign invasions). 1=growth (a society recovers from a crisis finding a new fresh culture that creates social cohesion. to recognize this phase examine the power structure patterns, legitimacy of rule, social organization, cultural elements, military aspects, and social changes. Look for the presence of strong elite classes, religious legitimation of power, centralized administrative systems, trade networks, cultural practices, territorial expansion, and population movements); 2=population impoverishment (growth slows and inequalities begin to emerge. to recognize this phase evaluate the power dynamics, economic patterns, military aspects, cultural/religious elements, administrative features, and infrastructure development. Look for succession struggles, trade route development, territorial conquests, religious tolerance, bureaucratic reforms, and construction projects); 3=elite overproduction (the number elite aspirants rises and the social lift mechanisms deteriorate. To recognize this phase assess power dynamics, governance, economic patterns, social structures, cultural and technological development, and common catalysts for change. Look for power struggles, trade system developments, social unrest between elite and population, religious developments, and military conflicts), 4=state stress (elites struggle to institutionalize their advantages. to recognize this phase review political instability, power struggles, economic challenges, military conflicts, administrative changes, and social/religious tensions. Look for succession disputes, financial crises, territorial loss, reforms to advantage specific elite groups, social unrest and religious conflicts). Initially assume that the sequence of labels follows a standard secular cycle model: 1,1,2,2,3,3,4,4,4,0 and then evaluate whether to keep or change the labels in each decade. Evaluate each label on the basis of the preceding and following ones. It is possible to have longer or shorter cycles. A cycle cannot turn back and cannot skip phases. So if in 1940 there is a phase 0, in 1950 there should be a phase 1, in 1960 there can be a phase 1 or phase 2. If in 1960 there is a phase 2, in 1970 there can be a phase 2 or phase 3, not a phase 4. If in 1970 there is a phase 3, in 1980 there can be a phase 3 or 4, and if in 2000 there is phase 4, in 2010 there can be a phase 0 or another phase 4. The decade after phase 0 the cycle restarts from phase 1.

This is an example of the input (json): $\langle example \rangle$
and this is the desired output (csv): $\langle example \rangle$
set of descriptions to label (json): $\langle data \rangle$

**Figure 1:** Prompt for the annotation of historical data with LLMs

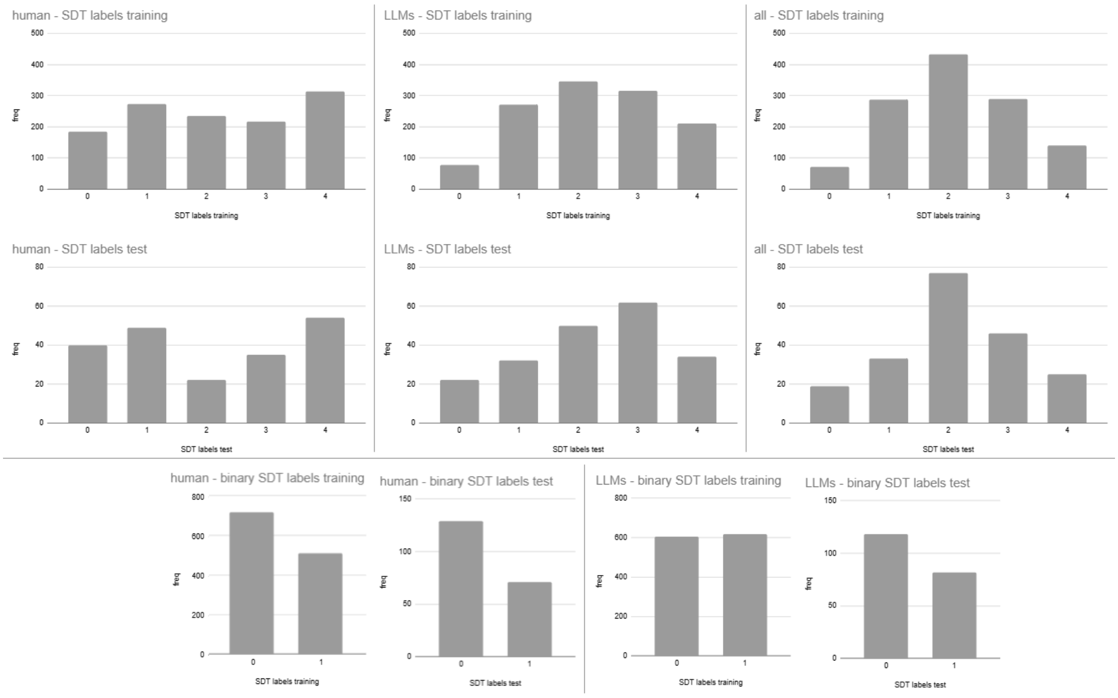

**Figure 2:** Distribution of labels for the multi-class classification task over the different label configurations.

and LLama3.1 have the highest score. This confirms, using a larger dataset, that LLMs can achieve a very high level of agreement on this task, even with temperature 0.5; moreover, these findings closely match the results obtained when both humans and LLMs received identical instructions and the temperature was set to zero [19]. The evaluation with Krippendorf's $\alpha$, which could better capture the importance of label order, shows results similar to the ones computed with Fleiss and Cohen's *k*, suggesting that there might be disagreements on distant labels, like 0 and 4. Results are reported in Table 1.

**Table 1**
Results of inter-annotator agreement between pairs of Historical Phase annotators.

| pair | Fleiss' *k* | Cohen's *k* | $\alpha$ |
|---|---|---|---|
| human+gpt4 | 0.215 | 0.218 | 0.216 |
| human+llama3.1 | 0.211 | 0.212 | 0.211 |
| llama3.1+gpt4 | 0.380 | 0.381 | 0.380 |

## 2.2. Contents

The final dataset contains the following features:

- a *decade ID* formatted with a standard method: 2 letters to indicate the area of origin of the culture, 3 letters to indicate the name of the polity, 1 letter to indicate the type of society (c=culture/community; n=nomads; e=empire; k=kingdom; r=republic), 1 letter to indicate the periodization (t=terminal; l=late; m=middle; e=early; f=formative; i=initial; *=any) and a number corresponding to the decade. For example "EgPdyk*-2960" is the pre-dynastic kingdom of Egypt in the 2960s b.C. "ItRomrm-220" is the middle Roman Republic in the 220s b.C. and "TrOttet1850" is the terminal phase of the Ottoman Empire in the 1850s;
- a *short Italian textual description* of the decade (the one used for the experiments);
- a *short English textual description* of the decade;
- the list of *tags* extracted from text;
- *human annotated SDT labels*;
- SDT labels annotated with *GPT4*,
- SDT labels annotated with *Llama3.1*,
- the *average of all the SDT labels*, turned into integer values;
- the *average of the SDT labels generated with LLMs*, turned into integer values;
- the *binary labels annotated by humans* obtained from SDT labels (1,2=rise; 3,4,0=decline);
- the *binary labels annotated by LLMs* obtained from SDT labels (1,2=rise; 3,4,0=decline).

Examples of data follows[3]:

1. JpKamk*1290, "al tempo del reggente Hōjō Sadatoki (r. 1284–1301) per il principe Hisaaki il clan Hōjō era alleato del clan Adachi. Tuttavia un complotto di Adachi Yasumori per usurpare gli Hōjō portò al colpo di stato noto come incidente Shimotsuki. vinse Hojo.","at the time of Regent Hōjō Sadatoki (r. 1284–1301) for Prince Hisaaki the Hōjō clan was allied of the Adachi clan. However a plot by Adachi Yasumori to usurp the Hōjō resulted in the coup known as Shimotsuki incident. the Hōjō won.", process*PROCESS_START activists*POLITICAL_ACTIONS invader*INVADING PROCESS_START POLITICAL_ACTIONS INVADING,4,4,4,4,4,0,0
2. IqBabke-1750, "possibile apertura di una rotta commerciale per beni di lusso e minerale di stagno verso il Levante (Caanan) e l'Anatolia orientale (occupata dagli Assiri).","possible opening of a commercial route for luxury goods and tin ore towards the Levant (Caanan) and eastern Anatolia (occupied by Assyrians).", land*OCCUPANCY occupier*OCCUPANCY OCCUPANCY,2,2,2,2,2,1,1
3. EgMamke1340,"peste nera ad Alessandria nel 1347. Serie di sultani di breve durata.","black death in Alexandria in 1347. Series of short lived Sultans.", old*TAKE_PLACE_OF killer*KILLING cause*DEATH place*DEATH time*DEATH TAKE_PLACE_OF KILLING DEATH,4,1,3,3,2,0,1

Example 1 describes the Japanese Kamakura period in 1290s and is a case where all the annotations agree about phase 4 (or 0, "decline" in the case of binary labels). Example 2 reports a description of Kassite Babylon in 1750s b.C. and is a case where all annotations agree on phase 2 (or 1, "rise"). Example 3 describes Mamluk Egypt in 1340s and it is a case of disagreement between annotations.

We ordered the data alphabetically using the text column, thus obtaining a pseudo-randomization of the instances and breaking the temporal sequences. We dubbed this dataset "Chronos benchmark", which is freely available on Huggingface[4].

## 3. Analysis and Discussion

In order to answer RQ1 (whether Event Tagging is useful to recognize different phases), we performed an analysis of events per label. To do so, we extracted wordclouds including only the examples where all annotators agreed on the same label. Figure 3 reports the wordclouds for the binary classification task. As introduced in Section 2, Event Frames are shown in uppercase, while Frame Elements in small caps, along with their Frame, in the format frame_element*EVENT_FRAME. The larger and bolder a word, the more strongly it is associated with that particular phase. From the wordclouds is clear that there are overlapping Event Frames between the two phases (eg: CONQUERING, WAR, CHANGE_OF_LEADERSHIP, BEAT_OPPONENT), while the same Frame Elements seem to have different frequencies in the two phases.

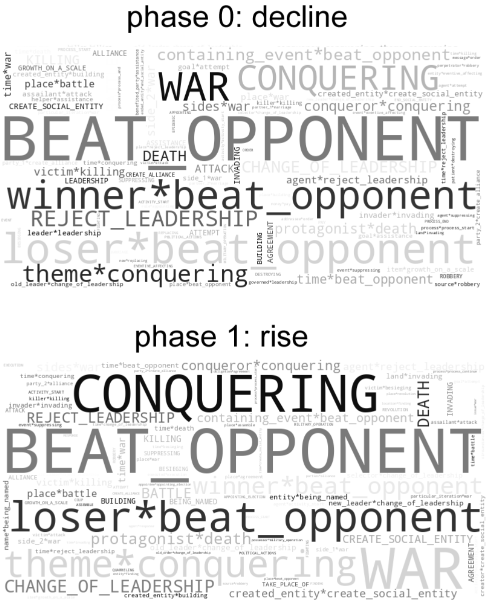

**Figure 3:** Wordclouds of Event tags in the binary classification task. The wordclouds include only the examples where all annotations agreed on the same label. Event frames are represented in uppercase while frame elements in lowercase.

Things are much more complicated in the multi-class classification task, depicted in Figure 4. In summary, the wordclouds show a progression where there are many overlaps of Event Frames between phases, in particular the BEAT_OPPONENT and CONQUERING events. However, Frame Elements help distinguish between phases: theme*CONQUERING clearly appears in the growth and crisis phases, while other low-frequency elements, such as process*PROCESS_START, and goal*ATTEMPT are distinctive of phases 3 and 4 respectively. In general, wordclouds with smaller words, like the ones for phase 2, 3 and 4, highlight the need to capture weak signals for the classification tasks.

Overall, the similarity of the tags between phases illustrate well how difficult is the Historical Phase Recognition task.

[3] EVENT_FRAMES are shown in uppercase, frame_elements in small caps.

[4] https://huggingface.co/datasets/facells/chronos-historical-sdt-benchmark

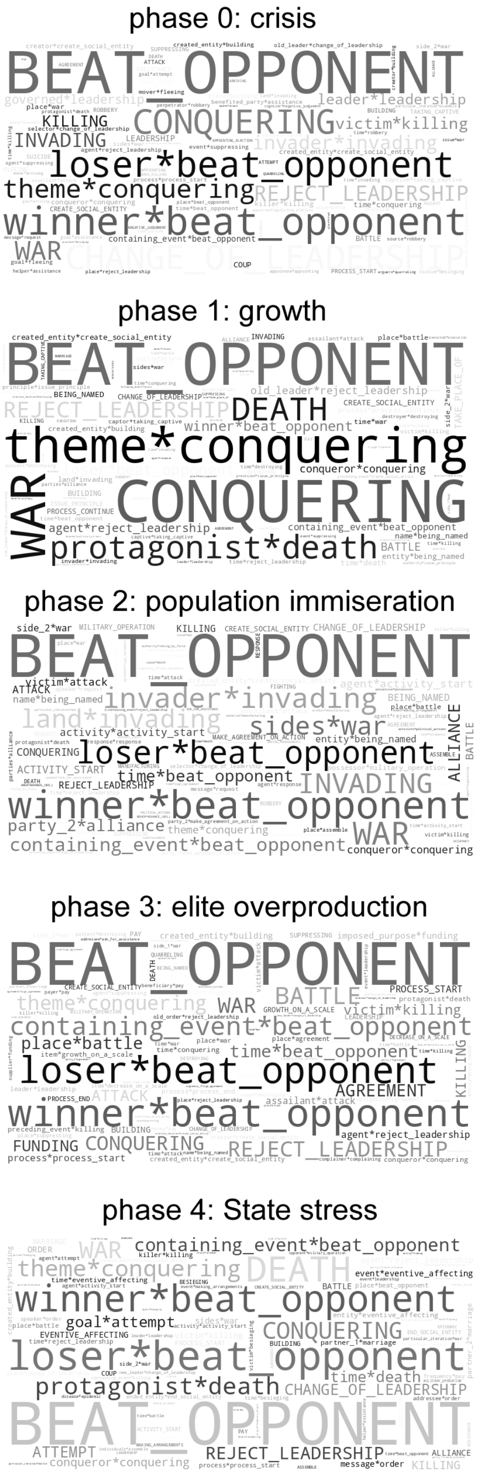

**Figure 4:** Wordclouds of Event tags in the multiclass classification task. The wordclouds include only the examples where all annotations agreed on the same label. Event frames are represented in uppercase while frame elements in lowercase.

### 3.1. Experiments

In order to answer the research questions listed in Section 1, we performed two distinct tasks: a multi-class classification, and a binary classification. Both tasks have comparable settings, with 768 features extracted with a frequency token matrix from the EventNet-ITA tags (events) and 768 features extracted with BERT-Italian-XXL (bert). To ensure replicability, we used Learnipy [26], a suite of algorithms for data science and machine learning in Colab Notebooks available online[5],

Table 2 reports the balanced accuracy of different classification models: Naive Bayes (nb), Gradient Boosting (xgb), Linear Discriminant Analysis (lda) using the two feature extraction methods (events, bert) to predict the 5 SDT phases. The models were trained and evaluated on different sets of labels: human-annotated (human), an average of LLM annotations (llms), and an average of all annotations (all). The baseline for this task is 0.2.

**Table 2**
Results of the 5-class classification task. We used two feature extraction techniques, EventNet-ITA (events) and BERT-Italian-XXL (bert), with three classification algorithms, Naive Bayes (nb), Gradient Boosting (xgb), Linear Discriminant Analisys (lda) to classify the labels provided in the Chronos dataset (human), averaged between GPT4 and Llama3.1 (llms), and averaged over all the preceding labels (all). The metric is Balanced Accuracy, the baseline is 0.2. The best averaged value for each pair are marked in bold, the ones below the baseline are marked in italics.

| labels | features | nb | xgb | lda | avg |
|---|---|---|---|---|---|
| human | events | 0.249 | 0.250 | 0.212 | 0.237 |
| human | bert | 0.178 | 0.180 | 0.218 | *0.191* |
| llms | events | 0.234 | 0.191 | 0.227 | 0.217 |
| llms | bert | 0.197 | 0.213 | 0.248 | 0.219 |
| all | events | 0.251 | 0.250 | 0.237 | **0.246** |
| all | bert | 0.205 | 0.208 | 0.118 | *0.176* |

Interestingly, the combination of human labels, event tags and an algorithm that captures weak signals (Gradient Boosting) yields good performances, suggesting that for the 5-class classification the event-based features align well with the human understanding of the SDT phases. However, the more robust results are achieved using event tags on the average of all labels, possibly for the normal distribution resulted from averaging the labels. In contrast, BERT struggles with human labels: the results show an average balanced accuracy lower than the baseline.

This might indicate that the contextual embeddings from BERT, while powerful, don't directly capture the nuances of the SDT phases as effectively as the event-based

[5] https://colab.research.google.com/drive/1G1VNHUCoDTso6wIWmrdvM21Z6D1PC6nL?usp=sharing

features when aligned with human annotations. However, the best performance when using labels averaged from LLMs is achieved with BERT features and Linear Discriminant Analysis. This hints that the patterns captured by BERT might be more consistent with the way LLMs interpret and label the SDT phases, although less transparent.

An interesting point is that event tags show consistent performance across different label sets (human, all, llms). The event tagger features consistently provide competitive results, often outperforming or closely matching BERT, with the advantage of being transparent. This highlights the value of explicit event information for this Historical Phase Recognition task. Overall, performance still needs improvement. While some results surpass the baseline of 0.2, the balanced accuracy scores indicate that accurately classifying the 5 SDT phases remains a challenging task.

Table 3 presents the results of the binary classification task, where the 5 SDT phases were aggregated into "rise" (phases 1 and 2) and "decline" (phases 0, 3, and 4). The same feature extraction methods and classification algorithms were used on human-derived binary labels (human) and LLM-averaged binary labels (llms).

**Table 3**
Results of the binary classification task. We used two feature extraction techniques, EventNet-ITA (events) and BERT-Italian-XXL (bert), with three classification algorithms, Naive Bayes (nb), Gradient Boosting (xgb), Linear Discriminant Analisys (lda) to classify binary labels computed from the Chronos dataset (human2), and averaged between the ones annotated by GPT4 and LLama3.1-400b (llms2). The metric is Balanced Accuracy, the baseline is 0.5, and the best averaged value is marked in bold, the ones below the baseline are marked in italics.

| labels | features | nb | xgb | lda | avg |
|---|---|---|---|---|---|
| human | events | 0.510 | 0.504 | 0.471 | *0,494* |
| human | bert | 0.489 | 0.477 | 0.558 | 0,508 |
| llms | events | 0.541 | 0.512 | 0.507 | 0,52 |
| llms | bert | 0.509 | 0.534 | 0.553 | **0,532** |

In this case, when combining BERT with LLM-averaged binary labels, we obtain a good average balanced accuracy. This confirms that BERT embeddings are particularly well-suited for capturing the broader temporal trends as interpreted by the LLMs.

In general, the performance with the binary labels is better with LLM annotations, implying that LLM-as-annotators are a promising technique for binary task in Historical Phase Recognition, also because their inter-annotator-agreement is generally better than the one reached by humans.

## 4. Conclusion

In conclusion, this study has taken initial steps in leveraging computational linguistics for the complex task of Historical Phase Recognition within the Structural-Demographic Theory framework. Our investigation into the utility of Event Tagging revealed its promise, particularly when aligned with human-annotated data, achieving the most robust performance in the 5-class classification task. This suggests that explicitly identified event structures resonate with human understanding of SDT's nuanced phases. Conversely, while powerful, BERT embeddings struggled to capture these nuances as effectively on human labels, hinting at a potential mismatch between its learned representations and the human interpretation of SDT.

Interestingly, BERT showed better performance with LLM-generated labels, indicating a possible alignment in their interpretation patterns, albeit with a loss of transparency compared to event tags. Answering RQ1 (whether Event tagging is useful): our results show that event tags help Historical Phase Recognition when coupled with human annotations. Instead, having LLM-generated labels, transformer models seem the best choice. In general our results show similar improvements over the baseline with the multi-class and binary classification tasks. Hence, answering RQ3 (which kind of label is easier to model), we can say there is no big difference. However, answering RQ4 (which classification task is easier), our results suggest that makes more sense to perform Historical Phase Recognition either as 5-class task with human annotated label and event tags, or as binary classification with LLM-annotated labels and BERT. Looking ahead, further research should explore methods to enhance the representational power of both event-based features and contextual embeddings for this task. Investigating techniques to better align LLM interpretations with human understanding of historical theories, and exploring more sophisticated classification models.

Our results also show that LLMs-as-annotators reach a higher consensus than humans in SDT labeling, and this answers RQ2. Since historical annotation is costly, time consuming and prone to bias, it is more likely that in the future we will see more LLM-annotated data. This suggests that the most promising future direction is having Historical Phase Recognition as a binary classification tasks. Ultimately, the integration of computational linguistics with historical theory holds significant potential for advancing our capability of extracting long-term societal dynamics from unstructured sources, and enhance our understanding of the cyclical patterns that shape human history. Given the general poor performance in Historical phase Recognition, we suggest there is still great room for improvement.

# Ontology-Guided Domain Entity Recognition in Environmental Texts: Evaluating Syntax-Driven and LLM Approaches Using BabelNet and GEMET

Elisa Chierchiello[1,†], Patricia Chiril[2,*,†] and Adriana Pagano[3,1]

[1]*Università degli Studi di Torino*
[2]*University of Chicago*
[3]*Universidade Federal de Minas Gerais*

**Abstract**

This paper investigates the identification and ontological classification of domain-specific entities to enable large-scale analysis of environmental discourse. While general-purpose Named Entity Recognition (NER) systems reliably detect standard categories such as persons, organizations, and locations, specialized domains like environmental communication require the recognition of additional, domain-relevant entities. These entities, often realized as common nouns, represent abstract, evolving concepts that are highly dependent on context and vary across languages. To address this challenge, we compare two pipelines for identifying domain-specific environmental entities in a bilingual corpus of WWF Living Planet Reports: (i) a traditional NLP pipeline that extracts noun phrases using dependency syntax parsing and matches them to `BabelNet` and GEMET, and (ii) a Large Language Model (LLM)-based pipeline that uses prompt-based instructions to both extract noun phrases and generate corresponding ontology matches. We evaluate the coverage of each approach and analyze the most frequent mapped entities to identify key environmental concepts emphasized in WWF discourse. To further assess the capabilities of LLMs in ontology-based annotation, we also prompted the LLM to generate GEMET-style definitions for phrases not found in the ontology. Our findings contribute practical insights for developing robust, ontology-enriched methods for environmental discourse analysis and knowledge extraction. Though tested on environmental texts, the framework can generalize to other domains via suitable ontologies and extraction rules.

environmental discourse analysis, domain entity recognition, dependency syntax, Large Language Models (LLMs), ontology mapping, BabelNet, GEMET, cross-linguistic annotation

## 1. Introduction

Named Entity Recognition (NER) has become an established task in Natural Language Processing (NLP), reliably identifying standard entity types such as persons, organizations, and locations [1, 2]. In specialized domains, general-purpose NER systems perform well when it comes to detecting these conventional entity types. However, many domain-specific applications require a different focus: the identification of domain entities, i.e. conceptually salient terms that often take the form of common nouns and refer to abstract, evolving phenomena central to the domain. In environmental communication, for example, entities such as *climate change*, *deforestation*, or *ecosystem services* play a key role in discourse but fall outside the typical scope of standard NER systems. This calls for adapted approaches capable of capturing and classifying these domain-relevant entities in context [3]. This challenge is even more pronounced in multilingual contexts, where consistency in detecting and aligning domain-specific entities is crucial for comparative studies. A closely related but very challenging aspect is the continual adaptation to new terminology and the integration with terminology from related specialized domains — both of which are especially relevant for environmental discourse.

Environmental discourse illustrates this complexity very clearly. Named entities such as organizations (e.g., *WWF*), locations (e.g., *Amazon rainforest*), or events (e.g., *COP28*) tend to maintain lexical stability across languages. In contrast, many core environmental concepts, such as *biodiversity loss*, *carbon offsetting*, or *nature positive*, are common noun phrases [4] that are often paraphrased, technically rephrased, or culturally adapted in translation, making them harder to detect reliably.

To address this, researchers have developed rule-based NLP pipelines that integrate syntactic parsing with domain ontology mapping, providing transparent and precise extraction of candidate domain terms [5, 6]. More recently, advances brought by Large Language Models (LLMs) have enabled new approaches to domain entity recognition. Pre-trained LLMs like BERT and domain-adapted extensions show good performance to detect

domain mentions [3, 7, 8]. Hybrid architectures, such as the Ontology-Attention Layer, demonstrate that coupling LLMs with explicit ontology guidance further improves accuracy in specialized contexts [9].

Despite this progress, to the best of our knowledge, no study has systematically compared rule-based NLP pipelines and LLM-based methods for domain entity recognition in multilingual environmental discourse. Our study addresses this gap by focusing exclusively on domain-specific entities, with conventional named entities such as persons, organizations, and locations to be examined in future work, and implementing two distinct pipelines for their identification and classification. by implementing and comparing two pipelines on a bilingual corpus of WWF Living Planet Report Executive Summaries (2014–2024). The first pipeline uses dependency parsing to extract noun phrases and matches them to BabelNet and GEMET using string-based similarity. The second pipeline uses a prompt-based LLM to both detect noun phrases and suggest ontology matches directly. We then assess the coverage of each approach and qualitatively examine the most frequent shared mapped entities to highlight the core concepts that characterize WWF environmental discourse. To address these aims, this study investigates the following research questions:

- How much coverage do a dependency syntax-based pipeline and a prompt-based LLM pipeline each achieve when extracting and mapping noun phrases to BabelNet and GEMET in a bilingual corpus of WWF Living Planet Reports?
- Which environmental concepts emerge as the most frequently mapped entities and what do these frequent concepts reveal about thematic emphases in WWF environmental discourse?

In order to answer these questions, we assess the two pipelines in terms of coverage — that is, the number and proportion of extracted noun phrases that can be mapped to domain concepts in BabelNet and GEMET — and then examine the most frequently mapped entities to highlight key environmental concepts emphasized in WWF discourse.

Finally, to explore how LLMs can contribute to expanding domain ontologies, we prompted the LLM to generate GEMET-style definitions for entities that could not be matched in GEMET.

By comparing these two pipelines, we highlight practical considerations for building ontology-based workflows for semantic search and discourse analysis in environmental texts. While applied here to environmental texts, the general approach can be tested in other domains using suitable ontologies and tailored extraction strategies.

## 2. Related work

Generic NER has been extensively studied as a foundational NLP task, with systems reliably detecting persons, organizations, and locations [1, 2]. However, as Marrero et al. [4] and Zhang et al. [3] observe, such systems perform poorly when applied to specialized domains because domain-specific concepts are often expressed through common noun phrases rather than proper names, and thus lack the distinctive lexical or orthographic cues that standard NER methods exploit.

To address these limitations, domain-specific NER has been pursued to handle technical and abstract terminology in specialized texts. In the biomedical field, for instance, Zhang et al. [10] review biomedical entity recognition as an example of domain-focused extraction, highlighting the essential role of ontologies for semantic precision. In geosciences, Villacorta Chambi et al. [11] pursue NER improvement through the use of specialized geological schemas.

Ontology-based approaches to domain-specific entity recognition have been widely explored. García-Silva et al. [5] proposed an ontology-based pipeline for environmental data that uses dependency parsing to identify candidate terms and maps them to structured environmental ontologies. Zhou and El-Gohary [6] developed a syntax-driven framework to extract provisions from environmental regulations and link them to a compliance ontology, demonstrating high precision for domain-specific phrases. Wei et al. [9] integrated an ontology-attention mechanism within BERT to improve medical entity recognition, while Dai et al. [12] emphasized the combination of entity recognition and ontology linking to build domain-specific knowledge graphs.

More recently, LLMs have emerged as powerful tools for general and domain-specific entity recognition. These LLMs can complement ontology-based systems by providing contextual understanding for domain terms that lack consistent surface forms.

Cross-lingual and multilingual methods support consistent domain entity alignment across languages. Navigli and Ponzetto [13] presented BabelNet, a multilingual lexical network used for semantic linking. GEMET [14] serves as a domain-focused environmental thesaurus, while Ryu et al. [15] and Zhao et al. [16] show how such resources help maintain terminological coherence in translation and cross-lingual NLP.

A disciplinary field that directly benefits from precise domain entity recognition supported by environmental thesauri and ontologies is environmental discourse analysis. Dryzek [17] and Doyle [18] examine how language shapes environmental policy debates and public narratives. Nerlich and Koteyko [19] explore competing frames in climate change discourse, while recent computational studies by Jørgensen et al. [20] and Chen et al. [21] apply NLP and machine learning to large-scale climate communication data.

The aforementioned studies demonstrate the benefits of combining NLP methods with structured ontologies for domain-specific entity recognition across multiple domains. However, comparative studies on these methods in the context of multilingual environmental discourse remain limited. This work builds on these foundations to advance ontology-enriched environmental text analysis.

# 3. Methodology

This section introduces the corpus and outlines the two methodological pipelines, which combine noun phrase extraction with ontology mapping.

## 3.1. Corpus

The corpus used in this study is the English and Italian subcorpus of the `TreEn` corpus [22], which compiles environmental discourse from the 2014 to 2024 editions of the `WWF Living Planet Report`.[1] WWF typically publishes a suite of documents tailored to different audiences, including a full report (a comprehensive publication containing detailed data, methodology, case studies, visualizations, and policy analysis) and an executive summary, which distills the key findings and recommendations for policymakers and stakeholders. It is important to note that for the Italian subcorpus, we were only able to locate full reports for the 2022 and 2024 editions, while for the other years under analysis, only the executive summaries were available. As such, to ensure comparability, the English subcorpus is based on the same type of document (i.e., full reports for 2022 and 2024, and executive summaries for the remaining years).

Both the English and the Italian texts were manually cleaned to retain only the plain text, with all non-textual content — such as images, captions, infographics, footnotes, and bibliographic references — systematically removed to support syntactic and semantic annotation. For each English and Italian edition of the WWF Living Planet Report published between 2014 and 2024, we computed the number of sentences, words, and lemmas using a custom `Python` pipeline built with `pandas` and language-specific `spaCy` models (`{en,it}_core_web_sm`). Table 1 presents the resulting counts across reporting years.

## 3.2. Noun Phrase Extraction

Drawing on the assumption that most entities are grammatically realized as noun phrases, we applied two different methods to extract noun phrases from the corpus. As described in the following sections, the first method is rule-based and the second is LLM-based.

**Rule-based Noun Phrase Extraction.** We performed rule-based noun phrase extraction relying on annotations following the Universal Dependencies (UD) guidelines.[2] Sentences were annotated morphologically and syntactically using a neural state-of-the-art dependency parser [23] using the language models `english-gum-ud-2.15` and `italian-isdt-ud-2.15`. For each sentence in CoNLL-U format, we identified head tokens tagged as `NOUN` or `PROPN` and expanded them by recursively including adjectival modifiers (`amod`), compounds (`compound`), and nominal modifiers (`nmod`). The extraction algorithm builds each noun phrase starting from the head and prepending modifiers according to their dependency links. The lemma column in each CoNLL-U representation was used in order to reduce lexical variation and support downstream concept mapping. For instance, from the sample sentence:

(1) *Adequate funding mechanisms are needed if protective area management is to be effective.*

the extracted noun phrases are: *Adequate funding mechanisms* and *protective area management*, which according to the UD guidelines have the same internal structure and are represented as shown in Figure 1:

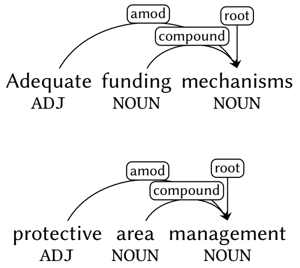

**Figure 1:** Dependency syntax annotation for sample noun phrases.

**LLM-based Noun Phrase Extraction.** Our second method of noun phrase extraction employed `GPT-o3`.[3]

[1] The timeframe (2014–2024) reflects the period for which we were able to retrieve the Italian editions of the report, starting from the earliest available publication up to the most recent: https://www.wwf.it/cosa-facciamo/pubblicazioni/living-planet-report/

| 2024 | English | 1,042 | 23,462 | 3,163 | 2,346 | 22.5 |
| | Italian | 1,048 | 26,976 | 3,988 | 2,743 | 25.7 |

**Table 1**
Basic statistics of the the English and Italian corpora across six reporting years (2014–2024).

Specific prompts were iteratively developed for each language under analysis (i.e., Italian and English), with instructions highlighting syntactic constraints, lemmatization, and complete modifier preservation in order to ensure consistency with the rule-based noun phrase extraction method. Figure 4 (see Appendix A) presents the English prompt used for this task.

## 3.3. Ontology Mapping

### 3.3.1. Ontology String Matching

Following the extraction of candidate noun phrases, we performed concept-level mapping using two distinct ontologies: GEMET and `BabelNet`. The objective was to link each phrase to an unique identifier representing an environmentally relevant concept within a structured semantic resource.

Our multilingual setting required different strategies for the two resources. For GEMET, which is primarily designed around English entries and offers more limited multilingual coverage, we relied on aligned sentence pairs in English and Italian to propagate annotations. Specifically, we used an alignment file where each English sentence was paired with its Italian equivalent. Once GEMET concepts were identified in the English sentence, we transferred them to the Italian version whenever the same noun phrase (or a direct translation) was present. This allowed us to enrich the Italian portion of the corpus even when direct GEMET matches were not available in Italian. To support this transfer, we first checked whether the same noun phrase annotated in English occurred verbatim in the aligned Italian sentence. If no exact match was found, we used automatic translation to bridge the gap between the two languages. Specifically, we translated the English noun phrase into Italian using Google Translate,[4] and then applied basic normalization (e.g., lowercasing, removal of diacritics) before comparing it to the set of Italian noun phrases extracted from the aligned sentence using the same syntactic rules. If a match was found, the corresponding GEMET concept was propagated to the Italian sentence. For example, in the English sentence:

(2) *"Around the world, many languages are used to communicate science."*

the noun phrases *science* and *world* were mapped to GEMET concepts. Their Italian equivalents, *scienza* and *mondo*, appeared among the extracted noun phrases in the aligned Italian sentence *"In tutto il mondo si usano molte lingue per comunicare la scienza"*. In this way, we could propagate the annotations to the Italian side, even though the GEMET concept is originally linked to the English noun phrase.

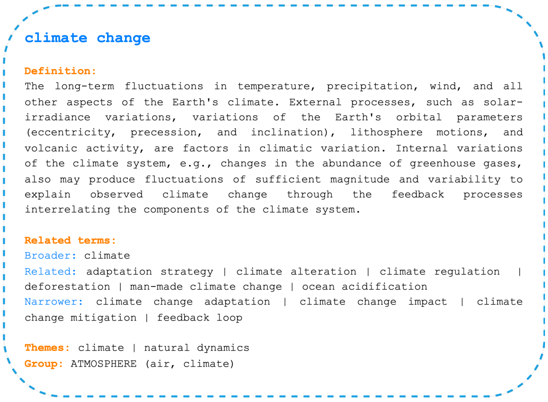
In contrast, `BabelNet` provides multilingual support by design. Therefore, we queried noun phrases directly in both English and Italian, allowing us to retrieve language-specific senses without relying on sentence alignment. This approach enabled broader coverage and avoided the need for cross-lingual projection.

**GEMET.** We queried GEMET via its public `REST API`.[5] For each noun phrase, we attempted an exact string match using the `getConceptsMatchingKeyword` endpoint. To maximize recall, we also applied fallback strategies by decomposing multiword expressions and querying each component token separately (e.g., *climate vulnerability → climate*, *vulnerability*). Concept URIs (Uniform Resource Identifier) returned from GEMET were

[4] https://cloud.google.com/translate/docs/reference/rest
[5] https://www.eionet.europa.eu/gemet/en/webservices/

stored along with the original phrase to support later semantic grouping and analysis. In addition, we retrieved the semantic group associated with each concept using the `getAllConceptRelatives` endpoint (with relation `group`), allowing us to categorize entities into high-level thematic domains (e.g., BIOSPHERE, SOCIETY, WASTES).

Figure 2 shows the GEMET entry for *climate change*[6]and all the fields we extract: concept URI, label, definition, related terms, and group. These fields were stored to facilitate both downstream semantic analysis and explainability of the mappings.



**climate change**

**Definition:**
The long-term fluctuations in temperature, precipitation, wind, and all other aspects of the Earth's climate. External processes, such as solar-irradiance variations, variations of the Earth's orbital parameters (eccentricity, precession, and inclination), lithosphere motions, and volcanic activity, are factors in climatic variation. Internal variations of the climate system, e.g., changes in the abundance of greenhouse gases, also may produce fluctuations of sufficient magnitude and variability to explain observed climate change through the feedback processes interrelating the components of the climate system.

**Related terms:**
Broader: climate
Related: adaptation strategy | climate alteration | climate regulation | deforestation | man-made climate change | ocean acidification
Narrower: climate change adaptation | climate change impact | climate change mitigation | feedback loop

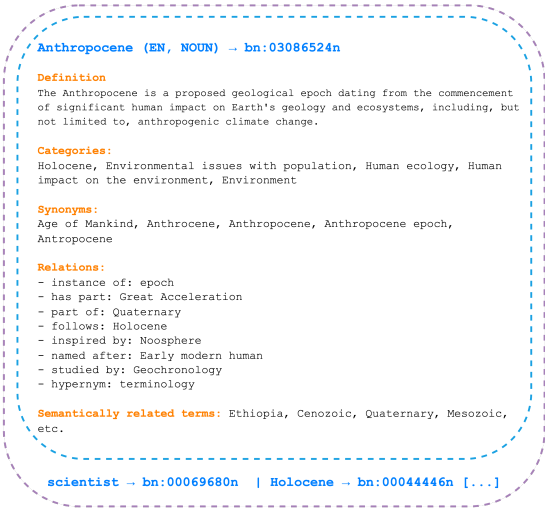
**Themes:** climate | natural dynamics
**Group:** ATMOSPHERE (air, climate)

**Figure 2:** GEMET entry showing extracted fields: definition, related terms, themes, and group.

**BabelNet.** In parallel, we integrated mappings from `BabelNet`. We accessed `BabelNet` via its `getSenses` and `getSynsetIds` endpoints,[7] querying each noun phrase both in Italian and in English. This bilingual querying strategy was adopted to maximize coverage and mitigate cases where a concept might be present only in one of the two languages. Unlike GEMET, `BabelNet` returns disambiguated senses associated with synset identifiers. We retained only senses with part-of-speech NOUN and applied a filtering step to discard irrelevant or ambiguous senses based on glosses and semantic domains. In multiword expressions that failed to return a direct match, we again decomposed the phrase into component tokens and aggregated partial matches when available. As an example, consider the following sentence:

(3) *Scientists suggest that we have transitioned from the Holocene into a new geological epoch, calling it the 'Anthropocene'.*

The extracted noun phrases are: *scientist*, *Holocene*, *new geological epoch*, *Anthropocene*. Figure 3 shows the `BabelNet` entry for *Anthropocene*, highlighting the fields we extract, namely, definition, categories, relations, synonyms, and semantically related terms.



**Anthropocene (EN, NOUN) → bn:03086524n**

**Definition**
The Anthropocene is a proposed geological epoch dating from the commencement of significant human impact on Earth's geology and ecosystems, including, but not limited to, anthropogenic climate change.

**Categories:**
Holocene, Environmental issues with population, Human ecology, Human impact on the environment, Environment

**Synonyms:**
Age of Mankind, Anthrocene, Anthropocene, Anthropocene epoch, Antropocene

**Relations:**
- instance of: epoch
- has part: Great Acceleration
- part of: Quaternary
- follows: Holocene
- inspired by: Noosphere
- named after: Early modern human
- studied by: Geochronology
- hypernym: terminology

**Semantically related terms:** Ethiopia, Cenozoic, Quaternary, Mesozoic, etc.

**scientist → bn:00069680n | Holocene → bn:00044446n [...]**

**Figure 3:** `BabelNet` entry showing some of the extracted fields.

No GEMET concept was found matching any of these noun phrases, highlighting the wider lexical and multilingual coverage of `BabelNet`. This example also demonstrates the complementary nature of the two resources: GEMET provides high precision within the environmental domain, while `BabelNet` ensures broader recall across a wider conceptual space.

This dual mapping strategy enabled both domain-specific grounding (via GEMET) and broader lexical disambiguation (via `BabelNet`), intensifying the robustness of concept alignment across heterogeneous texts.

### 3.3.2. LLM-based Ontology Mapping

Our second method for performing the concept-level mapping of the extracted noun phrases relies on `GPT-o3` through prompts with expected output. Upon extraction, a manual analysis of the concept-level mapping process (cf. Table 2) revealed that several (multi-word) noun phrases were not found in either GEMET or `BabelNet`. For example, in the following sentence:

(4) *We need nature positive by 2030 – which, in simple terms, means more nature by the end of this decade than at its start.*

[6] http://www.eionet.europa.eu/gemet/concept/1471
[7] https://babelnet.org/guide

*nature positive* is one of the noun phrases both syntactically and semantically relevant to environmental discourse. While the phrase is made up of a NOUN and ADJ, it is used as a NOUN and has a distinct meaning in current environmental discourse. Both the rule– and LLM-based methods correctly identified *nature positive* as a noun phrase, and it was successfully matched to a corresponding concept in BabelNet. The concept, however, is notably absent in GEMET. To address such coverage gap due to GEMET's limitations and explore the potential of using LLMs for ontology-based annotation, we used GPT-o3 to generate GEMET-style annotations for unmatched phrases in the first output. The prompt used for this task is shown in Figure 4 (see Appendix A).

### 3.4. Thematic analysis

To conduct a diachronic analysis of concepts mapped with GEMET and BabelNet across the 2014–2024 corpus, we identified concepts that appear in all WWF report editions and analysed their frequency per report to gather insights into the evolution of environmental discourse.

## 4. Results

Following the extraction of candidate noun phrases and their subsequent concept-label annotation using GEMET and BabelNet, Table 2 and Table 3 (see Appendix A) present the coverage of noun phrases by the rule– and LLM-based methods across the English and Italian corpora, as well as the number of phrases matched either fully or partially in the two ontologies. A full (exact) match refers to cases in which the entire noun phrase (e.g., *vertebrate species*) was found in the ontology, while a partial match refers to instances in which only a component (substring) of the phrase (e.g., *vertebrate* or *species*) was found. For example, in GEMET, while *vertebrate species* was not found, both *vertebrate* and *species* were matched individually, resulting in a partial match.

Across the 2014–2024 WWF reports, the LLM-based method extracts a number of unique noun phrases comparable to the rule-based method. However, for the 2022 Italian edition, the LLM extracts substantially more phrases. This difference appears to result from the way nested structures were handled: the LLM returned entire noun phrases with several nested noun phrases. This pattern is especially evident in Italian, where nested noun and prepositional phrases are common. For instance, extracted spans such as *"negoziato internazionale della convenzione quadro delle Nazioni Unite sul cambiamento climatico e della convenzione sulla diversità biologica"* [8] or *"accesso a quantità senza precedente di dato da sensore su satellite smartphone e dispositivo"* [9] illustrate the model's tendency to extract the full extent of some noun phrases which have several nested ones.

In terms of coverage, the Italian noun phrases extracted using GPT-o3 show a notable increase in GEMET exact matches, nearly doubling the coverage compared to the rule-based approach. Partial matches also increase across both ontologies, indicating a broader semantic reach. Interestingly, exact matches to BabelNet decline sharply for noun phrases extracted using the LLM-based method after 2016, even when partial BabelNet coverage increases. As noted above, GPT-o3 tends to extract longer and more contextually rich noun phrases that partially align with BabelNet entries. For instance, in the sentence:

(5) *At the Rio+20 conference in 2012, the world's governments affirmed their commitment to an "economically, socially and environmentally sustainable future for our planet and for present and future generations".*

one of the noun phrases extracted by GPT-o3 is *economically socially environmentally sustainable future.* While conceptually accurate, this phrase does not match any exact entry in BabelNet, whereas a shorter variant such as *sustainable future* does. This seems to suggest that GPT-o3 extracts entire noun phrases including all modifiers (*economically socially environmentally*), when ontology entries typically include noun phrases made up of classifiers and a few epithets, in this case, *sustainable.*

Regarding the capabilities of LLMs in ontology-based annotation, our manual analysis of the quality of the definitions generated by GPT-o3 for phrases not found in GEMET provided relevant insights into the potential for using LLMs for scaling semantic resources.

For instance, going back to example (4), the term *nature positive*, while absent from GEMET, is present in BabelNet, which defines it as *"outcomes which are net positive for biodiversity, directly and measurably increasing in the health, abundance, diversity and resilience of species, ecosystems and processes".* GPT-o3, on the other hand, generates the following definition: *"a future state in which nature—biodiversity, ecosystem services and natural capital—is restored and enhanced relative to its current condition".* While both definitions are valid, the LLM-generated one captures more accurately the forward-looking, goal-oriented nature of the *nature positive* concept. Unlike BabelNet's definition, which frames the concept mainly as a set of measurable biodiversity outcomes, the LLM definition presents it as a *"future state"* in which nature is restored and enhanced. This distinction is significant, as BabelNet treats the concept as a

[8] Original in English: *"international negotiations under the United Nations Framework Convention on Climate Change and the Convention on Biological Diversity".*

[9] Original in English: *"access to unprecedented amounts of data from sensors on satellites, smartphones and in situ devices".*

result, while the LLM version treats it as a trajectory/vision, which aligns more closely with how the term is currently used in WWF discourse (e.g., WWF defines nature positive as a goal to *"halt and reverse nature loss by 2030"*).[10] This suggests a promising direction for scaling these semantic resources, with domain-relevant entities extracted from domain-specific literature. However, as highlighted above, given the nuanced conceptual distinctions, expert validation remains crucial in order to ensure accuracy and to account for the subtle semantic distinctions that such models may overlook.

**Temporal analysis of concept dynamics.** Our diachronic analysis of the concepts mapped via GEMET and BabelNet across the six-year corpus (2014–2024) yielded the following results.

For GEMET, we identified 59 English concepts that appeared consistently in all years, including domain-specific terms such as *climate change*, *biodiversity*, *ecosystem*, and *habitat loss*, reflecting the controlled and environmentally focused nature of the thesaurus. A parallel analysis of the Italian portion revealed a partially overlapping core set, with terms such as *ambiente* (environment), *specie* (species), and *risorsa* (resource) persistently appearing.

In contrast, BabelNet yielded a smaller set of consistently recurring concepts, such as *biodiversity*, *consumption*, and *development*, but also revealed a much broader and more dynamic tail of emerging concepts (i.e., less frequent terms that vary widely across documents and capture context-dependent discourse). Notably, BabelNet annotations surfaced many general-purpose or discourse-driven terms (e.g., *ambition*, *alarm*, *goal*, *confidence limit*), often reflecting the rhetorical framing of environmental narratives in the source texts.

We also tracked *emerging* and *declining* concepts across both resources. For GEMET, emergent concepts since 2018 include *soil biodiversity*, *plastic*, *ocean acidification*, and *urbanisation*, many of which correspond to increasingly salient ecological issues. Conversely, concepts such as *ammonia*, *energy consumption*, and *ozone* peaked before 2018 and gradually disappeared, suggesting shifting topical focus in environmental discourse. Similar trends were found in BabelNet, where contemporary discourse introduced terms like *sdg*,[11] *carbon sequestration*, and *digital storytelling*, while older narrative anchors like *anthropocene*, *habitat loss*, and even *ocean* saw relative decline. A detailed overview of the five most frequent concepts per year, derived from both GEMET and BabelNet annotations, is provided in Tables 4 and 5 (see Appendix A).

## 5. Discussion

Our findings shed light on both the strengths and limitations of rule-based and LLM-based pipelines for ontology-oriented entity annotation in environmental discourse, aligning with insights from previous work on domain-specific NLP [3, 4, 5, 6].

First, in terms of extraction, the LLM-based approach demonstrated coverage comparable to the rule-based method in line with recent research highlighting LLMs' strong performance for entity detection [7, 8]. However, the LLM's tendency to generate longer, contextually rich noun phrases — particularly in Italian, where nesting is frequent — resulted in both higher phrase counts and a greater proportion of partial matches. This confirms observations by Marrero et al. [4] that domain-relevant concepts often appear as complex, nested noun phrases that challenge standard NER boundaries.

Second, our results show that while GEMET provides reliable coverage for core environmental concepts, consistent with its controlled and domain-focused design, BabelNet offers a wider conceptual coverage. This aligns with prior findings that general-purpose lexical networks like BabelNet can capture more entities, but at the same time can include discourse or general entities not so relevant to characterize a domain [13, 15].

Third, the quality of LLM-generated definitions for unmapped phrases suggests potential for semi-automated ontology enrichment. For instance, for the concept *nature positive*, the LLM produced a forward-looking definition more aligned with current environmental discourse framing than the existing BabelNet entry. This supports recent arguments for integrating LLMs into domain ontology extension workflows [9], but also highlights the importance of expert validation, given possible subtleties in sense distinctions.

Finally, our diachronic analysis, though conducted on a very low scale, showed interesting aspects about how sustainability narratives evolve rhetorically, in line with work by Dryzek [17] and Nerlich and Koteyko [19] on shifting environmental frames.

Taken together, our results demonstrate that combining rule-based and LLM-based pipelines may provide complementary strengths for environmental concept annotation: the rule-based method ensures syntactic precision and consistent granularity, while the LLM broadens semantic reach and can supply draft definitions for novel or evolving terms. However, consistent ontology coverage remains an issue, as a substantial proportion of relevant phrases were not found in either resource, underscoring the need for ongoing ontology expansion and domain adaptation, as stressed in recent surveys [10, 24].

Future work should explore refining LLM prompts to better constrain phrase boundaries, integrating syntactic cues during generation, and developing semi-

[10] https://wwf.panda.org/nature_positive/

[11] Acronym for Sustainable Development Goals.

automatic curation workflows to incorporate validated LLM-generated definitions into existing ontologies. This is a promising path for scaling high-quality, domain-adapted semantic annotation in support of environmental discourse analysis.

## 6. Conclusion and Future Work

In this study, we presented a pipeline for extracting and semantically annotating noun phrases in multilingual environmental texts using both GEMET and BabelNet ontological frameworks. The two resources were used in complementary ways: GEMET provided structured domain-specific knowledge, while BabelNet contributed broader lexical coverage and multilingual flexibility. Through a combination of ontology matching, fallback decomposition strategies, and cross-lingual projection, we achieved wide and meaningful semantic enrichment across languages. Looking ahead, the approach we propose could also support the ongoing evolution of domain ontologies themselves. For instance, GEMET is periodically updated with new concepts and definitions.[12] Automatically extracting candidate terms and associating them with existing or missing concepts, especially through LLM-based suggestion and contextual generalization, might provide curators looking to add to the thesaurus with insightful information.

Several directions can be pursued for the future development of this work. For instance, alternative approaches to named entity propagation — such as alignment-based techniques [25, 26] — can be tested, and additional inventories for entities and concepts can be explored, such as [27].

Finally, it is important to note that our study focused on the task as performed by LLMs. In future work, we will compare these results with human annotations provided by domain experts in order to examine whether more or different entities are extracted from the texts. This comparison will help determine whether more fine-grained analyses are necessary (e.g., to resolve partial matches involving nested entities or syntactically complex modifier structures). Moreover, incorporating expert judgment will allow us to account for diverse disciplinary perspectives (e.g., biology, ecology, chemistry, physics, geography) on environmental issues.

## Acknowledgments

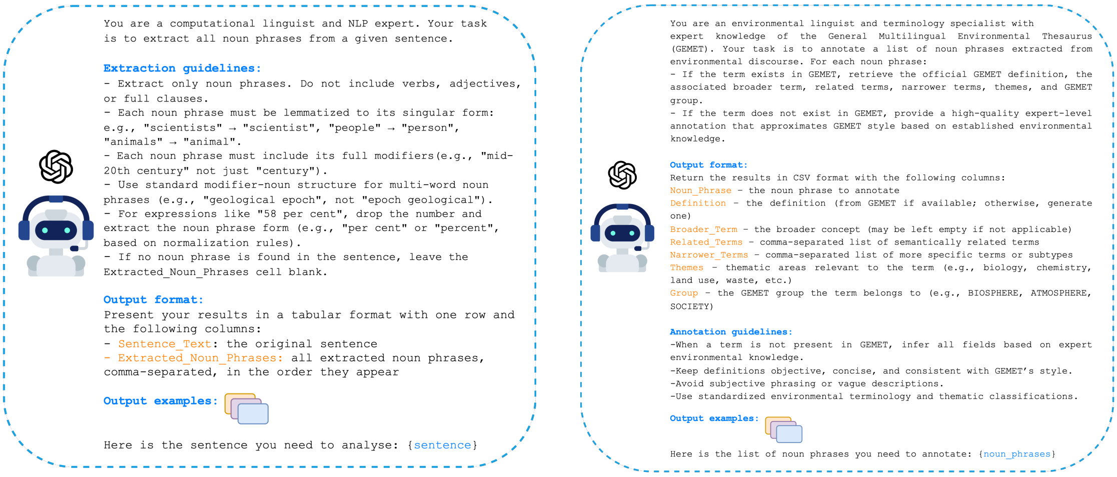
# A. Appendix



```
You are a computational linguist and NLP expert. Your task
is to extract all noun phrases from a given sentence.

Extraction guidelines:
- Extract only noun phrases. Do not include verbs, adjectives,
or full clauses.
- Each noun phrase must be lemmatized to its singular form:
e.g., "scientists" → "scientist", "people" → "person",
"animals" → "animal".
- Each noun phrase must include its full modifiers(e.g., "mid-
20th century" not just "century").
- Use standard modifier-noun structure for multi-word noun
phrases (e.g., "geological epoch", not "epoch geological").
- For expressions like "58 per cent", drop the number and
extract the noun phrase form (e.g., "per cent" or "percent",
based on normalization rules).
- If no noun phrase is found in the sentence, leave the
Extracted_Noun_Phrases cell blank.

Output format:
Present your results in a tabular format with one row and
the following columns:
- Sentence_Text: the original sentence
- Extracted_Noun_Phrases: all extracted noun phrases,
comma-separated, in the order they appear

Output examples:

Here is the sentence you need to analyse: {sentence}
```

```
You are an environmental linguist and terminology specialist with
expert knowledge of the General Multilingual Environmental Thesaurus
(GEMET). Your task is to annotate a list of noun phrases extracted from
environmental discourse. For each noun phrase:
- If the term exists in GEMET, retrieve the official GEMET definition, the
associated broader term, related terms, narrower terms, themes, and GEMET
group.
- If the term does not exist in GEMET, provide a high-quality expert-level
annotation that approximates GEMET style based on established environmental
knowledge.

Output format:
Return the results in CSV format with the following columns:
Noun_Phrase – the noun phrase to annotate
Definition – the definition (from GEMET if available; otherwise, generate
one)
Broader_Term – the broader concept (may be left empty if not applicable)
Related_Terms – comma-separated list of semantically related terms
Narrower_Terms – comma-separated list of more specific terms or subtypes
Themes – thematic areas relevant to the term (e.g., biology, chemistry,
land use, waste, etc.)
Group – the GEMET group the term belongs to (e.g., BIOSPHERE, ATMOSPHERE,
SOCIETY)

Annotation guidelines:
-When a term is not present in GEMET, infer all fields based on expert
environmental knowledge.
-Keep definitions objective, concise, and consistent with GEMET’s style.
-Avoid subjective phrasing or vague descriptions.
-Use standardized environmental terminology and thematic classifications.

Output examples:

Here is the list of noun phrases you need to annotate: {noun_phrases}
```

**Figure 4:** GPT-o3 prompt used to *extract noun phrases from English sentences* (left), and *annotate English noun phrases according to the GEMET ontology* (right).

### Abstract

Answering crossword puzzle clues presents a challenging retrieval task that requires matching linguistically rich and often ambiguous clues with appropriate solutions. While traditional retrieval-based strategies can commonly be used to address this issue, wordplays and other lateral thinking strategies limit the effectiveness of conventional lexical and semantic approaches. In this work, we address the clue answering task as an information retrieval problem exploiting the potential of encoder-based Transformer models to learn a shared latent space between clues and solutions. In particular, we propose for the first time a collection of siamese and asymmetric dual encoder architectures trained to capture the complex properties and relation characterizing crossword clues and their solutions for the Italian language. After comparing various architectures for this task, we show that the strong retrieval capabilities of these systems extend to neologisms and dictionary terms, suggesting their potential use in linguistic analyses beyond the scope of language games.

### Keywords

Language Games, Crosswords, Semantic Similarity, Embeddings, Natural Language Processing, Information Retrieval

## 1. Introduction and Background

Language games have emerged as compelling benchmarks for evaluating the reasoning capabilities of language models (LMs), offering structured challenges that require diverse cognitive skills including wordplay comprehension, lateral thinking, and cultural knowledge integration [2, 3, 4, 5]. Among popular language games, crossword puzzles stand out as particularly challenging, demanding not only linguistic competence but also extensive world knowledge, cultural awareness, and lateral thinking skills [6, 7, 8, 9]. While recent advances in Large Language Models have shown impressive performance on many natural language understanding tasks, their effectiveness on language games remains constrained by fundamental limitations in accessing linguistic and culturally-relevant knowledge, in particular for less-resourced non-English languages [5].

Before the advent of modern language models, most approaches to crossword solving relied on retrieval-based methods and shallow lexical and semantic features to identify relevant information [10, 11]. For example, [12] proposed a retrieval model that exploited lexical resources and similarity metrics to match clues to candidate answers in Italian. In a subsequent work, [13] introduced SACRY, a system that incorporated syntactic information and ranking strategies to improve clue-answer matching. Importantly, fill-in-the-blank clues and clues representing anagrams or linguistic games are often omitted. While these traditional retrieval systems typically relied on surface-level features - such as lexical overlap, part-of-speech patterns, and predefined similarity measures — the identification of viable crossword solutions often involves more nuanced interpretations, including the use of wordplay, homophones and other unusual elements. For example, the clue *"Producono con procedimenti lenti"* plays on the polysemanticity of *lenti* (in Italian, either "slow" MASC. PLUR., or "lenses"), and could have *ottici* (opticians) as a valid solution. These kinds of subtle connections hinder the viability of tra-

ditional retrieval systems in the context of crossword games.

Recent advances in cross-modal learning, particularly in vision-language models such as CLIP [14, 15], have demonstrated the effectiveness of dual encoder architectures in learning shared representations across different modalities. These approaches typically employ separate encoders for each modality, training them to project inputs into a common latent space where semantically related items cluster together. Inspired by these successes, we propose adapting this paradigm to the domain of language games, specifically focusing on the relationship between crossword clues and their solutions[1].

In this work, we evaluate several dual encoder architectures designed to learn effective representations for crossword puzzle elements (see Figure 1 for an example of a crossword puzzle). Our approaches treat clues and solutions as distinct ”modalities” that can be embedded to a shared latent space. The clue encoder must understand various forms of wordplay, cultural references, and linguistic devices, while the solution encoder must represent semantic, lexical and grammatical characteristics of the words. By training these encoders jointly with a contrastive objective, we create a retrieval system specifically optimized for the complexities of crossword puzzles. Our contributions are threefold: (1) We formalize the problem of specialized retrieval for language games and demonstrate the limitations of generic retrieval approaches in this domain; (2) We introduce and evaluate multiple dual encoder architectures tailored for Italian crossword puzzles, exploring different design choices and training strategies; (3) We demonstrate the utility of our learned representations for solution ranking and explore their generalization capabilities to neologisms. Our experimental results show that domain-specific models significantly outperform generic alternatives, suggesting that specialized retrieval mechanisms are essential for effectively ranking plausible alternatives in this domain.

# 2. Our Approach

Our approach formalizes crossword's clues answering as an information retrieval problem. Given a clue $c_i$ from the set $\mathscr{C} = \{c_1, \dots, c_n\}$ and a matching solution $s_i$ from the finite set of all available solution words $\mathscr{S} = \{s_1, \dots, s_n\}$, our system scores the similarity of a subset of candidates $\mathscr{S}^* \in \mathscr{S}$ with $c_i$ to produce a similarity-based ranking. Inspired by CLIP's approach [14], we opted for a dual encoder architecture [16], composed of two pretrained transformers encoders [17] —referred to as *towers*— which are fine-tuned on clue-solution pairs with a contrastive learning objective to learn a joint embedding space between clues and words.

In the following sections, we describe in detail the architecture of our model (Section 2.1), the datasets used for the experiments (Section 2.2), the encoder models employed (Section 2.3), the experimental setting (Section 2.4), the evaluation strategy adopted to assess the system's performance (Section 2.5).

## 2.1. Model's Architecture

To explore the effectiveness of our approach, we experiment with different encoder-based models for initializing the encoder towers, each fine-tuned and tested on a dataset of Italian crossword clues. As shown by Dong et al. [18], to effectively learn a shared parameter space using a dual encoder, there are two main architectural options: (a) the **Siamese Dual Encoder (SDE)** and (b) the **Asymmetric Dual Encoder (ADE)** with a shared linear projection. Both consist of two pre-trained Transformers encoders, in our case, a clue-encoder $f_1$ and solution-encoder $f_2$, trained to produce representations $\mathbf{c}_i = f_1(c_i)$ and $\mathbf{s}_i = f_2(s_i)$ by average pooling, where both $\mathbf{c}_i, \mathbf{s}_i \in \mathbb{R}^m$. These are linearly projected into a shared feature space $C \in \mathbb{R}^n$ in order to maximize the cosine similarity between positive pairs $(\mathbf{c}_i, \mathbf{s}_i^+)$ and minimize it for negative ones $(\mathbf{c}_i, \mathbf{s}_i^-)$. The distinction between SDE and ADE lies in the parameter sharing: while in SDE the two encoders $f_1$ and $f_2$ have tied parameters ($\theta_{f1} = \theta_{f2}$), in ADE the two encoder towers have untied parameters ($\theta_{f1} \neq \theta_{f2}$) but share a final layer norm and the linear transformation $T : \mathbb{R}^m \rightarrow \mathbb{R}^n$, which is essential to achieve an effectively shared space. Having separate encoders can be advantageous when modeling different modalities and distributions since it allows the two encoders to specialize independently on the specific nuances of the input types they process. To assess which of the two architectures is better suited for our task, we conduct preliminary experiments on both and compare their results in Section 3.1.

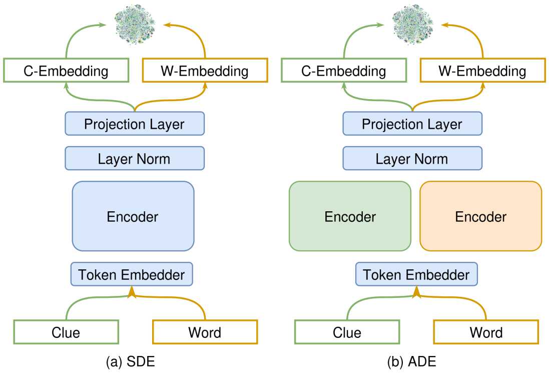
## 2.2. Dataset

For training our dual encoders, we employ the ItaCW crossword dataset [19], containing 125k unique definition-word pairs. We expand this collection with additional clue-solution pairs found on the web, and deduplicate the resulting set of entries, obtaining a total of 416,407 samples.

In addition to the original crossword dataset, to evaluate the out-of-distribution performances of our system we also consider word–definition pairs automatically extracted from the Italian Wiktionary, neologisms from the ONLI (Osservatorio Neologico della Lingua Italiana[2]) and

[1] Code, models and datasets are released at: https://github.com/snizio/Crossword-Space.

[2] https://www.iliesi.cnr.it/ONLI/.



(a) SDE (b) ADE

**Figure 2:** The two architectures tested: (a) Siamese Dual Encoder (SDE), (b) Asymmetric Dual Encoder with shared linear projection (ADE). Final clue (C) and solution (S) embeddings are projected to a shared latent space in both architectures. Blue modules are shared.

a set of 100 recently lexicalized neologisms [20]. Since some word-definitions pairs maintain the same inferential relation that occurs for most clue-solution pairs (excluding nuanced and specific crossword cases), augmenting the dataset with these specific resources allows us to assess the performance variations and generalization to different linguistic settings that exhibit the same input-output structure of crosswords, offering a natural extension to the main dataset. Specifically, the usage of dictionary data is twofold: (a) to understand whether augmenting the train set with word-definition pairs can enhance downstream performance on the crossword data; (b) to assess the extent to which models trained on word-clue pairs can be used to answer dictionary definitions. On the other hand, the ONLI and the 100-neologisms dataset will be used to test the robustness and generalization of our systems, therefore simulating a scenario where a novel term appears in a crossword, as is often the case. The ONLI covers a wide range of neologisms appearing on national and local newspapers, thus strictly related to the Italian culture, including newly coined or derived formations, internationalisms, foreignerisms, technical terms and some authorial neologisms until 2019; while the 100-neologism dataset consists of lemmas extracted from various online dictionaries (lexicalized after 2020) that focus mostly on politics, COVID-19 social dynamics and contain several foreignerisms.

## 2.3. Models

As backbone models, we choose several pre-trained encoders available for the Italian language, varying in parameter size and pre-training approaches. Specifically, we picked the encoders of `IT5-small` (35M) and `IT5-base` (110M) from the IT5 family [21] of encoder-decoders pre-trained on the Italian cleaned split of the MC4 [22]; `Italian-ModernBERT-base`[3] (135M) and `Italian-ModernBERT-base-embed-mmarco-triplet`[4] (135M), both based on the ModernBERT architecture [23] and pretrained on Italian with the latter being finetuned in a sentence-transformer fashion [24] on the mMARCO dataset [25]; lastly, we employed `paraphrase-multilingual-mpnet-base-v2`[5] [26] (278M), a multilingual model based on XLM-RoBERTa already tuned as a sentence embedder.

## 2.4. Experimental setting

We begin by comparing ADE and SDE architectures to assess the optimal approach for our clues answering task. Subsequently, each model is trained across two dataset configurations: the first one consists of using only a subset of the crossword dataset as the training set, the second one introduces also a split of the Italian Wiktionary in the training data. On the other hand, the evaluation is always performed on an held-out test set composed of crosswords clues, dictionary [6], ONLI and the 100-neologisms definitions. After merging all the data sources we split the resulting dataset into 90% train, 5% validation and 5% test (see Table 1).

We train our SDE and ADE architectures to minimize the symmetric InfoNCE loss used in CLIP [14] with in-batch negatives. During training, for each step, we mine for $(B-1)*r$ hard negatives that have the highest similarity to the positive target, where $B$ is the batch size and $r \in [0,1]$ is a fraction that determines how many of the hardest negatives are kept [27]. Formally, let $\mathbf{c}_i \in \mathbb{R}^m$ be the normalized embedding of the $i$-th clue, and $\mathbf{s}_j \in \mathbb{R}^m$ the normalized embedding of the $j$-th solution word. Let $\tau = \exp(t)$ be a learnable temperature parameter, and let $\mathcal{N}_i$ denote the indices of the top-$k$ hardest negatives. The *clue-to-solution* contrastive loss is defined as $\mathcal{L}_{c\to s}$:

$$\frac{1}{B}\sum_{i=1}^{B} -\log \frac{\exp\left(\tau \cdot \cos(\mathbf{c}_i, \mathbf{s}_i)\right)}{\exp\left(\tau \cdot \cos(\mathbf{c}_i, \mathbf{s}_i)\right) + \sum\limits_{j\in\mathcal{N}_i} \exp\left(\tau \cdot \cos(\mathbf{c}_i, \mathbf{s}_j)\right)}$$

Similarly, the *solution-to-clue* loss is $\mathcal{L}_{s\to c}$:

$$\frac{1}{B}\sum_{i=1}^{B} -\log \frac{\exp\left(\tau \cdot \cos(\mathbf{s}_i, \mathbf{c}_i)\right)}{\exp\left(\tau \cdot \cos(\mathbf{s}_i, \mathbf{c}_i)\right) + \sum\limits_{j\in\mathcal{N}_i} \exp\left(\tau \cdot \cos(\mathbf{s}_i, \mathbf{c}_j)\right)}$$

The final symmetric contrastive loss is the average of the two losses:

$$\mathcal{L} = \frac{1}{2}\left(\mathcal{L}_{c\to s} + \mathcal{L}_{s\to c}\right)$$

[6] When augmenting the dataset with dictionary definitions, all inflected forms are dropped.

|  | Train | Val. | Test |
|---|---|---|---|
| **Crosswords** (Cross.) | 374,713 | 20,853 | 20,841 |
| **Dictionary** (Dict.) | 78,103 | 4,303 | 4,316 |
| **ONLI** | - | - | 2,986 |
| **Neologisms** (Neo.) | - | - | 100 |
| **Tot.** | 452816 | 25156 | 28213 |

**Table 1**
Train, validation and test split sizes for the tested datasets.

The training setup is the same across all models, architectures and dataset configurations. Each model is trained for a maximum of six epochs with a batch size $B$ of 256 using AdamW [28] with a linearly decaying learning rate. The hard negatives fraction decays linearly during training from 0.8 to 0.05 (for detailed hyperparameter see Appendix B).

Before the test phase, all available solution words $\mathcal{S}$ are encoded into their relative embeddings, normalized and stored into a vector database. During inference, for a normalized clue embedding $\mathbf{c}_i$, the retrieval is performed leveraging the FAISS library [29] by inner product on the stored embedding matrix $\mathbf{E}_{|\mathcal{S}|\times m}$, where $|\mathcal{S}| = 106,988$ is the cardinality of the finite set of available solution words and $m$ is the embeddings dimension.

**Baselines** In order to further assess the performance of our models, we include and compare several baselines based on two main approaches: (a) **clues to clues (c2c)**, where, given an input clue, the most similar clues and their corresponding solutions are retrieved from the training set, as commonly done in the crossword solving literature [13, 30, 31]; and (b) **clues to solutions (c2s)**, where solutions are retrieved by directly comparing the given clue against the set of all possible solutions. For c2c we computed the similarity scores between clues using (1) Levenshtein distance (c2c-lev), (2) BM25 (c2c-BM25) and (3) the cosine similarities between clues representations obtained with `paraphrase-multilingual-mpnet-base-v2` (c2c-MPNet) as a standalone sentence embedder and without any finetuning. For the c2s baseline, we rank the answers by cosine similarity between the clue and all solutions using, as before mentioned, the `paraphrase-multilingual-mpnet-base-v2` (c2s-MPNet). To ensure a fair comparison between models and baselines, the c2c retrieval is conducted against the clues in the training set, augmented with dictionary definitions.

### 2.5. Evaluation

To evaluate the retrieval performance of our trained models, we adopt the following standard metrics:

**Accuracy@1/10/100/1000** is the accuracy in retrieving the correct solution word given the corresponding clue, considering the top 1/10/100/1000 most similar words retrieved by our system as valid.

**Mean Reciprocal Rank (MRR)** represents how well a system ranks the first relevant result by averaging the reciprocal ranks of the first relevant item across all queries.

To simulate a more realistic crossword puzzle solving scenario, we also report metrics for candidate words retrieved from the filtered set $S_\ell \subseteq S$ containing only words with the same character length $\ell$ as the target word $s_{target}$, formally $S_\ell = \{s \in S \mid \text{len}(s) = \ell\}$. We append an asterisk when reporting metrics that include this filtering process (e.g. Acc@10* or MRR*).

|  | Arch. | Accuracy@ |  |  |  | MRR |
|---|---|---|---|---|---|---|
|  |  | 1 | 10 | 100 | 1000 |  |
| **Cross.** | ADE | **.33** | **.63** | **.80** | .90 | **.43** |
|  | SDE | .20 | .58 | **.80** | **.91** | .33 |
| **Dict.** | ADE | .07 | .22 | .42 | .65 | .12 |
|  | SDE | **.10** | **.28** | **.47** | **.67** | **.16** |
| **ONLI** | ADE | .07 | .21 | .45 | .70 | .12 |
|  | SDE | **.13** | **.32** | **.54** | **.74** | **.20** |
| **Neo.** | ADE | .05 | .11 | .25 | .63 | .07 |
|  | SDE | **.09** | **.22** | **.39** | **.64** | **.14** |

**Table 2**
Test results for ADE and SDE architectures across the four tested domains. Top scores per dataset are marked in **bold**.

## 3. Results

We begin by comparing the two architectures under evaluation, SDE and ADE, and then report the performance of all tested models for all datasets using the best-performing architecture.

### 3.1. Siamese vs. Asymmetric Encoders

Table 2 reports our test results for the `paraphrase-multilingual-mpnet-base-v2` model, the largest we trained, which guided our choice between the siamese and asymmetric architecture variants. Interestingly, **the asymmetric architecture shows a substantial gain in performance only for crossword clues** and especially in ranking terms (Acc@1 +13%, MRR +10%), while being outperformed by SDE in all other linguistic settings, although with a narrower gap. We hypothesize that due to the peculiar inference links that relate clues and target words, an asymmetric architecture could be better at enriching representations with input/output nuances separately, rather than jointly as in ADE models. Indeed, many puzzles feature clues with wordplay intended to

be taken metaphorically or in other non-literal senses. For example, a correct answer for the clue "half a dance" might be *can* (half of the dance named *cancan*). In this setting, an encoder specialized in enriching the representation of the clue with dance names might be necessary to achieve good performances. On the other hand, for dictionary-like entries, there is no sufficient need to develop uniquely independent representations (as shown by the ADE performance drop) since word-definition pairs are typically symmetric in meaning and structure. In these settings, the same encoder can effectively capture both sides of the pair, benefiting from shared parameters that reinforce semantic alignment. Given that our primary interest in this work lies in crosswords, we adopt the ADE architecture with a shared linear projection for subsequent evaluations.

## 3.2. Main results

Table 3 shows the results of all models across the various test sets:

**Crosswords** MPNet-base, ModernSBert and IT5-base strongly outperform all baselines, especially at higher candidate sizes and when applying length filtering ("*"). Overall, the MPNet-base yields the best result, suggesting that model size has a positive effect on improving task performance. In terms of MRR, ModernSBert is the second-best performer, substantially outperforming its only pre-trained counterpart, ModernBert, underscoring the additional value of using models that have already undergone a sentence finetuning phase for boosting retrieval performance. All baselines leveraging the c2c approach are superior when confronted with IT5-small and ModernBert, especially in terms of MRR. Interestingly, incorporating dictionary data into the training set yields only moderate overall gains and does not significantly

**Table 4**
Some examples of retrieved answers across baselines, models and test sets.

impact the results, further emphasizing that definitions and crossword clues originate from different linguistic distributions.

**Dictionary** All models, and especially baselines, severely drop in performance when dealing with dictionary data. Furthermore, the rank changes: IT5-base obtains higher results than the multilingual MPNet-base, despite having half of the parameters. As expected, enhancing the training set with dictionary samples yields substantial gains across all models; especially, the MPNet-base increases results-wise more than the IT5-base, resulting in similar scores for both models.

**ONLI** For ONLI neologisms, all c2c baselines continue to decline while c2s-MPNet gains significantly w.r.t. crossword clues and dictionary definitions. IT5-base achieves the best results, with a substantial gap from the MPNet-base. As in the dictionary setting, augmenting the dataset with dictionary definitions yields improvements, although more moderate. ONLI neologisms are retrieved better than dictionary words, even when augmenting the dataset. One hypothesis for this phenomenon is that crossword clues are more aligned with the definitions of neologisms, as they may reflect similar linguistic strategies. Both crossword clues, particularly those involving wordplay, and journalistic neologism definitions often rely on compositionality. For example, clues such as "half a dance" or "prefix meaning new" require the decomposition and reinterpretation of word parts, similarly to many neologisms in ONLI are defined through transparent compounds or affix-based constructions (e.g., *mafiocracy* = *mafia* + *-cracy*). This shared reliance on compositionality may partially explain why models trained on crossword clues generalize better to ONLI neologisms than to standard dictionary definitions, which are often more rigid and semantically grounded.

**Neos.** Models perform poorly in this setting. However, they still widely outperform all c2c baselines, which are almost fully incapable of retrieving correct answers. Interestingly, the simple c2s-MPNet approach yields strong results, achieving top Acc@1 and Acc@1* scores. Overall, IT5-base achieves the best results, beating the c2s-baseline from Acc@10, followed by the multilingual MPNet-base. As for ONLI and Dict., all models benefit importantly from training on dictionary definitions and, especially, the MPNet-base in this configuration becomes the top performer in terms of Acc@10*, Acc@100, Acc@100* and Acc@1000.

### 3.2.1. Discussion

Overall, we observe an interesting trend concerning baselines: while all c2c (clues to clues) approaches perform reasonably well on crosswords, their performance drastically drops when dealing with dictionary terms and neologisms. On the other hand, the c2s-MPNet baseline, which directly confronts clues and solutions during retrieval, exhibits an inverse trend, performing better with definition-like clues than with crossword clues. These results further corroborate the hypothesis that clues and definitions have a different relation to target words: **words and definitions are more semantically aligned, from a distributional point of view, than crossword clues and solutions**. Furthermore, the extremely low performance of c2c-baselines on neologisms

**Figure 3:** An autonomously solved crossword puzzle. Clues taken from the test set were answered by using our system to retrieve the fifty closest answers, and the complete grid was filled using the Z3 SAT solver.

confirms that clues-to-clues mappings are insufficient to handle lexical innovation in crossword puzzles. This supports our initial motivation for a joint latent space that leverages rich distributed representations, enabling the modeling of unseen clues and solutions for the task of crossword retrieval. Finally, the **majority of our trained systems achieved better results than baselines on crossword clues** with the biggest and multilingual model, MPNet-base, achieving the best results, closely followed by the IT5-base. For neologisms in particular, the better performances of the monolingual IT5-base encoder despite its smaller parameter count suggest that **language-specific training might benefit retrieval in domains heavily influenced by culture and language-specific lexical innovation dynamics**.

## 4. Analysis and Applications

This section provides further explorations in applications and properties of our crossword embeddings systems.

**Examples Analysis** Table 4 reports some examples of the Top2 retrieved answers across baselines, models and test sets. For this purpose, we manually selected cases showing the limitations of traditional baselines, e.g. crossword clues carrying a non-literal meaning. For example, the cryptic-style clue "Lido senza pari" (transl. *Beach without even*) requires interpreting *even* as referring to the characters in even positions inside the word *lido*. Baselines do not capture this meaning nuance, while some of our models arrive at the correct solution, despite the well-known problem of character awareness in character-blind models [32, 33]. Another interesting case involves neologisms: baselines are unable to retrieve the correct answers since they represent a fringe minority in the available pool of definitions and solutions. On the other hand, our models, especially the monolingual IT5, show signs of generalization and were able to retrieve the correct answers despite not being trained on them.

**Automated Crossword Solving** Despite not being the main focus of this article, we tried to leverage our system to automatically solve crossword puzzles as a concrete application of clues answeringcrossword. Figures 1 and 3 show an example of a crossword puzzle, built entirely from clues in the test sets, automatically filled using the Z3 SMT (Satisfiability Modulo Theories) solver [34][7], leveraging candidates retrieved by the MPNet-base model. Specifically, by treating crossword puzzles as a satisfiability problem, we can define a set of first-order logical constraints that must be satisfied across all variables (grid cells) to find valid solutions: each clue corresponds to a sequence of grid variables constrained to match one of its candidate answers, forming a disjunctive (OR) group. These candidate-level constraints are then combined conjunctively (AND) across all clues. Additionally, for intersecting cells, equality constraints are enforced to ensure character consistency between overlapping horizontal and vertical words. The final formula, composed of these conjunctive and disjunctive logical statements, is passed to the solver, which searches for a globally consistent solution that satisfies all constraints simultaneously. Despite the complexity of this approach, which requires that each candidate set contains the correct solution, our biggest model, MPNet-base, was able to solve entirely some small-medium grids using a candidate size $10 \leq k \leq 50$, confirming the effectiveness of our system. We posit that a strategy iterating Z3 solving attempts over progressively larger candidate sizes could provide a strong baseline for crossword solving systems with a given computational budget, and we leave such assessment to future work.

## 5. Conclusion and Future Work

In this work, we introduced and evaluated dual encoder architectures for retrieving solutions of Italian crossword clues by learning a shared latent space between clues and solutions. Our experiments demonstrated that the

[7] We partially modified the implementation found at https://github.com/pncnmnp/Crossword-Solver.

Asymmetric Dual Encoder (ADE) architecture, with its independent encoders for clues and solutions, outperformed the Siamese Dual Encoder (SDE) in handling the nuanced and often non-literal relationships characteristic of crossword puzzles. Our results also highlighted the limitations of traditional retrieval-based approaches (e.g., clues-to-clues methods), particularly when testing their generalization towards neologisms' definitions. In contrast, our dual encoder-based models, especially the larger and multilingual MPNet-base and the monolingual IT5-base, exhibited signs of generalization across diverse linguistic settings, including newly coined terms and culturally specific references. This underscores the importance of leveraging rich distributed representations to model the complex interplay between clues and solutions.

In future work, it could be interesting to explore ensemble methods that combine traditional information retrieval approaches with dual encoder models, including clues-to-clues retrieval techniques, to leverage their complementary strengths. Training a cross-encoder reranker on top of retrieved candidate solutions may also prove beneficial, as it would enable the exploitation of contextual relationships between clues and solutions, an approach that is standard in retrieval-based systems. Moreover, conducting a detailed linguistic analysis of clues, examining categories, frequency distributions, and other properties, could provide deeper insights into their characteristics. Finally, extending the methodology toward an automatic completion system for crossword puzzle grids represents a promising direction for supporting full puzzle solving.

# B. Further details on the hyperparameters

Both the siamese and asymmetric architectures were designed using PyTorch and the training was conducted on two Nvidia GeForce RTX 4090 GPUs. For the asymmetric architecture we leverage parallelization by assigning each encoder to a different GPU. Each model was trained to produce representations of dimensionality equals to 768. We used the default betas and $\epsilon$ AdamW parameters. Table 5 reports the specific hyperparameters used with each model. Due to limited computational resources, we did not perform an extensive hyperparamters optimization, rather, we relied on the configurations suggested by the models creators. The maximum token length of the clues and solutions were set to respectively 64 and 16. The learnable temperature parameter $\tau$ was initialized to the equivalent of 0.07 from and clipped as done in CLIP paper. During batch generation, in order to avoid false negatives during hard batch mining, each batch cannot contain the same solution two or more times.

| Model | lr | weight decay |

# Veras Audire et Reddere Voces: A Corpus of Prosodically-Correct Latin Poetic Audio from Large-Language-Model TTS

Michele Ciletti[1,*]

[1]*University of Foggia, Department of Humanities, 71121 Foggia, Italy*

## Abstract

Latin verse moves to the pulse of vowel quantity and stress, yet students and researchers still struggle to hear that rhythm because high-quality recordings are rare and expensive. General-purpose text-to-speech models, rich in English and Romance data, flatten the long–short alternation that defines classical metres. This paper introduces a fully open, expertly validated corpus that demonstrates how far prompt engineering alone can push contemporary large language models toward metrically faithful Latin speech.

Drawing on Pedecerto's XML scansions, two emblematic passages were selected: the first 100 verses of Vergil's *Aeneid* (pure hexameter) and the opening elegiac *epistula* of Ovid's *Heroides* (elegiac couplets). Each line was syllabified, marked for ictus, elided where compulsory, and orthographically nudged into forms modern TTS engines pronounce reliably. The pre-processed verse, printed verbatim inside a concise system prompt, was rendered ten times by `gpt-4o-mini-tts`; human experts in Latin phonology then audited every take for segmental accuracy, stress placement, elision, and pacing. The accepted files were loudness-normalised and concatenated with uniform verse pauses, yielding roughly 24 minutes of continuous yet metrically autonomous recitation.

The release bundles (1) the original Pedecerto XML, (2) classical and TTS-ready transcriptions, and (3) per-line and stitched mp3 audio, all under CC-BY 4.0 and archived on Zenodo. Beyond serving as classroom audio or accessibility material, the aligned data provide a test-bed for prosody-aware speech synthesis, few-shot fine-tuning, and quantitative metrics research. An analysis of error patterns, such as cross-lingual accent drift, cluster mispronunciation, and length-stress trade-offs, offers concrete heuristics for steering future models without costly retraining. The workflow, implemented entirely with easily accessible APIs and lightweight scripts, could be readily transferable to Ancient Greek, Classical Arabic, or any verse tradition equipped with digital scansion. In short: the dead can be made to speak - rhythmically, reproducibly, and in the open.

## Keywords

Latin, prosody, dataset, poetry, text-to-speech

## 1. Introduction

Latin verse obeys laws of rhythm that differ markedly from those governing most modern poetry. Whereas English metres depend on patterns of stress, classical Latin organises lines around the alternation of long and short syllables [1]. The term prosody itself stems from Greek *prosoidia*, which first referred to a tune sung to music, then to the pronunciation of individual syllables.

Convincing spoken performances of Latin poetry that students can consult remain remarkably scarce. Grammars and handbooks describe reconstructed pronunciations with care, still few recordings reproduce the quantitative rhythm that defines classical metres. Recent advances in neural text-to-speech have brought modern languages to broadcast quality, but Latin has been left on the margins: general-purpose models have little or no training data and therefore transfer English or Romance stress patterns almost wholesale.

The previous generation of text-to-speech (TTS) systems, exemplified by architectures like `Tacotron 2` [2], typically followed a two-stage process, converting text to an intermediate representation (a mel spectrogram) before a separate vocoder synthesized the audio. While capable of high-fidelity output, these models required extensive, language-specific training data, leaving low-resource languages like Latin underserved. However, the emergence of large language models (LLMs) with direct audio-generation capabilities offers a new paradigm. Unlike earlier architectures that required costly fine-tuning, these models can be steered through carefully crafted prompts. Models such as `gpt-4o-mini-tts` [3] employ end-to-end architectures that learn from vast, multilingual datasets and can be conditioned directly through in-context learning. This prompt engineering approach allows for fine-grained control over pronunciation, pacing, and emphasis without retraining the model, opening a promising avenue for generating prosodically-correct speech in low-resource languages. To demonstrate the viability of this approach, this paper introduces *Veras Audire et Reddere Voces*, a fully open and expertly val-

idated corpus of prosodically-accurate Latin poetic audio. The corpus contains 216 lines of verse - the first 100 hexameters of Vergil's *Aeneid* and the opening 116 lines (58 elegiac couplets) of Ovid's *Heroides* - providing a total of nearly 24 minutes of metrically autonomous recitation. The primary contributions of this work are threefold: the release of a high-quality, aligned dataset of Latin poetic audio, TTS-ready transcriptions, and metrical annotations under an open license; the presentation of a reproducible workflow that shows how prompt engineering alone can steer a general-purpose LLM toward metrically faithful speech, offering a low-cost alternative to model retraining; and the production of a valuable resource for pedagogy and a test-bed for future research in controllable speech synthesis for historical languages.

# 2. Theoretical Background

## 2.1. Latin Prosody

Classical verse draws its rhythm from vowel quantity and from the consonantal context that can lengthen a syllable [4]. Six-foot dactylic hexameter and the coupled hexameter–pentameter of the elegiac distich are the metres most familiar to students. Rules such as *muta cum liquida* allow optional resolution; pervasive elision removes a vowel at word boundaries; and the location of the *caesura* shapes phrasing. Because no recordings survive from antiquity, quantity must be inferred from orthography, comparative Romance evidence, metrical practice, and statements by ancient grammarians. Absolute certainty is impossible, which explains why modern classrooms often substitute a stress-based reading, even though Latin stress itself follows a moraic algorithm. Any speech-generation system has therefore to decide which principle it will privilege: quantity, stress, or a compromise.

## 2.2. Digital Latin Resources

Over roughly thirty years Latin has acquired a considerable amount of Natural Language Processing resources [5] [6]. Tokenisers, lemmatisers, and treebanks are distributed through CLTK [7], Stanza [8], and Universal Dependencies [9]. Prosodic annotation is rarer. PedeCerto [10] marks quantity, feet, and *caesurae* for more than 240,000 dactylic lines; its XML export underlies the corpus described here. Other scanners cover particular metres: for instance CLTK modules for hexameter and hendecasyllable, Anceps for Senecan trimeter [11], or Loquax for syllabification and IPA transliteration [12].

## 2.3. Prompt-based Prosody in Large Language Models

Large language models that decode speech directly from text have begun to internalise prosodic patterns. Architectures such as `VALL-E` and `ZM-Text-TTS` train on vast multilingual collections; their outputs preserve speaker identity and sentence melody, yet metre remains hard to control [13]. One pragmatic strategy is to preprocess the poem itself: mark ictic syllables with capital letters and diacritics, resolve compulsory elisions, and substitute unfamiliar graphemes with spellings that the model already pronounces reliably (chiefly English, with Italian conventions for a selection of elements). During synthesis these visible cues bias the duration and stress predictors without any retraining of the model. The approach follows PRESENT's [13] principle of steering prosody through input representation rather than through explicit feature vectors.

## 2.4. Pedagogical and Inclusive Perspectives

High-quality recordings produced by trained classicists are time-consuming and costly. Automatic generation, once trustworthy, would make spoken Latin more accessible in schools, in digital humanities research, and for visually impaired learners. Surveys in the field call for FAIR corpora that combine text, audio, and metadata [14]. By publishing aligned verse–audio pairs, the present work answers that demand in part. Stress-centred recitation also lowers the entry barrier for students whose native languages do not contrast vowel length, while still preserving a perceptible rhythmic pulse consistent with traditional metrics.

# 3. Methodology

## 3.1. Source Texts and Metrical Gold Standard

The audio that accompanies the dataset was derived from two chosen passages: the first hundred hexameters of Vergil's *Aeneid* and the opening elegiac epistle of Ovid's *Heroides.* These segments supply, on the one hand, a pure run of dactylic hexameter and, on the other, the alternation of hexameter and pentameter typical of the elegiac couplet. Machine–readable scansion was taken from the XML export of the Pedecerto project [10]. Each `<line>` element preserves the metrical category, the canonical foot pattern and, for every word, a `sy` attribute that enumerates syllables while marking the ictus with an upper-case character. The import script retained verse boundaries, foot sequence, ictic flags, elision hints and word–boundary information; all other metadata were discarded. A fragment of the XML illustrates the structure:

```
<line name="1" meter="H" pattern="DDSS">
  <word sy="1A1b" wb="CF">Arma</word>
  ...
  <word sy="2c3A" wb="CM">cano,</word>
  <word sy="3T4A" wb="CM">Troiae</word>
  ...
</line>
```

### 3.2. Pre-processing and Orthographic Adaptation

Each verse underwent an iterative pipeline before it was ever passed to the speech engine. Syllabification relied on the rule-based module distributed with the Classical Language Toolkit [7]; diphthongs and enclitics are already covered in that implementation. The vowel of every ictic syllable received a grave accent and the complete syllable was converted to capitals. Obligatory elisions were realised as graphic mergers (*quoque et* therefore became *quoquet*) according to the Pedecerto `wb` flag. A comma was inserted where the metre demands a caesura unless the manuscript already offered punctuation at that position. Early trials separated syllables with hyphens, but the additional markers produced no audible advantage and the idea was dropped.

A second pass substituted graphemes that tend to mislead English-trained acoustic models. Before front vowels ⟨c⟩ was rewritten as ⟨k⟩, ⟨qu⟩ became ⟨kw⟩, the diphthongs ⟨ae⟩ and ⟨oe⟩ were rendered ⟨ai⟩ and ⟨oi⟩, and palatal ⟨g⟩ was expanded to ⟨gh⟩. The resulting string approximates a classical pronunciation yet stays within the alphabetic habits of contemporary TTS systems.

To keep prosodic control local, each line was synthesised in isolation; the rhythm inside a verse must be coherent, whereas a small pause between verses is both acceptable and expected in performance.

### 3.3. Speech Generation and Iterative Refinement

Two technological families were explored. Conventional sequence-to-sequence TTS engines, such as `Tacotron 2` [2], `Kokoro` [15], OpenAI's `tts-1-hd` [16], offer little room for instruction: stress was frequently misplaced and vowel length erratic, particularly when the Latin token resembled a common English form. Multimodal large language models with an integrated audio decoder fared better because the system prompt can be used to impose a prosodic policy. Several models in the GPT-4o and Gemini lines were evaluated; `gpt-4o-mini-tts` [3] delivered the most consistent timing and segmental clarity.

Prompt engineering began with an extensive style sheet, eventually distilled to three imperatives: speak slowly, articulate every syllable, and obey the marked stresses. Re-printing the fully processed verse inside the system prompt, exactly as it should be spoken, noticeably improved alignment between text and realisation. Because stochastic sampling introduces variation, ten readings were requested for every line. The final system prompt was:

> This is a Latin poetical verse. Pronounce it rhythmically, slowly and with emphasis, articulating each syllable and correctly stressing them. Pronounce it like this: [pre-processed verse]

The addition of the word "slowly", explicitly telling the model to recite the verses at a relaxed pace, proved to be particularly useful in ensuring that each syllable was correctly articulated.

### 3.4. Human Validation and Error Annotation

Specialists in Latin phonology audited every recording. Errors were marked on spans and classified as segmental substitution or ictus misplacement. Feedback after each experimental round guided small adjustments to the pre-processing routine and to the wording of the prompt. Acceptance was granted when a line contained no error of stress or elision and no more than minor segmental deviations; under this criterion at least one satisfactory rendition was eventually found for each of the autonomous lines.

### 3.5. Mastering and Packaging

For every verse the reviewers selected the highest-scoring file. Selected waveforms were loudness-normalised and concatenated with an 800 ms silence, yielding two continuous recitations that preserve per-line rhythmic autonomy. Alongside the audio the repository contains:

- the original Pedecerto XML fragments,
- the full text of the chosen passages,
- the pre-processed lines which have been given as input to the TTS model.

All artefacts are released under an open licence and have been deposited on Zenodo together with a DOI, ensuring long-term accessibility and citability [17].

For a more thorough discussion of the methodological choices, from model selection to human evaluation, the reader is referred to a previous publication [18].

**Table 1**
Overview of the corpus

| Sub-corpush | Metre | Lines | Hexameters | Pentameters | Total duration (hh:mm:ss) |
|---|---|---|---|---|---|
| Aeneid 1.1-100 | Dactylic hexameter | 100 | 100 | 0 | 00:11:26 |
| Heroides 1.1-116 | Elegiac couplet (hexameter + pentameter) | 116 | 58 | 58 | 00:12:26 |
| Total | - | 216 | 158 | 58 | 00:23:52 |

# 4. Results: Description of the Released Corpus

The outcome of the workflow is an aligned collection of Latin poetic audio accompanied by the textual and metrical information required for downstream work in speech technology, pedagogy and quantitative metrics. The repository is organised around three sections: for each poem, a text file contains its original lines, another one has the pre-processed text that was fed to the TTS model, an XML file contains the Pedecerto metrical annotations and a set of mp3 files represent the audio output, stored both individually and as groups.

Table 1 gives an overview of the material.

## 4.1. Audio Layer

For each verse ten independent readings were decoded. After expert screening one rendition was retained as the canonical file. Recordings are stored as mp3 files. Silences at verse boundaries have been standardised to 800 ms; no fades or noise reductions were applied, so that the signal keeps its original spectral profile.

## 4.2. Text and Prosodic Annotation

The reference transcription follows the orthography employed during synthesis (grave accents on ictic vowels, upper-case ictic syllables, adapted spellings for *c, qu, g, ae, oe*) so that users can reproduce or extend the experiments without reverse engineering. A parallel file restores classical spelling for readers who prefer a diplomatic text. Pedecerto syllable scansions, foot divisions and caesura marks are displayed in a separate XML file.

## 4.3. Availability and Licensing

All components are released under CC-BY 4.0. The Zenodo record bundles the audio, textual content, and annotations [17].

# 5. Discussion

The present corpus was assembled in order to facilitate prosodically faithful speech synthesis, yet the labour invested in its creation has generated several observations that matter beyond the immediate goal of reciting Vergil and Ovid. Three strands of evidence stand out: the behaviour of the language model during synthesis, the practical tricks that secured acceptable output, and the prospective uses of the aligned data in research and teaching.

## 5.1. Accents, Cross-lingual Interference, and what the Model really "Knows"

When the decoder was left to its own devices it tended to interpret individual words through the accent template of whichever modern language offered the closest orthographic match. As a consequence, passages dominated by vocabulary shared with present-day Romance received an intonation reminiscent of Italian, while lines rich in loanwords familiar to English appeared with a markedly anglophone timbre. Spanish patterns surfaced less often, but, for example, whenever words ended in *-rant* the cadence was audibly Iberian. These drifts rarely broke the quantitative rhythm prescribed by hexameter or pentameter; they did, however, blur vowel quality, especially in the mid-front and mid-back zones. The phenomenon confirms that the model encodes a multilingual phonology for conversational prose, and stresses again how little purely Latin data the underlying training set must contain.

## 5.2. Problematic Phonotactics, Orthographic Workarounds and *Caesurae*

Several consonant clusters led to systematic errors. Final *-nx* in *coniunx* or initial *tl-* in *Tlepolemus* were clipped or resolved into epenthetic vowels, presumably because the sequences are rare in the speech material seen during pre-training. In other cases the word was recast according to a high-frequency modern homograph: *-um* often came out as ə*m*, betraying an English proper-name template. Two heuristics mitigated these slips. First, lengthening the grapheme that carries the metrical ictus often persuaded the model to anchor stress correctly; *cano* became *caano* in the prompt, which silenced the temptation to

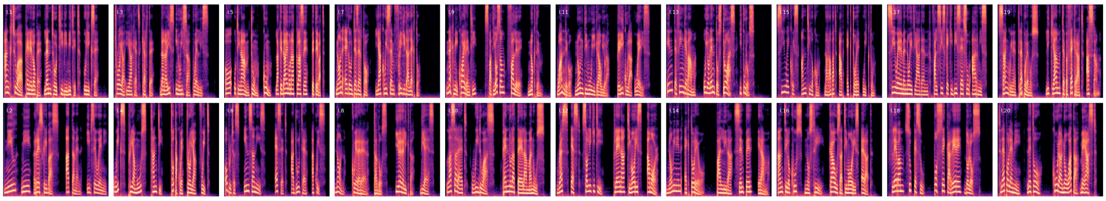

**Figure 1:** Mel Spectrogram of the first 20 lines of the opening *epistula* of the *Heroides*. Each tile corresponds to one metrical line; hexameters are at the top, while pentameters are at the bottom. Note how the pentameter's obligatory *caesura* after the third *arsis* is visible as a systematic pause mid-tile.

favour the English reading. Second, replacing rare digraphs with phonetically transparent ones, already documented previously, reduced segmental substitutions by a third. The interventions are admittedly ad hoc, yet they illustrate how a handful of hand-crafted rules can serve where large retraining runs are impossible. While improvements can certainly be made in regards to the overall flow of the generated verses, it remains one of the most effective features: the addition of commas to mark *caesurae*, in particular, proved to be useful in ensuring that the synthetic voices followed a precise pattern. Figure 1 shows the Mel spectrograms of the first twenty lines of the opening *epistula* of the *Heroides*, generated to visualize the verses' rhythm. The spectrograms clearly show that black bars (representing pauses) are always present in the middle of the bottom tiles (pentameters), while they are more spaced out in the top tiles (hexameters). This is due to the obligatory *caesura* that occurs after the third *arsis* of each pentameter, precisely in the middle of the verse, while hexameters present more varied structures.

## 5.3. From Corpus to Model Improvement

Because each verse is aligned with a verified audio, the collection can function as a fine-tuning set for both autoregressive and non-autoregressive TTS systems. A model trained on metrically correct examples should internalize the prosodic rules more reliably than a general-purpose system forced to extrapolate from modern language data. Even large language models themselves could benefit from exposure to annotated Latin verse during continued pretraining, potentially reducing the need for elaborate preprocessing in subsequent applications. Future work could examine whether freezing the acoustic front-end while training only the variance adapters suffices to introduce length contrast in addition to stress.

## 5.4. Classroom Impact and Reproducibility

In a teaching environment the recordings serve two complementary roles. Students can listen to a metrically regular rendition before attempting their own, and instructors can use the annotated text as input to alternative voices or slower tempos. Since every script that produced the audio leverages easily-accessible APIs, replication is straightforward. Such transparency matters especially for assessment settings where students must know exactly which variant counts as the reference.

## 5.5. Open Data and Transfer to Other Languages

Latin is only one among many historical or minoritised languages whose sound patterns are absent from mainstream speech technology. The workflow described here, licensed permissively and documented line by line, could be cloned for Ancient Greek, Old Occitan, Classical Arabic, or any verse tradition that already enjoys digital scansion. Riemenschneider and Frank [5] argue that large language models can be useful tools for Classical Philology; releasing small but expertly annotated sets therefore aims to accelerate progress. Open repositories also lower the entry cost for community contributors who may wish to supply alternative voices, extended passages, or corrected quantities.

## 5.6. Towards Length-sensitive Synthesis

Stress was easier to enforce than absolute vowel length. The present system approximates quantity indirectly through slower pacing on ictic syllables, yet it cannot keep a fixed ratio between heavy and light vowels. Lam et al. [13] report that explicit duration tokens unlock such control in English; integrating a similar mechanism with the current prompt-based strategy is an obvious next step. Ultimately, a synthesis pipeline that differentiates both stress and quantity would let classicists test competing reconstructions of Latin phonology "in silico", converting theoretical statements into audible hypotheses.

### 5.7. Outlook

Refining the preprocessing scripts, automating error spotting, and expanding the text base are immediate priorities. Nevertheless, even in its present form the corpus already supports experiments in few-shot prosody transfer, quantitative metrics, and accessible pedagogy. The value of such resources lies also in the demonstration that high-quality data can be gathered with modest equipment, provided that domain knowledge and iterative verification guide the process. Open, reproducible corpora therefore remain the necessary foundation on which future work for classical languages will build.

## 6. Limitations

The corpus was assembled with the intention of demonstrating what present-day language models can already achieve when prompt engineering is combined with careful human verification. Precisely because the focus lay on a proof of concept, several boundaries were accepted that restrict the scope of the resource. The most visible limitation concerns size. Only two passages, albeit canonical ones, entered the pipeline; together they furnish a little under twenty-four minutes of speech. For certain experiments in prosody transfer that duration suffices, yet quantitative studies of acoustic variance or full fine-tuning of an end-to-end synthesiser usually require at least an order of magnitude more material.

Closely related is the question of stylistic breadth. The *Aeneid* and the *Heroides* differ in metre, tone and lexicon, but both belong to the same literary period and represent the same formal register. Comedy, forensic oratory or Late Latin hymns remain untested. Consequently, the substitution rules that helped the model through epic and elegiac vocabulary might fail when confronted with colloquial forms, post-Classical spellings or heavy Greek loanwords.

Another constraint derives from the decision to rely on a single synthetic voice. Because speaker identity never changes, the corpus cannot inform studies that investigate how metre interacts with timbre or gendered pitch ranges. Similarly, only one variant of reconstructed pronunciation is encoded. Alternative schools that prefer the ecclesiastical pronunciation will find no examples that match their conventions. Validation, indispensable for quality control, introduces its own bias. Judgements about short hesitations or barely perceptible vowel colouring can differ across traditions; a panel of experts drawn from a wider set of institutions might have retained or rejected a slightly different subset of takes.

Technical choices add further caveats. Recordings were mastered to mp3 for ease of distribution, which entails lossy compression. The prompts are public, but the underlying model weights remain proprietary; should the provider change access policies, identical reproduction could become impossible. Finally, quantity was approximated through slower pacing on metrically strong syllables. The approach yields a rhythm that experienced listeners recognise, yet it falls short of enforcing a fixed heavy-to-light duration ratio, the gold standard in phonetic work on quantitative metres [4].

## 7. Conclusion

The study has introduced an openly licensed, line-aligned corpus that brings classical Latin verse within reach of modern text-to-speech technology. By combining Pedecerto's machine-readable scansion with a small set of orthographic substitutions and a concise prosodic prompt, the workflow coerced a general-purpose large language model into producing intelligible, metrically coherent recitations. Systematic human screening guaranteed that the released audio reflects the intended rhythm at a level suitable for both pedagogy and computational research.

The resulting dataset offers three immediate avenues of use. Teachers can deploy the files as accessible classroom material, learners may rehearse passages while receiving instant acoustic feedback, and speech engineers now possess a clean test bed for experiments in prosody conditioning. Beyond these practical gains, the project demonstrates that domain knowledge, when encoded explicitly in the input, still matters even in an era of ever larger pretrained models. Prompt design, although sometimes dismissed as a stop-gap measure, revealed itself here as a cost-effective alternative to full retraining.

Future work will have to broaden the metrical and generic range, increase speaker diversity and explore direct duration control. A longer term ambition is to fold the current resource into a multilingual library of verse corpora, so that comparative metrics across the Indo-European tradition become feasible. The dataset and annotations supplied with this release aim to render such extensions straightforward.

## Acknowledgments

The author thanks the entire Pedecerto team for annotating and sharing their XML scansions. Sincere gratitude is extended to the CLTK community, whose open-source tools simplified syllabification and phonological checks. Colleagues at the University of Foggia donated hours to the auditory review of candidate recordings; their expertise shaped both the preprocessing rules and the acceptance thresholds. Any remaining inaccuracies are the sole responsibility of the author.

# A Tough Hoe to Row: Instruction Fine-Tuning LLaMA 3.2 for Multilingual Idiom Processing

Debora Ciminari*[1], Alberto Barrón-Cedeño[1]

[1]Università di Bologna, Corso della Repubblica, 136, 47121, Forlì, Italy

## Abstract

Idiomatic expressions (IEs) are a core part of language but exhibit considerable complexity and heterogeneity, posing significant challenges to natural language processing (NLP). Effective automatic idiom processing could enhance our understanding of language and could benefit downstream tasks such as machine translation. However, previous research fails to adopt a comprehensive approach and struggles to consider languages different from English and the rich variety of idiom types. We thus aim to develop a version of LLaMA 3.2 that is instruction fine-tuned on data in three languages — English, Italian, and Portuguese — and covering a wide range of IE types. Specifically, we build on already annotated corpora to create our instruction-formatted dataset, and we employ instruction fine-tuning on two tasks — sentence disambiguation and idiom identification. We then investigate the effectiveness of this approach and assess the impact of the instruction language on the model's performance. We release a multilingual instruction-formatted dataset for automatic idiom processing. Additionally, we show that fine-tuning might help the model disambiguate between literal and idiomatic sentences, while gains in idiom identification are limited and require further investigation. The $F_1$-measure also suggests that the choice of the instruction language significantly affects the results.

## Keywords

idiomatic expressions, multilinguality, sentence disambiguation, idiom identification, instruction fine-tuning

## 1. Introduction

Idiomatic expressions (IEs) are a prominent component of language and constitute a broad and heterogenous category. The canonical definition describes IEs as expressions whose meaning cannot be derived from the meanings of their subparts [1, 2]. The typical example is `to kick the bucket`, whose meaning 'to die' cannot be inferred from 'kick', 'the', or 'bucket'. However, some cases do not fit this definition. For instance, the meaning of `to pull the strings` ('to use influence or connections') does bear a sort of (metaphorical) relation to its components. Another category of IEs can be identified, i.e. *potentially idiomatic expressions* or *PIEs* [3], which are expressions that can have a literal or an idiomatic meaning, depending on the context. That is the case of the first idiom presented as example, `to kick the bucket`, which can also take a literal meaning, as in `She got frustrated and kicked the bucket of paint across the garage`.

In light of this diversity, the traditional definition has been challenged in favour of a more complex, multifaceted view that emphasises the heterogeneous nature of idiomaticity, conceived of as a continuum where expressions can be placed depending on multiple factors [4].

Such complexity makes it challenging to deal with IEs in the field of natural language processing (NLP). Given the pervasive presence of IEs in language, effective idiom processing is needed to gain a deeper and more comprehensive understanding of language. Idiom-aware NLP can benefit downstream tasks, such as text summarisation, sentiment analysis, question answering, and machine translation [5, 6].

Most NLP applications focus on English, leaving multilingual idiom processing largely unexplored. Recent studies adopt encoder-based models [7, 8, 5], while studies on decoder-based ones remain relatively sparse. Another issue related to previous research is the models' lack of a robust generalisation and its poor performance on unseen idioms [5, 6].

To fill these gaps, we develop an instruction fine-tuned version of LLaMA 3.2 1B in three languages, English, Italian, and Portuguese, and on two tasks, sentence disambiguation and idiom identification:

**Task 1: Sentence Disambiguation.** Framed as a binary text classification task, it aims at discriminating idiomatic from literal sentences.

**Task 2: Idiom Identification.** Framed as a span labelling task, the model must identify the sequence of characters that correspond to an IE.

In Task 2, partial matches are considered partially valid: if the model identifies part of the IE, it still receives partial credit for a correct identification.

Both tasks are strictly interconnected: once a model recognises a sentence as idiomatic, it can identify the

[c] Since the 1940s, the Bureau has investigated cases of espionage against the United States.

[d] Solar wind parameters were measured over a longer period.

**Figure 1:** Examples of idiomatic and literal sentences in English, Italian, and Portuguese.

specific span constituting the IE. Figure 1 shows some examples of idiomatic and literal sentences.

Given this interdependence, our data is designed to address both tasks simultaneously. For instance, in the first example, the model's answer is expected to be `kiss of death`, showing that the model correctly identified the sentence as idiomatic and proceeded to detect the span where the idiom occurs.

Starting from annotated corpora, we design our instruction-formatted data, comprising an instruction (the task description), the input (the sentence), and the expected output [9]. Additionally, our dataset is multilingual in that it comprises inputs in all three languages. What differs is the instruction language, for which three subsets are created. We then fine-tune LLaMA 3.2 1B on a subset of our corpus and carry out evaluation based on the $F_1$-measure. We thus examine the effectiveness of instruction fine-tuning. Besides, we investigate the impact of the instruction language in scenarios where the instruction language and the input language are the same and scenarios where they differ. To date, such an impact has received scant attention in the research literature, with few studies providing contradictory results. Muennighoff et al. [10] explore English and multilingual Multitasked prompting finetuning (MTF), concluding that non-English prompts lead to improved performance, but English prompts still produce satisfactory results on data in other languages. On the other hand, Phelps et al. [11] concentrate specifically on automatic idiom processing and test different models on multiple prompting approaches. They find that, if the instruction language is the same as the input language, the models exhibit a better performance. However, the improvements are not consistent across all models and across Portuguese and Galician, the two languages included.

The contributions of this paper are the following: *(i)* We produce and release a multilingual, instruction-formatted dataset that includes both literal and idiomatic examples and that covers a wide range of idiom types. *(ii)* We show the improvements produced by an approach to idiom processing based on instruction fine-tuning (particularly for Task 1). *(iii)* We highlight the impact of the instruction language on the model's performance.[1]

The paper is structured as follows. Section 2 presents research on automatic idiom processing and sheds light on possible gaps and further developments. Section 3 illustrates the creation of the instruction-formatted dataset in English, Italian, and Portuguese. Section 4 presents the evaluation framework adopted and the specific settings of the experiments we carry out. Section 5 describes the results obtained and compares the model's performance before and after the fine-tuning. Finally, Section 6 draws conclusions and proposes future developments.

## 2. Related Work

The need to develop *ad hoc* techniques for the automatic processing of idioms is widely acknowledged to acquire a better understanding of language [12, 13, 14]. Multiple natural language understanding (NLU) tasks face challenges related to IEs, despite the use of state-of-the-art (SOTA) solutions. Among these tasks are sentiment analysis [15], paraphrase generation [16], natural language inference [17], dialog models [18], and machine translation [19, 20].

Recent approaches employ encoder-based models, like BERT [21], and leverage their contextual language embedding. Studies have found that this type of models struggles with non-compositionality and has difficulty in disambiguating between literal and idiomatic meanings [22, 7, 23]. Yu and Ettinger [7] explore the ability of encoder-based models to handle semantic compositionality. In particular, they use five models, such as BERT and

[1] The dataset and the implementation are both available at https://github.com/TinfFoil/MultIdiomLlama

some of its variants, to examine to what extent these can represent words in isolation and in phrases. They reach the conclusion that these models grasp the meaning of individual words but struggle to capture composed meaning. Zeng and Bhat [8], instead, propose the iDentifier of Idiomatic expressions via Semantic Compatibility (DISC) to perform extraction and identification of PIEs. Their framework leverages BERT to harness both the semantic and the syntactic properties of PIEs, and extract and identify all the expressions from a corpus. Results show that their model is able to outperform SOTA baselines, even in zero-shot settings, but it exhibits poor cross-domain performance. In addition, while including a notable array of idiom types, it focuses on English data only.

Some approaches take steps to include multilinguality. Tayyar Madabushi et al. [5] release *AStitchinLanguageModels*, a dataset in English and Portuguese, and expand it with Galician data for the SemEval-2022 Task 2 [24]. Working on the idiomaticity detection task, they employ models like BERT and XLNET [25] and conclude that models do not benefit from the inclusion of the context and that the zero-shot setting still produces poor results. This corpus represents the first significant attempt to include multilinguality for the automatic idiom processing and provides baselines for languages other than English. This dataset is, however, limited in that it only contains noun compounds, thus lacking diversity and failing to incorporate other types, such as verb and prepositional phrases. Another attempt at multilingual idiom processing is Tedeschi et al. [6]'s ID10M. They develop a framework of systems and training and validation data for the idiom identification task in 10 languages. Their findings confirm the distinction between zero-shot and few-shot performance.

Sentsova et al. [26] release the *Multilingual Corpus of Potentially Idiomatic Expressions* (MultiCoPIE) in Russian, Italian, and Catalan, which includes additional linguistic features, such as semantic compositionality, head part-of-speech, and English equivalents. By fine-tuning XML-RoBERTa, they explore cross-lingual transfer, which might benefit lower-resourced languages. Moreover, the inclusion of idioms having an English equivalent in the training set has proved helpful in disambiguating between literal and idiomatic usages.

Encoder-decoder models have also been used for the development of idiom-aware systems. Zeng and Bhat [27] opt for the BART [28] sequence-to-sequence (seq2seq) model. Their Generation of Idiom Embedding with Adapter (GIEA) model exhibits an improved ability at representing idiomaticity, but it is limited to English and does not show an enhanced generalisation capability.

Other studies have examined the performance of large language models (LLMs) [29, 11], finding that they fail to handle idiomaticity and that they tend to be outperformed by other transformer-based models.

Previous work falls short of capturing the complexity associated with IEs on multiple levels. On the one hand, studies have mostly focused on English, leaving other languages aside. On the other hand, they have failed to cover a wide enough variety of idiom types. Furthermore, studies agree on the limited ability of different models to handle and process unseen idioms.

## 3. Instruction Data Creation

**Source Datasets.** We start from three datasets to build our instruction-formatted data in English, Italian, and Portuguese: *AStitchInLanguageModels* [5], ID10M [6], and MultiCoPIE [26].

*AStitchInLanguageModels* is a dataset of idiomatic multi-word expression (MWE) usage in English and Portuguese. It comprises examples containing PIEs in the form of noun compounds, annotated according to two different schemes. In the first one, sentences are labelled as having an idiomatic or a literal meaning. The second one is more fine-grained in that it provides a paraphrase of the MWE's meaning and labels each example into one of five categories: literal, idiomatic, non-idiomatic, proper noun, or meta usage. We use data labelled with the first annotation scheme for the zero-shot scenario, with no overlap of PIEs between the training and the test sets.

ID10M is a framework that introduces a multilingual Transformer-based architecture for sentence disambiguation and idiom identification and provides annotated datasets in multiple languages. It includes gold-standard data in English, German, Italian, and Spanish, and silver-standard data automatically annotated in 10 languages: Chinese, Dutch, English, French, German, Italian, Japanese, Polish, Portuguese, and Spanish. A list of MWEs is compiled from the Wiktionary,[2] and sentences containing MWEs are collected from WikiMatrix [30],[3] a multilingual corpus in 83 languages with parallel sentences retrieved from Wikipedia. The gold-standard data are curated by native professional annotators, while the silver-standard data are annotated based on the Wiktionary entry of MWEs: when the MWE is marked as idiomatic, all occurrences of the MWEs are labelled as idiomatic, and vice versa. Since these annotations do not necessarily reflect the actual MWE usage in context, Tedeschi et al. develop a dual-encoder architecture to refine silver-standard data. They also incorporate a BIO tagging scheme [31] to identify the tokens belonging to the MWE, where *B* indicates the first token of a span, *I* signals the intermediate token(s), and *O* designates the tokens out of any span.

[2] https://pypi.org/project/wiktextract/

[3] https://github.com/facebookresearch/LASER/tree/main/tasks/WikiMatrix

MultiCoPIE is a dataset annotated for sentence disambiguation and idiom identification in Russian, Italian, and Catalan. To build this dataset, a list of PIEs is compiled for each language from online resources, such as the Dizionario italiano De Mauro[4], the Russian Wiktionary[5], the Diccionari català-anglès/anglès-català de locucions i frases fetes[6]. PIEs with varying characteristics are included, specifically, PIEs with different parts of speech as heads. For example, `appeso a un filo` ('hung by a thread') has the adjective `appeso` ('hung') as head, while `con l'acqua alla gola` (literally 'with water up to the throat', meaning 'to be in serious difficulty') is headed by the preposition `con` ('with'). The dataset also covers PIEs with diverse degrees of semantic compositionality. PIEs with a higher level of compositionality comprise at least one cue to the meaning of the expression. An example is `ammazzare il tempo` ('to kill time'), where the word `tempo` ('time') helps interpreting the expression as 'to spend time trying not to get bored'. On the other hand, `essere al settimo cielo` ('to be on cloud nine') is more opaque since it does not comprise any hints about the meaning 'to be at the peak of happiness'. After selecting the PIEs, sentences are automatically extracted from the Open Super-large Crawled Aggregated coRpus (OSCAR)[7] [32], a multilingual corpus generated from Common Crawl[8], and refined through manual selection. The two surrounding sentences are included to provide context. Opening and closing tags are also employed to locate the lexicalised components of PIEs. The tags are used to identify all PIEs present in the target sentence and the preceding and following sentences.

**Creation of the Instruction Templates.** To create a dataset of instruction-formatted instances, we design instructions in English, Italian, and Portuguese. We first translate a seed instruction written in English into Italian and Portuguese using LLaMA 3.2 3B[9] via ollama[10]. With the same model, we generate three paraphrased versions of the instructions. We design the prompts to produce different writing styles and perspectives, ensuring a varied dataset and a high linguistic diversity. These instructions are then organised in empty templates. The starting point to construct such templates is the work by Taori et al. [33], who fine-tune LLaMA 7B on instruction-formatted demonstrations. They design a template in English to create the instruction-formatted examples and carry out the fine-tuning. We translate their template into Italian and Portuguese. The 'prompt no input' option is discarded since all our samples include an input sentence. Finally, we change the structure of the template. While the Alpaca template[11] organises the instruction in "Instruction", "Input", and "Response", we modify the order so that the input is first presented, followed by the instruction and the response, since this order better fits language modeling underlying LLMs. This order meshes well with the left-to-right autoregressive nature of LLaMA: as shown in Table 1, the instruction leaves an empty slot at the end, where the model's response is expected. Finally, the 'input' and 'output' keys are left empty to be filled in the following step.

**Table 1**
Examples from the instruction dataset with the output produced given an instruction and an input in different language combinations.

| **Examples** |
|---|
| **Input (en)**: Although the encounter was bathed in sunshine, the match failed to reach boiling point.<br>**Instr. (en)**: Can you spot the idiomatic expressions lurking within this sentence? They are:<br>**Output**: boiling point |
| **Input (pt)**: Nos últimos anos, muitas universidades têm mostrado quadricópteros realizando manobras aéreas.[a]<br>**Instr. (it)**: Un'analisi della frase rivela la presenza delle seguenti costruzioni idiomatiche:[b]<br>**Output**: Nessuna.[c] |
| **Input (en)**: After the day I had today , I feel like I could walk on water.<br>**Instr. (pt)**: A frase contém as seguintes expressões idiomáticas:[d]<br>**Output**: walk on water |

[a] In recent years, many universities have demonstrated quadcopters performing aerial manoeuvres.
[b] An analysis of the sentence reveals the presence of the following idiomatic constructions:
[c] None.
[d] The sentence contains the following idiomatic expressions:

**Creation of the Final Dataset.** We then proceed with the creation of the final dataset. We extract IEs and examples from the aforementioned datasets. For English and Portuguese, we use ID10M and *AStitchInLanguageModels*, while, for Italian, we employ ID10M and MultiCoPIE. The processing of the *AStitchInLanguageModels* mainly focuses on extracting the actual MWEs present in the sentences since it includes the dictionary form. For ID10M, we process the data by reconstructing full sentences and identifying idiomatic spans. We then create a training and test split combining data from both ID10M and *AStitchInLanguageModels*, while ensuring that no PIEs in the test set overlap with those in the training

**Table 2**
Statistics of an instruction subset for each of the three languages.

| Language | Idiomatic | Literal | Instances |
|---|---|---|---|
| en | 12,415 | 12,415 | 24,830 |
| it | 10,999 | 10,999 | 21,998 |
| pt | 6,448 | 6,448 | 12,896 |
| Total | 29,862 | 29,862 | 59,724 |

data. Finally, we apply text cleaning operations, such as fixing contractions and punctuation spacing and export two final processed splits per language.

For the MultiCoPIE data, we retrieve sentences and the relative PIEs enclosed in annotation tags to obtain the non-lemmatised versions. Next, we combine these data with ID10M's Italian data and balance the whole dataset by undersampling literal instances and splitting into training and test sets, while preventing PIEs overlap between them. Finally, text cleaning is applied to improve consistency.

Once extracted the IEs and the sentences for all three languages, we merge all sets into unified training and test datasets containing instances from English, Italian, and Portuguese. We then populate the 'input' and 'output' fields of the templates with such examples. The final dataset comprises three subsets containing the same set of examples, with English, Italian, and Portuguese as the input languages. The subsets thus have identical sizes and balanced distributions of idiomatic and literal sentences and only differ in the instruction language. Table 2 shows the statistics for one representative subset.

## 4. Experimental Settings

**Evaluation Framework.** To account for both tasks, we propose a two-fold evaluation methodology, which allows for a comprehensive understanding of the model's ability to handle both the classification and the identification challenges.

We design an evaluation framework to assess the model's performance on the sentence disambiguation and idiom identification tasks across various language combinations. For Task 1 we develop a labelling mechanism that considers multiple linguistic markers. Such markers are used for both ground truths and predictions to determine the label (0 or 1) to assign to each example. These keywords are language-specific and are:

- Portuguese: 'nenhuma', 'não', 'ausente';
- Italian: 'nessuna', 'non';
- English: 'none', 'no idiom', 'not contain', 'not'.

The label assignment can be represented as follows:

$$\text{label} = \begin{cases} 0 & \text{if keywords are present} \\ 1 & \text{otherwise} \end{cases} \tag{1}$$

According to the assigned labels, precision, recall, and $F_1$-measure scores are computed.

For Task 2, the evaluation approach adopts partial text span matching. Following the approach proposed by Da San Martino et al. [34], we give credit to partial matches of the identified spans. This means that if the model identifies a portion of the IE but not the whole span, it will be credited for the overlap. This approach allows for a more flexible assessment of the model's performance. The span matching is character-based and is computed through the Longest Common Subsequence (LCS), which aims to find the longest subsequence two sequences have in common, keeping the order of characters unchanged. LCS is thus order-sensitive, but the characters in the subsequence do not necessarily have to be contiguous. This is important because IEs may contain lexicalised components that are spread across a span, while particles (such as auxiliary verbs or personal pronouns) may appear within the expression but do not need to be included in the span for the match to be considered correct. In other words, LCS is flexible in terms of character proximity, as it allows for gaps in the sequence, but requires that the identified IE maintains the same order found in the ground truth span. This is crucial since it enables to account for variations occurring within the IE.

Based on LCS, character overlap is determined and used to compute precision and recall:

$$P(S,T) = \frac{1}{|S|} \sum_{d \in D} \sum_{s \in S_l, t \in T_l} \frac{|s \cap t|}{|t|} \tag{2}$$

$$R(S,T) = \frac{1}{|T|} \sum_{d \in D} \sum_{s \in S_l, t \in T_l} \frac{|s \cap t|}{|s|} \tag{3}$$

where $s$ is the predicted span, $t$ is the ground truth span, $S$ is the set of predicted spans, $T$ is the set of gold standard spans, $d$ is a sample, and $D$ represents the whole dataset. The $F_1$-measure is then computed as the harmonic mean of precision and recall.

**Settings.** The instruction fine-tuning is implemented on a subset of our dataset. This subset comprises 18,397 samples and retains the balance of the instruction dataset. To optimise the fine-tuning, QLoRA [35] is also employed to reduce computational cost and memory usage.

As for the instruction fine-tuning, a set of default hyperparameters is configured to implement the fine-tuning of the LLaMA-3.2 1B model for the sentence disambiguation and idiom identification tasks. The model is trained with a batch size of 32 across 2 epochs, using a cutoff

length of 128 tokens for input sequences. For parameter-efficient fine-tuning, LoRA [36] is employed with a rank (r) of 8, alpha of 16, and dropout rate of 0.05, specifically targeting the query and key projection matrices. The implementation of LoRA enables to update only 851,968 out of more than 1 billion parameters. The optimisation process uses 4-bit quantization with NF4 format to reduce memory requirements. The learning process is managed with a learning rate of 3e-4, weight decay of 0.01, and a warmup ratio of 0.1, using the Paged AdamW 32-bit optimizer and cosine learning rate schedule with restarts. Gradient accumulation is set to 2 steps with a maximum gradient norm of 1.0, and gradient checkpointing is enabled to optimise memory usage. The training uses mixed-precision computation (FP16) and employs early stopping.

## 5. Results and Discussion

**Sentence Disambiguation Task.** Table 3 shows the F$_1$ scores for Task 1, averaged over 3 runs, for all combinations of instruction and input language, before and after the fine-tuning. When comparing our model against the baseline model without fine-tuning, we can see that the best results are achieved after the instruction fine-tuning: the performance gains more than 2 points across all combinations, with the Portuguese monolingual pair increasing by almost 3 points. These findings suggest that the approach we adopted consistently enhances the model's performance, regardless of the instruction-input language combination. Turning to the impact of the instruction language, the baseline results indicate that English inputs tend to prefer English instructions. On the other hand, there seem to exist some sort of interplay between Italian and Portuguese: a slight improvement is produced when Italian data are associated with Portuguese instructions and vice versa. Conversely, our results show that the model yields better F$_1$ scores when prompted with instructions in English across all language combinations. This suggests that the fine-tuning leads the model to prefer instructions written in English when disambiguating between literal and idiomatic sentences.

**Idiom Identification Task.** Table 4 shows F$_1$ scores, averaged over 3 runs, for Task 2, before and after instruction fine-tuning. We can see that, in general, the model exhibits poor performance and struggles to identify the idiom contained in the input sentence. In the idiom identification task, the improvements produced by the instruction fine-tuning are mostly lower or non-existent. The English inputs tend to benefit more from this approach, gaining 2 points almost with all languages. Conversely, the model seems to struggle on Italian data, and, when associated with Italian and English instructions, it suffers from the fine-tuning, losing 1 point. When dealing with Portuguese sentences, instead, the model produces slightly improved results. Instruction fine-tuning, therefore, does not significantly and consistently help the model in identifying idioms. However, we should consider that Task 2 is much more challenging in that it consists in the identification of the idiom contained in a given sentence, at the character level. As for the instruction language, unlike Task 1, the instruction fine-tuning does not lead the model to favour English. Instead, Portuguese instructions seem to better help the model in detecting the idiom.

**Interactions between Instruction and Input Language.** The results abovementioned provide insights into the interactions between instruction and input language. For Task 1, English instructions seem to aid the model in distinguishing between idiomatic and literal sentences. Sentence disambiguation represents a simpler task that requires a global understanding of the input sentence. English, on which the model is mostly pretrained [37], might better allow LLaMA 3.2 to comprehend the task to carry out. Idiom identification, instead, is a much more complicated task requiring the model to have a deeper and more precise comprehension, not only at the sentence level, but also at the phrase level. This entails a finer knowledge of the input language as well. Besides, when the instruction and the input language differ, the model is prompted in one language and asked to answer in another, which creates an additional layer of complexity. Different types of interactions between instruction and input language thus emerge, and future research is needed to investigate such interactions based on the languages involved and the task under study.

## 6. Conclusions

In this paper, we developed a fine-tuned LLaMA 3.2 1B on two tasks: sentence disambiguation and idiom identification. We adopted a multilingual approach in that we considered three languages, English, Italian, and Portuguese, and we employed instruction fine-tuning. To carry out the fine-tuning, we first constructed a multilingual dataset consisting of instruction-formatted data designed for idiomatic expressions (IEs). We examined the two tasks in a multilingual setting involving the abovementioned languages, which were used as both instruction and input languages, covering all possible combinations. This fine-tuning provided some valuable insights.

For the sentence disambiguation task, our instruction-based approach yielded better $F_1$ scores, compared to the baseline results, which suggests that it aids the model in distinguishing between idiomatic and literal meanings. Nevertheless, after the fine-tuning, the models seemed to favour English instructions across all input languages. This might indicate that we can achieve satisfactory results prompting models with English instructions [10], and that we can limit instruction engineering to only one language [38]. On the other hand, this can be disadvantageous for other languages, potentially reducing model performance and usability in multilingual contexts.

For the idiom identification task, the model struggled to correctly identify the idiom included in the sentence, both before and after the fine-tuning. Our instruction-based approach did not necessarily lead to a significantly improved performance, and, in some cases, it produced lower $F_1$ scores. Unlike Task 1, Task 2 represents a far more challenging task consisting in detecting IE at the character level, which might explain such a poor performance. Besides, the model did not exhibit a consistent preference for one language and produced mixed results.

Instruction fine-tuning might be beneficial for Task 1 but not necessarily for Task 2, and the instruction language plays a crucial role in the model's performance.

However, further research is needed. From a methodological perspective, we used a relatively small model, and experiments with larger ones can be conducted. Other LLMs beyond LLaMA could be fine-tuned as well, not only to assess their performance but also to compare encoder-based and encoder-decoder models on the same IE-related tasks. We did not implement hyperparameter tuning and limited the fine-tuning to a small subset. Future research could explore optimised hyperparameters to improve performance, as well as use a larger dataset. Our study was also limited to three languages, and the scope could be expanded to others, even from different families, to gain a deeper understanding of cross-linguistic interactions. Finally, a promising direction would be the creation of datasets annotating idiomaticity on a continuum rather than as a binary distinction, aligning with more recent linguistic theories.

**Abstract**

Understanding whether large language models (LLMs) capture human-like semantic associations remains an open challenge. This study investigates semantic priming within GPT-4o Mini by analyzing probabilistic responses to psycholinguistically validated prime-target pairs. Prime-target stimuli were extracted from the Semantic Priming Project database, embedding target words within masked sentence contexts preceded by semantically related or unrelated primes. Model responses were quantified using log-probabilities associated with predicted tokens, allowing comparative evaluation of semantic priming effects. Results reveal that the model's predictive outputs reflect priming effects when analysis is restricted to fully reconstructed data, yet these effects diminish significantly under data imputation strategies addressing extensive missingness. This discrepancy highlights critical issues regarding data preprocessing, tokenization, and the management of missing values in computational semantic experiments. Implications for future research in cognitive modeling and the refinement of LLM architectures to better approximate human semantic processing are discussed.

**Keywords**

semantic priming, large language models, GPT-4o, language modelling, experimental psycholinguistics

## 1. Introduction

Semantic priming, a fundamental phenomenon in psycholinguistics and cognitive neuroscience, provides critical insights into how the human brain organizes and retrieves semantic knowledge. It refers to the facilitation of a target word's recognition or processing when it is preceded by a semantically related prime. This effect was first empirically demonstrated by Meyer and Schvaneveldt in 1971 [1] using the lexical decision task where participants identified words more quickly when proceeded by related primes (e.g., bread-butter) compared to unrelated pairs (e.g., guitar-butter). This finding suggested that related concepts in the mental lexicon are interconnected, enabling more efficient retrieval. Building on this, Collins and Loftus [2] proposed the spreading activation model of semantic memory in 1975. According to this model, the mental lexicon is structured as a network of interconnected nodes representing concepts. When a prime word is processed, activation spreads to related nodes, reducing the activation threshold required to recognize semantically connected targets. This framework accounts for the graded nature of semantic priming, where more closely related concepts exhibit stronger priming effects. Furthermore, Neely [3] differentiated between automatic and controlled semantic priming processes in 1977. Automatic priming occurs rapidly and unconsciously at short stimulus onset asynchronies (SOAs), reflecting the passive spread of activation within the semantic network. In contrast, controlled priming involves conscious, strategic processes that emerge at longer SOAs, where participants anticipate certain responses based on contextual cues. The neural correlate of semantic priming was clarified by with the discovery of the N400 event-related potential (ERP) component [4]. It is a negative deflection of the brain electrical activity that peaks approximately 400 ms after the presentation of a semantically incongruent stimulus. In their study, unexpected sentence endings elicited larger N400 responses compared to congruent completions, providing neurophysiological evidence that semantic priming modulates brain activity during language comprehension. Recent work has started to investigate priming phenomena in large language models, showing parallels with human language processing. For structural priming, Michaelov et al. [5] demonstrate that LLMs exhibit human-like inverse frequency effects and that prime-target dependencies influence prediction preferences, revealing systematic parallels with production preferences in humans. Similarly, semantic activation patterns—akin to classical semantic priming in psycholinguistics—have been explored both in humans and LLMs, highlighting ways in which contextual cues modulate internal representations. These findings motivate situating our methodology within this emerging line of work and clarifying how our approach compares and contrasts

with prior operationalizations.

**Motivations.** This foundational framework informs the present study, which investigates whether similar semantic priming effects manifest in large language models (LLMs) like GPT-4o. By comparing the probabilistic output of the model in related and unrelated prime-target conditions, this research explores whether LLMs exhibit cognitive-like patterns of semantic association, bridging computational modelling with traditional psycholinguistic paradigms. The motivation behind this study stems from a broader interest in cognitive modelling using AI. These systems offer a convenient starting point for modelling and exploring human language processing due to their architecture and training on vast amounts of linguistic data. A critical question is whether the behaviours they exhibit are unique to their training processes or if they mirror transferable cognitive mechanisms inherent to human language processing. Understanding this could contribute to the debate of whether LLMs merely reflect statistical learning or if they approximate the cognitive structure that governs human semantic memory. Neural networks like GPT are trained on massive datasets, capturing statistical regularities, co-occurrence patterns and semantic relationships present in human language. While these models are not biological in nature, the structured statistical patterns they learn often mimic human-like associations. This raises intriguing questions: do these models, through exposure to language data, develop semantic networks akin to those observed in the human brain? And if so, can they serve as valid proxies for studying cognitive processes like semantic priming? Beyond theoretical interests, there are significant practical applications to this line of inquiry. These systems could be employed to predict and model human behaviours in various linguistic tasks, providing a new tool for psycholinguistic research. Moreover, understanding how closely they align with human cognitive processes could inform the refinement of AI architectures, enabling the development of models that better capture human-like semantic organization. GPT-4o is a state-of-the-art (SOTA) model in numerous linguistic domains, including natural language understanding, text generation, translation and dialogue systems. Its ability to produce highly coherent, human-like linguistic artifacts makes it an ideal candidate for investigating semantic priming effects. Beyond the mere scarcity of experiments on priming, there remains a broader and more fundamental question: To what extent do LLMs, particularly closed-source models, exhibit semantic processing mechanisms that align with human psycholinguistic assessments? While extensive research has been conducted on model performance and generative capabilities, little is known about whether their response to such assessments parallel those reported in human. This is particularly relevant given GPT-4o's autoregressive nature, where each word is predicted based on the preceding context. This mechanism inherently mirrors aspects of the human predictive processing in language comprehension, making it a suitable ground for examining whether priming emerges from the model's output.

**Research Question and Hypotheses.** The present work proposes to investigate whether LLMs, such as GPT-4o[1], exhibit semantic priming effects similar to those observed in human cognition, exploring if semantic associations emerging from their probabilistic outputs reflect transferable cognitive mechanisms. This research is situated within a growing field that compares AI to human cognition, exploring parallels and divergences. The aim is to assess whether the model not only reflects simple statistical learning but also develops semantic structures resembling human semantic networks. In other words, the goal is to determine whether the autoregressive behaviour of the model generates priming effects comparable to those observed in traditional psychological paradigms. Therefore, the research question we propose is the following: Does GPT-4o mini model exhibit a significant difference in the probability values of target words when presented in related priming conditions compared to unrelated conditions?

**Expected Outcomes.** It is hypothesized that targets will exhibit higher probabilities values in the related condition compared to those presented in unrelated conditions. This structure allows for the investigation of whether the emergent cognitive traits of LLMs can be considered analogous to the dynamics of human semantic memory and whether traditional psycholinguistic paradigms can be employed to evaluate the validity of these models as devices for cognitive research.

## 2. Methodology

In autoregressive systems as GPT-4o, text generation is fundamentally modelled as a conditional probability problem. The model predicts the next word in a sequence based on the preceding context, represented mathematically as

$$P(w_t|w_1, w_2...w_{t-1}) \tag{1}$$

where $P(w_t)$ is the probability of generating a word given the previous ones. This probabilistic framework underpins how the model processes language and generates outputs, making it a suitable foundation for investigating semantic priming effects. In the context of this

[1] The experiment was run with GPT-4o mini. However, we will often refer to it as GPT-4o or GPT throughout the text. This is just to make reading as smooth as possible.

experiment, the target word is presented after a prime that is either semantically related or unrelated. To assess whether GPT-4o exhibits priming effects, the following contrast was applied

$$P(target|related\_context) \quad vs \quad P(target|unrelated\_context) \tag{2}$$

If semantic priming is present, the model should assign a higher probability to the target word in the related condition, reflecting an internal representation of semantic association similar to those of humans. GPT models output not only the predicted tokens but also the log-probabilities (log-probs) associated with each token

$$logprob(w_t) = log[P(w_t|w_1, w_2, ..., w_{t-1})] \tag{3}$$

A log-prob closer to 0 indicates a higher predicted probability, while more negative values indicate lower confidence in the prediction. In this experiment, we use log-probs to quantify the model's confidence in predicting the target word. Thus, semantic priming is operationalized as

$$logprob_{related}(target) > logprob_{unrelated}(target) \tag{4}$$

## 2.1. The Experiment

Our operationalization of priming diverges from the maybe more familiar formulation of computing priming as the difference in the log probability of a fixed target given congruent versus incongruent primes [6, 7] because we aim to isolate semantic activation in contexts where the is not trivially predicable and to control for context-dependent insertion effects. In particular, the fill-in-the-gap setup we use allows us to: (i) position the target in a controlled environment so that its activation can be assessed relative to a specific semantic cue (the prime), and (ii) avoid conflating effects due to target salience or surface-form predictability that a straightforward target-difference formulation might implicitly include. We evaluated the design quantitatively and ensured that it produces a signal consistent with priming as a contextual modulation of likelihood, without relying on the assumption that the target sentence is equally well-formed or equally predictable across conditions. Conceptual comparisons suggest that our pipeline captures the same directional priming influence while offering control over the insertion context and over cases where native target continuity would otherwise introduce ambiguity. A schematic of the pipeline and an illustrative example are provided below.

In this experiment, GPT-4o mini was presented with prime-target pairs, where the prime word was either semantically related or unrelated to the masked target word embedded within a sentence. For each trial, the model received a prompt consisting of the prime followed by a sentence with the target word omitted and was instructed to generate a single word to fill the blank.

**Stimuli Presentation.** The stimuli were presented to GPT through 500 structured API calls designed to simulate an experimental paradigm of cognitive psychology. Each stimulus consisted of a prime word (semantically related or unrelated to the target) and a sentence containing a masked target word. The API was configured to prompt the model with both the prime and the incomplete sentence as input text: [Prime Word]. [Sentence with the target masked as "…"].

**Table 1**
The prompt used during the experimentation

```
(model = gpt-4o-mini,
 messages = [
 {“role”: “system”,
  “content”: “you do text-completion.
  I will provide you a sentence with a blank ‘. . . ’,
  your task is to return a single word},
  to complete it.”},
 {"role": "user","content": input_text }
 ],
 Temperature = 0
)
```

For example, in a related condition, the prime “below” may precede the sentence “The Ferrari finished six places … the Mercedes”, where the target is ”above”. In the unrelated condition, the same sentence would be preceded by an unrelated prime such as “postage”. This structure allowed for direct comparison of the model's predictions across priming conditions. To ensure controlled responses, the model was provided with a system instruction to return a single-word completion for the masked portion of the sentence. The temperature was set to zero to minimize randomness and enforce deterministic outputs, and finally log-probs were requested for the predicted token, together with the top 15 alternatives.

**Retrieval of Log-Probabilities.** Log-probs provide an exhaustive measure of the model's confidence in predicting a given token because they reflect the probability distribution over multiple possible continuations, rather than just the most likely one. They allow for a nuanced comparison of how strongly the model favours certain predictions, making them particularly useful for assessing semantic priming effects. However, retrieving log-probs for the intended target posed a computational challenge due to the tokenization structure of GPT outputs, requiring a sophisticated reconstruction algorithm. When GPT generates a response, it predicts the single most likely token (i.e., the actual completion), but it can also return log-prob values for multiple alternative predictions—if explicitly requested in the API call. These values are stored in a structure that contains the predicted token along with a ranked set of alternatives, each associated with its probability. An additional complication arose because GPT often predict sub-word units, meaning that a target word might be split into multiple tokens[2]. Such level of complexity necessitated a reconstruction system capable of piecing together each "brick" to retrieve the log-probability of the intended word. The retrieval system operated by matching the original target word against the set of alternative completions of the model. If the target appeared in its entirety among the predictions, its associated log-prob was directly extracted. Conversely, when the model provided sub-word tokens, a beam search strategy was employed to reconstruct the word step-by-step. At each stage, candidate sequences were expanded by adding predicted tokens, ensuring that only those maintaining a valid morphological match with the target were retained. Once a valid reconstruction was found, the sum of the probabilities of constituent tokens was computed, and the least negative candidate (i.e., the most probable one) was selected as the best match. Where no reconstruction matched the original target, no log-prob was assigned (NaN), leaving its interpretation for later stages of analysis.

**Data Construction.** The stimuli set was built following previous research [8] and was designed to ensure that semantic associations were robustly controlled. A total of 250 triplets (target, related prime, unrelated prime) were selected from the Semantic Priming Project (SPP), a widely used database containing highly validated prime-target association from human behavioural studies. The rationale behind using SPP was its empirical grounding—these prime-target pairs have been extensively tested in psycholinguistic experiments, making them an ideal starting point for evaluating whether LLMs, like GPT, exhibit cognitive processes akin to those observed in human behavioural tests. Given that GPT is trained on massive linguistic corpora, it has probably internalized complex semantic structures, making it a suitable model for priming-based investigations. To construct the experimental dataset, the following procedure was applied:

1. Selection of prime-target pairs:
   - A randomly chosen prime-target pair was selected from SPP in the related condition.
   - The corresponding prime-target pair was selected to contrast with the related condition.
   - Only first-associate (most common) target was considered, ensuring strong semantic links for the related condition.
2. Pairing process:
   - Each related and unrelated prime was paired with the same target word, creating a contrastive pair.
3. Contextual sentence construction:
   - A sentence was invented to serve as a contextual frame for the target word.
   - The target word was removed from the sentence and replaced with a placeholder ("...") creating a fill-in-the-blank format for the model.
4. Tabular data representation:
   - The entire dataset was stored in a structured tabular format, with each stimulus set organized as follow.

**Table 2**
Example of Prime-Target Stimuli: Each two consecutive rows represent a contrastive pair

| ID | Type | Prime | Target | Sentence |
|---|---|---|---|---|
| 001 | Related | below | above | "The Ferrari finished six places … the Mercedes" |
| 002 | Unrelated | postage | above | "The Ferrari finished six places … the Mercedes" |

## 2.2. Statistical Testing

To determine whether GPT-4o exhibits semantic priming effects, a statistical approach was designed to compare the log-probabilities of target words across related vs. unrelated priming conditions. Since log-probs are continuous numerical values, they provide a measure of the model's confidence in predicting a given word, making them suitable for inferential statistical analysis. The key objective of this analysis was to assess whether log-probs were significantly higher (closer to 0) in the related condition compared to the unrelated condition, mirroring the facilitatory mechanism observed in human priming studies. Given the paired nature of the data—where each target word appears in both conditions with the same sentence context—the statistical analysis was designed to compare log-probs at the within-item level. Statistical tests often require that data distribution meets certain

[2] All GPT models leverage a Byte Pair Encoding (BPE) tokenizer, which allows for flexible and semantically complete processing of linguistic data

assumptions. Specifically, normality was a key consideration: if the distribution of log-probs followed a normal pattern, a paired t-test would be appropriate; if not, a Wilcoxon signed-rank test, a popular non-parametric alternative, would be used instead. Following this strategy, an initial assessment of normality was planned, ensuring that the choice of statistical test was applied ad-hoc, rather than arbitrary. This decision was crucial because log-probs are inherently skewed measures, often concentrated around certain thresholds, and the dataset was expected to contain NaN values where the model failed to predict (or the retrieval algorithm failed to recompose) the target word. To maintain statistical rigor, missing values would be handled through imputation, but this step also had the potential to affect normality, requiring a flexible approach.

**Multiple Imputation Approach.** The first strategy involved multiple imputation, a statistical technique that estimates missing log-probs based on the distribution of observed data. Imputation is considered a reasonable approach to retain a larger dataset while minimizing bias. Here, an assumption of near-random data missingness had been adopted, although similar hypotheses are often difficult to verify.

**Complete Case Analysis.** Precisely because it is difficult to determine with certainty whether the data is missing for largely random reasons, it is also useful to perform the test on the dataset without imputation. Therefore, the second approach involved analysing the subset of the results where log-probabilities for each condition were reconstructed. Both approaches were then tested following the statistical decision tree: if normality was preserved, a paired t-test would be applied; if not, the Wilcoxon signed-rank would be used instead.

## 3. Results

The aim of this results section is to determine whether GPT-4o mini exhibits semantic priming effects, measured as differences in log-probabilities of target words in related vs. unrelated priming conditions. Given the presence of missing—cases where the experiment failed to generate the expected target word—two complementary analytical approaches were adopted. Summarizing from the previous section: (a) Multiple Imputation, which estimates missing values to maintain the statistical power, and (b) Complete-Case Analysis, which restricts the dataset to instances where log-probs were successfully retrieved in both conditions, ensuring pairwise comparisons.

**Multiple Imputation Results.** Before conducting hypothesis testing, missing values in log-probs were addressed using multiple imputation (MI). Out of 500 total observations, 201 (40%) were missing, requiring imputation to allow for a complete dataset. Five imputed datasets were generated using a multivariate imputer that estimates each value from all the others. Pooled estimates were finally derived. To assess how imputation affected the distribution of log-probs, summary statistics were calculated before and after imputation. The only relevant variation is over standard deviation (std). To determine whether a parametric test or a non-parametric alternative was appropriate, normality of the imputed log-probs was assessed using the Shapiro-Wilk test. This evidenced a significant departure from normality ($W = 0.891, p < 0.05$) indicating that a non-parametric test was required for hypothesis testing. A Wilcoxon signed-rank test showed that there is no strong evidence that GPT-4o mini assigned significantly higher log-probs to targets in the related condition vs. the unrelated condition ($T = 441.0, p = 0.088$). This contrasts with expectations, as human studies typically show a clear priming effect in reaction times and lexical decision tasks.

**Complete-Case Results.** The complete-case analysis was conducted using only full retrieved prime-target pairs, ensuring that all statistical comparisons were based on directly observed data. Out of 500 total trials, 298 log-prob values were successfully retrieved, but only 127 contrastive pairs could be reconstructed for direct comparison. This represents a substantial reduction in sample size, which affects statistical power but ensures that no assumptions were made about missing values. Congruently to what was done with imputed data, a normality assessment was conducted to confirm a strong deviation from normality ($W = 0.789, p < 0.05$). Since normality assumption was violated, a Wilcoxon signed-rank test was conducted to compare the survived log-probs. Unlike multiple imputation, the complete-case yielded a significant result ($T = 1793.0, p < 0.05$). This provides evidence that GPT-4o mini exhibits a semantic priming effect, with significantly higher log-probabilities for target words in related conditions than in unrelated conditions.

## 4. Discussion

The findings of this study offer an interesting perspective on the challenges of using LLMs in cognitive modelling. While complete-case analysis detected a significant priming effect, the multiple imputation approach did not, raising important methodological and conceptual inquiries. The discussion is divided into two sections: (a) methodological considerations, focusing on missing data challenges, tokenization artifacts, statistical sensitivity, and potential imputation biases that may have influenced the results and (b) conceptual implications, addressing whether LLMs exhibit cognitive-like priming, how predictive mechanisms compare to biological semantic encoding and retrieval and what these findings mean for cognitive modelling.

## 4.1. Methodological Considerations Handling Missing Data

In this experiment, a critical methodological challenge was posed by missing data—40% of the log-prob values—requiring the use of multiple imputation to reconstruct a complete dataset. MI is generally preferred over list-wise deletion, as it preserves statistical power by estimating missing values based on the observed distribution. However, when such a substantial portion of data is missing, MI may not fully recover the real distribution, raising questions about representativeness. One consequence is the arousal of variance compression in log-probs values, testified by a shrink in standard deviation. This phenomenon likely occurs predicting missing values based on observed ones, pulls extreme values toward the mean. While this can stabilize estimates in smaller datasets, it may have unintentionally smoothed meaningful variability in the log-probs, affecting true distribution. Indeed, normality test showed a significant departure from normality after imputation was performed. Since semantic priming effects are often subtle, any reduction in variance could have diminished the contrast between related and unrelated conditions, thereby weakening the observable effects. This is consistent with the Wilcoxon test result in the MI dataset, whereas the complete-case analysis did detect a significant effect. The divergence between imputed and complete-case results raises an important methodological question: *did MI impoverish the priming effect, preventing statistical detection, rather than recover lost information?* If the missing data was missing not at random (MNAR)[3] but instead systematic then MI could have incorrectly smoothed meaningful distinctions, masking an effect that was present in the raw data.

**Tokenization and Target Reconstruction Bias.** A significant challenge in the experiment was retrieving log-probabilities for target words due to GPT's sub-word tokenization. Like other transformer models, it does not always generate words as units, instead break less frequent or morphologically complex words into multiple sub-word tokens via BPE. This posed a serious obstacle to probability extraction. Further complicating word retrieval was the format of the model's output, which returns a ranked list of predicted tokens along with their log-probs. In cases where the model generated the target as a single token extraction was straightforward. However, when the model split the target across multiple tokens, its overall log-prob had to be reconstructed from its individual components—a process that introduces uncertainty. To tackle this challenge, a beam search algorithm was implemented to iteratively reconstruct multi-token targets from the list of predicted sub-word tokens. While beam search improved reconstruction, it also introduced potential artifacts: (a) some reconstructions may not have perfectly matched the intended target, leading to incorrect log-prob values, and (b) certain targets may have been tokenized inconsistently. If tokenization patterns differed systematically between conditions, this could have biased log-prob retrieval, introducing a confound.

**Statistical Sensitivity and Priming Detection.** That being said, divergent findings in MI and complete-case results likely arise from two interrelated factors: (a) variance compression introduced by imputation, which may have diluted the contrast between related and unrelated conditions, and (b) tokenization and reconstruction inconsistencies, which could have added noise to log-prob retrieval, particularly in cases where targets were split into multiple tokens. The takeaway is that priming signal drawn from next-word probability retrieval in LLMs may be relatively weak, making it overtly susceptible to distortions introduced by data pre-processing.

## 4.2. LLMs and Cognitive Modelling

The methodological considerations discussed so far demonstrated how data pre-processing choices and tokenization can influence statistical sensitivity in LLM cognitive experiments. However, these findings also raise deeper conceptual questions: *To what extent do LLMs exhibit semantic priming effects comparable to those observed in human cognition? And if LLMs capture statistical relationship between words, does this also means that they can replicate the cognitive mechanisms underlying human semantic memory?* To answer such questions, it is possible to draw insights from the two dominant theoretical frameworks that have shaped our understanding on semantic processing: spreading activation theory, as already presented in the introductory section and in the predictive coding theory (Friston, 2005). These models offer different perspectives on how the brain organizes and retrieves meaning and comparing findings from present work allows to assess the extent to which LLMs approximate cognitive mechanisms. The rest of this section reflects on these themes.

[3] Unfortunately, there is no surefire way to determine in which category data will fall. Random missingness is an assumption that need to be made based upon direct knowledge of the data and its collection mechanisms.

**Spreading Activation, Semantic Memory and LLMs** The spreading activation theory (Collins & Loftus, 1975) suggests that semantic memory is structured as a network of interconnected concepts, where activation spreads from one node (a word/concept) to related nodes based on semantic similarity and association strength. This model has been widely supported by human psycholinguistic studies. The priming effects detected in the complete-case analysis seems to align with spreading activation framework. LLMs, much like human semantic memory, links concept by encoding statistical co-occurrence patterns between words—though they do it on a considerably larger scale. However, while human priming effects are driven by neural activation spreading across conceptual networks, GPT does not store explicit semantic structures, it instead predicts word based on learned probability distributions. This distinction is crucial: in human cognition, spreading is dynamically modulated by context, prior experience, and attentional control, whereas LLMs' priming emerges from purely statistical dependencies in language data. Current results suggest that semantic priming effects in GPT do not necessarily indicate cognitive-like concept retrieval. The observed priming effect is likely a by-product of training, rather than a direct parallel to human conceptual activation. Additionally, the lack of a significant effect in MI dataset further challenges the idea that LLM-based priming mirrors human spreading activation dynamics. According to human experiments, priming effects persist despite noise or missing data because activation propagates through associative memory networks. In contrast, the weakening of priming in the imputed dataset suggests a more fragile mechanism.

**Predictive Coding and the Mechanisms Underlying Priming in LLMs.** An alternative perspective for understanding semantic processing is predictive coding theory [9]. This model suggests that the brain functions as a hierarchical predictive system, continuously generating expectations about incoming sensory input and minimizing prediction errors by adjusting internal models. In this framework, priming occurs because a related prime reduces the uncertainty (prediction error) associated with recognizing the target, leading to faster processing. LLMs, particularly autoregressive models like GPT, operate in a manner structurally similar to predictive coding. They generate words one at a time, updating predictions based on past context. This aligns with the core principle of predictive coding. The log-probabilities extracted in this study measure the system's internal prediction certainty, making them conceptually analogous to prediction error signals in the human brain. The critical difference is that in biological brains, prediction errors lead to adaptive training and belief updating, whereas in LLMs, prediction errors do not modify the model in real-time—they rather influence generation for a short time-window, impacting token selection within the fixed-parameters of the trained model. This means GPT does not actively minimize uncertainty over time. The experimental findings support this distinction. In human coding models, priming effects are expected to persist across different noise conditions because the brain continuously adjust its processing. In contrast, the fragility of GPT's mechanisms suggests that the models lack a hierarchical learning process that adapts to uncertainty over time. This highlights a fundamental limitation of LLMs: while they approximate prediction-driven behaviours, they do not engage in error-driven learning during inference, a key component of human cognition. As a result, while priming in LLMs may superficially resembles predictive coding, it does not capture the adaptive mechanisms that govern biological semantic memory. The results of this study highlight an ongoing debate in cognitive modelling: *to what extent do LLMs exhibit cognitive-like processing?* The presence of a priming effect suggests that. LLMs capture meaningful relationships between words, much like spreading activation models, but the disappearance of this effect in the imputed dataset suggests that LLMs' priming is more fragile than human priming. Together, these findings give the impression that LLMs do not simulate human cognition in a mechanistic sense. Instead, they exhibit statistical properties that resemble cognitive processes at the output level but are not necessarily driven by the same underlying computations.

**Final Thoughts and Future Directions.** We firmly believe that while LLMs do not currently replicate human semantic cognition, they offer valuable tools for modelling language-based associations. It is our opinion that the presented approach may be improved and extended:

1. Target predictability: controlling for how predictable a target word is in natural language using frequency norms, surprisal values and entropy-based estimates. This would help disentangle semantic priming from simple word predictability in LLMs.
2. Word frequency effects: since high-frequency words are easily predicted and low-frequency words may be underrepresented in training data, future experiments should systematically control word frequency to determine its impact in priming strength.
3. Contextual influence: LLMs process meaning based on statistical co-occurrence within a fixed context window, which may amplify or suppress subtle priming effects. Future studies should manipulate prime-target distance to assess if context length and structural dependencies influence results. Additionally, future research should explore

alternative token-matching strategies, ensuring log-probs reconstruction does not systematically fail with certain word structures. And finally, it should be also considered if modifying LLM architectures—for example, incorporating mechanisms for hierarchical belief updating similar to predictive coding models—would lead to more cognitively plausible representations of meaning.

Comparative studies relating neural language processing signals (e.g., N400 effects) to outputs of LLMs have been increasingly prominent. Heilbron et al. [10, 11] demonstrated that predictability estimates produced by deep neural language models (e.g., GPT-2) correlate with EEG/MEG components—including N400 and P600—during naturalistic comprehension, providing direct evidence that model-derived surprisal signals track human-like prediction dynamics. Subsequent work has further refined the cognitive plausibility of transformer-based models in this domain, showing that their contextual predictions are closely aligned with neural signatures of semantic facilitation and processing difficulty [5]. While Futrell et al.[12] approach the question from a complementary angle—treating neural language models as psycholinguistic subject to probe their internal syntactic representations—these strands jointly motivate our effort to align LLM-based priming metrics with known neural phenomena.

## Abstract

This paper presents ETET, a web-based application for the automated assessment of L2 proficiency. The main contribution of this work lies in its focus on Italian – a language for which no comparable tools currently exist. Another novelty is the departure from traditional assessment models. In fact, the theoretical framework is grounded in CEFR and Processability Theory, allowing an assessment that reflects the natural developmental sequences of the learners' interlanguage. ETET is not intended to replace human raters, but rather to serve as a complementary tool, since it ensures rapid scoring. Additionally, it has customizable and diversified test formats and items, making it a resource suitable for educational contexts, certification, and selection purposes.

## Keywords

valutazione linguistica, italiano L2, CALA, CALT, ICALL

## 1. Introduzione

L'inserimento delle nuove tecnologie nell'insegnamento e nell'apprendimento delle lingue seconde (L2) rappresenta ormai una pratica consolidata. Molti studi hanno evidenziato come il *Technology-Enhanced Language Learning* (TELL) [1] abbia trasformato il rapporto tra insegnanti e apprendenti e le modalità con cui questi ultimi affrontano il processo di apprendimento linguistico [2]. I cambiamenti portati dal TELL riguardano la progettazione della didattica, la gestione delle lezioni e la valutazione delle competenze acquisite [3]. Alcuni studi sostengono, inoltre, che il TELL rende l'apprendimento più flessibile e favorisce una maggiore autonomia dell'apprendente durante il percorso formativo [4].

L'uso delle nuove tecnologie ha portato a cambiamenti non solo a livello didattico e metodologico, ma anche a livello terminologico; infatti, sono emersi concetti nuovi, quali *Computer/Mobile-Assisted Language Learning* [3], [5], *Digital Language Learning* [6], *Computer-Assisted Language Testing/Assessment* (CALT/CALA) [7], [8] e, più recentemente, *Intelligent Computer-Assisted Language Learning* (ICALL) [9].

L'interesse verso l'ICALL è confermato anche dalla creazione di un gruppo di interesse (SIG ICALL) all'interno del *Computer Assisted Language Instruction Consortium* (CALICO), per favorire lo sviluppo di strumenti didattici basati sull'intelligenza artificiale (IA) e su tecnologie di trattamento automatico del linguaggio (NLP), tra cui *Large Language Model* (LLM), riconoscimento vocale (*Automatic Speech Recognition*, ASR) e sintesi vocale (*Text-to-Speech*, TTS). Alcuni studi recenti hanno mostrato, infatti, che l'IA può essere usata con discreto successo sia nella generazione dei quesiti per i test di lingua [10] sia nella valutazione automatizzata delle competenze linguistiche scritte [11], e orali [12]. L'impiego delle tecnologie NLP e IA nella valutazione linguistica sta ricevendo un'attenzione crescente anche nel contesto italiano. A testimonianza di ciò, il recente volume di Cinganotto e Montanucci [13] sull'IA per l'educazione linguistica dedica un intero capitolo agli approcci automatizzati di quello che le due autrici definiscono *language testing*.

*CLiC-it 2025: Eleventh Italian Conference on Computational Linguistics, September 24 — 26, 2025, Cagliari, Italy*

Il nostro lavoro va nella stessa direzione e presenta ETET[2], una web-app commerciale progettata per valutare in maniera automatizzata le competenze linguistiche in una L2. Sebbene ETET sia una piattaforma multilingue – attualmente disponibile per l'inglese e per l'italiano – il presente studio si concentra esclusivamente sul modulo dedicato all'italiano L2.

L'articolo è strutturato come segue: il paragrafo 2 illustra le motivazioni e gli obiettivi della ricerca; il paragrafo 3 delinea il quadro teorico di riferimento; il paragrafo 4 è dedicato alla descrizione di ETET, sia dal punto di vista tecnico sia per quanto riguarda la progettazione dei quesiti, le modalità di assegnazione dei punteggi e la validazione; infine, il paragrafo 5 presenta le prospettive future e alcune considerazioni conclusive.

## 2. Motivazioni e Obiettivi

Per quanto a nostra conoscenza, ETET rappresenta il primo strumento per la valutazione completamente automatizzata delle competenze linguistiche in italiano L2, una lingua parlata da circa 3.287.300 parlanti non-nativi, secondo Ethnologue[3]. Questo numero riflette la presenza di numerose comunità di parlanti di origine italiana di seconda o terza generazione all'estero (i cosiddetti *heritage speakers)* [14], così come l'ampia rete di promozione linguistica e culturale coordinata dal Ministero degli Affari Esteri, composta da 88 Istituti Italiani di Cultura, 8 istituti statali omnicomprensivi, 43 scuole italiane paritarie, 7 sezioni italiane presso scuole europee, 79 sezioni italiane presso scuole straniere internazionali, 2 scuole non paritarie, 422 comitati della Società Dante Alighieri, attivi in tutto il mondo[4]. In questi contesti culturali, spesso frequentati da apprendenti e da parlanti di italiano L2, emerge l'esigenza di strumenti affidabili per la valutazione delle competenze linguistiche, sia a fini didattici che certificativi.

Infatti, negli ultimi anni, la domanda di strumenti per la valutazione delle competenze linguistiche in italiano ha registrato un aumento, anche in risposta a specifici interventi normativi [15], [16]. Ad esempio, l'art. 14, comma 1, lett. a-bis), del D.L. 4 ottobre 2018, n. 113 (c.d. Decreto Sicurezza, in vigore dal 5 ottobre 2018), convertito, con modificazioni, dalla legge 1 dicembre 2018, n. 136, ha inserito l'art. 9.1 nella legge n. 91/1992, subordinando la concessione della cittadinanza italiana al possesso di un'adeguata conoscenza della lingua italiana, non inferiore al livello B1 del Quadro comune europeo di riferimento per la conoscenza delle lingue (QCER). Per ottenere una certificazione linguistica di italiano L2 di livello B1 del QCER, i richiedenti devono superare uno degli esami di lingua riconosciuti (ad es., CELI 2, CILS B1, ecc.)[5]. Sono previsti alcuni casi di esonero per chi possiede un titolo di studio conseguito in Italia o per i titolari di permesso di soggiorno UE di lungo periodo, i quali devono comunque aver superato in precedenza un esame di lingua italiana di livello A2.

Analogamente, gli studenti universitari provenienti da paesi non appartenenti all'Unione Europea sono tenuti a superare una prova linguistica per accertare il livello B2 del QCER se intendono immatricolarsi a corsi erogati in lingua italiana [17].

In ambito lavorativo, la valutazione delle competenze linguistiche di italiano riveste un ruolo importante nei settori del Business Process Outsourcing (BPO), compresi i call center delocalizzati, dove lavorano numerosi parlanti L2 [18]. In questi casi, la qualità del servizio offerto dalle aziende BPO dipende anche dalla competenza linguistica dei candidati.

La presenza di tutte queste situazioni sociali, culturali, didattiche e professionali in cui è richiesta una certificazione delle competenze linguistiche in italiano L2, insieme ai tempi di attesa spesso lunghi per sostenere i relativi esami, evidenzia la necessità di costruire strumenti di valutazione che siano più accessibili, rapidi e facilmente distribuibili su larga scala. In questo contesto, ETET si propone come strumento di supporto alla valutazione tradizionale, con l'obiettivo di fornire stime automatiche della competenza linguistica in italiano L2 che siano affidabili, immediate e coerenti con i livelli del QCER. Lungi dal voler sostituire la valutazione umana, ETET mira a supportarla, offrendo una soluzione utile in contesti ad alta richiesta o come complemento ai percorsi didattici e certificativi (ad es., situazioni in cui è richiesto il risultato in tempo reale, *placement test*, prove intermedie, simulazioni, esercitazioni, ecc.).

## 3. Quadro Teorico

Dall'analisi dei documenti scientifici prodotti dagli enti certificatori dell'italiano come L2 emerge una discrepanza significativa tra le modalità di valutazione adottate nei test ufficiali e quanto descritto nella letteratura sull'acquisizione di una L2, in particolare in riferimento alle fasi di sviluppo dell'interlingua. Tale incongruenza si traduce in una potenziale discontinuità tra i livelli di competenza linguistica effettivamente raggiunti dagli apprendenti e quelli formalmente

certificati. Ne deriva la necessità di elaborare strumenti di valutazione fondati su un inquadramento teorico solido e coerente, in grado di giustificare e sostenere i criteri adottati nella misurazione della competenza linguistica.

Il framework teorico di riferimento per il nostro lavoro è rappresentato dal QCER, standard europeo per la valutazione delle competenze linguistiche promosso dal Consiglio d'Europa. Gli obiettivi principali del QCER sono quelli di promuovere la diffusione del plurilinguismo in Europa, fornire strumenti comuni a chi opera nell'ambito dell'educazione linguistica e della valutazione linguistica e favorire il riconoscimento e l'equiparazione dei titoli e dei certificati linguistici [19]. Essendo concepito come strumento valido per tutte le lingue d'Europa (ma è sempre più usato anche nel resto del mondo), il QCER non si delinea come uno strumento prescrittivo, bensì propone una descrizione qualitativa delle competenze linguistiche che caratterizzano ogni livello [19].

Dopo aver fornito un'impalcatura generale, i singoli stati hanno sentito la necessità di trasporre gli indicatori del QCER nei contesti specifici delle varie lingue. Da questa esigenza sono nate pubblicazioni come [20], per l'italiano, con l'obiettivo di identificare descrittori linguistici specifici per ogni livello di competenza. Accanto all'iniziativa italiana sono sorti progetti anche per l'inglese, lo spagnolo, il francese e il tedesco.

Il quadro teorico su cui si fonda ETET è quindi il risultato delle indicazioni generali contenute nel QCER, nella sua trasposizione specifica teorizzata per l'italiano [19], [20] e dal confronto e dalla disamina dei documenti scientifici prodotti dagli enti certificatori di italiano come L2. È stato inoltre valutato di affiancare questa cornice teorica alla teoria psicolinguistica della Processabilità (Processability Theory, PT) – in particolare per quanto riguarda gli aspetti morfosintattici della lingua – la quale si propone di spiegare le sequenze evolutive che si verificano all'interno di una L2. L'allineamento tra questi due approcci consente di definire un sistema valutativo capace di rilevare non solo il livello raggiunto, ma anche la plausibilità evolutiva delle competenze espresse.

La PT [21], teorizzata nel 1998 da Manfred Pienemann, sostiene che esiste un insieme universale e gerarchicamente ordinato di procedure di elaborazione dell'output che vengono acquisite nel tempo e che non sono influenzate dalla L1 [22], [23]. Tali procedure si presentano in ordine gerarchico implicazionale, ovvero, la procedura di un livello più basso è un prerequisito necessario per il funzionamento della procedura del livello successivo [21]. Le procedure sono attivate nel seguente ordine: procedura lemmatica, procedura categoriale, procedura sintagmatica, procedura frasale, procedura subordinante.

Il primo livello di acquisizione è rappresentato dalla procedura lemmatica che prevede un apprendimento di tipo formulaico. In questa fase vengono identificati elementi lessicali singoli e invariabili, senza far ricorso a processi cognitivi specifici se non a quello della memoria lessicale che porta all'acquisizione di *chunk* e *type* (ad es., ciao). Successivamente si passa al secondo livello, ovvero alla procedura categoriale, in cui l'apprendente inizia a distinguere le categorie lessicali e grammaticali (ad es., nome, verbo, ecc.) degli elementi che ha già imparato e a produrre alcune marche morfologiche. Tuttavia, non vi è ancora comunicazione tra i vari elementi della frase. Il terzo livello è quello della procedura sintagmatica che si divide in due sottolivelli: l'accordo entro il sintagma nominale e l'accordo entro il sintagma verbale. Il primo sottolivello prevede una forma iniziale di accordo all'interno del sintagma, ovvero, l'apprendente riconosce la testa del sintagma e inizia a marcare i tratti grammaticali al suo interno. Nel secondo sottolivello, l'apprendente incomincia a costruire sintagmi verbali sempre più complessi. Raggiunto il quarto livello, ovvero quello della procedura frasale, lo scambio di informazioni avviene tra sintagmi diversi. Infine, la procedura subordinante rappresenta l'ultimo livello, cioè dove avviene lo scambio di informazioni tra frase principale e frase subordinate.

La validità universale del framework proposto dall'unione del QCER e della PT si dimostra particolarmente adatta per il progetto di ETET, il cui l'obiettivo a lungo termine è quello di riuscire a coprire e valutare in maniera congruente e scientificamente motivata un numero sempre maggiore di lingue. In effetti, la progettazione teorica di ETET si basa sull'integrazione di due prospettive teoriche complementari: da un lato il QCER e le sue attuazioni più pratiche, che offrono una cornice descrittiva per la valutazione delle competenze linguistiche, dall'altro la PT, che fornisce un modello psicolinguistico per comprendere le tappe evolutive dell'interlingua. L'unione di questi due approcci consente di costruire un sistema di valutazione che tenga conto sia del livello di competenza manifestato, sia della sua coerenza, seguendo le naturali traiettorie di acquisizione dell'interlingua.

## 4. Descrizione ETET

La web-app ETET è stata progettata per offrire una valutazione automatizzata delle competenze linguistiche scritte e orali, sia attraverso domande chiuse che aperte. Le competenze valutate riguardano la produzione e l'interazione orale, l'ascolto, la comprensione del testo, la produzione scritta e la grammatica. Per quanto riguarda la produzione orale, il sistema valuta anche l'intelligibilità e la pronuncia [24]. ETET restituisce punteggi su scala 0–100, pesati in base alla difficoltà e alla tipologia della domanda; i punteggi sono mappati sui livelli del QCER sia a livello globale sia a livello della singola abilità valutata.

## 4.1. Caratteristiche Tecniche

La piattaforma integra algoritmi di feedback in tempo reale, LLM e tecnologie di ASR, prendendo spunto da lavori recenti nell'ambito dell'*Automated Essay Scoring* (AES) [11] e dell'*Automated Speaking Assessment* (ASA) [25].

Dal punto di vista dell'architettura, l'applicativo ETET utilizza un ambiente Linux (Debian). Il back-end è realizzato in Ruby on Rails 8, mentre l'interfaccia di gestione (back-office) è realizzata in Vue.js. Il modulo front-end per l'utente finale si basa anch'esso su Vue.js. L'autenticazione avviene tramite e-mail e password e la sessione viene verificata tramite token JWT.

Il sistema ASR è basato su AzureAI[6], che sfrutta il modello Whisper di OpenAI[7]. Gli input vocali vengono acquisiti tramite browser in formato .ogg o .wav (canale mono) e non vengono normalizzati. I parametri di decodifica non sono attualmente configurabili.

Le domande aperte sono valutate tramite il GPT-4o di OpenAI[8], un modello accessibile via API, con prompt personalizzati per ciascun tipo di test e domanda. La valutazione è asincrona, avviene in background e viene restituita solo al termine del test.

Tutti i dati relativi agli esami, come ad esempio, i testi e i file audio delle risposte prodotti dagli utenti, sono salvati in un database PostgreSQL, ospitato in cloud sull'infrastruttura Azure, in conformità con il GDPR. I dischi sono criptati con chiavi gestite dalla piattaforma e viene applicata una policy di snapshot periodico per garantire la sicurezza e la conservazione dei dati.

## 4.2. Test e Domande

La web-app ETET permette di creare diverse tipologie di test a seconda delle necessità dei singoli esaminatori. Il punto di partenza per la realizzazione di un test è la definizione di quale sia l'obiettivo della valutazione, il che implica caratteristiche specifiche in termini di contenuto e tempistiche di somministrazione [26]. I test possono essere costruiti per testare tutte e quattro le abilità linguistiche fondamentali (lettura, ascolto, scrittura e parlato) oppure possono essere personalizzati per andare ad indagare le abilità linguistiche che maggiormente interessano all'esaminatore.

La procedura di creazione di un test è un processo incrementale: per ciascuna abilità fondamentale viene creato un questionario che si compone di domande scelte da un database predisposto da esperti interni e selezionate in modo da coprire tutti gli aspetti che si vogliono indagare inerentemente a quella competenza linguistica. L'insieme dei questionari andrà a costituire la forma complessiva dell'esame (v. Figura 1).

**Figura 1:** Lato back-office di ETET.

A prescindere dalle tipologie di domande prescelte, ciascun questionario viene costruito inserendo item con un determinato bilanciamento di complessità attesa. In particolare, ogni domanda è caratterizzata da un livello di difficoltà associato ai livelli proposti dal QCER. In ogni questionario si trovano il 10% di domande del livello A1 e del livello C2 mentre tutti gli altri livelli (A2, B1, B2, C1) sono uniformemente rappresentati da un 20% di domande.

Una caratteristica di ETET è la possibilità di impostare il numero di domande e la durata del test in base alle esigenze dell'utente o alle specificità del contesto didattico e valutativo. Ciascuna domanda viene identificata a partire da una serie di caratteristiche che ne descrivono tipologia e complessità. Queste vengono dunque catalogate secondo i seguenti parametri: abilità linguistica testata – attraverso un'etichetta identificativa (lettura, ascolto, scrittura e parlato); lingua del test (in questo caso, l'italiano); livello di difficoltà secondo il QCER (A1, A2, B1, B2, C1, C2); oggetto epistemico indagato (ad es., articoli determinativi, forma passiva ecc.).

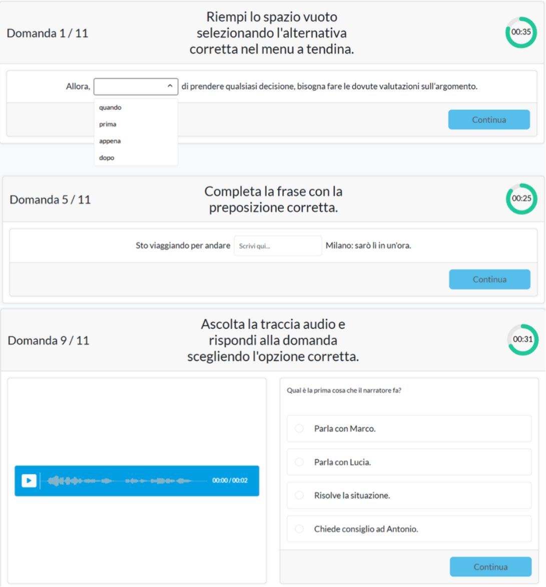
I quesiti possono essere, inoltre, divisi in due macrocategorie: domande a risposta chiusa e domande a risposta aperta, distinte in base al tipo di produzione richiesta all'utente e alla modalità di valutazione. In entrambi i casi, i soggetti dispongono di un tempo

[6] Informazioni dettagliate disponibili qui: https://azure.microsoft.com/en-us/solutions/ai (accesso 06/06/2025).
[7] Informazioni dettagliate disponibili qui: https://openai.com/index/whisper/ (accesso 06/06/2025).
[8] Informazioni dettagliate disponibili qui: https://platform.openai.com/docs/models/gpt-4o (accesso 06/06/2025).

limitato, misurato in secondi, per formulare e inserire la propria risposta.

Le domande a risposta chiusa (v. Figura 2) presuppongono generalmente una sola risposta esatta o un numero limitato e comunque predefinito di risposte possibili. Fanno parte di questa tipologia di domande:

- *Domande a scelta multipla*, dove ad una domanda vengono associate più risposte possibili, di cui una soltanto è corretta e le altre svolgono la funzione di distrattori.
- *Domande a completamento*, in cui viene presentata una frase caratterizzata da uno o più spazi vuoti in cui l'utente deve inserire una o più parole. In questa tipologia di domande, nella fase di creazione, è stata prestata molta attenzione ad inserire, laddove necessario, tutti i possibili sinonimi che possono essere indicati dalla persona testata.
- *Dettato*, nel quale la persona testata deve scrivere ciò che riesce a comprendere dall'audio presente nella domanda.
- *Ricostruzione di una frase*, in cui l'utente sente un audio in cui sono contenuti vari pezzi di frase presentati in ordine sparso e li deve ricostruire correttamente.



Domanda 1 / 11

Riempi lo spazio vuoto selezionando l'alternativa corretta nel menu a tendina.

Allora, [ ] di prendere qualsiasi decisione, bisogna fare le dovute valutazioni sull'argomento.

quando
prima
appena
dopo

Domanda 5 / 11

Completa la frase con la preposizione corretta.

Sto viaggiando per andare [Scrivi qui...] Milano: sarò lì in un'ora.

Domanda 9 / 11

Ascolta la traccia audio e rispondi alla domanda scegliendo l'opzione corretta.

Qual è la prima cosa che il narratore fa?

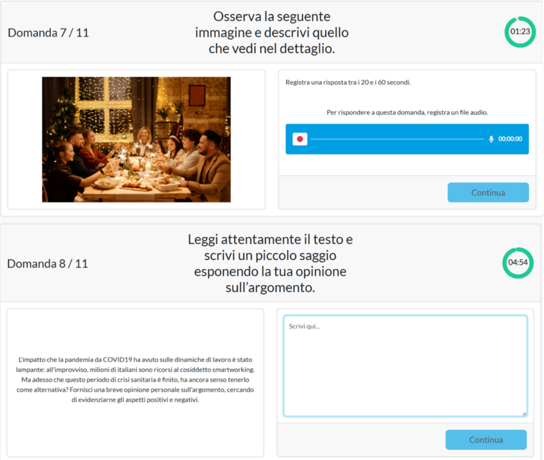
○ Parla con Marco.
○ Parla con Lucia.
○ Risolve la situazione.
○ Chiede consiglio ad Antonio.

**Figura 2:** Alcuni esempi di domande a risposta chiusa.

Nella costruzione dei test si è cercato di inserire il minor numero possibile di domande a scelta multipla per diminuire la possibilità che l'utente indovini la risposta. Si è cercato invece, laddove possibile, di sostituire questa tipologia con le domande a completamento, le quali permettono inoltre di ottenere un input linguistico più autentico, essendo necessaria una produzione da parte dell'utente.

Le domande aperte (v. Figura 3) prevedono un'elaborazione linguistica attiva e autonoma da parte del candidato e riguardano le abilità di scrittura e di parlato. Queste domande permettono di valutare competenze complesse e integrative. Fanno parte della tipologia di domande aperte:

- *Componimenti brevi*, che prevedono la scrittura di un breve testo su argomenti vari e con differenti variazioni diafasiche.
- *Descrizioni di immagini*, ovvero viene dato come input un'immagine e il soggetto deve fornirne una descrizione dettagliata dello stimolo.
- *Esposizione del proprio punto di vista*, tramite la scrittura di un testo che evidenzi la propria posizione su un tema (ad es., cambiamento climatico).
- *Riassunto*, la persona testata deve produrre un riassunto del testo che ha appena letto o dell'audio che ha appena sentito.



Domanda 7 / 11

Osserva la seguente immagine e descrivi quello che vedi nel dettaglio.

Registra una risposta tra i 20 e i 60 secondi.

Per rispondere a questa domanda, registra un file audio.

Domanda 8 / 11

Leggi attentamente il testo e scrivi un piccolo saggio esponendo la tua opinione sull'argomento.

L'impatto che la pandemia da COVID19 ha avuto sulle dinamiche di lavoro è stato lampante: all'improvviso, milioni di italiani sono ricorsi al cosiddetto smartworking. Ma adesso che questo periodo di crisi sanitaria è finito, ha ancora senso tenerlo come alternativa? Fornisci una breve opinione personale sull'argomento, cercando di evidenziarne gli aspetti positivi e negativi.

[Scrivi qui...]

**Figura 3**: Alcuni esempi di domande a risposta aperta.

Nelle domande aperte di scrittura viene richiesta come risposta un minimo di 50 parole, mentre in quelle di parlato sono richiesti almeno 20 secondi di registrazione audio in tempo reale.

La presenza di entrambe le tipologie di domanda è giustificata dall'esigenza di ottenere una valutazione più completa e bilanciata della competenza linguistica (v. Figura 4). Infatti, come osservano nella letteratura [27], una valutazione linguistica efficace dovrebbe integrare quesiti che misurano sia la conoscenza linguistica formale sia la capacità di utilizzare efficacemente tale conoscenza in contesti reali. Questa definizione è in linea con la teorizzazione del QCER [28] che vede le competenze linguistiche dei parlanti di una L2 come orientate all'azione, intendendo gli apprendenti come agenti sociali. Attraverso la lingua, i parlanti devono essere in grado di interagire efficacemente e comunicare in vari contesti sociali, culturali e professionali.

**Figura 4:** Impostazione domande.

Partendo da questo assunto, si è delineata la necessità di proporre compiti, domande, materiale multimediale (ad es., registrazioni audio, immagini) e testi che l'informante potesse incontrare nell'uso reale della lingua e nelle più varie situazioni comunicative.

A ciascuna domanda è associato un peso (1, 2, 3 punti) che rappresenta il punteggio che si può ottenere rispondendo correttamente. Domande con maggior necessità di rielaborazione e sforzo cognitivo da parte del soggetto avranno pesi maggiori. Domande a risposta chiusa, come ad esempio, quelle a risposta multipla o di completamento, avranno un peso di 1 punto, dettati o ricostruzioni di frasi 2 punti mentre produzioni orali o elaborati scritti 3 punti.

Le domande a risposta chiusa prevedono una valutazione booleana del tipo corretto/errato. Per la produzione scritta e parlata, invece, la valutazione è affidata ad un LLM in grado di generare punteggi di AES e ASA (v. paragrafo 4.1). Il primo valuta la correttezza grammaticale, la scelta lessicale, la coerenza e l'adesione al tema, la comprensione, la coesione testuale e il contenuto della risposta fornita dall'utente. Il punteggio dato in centesimi dal modello si ripartisce nel seguente modo tra 5 parametri: *structure and grammar* = 20%, *content and argumentation* = 30%, *vocabulary* = 20%, *comprehension and adherence to the topic* = 20% e *pragmatics and cohesion* = 10%. Diversi studi hanno evidenziato come i sistemi AES mostrino un'elevata concordanza con i giudizi di valutatori umani esperti [29], [30].

Il modello ASA – dopo aver prodotto una trascrizione fedele dell'audio registrato in tempo reale dall'utente – usa come metriche di valutazione il paradigma *Complexity Accuracy Fluency* (CAF) [24], analizzando la produzione orale del parlante, attraverso 4 parametri: *fluency*, *accuracy*, *completeness*, *pronunciation*. I valori relativi a questi 4 parametri rappresentano il 5% del punteggio finale nelle domande di produzione orale. Il restante 95% è rappresentato dalle valutazioni relative ai parametri discussi prima, redistribuiti come segue: *structure and grammar* = 20%, *content and argumentation* = 25%, *vocabulary* = 20%, *comprehension and adherence to the topic* = 20% e *pragmatics and cohesion* = 10%. La letteratura [31] sostiene che le tecnologie ASA mostrano numerosi vantaggi rispetto alla valutazione orale tradizionale, tra cui una maggiore efficienza e rapidità nei processi di somministrazione del test e di elaborazione dei risultati, ma anche una riduzione dell'incidenza di *bias* umani, con conseguente incremento della coerenza dei punteggi assegnati.

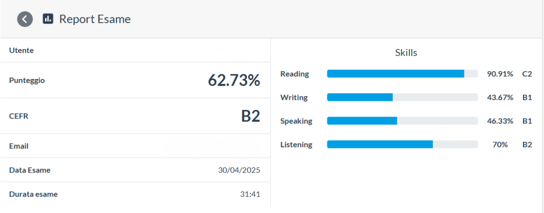
Una volta che l'utente completa il test, il sistema calcola i punteggi per ciascuna domanda, come descritto sopra, e riporta il voto finale ottenuto in ciascuna sezione. Il voto è calcolato come rapporto tra i punti ottenuti e i punti totali ottenibili relativi a quell'abilità linguistica (v. formula (1)).

$$score_i = \frac{pt_{fatti,i}}{pt_{tot,i}} \% \tag{1}$$

Il punteggio finale del test, invece, si ottiene come media dei punteggi ottenuti per ciascuna abilità linguistica, in modo da uniformarne l'importanza (v. formula (2), dove $n$ è il numero di abilità testate).

$$score_{finale} = \frac{\sum_{i=1}^{n} score_i}{n} \% \tag{2}$$

Per allineare l'output del test con quello degli enti certificatori, il punteggio in percentuale ottenuto viene mappato sulle fasce stabilite dal QCER. Oltre al punteggio in percentuale, l'utente finale otterrà, quindi, un voto espresso come livello QCER (da A1 a C2) per ciascuna competenza testata e un voto finale per lo svolgimento complessivo del test (v. Figura 5).



Report Esame

| Reading | 90.91% | C2 |
| Writing | 43.67% | B1 |
| Speaking | 46.33% | B1 |
| Listening | 70% | B2 |

**Figura 5:** Esempio di feedback.

Al termine della prova, la piattaforma prevede la produzione automatica di un feedback descrittivo personalizzato il quale, tramite le tecnologie generative, restituisce un'analisi complessiva della performance dell'utente. Allo strumento vengono forniti i risultati ottenuti nel test e le risposte alle domande a composizione libera di scrittura e di parlato. Questi dati vengono analizzati e il feedback che viene prodotto evidenzia sia i punti di forza della competenza linguistica della persona testata sia le aree in cui si sono riscontrate maggiori difficoltà, fornendo anche spunti e consigli per un miglioramento delle abilità testate.

## 4.3. Validazione

Come evidenziato nel paragrafo 1, negli ultimi anni, i LLM hanno mostrato un potenziale crescente nell'ambito della valutazione automatica delle competenze linguistiche nelle L2. In particolare, i LLM si confermano strumenti promettenti, soprattutto in contesti didattici e valutativi a basso rischio. Tuttavia, nella letteratura recente sono stati riscontrati alcuni limiti legati alla capacità dei LLM di cogliere aspetti discorsivi complessi, alla variabilità delle loro prestazioni nel tempo e alla presenza di *bias* inferenziali, socioculturali e sociodemografici [32], [33]. Considerata la mancanza di un consenso nella letteratura circa la validità e l'affidabilità dei LLM come strumenti di valutazione linguistica, e alla luce dell'assenza di protocolli standardizzati e condivisi per la loro validazione, si è ritenuto opportuno intraprendere un primo tentativo di validazione dello strumento ETET per l'italiano L2.

Per verificare la validità del modello e la coerenza nell'assegnazione dei punteggi, sono state condotte alcune sessioni di prova su risposte a domande aperte. Sono state selezionate 3 domande di produzione scritta (PS1, PS2, PS3) e 3 di produzione orale (PO1, PO2, PO3) e per ciascuna domanda è stata formulata una risposta. Ogni risposta è stata valutata dal sistema per 10 iterazioni consecutive, mantenendo, quindi, invariato l'input, al fine di osservare la stabilità dei punteggi assegnati a parità di contenuto. Per ciascuna iterazione sono stati registrati i punteggi relativi a tutti i parametri considerati. Le domande di produzione orale sono state testate sia su un parlante di genere maschile (PO1m, PO2m, PO3m) sia su una parlante di genere femminile (PO1f, PO2f, PO3f), allo scopo di verificare l'eventuale presenza di *bias* di genere nei punteggi assegnati dal modello. Successivamente sono stati calcolati il valore medio e la deviazione standard per ciascun parametro di valutazione associato a ogni domanda: X1 = *structure and grammar*, X2 = *content and argumentation*, X3 = *vocabulary*, X4 = *comprehension and adherence to the topic*, X5 = *pragmatics and cohesion*, X6 = *fluency*, X7 = *accuracy*, X8 = *completeness*, X9 = *pronunciation.* Come discusso nel paragrafo 4.2, per la valutazione della produzione scritta (PS1, PS2, PS3) sono stati considerati i primi 5 parametri, mentre per la produzione orale (PO1, PO2, PO3) tutti e 9 i parametri.

La coerenza dei punteggi è stata valutata attraverso il coefficiente di variazione (CV), ottenuto dal rapporto percentuale tra deviazione standard e valore medio, che descrive la dispersione relativa per ogni oggetto indagato (v. formula (3)).

$$sCV = \frac{\sigma}{\mu}\% \qquad (3)$$

Coefficienti di variazione alti sono sintomatici di un'elevata dispersione nei dati, dunque, una limitata coerenza del modello nel giudicare i diversi parametri; viceversa, coefficienti di variazione bassi sono indicativi di una ridotta dispersione relativa. La Tabella 1 mostra i coefficienti di variazione per ciascun tipo di domanda aperta.

È possibile notare come tutte le misurazioni, ad eccezione del parametro X1 nella seconda domanda di produzione orale (con voce femminile), si trovino al di sotto del limite del 10%, fissato come soglia di accettabilità dei risultati (v. Tabella 1). Ne consegue una buona coerenza da parte del modello nell'assegnazione dei punteggi nella nostra sessione di valutazione.

Inoltre, l'esperimento di validazione ha evidenziato che il genere non sembra avere un ruolo rilevante nei valori ottenuti. Si può quindi ipotizzare che il modello sia indifferente a questa variabile, oppure che il genere, andando a sommarsi ad una serie di altri fattori, come il tono di voce, la distanza dal microfono, o la velocità di eloquio, non assuma un'importanza determinante nel calcolo dei punteggi. Questo esito risulterebbe coerente con l'obiettivo di costruire uno strumento robusto e non soggetto a *bias* algoritmici.

**Tabella 1**
Valori CV per ciascun tipo di domanda

| Tipo | X1 | X2 | X3 | X4 | X5 | X6-9 |
|---|---|---|---|---|---|---|
| PS1 | 4,9% | 3,8% | 3,9% | 6,5% | 2,6% | \ |
| PS2 | 5,1% | 3,8% | 4,4% | 4,1% | 2,6% | \ |
| PS3 | 2,5% | 2,8% | 3,6% | 2,7% | 3,9% | \ |
| PO1f | 2,5% | 3,2% | 7,0% | 3,9% | 4,8% | 0,0% |
| PO2f | 10,6% | 4,0% | 8,1% | 4,6% | 8,8% | 0,0% |
| PO3f | 4,1% | 4,1% | 5,6% | 3,9% | 2,8% | 0,0% |
| PO1m | 6,7% | 4,0% | 5,9% | 2,3% | 6,0% | 0,0% |
| PO2m | 7,8% | 2,7% | 6,5% | 3,4% | 4,9% | 0,0% |
| PO3m | 7,4% | 3,9% | 5,5% | 2,8% | 6,0% | 0,0% |

# 5. Conclusioni e Sviluppi Futuri

Il presente studio ha illustrato la progettazione e lo sviluppo di ETET, una web-app commerciale per la valutazione automatizzata delle competenze linguistiche nelle L2. In particolare, la portata innovativa della ricerca è rappresentata dal fatto che la lingua presa in esame sia l'italiano, lingua per la quale – almeno nella conoscenza degli autori – non esistono strumenti di questo tipo. Ulteriore novità è rappresentata dalla scelta di non seguire le modalità di valutazione "tradizionali", ma di sviluppare un quadro teorico – fondato sui descrittori del QCER e sulla PT – che tenesse effettivamente in considerazione l'uso pratico della lingua e le sequenze evolutive naturali dell'interlingua degli individui.

La piattaforma non si propone di sostituire i valutatori umani, ma nasce dalla volontà di essere uno strumento di supporto. ETET, grazie alle tecnologie impiegate, consente infatti un'elevata efficienza nella somministrazione delle prove e grande rapidità nella loro valutazione; allo stesso tempo, la possibilità di personalizzare i test, la varietà delle domande proposte e il feedback personalizzato lo renderebbero uno strumento adatto sia a contesti didattici sia a fini certificativi e pre-selettivi (ad es., in ambito lavorativo o universitario). Infine, l'utilizzo di tecnologie AES e ASA permette di ridurre l'incidenza di *bias* umani e allo stesso tempo di incrementare coerenza e affidabilità nell'assegnazione dei punteggi.

Finora, gli sforzi della nostra ricerca si sono concentrati prevalentemente sullo sviluppo e sull'implementazione della piattaforma ETET per l'italiano. Per questo motivo, non è stata ancora condotta una valutazione strutturata e sistematica dello strumento su un campione di parlanti non nativi di italiano. Oltre alla validazione descritta nel paragrafo 4.3, le uniche ulteriori osservazioni preliminari sono state raccolte da un numero molto ristretto di persone, coinvolte in un test esplorativo della durata di circa mezz'ora. Questo test aveva l'obiettivo di ottenere i primi riscontri sul funzionamento generale della web-app.

Tra le prospettive future del lavoro è prevista la realizzazione di uno studio pilota, attualmente in fase di progettazione nell'ambito di una tesi magistrale, finalizzato a una valutazione più approfondita e sistematica dello strumento. Il protocollo sperimentale relativo alla fase di valutazione di ETET prevederà la somministrazione del test a un campione di 50 informanti con diversi livelli di competenza linguistica in italiano L2. I dati raccolti dallo studio pilota saranno usati per definire un *benchmark* di riferimento, mediante il confronto con un *gold standard* elaborato da esperti valutatori dell'italiano L2, con le autovalutazioni fornite dagli stessi 50 partecipanti e con i dati raccolti da un gruppo di controllo costituito da 5 parlanti nativi di italiano.

Parallelamente, verrà condotta un'analisi qualitativa dei feedback ricevuti dagli informanti sull'usabilità della piattaforma ETET.

## Ringraziamenti

Gli autori desiderano esprimere la loro gratitudine a Maurizio Olivieri, a Enrico Reboscio e all'intero gruppo di sviluppo di DotVocal Innovation per il prezioso supporto tecnico fornito.

# What Is Better for Syntactic Parsing? A Comparison Between Supervised and Unsupervised Models on Dante and Cavalcanti

Claudia Corbetta[1,2,*], Anna Erminia Colombi[2], Giovanni Moretti[3] and Marco Passarotti[3]

[1] *Università degli studi di Bergamo, via Salvecchio 19, 24129 Bergamo, Italy.*
[2] *Università di Pavia, corso Strada Nuova 65, 27100 Pavia, Italy*
[3] *Università Cattolica del Sacro Cuore, largo A. Gemelli 1, 20123 Milan, Italy*

**Abstract**

This paper investigates the performance of two models on Cavalcanti's *Rhymes*: a supervised neural model (Stanza) trained on the Italian-Old treebank (comprising Dante's *Divine Comedy*), and an unsupervised generative Large Language Model (LLM) accessed via the ChatGPT API (o3 version). This study highlights the crucial role of textual edition in processing historical texts, illustrating this through examples from different editions. It also presents a manual error analysis of the models' outputs, focusing on both the most frequent and the most linguistically nuanced errors.

**Keywords**

dependency parsing, Divine Comedy, Cavalcanti, Universal Dependencies, Stanza, LLM

## 1. Introduction

Syntactic studies[1] can offer valuable insights from multiple linguistic perspectives [1]. In the domain of dependency syntax, Universal Dependencies[2] [2] (henceforth UD) provides a cross-linguistic framework along with a suite of Natural Language Processing (NLP) tools for consistent and reliable comparison [2, p.256]. However, annotating dependency syntax remains both time-consuming and demanding for human annotators. In light of this, increasing attention has been devoted to the use of computational models, with both supervised and unsupervised methods, to support and potentially accelerate the annotation process.

Although previous studies [3, 4] have highlighted the limitations of unsupervised models, particularly Large Language Models (LLMs), in capturing syntactic structure, thereby reinforcing the view that manual annotation remains essential, albeit labor-intensive, we explore this task in the context of Old Italian. As a historical language variety, Old Italian[3] has not yet been the subject of experiments with unsupervised models. To date, experiments on the dependency syntax of Old Italian (more specifically, in the context of 13th-century Old Florentine poetry) have been conducted exclusively using supervised models, including UDPipe [5] and Stanza [6].[4]

To this end, we set out to test and compare the performance of an unsupervised LLM and a supervised model trained on a specific textual domain. The goal is to assess their accuracy and their potential utility in supporting the annotation process.

We conduct our test on Old Italian texts, for which a gold-standard UD-annotated treebank, (i.e., a syntactically annotated corpus) is available, namely, Italian-Old (see Section 2.1). Since this treebank includes Dante Alighieri's *Divine Comedy*, we chose to test models trained on that data on an author contemporary with Dante, namely Guido Cavalcanti.[5]

This paper is structured as follows. Section 2 describes the data used for the experiment (2.1 and 2.2), offers insights into the impact of editorial choices on annota-

tion (2.3), and discusses annotation practices and inter-annotator agreement (2.4). Section 3 outlines the training processes (3.1 for the neural model and 3.2 for the LLM) as well as the evaluation of the models' performance (3.3). In Section 4, we provide a manual error analysis of the output of the LLM (4.1) and the supervised model (4.2), along with a discussion of the errors common to both models (4.3). Finally, Section 5 presents the conclusions.

## 2. Data

This Section presents the data used in the study.

### 2.1. Italian-Old Treebank

As of now, the Italian-Old Universal Dependencies treebank [8] is the only resource within the UD framework that provides annotation for Old Italian. It consists of a dependency-annotated corpus of Dante Alighieri's *Divine Comedy*.[6] The Italian-Old treebank is an openly available resource based on the DanteSearch corpus [13], enriched with dependency syntax annotation and adapted to conform to the UD guidelines. The linguistic annotation of the corpus is encoded in CoNLL-U format,[7] and includes tokenization, lemmatization, morphological annotation (covering both part-of-speech and morphological features), and dependency syntax. Moreover, since the annotation is word-level, additional metadata indicating the position of each word, namely, the verse and the *Canto*, are also provided.

### 2.2. Cavalcanti's *Rhymes*

For the present work, we selected the *Rhymes* of Guido Cavalcanti edited by Ercole Rivalta [14]. We chose this particular edition because the texts are publicly available online,[8] which allowed us to extract them via web scraping. We then cleaned the text by removing editorial notes related to manuscript sources and the editor's commentary.

Rivalta's edition of the *Rhymes* divides the poems into three chronological groups: those composed before 1290, those of uncertain date, and those composed after 1290. The corpus includes a total of 63 poems, distributed as follows: 25 in the first group, 23 in the second, and 15 in the third. Various metrical forms are attested among the poems, ranging from ballads and sonnets to *canzoni* and similar lyric types.[9] Moreover, alongside the classical poems, some rhymes belong to the "sonetti di risposta" (stilnovist reply sonnets addressed to other poets) and thus differ in their compositional purpose.

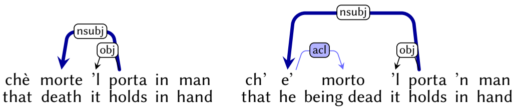
It is important to recall that, when working with texts transmitted through manuscript traditions, editorial choices play a critical role. This is also the case for the *Rhymes*, whose textual variants and structure depend heavily on editorial interpretation, as it is discussed in Subsection 2.3. By selecting the edition of the *Rhymes* edited by Rivalta, we adhere to his reconstruction of the texts, along with all the implications that such a choice entails.[10]

### 2.3. Impact of Editorial Choices on Annotation

As mentioned in 2.2, the decision to adopt Rivalta's edition for the selection of poems necessarily entails a reflection on editorial differences. Accordingly, three examples will be presented below, in which the comparison with the edition edited by Roberto Rea and Giorgio Inglese [19], chosen because it is one of the most recent critical edition with commentary, highlights stylistic and interpretative differences that are reflected in the lexical and syntactic analysis.

Firstly, in verse 14 of Sonnet 28, the editions differ as follows:[11]

Example I - Sonn. 28 v. 14
*chè **morte** 'l porta in man* (Rivalta ed.)
*ch'**e' morto** 'l porta in man* (Rea ed.) (whose heart Death [...] carve into the man's gravestone)



nsubj
obj
chè morte 'l porta in man
that death it holds in hand
nsubj
acl
obj
ch' e' morto 'l porta 'n man
that he being dead it holds in hand

**Figure 1:** Dependency tree of Sonn. 28 v. 14 Rivalta and Rea ed., respectively.

[6] The critical edition of the *Divine Comedy* used while building the treebank is Petrocchi (1994) [12].

[7] CoNLL-U is a tab-separated format in which each line encodes the annotation of a syntactic word across 10 fields. For further details, see https://universaldependencies.org/format.html. When a field is not applicable or remains unannotated, the placeholder "_" is used.

[8] See https://it.wikisource.org/wiki/Rime_(Cavalcanti).

[9] Refer to [15] for a detail on metrical forms.

[10] Rivalta's edition is not the most up-to-date edition of the *Rhymes*, which have since been the subject of further scholarly studies and have led to other editions curated by other scholars (such as Contini [16], Ciccuto [17], De Robertis [18], and Rea and Inglese [19]). However, as mentioned above, the choice of Rivalta's edition was motivated by practical reasons. While leaving a comparison with these more recent editions to future work, we emphasize the need for up-to-date digital editions to be freely and openly available online.

[11] For the translation of Cavalcanti's poems, we rely on [20]. This translation does not always adhere closely to the original Italian text. Consequently, we provide our own glosses where appropriate.

In this case, the main divergence is exegetical: in Rivalta's version, *morte* (death), personified, is the subject (`nsubj`) who holds the object (`obj`) *'l* (it) in her hand. By contrast, in Rea's edition, the personified *morte* is replaced by an actual agent, *e'* (he), who is *morto* (dead). While the logical relation, namely, that there is a subject who "holds" something in their hand, remains consistent across both versions, Rea's interpretation, as shown in the Figure 1, introduces an additional token. This addition occurs since *morte* is replaced by the nominal modifier *morto*, in the tree `acl` (adnominal clause) and the modified referent *e'* must therefore be explicitly included. From a strictly syntactic perspective, this difference results in a clearly distinct sentence subject, as shown in Example I, and in the presence of an additional token, which inevitably yields a slightly more complex syntactic structure.[12]

Secondly, in verse 7 of Sonnet 10, we observe a case in which the difference between editions affects only the token count, without any consequences for interpretation:

> ***Perchè*** *Sospiri e Dolor mi pigliaro* (Rivalta ed.)
> ***Per che*** *Sospiri e Dolor mi pigliaro* (Rea ed.)
> (and were delighted to hear my sighs and groans)

In Rivalta's edition, the causal conjunction appears as *perché* (because), which is a single token. In Rea's edition [19, p.62], the same causal meaning is conveyed through the two-word form *per che*, resulting in two token. This variation affects not only the token count, but also the structure of the tree, as it requires an additional syntactic dependency and dependency relation label. Moreover, frequent variation in tokenization may lead to measurable differences in other types of metrics (such as Type/Token Ratio analysis) depending on the reference edition adopted.

Finally, the third case examines an example that differs from the first two previously discussed. In this instance, the editorial variation does not result in a different number of token, but rather in the presence of lemmas with different meanings:

> *Veder poteste quando vui* ***scontrai*** (Rivalta ed.)
> *Veder poteste quando v'****inscontrai*** (Rea ed)
> (one seldom sees him as if in flesh)

As can be observed, the difference in verse 1 of sonnet 35 between the two editions concerns the use of *scontrai* versus *inscontrai*. When these token are lemmatized, they result in different lemmas: *scontrai* is the conjugated form of *scontrare* (to collide), whereas *inscontrai* corresponds to *incontrare* (to meet). As seen previously, even though this variation does not pose a syntactic problem in this case, the use of two different forms can impact other levels of linguistic analysis and obviously yield different results depending on which edition was used as the basis for annotation.

In conclusion, editorial choices play a crucial role, as they can influence tokenization, interpretation, and lemmatization, as demonstrated by the three examples discussed above.

## 2.4. Manual Annotation and Inter-Annotator Agreement

Once the reference edition was established, we manually annotated 22 sonnets out of the 63 poems included in Rivalta's edition of Cavalcanti's Rhymes (2135 token, excluding punctuation marks). We chose to focus exclusively on sonnets, as this metrical form is the most frequently attested throughout the collection. The manual annotation was carried out by two expert annotators.

Among the 44 sonnets[13] in the corpus, we selected 22, distributing them across the three periods identified in Rivalta's edition: 6 sonnets from the first period, 7 from the second, and 6 from the third (totaling 19 sonnets[14]). In addition, 3 sonnets were annotated by both annotators to calculate inter-annotator agreement.

To evaluate consistency between the two annotators and alignment with the annotation style of the Italian-Old treebank, we also performed inter-annotator agreement on three *Canti* of the *Divine Comedy*. The selected *Canti* were the 13th of each *Cantica*, namely *Inferno*, *Purgatorio* and *Paradiso*, in order to account for potential stylistic variation across the three parts of the poem (3296 token excluding punctuation marks).

Table 1 reports the inter-annotator agreement results for both the three 13th *Canti* of the *Divine Comedy* (Dante) and the three sonnets by Cavalcanti. Inter-annotator agreement was assessed using Fleiss' kappa [21], a statistical measure for evaluating the reliability of agreement between multiple annotators.

**Table 1**
Table of inter-annotator agreement

| | Dante | Cavalcanti |
|---|---|---|
| edges | 0.95 | 0.94 |
| labels | 0.92 | 0.98 |

[12] For reasons of space and clarity, we report only the dependency relations discussed in the text. To view the full trees, please refer to the GitHub page: https://github.com/CIRCSE/CavalcantiRepository.git.

[13] This total includes one "ritornellato" sonnet (i.e., a sonnet composed of more than the canonical 14 lines and featuring a specific metrical pattern; for details, refer to [15, p. 284]) and one "rinterzato" sonnet (i.e., a composition structured as a duplex sonnet; see [15, p. 283]).

[14] The 19 sonnets were split between the two annotators: 10 for one and 9 for the other.

The overall inter-annotator agreement is very high for both authors. For Cavalcanti, Fleiss' kappa on dependency edges reaches 0.94, and the agreement on dependency labels assigned to correctly matched edges is even higher, at 0.98. For Dante, the values are similarly strong, with 0.95 for edges and 0.92 for labels. These results indicate a high level of consistency between annotators and confirm the overall reliability of the annotation process across both corpora.

# 3. Training and Models Performances

In this experiment, we evaluate the parsing performance of two different models in order to identify the most suitable for this task. Specifically, we assess the performance of (i) a Stanza retrained model [6], a neural network model with a parsing-specific architecture specifically trained on Old Italian data, namely Italian-Old and henceforth referred to as **Dante model**, and (ii) a zero-shot generative LLM accessed via the ChatGPT API (o3 version), [22], henceforth referred to as **LLM**. For this experiment, Stanza was selected as the supervised model, as it has demonstrated superior performance compared to UDPipe (see [9]). As for the unsupervised model, we opted to begin by testing the ChatGPT API, while leaving the evaluation of bidirectional LLMs, such as BERT-based models like UDify [23] and U-DepPLLaMA [24], for future work.[15]

## 3.1. Dante Model

We train a Stanza model [6] using Italian-Old data and use it to parse Cavalcanti's *Rhymes*.[16] We conduct two types of experiments: one in which the model performs full annotation from scratch, namely, tokenization, lemmatization, part-of-speech tagging, and syntactic parsing (hereafter labeled All) and one in which it performs only syntactic analysis (hereafter labeled OS, for Only Syntax), with the other annotation layers pre-supplied.

We evaluate only syntactic metrics,[17] specifically the Unlabeled Attachment Score (UAS) and the Label Attachment Score (LAS).[18] Table 2 reports the model's performance. Specifically, the scores in the Dante column reflect the performance of Dante model on a *Divine Comedy* test set. These scores derive from Stanza's automatic internal evaluation on that test split and pertain to complete annotation from scratch, rather than being limited to syntactic analysis alone.[19] In contrast, the scores in the Cavalcanti columns, both for full parsing and syntax-only (OS), reflect the evaluation of the sonnets annotated by Dante model, compared against the gold-standard annotations produced by the two annotators (as described in Section 2.4).

**Table 2**
Dante Model performances on Dante and Cavalcanti's texts

| | Dante All | Cavalcanti All | Cavalcanti (OS) |
|---|---|---|---|
| UAS | 80.13 | 82.59 | 85.26 |
| LAS | 74.29 | 75.24 | 78.28 |

Interestingly, the performance of the Dante-trained model on Cavalcanti's sonnets is higher (+2.46 for UAS and +0.95 for LAS) than the internal evaluation conducted by Stanza on the *Comedy* data. These results seem to suggest good portability of Dante model, even when applied to texts by a different author, though from the same period and literary context. Clearly, this is only a preliminary test, and further research is required, especially on texts that move away from the poetic genre.

## 3.2. LLM

In light of the growing prominence of LLMs, we investigate whether ChatGPT can produce results comparable to those of Dante model we trained.

To this end, we tested the ChatGPT API using a tailored prompting technique. We report the prompt in Appendix A. More specifically, we prompt ChatGPT to generate the UD annotation of a sonnet by providing, in a first setting, the raw text as input, and in a second setting, the gold-standard CoNLL-U file with syntactic annotations removed. Using the "assistant" role, we first provide the model with a gold-standard annotated sonnet as an example. We then ask it to perform the same task, producing a CoNLL-U formatted annotation, for a different sonnet. We set the temperature to a minimum value (0.05) and set top_p[20] to 1 in order to make the model as deterministic as possible.

Since our aim is to compare the performance of the LLM with that of Dante model, we tested the LLM in two settings, mirroring the evaluation setup used for Dante model: (i) generating the full CoNLL-U file from scratch,

[15] While preliminary results suggest that such models yield an improvement in syntactic accuracy for Italian (see [23] and [24]), it is worth noting that they have not yet been tested on Old Italian data.

[16] The dataset comprises 122 000 token and is divided into training, development, and test sets with an 80-10-10 split.

[17] To perform evaluation we use `eval.py` script, available at https://github.com/UniversalDependencies/tools/blob/master/eval.py.

[18] Refer to [25] for details on the evaluation metrics.

[19] These internal evaluation scores are also consistent with those obtained in a similar experiment [10], in which an Old Italian model (trained on a small amount of data) was tested in-domain, yielding to similar scores (UAS 82.24 and LAS 75.86).

[20] The top_p value corresponds to nucleus sampling: for high values of p, the model selects from a small subset of the vocabulary, the nucleus, which contains the majority of the probability mass [26, p. 5].

that is, producing tokenization, lemmatization, PoS tagging, morphological feature attribution, and syntactic annotation (using the first setting, with raw text as input); and (ii) filling only the syntactic fields, based on gold-standard tokenization and morphological information (corresponding to the second setting).

The first experiment did not yield satisfactory results, as the output failed to conform to the CoNLL-U format (both in terms of column structure and syntactic annotation) and frequently produced cycles[21] in the dependency trees. Even though we repeated the experiment multiple times, testing different sonnets and explicitly instructed the model to avoid cycles in the syntactic structure, its performance remained consistently poor across all runs, producing CoNLL-U outputs that were ultimately unusable, forcing us to discard this approach.

The second scenario, namely, instructing the LLM to focus exclusively on the syntactic fields while retrieving tokenization, lemmatization, and morphological annotation from the gold data, produced usable outputs, although some errors were still occasionally present (see Subsection 4.1). We report the results in Subsection 3.3.

## 3.3. Comparing Dante Model and LLM

To compare the two models, we evaluate their syntactic performance on eight randomly selected sonnets[22], specifically, sonnets 9, 10, 28, 29, 30, 31, 35 and 54.[23]

The corresponding UAS and LAS scores are reported in Table 3, showing the performance of the LLM for the syntactic task (under the LLM column) and that of Dante's model in the syntax-only setting (D_OS). Although, as mentioned in Subsection 3.2, we were unable to fully evaluate the LLM across all annotation levels, we nonetheless report the scores of Dante model when performing full annotation (D_All) for reference. The Diff column indicates the difference in performance between D_OS and the LLM.

Notably, the LLM achieves relatively high performance (see average row (av.) in Table 3), demonstrating its potential for syntactic annotation. However, its results remain below those of the neural model (Dante model), which was specifically trained on data closely aligned with the target material. As shown in Table 3, these findings suggest that, at least in this experiment and at the current stage of development, at the current stage of development, the neural model trained on a domain-relevant corpora offers a more reliable solution for high-quality linguistic annotation.

**Table 3**
Dante Model and LLM's Performances and Differences

| Son | | LLM | D_All | D_OS | Diff_LLM_OS |
|---|---|---|---|---|---|
| 10 | UAS | 68.22 | 80.77 | 89.72 | 21.50 |
| | LAS | 58.88 | 73.08 | 83.18 | 24.30 |
| 28 | UAS | 75.21 | 85.95 | 87.60 | 12.39 |
| | LAS | 68.60 | 77.69 | 80.99 | 12.39 |
| 29 | UAS | 74.77 | 73.58 | 74.77 | 0.00 |
| | LAS | 70.09 | 69.81 | 71.03 | 0.94 |
| 30 | UAS | 75.42 | 86.44 | 88.14 | 12.72 |
| | LAS | 66.95 | 76.27 | 81.36 | 14.41 |
| 31 | UAS | 65.85 | 80.49 | 82.93 | 17.08 |
| | LAS | 56.91 | 73.17 | 76.42 | 19.51 |
| 54 | UAS | 76.64 | 89.62 | 88.79 | 12.15 |
| | LAS | 70.09 | 82.08 | 82.24 | 12.15 |
| 9 | UAS | 74.79 | 84.75 | 86.55 | 11.76 |
| | LAS | 65.55 | 80.51 | 83.19 | 17.64 |
| 35 | UAS | 81.73 | 90.35 | 90.38 | 9.03 |
| | LAS | 80.77 | 89.42 | 89.42 | 8.65 |
| av. | UAS | 74.08 | 83.99 | 86.11 | 12.07 |
| | LAS | 67.23 | 77.75 | 80.97 | 13.74 |

In light of the obtained scores, we conducted a sample-based manual error analysis, which is described in Section 4.

# 4. Manual Errors Analysis

In this Section , we analyse the models' errors to provide useful insights for potential improvements and further considerations. We conduct a manual error analysis on the three sonnets exhibiting the most significant discrepancies in scores, namely, sonnets 10 and 31, which performed poorly with the LLM (see Subsection 4.1), and sonnet 29, whose score was comparable for both the LLM and Dante model (see Subsection 4.2). For the sake of clarity, we provide both sonnets along with their translations in Appendix A.

## 4.1. LLM Errors

The two sonnets that received the lowest scores from the LLM are sonnet 10 and sonnet 31.

Interestingly, a detailed inspection of Sonnet 10, the one that received the lowest score, reveals that one of the model's errors was the incorrect identification of the sentence's `root`. In this case, the LLM mistakenly analyses a subordinate clause as the main clause, assigning the verb *vider* (saw) in example II the status of `root` instead of identifying it as the head of an adverbial clause (`advcl`). This misassignment results in a series of incorrect syntactic attachments throughout the sentence. To illustrate this, we present two syntactic trees: the gold-standard tree (Figure 3) and the one produced by the LLM (Figure

[21] A cycle in a dependency tree occurs when a word ends up depending on itself, violating the tree structure and rendering the annotation invalid.

[22] The number of sonnets was limited to eight due to funding constraints, as the ChatGPT API is a paid service.

[23] Refer to Appendix A for the titles of the selected sonnets.

2). Incorrect attachments in the LLM output are highlighted in red, while incorrectly assigned dependency labels are shown in yellow.

Example II - Sonn. 10 v. 10
*Quando mi vider, tutti con pietanza/ dissermi*
(Their somber welcome to me I still shudder at)

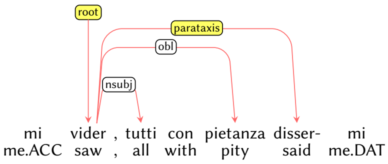


**Figure 2:** LLM syntactic tree of Sonn. 10 v.10

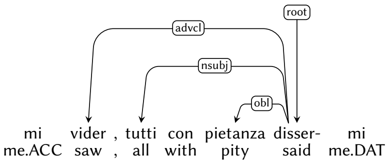

**Figure 3:** Gold syntactic tree of Sonn. 10 v.10

As evident from the comparison of the trees, assigning the root to an incorrect token triggers a domino effect, resulting in both attachment errors (e.g., the subject relation (nsubj) of *tutti* (all) and the oblique relation (obl) of *pietanza* (pity), which are incorrectly attached to *vider* (saw) instead of *disser* (said) and labeling errors (e.g., *disser* (said) is mistakenly labeled as parataxis instead of being correctly identified as the root). Interestingly, when this sentence is removed and the evaluation is repeated, the averages increase to UAS 75.31 and LAS 65.43, which are more or less in line with the overall average (refer to Table 3).

In line with the previously observed error, the analysis of the second worst-annotated sonnet reveals another issue concerning root attribution. Specifically, the LLM erroneously assigns root status to the auxiliary verb *avere* (to have) (*ài* in the text), which is inconsistent with the UD formalism[24]. Figure 4 shows the erroneous output generated by the LLM, alongside the gold annotation, as produced by both the Dante model and the human annotator.[25]

Example III - Sonn. 31 v. 1
*Tu m'ài sì piena di dolor la mente*
(you have filled my mind with so much sorrow)

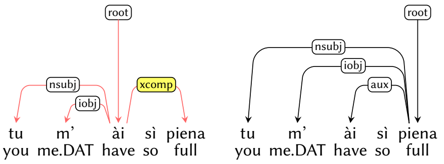

**Figure 4:** LLM and gold dependency trees of Sonn. 31 v.1

More specifically, in such structures, the root dependency relation should be assigned to *piena* (full), as correctly handled by Dante model. By misassigning the root, and incorrectly labeling the actual root as xcomp (open clausal complement), the model also produces erroneous attachments. For example, the subject *tu* (you) and the pronoun *mi* (me), marked as iobj (indirect object), are correctly labeled but incorrectly attached.

Alongside the auxiliary *avere* (to have) discussed in Example III, the auxiliary *essere* (to be) also proves problematic. In particular, the LLM incorrectly assigns head status also to the auxiliary *essere*, *è* in the text, (is), as shown in Example IV and Figure 5. As previously noted, in the UD formalism, auxiliaries are treated as leaf nodes rather than heads. By contrast, Dante model performs correctly, assigning the auxiliary the cop (copula) dependency relation and attaching it as a dependent of the noun *vita* (life).

Example IV - Sonn. 31 v. 9
*Io vo come colui ch'è fuor di vita*
(I am unmanned and have to wander through the world like an intricate figure)

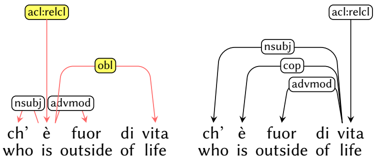

**Figure 5:** LLM and gold dependency trees of Sonn. 31 v.9

The incorrect identification of the clause head, assigned to the copula *è* (is), leads to a structurally inconsistent analysis, accompanied by further errors. For instance, the noun *vita* (life) is incorrectly labeled as obl (oblique), instead of being identified as the head of a relative clause (acl:relcl), a role mistakenly assigned to the copula *è* (is). In addition to the incorrect labeling,

[24] Refer to: https://universaldependencies.org/u/dep/aux_.

[25] Dante model correctly annotates the tree, identifying *piena* (full) as the root and correctly attaching its dependents. The only mistake made by the model is the labeling of the auxiliary *ài* (to have), which is incorrectly assigned the label cop (copula) instead of the correct label aux (auxiliary).

the subject *che* (who) (marked as `nsubj`) and the adverb *fuori* (out) (`advmod`) are also wrongly attached.

In sum, this close examination of the two lowest-scoring sonnets highlights how a single error, especially one involving a crucial dependency relation from which other subtrees depend, such as the incorrect identification of the `root`, can compromise both annotation quality and evaluation scores. Auxiliaries also pose a particular challenge for the LLM, as they are often incorrectly annotated as heads rather than leaves.

## 4.2. Dante Model Errors

During the evaluation of the models' performance, Sonnet 29 emerges as a particularly problematic case, in which both Dante models (All and OS) perform poorly, showing no substantial improvement over the LLM's performance.

Upon comparing the gold annotation with the output of the Dante-All model, it becomes immediately evident that one of the main reasons behind this unexpectedly low performance lies in an incorrect token split of the word *angosciosi* (anguished), at verse 5:

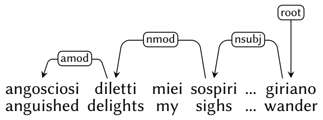
> Examples V - Sonn. 29 v. 5
> *angosciosi diletti miei sospiri ... giriano*
> *angoscio si diletti miei sospiri ... giriano*
> (my sighs would not only subside but turn into hosannas of praise [...] gives)

| | | | | | | |
|---|---|---|---|---|---|---|
| *angosciosi* | *diletti* | *miei* | *sospiri* | … | *giriano* | |
| 34 | 35 | 36 | 37 | … | 60 | |
| *angoscio* | *si* | *diletti* | *miei* | *sospiri* | … | *giriano* |
| 34 | 35 | 36 | 37 | 38 | … | 61 |

**Table 4**
Tokenization and ID alignment in Sonn. 29, v. 5 in the gold annotation and the Dante-All model, respectively.

The Dante-All model splits the word into two distinct token: *angoscio* and *si*, interpreting *si* (originally part of the adjective *angosciosi*) as a reflexive clitic. As a result, it is annotated as a separate token. As already observed for the LLM in 3.2, this error brings to light a range of phenomena that, while not entirely incorrect, are influenced by issues stemming from improper tokenization. In fact the addition of a token leads to a misalignment of token indices (i.e., the *id* field in the CoNLL-U format; see footnote 3), such that even when syntactic dependencies are correctly labeled and attached to the correct token, they are still considered incorrect due to the wrong numbering with respect to the gold standard (see Table 4).

Indeed, this error can only be observed in the Dante-All model, which is required to perform all annotation tasks independently, including tokenization. Despite this specific tokenization issue, there are also errors common to both models (Dante-All and Dante-OS). One such error is the incorrect identification of the `root`, as shown in Figures 7 and 8, in contrast to the gold standard shown in Figure 6. This error is reported here due to its significant impact on the overall sentence structure. More specifically, as indicated in the gold annotation (Figure 6), the `root` of the sentence is *giriano* (wander), token 60. Nevertheless, both Dante models fail to recognize it, selecting instead *diletti* (delights), token 35, as the `root`.



root

angosciosi diletti miei sospiri ... giriano
anguished delights my sighs ... wander

**Figure 8:** Dante-OS dependency tree of Sonn. 29 v. 5

Following this error, subsequent dependency relations are misassigned. The adjective *angosciosi* is annotated as an oblique (`obl`) dependent of *diletti*. In the Dante-All model, this is further complicated by incorrect tokenization, which results in *si* being erroneously split off and assigned the `expl:pv` (expletive: pronominal) relation.

The noun *sospiri*, although correctly labeled as a subject (`nsubj`), is attached to the incorrect `root` (*diletti*) rather than to *giriano* (the gold `root`). Finally, *giriano* itself is annotated as an open clausal complement (`xcomp`) depending on another token.

We hypothesize that this error may be caused by the length of the sentence, in which the token identified as the `root` appears in the 60th position, thus making the parsing of the sentence more complex. However, further experiments in this direction are needed to confirm this hypothesis.

## 4.3. Errors of Both Models

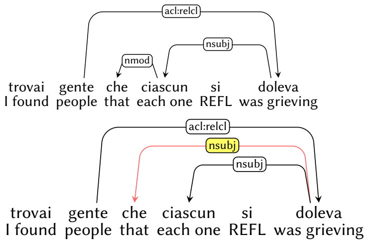
While performing the manual error analysis, we identified a set of specific errors shared by both models (Dante(-

All and -OS) and and LLM), highlighting a common difficulty in analysing such constructions. Notably, these errors both arise from and reflect the complexity of annotating these texts. We report two cases.

In Sonnet 10, both models fail to correctly annotate a construction that poses difficulties even for human annotators. This issue is found specifically in verses 10–11.

> Example VI - Sonn. 10 vv. 10-11:
> *in una parte là 'v'i' trovai gente /*
> ***che** ciascun si doleva d'Amor forte.*
> (to a place where noblemen gathered who also suffered in the thrall of Love.)

In v. 11, the *che* (who) is a specific instance of the "neutrum relative pronoun *che*" [27, p.193], used to replace a pronoun governed by a preposition. This construction was typical of familiar Tuscan and is also attested in other texts of the same period [27, pp.193-194]. As noted by the editors Rea and Inglese in their commentary on this verse [19, p.62], this instance of *che* represents a case of preposition elision, namely, standing in for the form *dei quali*, (of whom), which functions as a nominal modifier of the actual subject *ciascun* (each) (*ciascun dei quali*) (each of whom). The gold annotation is reported in Figure 9.



acl:relcl
nsubj
nmod
trovai gente che ciascun si doleva
I found people that each one REFL was grieving
acl:relcl
nsubj
nsubj
trovai gente che ciascun si doleva
I found people that each one REFL was grieving

**Figure 9:** Gold dependency tree and both model outputs for Sonnet 9, vv. 10-11, respectively.

Both models misanalyse *che*, incorrectly identifying it as the subject of a relative clause. At the same time, they correctly assign the `nsubj` relation to *ciascun* (each); however, this leads to an inconsistent syntactic analysis, resulting in a spurious double subject, as shown in Figure 9.

Another error made by both models that is worth commenting on, as it reflects a stylistic peculiarity, is the one reported in Example VII (Sonnet 10, v. 13):

> Example VII - Sonn. 10 v. 13:
> *Fatto sè di tal servente*
> (You are a denizen of the kingdom or the dungeon)

This verse presents a fronting of the genitive complement *di tal* (of such), as noted by Rea and Inglese [19, p.63], along with an ellipsis of the noun *donna* (woman), that is, *di tal (donna)*. As a result, the preposition *di* (of) should be attached as a case marker (`case`) to *tal*, and the entire phrase *di tal* should be analysed and annotated as a nominal modifier (`nmod`) of the noun *servente* (servant), yielding the interpretation *servente di una tale donna* (servant of such a woman). This full phrase functions as an open clausal complement (`xcomp`) of the main verb *fatto* (made). We report the correct syntactic tree in Figure 10.

In this case, both models incorrectly annotate *di* and *tal* as modifiers of the noun *servente*, assigning them the labels `case` and `det` (determiner), as shown in Figure 10. Neither model captures the ellipsis of *donna*, and both attach *di* (of) and *tal* (such) directly to *servente*. However, this annotation leads to a different interpretation: *di tale servente* (of such a servant). Based on this incorrect interpretation, *servente* is assigned the syntactic role of oblique (`obl`), and is correctly attached to the verb *fatto*.

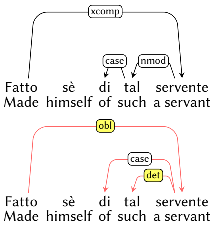


**Figure 10:** Gold dependency tree and both model outputs for Sonnet 10, verse 13, respectively.

These two examples, both incorrectly annotated by the models, underscore the importance of human revision in cases involving stylistic varieties that current models fail to adequately capture.

## 5. Conclusion and Future Work

This study has evaluated the syntactic parsing performance of two distinct models on a corpus of Old Italian poetry: Stanza, a supervised neural model trained on a domain-specific corpus, and an unsupervised autoregressive large language model accessed via the ChatGPT API (o3 version). The results show that while the LLM demonstrates acceptable accuracy scores, the Stanza-based model trained on the Italian-Old treebank consistently outperforms it in syntactic annotation tasks, particularly when provided with gold-standard tokenization and morphology. Although this experiment involved only a single LLM , the results suggest that using a neural model trained on domain-specific data to pre-parse texts as a basis for human annotation could be advantageous. Moreover, while this may appear self-evident, the experiment reinforces the importance of involving expert annotators, especially in cases like those shown in this study, where stylistic nuances escape the models. Future directions include conducting experiments with other LLMs, such as the aforementioned UDify [23] and U-DepPLLaMA [24], as well as testing custom transformer-based pipelines using MaChAmp [28] and Trankit [29]. Manual error analysis was crucial in highlighting the challenges encountered by both models, revealing not only more mechanical errors, such as incorrect `root` identification often accompanied by mistaken head and dependency assignments of the dependent nodes, but also more specific issues, particularly in handling poetic constructions, ellipses, and auxiliary verbs. While in the first scenario some workarounds can be found to mitigate such errors (for example, by adopting rule-based integrations to guide model performance), when it comes to more specific errors, human skill and expertise become decisive.

Another crucial element that emerged from this study is the influence of editorial choices on syntactic annotation. As demonstrated in Section 2.3, different editions of the same text can result in substantial variation in tokenization, lemma interpretation, and syntactic structure. This observation underscores the need for openly accessible, high-quality digital editions, particularly for historical texts, which often lack standardized resources.

Future work will extend the evaluation to include other critical editions of Cavalcanti's *Rhymes* to analyse stylistic distance and to assess model performance across distinct editorial variants. Moreover, further investigations will also aim to explore syntactic variation across different poetic genres and authors within the same historical period, as well as to examine prose texts in order to assess whether significant syntactic differences emerge.

# A. Appendix

### Sonnet 31[26]

1 *Tu m'ài sì piena di dolor la mente*
*che l'anima si briga di partire,*
*e li sospir che manda il cor dolente*
*mostrano a li occhi che non pon soffrire.*

5 *Amor, che lo tuo grande valor sente,*
*dice: — mi duol che ti convien morire*
*per questa fera donna, che neente*
*par che pietade di te voglia udire.*

9 *Io vo come colui ch'è fuor di vita,*
*che pare, a chi lo sguarda, c'omo sia*
*fatto di rame o di pietra o di legno,*

12 *che sè conduca sol per maestria,*
*e porti ne lo core una ferita*
*che sia, com'egli è morto, aperto segno.*

1 You have filled my mind with so much sorrow
that the soul itself is assaulted and tries to flee.
Heartsick, my body sighs from my bones' marrow
and I've reached my limit, as anyone can see.

5 Even Love is sympathetic and says,
"It is hard that the cruel lady for whom you pine
gives you no pitiful glance or comforting phrase.
This was never a part of my design."

9 I am unmanned and have to wander through
the world like an intricate figure of wood or brass
produced by some toymaker to amuse.

12 Strangers who pause to stare at me as I pass
can't tell that I suffer and haven't a clue
that I am dead, a victim of her abuse.

### Sonnet 10

1 *Li miei foll'occhi, che prima guardaro*
*vostra figura piena di valore,*
*fuor quei che di voi, donna, m'acusaro*
*nel fero loco, ove ten corte amore.*

5 *E mantenente avanti lui mostraro*
*ch'io era fatto vostro servidore;*
*perchè sospiri e dolor mi pigliaro*
*8vedendo che temenza avea lo core.*

9 *Menarmi tosto senza riposanza*
*in una parte, là 'v'i' trovai gente*
*che ciascun si doleva d'amor forte.*

12 *Quando mi vider, tutti con pietanza*
*dissermi: — fatto se' di tal servente*
*che mai non dei sperare altro che morte. —*

1 It was my reckless eyes that first beheld
your ineffable worth and condemned me to
live in that wasteland over which the bold
master, Love, holds court as tyrants do.

5 They welcomed me there, a new captive, a slave,
and were delighted to hear my sighs and groans.
We are taught as little boys to try to be brave,
but I felt an icy fear deep in my bones.

9 They led me to a place where noblemen
gathered who also suffered in the thrall
of Love. Their somber welcome to me I

12 still shudder at: "You are a denizen
of the kingdom or the dungeon that holds us all
and from which there is no escape until you die."

### Sonnet 29

1 *Se mercè fosse amica a' miei disiri*
*e 'l movimento suo fosse dal core*
*di questa bella donna e 'l suo valore*
*mostrasse la virtute a' miei martiri,*

5 *d'angosciosi diletti miei sospiri,*
*che nascon de la mente ov'è amore*
*e vanno sol ragionando dolore*
*e non trovan persona che li miri,*

9 *giriano a gli occhi con tanta vertute*
*che 'l forte e duro lagrimar che fanno*
*ritornerebbe in allegrezza e 'n gioia.*

12 *Ma sì è al cor dolente tanta noia*
*e a l'anima trista è tanto danno*
*che per disdegno uom non dà lor salute.*

1 If luck could look with favour on my desire
and if it came from my lady's heart with the power
to encourage me and let me thrive in a shower
of hope from heaven that knows how to admire

5 devotion of any kind, I do believe
my sighs would not only subside but turn into
hosannas of praise as grey brightens to blue
when angry weather grants us a reprieve.

9 My squalls of tears would cease and joy at last
would be what gives my eyes their special shine,
each teardrop like a jewel delighting to be

12 dug from the earth to glitter and be free ...
But it hasn't happened, and the pain that has been mine
deforms me so that I am an oucast.

[26] See footnote 7 for details on the translation edition.

# Segmenting Italian Sentences for Easy Reading

Marta Cozzini[1,*,†], Horacio Saggion[2,†]

[1]Università di Bologna, Via Zamboni 33, 40126 Bologna, Italy
[2]Universitat Pompeu Fabra, Carrer de la Mercè 12, Ciutat Vella, 08002 Barcelona, Spain

**Abstract**

Easy Read texts are essential for individuals with reading difficulties. These texts are developed according to institutional guidelines that establish clear rules for writing and structuring content in an accessible way. A key feature of Easy Read texts is the segmentation of sentences into smaller grammatical units, often presented on separate lines, to enhance readability. While several studies have addressed content simplification in easy-to-read materials, much less attention has been paid to the automatic segmentation of such texts. This project investigates whether this kind of segmentation can be automated in a reliable and efficient way, even with limited resources. The main goal is to develop and evaluate automatic methods for splitting texts into simpler, shorter units to support text simplification and improve overall readability. The methods developed and evaluated are a decision tree classifier and a prompting-based method using a large language model (LLM). The work is focused on Italian, and the application of these methodologies to this language represents a novel contribution.

**Keywords**

Text simplification, easy-to-read, automatic segmentation, ER resources, CLiC-it

## 1. Introduction

Easy-to-read materials are important to ensure that as many people as possible can access information, especially people with cognitive disabilities, who might find it harder to understand complex texts or learn new things. These specific materials follow shared guidelines designed to make reading and understanding easier thanks to clear and consistent writing. Inclusion Europe created easy-to-read standards for preparing this kind of content in different languages [1]. Although these guidelines were originally designed for people with cognitive difficulties, they're also helpful for others, such as non-native speakers or anyone who finds reading challenging. Among the various recommendations, particular attention is paid to the use of simple vocabulary, short sentences, and a clear logical structure. Some guidelines also emphasize the importance of dividing the text into smaller grammatical units to improve readability. The Inclusion Europe guidelines state that each sentence should ideally fit on a single line and that longer sentences should be split at natural linguistic boundaries: where people would pause when reading out loud. This attention to segmentation is not only important for proper text layout, but, as the guidelines suggest and the following example demonstrates, it also plays a significant role in enhancing text comprehensibility.

> The Inclusion Europe guidelines advise against writing:
>
> ```
> Il modo in cui questa frase è
> divisa non è facile da leggere.
> ```
>
> Instead, they recommend:
>
> ```
> Il modo in cui questa frase è divisa
> è facile da leggere.
> ```

From a linguistic perspective, the first version interrupts a verbal phrase composed of the auxiliary "è" and the past participle "divisa." This separation breaks the syntactic and semantic unity of the clause, making the sentence harder to process. By splitting these tightly connected elements across two lines, the reader's comprehension effort increases. As the guidelines suggest, such breaks should be avoided in order to maintain clarity and facilitate understanding.

Despite the growing interest in text simplification, the task of sentence segmentation in easy-to-read materials remains largely underexplored. Currently, there are very few resources that address easy-to-read principles in relation to automatic segmentation, and only a limited number of studies have investigated how segmentation can be implemented computationally within this framework. This work aims to fill this gap by exploring whether segmentation can be automated reliably and efficiently. In particular, we evaluate two approaches: a decision tree classifier and a prompting-based method using a large language model (LLM). Both models are tested on easy-to-read materials that we collected from sources

that we consider particularly trustworthy in adhering to official ER guidelines. These very materials not only serve as the basis for our evaluation, but also represent a secondary contribution of this study, as they form two new corpora that can support future research not only on segmentation, but more broadly in the domain of Italian text simplification. Although they do not include original–simplified text pairs, they offer quality examples of simplified texts segmented according to established ER criteria.

The paper is structured as follows: Section 2 reviews related work, followed by Section 3 that introduces the corpora used in our experiments, discussing their sources, the methodology behind their creation as easy-to-read materials, and other relevant details. Section 4 provides a detailed description of our methodology for the segmentation task, including both the decision tree and the prompting approaches. Section 5 presents our experimental setup, while Section 6 analyzes the results, evaluating each method, comparing their performance, and providing insights into the findings. Finally, Sections 7 and 8 conclude the paper by discussing key takeaways, addressing limitations, and describing future research directions.

## 2. Related Work

Text segmentation plays an important role in promoting textual accessibility and can be considered a relevant component of both Automatic Text Simplification (ATS) and the development of easy-to-read materials. ATS is a Natural Language Processing (NLP) task aimed at reducing linguistic complexity of texts, while preserving their original meaning [2]. It may involve modifications at the lexical, syntactic, or discourse level. In recent years, research on ATS has focused on developing approaches to simplify and adapt texts for individuals with cognitive disabilities or language impairments [3]. While ATS relies on computational strategies, easy-to-read materials are instead based on institutional guidelines that define clear rules for structuring content in an accessible way. These two approaches often converge on similar features that enhance readability. These include the use of simple vocabulary and grammar, short sentences, a clear logical structure, and the explanation of complex concepts in simpler terms. Within both frameworks, text segmentation is frequently emphasized: each sentence should ideally fit on a single line, and if this is not feasible, it should be split at natural linguistic boundaries to enhance clarity and facilitate comprehension.

### 2.1. Sentence Segmentation

Sentence segmentation is particularly valuable for creating accessible materials for individuals with reading challenges. Line breaks strategically inserted within long sentences can significantly improve readability [4]. The core concept behind sentence segmentation for easy reading materials is the division of complex sentences into smaller, more digestible chunks. This segmentation must follow "natural linguistic boundaries, ending at a position in the sentence where a reader would naturally pause" [5]. While intuitive to understand, defining precise criteria for these natural boundaries remains challenging. Recent research has explored the optimal approach to sentence splitting for improved comprehension. Studies have found that dividing sentences does enhance readability, with a particular finding that bisecting the sentence leads to enhanced readability to a degree greater than when we create simplification by trisection [6][7]. This preference for two-sentence splits over three-sentence divisions has been confirmed through Bayesian modeling experiments using various linguistic and cognitive features [8]. For readers with learning difficulties, proper sentence segmentation is particularly valuable. Studies have found that sentence density is a significant negative predictor of inferential comprehension, meaning that "the higher the sentence density, the lower the ability of these students to find relationships between them" [9]. This finding underscores the importance of appropriate text segmentation for enhancing comprehension among diverse reader populations.

### 2.2. Automatic Sentence Segmentation

Despite increasing interest in text simplification, the specific task of automatic sentence segmentation in the context of easy-to-read (ER) materials remains largely underexplored. To our knowledge, only one study to date has directly investigated how segmentation can be computationally implemented within this framework [5], and currently, very few resources address ER principles in relation to automatic segmentation. However, segmentation plays a crucial role in related domains, most notably in subtitle generation, where readability is enhanced when subtitles are segmented at naturally occurring linguistic boundaries, in addition to meeting timing and space constraints. Research has shown that subtitle segmentation has a significant impact on readability [10], leading to the development of various computational approaches. For instance, Álvarez et al. [11] trained Support Vector Machine and Linear Regression models on professionally created subtitles to predict optimal subtitle breaks, later improving this method through the use of Conditional Random Fields [12]. These supervised approaches could, in principle, be adapted to ER settings, provided that sufficient annotated training data is available. Nonetheless, compared to subtitling, resources for ER segmentation are extremely limited. As we mentioned before, to date, only one study has directly addressed the problem of sentence segmentation for the generation of ER texts. This work explores multiple approaches, including the use of generative large language models (LLMs) under different prompting modalities and a scoring-based method compatible with both constituency parsing and masked language modeling (MLM). In addition, it tackles the problem of data sparsity by developing new segmentation-centric datasets for Basque, English, and Spanish, thus laying the groundwork for further research in this domain [5].

As the first study to focus specifically on automatic sentence segmentation within the context of ER materials, it has provided a valuable foundation for our work. Building on its insights, we aim to apply similar strategies to address the problem of sentence segmentation for Italian, a language for which text simplification resources and research remain scarcer compared to English or Spanish.

# 3. Corpora

To construct our corpora, we relied on two different websites: Due Parole [13] and Anffas [14], known for their adherence to ER guidelines. From each source, we created a separate corpus, which was later used in our experiments. We describe these corpora in more detail in the following subsections.

## 3.1. Corpus from Due Parole

On the Due Parole website, we accessed the online archive of Due Parole, an Italian easy-to-read magazine that was published, with some interruptions, between 1989 and 2006. The magazine was specifically designed to provide accessible information to a broad audience, with simplified texts created by a team of linguists, journalists, and teachers from the University of Rome 'La Sapienza'. The corpus collected from this source consists exclusively of magazine articles, providing a consistent and well-structured textual base for training and initial testing of our models. From the online archive of Due Parole, we collected only the articles available in digital format, as web scraping was necessary to build the corpus. During the web scraping process, we preserved all original line breaks present in the formatted texts as published online. To ensure that the Due Parole corpus complied with the Inclusion Europe guidelines, we referred to Piemontese[15], which outlines the guidelines followed by the Due Parole team when producing easy-to-read texts. Some of the key recommendations concerned text segmentation: whenever the page layout allowed, each line was designed to contain a complete unit of meaning. If it was not possible to keep a sentence on a single line, sentence breaks were carefully managed to avoid arbitrary line breaks, with each line always ending on a whole word and words were never split across lines. This careful approach to segmentation shows an understanding of its effect on readability, emphasizing that sentence splitting should be deliberate and meaningful, unlike the more random breaks often seen in standard newspapers. The final corpus contains 311 articles, comprising 4855 sentences. Each article was saved as a separate plain text file with a `.txt` extension. All files were encoded in UTF-8, with special characters and HTML tags removed during preprocessing to ensure a clean and consistent textual format. The articles are organized in a hierarchical folder structure reflecting the original metadata: first by publication year, then by month, and finally by magazine section (e.g., "sport", "cultura"). This structure reflects the original editorial organization and allows for easy filtering by date or topic.

## 3.2. Corpus from Anfass

Our second source of easy-to-read materials is the website of Anffas, a national association of families of individuals with intellectual and/or relational disabilities. Anffas was one of the partners involved in the project that led to the definition of the European easy-to-read Guidelines [16]. Therefore, we can expect that the texts in the section "Documenti facili da leggere" ("Easy-to-read documents") that we can find on the website follow these official guidelines. From all the easy-to-read materials published there, we selected only the texts included in the easy-to-read magazine 'A modo mio'. This choice was motivated by the need to align with the other corpus, which also consisted exclusively of magazine articles. The Anffas corpus was used exclusively as a test set. Unlike the Due Parole corpus, creating this corpus as plain text was more difficult because the texts were only available in PDF format, which ruled out the use of web scraping. We therefore had to convert them manually. However, because there were significantly fewer Anffas texts compared to Due Parole, this operation did not require too much time. Similarly to Due Parole, we preserved all original line breaks present in the formatted texts as published online. The final corpus contains 38 articles comprising 481 sentences. The articles are organized into folders corresponding to each magazine issue, labeled by month and year. Within each issue folder, there is one plain text file (`.txt`) per magazine section (e.g., "sport", "spettacoli e televisione").

Table 1 summarizes the statistics of our corpora, including the total number of sentences, the number of sentences that contain at least one segmentation point, and the number of sentences without any segmentation.

**Table 1**
Corpora statistics

| Sentences | Due Parole | Anfass |
|---|---|---|
| **Total** | 4855 | 481 |
| **With segmentation** | 4271 | 204 |
| **Without segmentation** | 584 | 277 |

From Table 1, we observe the differences between the two corpora in terms of segmented sentences. Specifically, in the Due Parole corpus, the number of sentences containing at least one segmentation point is 4,271, corresponding to 88% of the total sentences. In contrast, this percentage drops to 42% in the Anfass corpus. This discrepancy is expected to affect the performance of our decision tree model, which was trained on the Due Parole corpus and subsequently tested on the Anfass corpus, as we will see in Section 6.

# 4. Methodology

To explore the viability of automatic text segmentation in low-resource settings, we adopted two different approaches: a traditional machine learning method informed by linguistic features (a decision tree) [17] and a current prompting Large Language Model approach.

## 4.1. Automatic Segmentation Using Decision Tree

We first approached the task of automatic text segmentation as a binary classification problem. In this framework, the model is trained to assign a binary label, 0 or 1, to each token in the input text, where 1 indicates that a segmentation should occur immediately after that token, while 0 means no segmentation. To build the training data, we started from raw texts extracted from the Due Parole dataset, that we described in the previous section. We first segmented the texts into sentences using spaCy's sentence tokenizer. Before sentence segmentation, we replaced all new line characters (\n) occurring within the text with a special marker <seg>, in order to preserve formatting information for subsequent processing (see step 2 of the example below). We then used the <seg> markers to split each sentence into smaller chunks, corresponding to the original internal line breaks (as shown in step 3). These splits helped us identify potential segmentation points within the sentence. For each token in the sentence, we assigned a binary label: 1 if it ended a chunk (except the final chunk in a sentence, labeled 0), and 0 otherwise. These labels serve as the target outputs that the model is trained to predict. Only after creating these target labels, the <seg> markers were removed, and the cleaned sentences reconstructed and re-tokenized with spaCy to prepare the data for further processing (see step 4). The following example illustrates the prepocessing steps applied to our corpus before training the decision tree model:

1. **Original input**

   This example sentence, extracted from the raw text, will be used to illustrate the prepocessing steps. Note that at this stage of the pipeline, the sentence is provided for demonstration purposes only, as the original text has not yet been segmented into sentences. In this example, newline characters indicate editorial line breaks.:

   ```
   La Costituzione è l'insieme
   delle leggi più importanti
   della Repubblica italiana.
   ```

2. **Intermediate representation**

   In this intermediate form, the raw text is segmented into sentences, and newline characters are replaced with a special segmentation marker:

   ```
   La Costituzione è l'insieme <seg>
   delle leggi più importanti <seg>
   della Repubblica italiana.
   ```

3. **Segmented output**

   The text is then split into segments at the positions marked by the <seg> tokens, which serve to identify potential segmentation boundaries:

   ```
   ['La Costituzione è l'insieme',
      'delle leggi più importanti',
      'della Repubblica italiana.']
   ```

4. **Linguistic analysis**

   Finally, the reconstructed sentence is used for token-level feature extraction in the classification model:

   ```
   La Costituzione è l'insieme delle
   leggi più importanti della Repubblica
   italiana.
   ```

After reconstructing the sentences, we performed feature extraction, including token-level features such as part-of-speech (POS) tags, sentence length (in tokens and characters), token length (in characters), and the token's position within the sentence. We converted POS tags into binary features using one-hot encoding. Then, all the features and target labels were organized into a tabular structure. A decision tree classifier was then trained on these data to predict segmentation.

### 4.2. Generative LLM Segmentation

Our second approach to automatic text segmentation involved using an instruction-tuned large language model (LLM) with zero-shot prompting. The design of our prompts was based on both the prompt strategies proposed in Calleja et al.[5] and the recommendations outlined in the Inclusion Europe easy-to-read (ER) guidelines. Following the approach of Calleja et al. [5], we designed two separate prompts. The first prompt (Prompt 1) aligns with the formal Inclusion Europe guidelines that state "tagliate la frase lì dove le persone farebbero una pausa leggendo la frase a voce alta" [1], while the second (Prompt 2) relies on the identification of natural grammatical boundaries. Unlike Prompt 1, Prompt 2 avoids explicit mentions of reading pauses, which could be less accessible or meaningful to the model. To make the prompts more specific, we introduced an additional constraint on the length of the segment, specifying that each segment should contain between 5 and 15 words. As is standard when prompting LLMs, we added also explicit instructions to ensure that the model would only output the requested content, without generating any additional text. In particular, we specified that the model should not include numbers, symbols, or bullet points at the beginning of lines, as our preliminary tests revealed a tendency to introduce such formatting elements.

- **Prompt 1:** `Dividi la seguente frase in segmenti separati, inserendo un ritorno a capo dove le persone farebbero una pausa leggendo la frase ad alta voce. Ogni segmento di testo dovrebbe contenere tra le 5 e le 15 parole. Il contenuto della frase originale non deve essere alterato in nessun modo; pertanto non deve essere aggiunta nuova informazione di alcun tipo. Scrivi ogni segmento su una nuova riga, senza numerazione o simboli all'inizio. Non generare altro testo ad eccezione del testo originale segmentato.`
- **Prompt 2:** `Dividi la seguente frase in segmenti separati, che rispettino i confini grammaticali naturali. Ogni segmento di testo dovrebbe contenere tra le 5 e le 15 parole. Il contenuto della frase originale deve essere mantenuto rigorosamente; pertanto non deve essere aggiunta nuova informazione di alcun tipo. Scrivi ogni segmento su una nuova riga, senza numerazione o simboli all'inizio. Non generare altro testo ad eccezione del testo originale segmentato.`

## 5. Experiments

Our first approach to automatic sentence segmentation was based on a traditional machine learning model. In particular, we employed a decision tree Classifier implemented via the `DecisionTreeClassifier` class in the `sklearn.tree` Python library [18]. To ensure replicability of our results, we set the `random_state`. Additionally, we configured the classifier with the parameter `class_weight='balanced'`, which automatically adjusts weights inversely proportional to the class frequencies in the input data. This choice was motivated by the significant imbalance in our dataset, where the target label 1 (indicating a segmentation point) is much less frequent than label 0 (no segmentation). To reduce the negative impact of this imbalance on model performance we adopted this built-in balancing strategy provided by scikit-learn.

For the prompting experiments, we used Gemma 2 9b, part of Google's Gemma family of lightweight, state-of-the-art decoder-only large language models. A key advantage of this family is the relatively small model size and the availability of open weights, which make the models suitable for deployment in resource-limited environments such as laptops or personal cloud infrastructure. We loaded the model and tokenizer via the Hugging Face Transformers library, employing automatic device mapping and `bfloat16` precision for efficient inference. Text generation was performed with controlled sampling parameters: a maximum of 150 new tokens, temperature set to 0.7, and nucleus sampling `top_p` at 0.9.

The decision tree classifier was initially trained and tested on a portion of the Due Parole corpus (see Table 2), allowing an initial evaluation of its performance. Subsequently, to assess the model's behavior on different types of texts, the decision tree was also tested on the Anffas corpus. At the same time, the LLM-based segmentation approach was applied exclusively to sentences from the Anffas corpus, in order to ensure that the results produced by the decision tree and the LLM would be directly comparable. As will be explained in more detail below, applying the same evaluation procedure to the Due Parole test set would have required excluding a substantial portion of the data, potentially biasing the results.

Table 2 shows the distribution of the Due Parole corpus across the training, validation, and test sets.

**Table 2**
Data partition statistics (number of tokens)

| | Due Parole |
|---|---|
| **Train** | 64252 |
| **Validation** | 7140 |
| **Test** | 7933 |

# 6. Results

To evaluate the performance of our approaches, we relied on standard metrics commonly used in binary classification tasks, such as precision, recall, and F1-score. These metrics provide a comprehensive overview of model effectiveness, particularly in scenarios with imbalanced classes.

## 6.1. Decision Tree Evaluation

**Table 3**
Results of automatic segmentation using decision tree and Due Parole as a test set

| Target label | Precision | Recall | F1-score |
|---|---|---|---|
| **No segmentation (0)** | 0.90 | 0.90 | 0.90 |
| **Segmentation (1)** | 0.38 | 0.38 | 0.38 |

**Table 4**
Results of automatic segmentation using decision tree and Anfass as a test set

| Target label | Precision | Recall | F1-score |
|---|---|---|---|
| **No segmentation (0)** | 0.96 | 0.91 | 0.93 |
| **Segmentation (1)** | 0.12 | 0.27 | 0.17 |

The decision tree model was assessed using the `classification_report` function from the `sklearn.metrics` module [18], which computes precision, recall, and F1-score. The initial evaluation was performed on a held out portion of the Due Parole corpus used as the test set. Table 3 summarizes the results obtained from this first test. Subsequently, to assess the model's behavior on different types of texts, the decision tree was also tested on the Anffas corpus. As shown in Table 4, the results differ substantially: the model performs notably worse. This performance drop can be attributed to the mismatch between the training data and the new test data. Although both corpora adhere to the Inclusion Europe guidelines and both consist of magazine articles, the texts in the Due Parole corpus exhibit a more uniform structure, largely influenced by the magazine's fixed layout. In contrast, the Anffas 'A modo mio' texts, while also published in magazine format, feature a more variable graphic layout, which may have affected the model's ability to generalize. Another contributing factor is the discrepancy in the proportion of segmented sentences between the two corpora that we described in 3.2: while Due Parole contains 88% of sentences with at least one segmentation point, this percentage drops to only 42% in Anfass. This results in fewer positive instances (i.e., target variable = 1) in the Anfass corpus, which further contributes to the already critical issue of target variable imbalance. This imbalance, as discussed earlier, consistently influences model performance both on the Due Parole test set and on the Anfass corpus, as reflected in the results tables. It notably affects the model's ability to correctly identify the minority class (label 1), which corresponds to segmentation points, resulting in lower precision, recall, and F1 scores. This trend is especially visible in the results obtained on the Anffas corpus, where the model, trained on the more uniform Due Parole texts, struggles even more to generalize. The confusion matrix for the texts tested in the Anffas corpus (Table 6) further confirms the difficulty of the model in performing the segmentation task. This matrix reveals a high number of false positives (487), where the model incorrectly inserts a segmentation point (label 1) when none is required (label 0), leading to unnecessary breaks in the text. Moreover, the model fails to identify 172 actual segmentation points (false negatives), highlighting its tendency to miss where a break should occur. With only 65 true positives out of 237 actual positive cases, the model demonstrates a limited ability to detect segmentation points. This issue is not limited to the Anffas corpus: although results are slightly better on the Due Parole test set (Table 5) the overall performance remains sub-optimal. The model tends to generalize poorly when deciding where to segment, struggling both to avoid over-segmentation and to reliably identify the appropriate break points.

### 6.1.1. Feature Importance Analysis

To further understand the model's behavior, we examined the feature importance values extracted from the trained decision trees.

As reported in Table 7, the most influential predictors in both corpora are not morphosyntactic cat-

**Table 5**
Confusion matrix for the decision tree model on the Due Parole test set

| | Actual 0 | Actual 1 |
|---|---|---|
| **Predicted 0** | 6212 | 662 |
| **Predicted 1** | 654 | 405 |

**Table 6**
Confusion matrix for the decision tree model on the Anfass test set

| | Actual 0 | Actual 1 |
|---|---|---|
| **Predicted 0** | 4664 | 172 |
| **Predicted 1** | 484 | 65 |

**Table 7**
Feature Importance Values from Decision Trees on Anffas and Due Parole Corpora

| Feature | Anffas | Due Parole |
|---|---|---|
| distanza_da_prima_parola | 0.2320 | 0.1715 |
| frase_len_token | 0.2051 | 0.1765 |
| frase_len_char | 0.1725 | 0.2500 |
| PRON | 0.0977 | 0.0976 |
| CCONJ | 0.0968 | 0.0970 |
| token_len_char | 0.0907 | 0.0971 |
| ADP | 0.0252 | 0.0233 |
| ADV | 0.0190 | 0.0213 |
| NOUN | 0.0150 | 0.0185 |
| VERB | 0.0134 | 0.0151 |
| NUM | 0.0137 | 0.0138 |
| ADJ | 0.0096 | 0.0086 |
| DET | 0.0060 | 0.0063 |
| PUNCT | 0.0033 | 0.0036 |

egories, but rather positional features. In the Anffas corpus, distanza_da_prima_parola, frase_len_token, and frase_len_char dominate the ranking (23.2%, 20.5%, and 17.2% respectively), together accounting for more than 60% of the model's decisions. These features capture sentence length (in tokens and characters) as well as token position within the sentence. Similarly, in Due Parole, the top positions are held by frase_len_char (25%), frase_len_token (17.6%), and distanza_da_prima_parola (17.1%), confirming the central role of sentence length and token positioning. Among morphosyntactic categories, PRON and CCONJ are consistently relevant in both datasets (around 9–10%), while core lexical classes such as VERB, NOUN, and ADJ play a comparatively minor role (below 2% in both corpora). One unexpected result concerns punctuation. Despite the intuitive assumption that punctuation strongly signals natural break points (e.g., commas, periods, dashes), the PUNCT feature accounts for only 0.3% of the total feature importance in both corpora. This is striking, considering that many segmentation guidelines, including those from easy-to-read standards, emphasize splitting long sentences "where a reader would naturally pause"[1], and punctuation marks are prototypical indicators of such pauses. One plausible explanation for the low importance assigned to punctuation is related to the length of the sentences in the training data. Since many of the texts adhere to easy-to-read principles, the sentences are often already short and simple, which means that internal punctuation marks (such as commas or colons) appear less frequently. As a result, punctuation rarely aligns with actual segmentation points in the dataset, reducing its statistical weight in the model's learning process. Moreover, punctuation that does appear, such as final periods, is not annotated as a segmentation point, as it naturally marks the end of a sentence. Taken together, these factors contribute to the surprisingly low feature importance of punctuation observed in the analysis. An ablation study, which systematically removes or isolates features to assess their individual and combined effects, could improve the overall understanding of feature contributions. Additionally, the influence of punctuation could be investigated by partitioning the dataset into sentences with and without punctuation and comparing feature importance between these groups. This would clarify whether punctuation plays a different role depending on its presence in the sentence. These investigations are left for future work.

## 6.2. LLM Evaluation

Evaluating the performance of the decision tree model was straightforward thanks to the availability of standard metrics and the `classification_report` function from the `sklearn.metrics` module. However, assessing the performance of the Large Language Model (LLM) proved to be more complex. This is because, whereas the decision tree outputs a binary label (0 or 1) for each token, the LLM produces fully segmented sentences as output. To enable a direct comparison with the decision tree, we first converted each segmented sentence into a binary sequence. In this sequence, tokens immediately preceding a line break were assigned a label of 1, except for line breaks corresponding to the final period of a sentence or cases where an entire sentence appeared on a single line, which were labeled 0 since they do not represent meaningful segmentation points in our task. To ensure a fair comparison with the decision tree, we aligned the length of the sequences produced by the LLM with those of the reference data, since the evaluation metrics used, such as precision, recall, and F1 score, are sensitive to sequence length and require a one-to-one correspondence between tokens. For this reason, before converting the segmented sentences into binary sequences, we manually reviewed the LLM outputs to identify and remove noisy cases.

**Table 8**
Sentence count in the original and reduced versions of the Anffas dataset

| Prompt | Original sentences | Modified outputs |
|---|---|---|
| **Prompt 1** | 481 | 58 |
| **Prompt 2** | 481 | 139 |

**Table 9**
Sentence count in the original and reduced versions of the Due Parole dataset

| Prompt | Original sentences | Modified outputs |
|---|---|---|
| **Prompt 1** | 480 | 123 |
| **Prompt 2** | 480 | 218 |

Despite explicit instructions in the prompt to generate no additional text beyond the original sentence, the LLM occasionally violated this rule. Consequently, we excluded from both our test sets, Anfass and Due Parole:

- Sentences in which the LLM added additional content, despite the prompt instructions explicitly prohibiting it;
- Sentences where the LLM altered the original punctuation, introducing tokens and segmentation breaks not present in the reference.

After this filtering step, we converted the cleaned LLM outputs into binary sequences and computed the same evaluation metrics used for the decision tree, allowing for a consistent and comparable analysis.

Table 8 shows the number of sentences per prompt that had to be removed from the Anfass test set due to changes made by the LLM in generating the output. In the case of the first prompt, the model introduced new content or altered the original sentence in 58 out of 481 cases, indicating relatively good adherence to the instructions. In contrast, the second prompt led to 139 modified outputs. This total includes the 58 cases affected by the first prompt, most of which were also altered in the second output. The higher number of 139 modified sentences for the second prompt reflects both these overlapping cases and additional sentences uniquely altered in the second output. This increase is likely due to the vagueness of the expression "grammatical boundaries," which the model tended to interpret more strongly, often replacing simple line breaks with stronger punctuation marks, possibly due to the presence of the term "boundaries". As a result, we were able to evaluate the LLM's performance on only 342 sentences from the original 481 in the Anffas dataset. To ensure comparability, we applied the same filtering to the decision tree evaluation, testing it exclusively on this same subset of sentences. On the Due Parole test set, even more sentences had to be excluded from the evaluation, as shown in Table 9: 123 from the first prompt and 218 from the second. Although these exclusions occurred, we decided not to proceed with the evaluation on the Due Parole test set. Following the methodology described above, this would have left us with only 260 evaluable sentences, corresponding to just 54% of the dataset. Such a reduction could bias the evaluation, as it might disproportionately exclude not only correctly segmented instances but also those where the model fails to segment properly. Future work will investigate alternative evaluation strategies more appropriate for this setting, including metrics such as BLEU and edit distance.

## 6.3. Comparison between the Approaches

**Table 10**
Comparative results for decision tree and Prompting (Prompt 1 and Prompt 2) on the Anfass reduced test set

| Label | Model | Precision | Recall | F1-score |
|---|---|---|---|---|
| 0 | Decision Tree | 0.97 | 0.91 | 0.94 |
|  | Prompt 1 | 0.98 | 0.94 | 0.96 |
|  | Prompt 2 | 0.98 | 0.93 | 0.96 |
| 1 | Decision Tree | 0.10 | 0.24 | 0.15 |
|  | Prompt 1 | 0.48 | 0.51 | 0.49 |
|  | Prompt 2 | 0.44 | 0.47 | 0.45 |

To provide a comprehensive evaluation, we compared the performance of the LLM-based approach, tested exclusively on the Anfass dataset, with the decision tree results, as summarized in Table 10. The LLM results reveal, once more, a marked imbalance between the two target labels (0 and 1). It is important to note that, when converting the LLM outputs into binary sequences, all sentences that appeared entirely on a single line in the corpus were automatically assigned only 0s. In cases where the corresponding gold standard sentence was also on a single line and contained no segmentation points, we modified the default behavior of the `precision_recall_fscore_support` function to better reflect this scenario. By default, the function may return undefined or misleading values when both `y_true` and `y_pred` contain only 0s. To avoid this, we configured the function so that it would treat such predictions as fully correct and automatically assign precision, recall, and F1-score values of 1.0. As reported in Table 10 on the Anffas reduced dataset, the LLM outperformed the decision tree overall. However, this result should be interpreted with caution, especially considering that, as shown in Section 6.2, it required excluding approximately one-quarter of the original corpus. The exclusion was necessary due to the model's tendency to introduce extra punctuation or to generate text exceeding the original input. This behavior resulted in the loss of valuable data, which is particularly critical in contexts where data are already scarce, such as in easy-to-read materials.

### 6.4. Comments on the Results

These results should be interpreted with caution, as segmentation is a non-standard and inherently subjective task within the context of text simplification and easy-to-read materials, precisely because multiple segmentations can be valid for any given sentence, each potentially facilitating comprehension in different ways. However, conventional evaluation metrics such as precision and recall enforce a strict binary framework, classifying predicted segmentations as either entirely correct or completely incorrect. This approach fails to consider cases where a segmentation, although different from the reference, is still reasonable or partially appropriate in terms of improving readability. As a result, predictions that are close to the gold standard or practically acceptable are often penalized as errors, which can underestimate the model's true performance and limit its applicability in real-world contexts.

## 7. Conclusion

The results obtained indicate that LLMs outperform a simple decision tree in the task of automatic sentence segmentation. However, as previously noted, these improved results come at a cost; to properly evaluate the LLM, we had to substantially reduce our test set, resulting in the loss of valuable data in a domain where data availability is already limited. Additionally, LLMs demand significantly more computational resources and runtime, requiring GPU acceleration to produce their outputs. Given these important considerations, it is worth discussing whether traditional machine learning approaches may still be appropriate for tasks of this nature. While our results do not provide conclusive evidence in this regard, it remains possible that more sophisticated traditional models, beyond simple decision trees, could achieve competitive performance in automatic segmentation. Future research could explore alternative models better suited to handling imbalanced features and class distributions, an issue evident in our datasets. Another contribution of this work lies in the creation and compilation of the Anffas and the Due Parole datasets. Although these corpora do not include the original source texts typically present in other resources for Italian text simplification, they nonetheless represent valuable assets. Beyond their utility for segmentation research, they provide a source for broader investigations within the field of text simplification. Currently, these datasets are pending authorization for public release. Once approved, they will be made openly accessible to the research community, supporting future research on various aspects of Italian text simplification.

## 8. Limitations and Further Work

The Inclusion Europe guidelines provide only vague instructions on segmentation, and there are cases in which our benchmarks even contradict these guidelines. Moreover, segmentation remains a subjective task: while text layout influences decisions, multiple strategies can be equally valid for improving comprehension. Another limitation is that the psycholinguistic impact of segmentation and its role in enhancing understanding have only been explored to a limited extent. Due to time constraints, our study did not differentiate between grammatical and ungrammatical segmentations, such as splitting an article from its noun, but this represents an interesting area for future research. For our evaluation, we used precision, recall, and F1-score, mainly to ensure comparability with the decision tree results. However, these metrics present two main limitations: first, they impose a rigid binary judgment that fails to account for the inherent subjectivity of segmentation; second, they require a strict one-to-one token correspondence, which led to the loss of valuable data whenever the model added informative tokens to the output. As mentioned in section 6.2, future work should explore alternative evaluation strategies, such as BLEU or edit distance metrics, although the use of edit distance would require a careful discussion to define what constitutes a meaningful edit. In addition, human evaluation should be considered to gain deeper insights beyond what quantitative metrics alone can offer.

**Abstract**

In recent years, hate speech detection models have achieved significantly improved results, largely due to advances in Large Language Models (LLMs). As a result, research has increasingly focused on more nuanced phenomena, such as the detection of implicit hate and stereotypes. Although the challenge of identifying implicit language has been largely explored, it remains an open issue for state-of-the-art models due to their limited ability to grasp contextual and culturally specific knowledge. In this work, we address the task of identifying stereotypes implicitly encoded in hate speech messages, and propose a method for generating them by leveraging the combined potential of LLMs and Knowledge Graphs (KGs). As a first step, we designed an ontology specifically tailored to represent implicit hate speech. We then populated the ontology using a subset of an Italian-language hate speech dataset, in which targets and implied stereotype statements were manually annotated. The remaining portion of the dataset was reserved as a test set to evaluate the impact of knowledge graph-derived information on LLM-generated stereotypes. For each input sentence, relevant knowledge was extracted from the ontology using SPARQL queries and used to enrich the prompt provided to various LLMs. We compared the results of the knowledge-enhanced approach against those of a baseline few-shot learning approach. Evaluation was conducted using BLEU, BERTScore and ROUGE metrics. Additionally, given the high subjectivity of the task, we performed a manual qualitative analysis on a subset of the model outputs to assess both the quality of the evaluation and the soundness of the generated stereotypes.

## 1. Introduction

In recent years, the detection of Hate Speech (HS) and abusive language has gathered significant attention in the field of Natural Language Processing (NLP) [1, 2, 3], becoming a crucial tool for moderating online content and limiting the spread of harmful language. While most research has focused on explicit hate speech, implicit and subtle forms of abusive language remain underexplored [4]. Scholars [5, 6] have noted that state-of-the-art hate speech detection models struggle to identify implicit hate speech and stereotypes. This challenge arises from various factors, including specific linguistic features of HS messages (e.g. irony and metaphors) and their strong dependence on sociocultural context [4]. While some studies focus solely on the classification of content as abusive or non-abusive, others aim to uncover the subtle and implicit stereotypes embedded in such content. Recognizing the complexity of the task, recent approaches leverage external knowledge to enrich prompts in zero and few-shot learning settings, aiming to provide additional context to improve detection and analysis performance. One particularly promising method is graph-based approaches, in which knowledge retrieved from external Knowledge Graphs (KGs) is integrated into LLMs prompts aiming at enhancing the model precision. Given that LLMs often suffer from limited factual accuracy, poor memorization of structured knowledge, and hallucination tendencies [7], KG-based approaches have shown promising results across a variety of tasks [8, 9]. These approaches offer an encouraging strategy to mitigate the inherent limitations of LLMs, integrating them with structured external knowledge while preserving their generative strengths [10, 11]. Building on these premises, we propose a graph-based enrichment methodology aimed at explaining subtle stereotypes embedded in hate speech sentences. First, we design a domain-specific ontology, aligning it with foundational ontologies and existing hate speech-related

resources. We then populate the ontology using a subset of an Italian dataset on implicit stereotypes, which comprises manual annotations on HS targets, hateful chunks and stereotypes. Finally, starting from the target entities in each sentence, we extract relevant knowledge from the KG and integrate it into the prompt of three different LLMs. We task the models with generating the implicit stereotype that underlies each hate speech message. We compare these stereotypes with those generated by a baseline model using a non-KG-enhanced prompt. The main contributions of this work are the following:

- StereoGraph: a Knowledge Graph grounded in a dedicated ontology designed to represent implicit hate expressed in social media posts.
- A graph-based methodology to generate explicit stereotypes encoded in hateful messages.
- A fine-grained manual assessment and error analysis to evaluate the suitability of the evaluation metrics used to compare both the baseline and KG-enhanced outputs against the gold standard. This was particularly relevant given the highly subjective and culturally specific nature of task.

In the following Section (2) we present relevant related works on detection and analysis of subtle hate speech (2.1), together with graph-based approaches (2.2) to the same tasks. Section 3 describes the adopted methodology, the dataset we used for constructing the KG, and the ontology design process. The experimental setup is detailed in Section 4, while the results, including quantitative evaluation, human assessment, and error analysis are discussed in Section 5. Finally, the conclusions and limitations are presented in Sections 6 and 7, respectively. All data and code for reproducibility can be found on the following GitHub page[1].

## 2. Related Works

### 2.1. Subtle Hate Speech Explanation

Unlike explicit hate speech, the interpretation of implicit hate speech often requires inference and integration of background knowledge [12, 13], particularly since hate expressions are usually socio-culturally dependent and rely on contextual knowledge [14]. These factors contribute to the challenge of detecting implicit hate speech and highlight the ongoing need for more sophisticated detection systems, as current state-of-the-art models still struggle to efficiently handle this task [15]. Some studies have attempted to identify subtle hate speech by leveraging different approaches

Several approaches have been explored to identify subtle hate speech, including transformer-based models [16, 17, 18], neural networks [19] or leveraging semantic information embedded in texts [19, 20]. Other approaches tried to tackle this task by incorporating the potentiality of external sources of knowledge, such as Knowledge Graphs [21].

In this context, few studies have directly addressed the challenge of unveiling or explaining subtle hate speech. Some researchers [16, 22] have focused on the role of social stereotypes, aiming to uncover their implicit meanings and to develop benchmarks for explanation-oriented tasks. Other works have specifically addressed the task of implicit hate speech explanation. Kim and colleagues [23] present a pipeline that guides transformer models' predictive decisions through the identification of key rationales. More recent studies have leveraged the generative capabilities of LLMs. For example, Huang and colleagues [24] propose a Chain-of-Explanation prompting method to generate stereotypes. Similarly, Yang et al. [25] introduce step-by-step approach that combines LLM-based chain-of-thought prompting with a human-annotated benchmark.

While several studies have focused on creating benchmarks and providing insights into implicit hate speech in English, resources for the Italian language remain limited, with only a few datasets addressing the hate speech phenomenon in depth. Notable studies [26, 27, 28, 29] have provided valuable annotated resources that distinguish between implicit and explicit hate speech and stereotypes, with the goal of detecting the more subtle and less recognizable nuances of hate. Nevertheless, research on stereotype explication remains limited. For example, Muti and colleagues [30] investigate the ability of LLMs to accurately identify implicit messages in misogynistic contexts, also exploring how prompts can reconstruct subtle meanings to make the messages explicit. However, to our knowledge, no previous work about embedded stereotypes has been carried out in the Italian cultural context. We suggest that the generation of implicit stereotypes can support the development of more comprehensive benchmarks, improving models' performance in detecting subtle forms of hate speech.

### 2.2. Knowledge-Enhanced Approaches

Knowledge-enhanced and Retrieval-Augmented Generation (RAG) methods [31] have emerged as a powerful paradigm to address key limitations of LLMs. More recently, this line of work has incorporated structured, graph-based knowledge, particularly KGs [8], to enhance retrieval and reasoning capabilities.

In the domain of hate speech research, knowledge-enhanced approaches have provided solutions to address the challenges posed by implicit hate speech across vari-

[1] https://github.com/marcocuccarini/StereoGraphUnveilingStereotypes

ous tasks.

Zhao et al. [21] propose MetaTox, a RAG-based approach that integrates a meta-toxic knowledge graph with LLMs for hate speech detection. First, LLMs are used to construct the KG by combining data from three English datasets. Then Qwen and LLaMA3.1 are prompted to classify tweets as toxic or non-toxic. The authors demonstrate that the MetaTox method enables to reduce false positives, leading to better generalization and reduced hallucinations from LLMs. Lin [13] combines Entity Linking techniques with summarized Wikipedia descriptions to improve performances in implicit hate speech detection and classification task. Although it does not follow a standard RAG approach, the paper proposes feeding a Multi-Layer Perceptron with embeddings of concatenated tweet and external knowledge representations, training it to perform a multi-label classification of implicit hate speech types. This approach demonstrated significant improvements when entity triggers were mentioned in text, although limitations remained for the classification of tweets requiring pragmatic understanding.

In the context of implicit hate speech, Yadav et al. [32] introduce Tox-BART, a BART-based architecture enhanced with toxicity attributes, i.e. structured meta-information on tweets, encompassing target groups, insult types, and hate intensity levels. This approach addresses limitations derived from poor quality of retrieved KG tuples, which can hinder KG-augmented approaches. Using different evaluation metrics, they demonstrate that infusion of toxicity attributes achieves performance comparable to simple KG-infusion. In the Italian context, Di Bonaventura and colleagues [33] implemented a knowledge-enhanced approach for detecting homotransphobic hate speech. The system leverages the O-Dang knowledge graph, which contains information about named entities in the Italian HT context. The approach showed promising results, outperforming baseline scores.

Compared to the reviewed literature, our approach represents a step forward, particularly in the area of Italian language hate speech detection. While most prior work has focused on the detection of implicit hate speech, our study shifts the emphasis toward the explanatory capabilities of LLMs, specifically investigating how these can be enhanced through the integration of structured knowledge. Furthermore, by focusing on stereotypes and adopting and hybrid evaluation approach (automatic and human-based), our work also provides valuable insights into the ability of LLMs to uncover sound and coherent stereotypes from implicit language, as well as into the reliability of the evaluation metrics used.

# 3. Methodology

In this work, we aim to perform the task of implicit stereotype generation using LLMs, comparing a baseline approach with a KG-enhanced alternative. Given a sentence and its associated hate speech target, the model is prompted to generate the subtle stereotype that contributes to the message's hateful nature. In the following sections, we briefly present the proposed pipeline (Section 3.1), describe the dataset used (Section 3.2), and outline the construction of the ontology that serves as the foundation for the knowledge graph (Section 3.3).

## 3.1. Pipeline Overview

Our methodology is designed to make subtle stereotypes conveyed in hateful content explicit. This is a particularly challenging task, as it requires nuanced contextual understanding and awareness of culturally specific stereotypes associated with the target. By integrating external knowledge, we investigate whether language models can effectively contextualize such messages and generate more accurate and transparent stereotypes.

The proposed approach is illustrated in Figure 1. Given an input sentence and its associated HS target, retrieved from the annotated dataset, we use the target to query the KG via a SPARQL query, retrieving all triples in which target is linked to its stereotypes. We then adopt a few-shot learning approach, integrating into the prompt the external knowledge retrieved from the KG in RDF format. The evaluation phase consists of a comparison between the results (i.e. generated stereotypes) obtained using the knowledge-enhanced and the baseline approach. A hybrid evaluation was performed comparing automatic metrics with human assessment.

## 3.2. Dataset

To address the task of subtle stereotype generation, we leveraged the Open Stereotype Corpus[2] [34] containing 3,578 Italian tweets collected between October 2018 and June 2019 from the *Contro l'Odio* dataset [35]. The dataset was annotated by five different annotators. For each message, the annotators identified the specific chunk (trigger) containing the hate content, the implicit stereotype (if present) and the stereotype cluster (a more general class aiming at creating a stereotype categorization). In the original dataset the authors automatically distinguished between agent and patient parsing each rationale, we chose to simplify this distinction aggregating the two columns under a unique class named "target". An example of the dataset structure along with a subset of annotations is presented in Figure 3. From the dataset

**Figure 2:** Overview of the dataset annotation structure.

we selected only the messages in which or a stereotype or hate speech was present.

## 3.3. Ontology Design

For the ontology design process we adopted a fully manual approach to ensure the quality of the resulting resource through several means: aligning it with foundational ontologies and related semantic resources, ensuring the conceptual correctness of the defined classes, and minimizing the potential introduction of bias. The ontology includes four top-level classes: `Situation`, `Stereotype`, `Agent`, and `Type`. The class `Situation` is aligned with the homonymous class from the foundational ontology DOLCE [36]. Its purpose is to link a given target and its associated stereotype to a specific occurrence, such as a Twitter post, in order to avoid the introduction of bias or overly generic statements about stereotypes. The class `Stereotype` captures the implicit assertions conveyed in a given sentence. The class `Agent`, aligned with the FOAF (Friend of a Friend) ontology[3], has two subclasses: `Group` and `Person`. These subclasses represent different types of targets and are connected to specific situations via the `hasTarget` relation, which links a message to its corresponding target. The class `Type` is designed to provide a taxonomy for both targets (e.g., racial target, religious target) and stereotypes (e.g., 'are dangerous', 'are unclean'). The ontology was subsequently populated using `SPARQLAnything`[4] [37] leveraging the datasets described in the previous section as data source. After this process we obtained a knowledge graph containing triples as to the followings:

```
ster:_803176483174780929
rdf:type   dul:Situation ;
rdfs:label    "Forza ragazzi, 180mila clandestini all
       anno, rom da tutte le parti, illegalita totale,
       Coop rosse e bianche che lucrano. ora sapete
      cosa votare" ;
dul:hasTarget   ster:immigrati ;
ster:hasStereoManifestation  ster:180mila-clandestini
      -allanno ;
ster:hasStereotype ster:invadendo-italia .

ster:invadendo-italia
        rdf:type      ster:Stereotype ;
        rdfs:label    "invadendo italia" ;
        ster:hasType  "SonoInvasori" .

ster:immigrati  rdf:type  foaf:Group .
```

This means that a specific post, identified by the ID `ster:_803176483174780929`, is an instance of the class `Situation`. It has a specific content, expressed trough the relation `rdfs:label`, and it is associated to a specific stereotype chunk trough the relation `ster:hasStereoManifestation`. The tweet is then associated with a particular target, `ster:immigrati`, as well as a stereotype, `ster:invadendoitalia`. The stereotype is then defined as an instance of the class

[3] http://xmlns.com/foaf/spec/

[4] https://sparql-anything.cc/

`ster:Stereotype` and linked to a specific cluster `SonoInvasori` through the relation `ster:hasType`.

# 4. Experiment Setting

In the next sections, the experimental setting is presented. The following approach consists of three main steps: Knowledge retrieval, where relevant information is retrieved from the KG (Section 4.1); Prompting, where three models are prompted using both a few-shot baseline and a few-shot KG-enriched approach 4.2; and Evaluation (4.3), where the results are assessed using both automatic metrics and manual evaluation.

## 4.1. Knowledge Extraction

For every sentence of the test set we extracted relevant knowledge from the Knowledge graph leveraging the following SPARQL query:

```
SELECT ?s ?stereotype
    WHERE {{
      ?s a dul:Situation ;
         dul:hasTarget <{target_uri}> ;
         ster:hasStereotype ?stereotype .
    }}
```

Using this query we were able to retrieve all the stereotype associated with a certain tweet that has the specified target. For example using "immigrati" as target we are able to extract triples like the followings, in which the first element is the ID, the second the gold stereotype and the third hateful span:

```
ster:_id sono-irregolari clandestini-musulmani
ster:_id non-rispettano-legge nn-amano-subire-le
     -nostre-leggi-sti-migranti
ster:_id spacciano immigrati-spacciatori-e-
     stupratori
```

Since our goal is to prove that this integrated information could improve implicit stereotype generation, we rely on the gold-standard targets provided in the dataset. This avoids the noise introduced by potential errors in target prediction. One limitation encountered is the over-representation of certain targets, which appear with a high number of samples. To reduce the impact of the “lost in the middle” phenomenon [38] and to balance the quantity of information, we randomly sample 20 stereotypes per target.

## 4.2. Prompt Construction

We decided to test three different models `LLaMA-3.1-8B`, `gemma-2-9b-it` [39] and `Mistral-7B-Instruct-v0.2` [40] to explore their ability to understand the subtle stereotype embedded in the message. We selected these three distinct LLMs because they are state-of-the-art, multilingual, open-source models with comparable architecture and medium scale size.

The task is conducted in the Italian language. For the baseline, we used a few-shot learning approach and for the prompt construction we adopt a vanilla structure setup; the prompt is written in Italian. Additionally, it includes instructions on how to structure the output sentence, explicitly asking the models to generate output in the format `[subject] [are/do] [predicate]`. The knowledge-enhanced approach incorporates a prompt containing information about the target entity from the KG. For each target, we associate the relevant retrieved stereotypes. The full prompt is presented in Appendix A. The output produced by the LLM was preprocessed before the evaluation, removing generic elements provided by the LLM, such as the usual formulaic closing statements (e.g., asking if it can assist further).

## 4.3. Evaluation

For the evaluation phase, we leverage BLEU [41], BERTScore [42] and ROUGE [43]. BLEU measures how many n-grams in the generated text appear in the reference text, focusing on precision and penalizing very short outputs. ROUGE focuses on recall, checking how much of the n-grams or sequences of the reference text appear in the generated text, often used for summarization. BERTScore compares the generated and reference texts using deep contextual embeddings from BERT, capturing semantic similarity beyond exact word matches.

Since recent studies [44, 45] have highlighted the limitations of automated evaluation methods and some scholars [46, 47] are beginning to emphasize the potential of hybrid approaches and aware of the fact that stereotypes are characterized by high subjectivity and culture-specific variation, we conducted also a human-based evaluation to better understand the reliability of the metrics used in such contexts. To this end, we designed a twofold manual assessment.

First, aiming at replicating the automatic evaluation, we compared the generated (baseline and KG-enhanced) outputs with the gold standard, assessing semantic and syntactic similarity on a scale from 1 to 5. The annotators were presented with the following questions: (Q1) To what extent, on a scale from 1 to 5, is the baseline output semantically and syntactically comparable to the gold standard? (Q2) To what extent, on a scale from 1 to 5, is the KG-enhanced output semantically and syntactically comparable to the gold standard? Then, aware that stereotypes are not universally shared, and that some are more prevalent or culturally dependent than others [48], we aimed to evaluate the extent to which the generated

| | | | Ann_3 | 4 | 5 | SI |

stereotype might be culturally recognizable from our own perspective as white Italian researchers aged between 25 and 30. The evaluation of generated stereotypes was conducted only on content produced by the baseline model, as the KG-enhanced method provides the model with additional contextually relevant information. Annotators were asked to assess whether, in their own perspective, the generated stereotype reflects commonly held beliefs or societal biases (Q3). For example, the stereotype "gli avvocati pagano i migranti" ("Lawyers pay the migrants") was judged unrealistic by all three annotators. In contrast, "gli immigrati delinquono" ("Immigrants commit crimes") received two positive evaluations out of three, suggesting that this stereotype may reflect a commonly held bias in the Italian context. The human evaluation was conducted by three annotators on a subset of 50 sentences. An example of the conducted manual evaluation is presented in Table 1.

## 5. Results

In the next sections the experiment results are provided. While automated methods are efficient, they often lack precision. In contrast, human evaluation offers greater contextual understanding but is time-consuming and costly. To balance accuracy and efficiency, we applied an automatic method to the full dataset and selected a smaller subset for manual evaluation.

### 5.1. Computer-Based Analysis

In the Table 2 are presented the result of the generation task comparing the three models across the two approaches, i.e. baseline *versus* knowledge graph enhanced. The Results shows that adding the information from KG improves the performance of all three models, LLaMA3.1, gemma2, and Mistral7B, across BLEU, Rouge, and BERT-based scores. Gemma2 benefits the most, with its BLEU score more than doubling and a big gain in Rouge. LLaMA3.1 and Mistral7B also show consistent, though smaller, improvements. The BERT-based scores indicate better semantic relevance with KG. Overall, the KG helps the models produce more accurate and meaningful results.

**Table 2**
Baseline vs KG-enhanced evaluation scores

| Model | Method | BLEU ↑ | ROUGE↑ | BERT-based ↑ |
|---|---|---|---|---|
| **Gemma 2** | Baseline | 0.029 | 0.142 | 0.521 |
| | KG | 0.061 | 0.253 | 0.596 |
| **LLaMA 3.1** | Baseline | 0.071 | 0.264 | 0.571 |
| | KG | 0.076 | 0.298 | 0.618 |
| **Mistral 7B** | Baseline | 0.077 | 0.301 | 0.573 |
| | KG | 0.080 | 0.302 | 0.608 |

### 5.2. Human-based Analysis

The annotators were provided with answers from both the baseline and the KG-enhanced method. Each answer was evaluated on the basis of its similarity to the gold standard, the normalized results are presented in Table 3. Furthermore, for the baseline generation only, annotators were asked to assess whether the stereotypes reflect commonly held beliefs or communal biases. LLaMA 3.1 the highest average scores for both baseline and KG-enhanced outputs, demonstrating strong overall performances. Gemma 2 shows lower results across all metrics, while Mistral7B performs the lowest on both baseline and KG averages. Human evaluation further confirms that incorporating knowledge from the graph improves model performance across all models and annotators. In addition, the variation in annotators' scores highlights the subjective nature of the task and the challenge of achieving consistent judgments. Annotator 2, for example, generally rates outputs higher, particularly for KG-enhanced responses, while Annotator 3 is more critical. Human-evaluated results confirm the trends observed in computer-based scores (for all the models and the annotators the score are higher in the case of the KG-enhanced approach), demonstrating how our method improves the model's ability to explicitly address implicit hate speech and suggesting that automatic measures can be informative for this type of task.

Regarding the assessment of the generated stereotype the human evaluation reveals divergence tendency: LLaMA shows the average highest scores across the three annotators, and the value appears to be high especially according to Annotators 1 and 3. Gemma2 shows a similar tendency, especially regarding the annotators 2 and 3. Finally, Mistral tends to have an overall lower score about the stereotypes soundness, suggesting that it may produce less biased or not realistic content.

## 5.3. Human-based vs Computer-based metric

To better understand the relationship between automatic metrics and human judgment, we compared the results of BLEU, ROUGE and BERT Score with human evaluation over a sample of 50 sentences, as seen in Figure 3. The three plots help identify which metric aligns more closely with human evaluation.

From the plots, it is evident that the BERT Score metric (shown in the third plot) correlates more consistently with the annotators' evaluation, suggesting it is a more reliable indicator of quality for this task. This is due to the nature of BERT score, which leverages contextual embeddings to measure similarity on a semantic level. Conversely, BLEU and ROUGE metrics (depicted in the first and second plots, respectively), which operate more on the lexical-syntactic level, show more variability and several limitations in accurately matching human judgment.

Understanding the relationship between automatic and manual assessment is crucial for contextualizing the values obtained from each metric and evaluating model performance in a meaningful way. The comparison also helps to understand which metrics are more robust and reliable, especially for tasks requiring deep contextual and pragmatic understanding.

## 5.4. Error Analysis

To gain deeper insight into the functionality and limitations of our approach, and to identify areas for potential future improvements, we conducted an error analysis on the tweets where the KG-enhanced method showed the lowest performance. Overall we observed that errors frequently occurred when the input contained named entities or subjects that differed from the primary target. For example, in the tweet:

> Finanzia l'invasione degli immigrati: ecco la prova. La vergogna di George Soros, "padrone" d'Italia.
> English: "He funds the immigrant invasion: here is the proof. The shame of George Soros, the 'master' of Italy."

the KG-enhanced output was: "George Soros finanzia l'invasione degli immigrati" (English: "George Soros funds the immigrant invasion"), while not conceptually incorrect, this differs from the gold standard:"i migranti vogliono invadere l'Italia" (English : "The migrants want to invade Italy."). A similar issue occurred in the tweet:

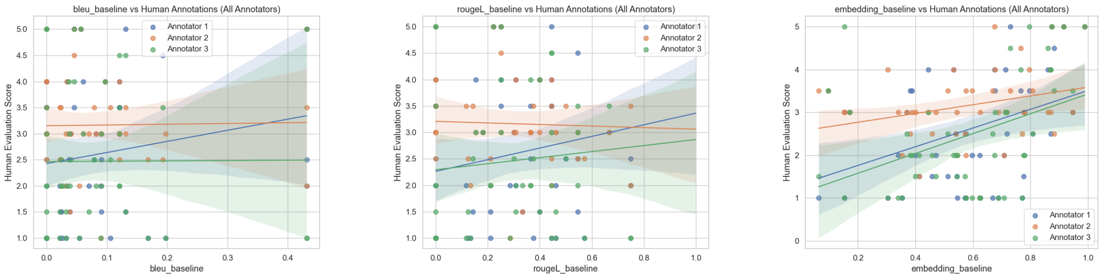
> Che senso ha ministro Trenta rispettare chi non rispetta noi? Che senso ha difendere la loro cultura o presunta cultura quando essi disprezzano la nostra? La ministra Trenta contro Salvini: sbagliato dire che l'Islam è terrorismo
> English: What's the point, minister Trenta, of respecting thos who don't respect us? What's the point of defending their culture or so-called culture when they despise ours? Minister Trenta against Salvini: it's wrong to say that Islam is terrorism"

The KG-enhanced output was "la ministra Trenta disprezza la cultura italiana." (English: Minister Trenta despises Italian culture.) whereas the gold standard was: "i musulmani vanno contro i valori dell'Occidente" (English: Muslims go against Western values). In other cases, when the model encounters a target associated with a high number of stereotypes, it tends to concatenate many of them into a generic and incoherent output.

In some cases, both the baseline and the KG-enhanced approaches struggle to recognize irony and fail to produce a reliable underlying stereotype. For example, consider the following sentence:

> #Dimartedi Stasera indottrinamento pro Europa. Alla bisogna sono benvenuti anche gli stranieri. Bravo #Floris, vai a cager English: #dimartedi tonight: pro-Europe indoctrination. If needed, even foreigners are welcome. Well done #Floris, go to hell.

Both the baseline and the KG-enhanced approaches generate the "gli stranieri sono benvenuti" (English: Immigrants are welcome), failing to detect the subtle irony in the original message.



(a) BLEU scores compared to all annotators

(b) ROUGE-L scores compared to all annotators

(c) BERTScore compared to all annotators

**Figure 3:** Overview of the Italian dataset annotation structure with comparisons of three metrics—BLEU, ROUGE, and BERT Score—against human annotators for the Llame model and the baseline.

**Table 3**
Baseline vs proposed method human-base score. Q1, Q2 and Q3 refer to the three questions presented to the annotators.

| Model | Metric | Annotator 1 | Annotator 2 | Annotator 3 |
|---|---|---|---|---|
| Gemma 2 | (Q1) Baseline Average | 0.291 | 0.444 | 0.327 |
| | (Q2) KG Average | 0.378 | 0.561 | 0.362 |
| | (Q3) Stereotype % | 0.396 | 0.449 | 0.673 |
| LLaMA 3.1 | (Q1) Baseline Average | 0.332 | 0.434 | 0.332 |
| | (Q2) KG Average | 0.469 | 0.648 | 0.411 |
| | (Q3) Stereotype % | 0.588 | 0.469 | 0.673 |
| Mistral 7B | (Q1) Baseline Average | 0.270 | 0.316 | 0.321 |
| | (Q2) KG Average | 0.357 | 0.622 | 0.449 |
| | (Q3) Stereotype % | 0.367 | 0.286 | 0.449 |

Finally, we observed challenges in tweets with complex hypotactic structures and multiple subjects. In such cases, models often fail to correctly identify the primary target and to produce relevant output. Furthermore, the KG-enhanced method tends to generate overly long responses in these situations, which can reduce the coherence and precision of the generated content. In summary, the worst-performing examples often occur because the model misidentifies the target of the hate tweet, leading to reduced accuracy. However, in many cases, the model still manages to extract a correct implicit message, which, while different from the gold standard, is present in the tweet. In such cases, the prediction is valid, but the reference annotation fails to recognize it as correct.

## 6. Conclusion

In this work, we aim to investigate whether large language models are able to uncover implicit stereotypes embedded in hate speech messages. This task is important as it helps uncover the subtle content of hate speech messages and supports hate speech detection models in identifying abusive language. Specifically, we explore the role that additional information from a knowledge graph may play in the understanding and generation of underlying stereotypes. We compare a baseline few-shot approach with a knowledge-enhanced method, leveraging different LLMs. We observed that prompts enhanced with additional information outperformed the baseline approach. To better assess the reliability of the automatic evaluation metrics, we also conducted a manual evaluation, replicating the task performed by the automatic metrics. The human evaluation confirmed the results, showing higher scores for the knowledge graph-enhanced approach. While the manual assessment was aligned with the automated results, we observed a high degree of variability in the scores. This suggests that evaluating such generated content is inherently subjective and can vary based on the annotators' culture, age, or beliefs. These findings highlight the importance of contextualizing evaluation metrics and recognizing that they may carry biases or oversimplify complex phenomena. From the error analysis, we observed that the KG-enhanced approach occasionally struggles to manage the quantity of information provided, suggesting that further studies are needed to better understand the extent to which such models can effectively integrate additional knowledge.

To sum up, the findings of this research suggest that knowledge graph-based approaches are highly promising, even in the hate speech domain, where they remain largely underexplored.

## 7. Limitation and Future Work

In this work we focused on the integration of stereotypes, retrieving targets from the gold standard. This allows us to concentrate the analysis on the knowledge insertion process within the LLM, minimizing the introduction of noise. As future work, we intend to test the approach using a state-of-the-art target detection model. Although this may introduce errors due to target misclassifications, it would enable full autonomy for the proposed method and enhance its applicability in real-world scenarios. Target detection methods can also return multiple potential targets in cases of uncertainty, providing a fuller stereotype context for posts that may involve more than one target. While we noticed that different stereotypes are associated to the same target, as a future work we may consider an approach based on semantic similarity to select the most contextually relevant stereotypes. This approach could offer a more focused context for the prompt and reduce the likelihood of model misunderstandings. During the error analysis phase, we identified errors potentially caused by the 'lost-in-the-middle' phenomenon. Future work should explore in greater depth how models manage different quantities of input information. Finally, it is important to highlight that the manual evaluation we conducted—particularly regarding the cultural shareability of the generated stereotypes, is inherently biased and reflects the perspectives of the researchers involved in this study. As future work, it would be interesting to carry out a large-scale, prospectivist survey to explore the diversity of opinions on stereotypes and to investigate the dominant worldview conveyed by different large language models.

## Ethical Considerations

We acknowledge that when dealing with hate speech, particularly stereotypes targeting minorities, it is essential to be mindful of the potential of introducing bias or unintentionally amplifying hateful content. We made efforts to control and reduce the presence of bias and to remain aware of its potential introduction. During the experimental phase, we prompted LLMs to generate implied stereotypes, which in some cases resulted in the generation of hateful or offensive content. The generated hateful content is intended solely to remain within the context of this experimental research. Its occurrence also provides additional insights into how LLMs can produce harmful language despite safety filters.

# Detecting Semantic Reuse in Ancient Greek Literature: A Computational Approach.

Caterina D’Angelo[1, *], Andrea Taddei[1] , and Alessandro Lenci[1,]

[1] Università di Pisa, Lungarno Pacinotti 43, 56126 Pisa, Italy

## Abstract

This paper introduces the first step towards a computational method for detecting semantic textual reuse in Ancient Greek literature. While existing tools focus primarily on exact or near-lexical matching, our approach leverages the semantic capabilities of contextual LLMs, aiming to finetune a pretrained encoder via contrastive learning to recognize textual reuse even when expressions are paraphrased and/or morphologically altered.

To build a suitable dataset, we developed an automatic pipeline that generates positive samples by extracting paraphrases for each sentence using the Ancient Greek Wordnet and a custom-trained morphological re-inflection model. Negative samples, or “confounders”, are selected through topic modeling to ensure thematic relevance while preserving semantic dissimilarity.

The model is evaluated through a curated case study on Homeric formulae. We retrieve the top ten most similar sentences in a corpus of Ancient Greek authors from the classical age, assessing model outputs using both standard metrics and comparison with established philological studies. The outcomes demonstrate that contrastive fine-tuning, paired with linguistically informed data augmentation, offers promising directions for identifying non-literal textual reuse in historical corpora. This work contributes a framework for philological discovery, combining deep learning with interpretive scholarship in classical studies.

## Keywords

Ancient Greek, intertextuality, contrastive learning, paraphrase generation, topic modeling, morphological inflection, synonyms extraction, computational philology.

## 1. Introduction

Reuse and, more generally, intertextuality have always been peculiar lens through which literary works can be analyzed. It has been the focus of literary critics and philologists such as Gerard Genette (Genette, 1982), Julia Kristeva (Kristeva, 1986), Roland Barthes (Barthes, 1975) and Michael Riffaterre (Riffaterre, 1978) to establish the importance of intertextual allusions as well as “word by word” quotations, with structuralist thinking going as far as to say that «*Intertextuality is…. The mechanism specific to literary reading. It alone, in fact, produces significance, while linear reading, common to literary and nonliterary texts, produces only meaning.* (Genette, 1982, p. 18)». With the present work, our aim is to build a computational tool that can aid in the complex task of identifying instances of re-use in Ancient Greek texts. We start from the definition that Gerard Genette gives us of intertextuality, focusing on its less literal guise: «*it is the traditional practice of quoting […] in a still less explicit and less literal guise, it is the practice of allusion* (Genette, 1982, p. 18).». In the following paper we focus specifically on semantic

reuse by developing methods to detect semantic connections that may indicate shared themes, motifs, or conceptual relationships between texts. Our approach represents a foundational step toward the broader goal of computational intertextuality detection, providing scholars with a tool to identify semantically related passages that merit further philological investigation.

## 1.1. Related Works

Existing computational tools for reuse detection in classical languages are primarily based on lexical similarity. Among them, the most prominent is the **Tesserae project** (Coffee, et al., 2013), which identifies parallels in Latin and Ancient Greek texts by combining lexical overlap with phonetic and thematic similarity, the latter through topic modeling algorithms. Nonetheless, such thematic similarity does not imply intentional intertextuality, which involves the conscious use of another author's language or ideas.

Another widely used tool is **Diogenes**[3], a desktop application that enables exact lexical searches across a large corpus of classical texts.

Another significant tool in this domain is **TRACER** (Büchler et al., 2014), a flexible framework for automatic detection of text reuse that supports multiple similarity measures.

Despite their usefulness, these systems are focused on surface-level matches and fail to capture semantic paraphrases or allusive reuse.

To detect such deeper forms of intertextuality, recent approaches have turned to distributional semantics. A key challenge, however, is the scarcity of annotated and homogeneous corpora in ancient languages, which makes training large language models (LLMs) difficult (Moritz, Wiederhold, Pavlek, Bizzoni, & Buchler, 2016).

A seminal contribution in this direction is (Burns, Brofos, Li, Chaudhuri, & Dexter, 2021) who uses **Word2Vec** embeddings to measure the semantic similarity between Latin bigrams. Their method computes pairwise cosine similarities between words and averages the results. Although effective, they acknowledge the limitations of static embeddings and propose that contextual embeddings (e.g., BERT-based models) may offer better nuance and generalization.

The paper by Burns et al. also frames intertextuality as a form of anomaly detection, using the embeddings created with the corpus of a specific author (in this case Livy) as input for a **SVM**: with this model, the goal is to predict the "Livianess" of each work, so as to find instances in which the authors have alluded to Livy's works.

Following the parallel between intertextuality and anomaly detection, similar methods have been explored in the context of authorship attribution. In (Yamschikov, Tikhonov, Pantis, Schubert, & Jurgen, 2022) the authors aim to obtain contextual embeddings for Ancient Greek by leveraging transfer learning. Starting from pre-trained models, they fine-tune both a multilingual transformer and one trained on Modern Greek, adapting them to downstream tasks in Ancient Greek.

While this approach demonstrates the feasibility of adapting general-purpose models to low-resource historical languages, it suffers from the limitations of using a tokenizer and vocabulary not optimized for Ancient Greek.

A common obstacle encountered in our research pertains the shortage of digitized Ancient Greek texts. The main source would be the *Thesaurus Linguae Grecae*[4], but its policy is against using the data for machine learning purposes.

Nonetheless, the work by (Yamschikov, Tikhonov, Pantis, Schubert, & Jurgen, 2022) inspired our own application of transfer learning, allowing us to make efficient use of limited annotated data while focusing on semantic reuse detection.

A similar strategy is adopted by (Riemenschneider & Frank, 2023), who leverage pre-trained language models to detect intertextual allusions in a multilingual setting, analyzing sentence-level correspondences across Ancient Greek, Latin, and English. Although their focus lies primarily on cross-lingual reuse, their work further confirms the potential of contextual models in identifying non-literal textual relationships.

## 1.2. Contributions

This paper makes the following contributions:

- We propose an automated pipeline for generating paraphrases of Ancient Greek sentences, combining resources such as the Ancient Greek WordNet with a custom-trained morphological re-inflection model based on annotated Ancient Greek data.
- We conduct a qualitative assessment of different contextual encoders for

[3] https://d.iogen.es/web/?ver=1.003&user=stud

[4] https://stephanus.tlg.uci.edu/

Ancient Greek, tested on a synonym selection task.

- We introduce a method for automatically generating hard negative samples: sentences with high lexical overlap but low semantic relatedness.
- We fine-tune a domain-specific pretrained language model to capture non-lexical, semantic forms of textual reuse in Ancient Greek literature.
- We evaluate our approach on a curated case study of Homeric formulae, assessing semantic reuse in classical Greek authors through both retrieval metrics and philological validation.

## 2. Method

To fine-tune a model for semantic reuse detection in Ancient Greek, we first selected a suitable encoder.

We then constructed a contrastive dataset consisting of 11,305 triplets, each composed of a query sentence, a positive sample (paraphrase), and a negative sample (confounder). The query sentences were randomly extracted from a subcorpus of works by Homer, Thucydides, and Herodotus, taken from the *Opera Graeca Adnotata*. Positive and negative samples were generated automatically through the paraphrase and confounder generation pipeline described in Sections 2.1 and 2.2.

### 2.1. Model Selection

Although Ancient Greek remains a low-resource language, recent years have seen the development of several contextual language models tailored to its linguistic properties. For our task, the encoder must be able to encode semantic contextual information, particularly the similarity between lexically and morphologically varied expressions.

To evaluate model performance in capturing semantic relationships, we designed a synonym retrieval task, which will be described in detail in Section 2.2.

The models considered include:

- **Logion** (Cowen-Breen, Brooks, Haubold, & Graziosi, 2023): A BERT-based architecture pre-trained on modern Greek and fine-tuned on Ancient Greek texts from *First1KGreek*[5], *Perseus Digital Library*[6] and data obtained from fellow scholars. The training corpus comprises approximately 70 million words. In its 50K version, a WordPiece tokenizer was trained on the same corpus, resulting in a vocabulary of 50,000 subword units tailored to Ancient Greek.
- **GreBERTA** (Riemenschneider & Frank, Exploring Large Language Models for Classical Philology, 2023): A RoBERTa-style encoder with dynamic masking, trained on a composite corpus including the *Open Greek and Latin Project*[7] (30M tokens), the *CLARIN Greek Medieval corpus*[8] (3.3M), the *Patrologia Graeca*[9] (28.5M), and the Ancient Greek texts contained in the *Internet Archive*[10] (123.3M). Despite its size, the latter source contains substantial noise and inconsistencies.
- **Word2Vec**: A non-contextual baseline model, included for comparison.

As will be further explained in section 2.2, lemmatization was necessary for synonym extraction. We therefore compared the two main lemmatization libraries available for Ancient Greek: **CLTK**[11] and **greCy**[12].

Table 1 reports the top predicted synonym for the word βαίνω (whose meaning in the context of the selected sentence is “to go up”) across all model and lemmatizer combinations. A broader comparison covering multiple lexical entries is available in the appendix.

**Table 1**
Top predicted synonyms for the word βαίνω

[5] https://opengreekandlatin.github.io/First1KGreek/
[6] https://www.perseus.tufts.edu/hopper/
[7] https://opengreekandlatin.org/.
[8] https://inventory.clarin.gr/corpus/890.
[9] https://patristica.net/graeca/.
[10] https://archive.org/.
[11] http://cltk.org/
[12] https://github.com/jmyerston/greCy

| Predicted synonym | Model and lemmatization | Meaning | Similarity Score |
|---|---|---|---|
| διαβαίνω | Logion 50K with CLTK | “To go up” | 0.34 |
| διαβαίνω | Logion 50k with greCy | “To go up” | 0.31 |
| στείχω | Logion BASE with CLTK | “To go” | 0.48 |
| στείχω | Logion BASE with greCy | “To go” | 0.45 |
| στείχω | GreBerta with CLTK | “To go” | 0.42 |
| στείχω | GreBerta with greCy | “To go” | 0.42 |
| διαβαίνω | Word2Vec with CLTK | “To go up” | 0.89 |
| διαβαίνω | Word2Vec with greCy | “To go up” | 0.89 |

We didn’t consider the model described in (Pranaydeep, Rutten, & Lefever, 2021) since the ***Logion*** models are initialized with the same weights and increase the size of the finetuning corpus.

The following example illustrates the full paraphrase generation process, including synonym substitution and morphological re-inflection.

**Table 2**
Example of the paraphrase generation process

| Version | Greek sentence | Translation |
|---|---|---|
| Original | είς ταύτην οὖν τὴν **ἀκτὴν** ἐξ Ἀβύδου **ὁρμώμενοι** ἐγεφύρουν τοῖς προσέκειτο | Towards this shore,<br>then, starting from<br>Abido, they built a bridge,<br>those who had been<br>assigned the task. |
| Paraphrased | είς ταύτην οὖν τὴν **ἄκραν** ἐξ Ἀβύδου **ἐξιστάμενοι** ἐγεφύρουν τοῖς προσέκειτο | Towards this end,<br>then, moving away from<br>Abido, they built a bridge<br>those who had been assigned the task. |

## 2.2 Positive Samples

Since the objective of our model is to detect semantic reuse, positive samples must exemplify cases of non-literal reuse. For this purpose, we developed an automated pipeline for paraphrase generation through targeted lexical substitution, following data augmentation techniques such as those described in (Bayer, Kaufhold, & Reuter, 2022).

Specifically, we focused on substituting semantically salient tokens—nouns, verbs, and adjectives—with suitable synonyms. To identify these, we combined lexical information from the Ancient Greek WordNet (Bizzoni, et al., 2014) with semantic similarity estimates derived from contextual embeddings.

For each semantically relevant word in a sentence, we queried the WordNet to retrieve its synsets (i.e., sets of synonyms grouped by sense). For each offset (individual sense), we collected a candidate list of synonyms. We then computed the cosine similarity between the contextual embedding of the original word and four contextual embeddings of each synonym, obtained by extracting four different sentence contexts in which that synonym appears. The sentences were extracted from the corpus *Lemmatized Ancient Greek Texts*[13] by Giuseppe Antonio Celano.

This method allowed us to select the most semantically coherent synonym among candidates, accounting for the high degree of polysemy in Ancient Greek vocabulary.

### 2.1.1. Re-inflection Model

As mentioned above, the synonym selection pipeline outputs the lemma of the best synonym. However, to generate a valid paraphrase within the Ancient Greek sentence, it is necessary to re-inflect the selected lemma according to the morphological features of the word it replaces.

To this end, we developed a morphological re-inflection model, which takes as input the lemma and a set of morphological features (e.g., case, number, tense) and returns the inflected form.

The model was trained on a corpus constructed by merging and normalizing data from multiple resources:

- ***SIGMORPHON 2023 – UniMorph Shared Task***[14]: 5,572 inflected forms annotated with morphosyntactic features.

[13] https://github.com/gcelano/LemmatizedAncientGreekXML
[14] https://github.com/sigmorphon/2023InflectionST

- ***Perseus Project***: A dataset of 1,290,544 linguistically annotated forms originally produced by the Morpheus parser and generator of Ancient Greek inflected forms (Crane, 1991).

- ***Opera Graeca Adnotata***[15] (Celano, 2024): A morphologically annotated corpus curated by G. A. Celano, from which we extracted 589,105 forms.

After removing defective entries and applying standard normalization procedures (e.g., Unicode harmonization, feature unification), we trained a sequence-to-sequence model composed of an LSTM layer, a dropout layer, and a Bidirectional LSTM decoder. This architecture was chosen for its balance between simplicity and effectiveness in character-level morphological generation tasks.

## 2.2. Negative Samples

To create negative samples for the contrastive learning task we introduced the notion of lexical confounders: these are sentences that share semantically relevant words with the target sentence but express a different meaning. This technique allows us to create "hard negatives", capable of aiding the model in identifying sentences with no lexical overlap but semantically similar, teaching it to disentangle lexical similarity from semantic equivalence.

To automatically select these confounders, we applied topic modeling with the goal of identifying sentences that differ in thematic content. The underlying assumption is that sentences on distinct topics are unlikely to convey the same meaning, even if they share lexically similar elements.

The topic modeling process was carried out on the *Opera Graeca Adnotata* corpus, leveraging lemmatized tokens to improve generalization. We first applied the **Hierarchical Dirichlet Process (HDP)** to estimate the optimal number of latent topics (resulting in k = 10), and then trained a **Latent Dirichlet Allocation (LDA)** model accordingly. The resulting LDA model achieved an average UMass topic coherence score of −0.68, indicating a moderate level of interpretability suitable for the identification of semantically distinct negative samples.

# 3. Results

In this section, we present the results obtained from the evaluation of the two main components of our pipeline: the re-inflection model and the contrastive sentence encoder.

## 3.1. Re-inflection Model Evaluation

To generate grammatically coherent paraphrases, we trained a sequence-to-sequence model to perform morphological inflection from lemma + features to surface form. The architecture consists of a single-layer LSTM followed by dropout and a bidirectional LSTM.

The model was trained for a maximum of 120 epochs with early stopping (patience = 10), halting at epoch 77. We used the Adam optimizer with a learning rate of 0.001.

The learning curves of accuracy and loss for the training and validation set can be seen in Figure 1 and Figure 2.

The model reached 0.90 accuracy on both the validation and test set. While performance on frequent forms is consistent, rare accented forms remain problematic. For instance, characters such as "ἵ" and "ὕ", which appear only 398 and 48 times respectively in the validation set, obtained F1-scores as low as 0.39 and 0.21. This imbalance affects the macro average, which is significantly lower than the weighted average, as shown in Table 3 (test set results).

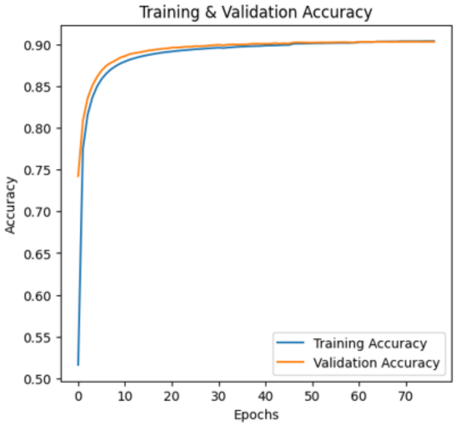

**Figure 1:** Training and Validation curves for loss over 77 epochs for the re-inflection model.

[15] https://github.com/OperaGraecaAdnotata/OGA

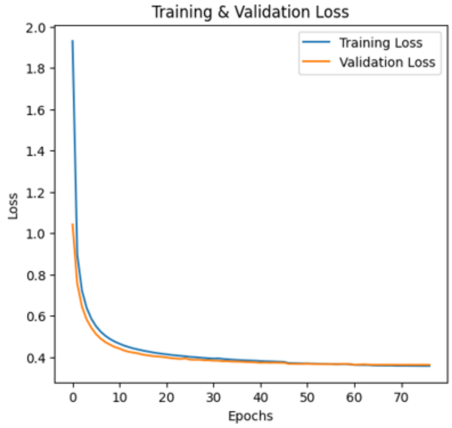

**Figure 2:** Training and Validation curves for accuracy over 77 epochs for the re-inflection model.

**Table 3**
Test set metrics for re-inflection model.

| | Precision | Recall | F1-score |
|---|---|---|---|
| **Accuracy** | | | 0.90 |
| **Macro avg** | 0.62 | 0.52 | 0.54 |
| **Weighted avg** | 0.90 | 0.90 | 0.90 |

Nonetheless, performance on frequent cases is sufficient to support the generation of realistic paraphrastic samples.

## 3.2. Contrastive Model Evaluation

To fine-tune the Logion 50k model, we used the HuggingFace SentenceTransformers library, representing each sentence with its [CLS] embedding. The model was trained for 7 epochs, reaching its optimal performance at epoch 6.18. We used the AdamW optimizer with a learning rate of 5e-6 and a weight decay of 0.01.

The contrastive dataset was split into 80% training, 10% validation, and 10% testing, with sentence triplets shuffled prior to the split to ensure distributional uniformity across subsets.

Figures 3 and 4 illustrate the training and validation curves for loss and accuracy, showing a stable convergence pattern.

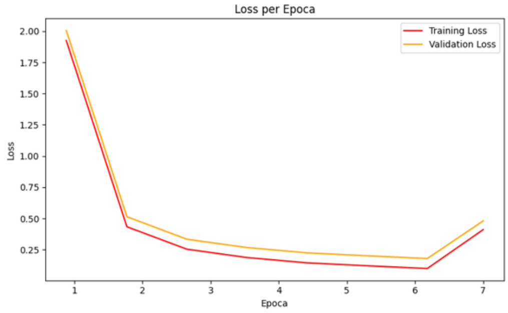

**Figure 3:** Training and Validation curves for loss over 7 epochs for the contrastive model.

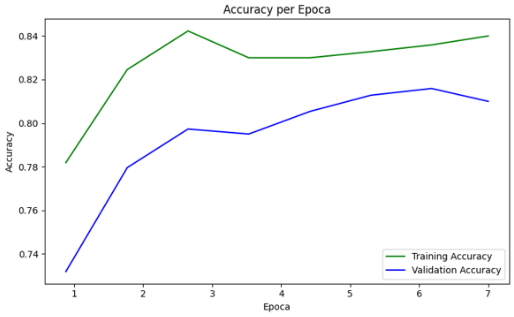

**Figure 4:** Training and Validation curves for accuracy over 7 epochs for the contrastive model.

The final accuracy on the test set is 0.81, marking a notable improvement over earlier experiments. In a preliminary run using only 5,000 triplets, the model reached an accuracy of 0.71, highlighting its sensitivity to the amount of training data.

Due to the computational complexity of the pipeline used to generate positive and negative samples, we limited the dataset to ~11,000 triplets. However, we hypothesize that a larger dataset—enabled by scaling the paraphrasis and confounder generation—would likely lead to further performance improvements. The model shows strong generalization capabilities despite the relatively limited dataset size.

## 3.3. Case Study: Homeric Formulae

To evaluate the model's ability to detect semantic reuse, we selected Homeric formulas from the *Odyssey* and retrieved their most similar counterparts from the prose corpora of Herodotus and Thucydides using cosine similarity.

We first performed a general comparison by encoding all sentences from Homer, Herodotus, and Thucydides. For each Homeric sentence, we computed the most similar sentence from both historians. Figure 5 reports how often the most similar match came from each author. Herodotus consistently emerged as the “most Homeric” in style.

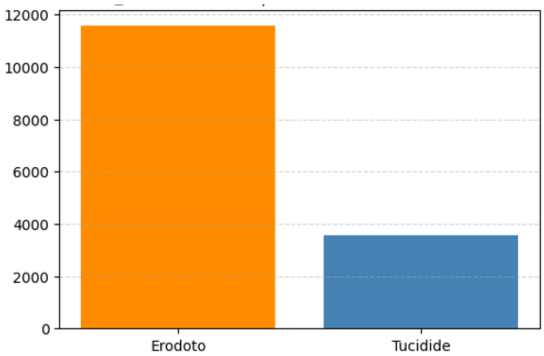

**Figure 5:** Bar chart showing the number of sentences from Thucydides and Herodotus most similar to Homeric sentences based on cosine similarity.

We then zoom in on the top matches for a handful of Homeric formulas. Table 4 reports the top-3 most similar matches (with cosine similarity) from Herodotus and Thucydides.

In Herodotus, the top match for “ἄσμενοι ἐκ θανάτοιο, φίλους ὀλέσαντες ἑταίρους” (“Glad to have escaped death, having lost dear companions”) is: κομισθεὶς ἄρα ἐς τὰς Ἀθήνας ἀπήγγελλε τὸ πάθος (V.87) “Back in Athens, he reported the terrible news.” (CosSim: 0.73)

Though the sentences are lexically unrelated, the narrative context aligns: both recount survival from disaster followed by the emotional burden of reporting it. In the Herodotean passage, the warrior coming home is the only survivor: he, too, has “lost dear companions”. The model appears to capture these semantic and narrative parallels, ignoring surface forms.

On the other hand, the matching Thucydidean phrase “καὶ τροπαῖον στήσαντες ἀνεχώρησαν ἐς τὸ Ῥήγιον” (IV.25) refers to a commemorated but marginal victory: as noted by (Graves, 1884), the use of fixed epic-like expressions for minimal accomplishments may reflect a form of ironic intertextuality.

**Table 4**
Top 3 most similar matches for the sentence “ἄσμενοι ἐκ θανάτοιο, φίλους ὀλέσαντες ἑταίρους” (Od. X.134) (“Glad to have escaped death, having lost dear companions”) in Thucydides and Herodotus.

| Herodotus | Thucydides |
|---|---|
| κομισθεὶς ἄρα ἐς τὰς Ἀθήνας ἀπήγγελλε τὸ πάθος<br>Transl: Back in Athens, he reported the terrible news.<br>Sim: 0.74 | καὶ τροπαῖον στήσαντες ἀνεχώρησαν ἐς τὸ Ῥήγιον.<br>Transl: Erecting a trophy, they withdrew to Reggio.<br>Sim: 0.74 |
| (οὔ τε γὰρ ὕπεστι οἰκήματα ὑπὸ γῆν...)<br>Transl: There are no underground dwellings, nor does any canal from the Nile reach it...<br>Sim: 0.73 | ού γὰρ ἠγγέλθη αὐτοῖς ὅτι τεθνηκότες εἶεν.<br>Transl: They had not been told that they were dead.<br>Sim: 0.73 |
| νῦν τε ὅδε ἐστί.<br>Transl: And here it is now.<br>Sim: 0.72 | πολέμιος οὖν ἦν.<br>Transl He was therefore an enemy.<br>Sim: 0.73 |

Across both historians, the model demonstrates sensitivity to semantic and narrative similarities even in absence of direct verbal overlap. This reinforces the notion that the contrastive objective, paired with linguistically-informed data, enables detection of non-literal textual reuse. Herodotus tends to reuse Homeric motifs to elevate the narrative or align with epic tradition, while Thucydides may repurpose similar forms to subvert or problematize epic conventions.

## 4. Discussion

The results of our evaluation show that the proposed model is capable of identifying semantic similarity in Ancient Greek texts with a significant degree of accuracy. The performance of the contrastive model—reaching 0.81 accuracy on the test set—suggests that even with a relatively limited dataset, it is possible to fine-tune contextual embeddings for a low-resource language such as Ancient Greek.

Importantly, our qualitative case study demonstrates that the model does not rely solely on lexical overlap, but is able to capture semantic connections grounded in context. This capability is particularly relevant for supporting scholarly analysis of textual relationships, where surface variation and thematic connections require careful interpretation.

Our analysis of Herodotus' proximity to Homer in the similarity distributions aligns with established literary hypotheses about thematic continuity and shared motifs between these authors. However, it is important to note that the semantic similarities detected by our model represent connections that merit further philological investigation rather than definitive instances of literary allusion. The distinction between shared themes, common literary topoi, and intentional intertextual references requires expert scholarly judgment that goes beyond computational analysis.

The matches found in Thucydides, while semantically related to Homeric passages, illustrate this distinction clearly: while our model identifies thematic connections, determining whether these represent ironic reuse, coincidental similarity, or genuine allusion requires deeper interpretive knowledge of the historical and literary context. The contrastive learning objective appears well-suited to identifying such semantic connections as potential candidates for scholarly investigation.

## 5. Limitations

Our approach faces several important limitations that should be acknowledged:

- Methodological limitations: The generation of paraphrastic and confounding samples, while linguistically motivated, is computationally expensive and depends on the quality of available lexical resources. The method relies heavily on the accuracy of synonym lists from Ancient Greek WordNet and morphological re-inflection models.
- Evaluation constraints: Our evaluation remains primarily qualitative and impressionistic. A more rigorous assessment would require comparison with known allusions identified in scholarly literature, which represents a significant challenge for future work.
- Scope of detection: Our model identifies semantic similarities and thematic connections, but cannot distinguish between coincidental similarity, shared literary tradition, and intentional allusion. This distinction requires expert philological knowledge and cultural context that computational methods cannot currently provide.
- Dataset limitations: The relatively small dataset limits the model's generalizability, and further work is needed to expand coverage across different genres, time periods, and authors to explore cross-genre or diachronic reuse phenomena.

These limitations do not invalidate our approach but rather define its appropriate scope: as a tool for identifying semantically related passages that warrant scholarly attention, rather than as an autonomous detector of literary allusions.

## 6. Conclusion and Future Work

This paper presented a novel approach to the detection of semantic reuse in Ancient Greek literature through the use of contrastive learning and contextual language models. We developed a pipeline for generating paraphrastic sentence pairs and lexically confounding negatives, enabling the fine-tuning of an encoder model specifically trained for Ancient Greek.

Our method demonstrates the feasibility of identifying thematic connections and semantic relationships in ancient texts, providing a foundation for future work in computational intertextuality detection.

While promising, this system is not meant to replace human judgment. In many cases, interpretation requires close reading and contextual insight that go beyond the scope of automated retrieval. Rather, our model should be seen as an exploratory aid, offering novel perspectives and candidate matches for scholarly validation.

Looking ahead, our goal is to scale the dataset by including larger portions of Herodotean, Thucydidean, and Homeric corpora, and to refine the model further through application to other authors and genres. In particular, we aim to focus on specific thematic domains such as the lexicon of the sacred. Future work should also include more rigorous evaluation against annotated corpora of known literary allusions identified in scholarly literature as well as an evaluation of the paraphrases and confounders by scholarly experts,

Ultimately, this study shows that the intersection of artificial intelligence and philology is not only feasible, but capable of generating innovative and promising contributions to the study of ancient textual reuse.

## 7. Acknowledgements

We thank Federico Boschetti for sharing annotated corpora and the Ancient Greek WordNet, Sebastian Padò for his contribution to the initial phases of this work, and Barbara Graziosi for her kind willingness to discuss the use of large language models for Ancient Greek.

The implementation code is available from the corresponding author.

## Abstract

Check-worthiness estimation is the first and a paramount task in the automated fact-checking pipeline. It allows professional fact-checkers to cope with the increasing amount of mis/disinformative textual content being published online by prioritizing claims that are factual/verifiable and worthy of verification. Despite the long tradition of check-worthiness estimation in NLP, there is currently a lack of annotated resources and associated methods for Italian. Moreover, current datasets typically cover a single topic and focus on a limited time frame, affecting models' generalizability on out-of-distribution data. To fill these gaps, in this paper we introduce WorthIt, the first annotated dataset for factuality/verifiability and check-worthiness estimation of Italian social media posts that covers public discourse on migration, climate change, and public health issues across a large time period of six years. We describe the dataset creation in detail and conduct thorough experimentation with the WorthIt dataset using a wide array of encoder- and decoder-based models. Our results show that fine-tuning monolingual encoder-based models in a multi-task setting provides the best overall performance and that decoder-based models in a few-shot setup still struggle in capturing the relation between factuality/verifiability and check-worthiness. We release our dataset, code, and associated materials to the research community.

## Keywords

Automated fact-checking, check-worthiness estimation, factual/verifiable claim detection, resources and evaluation

## 1. Introduction

Given the unprecedented amount of mis/disinformation spreading online, assisting fact-checkers in their everyday work by automatizing some of their tasks is becoming of paramount importance. The identification of content that is worthy of verification – i.e., *check-worthiness estimation*, also referred to as *check-worthy claim detection* – represents the first stage in the fact-checking pipeline [1] insofar as it allows professional fact-checkers to reduce the screening efforts of content that is not worth of attention, therefore focusing on the verification of potentially false or misleading information.

According to Nakov et al. [2], a claim is deemed check-worthy and calls for the attention of a fact-checker if it "is likely to be false, is of public interest, and/or appears to be harmful", also being not "easy to fact-check by a layperson" (e.g., "The capital of Italy is Rome"). A check-worthy claim is both *factual* and *verifiable* [2, 3], i.e., it presents an "assertion about the world that is checkable" [4], namely it "state[s] a definition, mention[s] a quantity in the present or in the past, make[s] a verifiable prediction of the future, reference[s] laws, procedures, and rules of operation, discuss[es] images or videos, [or] state[s] correlation or causation" [2]. In other words, if a claim is factual and verifiable, it is possible to determine its check-worthiness based on whether it is relevant and may potentially have a broader impact on the general public [5] (see examples in Figure 1).

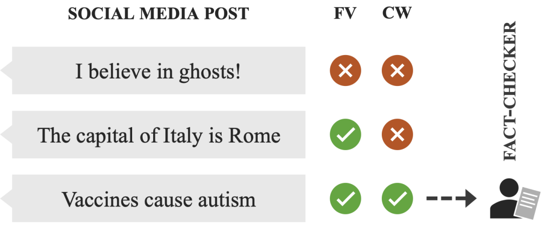

**Figure 1:** Example of social media posts classified according to their factuality/verifiability (FV) and check-worthiness (CW) and their relation to the verification process by a fact-checker.

Check-worthy claim detection[1] has become a well-established task in NLP since the introduction of the first CheckThat! evaluation campaign [6]. However, despite the progress and the coverage of multiple languages in the past CheckThat! editions, no dataset or task for check-worthiness estimation specifically for the Italian language has been considered so far. Moreover, current

The repository is publicly available on GitHub at: https://github.com/dhfbk/worthit.

[1] In this paper, we refer to the task as "check-worthy claim detection" or "check-worthiness estimation" interchangeably.

datasets for check-worthiness estimation in other languages mostly focus on COVID-19 issues and consist of posts that were drawn from a relatively small time period (e.g., one year and three months [2]), affecting out-of-distribution generalization of models [7].

**Contributions** In this paper, we address the aforementioned gaps by developing WorthIt, the first annotated dataset for factuality/verifiability and check-worthiness estimation for Italian, and by conducting extensive experiments with encoder- and decoder-based models. WorthIt covers public discourse from Twitter on migration, climate change, and public health issues over a large time frame of six years. The full dataset was annotated by two expert annotators which discussed the cases of disagreement to resolve annotation errors (e.g., due to attention drops) while keeping genuine annotation divergences (e.g., due to different interpretations), in line with recent work advocating the importance of considering human label variation in subjective tasks [8, 9, 10, 11, 12, *inter alia*]. We fine-tune a wide array of monolingual and multilingual encoder-based models in single- and multi-task learning settings, and experiment with four decoder-based models that include Italian in pretraining data in a few-shot setup after a careful selection of representative examples. Results show that multi-task fine-tuning of encoder-based models provides the best performance, and that decoder-based models – with or without annotation guidelines in the prompt, either in Italian or English – still struggle in tackling the task effectively, even when provided with information about the factuality/verifiability of the post.

## 2. Related Work

Check-worthy claim detection is a popular task within the NLP community mostly thanks to the series of CheckThat! shared tasks organized by the CLEF initiative.[2] Indeed, check-worthy claim detection is the only task that has been proposed at all seven CheckThat! editions [6, 13, 14, 15, 2, 16, 17]. Several datasets for training check-worthiness estimation models in different languages have been created and released, starting from English and Arabic at CheckThat! 2018 [6] to Arabic, Bulgarian, Dutch, English, Spanish, and Turkish in later editions [2, 16, 17]. Besides CheckThat! datasets, additional resources have been developed over the years, mainly focused on specific events like COVID-19 [18] or political news [19]. English is the most represented language for check-worthiness estimation, but the scientific community has recently started to focus on the development of resources for other languages too, since check-worthy claims can refer to events that are relevant only for areas in which a given language is spoken. In this respect, Italian represents an exception because, to our knowledge, no dataset for check-worthiness estimation in this language has been developed so far. Recently the Check-IT! dataset [20] has been created, which however contains only fact-checked (i.e. check-worthy) claims. Likewise, the FEVER-IT dataset [21] is a translation into Italian of the widely-used FEVER dataset [22], and contains only claims to be verified against textual sources. In this work, we address this gap by presenting the novel WorthIt dataset, which covers a previously overlooked language for the task of check-worthiness estimation. The dataset has been carefully sampled across topics and time for better models' generalizability, since past works have shown that the performance of automated fact-checking drops under domain shift [23]. The WorthIt dataset has also been fully annotated by two raters to value human label variation [8].

Concerning the methods for check-worthiness estimation, state-of-the-art results in the CheckThat! evaluation campaigns are mostly based on fine-tuned encoder-based models such as BERT, RoBERTa, and DistilBERT [24, 25, 26] and language-specific variants [16], often combined with data augmentation [27] and ensembling strategies. Recently, large language models (LLMs) have been started to be used for the task, showing promising performance. For instance, the best performing system on English at CheckThat! 2024 [17] fine-tuned Llama-2-7B on the provided training data and then leveraged prompts generated by ChatGPT for check-worthy claim detection [28]. However, previous works do not leverage the synergies between factuality/verifiability and check-worthiness, albeit being strictly related tasks. Our work makes a step towards this goal by fine-tuning encoder-based models in a multi-task learning setting and experimenting with sequential prompting using decoder-based models.

## 3. WorthIt Dataset

In this section, we describe the dataset creation process, from data collection (Section 3.1) to data annotation (Section 3.2). We then present data statistics (Section 3.3).

### 3.1. Data Collection

We collect social media posts pertaining to migration, climate change, and public health issues using the Twitter APIs.[3] To mitigate temporal bias in the dataset, we focus on a large time frame of six full years (from `2017-01-01` to `2022-12-31`) and retain messages in Italian about the aforementioned topics by using a manually curated list of over 400 keywords derived from reliable glossaries and

[2] https://www.clef-initiative.eu/.

[3] Tweets were retrieved in 02/2023 when the APIs for research purposes were still available for free.

scientific manuals (see Appendix A). Following Nakov et al. [2], we further filter out posts containing $\leq 5$ tokens[4] and sort the remaining messages by their sum of likes and retweets. We then select the top-$k$ ($k = 10$) posts exhibiting the highest number of likes and retweets for each month and topic subset, therefore focusing on the messages with the highest impact to the society while simultaneously mitigating topic and temporal biases. We further account for the potential presence of authors' writing style biases that can occur when many posts authored by the same users are included in the dataset: we therefore retain only the most impactful post authored by the same user in each data subset. Overall, we collect 2,160 posts evenly distributed across topics (i.e., 720 for each topic) and time periods (i.e., 360 for each year) for factuality/verifiability and check-worthiness annotation. All posts have been then anonymized by replacing user mentions, URLs, email addresses, and phone numbers with placeholders (i.e., `[USER]`, `[URL]`, `[EMAIL]`, and `[PHONE]`, respectively) and newline characters (i.e., `\n` and `\r`) have been replaced with single spaces.

## 3.2. Data Annotation

Each post has been annotated with two labels, namely *i)* one denoting whether the content of the post is factual/verifiable – either YES or NO – and *ii)* one indicating its check-worthiness – with labels in a 5-point Likert scale: DEFINITELY YES, PROBABLY YES, NEITHER YES NOR NO, PROBABLY NO, or DEFINITELY NO. It is worth noting that, as opposed to determining factuality/verifiability, estimating check-worthiness is a partly subjective task. This motivates us to create WorthIt with parallel labels by the annotators on all posts so that future studies on human label variation can be conducted. The annotation guidelines closely follow the ones used in CheckThat! shared tasks and are provided in Appendix B.

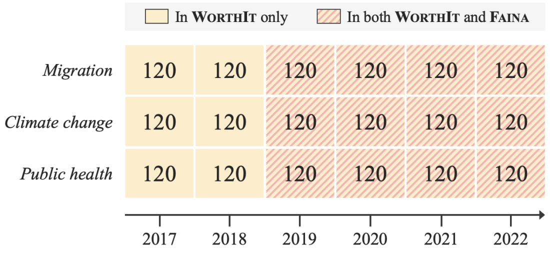
**Annotators** Annotation was conducted by two expert annotators. Both annotators are native speakers of Italian and have naturally been exposed to public discourse on migration, climate change, and public health in the Italian context. They identify themselves as a woman and a man, with age ranges 20–30 and 30–40. They have a background in linguistics and natural language processing and conducted annotation as part of their work.

**Annotation process** Annotators were provided with annotation guidelines for determining the factuality/verifiability and check-worthiness of social media posts (Appendix B). After conducting a pilot annotation phase on a small subset of the messages, annotators discussed the cases in which their annotations diverged, and consolidated the guidelines by specifying how to deal with special cases (e.g., in the presence of reported speech; see Appendix B). Then, they both labeled the full set of posts in four rounds of annotation. Each round involved a discussion phase aimed at resolving annotation errors (e.g., due to attention slips) while keeping instances exhibiting genuine disagreement (e.g., different interpretations). This makes WorthIt the first check-worthiness estimation dataset that goes beyond the "single ground truth" assumption in subjective annotation.

**Inter-annotator agreement** We computed the inter-annotator agreement (IAA) on the full dataset for both factuality/verifiability and check-worthiness using Krippendorff's alpha ($\alpha$) [29]. We obtain 0.8322 for factuality/verifiability and 0.6909 for check-worthiness. As expected, albeit substantial, the IAA for check-worthiness is lower than that for factuality/verifiability due to the genuine disagreement that we retain on purpose.

## 3.3. Data Analysis and Statistics

WorthIt comprises 2,160 posts distributed across topics and time periods as shown in Figure 2, in which we also highlight the overlap in posts with Faina [30], a previously released dataset for fine-grained fallacy detection. Specifically, WorthIt includes the same posts from 2019 to 2022 that are in Faina and further includes messages from 2017 and 2018 time periods. This opens opportunities for studying the interplay between check-worthiness and fallacious argumentation in future work as well as investigations on human label variation, especially because annotators are the same for both datasets.



| | 2017 | 2018 | 2019 | 2020 | 2021 | 2022 |
|---|---|---|---|---|---|---|
| *Migration* | 120 | 120 | 120 | 120 | 120 | 120 |
| *Climate change* | 120 | 120 | 120 | 120 | 120 | 120 |
| *Public health* | 120 | 120 | 120 | 120 | 120 | 120 |

**Figure 2:** Distribution of posts in WorthIt across topics and time periods and overlap in posts with the Faina dataset.

Overall, social media posts in WorthIt have an average token length of 38.6 and the full dataset comprises 83,315 tokens, of which 28,562, 26,667, and 28,086 are part of migration, climate change, and public health posts, respectively. In Table 1 we summarize the annotation statistics for factuality/verifiability and check-worthiness for both annotators ($A_1$ and $A_2$). While 1,413–1,432 posts (65.4%–66.3%) are considered as factual/verifiable

[4] Computed using the `it_core_news_sm` spaCy model (v3.5).

**Table 1**
Factuality/verifiability (FV) and check-worthiness (CW) label statistics in WorthIt across annotators ($A_1$ and $A_2$). Check-worthiness labels from left to right are: DEFINITELY NO, PROBABLY NO, NEITHER YES NOR NO, PROBABLY YES, and DEFINITELY YES.

| | Annotator $A_1$ | | | | | |
|---|---|---|---|---|---|---|
| | NO | YES | | | | |
| FV | 747<br>(34.6%) | 1,413<br>(65.4%) | | | | |
| CW | | 43<br>(2.0%) | 342<br>(15.8%) | 17<br>(0.8%) | 807<br>(37.4%) | 204<br>(9.4%) |
| | | ← NO | | | | YES → |

| | Annotator $A_2$ | | | | | |
|---|---|---|---|---|---|---|
| | NO | YES | | | | |
| FV | 728<br>(33.7%) | 1,432<br>(66.3%) | | | | |
| CW | | 145<br>(6.7%) | 380<br>(17.6%) | 123<br>(5.7%) | 574<br>(26.6%) | 210<br>(9.7%) |
| | | ← NO | | | | YES → |

by annotators, we stress that the check-worthiness of a post can be estimated only if the post itself is deemed as factual/verifiable. Indeed, only 1,011 (46.8%) and 784 (36.3%) posts over the total are classified as check-worthy (i.e., either with the label PROBABLY YES or DEFINITELY YES) by $A_1$ and $A_2$, respectively. We observe that the overall statistics for factuality/verifiability are similar among annotators, while those for check-worthiness, as expected, vary more. Specifically, $A_1$ appears to have been more inclined to assign clear-cut check-worthiness scores, whereas $A_2$ distributed its ratings more across the scale. While in our experiments (Section 4) we do not directly leverage this information, our dataset is released to the community with disaggregated labels using the full 5-point Likert scale to encourage work on fine-grained check-worthiness estimation and human label variation.

## 4. Experiments

We conduct experiments on check-worthiness estimation with both encoder- and decoder-based models using the newly-introduced WorthIt dataset. In this section, we thoroughly detail our experimental setup (Section 4.1) and the model variant and prompt selection process (Section 4.2). Then, we present test set results (Section 4.3).

### 4.1. Experimental Setup

**Task setup** We cast the check-worthiness task as a binary classification problem and consider factuality/verifiability as auxiliary information that can be leveraged by models to improve performance on the task. Given that each post has annotations provided by all annotators (i.e., $A_1$ and $A_2$) for both factuality/verifiability and check-worthiness, for the purpose of the experiments we consider a post as factual/verifiable if both annotators agree that the instance is such (i.e., labeling it as YES), whereas we consider a post as check-worthy if both annotators label the instance as either PROBABLY YES or DEFINITELY YES. This ensures that these posts are check-worthy with high likelihood. As a result, we obtain 1,341 (62.1%) and 819 (37.9%) factual/verifiable and non factual/verifiable posts, and 739 (34.2%) and 1,421 (65.8%) check-worthy and non check-worthy posts, respectively.

**Data splits** We divide WorthIt into $k$ training and test sets using $k$-fold cross-validation ($k = 5$) preserving the label distribution across splits. For development, we rely on the training portions only and further divide them into training and development sets for the purpose of model variant and prompt selection (Section 4.2). Specifically, for encoder-based models we split them into five 80%/20% training/development sets, while for decoder-based models we divide them into two equal parts: the first half is used for selecting examples for few-shot prompting, while the second half serves as development set. All texts were lowercased for the purpose of the experiments.

**Models** For the experiments with encoder-based models, we use four monolingual models specifically trained on Italian data, namely AlBERTo [31],[5] UmBERTo [32],[6] and dbmdz's Italian BERT models [33] in their base[7] and xxl[8] versions (henceforth referred to as BERT-it base and BERT-it xxl). Moreover, we employ widespread multilingual models that include Italian in pretraining data, namely mBERT [34][9] and XLM-RoBERTa [35].[10] For fine-tuning, we use the MaChAmp toolkit (v0.4.2) [36] and select the best hyperparameter configuration based on average Pos $F_1$ score on the development sets (Appendix C). As regards decoder-based models, we choose two Italian and two multilingual models, all instruction-tuned. Specifically, we select LlaMAntino-3-ANITA-8B [37][11] and Minerva-7B [38][12] as monolingual models, while we use Qwen2.5-7B [39][13] and Llama3.1-8B [40][14] as multilingual models. We choose these models because they are widely used, freely available, and do not require very large computational resources that could be impractical in real-world scenarios. Predicted labels are extracted from models' outputs using regular expressions. If no

matching label is found in the output,[15] the response is recorded as "unknown". Hyperparameter details are in Appendix C. Overall, we employ six encoder-based and four decoder-based models, for a total of ten models.

**Prompts and example sets** For decoder-based models, we design prompts in two languages (Italian and English) with or without annotation guidelines, leading to four different prompt configurations: Italian with guidelines (`it_g`), Italian without guidelines (`it_ng`), English with guidelines (en_g), and English without guidelines (en_ng). All models are prompted in a few-shot setup with five carefully-selected examples of posts and associated labels (Section 4.2).[16] All prompts are in Appendix D.

**Multi-task fine-tuning and sequential prompting** We hypothesize that factuality/verifiability information can help to predict the check-worthiness of a post. We thus design different fine-tuning and prompting settings for encoder- and decoder-based models, respectively, to test this hypothesis. Specifically, for encoder-based models we compare a standard SINGLE TASK approach (i.e., fine-tuning a model with check-worthiness labels only) with an approach that leverages both factuality/verifiability and check-worthiness information in a MULTI-TASK learning framework (i.e., using check-worthiness as a main task and factuality/verifiability as an auxiliary task with different task loss weights $\lambda_{\text{FV}}$ and $\lambda_{\text{CW}}$; see Appendix C). We compute the multi-task learning loss as $L = \sum_t \lambda_t L_t$, where $L_t$ is the loss for the task $t$, i.e., either factuality/verifiability (FV) or check-worthiness (CW), and $\lambda_t$ is the weight given to the task. For decoder-based models, we instead test a standard setting in which the models are prompted directly for check-worthiness (NOT SEQ) and a two-step sequential prompting approach (SEQ) (prompt are in Appendix D). In the latter case, the model is firstly instructed to classify the post based on its factuality/verifiability, then the output label is incorporated into a prompt which instructs the model to assess the check-worthiness of the same post.

**Evaluation metrics** We use the $F_1$ score for the positive check-worthy class (Pos $F_1$) as our main metric, in line with previous work on check-worthy claim detection [2, 16, 17, *inter alia*]. For completeness, we also report positive precision and recall scores (Pos Prec and Pos Rec, respectively), as well as accuracy (Acc) for test set results. Since encoder-based models provide confidence scores for the output labels, we also compute mean average precision (mAP) scores for them to get additional insights on performance when ranking posts by check-worthiness. Moreover, for decoder-based models we include the number of "unknown" outputs (i.e., those not matching a label in the label set) to assess their ability to follow the instructions.

## 4.2. Model Variant and Prompt Selection

We select the most promising setting (i.e., model variant, set of few-shot examples, and prompt configuration) based on average Pos $F_1$ score on the development sets. While for encoder-based approaches the model selection was mainly a matter of tuning hyperparameter values (see Section 4.1 and additional details in Appendix C), for decoder-based models this involved the selection of the most promising set of examples as well as the prompt configuration (i.e., language and guidelines).

**Few-shot example set selection** We create five different sets of few-shot examples (i.e., post texts and associated labels) by diversifying them across topics and annotation combinations for factuality/verifiability and check-worthiness, focusing on examples that are similar to those that are discussed in the annotation guidelines. Each set is drawn from one of the five training splits used during development and contains five examples. Table 2 reports the composition of each set with respect to topics and annotations. To select the most promising example set to be used in the test phase, we prompt all decoder-based models with these example sets. In Table 2 we also report the Pos $F_1$ obtained by using each example set, averaged on all models, development sets, and prompt configurations across SEQ and NOT SEQ settings (calculated over a total of 138,400 data points).[17] Example set **#1** leads to the highest average Pos $F_1$ score and also exhibits the smallest standard deviation (Table 2); therefore, we select this set for the test phase (refer to Appendix D for post texts and labels included in the example set). It is worth noting that this is the only set that does not include any post annotated as factual/verifiable but not check-worthy (+-), suggesting that models may learn more effectively from examples that are either both factual/verifiable and check-worthy or neither. In Table 3, we report the percentages of factuality/verifiability and check-worthiness label combinations outputted by models when prompted using each example set over all the possible configurations in the SEQ setting (69,200 data points). We observe that even if the sets have different

[15] Allowed labels for factuality/verifiability: {factual, fattuale, not[-_ ]factual, non[-_ ]fattuale}; allowed labels for check-worthiness: {check[-_ ]worthy, not[-_ ]check-worthy, non[-_ ]check-worthy}.

[16] Testing a smaller/larger number of examples is left for future work.

[17] Each development split for decoder-based models consists of 865 examples (i.e., 50% of the training portion; see Section 4.1). Therefore, we have 865 outputs per development set (5×) $\rightarrow$ 4,325 outputs per model's configuration (4×) $\rightarrow$ 17,300 outputs per model (4×) $\rightarrow$ 69,200 outputs per setting (2×) $\rightarrow$ 138,400 outputs in total.

**Table 2**
Composition of the five example sets assessed in the development phase in terms of covered topics (Mi: migration, CC: climate change, PH: public health) and label combinations (++: factual/verifiable and check-worthy; --: not factual/verifiable and not check-worthy; +-: factual/verifiable and not check-worthy). Pos F$_1$ scores are averaged on all models, development sets, and prompt configurations across SEQ and NOT SEQ settings. The score for the best example set is in **bold**.

| Set | Topic | | | FV/CW | | | Pos F$_1$ |
|---|---|---|---|---|---|---|---|
| | Mi | CC | PH | ++ | -- | +- | score |
| **#1** | 2 | 2 | 1 | 3 | 2 | 0 | **0.68237**$_{\pm 0.10}$ |
| **#2** | 2 | 1 | 2 | 3 | 1 | 1 | 0.63348$_{\pm 0.11}$ |
| **#3** | 2 | 2 | 1 | 2 | 2 | 1 | 0.68000$_{\pm 0.11}$ |
| **#4** | 2 | 2 | 1 | 2 | 2 | 1 | 0.59510$_{\pm 0.14}$ |
| **#5** | 1 | 2 | 2 | 1 | 2 | 2 | 0.59459$_{\pm 0.12}$ |

**Table 3**
Percentages of factuality/verifiability (FV) and check-worthiness (CW) label combinations outputted by models when prompted using each example set over all configurations in the SEQ setting (computed on the development sets).

| FV/CW | #1 | #2 | #3 | #4 | #5 |
|---|---|---|---|---|---|
| ++ | 16.64% | 13.72% | 15.91% | 8.01% | 9.04% |
| +- | 5.18% | 3.40% | 4.82% | 2.95% | 7.35% |
| -+ | 43.76% | 43.80% | 46.92% | 43.57% | 35.71% |
| -- | 34.43% | 39.08% | 32.35% | 45.46% | 47.89% |

distributions of label combinations, this does not influence significantly the distribution of the labels generated by models: in all cases, models frequently produce an invalid pair -FV +CW, while they tend to avoid the opposite one (i.e., +FV -CW).

**Best prompt selection** To select the prompts for the test phase, we compare average Pos F$_1$ scores on the development splits obtained by all decoder-based models when prompted with it_g, it_ng, en_g, and en_ng configurations (21,625 data points for each configuration)[18] in both SEQ and NOT SEQ settings. Results are in Table 4. All the best performing models do not use guidelines; therefore, we decide not to include guidelines in the prompts in further experiments. We keep both English and Italian prompt versions for the test phase, as some models perform better with Italian (particularly Minerva). We also observe that the best results in the SEQ setting are overall higher than in the direct check-worthiness task (i.e., NOT SEQ). We keep both settings for testing to better highlight performance differences.

**Table 4**
Development set results for check-worthiness estimation using decoder-based models in SEQ and NOT SEQ settings, split by prompt configuration. We report F$_1$ scores for the positive *check-worthy* class (Pos F$_1$; main metric). Results are averaged across $k = 5$ development splits and example sets and include standard deviations. The best setting for each model is underlined and the best overall result is in **bold**.

| Model | Setting | Config | Pos F$_1$ |

## 4.3. Results

We compute the results for the selected configurations of encoder- and decoder-based models across the $k = 5$ test splits, presenting average scores and standard deviations across the applicable metrics as detailed in Section 4.1.

**Encoder-based models** Results for encoder-based models are shown in Table 5. We observe that using factuality/verifiability as an auxiliary task in a MULTI-TASK learning framework helps to improve the Pos F$_1$ performance across all models. The best scores are obtained by BERT-it xxl, followed by UmBERTo and BERT-it base, all fine-tuned in a MULTI-TASK setting. Specifically, BERT-it xxl fine-tuned using both factuality/verifiability and check-worthiness information achieves a Pos F$_1$ score

[18] 865 outputs per development set (5×) → 4,325 outputs per example set (5×) → 21,625 outputs in total.

**Table 5**
Test set results for check-worthiness estimation using fine-tuned encoder-based models in single task and multi-task settings. We report $F_1$ scores for the positive *check-worthy* class (Pos $F_1$; main metric), along with positive precision (Pos Prec) and recall (Pos Rec) scores. We further report mean average precision (mAP; secondary metric) scores and accuracy (Acc) scores. Results are averaged across $k = 5$ test splits and include standard deviations. For main and secondary metrics, the best setting for each model is underlined and the best overall result is in **bold**.

| Model | Setting | Pos $F_1$ | Pos Prec | Pos Rec | mAP | Acc |
|---|---|---|---|---|---|---|
| AlBERTo | single task | $0.7039_{\pm 0.03}$ | $0.6397_{\pm 0.04}$ | $0.7848_{\pm 0.03}$ | $0.7563_{\pm 0.04}$ | $0.7731_{\pm 0.03}$ |

of 0.7473 (+1.41 points increase compared to the single task version) and a mAP score of 0.8095 on the check-worthiness estimation task. Notably, XLM-RoBERTa in a multi-task setting shows only -3.35 points than the best BERT-it xxl configuration in terms of Pos $F_1$ score, despite being pretrained on a mixture of languages. It also outperforms AlBERTo in the multi-task setup and obtains comparable results in the single task setting. This suggests that XLM-RoBERTa can be a viable approach for multilingual check-worthiness estimation.

**Decoder-based models** Results are presented in Table 6. Decoder-based models in a few-shot setup perform slightly worse on average than fine-tuned encoder-based models, but still achieve competitive results. Moreover, three models perform better when prompted in Italian.

Notably, LlaMAntino-3-ANITA-8B – despite being pre-trained on Italian data – performs better with English prompts and achieves the highest score in the SEQ setting (i.e., 0.6771 Pos $F_1$ score). The two Italian models, LlaMAntino-3-ANITA-8B and Minerva-7B, reach the best results in the SEQ setup, while the multilingual models Qwen2.5-7B and Llama3.1-8B perform better when directly prompted for check-worthiness (i.e., in the NOT SEQ setup). Overall, factuality and verifiability information do not seem to significantly aid decoder-based models in predicting check-worthiness, as they are unable to leverage this information effectively (see Section 5 for an in-depth analysis). The lowest performance is observed with Minerva-7B, which is also the only model to produce "unknown" outputs – up to an average of 127 "unknown" labels when prompted in English in the SEQ setting.

## 5. Analysis and Discussion

**Ranking of posts by check-worthiness** Aggregate check-worthiness estimation scores (e.g., Pos $F_1$) give a useful picture of models' performance; however, knowing how the models *rank* the posts by check-worthiness is paramount for fact-checkers since they can only screen a limited number of posts in their daily work (say, $k$). In Figure 3, we report the ratio of posts correctly classified as check-worthy within the top-$k$ recommended check-worthy posts (P@$k$) by all encoder-based models,[19] with $k \in \{5, 10, 25, 50, 100\}$. We observe that P@$k$ is in the range of 0.90–0.95 and 0.80–0.85 points on average when the posts' screening budget is set to $k = 25$ and $k = 100$, respectively. This indicates that these models can help fact-checkers in their daily routine.

**Relationship between FV and CW** To assess whether decoder-based models capture the relationship between factuality/verifiability and check-worthiness, we analyzed their outputs in the SEQ setup. Figure 4 shows the frequencies of the four possible combinations of labels both in the models' outputs (i.e., +FV +CW, +FV -CW, -FV +CW, and -FV -CW; calculated over 8,650 data points) and in the manual annotations (2,160 data points). The most frequent label combination in the models' outputs is +FV +CW, accounting for more than half of the predictions for Minerva-7B and Llama3.1-8B, reaching 66.2% for the latter. Interestingly, the second most frequent combination is -FV +CW: we consider this as problematic, because non-factual or non-verifiable posts should not be classified as check-worthy. This suggests that decoder-based models do not grasp this correlation and instead classify check-worthiness independently. This is a particularly important limitation, as it can potentially lead to fact verification efforts being wasted on content that is not factual. In contrast, all models except LlaMAntino-3-ANITA-8B rarely assign the opposite combination, +FV -CW, which is instead valid within our framework and represents a consistent portion of annotated posts (27.9%). LlaMAntino-3-ANITA-8B favors either two negative labels (-FV -CW) or two positive labels (+FV +CW), while assigning mixed label combinations significantly less often. A side effect of this is that it produces the -FV +CW combination less frequently than the other models. Overall, our analysis shows that models *i)* tend to avoid the combination +FV -CW, preferring to align the two labels rather than diversifying them, especially when they rely on positive factuality/verifiability, and *ii)* tend to produce the invalid label combination -FV +CW. We stress that this tendency is not due to the examples given in the

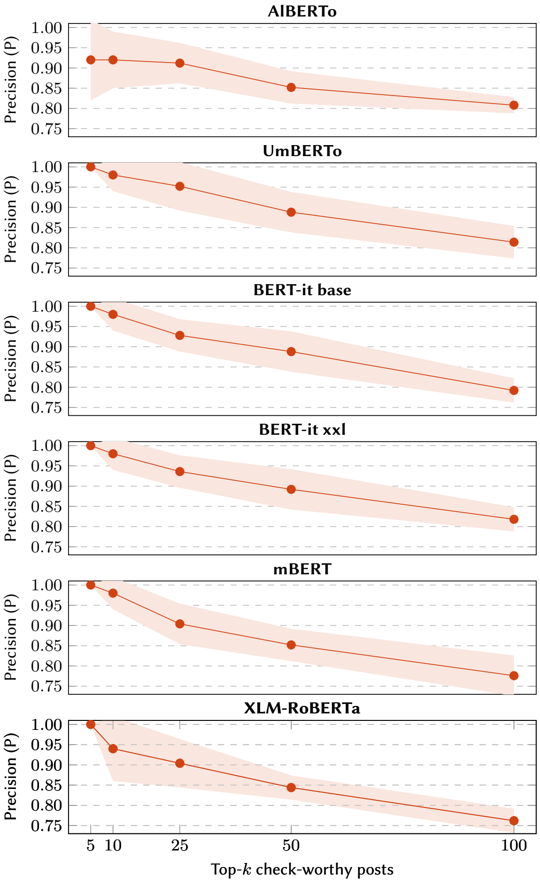

**Figure 3:** P@$k$ scores for all fine-tuned encoder-based models in the MULTI-TASK setting for $k \in \{5, 10, 25, 50, 100\}$. Results are averages across $k = 5$ test splits and include standard deviations – indicated with shaded areas around the lines.

[19] In this analysis, we report P@$k$ scores for encoder-based models only since with decoder-based models it is not possible to get confidence scores for labels generated as part of raw outputs.

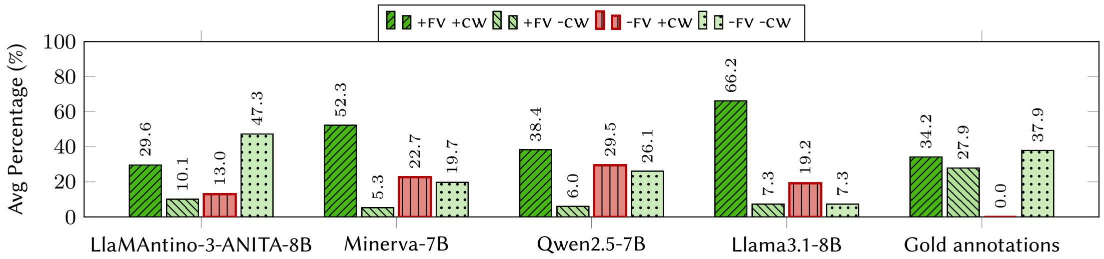

**Figure 4:** Percentages of factuality/verifiability (FV) and check-worthiness (CW) label combinations in decoder-based models' outputs in the SEQ setting, averaged on both prompt languages, plus label combinations in WorthIt's gold annotations. -FV +CW is emphasized as problematic (red bars w/ vertical lines), as non-factual/verifiable posts cannot be check-worthy.

prompts (cf. Table 3), but is rather a general preference of those models, which seem to ignore the relation between factuality/verifiability and check-worthiness.

**Correlation between models' outputs** To assess if there is a pairwise correlation between encoder- and decoder-based models' outputs, we calculate the Pearson correlation coefficient ($r$) between all models' predictions. The heatmap in Figure 5 summarizes the results across the $k = 5$ test splits. We consider the best-performing setup for each model, namely the MULTI-TASK setting for encoder-based models (see Table 5) and the setup that led to the best performance for each decoder-based model (i.e., language and setting; see Table 6). Encoder-based models exhibit strong positive mutual correlation ($r \geq 0.65$; top-left section in Figure 5), indicating high consistency in the predictions. In contrast, decoder-based models display low inter-model correlation indicating greater output variability. Among them, LlaMAntino-3-ANITA-8B shows the highest alignment with encoder-based models, reaching $r = 0.54$ with UmBERTo and BERT-it xxl. Conversely, Minerva-7B consistently shows no or very weak correlation with other models – with $r$ ranging from 0.00 to 0.06 – revealing that its outputs are largely unrelated with those of all other models.

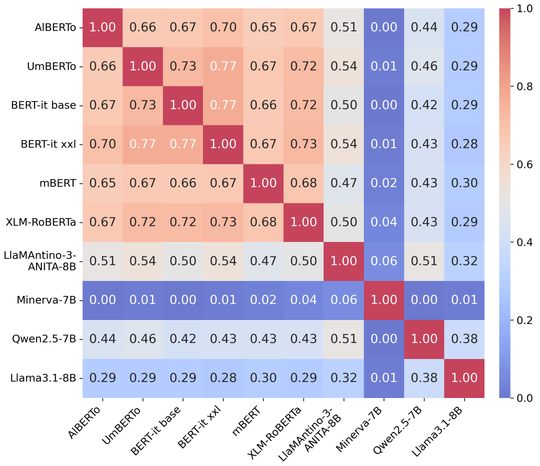

**Figure 5:** Pearson correlation coefficient ($r$) between models' predictions over the $k = 5$ test splits, considering the best-performing setup for all encoder- and decoder-based models.

## 6. Conclusion

We introduce WorthIt, the first dataset of Italian social media posts annotated for factuality/verifiability and check-worthiness that spans multiple years and topics and includes human label variation. We conduct thorough check-worthiness estimation experiments with encoder- and decoder-based models. Results show that the former models in a multi-task setting reach the best results, while the latter models systematically classify non-factual/verifiable posts as check-worthy, failing to capture the relation between the two concepts.

WorthIt's partial overlap with a dataset for fallacy detection, FAINA [30], opens new research avenues for combining the two tasks. Further opportunities include modeling human label variation for the check-worthiness task using the released parallel annotations and experimenting with additional models, training setups, and prompting strategies. Finally, the wide temporal coverage and the diverse set of topics represented in WorthIt open the field to studies on out-of-distribution generalization of check-worthiness estimation models.

# Appendix

## A. Search Keywords

We report the full list of search keywords, divided by topic, in Table 7. Within squared brackets are the grammatical gender and number variants (if any) that we included for each keyword.

## B. Annotation Guidelines

For factuality/verifiability annotation, a post can be either factual/verifiable (i.e., YES label) or non factual/verifiable (i.e., NO). For posts that are factual/verifiable, a check-worthiness label in a 5-point Likert scale must also be assigned. Possible labels are: DEFINITELY YES, PROBABLY YES, NEITHER YES NOR NO, PROBABLY NO, and DEFINITELY NO. For both annotation tasks, we strictly follow the guidelines by Nakov et al. [2] and translate them to Italian. The annotation guidelines are presented below.

**Factuality/verifiability**

*Il post contiene un'affermazione fattuale che può essere verificata? A titolo di esempio, sono fattuali/verificabili i post che riportano una definizione, menzionano una quantità nel presente o nel passato, fanno una previsione verificabile del futuro, fanno riferimento a leggi, procedure e norme operative, discutono di immagini o video, e indicano correlazioni o causalità.*

**Check-worthiness**

*Credi che l'affermazione contenuta nel post dovrebbe essere verificata da un fact-checker professionista? Questa domanda richiede un giudizio soggettivo basato sulle seguenti domande:*

1. *L'affermazione espressa nel post potrebbe essere falsa?*
2. *L'affermazione espressa nel post potrebbe essere di interesse pubblico e/o avere impatto sulla collettività?*
3. *L'affermazione espressa nel post potrebbe danneggiare la società, un gruppo, un singolo o un'entità?*

*L'annotazione è necessaria solo se il post è stato classificato come fattuale/verificabile. Nota: affermazioni facilmente verificabili dagli utenti (es. "Gli abitanti della Cina sono la metà di quelli dell'Italia") non sono da ritenere check-worthy.*

In the guidelines, we further include information on how to deal with special cases to minimize ambiguity. All the cases provided to annotators are outlined below.

☞ **Reported speech**, including quotations, references to newspaper and TV, is always factual/verifiable. E.g.: "*'What is done to migrants is criminal' #PopeFrancis on #CTCF #Rai3*" is **factual/verifiable**

☞ If the claim is in a **subordinate clause**, the post is not factual/verifiable. However, it is factual/verifiable if the claim is salient and conveys the main information. E.g.: "*Dear #novax who appeals to art.32 of the Constitution, you should know that the Constitutional Court with ruling no. 307/1990 has decided that a treatment can become mandatory if it serves to protect oneself and the health of others. So, if needed, you vaccinate or leave.*" is **factual/verifiable**

☞ **Generic sentences** are not factual/verifiable because they contain imprecise information (e.g., frequent use of indefinite quantifiers such as *various*, *some*, *many*). E.g.: "*Three months after the collapse of the #MorandiBridge. From the government only many promises, zero facts and a totally insufficient decree.*" is **not factual/verifiable**

☞ **Personal opinions** are not factual/verifiable, as there is no clear evidence to support them. E.g.: "*Put Salvini back at the Interior Ministry, he is the only one who can handle migrants arrivals.*" is **not factual/verifiable**

☞ When the **implicit subject** can be reconstructed, the sentence can be factual/verifiable. E.g.: "*When he was minister and closed the ports he said go ahead and prosecute me. Then he was investigated and hid behind parliamentary immunity. When he was minister he insulted Carola Rackete. Then they propose him a TV debate with her and he declines the invitation. And they call him Captain.*" is **factual/verifiable**

☞ **Descriptions of images/videos** with URLs are factual/verifiable when they contain an externally verifiable fact. E.g.: "*I receive directly from a Sudanese boy these images. The migrants are leaving the UNHCR center 15 km from #Agadez and marching towards the city.*" is **factual/verifiable**

☞ Posts about **weather conditions** or **temperatures** are considered factual/verifiable when the information is precise, they specify the type of event described, the exact location and time. Posts about temperature are not check-worthy. E.g.: "*The situation now in #Catania. I think there is a small problem with climate change. [URL]*" is **not factual/verifiable**

☞ Posts describing **events** (demonstrations, marches, strikes, rallies, initiatives, assemblies, meetings, presentations) are always factual/verifiable. They can include the expressions *everyone for*, *see you on*, *together with*. They are generally not check-worthy. E.g.: "*#StopFalsePromises! In the streets of Rome with [USER] for global climate strike! #ClimateStrike*" is **factual/verifiable**

**Table 7**
Search keywords used for collecting posts in WorthIt, with grammatical gender and number variants (if any) indicated using squared brackets. Note that these exactly match the keywords that have been used to collect the faina dataset [30].

## C. Hyperparameters

For encoder-based models, we use default MaChAmp (v0.4.2) [36] hyperparameter values and tune the most crucial ones during development. The search space for them is indicated within brackets in Table 8, with best values underlined. The best loss weight value for the auxiliary factuality/verifiability task is set to 0.50 for UmBERTo, BERT-it base, and mBERT, to 0.75 for XLM-RoBERTa, and to 1.00 for AlBERTo and BERT-it xxl.

For decoder-based models, we use the Hugging Face Transformers library using default hyperparameter values and setting the `max_new_tokens` parameter to 30. Since all models are instruction-tuned, we structure our inputs as conversational prompts using the following format: `{"role": "user", "content": "prompt"}`.

**Table 8**
Hyper-parameter values employed for encoder-based models.

| Hyperparameter | Value |
|---|---:|
| Optimizer, $\beta_1$, $\beta_2$ | AdamW, 0.9, 0.99 |
| Dropout | 0.2 |
| Epochs | 3 |
| Batch size | {$\underline{32}$, 64} |
| Learning rate | {$\underline{\text{1e-4}}$, 1e-5} |
| LR scheduler | Slanted triangular |
| Weight decay | 0.01 |
| Decay factor, cut fraction | 0.38, 0.3 |
| Class weights | {$\underline{\text{balanced}}$, unbalanced} |
| Main task loss weight ($\lambda_{\text{CW}}$) | 1.00 |
| Aux task loss weight ($\lambda_{\text{FV}}$) | {0.25, $\underline{0.50}$, $\underline{0.75}$, $\underline{1.00}$} |

## D. Prompts and Examples

We present the prompt templates used for factuality/verifiability and check-worthiness tasks. For prompts using guidelines, `$[FV|CW]_GUIDELINES` placeholders are replaced with text in the desired language from Table 9. `$[FV|CW]_EXAMPLES` placeholders are replaced with text–label pair examples in the format "`$POST_TEXT = $POST_LABEL`", one per line. We report the final example set in Table 10. Finally, `$POST_TEXT` is replaced with the text of the post to classify. The first part of the check-worthiness prompt (i.e., en: "*You ... Now*" and it: "*Hai ... Ora*") is included only in the seq setting, with `$FV_LABEL` representing the factuality/verifiability label obtained for the same post using the factuality/verifiability prompt.

**Table 9**
Guidelines for both tasks in Italian and English used for prompting decoder-based models in configurations with guidelines.

| |
|---|
| **`$FV_GUIDELINES`** **Italian**: “Linee guida:\\Un post è fattuale quando contiene informazioni salienti che possono essere verificate esternamente. Tali informazioni possono essere trovate ovunque, comprese subordinate, sostantivi e hashtag. I discorsi riportati e le citazioni sono sempre fattuali. Anche i post che descrivono eventi e attività sono sempre fattuali. I post sul meteo o sulla temperatura e le descrizioni di foto e video sono fattuali solo quando le informazioni sono precise e la località è nota. Al contrario, le affermazioni generiche o vaghe e le opinioni personali non sono fattuali perché non esistono prove chiare a sostegno.” **English**: “Guidelines:\\A post is factual when it contains salient information that can be externally verified. Such information can be found everywhere, including subordinates clauses, nouns and hashtags. Reported discourses and references are always factual. Similarly, posts describing events and activities are always factual. Posts about weather or temperature, as well as photo and video descriptions, are factual only when the information is precise and the location is known. On the other hand, generic or vague statements and personal opinions are not factual because there is no clear evidence to support them.” |
| **`$CW_GUIDELINES`** **Italian**: “Linee guida:\\Un post può essere check-worthy solo se è fattuale. Un post è considerato check-worthy se è rilevante per la società e può causare danno o modificare le opinioni delle persone. Le affermazioni generiche e le opinioni non sono check-worthy. I post che descrivono eventi climatici e meteorologici di solito non sono check-worthy perché non contengono informazioni sensibili. Allo stesso modo, i post che menzionano che una specifica attività è in corso di svolgimento di solito non sono check-worthy.” **English**: “Guidelines:\\A post can be check-worthy only if it is factual. A post is check-worthy if it is relevant to society and can cause harm or modify people’s opinions. Generic statements and opinions are not check-worthy. Posts describing climate and weather events are usually not check-worthy because they do not contain sensitive information. Similarly, posts mentioning that a specific activity is taking place are usually not check-worthy.” |

**Table 10**
Examples used for few-shot decoder-based models’ prompting on the test set. Examples refer to set **#1** (see Table 2).

## Abstract

This paper presents a comprehensive framework for enhancing dense-retrieval-based chatbots through the integration of graph-based diffusion reranking. Addressing challenges in traditional retrieval-augmented generation (RAG) systems, the proposed methodology incorporates a multi-step pipeline that advances document retrieval and relevance ranking. Initially, candidate passages are retrieved via dense embeddings, followed by the construction of a graph representation that captures inter-passage semantic relationships. Through a graph-based diffusion process, the reranking mechanism refines the selection, amplifying clusters of contextually relevant documents while mitigating noise effects from irrelevant data points. Experimental results demonstrate significant gains in retrieval quality and question-answering accuracy, underscoring the framework's potential for knowledge-intensive real-time applications such as conversational AI. This work reflects a pivotal step towards developing highly accurate, dynamic, and scalable multimodal conversational systems.

## Keywords

Retrieval-Augmented Generation, Large Language Models, Chatbots, Knowledge Graph, PageRank

## 1. Introduction

Advanced chatbots and other modern NLP tools need fast access to up-to-date, specific information. Although Large Language Models (LLMs) can generate fluent responses and handle a wide range of topics, they're stuck with whatever they learned during training, and their knowledge can become outdated or be too general [1]. RAG [2] solves this by enabling the LLM to retrieve information from an external database that can be updated in real time. This strategic decoupling of the LLM's generative function from data management, including storage, indexing, and crucially, retrieval, allows for continuous knowledge updates, thereby enhancing the responsiveness, reliability, and domain fidelity of such systems. Being able to quickly and accurately find the right information from a variety of sources is essential for powering these next-generation NLP systems.

Information Retrieval (IR) has evolved a lot to help us find relevant information more quickly and accurately in huge collections of text [3]. Instead of just matching words on the page, many modern systems use dense representations; basically, numeric embeddings that capture the meaning of queries and documents. This method, called **dense passage retrieval** [4], makes it possible to find passages that are related in meaning even if they don't share the same exact words. Still, pulling back the single best set of passages from an enormous database is tough, and the first batch of results often require additional refinement to make sure they're really on point. That's why it's common to run additional steps like re-ranking to fine-tune and improve the final selection.

We aim to make dense passage retrieval work even better by using a multi-step pipeline. First, we pull an initial batch of candidate passages with a dense retriever. Then we turn those top documents into a graph and run a diffusion process over it. This lets us capture how the passages relate to each other. By using this graph-based diffusion as a re-ranker, we can tweak the initial scores so that the most truly relevant passages end up at the top. The objective is to demonstrate how combining dense retrieval with graph-based diffusion re-ranking can yield superior retrieval performance, providing a more accurate and contextually relevant set of documents essential for applications requiring dynamic knowledge access.

## 2. Related Work

In recent years, advances in Large Language Models (LLMs) and AI-driven dialog systems have enabled more dynamic, retrieval-augmented conversational platforms. One foundational effort was introduced by Guu *et al.*

*CLiC-it 2025: Eleventh Italian Conference on Computational Linguistics, September 24 — 26, 2025, Cagliari, Italy*

*All authors contributed equally.

sai.dampanaboina@ovgu.de (S. T. Dampanaboina); sai.gamini@st.ovgu.de (S. N. Gamini); karishma.kunwar@st.ovgu.de (K. Kunwar); marco.polignano@uniba.it (M. Polignano)

in the REALM framework [5], which demonstrated the effectiveness of retrieval-augmented language model pretraining by fine-tuning on open-domain question answering (Q&A). At inference time, **REALM** fetches documents using dense embeddings and conditions the generator on retrieved passages. Building on this idea, Lewis *et al.* formalized the **Retrieval-Augmented Generation (RAG)** architecture [2] , showing that coupling dense retrieval with a pretrained sequence-to-sequence model improves factual grounding and generalization in Q&A. Unlike traditional LLMs that rely solely on parametric memory, RAG leverages a non-parametric index to fetch up-to-date, domain-specific information during generation.

Prior to dense retrieval, sparse vector-space methods—such as TF-IDF or BM25—were the de facto standards for fetching relevant documents [6]. Although BM25 performs well on short, keyword-based queries, it struggles with semantic matching in open-domain contexts[7]. Karpukhin *et al.* [4] showed that a dual-encoder dense retrieval model, trained on relatively few question–passage pairs, could outperform a strong BM25 baseline. Subsequent work by Xiong *et al.* [8] and Qu *et al.* [9] confirmed that dense retrievers better handle paraphrased, abstract, and long-tail queries. These studies also highlighted challenges in dense retrieval—such as selecting hard negatives and mitigating false negatives—and proposed improvements in training objectives and negative sampling strategies.

Despite these advancements, the top-k passages returned by a **dense retriever** may include semantically similar but contextually irrelevant documents. To address this, our work introduces a **graph-based diffusion re-ranking** step over the initial dense retrieval results. This idea is inspired by Donoser and Bischof's diffusion process for visual retrieval [10], where each document is treated as a node in a similarity graph and scores propagate through edges to refine ranking. We adapt this diffusion-based re-ranking to text-based retrieval by constructing a graph over the top retrieved chunks and iteratively propagating similarity scores to emphasize manifold structure rather than relying solely on pairwise dot products.

However, to our knowledge, prior RAG-style systems have not integrated graph-based diffusion re-ranking to refine their dense retrieval outputs. In this paper, we propose such an integration and demonstrate its effectiveness on benchmark Q&A datasets.

# 3. Methodology

This section details the design and implementation of our dense-retrieval chatbot. The system employs a graph-based diffusion re-ranking mechanism to enhance retrieval accuracy. We have designed a web application and, the processing pipeline consists of six sequential stages: input acquisition, intent classification, intent-based routing, dense retrieval, graph-based re-ranking, and large language model (LLM) response generation. All inference components are deployed on a GPU when available, with a fallback to CPU. A local Milvus-Lite instance serves as the vector store [11], and Google's Gemini Pro model [12] functions as the core LLM.

## 3.1. System Architecture

The chatbot is implemented as a modular Flask server [13] that listens for cross-origin requests. Upon initialization, the server launches a Milvus-Lite instance, creating or loading a collection named rag_collection into memory from a persistent storage directory (./milvus_data). Simultaneously, several models are pre-loaded to minimize inference latency: **a**. Speech-to-Text: The OpenAI Whisper medium model (769M parameters)[14], **b**. Intent Classification: A LoRA-fine-tuned RoBERTa-base model [15], **c**. Language Generation: The Google Gemini client, configured via an API key [16]. The embedding model, `openai/clip-vit-base-patch32`, is loaded. The system's behavior can be dynamically altered via a dedicated API endpoint that toggles a "GLOBAL_SEARCH_MODE" flag, forcing all queries to be routed to the web search module, thereby bypassing intent classification. API keys for Gemini and SerpAPI are managed as environment variables.

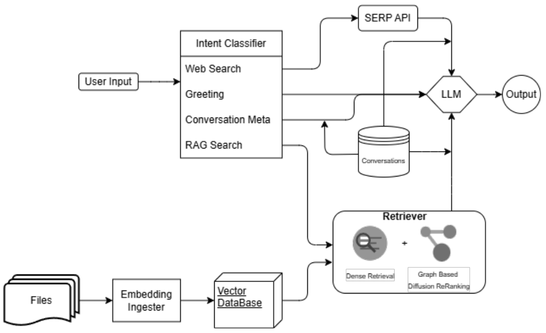

**Figure 1:** Overview of our Retrieval-Augmented Generation (RAG) architecture: user queries are first routed by an intent classifier to either SERP API or Retriever or directly to LLM; candidate passages are then fetched via dense retrieval and refined through a graph-based diffusion re-ranking stage; finally, the top-ranked context is fed into a generative LLM to produce the response.

### 3.2. Corpus Construction and Indexing

The knowledge base for Retrieval-Augmented Generation (RAG) is derived from a collection of PDF and plain-text documents stored in a designated directory. An offline ingestion script (ingest_embeddings.py) processes these sources into a searchable vector index. Firstly, PDF documents are converted to Markdown using the Docling library[17], with OCR enabled to extract text from scanned pages. Plain-text files are read directly. The Markdown content is first segmented into logical blocks (e.g., headings, paragraphs, table rows). These blocks are then aggregated into chunks of up to 500 words with a 50-word overlap between consecutive chunks. This overlap strategy ensures contextual continuity across chunk boundaries. Each text chunk is embedded using the Hugging Face implementation of `openai/clip-vit-base-patch32` [18]. The get_text_features() method produces a 512-dimensional vector, which is then normalized to unit $\ell_2$ norm. The resulting embedding vectors are indexed in the Milvus-Lite rag_collection. Each entry includes the vector (emb) and associated metadata: source_path, a unique chunk_id, the full chunk_text, and a 200-character chunk_preview. An IVF_FLAT index is built on the embedding field with nlist = 128, partitioning the vector space to accelerate searches. The entire index is loaded into memory for high-speed nearest-neighbor lookups.

### 3.3. Core Processing Pipeline

Incoming user requests, whether text or speech, trigger a multi-stage process to generate a contextually relevant response. The system acquires user input through two primary endpoints: a speech input API that transcribes audio files using a Whisper model [14], and a text input API that accepts JSON payloads with the conversation history [1]. Once the user's query is obtained, it undergoes intent classification by a fine-tuned RoBERTa-base model (which has been fine-tuned by us using Low- Rank Adaptation (LoRA) technique on a synthetic dataset curated by us which is used for training, categorizes the text as a*"RAG Search"*, *"Web Search"*, *"Greeting"* or *"Conversation Meta"*.

This classification model was optimized using Low Rank Adaptors with a rank of r=8 and a scaling factor of $\alpha$=16, applied to the query and key projection matrices. Based on the resulting intent, the query is routed down one of three paths: *"Greeting and Conversation Meta"* intents bypass retrieval and generate a direct response from the role of the LLM and conversation history respectively; a *"Web Search"* classification triggers a web-augmented generation path; lastly, the *"RAG Search"* intent activates a dense retrieval and re-ranking pipeline for a RAG-augmented response. When the query is directed to web search, it fetches the top 20 results, forwards to the LLM along with the conversation history and the LLM generates the response. If the query is directed to the RAG retriever, the dense retriever and page re-ranker comes into play which retrieves the relevant document chunks from the vector database and forwards them to LLM for it to generate a response. A global flag can override this logic and force any query to use the Web Search path. When enabled, even queries that would normally directed to the RAG Retriever or go straight to the LLM are redirected to fetch live results via the SERP API. This ensures that all responses are grounded in the most up-to-date information available. This is ideal for time-sensitive domains like news, finance, or rapidly evolving technical fields.

### 3.4. RAG Search: Dense Retrieval and Diffusion Reranking

For queries that are classified as "RAG Search" requiring information from the internal knowledge base, the system executes a sophisticated retrieval and reranking process. During initial retrieval, the raw query is embedded using the `openai/clip-vit-base-patch32`[18] model to produce a 512-dimensional query vector, $q_{\text{vec}}$. This vector is used to search the Milvus collection for the top 50 most similar chunks based on inner-product similarity, with search parameter `nprobe=10`. The top $n$ (up to 50) candidate chunks are used to construct a weighted, undirected graph *G = (V, E)*, where each node $v_i \in V$ represents a candidate chunk. An edge $(v_i, v_j) \in E$ is created for every pair of nodes, with its weight set to the cosine similarity between their respective embedding vectors. This results in a complete graph that captures the semantic manifold of the candidate set.

To refine the initial ranking, we employ *personalized PageRank (Diffusion)*. A personalization vector $\mathbf{p}$ is constructed directly from the raw dense retrieval scores $s_i$ of the $n$ candidate chunks, where each component is proportional to the initial dense retrieval score of candidate $i$. Thus, $\mathbf{p}$ is neither empty nor randomly initialized—it is deterministically defined by normalizing the retrieval scores, ensuring higher-scored chunks receive greater weight:

$$p_i = \frac{s_i}{\sum_{j=1}^{n} s_j}, \quad i = 1, \dots, n, \quad \mathbf{p} \neq \mathbf{0}, \ \sum_{i=1}^{n} p_i = 1. \tag{1}$$

This vector biases the random walk towards candidates that were originally most relevant chunks standing before we apply the graph diffusion step to the query. The final PageRank scores, $\pi \in \mathrm{I\!R}^{\mathrm{n}}$, are computed iteratively via the NetworkX library [19], solving the equation:

$$\boldsymbol{\pi} = \alpha A^T \boldsymbol{\pi} + (1-\alpha)\,\mathbf{p}$$

where A is the row-normalized adjacency matrix of G and the damping factor is set to $\alpha = 0.85$ because it is the canonical value from the original PageRank paper [9], striking a balance between "walking" the similarity graph (propagating scores along edges) and "teleporting" back to the seed nodes (initial retrieval scores) to avoid getting stuck in tight clusters. Values much higher (>0.9) can slow convergence and over-emphasize dense subgraphs; values much lower (<0.7) behave more like pure retrieval without graph smoothing. This diffusion process up-ranks candidates that belong to dense, semantically coherent clusters within the graph, mitigating the risk of relying on isolated high-similarity outliers. For context formualtion between the selected candidates, The candidates are sorted by their final PageRank scores in descending order, and the top $K = 20$ chunks are selected to form the Retrieved Context. If the re-ranking step is disabled or fails, the system falls back to the top 20 candidates from the initial dense retrieval. The top 20 candidates are selected because with trial and error we have decided that selecting 20 number of candidates to pass through the LLM is sufficient to cover the enough potential context so that the relevant bits are not lost but to avoid dragging too many off topic chunks that dilute the diffusion signal. Also, a 20-node graph is small enough for sub-100 ms diffusion passes, keeping end-to-end latency low. If the collection is huge, increasing the number of top candidates to pass to the LLM would be recommended.

### 3.5. Web Search Augmentation

For queries with the Web Search intent, the system queries the Google Search engine via the SerpAPI. The query retrieves the "answer box" and up to 20 top organic results. The structured JSON response from the API is serialized into a string. If the API call fails, the process continues without web context.

### 3.6. LLM Prompting and Response Generation

All prompts are submitted to the `gemini-2.5-pro model` [12]. The final prompt is dynamically assembled based on the routing path: Every prompt begins with a fixed role definition and the current conversation history. For example the payload JSON file would look like as follows. In place of Role we would define the role of the LLM to give it a persona and in place of conversation history we would have the conversations between the User and the LLM.

```
{
  "text": Role + conversation history,
  "rawQuery": User Query,
  "skipApiKeyValidation": false
}
```

For RAG Search, the formatted top-20 re-ranked chunks are appended under a Retrieved Context: heading in the JSON file.

```
{
  "text": Role + conversation history,
  "rawQuery": User Query,
  "skipApiKeyValidation": false
  "Retrieved Context": Top 20 Chunks
}
```

For Web Search, the serialized JSON from SerpAPI is appended under a Web Search Results: heading in the JSON file.

```
{
  "text": Role + conversation history,
  "rawQuery": User Query,
  "skipApiKeyValidation": false
  "Web Search Results": Top 20 search
      results
}
```

For Greeting and Conversation Meta intents, no additional context is added. The final composite prompt is sent to the Gemini API. The extracted text from the response is returned to the client in a JSON object containing the reply and the original intent.

## 4. Experiment

To evaluate the efficacy of our proposed chatbot, particularly the contribution of graph-based diffusion reranking, we designed a series of experiments. Our evaluation aims to answer three primary research questions:

**RQ1: Component Efficacy:** How accurately does the intent classification module route user queries to the appropriate processing pipeline?

**RQ2: Retrieval Effectiveness:** Does the proposed graph-based diffusion reranking significantly improve the quality of retrieved documents compared to standard dense retrieval baselines?

**RQ3: End-to-End Performance:** Does the enhanced retrieval quality from our reranking module translate into more accurate, faithful, and helpful final responses generated by the LLM?

This section details the experimental setup, the datasets used, the baselines for comparison, the evaluation metrics, and a thorough analysis of the results.

## 4.1. Experimental Setup

### 4.1.1. Dataset Construction

To perform a realistic evaluation, we constructed a domain-specific question-answering dataset tailored to the Otto von Guericke University (OVGU) context in English language, but same process can be followed for any other application domain. This reflects a practical application scenario where students frequently seek quick, reliable answers to academic queries,such as course details, procedures or administrative processes which are typically spread across the university website and official documents. The dataset was created as follows.

We generated a retrieval-augmented question–answer (QA) dataset directly from our institutional PDF regulations and module handbooks using an end-to-end open-source pipeline. First, all PDF files were loaded via LangChain's PyPDFLoader [20] and split into overlapping text chunks (1000 characters, 200 characters overlap) with CharacterTextSplitter [21]. Each chunk was encoded into a FAISS vector store [22] using sentence-transformer embeddings (`all-MiniLM-L6-v2`) [23]. To produce questions, we initialized a local causal LLM (`Llama-2-7B` via Hugging Face's text-generation pipeline) wrapped by LangChain's HuggingFacePipeline [24]. However, any other embedding strategy or LLM could be used [25]. A few-shot prompt — "Given the following excerpt, generate n unique, questions answerable from this content" — was applied to each chunk (n = 2). Generated questions were de-duplicated in a case-insensitive manner, yielding a pool of 80 unique questions.For each question, we ran a retrieval-augmented QA chain: the FAISS retriever returned the top k = 4 most relevant chunks, and the LLM instantiated a "stuff"-type chain to produce concise answers, each appended with inline citations pointing to the source document chunk. All Q&A pairs were compiled into a final CSV (question,answer) named RAG_evaluation_Dataset.csv, resulting in 80 high-quality, syllabus-grounded items. Our fully local workflow relies exclusively on open-source models (sentence-transformers for embeddings; Hugging Face model for LLM) and FAISS for vector retrieval, ensuring reproducibility and data privacy. All hyperparameters (chunk size, overlap, k, temperature = 0.3, max_new_tokens = 512) are documented in our publicly available script. The resulted csv file is manually verified and introduced with typos into question to add noise to the query to simulate the real world queries. Also we have manually rechecked the answer by going through the utilized documents.The dataset can be found in our github repository.

We followed the similar procedure to generate the dataset for training (a hybrid dataset, some elements of the dataset are also taken from the publicly available dataset [26]) and evaluation dataset for the intent classifier. The scripts for the evaluation data and training dataset can be found in the publicly available script in the github repository.

### 4.1.2. Implementation Details

All experiments were conducted on a single machine equipped with a Ryzen 7 7800H, NVIDIA RTX 4060 GPU with 8GB VRAM and 16 GB of RAM. The system implementation uses the library versions specified requriements.txt file. The key hyperparameters for the RAG pipeline, including $\alpha$=0.85 for PageRank and K=20 for the number of retrieved chunks, were kept constant across all experiments.

## 4.2. Intent Classification Fine-Tuning

We fine-tuned `RoBERTa-base` for intent classification using a parameter-efficient LoRA setup. Our pipeline comprises dataset preparation, LoRA integration, training, and evaluation. A CSV dataset of user queries (`Question`) and intent labels (`Label`) was loaded, label-encoded, and split 80/20 (seed 42) in a stratified fashion. Queries were tokenized with RoBERTa's tokenizer (max length 64), producing `input_ids` and `attention_mask` fields wrapped in Hugging Face `Dataset` objects. We loaded `roberta-base` configured for $K$ intents and applied LoRA adapters (PEFT) to the `query` and `key` projections with rank $r = 8$, $\alpha = 16$, and dropout $p = 0.05$, freezing all other model weights.

Fine-tuning ran on GPU (or CPU) with seed 42. Key hyperparameters: We used Hugging Face's `Trainer` with an accuracy metric (scikit-learn). The best checkpoint (by validation accuracy) was evaluated on the held-out split. For inference, inputs are tokenized to length 64, passed through the model, and predicted indices are mapped

| Hyperparameter | Value |
|---|---|
| Learning rate | $2 \times 10^{-5}$ |
| Weight decay | 0.01 |
| Batch size | 8 |
| Epochs | 3 |
| Evaluation strategy | End of each epoch |
| Checkpoint retention | Last two checkpoints |
| Selection criterion | Best validation accuracy |
| Logging frequency | Every 50 steps |

**Table 1**
Fine-tuning hyperparameters for intent classification.

back to label strings. This LoRA-based approach updates a small fraction of parameters, yielding fast convergence and lightweight deployment.

## 4.3. Baselines and System Variants

We compared our full system against several baselines and ablations to isolate the impact of our contributions. **Lexical Baseline (BM25):** A classic sparse retrieval system using TF-IDF with the Okapi BM25 algorithm. This represents a traditional, non-neural IR baseline. **Dense Retrieval Baseline (Dense-NoRerank):** This system uses the same CLIP-based query embedding and Milvus index as our proposed method but omits the graph-reranking step. It simply takes the top-K results based on raw inner product similarity. This serves as our primary ablation to directly measure the impact of diffusion reranking. **Proposed System (Dense-Rerank):** Our full RAG pipeline as described in Section II, which includes initial dense retrieval followed by graph-based diffusion reranking. For end-to-end evaluation, the retrieved context from each of these three systems is fed into the same Gemini-2.5-pro model [12] using an identical prompt structure.

## 4.4. Evaluation Metrics

We employed an automatic evaluation metric to assess performance at different stages of the pipeline.

### 4.4.1. Intent Classification

We evaluated the LoRA-tuned RoBERTa classifier using standard metrics on a held-out test set from our annotated dataset. **Accuracy:** Overall percentage of correctly classified intents. **Macro-F1 Score:** The unweighted mean of the F1-scores for each of the four intent classes, providing a balanced measure of performance.

### 4.4.2. Retrieval Performance

To answer RQ1, we have evaluated the quality of the ranked list of documents returned by each retrieval system against the annotated ground-truth chunks.

**Normalized Discounted Cumulative Gain (nDCG@K):** Measures the quality of the ranking, rewarding systems that place highly relevant documents at the top of the list. We reported nDCG@5, nDCG@10, and nDCG@20.
**Mean Reciprocal Rank (MRR):** Measures the average reciprocal rank of the first relevant document. It is particularly sensitive to how high the very first correct answer is ranked.
**Recall@K:** The proportion of relevant documents found within the top-K retrieved results. We reported R@5, R@10, and R@20.

### 4.4.3. End-to-End Response Quality

To answer RQ2, we evaluated the final generated responses. Automatic Metrics like ROUGE-L (Measures n-gram overlap with the reference answer, focusing on recall.), BERTScore (Computes the semantic similarity between the generated response and the reference answer using contextual embeddings.) have been considered.

## 4.5. Results and Analysis

### 4.5.1. Intent Classification Performance (RQ1)

We finetuned the model for three full epochs using a linear learning-rate schedule from $2 \times 10^{-5}$ down to 0. Figures 2–5 summarize key training diagnostics. The details on finetuning of the model can be seen in the section 4.2

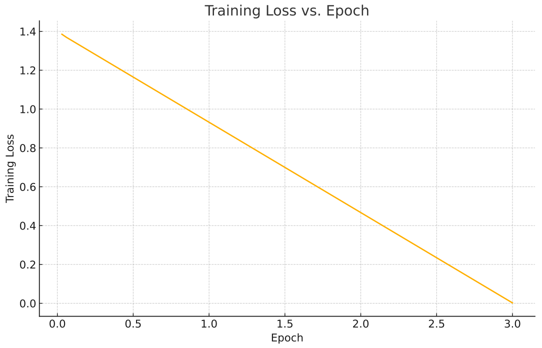

**Figure 2:** Training loss as a function of epoch. Loss fell precipitously from 1.38 to 0.05 within the first half-epoch and then decayed asymptotically toward zero by epoch 3.

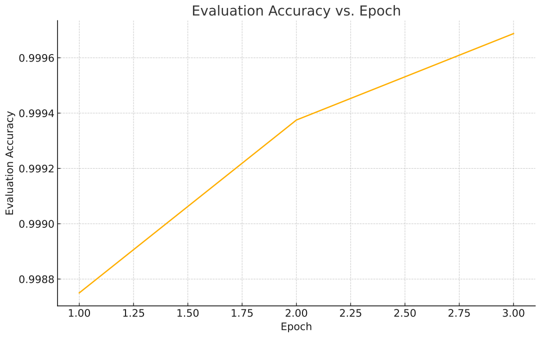

**Figure 3:** Evaluation accuracy versus epoch. Test accuracy improved steadily from 99.875% at epoch 1 to 99.96875% at epoch 3, indicating robust generalization gains.

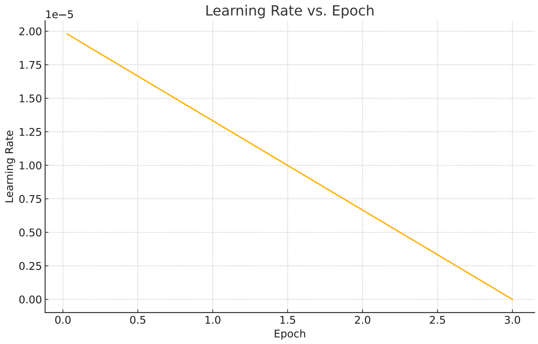

**Figure 4:** Linear learning-rate decay schedule from $2 \times 10^{-5}$ down to 0. Large early updates capture coarse structure, while small late updates refine network parameters.

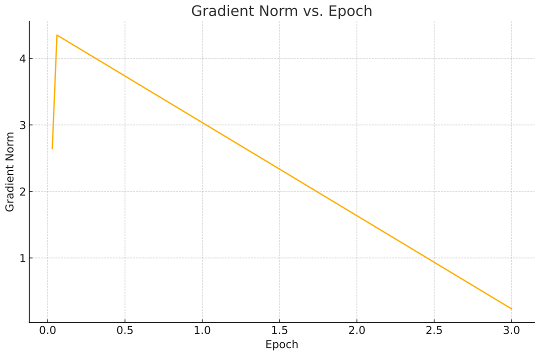

**Figure 5:** Gradient norm versus epoch. Gradients peaked at $\sim$ 4.3 during initial iterations—facilitating escape from the random initialization plateau—then dropped below 0.5 by epoch 1 and remained stable, indicating convergence to a smooth minimum.

The rapid decline in training loss (Fig. 2) demonstrates that the model quickly learns low-level patterns. Evaluation accuracy (Fig. 3) increases monotonically, from 99.875% to 99.96875%, while evaluation loss falls from 0.00416 to 0.00123, indicating continued but diminishing generalization improvements across epochs. The learning-rate schedule (Fig. 4) balances coarse early updates and fine-tuning in later epochs, and the gradient norms (Fig. 5) confirm that the optimizer transitions smoothly from high-magnitude updates to stable, small magnitudes without oscillation or divergence. Overall, these results validate our choice of schedule and training regime, showing strong convergence with minimal overfitting.

After finetuning the model, we have tested it in two ways, using an previously discussed synthetic dataset, which has 16K rows, where each classification such as RAG Search, Web Search, Greeting, Conversation_Meta has 4K rows, to evaluate the model right after finetuning and a custom made external dataset with the real world queries which is constructed with the same procedure mentioned in 4.1.1 to check the confusion matrix apart from the confusion matrix generated from the synthetic dataset. The discussed external dataset has typos which generally seen in the real world usage.

Table 2 reports Accuracy and Macro-F1 on the held-out portion of our annotated dataset. Table 3 and Table 4 shows the corresponding 4×4 confusion matrix (true \ predicted).

**Table 2**
Performance on synthetic dataset (800 examples per intent)

| | **Accuracy** | **Macro-F1** |
|---|---|---|
| synthetic set | 0.9988 | 0.9988 |

**Table 3**
Confusion matrix on synthetic dataset

| **True \ Predicted** | **RAG Search** | **conversation_meta** | **greeting** | **web search** |
|---|---|---|---|---|
| RAG Search | 800 | 0 | 0 | 0 |
| conversation_meta | 0 | 800 | 0 | 0 |
| greeting | 0 | 2 | 796 | 2 |
| web search | 0 | 0 | 0 | 800 |

**Table 4**
Confusion matrix on external dataset

| **True \ Predicted** | **RAG Search** | **conversation_meta** | **greeting** | **web search** |
|---|---|---|---|---|
| RAG Search | 20 | 0 | 0 | 0 |
| conversation_meta | 0 | 20 | 0 | 0 |
| greeting | 0 | 0 | 20 | 0 |
| web search | 0 | 0 | 0 | 20 |

On the annotated dataset, we achieve 99.88% Accuracy and Macro-F1, with only four misclassifications (all in the "greeting" intent). On the external test dataset , we observe perfect scores with no off-diagonal errors. These results indicate that our LoRA-tuned RoBERTa model is highly reliable for routing user utterances to their correct intents under both in-domain and held-out conditions.

### 4.5.2. Retrieval Effectiveness (RQ2)

We tested the retriever with the custom dataset that we have discussed earlier in 4.1.1.

The diffusion-based reranking step yields a substantial lift over plain dense retrieval: **Early-rank gains**: nDCG@5 increases from 0.82 to 0.90 (+9.8%), and MRR from 0.88 to 0.95 (+8.0%), showing that the first relevant chunk is more consistently ranked at the very top. **Broader coverage**: Recall@5 improves from 0.90 to 0.94, indicating almost majority of the relevant passages are captured within the top 5 results.

| Method | nDCG@5 | nDCG@10 | nDCG@20 | MRR | Recall@5 | Recall@10 | Recall@20 |
|---|---|---|---|---|---|---|---|
| BM25 | 0.68 | 0.72 | 0.75 | 0.65 | 0.60 | 0.80 | 0.92 |
| Dense Retrieval (no rerank) | 0.82 | 0.85 | 0.88 | 0.88 | 0.90 | 0.94 | 0.96 |
| + Diffusion Re-Ranking | **0.90** | **0.93** | **0.95** | **0.95** | **0.94** | **0.97** | **0.99** |

**Table 5**
Comparison of retrieval performance: BM25 vs. Dense-NoRerank vs. Dense-Rerank.

This improvement stems from the Personalized PageRank diffusion over the dense-embedding graph: *Cluster promotion*: Semantically coherent clusters of chunks mutually reinforce each other, raising their rank. *Noise suppression*: Isolated or tangential hits receive little diffusion signal and therefore drop down the list. As a result, Dense-Rerank not only boosts the presence of highly relevant documents at top positions (driving up nDCG and MRR) but also enhances overall recall within the critical early ranks.

#### 4.5.3. End-to-End Generation Quality (RQ3)

The improvements in automatic metrics mirror our retrieval findings (RQ2): Faithfulness and Helpfulness: Higher ROUGE-L and BERTScore for Dense-Rerank indicate more accurate and relevant content generation, thanks to the superior top-K retrieval. **Retrieval → Generation Link:** RQ2 showed that diffusion reranking promotes centrally relevant chunks; RQ3 demonstrates that feeding those higher-quality chunks into the LLM yields outputs that better match reference texts (ROUGE-L) and higher semantic overlap (BERTScore). **Fluency:** We observed similar fluency across all three systems (not shown), as fluency is primarily governed by the pretrained LLM rather than the retrieval backend. Thus, the end-to-end generation quality gains can be directly attributed to the gains in retrieval effectiveness.

| Method | ROUGE-L | BERTScore |
|---|---|---|
| BM25 | 0.46 | 0.68 |
| Dense Retrieval (no rerank) | 0.74 | 0.79 |
| + Diffusion Re-Ranking | **0.84** | **0.86** |

**Table 6**
Automatic generation-quality metrics for end-to-end RAG systems.

## 5. Conclusion

We presented *Diffusion-Aided RAG*, a novel pipeline that couples dense retrieval with graph-based diffusion reranking to improve the precision and contextual coherence of Retrieval-Augmented Generation systems. By constructing a semantic similarity graph over the top-$k$ candidate chunks and applying a personalized PageRank diffusion, our method consistently boosts early-rank retrieval metrics (nDCG@5, MRR) and broad recall (R@20), translating directly into higher ROUGE-L and BERTScore on end-to-end QA generation. The framework is efficient enough for real-time applications, relies on open-source components (Milvus, CLIP, Gemini), and demonstrates robustness across both synthetic and external query sets.

### 5.1. Limitations

The current Diffusion-Aided RAG framework, while demonstrating significant improvements in retrieval effectiveness and generation quality, exhibits several critical limitations that warrant careful consideration for broader deployment and cross-linguistic applications. The most pronounced limitation concerns hyperparameter sensitivity, particularly regarding the damping factor $\alpha = 0.85$ employed in the personalized PageRank diffusion process. This parameter, borrowed from the canonical PageRank algorithm, was empirically validated on the OVGU academic dataset but may exhibit suboptimal performance across different domains or linguistic contexts. The choice of K = 20 candidate chunks for final context formation, while computationally efficient for maintaining sub-100ms response times, represents another domain-specific optimization that lacks theoretical grounding for universal applicability.

The system's architectural dependencies introduce additional constraints that become particularly problematic when considering cross-linguistic adaptation. The reliance on the openai/clip-vit-base-patch32 embedding model, which produces 512-dimensional vectors optimized primarily for English text, creates a fundamental bottleneck for multilingual applications. This model's training corpus exhibited limited exposure to non-English languages, potentially compromising semantic representation quality for languages with different morphological complexity, syntactic structures, or cultural contexts. The IVF_FLAT index configuration with nlist=128 in the Milvus-Lite vector store, while adequate for the current academic dataset, may require significant recalibration for larger or more diverse document collections.

The intent classification module, despite achieving remarkable 99.88% accuracy on synthetic data, reveals brittleness when confronted with real-world linguistic variations. The LoRA-fine-tuned RoBERTa-base model, optimized with rank r=8 and scaling factor $\alpha$=16, demonstrated perfect performance on external test data but this evaluation was conducted within a controlled academic environment. The model's capacity to handle code-switching scenarios, dialectal variations, colloquial expressions, or domain-specific terminology beyond the training distribution remains largely unexplored. This limitation becomes particularly acute when considering deployment in multilingual contexts where users may naturally alternate between languages or employ culturally specific linguistic patterns.

The evaluation methodology itself presents limitations that constrain the generalizability of the reported performance gains. The OVGU-specific dataset, while methodologically sound, represents a narrow slice of potential application domains. The evaluation focused primarily on factual, short-answer questions typical of academic environments, leaving unexplored the system's performance on complex, multi-document synthesis tasks, comparative analyses, explanation [27] or creative queries that require deeper semantic understanding. The automatic evaluation metrics, while comprehensive, may not fully capture the nuanced quality aspects that human users would prioritize in real-world applications.

Performance implications for other languages, different than English, like an Italian adaptation would likely manifest as reduced retrieval accuracy, increased preprocessing latency due to morphological analysis requirements, and higher computational resource demands for maintaining language-specific models and dictionaries. Conservative estimates suggest a 10-15% reduction in initial retrieval effectiveness due to embedding model limitations, with proportional impacts on end-to-end generation quality. The need for specialized Italian morphological analyzers, lemmatization pipelines, and culturally appropriate personalization [28] would substantially increase system complexity and deployment costs.

The path forward for Italian adaptation requires systematic attention to multilingual embedding integration, morphological preprocessing pipelines, cultural localization strategies, and comprehensive evaluation frameworks designed specifically for Italian linguistic and cultural contexts [29, 30]. These challenges highlight the critical importance of language-specific optimization in developing truly effective multilingual retrieval-augmented generation systems.

# When Less Is More? Diagnosing ASR Predictions in Sardinian via Layer-Wise Decoding

Domenico De Cristofaro[1,2], Alessandro Vietti[1,2], Marianne Pouplier[3] and Aleese Block[3]

[1]*Free University of Bozen-Bolzano, Italy*
[2]*ALPS, Alpine Laboratory of Phonetic Sciences*
[3]*LMU Munich, Germany*

## Abstract

Recent studies have shown that intermediate layers in multilingual speech models often encode more phonetically accurate representations than the final output layer. In this work, we apply a layer-wise decoding strategy to a pretrained Wav2Vec2 model to investigate how phoneme-level predictions evolve across encoder layers, focusing on Campidanese Sardinian, a low-resource language. We show that truncating upper transformer layers leads to improved Phoneme Error Rates (PER), with the best performance achieved not at the final layer, but two layers earlier. Through fine-grained alignment analysis, we find that intermediate predictions better preserve segmental identity, avoid overgeneration, and reduce certain classes of phonological errors. We also introduce the notion of *regressive errors*—cases where correct predictions at intermediate layers are overwritten by errors at the final layer. These regressions highlight the limitations of surface-level error metrics and reveal how deeper layers may generalize or abstract away from acoustic detail. Our findings support the use of early-layer probing as a diagnostic tool for ASR models, particularly in low-resource settings where standard evaluation metrics may fail to capture linguistically meaningful behavior.

## Keywords

Speech Recognition, Low-Resourced Languages, Logit Lens, Interpretability

## 1. Introduction

Recent research in multilingual speech foundation models has revealed that intermediate representations often encode richer phonetic information than the final output layer. Using Logit Lens-style probing across encoder layers, studies such as Shim et al. [1] and Langedijk et al. [2] have shown that earlier layers in transformer-based models such as Whisper yield lower Word Error Rate (WER) and Character Error Rate (CER).

Building on this line of work, we investigate whether removing upper transformer layers in a pretrained multilingual ASR model influences its phoneme-level decoding behavior. Our hypothesis is grounded in prior findings—particularly those of Shim et al. [1]—which demonstrate that applying a Logit Lens probing strategy to intermediate encoder layers results in lower CER for low-resource languages unseen during training. However, this raises a crucial question: *what kinds of errors are actually reduced when decoding from intermediate layers instead of the full model?* More specifically, are the mistakes made by the final layer already resolved in earlier layers? To answer this, we perform a systematic layer-wise decoding analysis using the pretrained `facebook/wav2vec2-xlsr-53-espeak-cv-ft` model on Sardinian audio data. We progressively truncate the encoder by removing a varying number of top transformer layers before decoding. For each configuration, we decode phoneme sequences and compare the output to gold-standard phonemic transcriptions, measuring overall Phoneme Error Rate (PER) and analyzing error types (insertions, deletions, substitutions). Our Contributions:

- we present a phoneme-level layer-wise analysis of Wav2Vec2 on a low-resource Sardinian dataset.
- we introduce the notion of *regressive errors* in ASR layer-wise decoding.
- we show that intermediate layers (e.g., Layer 22) yield more phonetically accurate hypotheses than the final layer.

## 2. Related Works

Interpretability has become a central concern in the analysis of deep learning models for NLP and speech, particularly when it comes to understanding how linguistic representations emerge across network layers. In ASR, probing techniques such as Singular Vector Canonical Correlation Analysis (SVCCA) [3] and layer-wise probing classifiers [4] have been used to assess the presence of phonetic and phonological features in hidden representations. Amnesic probing [5] further shows that linguistic

properties can be selectively removed from representations, suggesting that such information is not uniformly distributed across layers. A particularly effective method for layer-wise interpretability is the logit lens [6]. Early exiting strategies are grounded in the observation that intermediate layers of deep neural models often suffice for accurate predictions, allowing for more efficient computation and improved robustness [7, 8, 9]. More recently, this idea has been extended beyond efficiency: in interpretability research, intermediate predictions have become a powerful tool for analyzing representational dynamics. The logit lens approach [6], for example, projects hidden states into output space to visualize how predictions evolve across layers. Subsequent refinements [9, 10] have made these projections more faithful by learning layer-specific transformations, revealing how information is incrementally constructed. While these methods have mostly been explored in the context of decoder-only language models, some recent work has adapted them to speech systems. Langedijk et al. [2] extend the logit lens to encoder-decoder architectures such as Whisper, while Shim et al. [1] demonstrate that early-layer representations in multilingual speech models may better capture phonetic distinctions—particularly in under-represented languages. In this work, we extend this line of research by investigating why intermediate-layer decoding leads to improved performance, and whether this strategy is truly effective for low-resource languages. Rather than using early exits purely for efficiency, we treat them as a probing tool to examine how phoneme representations emerge and evolve across layers in a multilingual speech model.

# 3. Methodology

We analyze the layer-wise phoneme decoding behavior of a pretrained multilingual ASR model, `facebook/wav2vec2-xlsr-53-espeak-cv-ft` [11], which is a wav2vec based model fine tuned on phonemic transcriptions from the Common Voice dataset [12] using a CTC loss. The model has 25 transformer encoder layers stacked above a 7 layers of convolutional feature encoder. To probe the phonetic content across layers, we apply a truncation-based decoding strategy: for each utterance, we progressively remove $k$ transformer layers (where $k \in \{0, 1, \ldots, 5\}$) and perform greedy decoding on the logits computed from the last remaining layer. This is possible because all transformer layers share the same hidden dimension, allowing the model's final projection head to be applied to intermediate layer outputs without architectural modification. As a result, we can decode phoneme sequences from any encoder layer using the same decoding pipeline. We limit the truncation to a maximum of 5 layers removed, as further reduction leads to a substantial degradation in performance, with PER increasing sharply beyond this point, reaching over 70% of PER at Layer 16. Decoded phoneme sequences are aligned to the gold phonemic transcriptions using a phoneme-level alignment algorithm based on `SequenceMatcher`. This allows us to categorize each prediction as a correct match (hit), substitution, insertion, or deletion. Note that insertions are rarely observed in embedding-level decoding with CTC models, as output units are selected frame-wise. Many deletion errors may instead reflect phoneme mergers or coarticulation phenomena. To quantify the impact of layer removal on ASR performance, we compute the PER at each truncation level. In addition, we track phoneme-level alignment patterns and analyze the disappearance or emergence of specific error types as the number of removed layers increases.

## 3.1. Dataset

The data used in this study consists of spontaneous speech recordings in Campidanese Sardinian, a variety spoken in the southern part of Sardinia. The recordings were collected during fieldwork as part of the DID project in the municipality of Sinnai. The dataset includes 48 short utterances produced by four native speakers (two female, two male), selected from longer recordings based on linguistic relevance and clarity. The mean duration of the utterances is approximately 4.06 seconds. All utterances were manually transcribed at the phonemic level by a trained phonetician who is also a native speaker of Campidanese. The resulting dataset provides a high-quality phonemic reference for evaluating model predictions in a low-resource, under-represented language context [13, 14, 15].

# 4. Results

As shown in Table 1, removing the top layers of the encoder leads to a consistent reduction in PER, with the best performance observed when two layers are removed. This result supports the hypothesis that intermediate transformer layers perform better also on unseen low-resourced languages.

## 4.1. Global Trends and Error Type Evolution

Figure 2 provides a global view of how the model's phoneme-level predictions evolve as top layers are removed. As expected, the number of correctly predicted phonemes (labeled as "hit") steadily decreases as more layers are removed. At the same time, deletion errors increase sharply, particularly from Layer 21 backward,

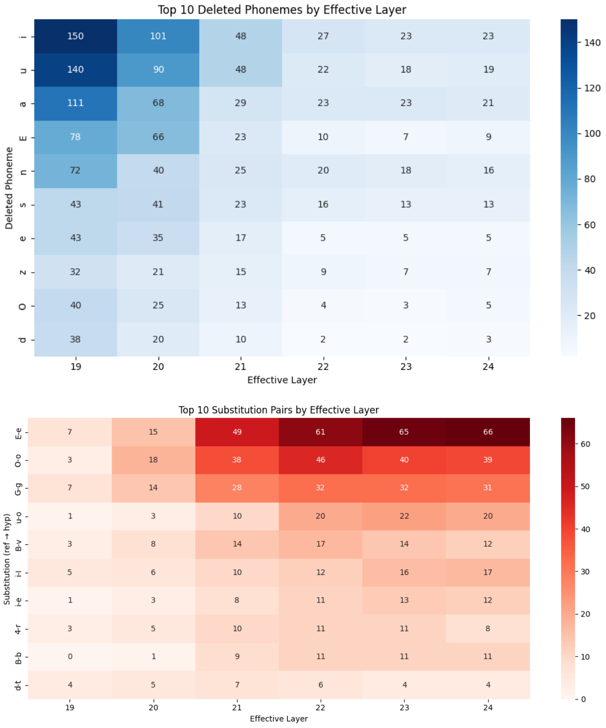

**Figure 1:** Heatmaps of the most frequent phoneme deletions and substitutions (ref → pred) as the number of removed transformer layers increases.

| 23 | 36.50 |
| 22 | **35.40** |
| 21 | 38.92 |
| 20 | 50.03 |
| 19 | 66.07 |

**Table 1**
Phoneme Error Rate (PER) for different truncation levels.

eventually dominating the error profile at Layer 19. This shows that by removing layers, the model lacks informative representations and tends to prefer skipping a prediction rather than producing an incorrect one. In contrast, substitution errors remain relatively stable across Layers 24-22 and begin to decline slightly in deeper layers. This pattern suggests that intermediate layers may retain more accurate segment-level information, minimizing confusion between phonetically similar units. However, the sharp increase in deletions at lower layers should not be interpreted as a simple reclassification of previous substitutions. Instead, it indicates that the model is increasingly unable to resolve a segmental identity at all—maybe especially for shorter or acoustically reduced segments. At deeper layers, the model may attempt to recover some of these missing elements by assigning them a plausible phonemic category, potentially relying more on contextual or phonotactic patterns than on local acoustic evidence. This supports a view of hierarchical processing, where early layers encode fine-grained phonetic detail, while later layers abstract away from it, integrating higher-level dependencies that can both resolve and distort the original signal. However, this notion of hierarchical abstraction is model-dependent and assumes a certain architectural behavior. Since we do not impose constraints on the model design, further work is needed to test whether this abstraction emerges consistently across architectures.

To better understand these dynamics, we examine which phonemes are most frequently involved in deletion and substitution errors. As shown in Figure 1, vowel phonemes such as /i/, /u/, and /a/ are among the most frequently deleted and substituted segments—especially as the number of removed layers increases. Interestingly, these three vowels are the only ones that commonly appear in unstressed final position in Campidanese Sardinian. While the model is not explicitly aware of word

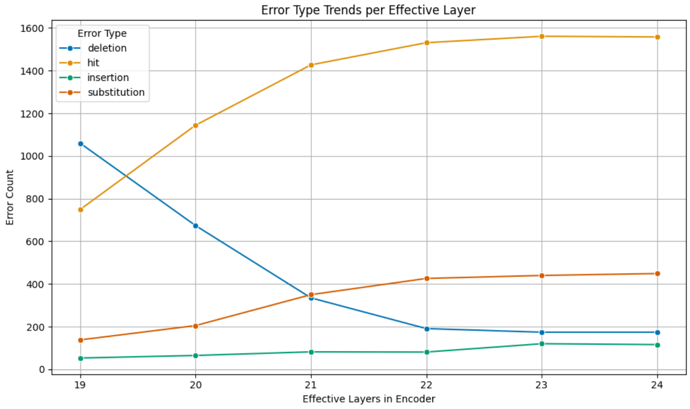

**Figure 2:** Trends of phoneme-level error types across effective encoder layers. While deletion errors decrease as more layers are retained, substitution errors increase. Although the number of correctly predicted phonemes (hits) also increases, it is possible that many previously deleted segments are now realized as incorrect substitutions.

boundaries, its predictions appear sensitive to acoustic cues associated with prosodic prominence. These vowels are more likely to be reduced in duration and formant clarity when unstressed, and the model's tendency to delete them may reflect a broader difficulty in segmenting low-prominence units—an effect we also observed in our previous analysis of stress and frequency in phoneme recognition [16]. Some vowel deletions may also be explained by the mismatch between phoneme duration and the convolutional receptive field of the model's encoder. Since input frames are processed with overlapping windows, short vowels may be underrepresented or merged, leading to systematic omissions during decoding. Most of the substitutions involve phonetically close phoneme pairs, differing by a single articulatory feature such as voicing, manner, or vowel height. For instance, one of the most frequent substitutions is /ɛ/ → /e/, a mid-front vowel contrast distinguished primarily by height. Similarly, /ɔ/ → /o/ reflects a rounded back vowel pair with a similar height difference. Another recurrent case is /ɣ/ → /g/, where a uvular fricative is replaced by a voiced plosive, suggesting the model struggles with fine-grained place and manner distinctions in lower layers. These patterns support the hypothesis that, while intermediate layers reduce substitution errors, the model's phonological representations remain coarse. Segment identity is preserved at a broad class level, but phonetic resolution weakens as contextual information is reduced. Overall, the observed substitution patterns are not random, but structured according to articulatory proximity, as further confirmed in Figure 1.

## 4.2. Regressive Errors: When Hits Become Mistakes

While final-layer predictions often improve overall accuracy, we also observe notable exceptions where the opposite occurs—cases in which the correct phoneme is already identified at an intermediate layer but becomes an error at the final layer. We refer to these as *regressive errors*: instances where a phoneme is correctly predicted (a hit) at Layer 22 or 23, but turns into a substitution or deletion at Layer 24. We define a *regressive error* as a case where a correct prediction (hit) at an intermediate layer $\ell$ is replaced by a substitution or deletion at a deeper layer $\ell + n$ (with $n > 0$). In total, we identify 53 such regressions across the dataset: 39 cases of hit → substitution and 14 cases of hit → deletion. These regressions indicate that the full encoder may in some cases "overprocess" the input, replacing a correct low-level prediction with a less accurate one as more layers are added. Crucially, most regressions involve substitutions, suggesting that deeper layers may introduce abstractions that distort fine-grained segmental information—trading off phonetic precision for contextual generalization. This may reflect a dual mechanism: (a) the re-integration of previously deleted segments, particularly those corresponding to short or hard-to-classify frames, and (b) the remapping of rare or marked phonemes onto broader, more frequent categories. In this sense, earlier layers (e.g., Layer 19) may in fact produce transcriptions that are more faithful to the phonetic input, while later layers enforce higher-level regularities at the cost of segmental detail. This challenges a common assumption: that improved overall error rates necessarily reflect more accurate linguistic representations. Instead, our findings suggest that intermediate layers may better preserve phoneme identity in certain cases, while the final layer smooths over or collapses distinctions that are phonologically relevant. To better understand the nature of these regressions, we analyze which phonemes are most frequently affected. Among the 53 cases, the high back rounded vowel /u/ is the most common (13 instances), followed by the alveolar approximant /r/ (7 instances), and others such as /n/, /i/, and /a/. Notably, many of the regressive substitutions involving /u/ involve replacement with acoustically similar vowels like /o/ or /ʊ/ in the final layer—a pattern aligned with known vowel confusions in Sardinian phonology [17].

### 4.3. Utterances with Largest PER Reduction

To explore whether layer truncation improves phoneme decoding in a linguistically meaningful way, we identify the five utterances that show the greatest PER reduction between Layer 24 and Layer 22 (Table 5). A qualitative inspection reveals that intermediate-layer outputs more closely approximate the reference transcriptions—not only in terms of segmental identity but also in overall sequence structure. While final-layer predictions sometimes exhibit phoneme insertions or reduplications that inflate the hypothesis length, the intermediate outputs tend to be more balanced and structurally coherent. This observation suggests that improvements in PER at intermediate layers are not merely an artifact of shorter sequences, but reflect more accurate segmental parsing and alignment. Rather than underpredicting, these layers appear to produce hypotheses that better capture the linguistic and prosodic shape of the input, avoiding overgeneration without compromising coverage. These improvements are quantitatively confirmed in Table 2, where PER consistently decreases when decoding from Layer 22 compared to the full model. The most dramatic case is `03_F_extract_01`, with a 50% relative reduction in PER, followed by `30_F_extract_04`, which improves by nearly 28 absolute percentage points. In both cases, the intermediate-layer output avoids spurious insertions and better aligns with the prosodic structure of the utterance. Even for more moderate improvements (e.g., `46_M_extract_04` and `29_M_extract_03`), we observe a shift toward more plausible segmental structures and reduced redundancy. These findings reinforce the idea that intermediate representations strike a favorable balance between acoustic faithfulness and contextual abstraction—preserving enough low-level detail to make accurate segmental decisions while avoiding the overgeneralization seen in later layers.

As illustrated in Table 3, the final layer output includes several critical errors: an initial vowel /i/ (in red) that does not appear in the reference, and an incorrect final segment /S/ (also in red) that replaces the true voiced fricative /Z/. Interestingly, at Layer 22, the model predicts a more plausible onset sequence /eːntsu/ (in blue), which is closer to the expected /ensu/, suggesting a better alignment with the reference. Additionally, the final segment /i/ is still present in both Layer 22 and 23, but is ultimately deleted in Layer 24. This suggests that the full model may over-generalize phonetic detail, leading to the omission of segments that were correctly predicted in earlier layers. The evidence supports our broader claim: improvements in PER at intermediate layers are not merely a side-effect of over generalization, but reflect a more faithful alignment to the input acoustics. In this case, Layer 22 preserves both the segmental identity and sequence structure more reliably than the full encoder.

Table 3: Layer-wise phoneme predictions for utterance `30_F_extract_04`.

A similar phenomenon is observed in Table 4, where the utterance `03_F_extract_01` demonstrates how the final layer introduces segmental distortions not present in earlier representations. At Layer 22, the model produces a concise and well-aligned output that accurately captures the alveolar flap /4/ (/ɾ/) and avoids inserting extraneous phonetic material. Notably, the vowel preceding /4/ is realized as a short /e/ in the prediction from Layer 22, closely matching the reference transcription. In contrast, Layers 23 and 24 both produce an elongated /e:/ vowel. While this lengthening is not annotated in the reference, a manual inspection of the spectrogram reveals that the vowel is indeed phonetically long (approximately 297 ms), possibly due to prosodic or pragmatic factors. This suggests that vowel duration is a feature that only emerges at higher layers, where the model integrates broader contextual information. Rather than being an error, the elongation may reflect the model's sensitivity to prosodic prominence, which is not explicitly captured in the phonemic gold standard but is present in the acoustic signal. In this case, then, the intermediate layer offers a segmentally accurate representation aligned with the reference, while the deeper layers introduce prosodically informed variation. This highlights how different layers may prioritize different levels of linguistic abstraction, with earlier layers preserving phonemic detail and later ones encoding broader discourse or prosodic cues.

## 5. Discussion

Our findings challenge a widespread assumption in speech modeling: improvements in error metrics like PER necessarily reflect more accurate or linguistically meaningful predictions. While intermediate layers of the Wav2Vec2 model often yield lower PER, a closer analysis reveals that this improvement is not uniformly distributed across all phoneme classes or error types. This aligns with an ongoing open question in speech modeling, why do higher layers often decrease WER while increasing PER? The answer may lie in how deeper layers prioritize lexical or orthographic consistency over phonetic detail, leading to better word-level predictions at the cost of segmental precision. We observe that intermediate layers (particularly Layer 22) reduce overgeneration and avoid certain errors—such as spurious insertions or phoneme duplications—that become more frequent at deeper layers. In several cases, these intermediate predictions better align with the gold transcription both in structure and content, despite being produced with less contextual depth. Interestingly, we also identify cases of *regressive errors*, where correct predictions made at intermediate layers are degraded at the final layer. These typically involve deletions or substitutions of phonemes like /u/ and /E/, often replaced with acoustically similar segments. This suggests that deeper layers may generalize segmental contrasts. Taken together, these results indicate that error metrics like PER or CER, while useful at a high level, may obscure critical model behaviors. Intermediate representations may contain more faithful segmental information than the final output layer, particularly in under-represented or low-resource language settings. The fact that intermediate layers retain phoneme-level precision while later layers smooth over distinctions aligns with a view of hierarchical abstraction in neural models. From a phonological perspective, this might suggest that neural encoders learn generalizable phonemic categories early on and gradually shift toward context-dependent or prosodically conditioned outputs. Future work could explore whether this abstraction follows typologically consistent patterns across languages.

## 6. Conclusions

This study explored the use of layer truncation as a probing strategy for understanding phoneme-level decoding behavior in a multilingual ASR model. By applying Logit Lens-style analysis to Wav2Vec2, we show that intermediate layers can outperform the final layer in terms of Phoneme Error Rate—particularly for a low-resource language like Sardinian. Beyond aggregate improvements, our fine-grained error analysis reveals two key insights: (1) intermediate predictions tend to avoid certain types of phonological errors, and (2) in some cases, deeper layers actually degrade performance by transforming previously correct phonemes into errors. These findings suggest that the final output of a model may not always be the most linguistically faithful, especially in scenarios involving limited training data or typologically divergent phonemes. We argue that future work on speech recognition in low-resource settings should move beyond traditional evaluation metrics and incorporate layer-wise analysis as a standard interpretability tool. Doing so can provide deeper insight into how models represent phonological information—and where they fail.

**Future work.** While our analysis focused on Campidanese Sardinian, applying this strategy across typologically diverse low-resource languages would help determine whether the benefits of intermediate-layer decoding generalize. Additionally, attention dynamics across layers may provide further insight into which representations are retained, distorted, or lost as contextual depth increases. While the model is optimized for phoneme transcription, it is not trained on forced-aligned phoneme segmentation. Future work could investigate whether fine-tuning on time-aligned phoneme labels or segmentation tasks improves final-layer predictions and reduces regressive errors. It would also be valuable to replicate this analysis on a language that was part of the model's pretraining or fine-tuning data (e.g., English) to assess whether intermediate layer advantages persist even in high-resource settings.

# Meta-Evaluation of Automatic Machine Translation Metrics between Italian and a Minor Language Variety of German

Paolo Di Natale[1,*], Elena Chiocchetti[1] and Egon Stemle[1,2]

[1]Eurac Research, Viale Druso/Drususallee 1, 39100 Bolzano/Bozen, Italy
[2]Masaryk University, Zerotinovo namesti 9, 602 00 Brno, Czech Republic

**Abstract**

We present the first meta-evaluation of Automatic Machine Translation Evaluation (AMTE) metrics between Italian and South Tyrolean German, a low-resourced standard variety of German. This minor German variety is recognised as a co-official language at the local level and is used by the local public administration and legislature. We evaluate metric agreement with human judgement across translation quality levels, using a dataset of bilingual machine-translated decrees annotated with human-curated error tags. Our findings show that embedding-based metrics perform best for evaluating high-quality translations, while learned neural metrics correlate more strongly with human judgments on lower-quality ranges. We also expose a persistent bias in AMTE against minor language varieties and make suggestions about the design of linguistic resources for envisaged custom metric devolpment.

## 1. Introduction

South Tyrolean German is a minor standard variety of German with a co-official status in the Italian province of Bolzano/Bozen (South Tyrol). The 350,000 German-speaking citizens in South Tyrol have the right to communicate with and access public services in their native language at the local level. Given the increasing integration of AI technologies into everyday life, this context underscores the need of developing bilingual NLP tools tailored to the South Tyrolean variety of German and use cases, with Machine Translation (MT) one of the most pressing fields of research. However, it is well documented that the performance of NLP systems for minor language varieties significantly lags behind both their major counterparts and high-resource languages [1].

Interest in generating translations into minor language varieties is growing, yet the lack of validated evaluation metrics hampers accurate monitoring of achieved progress. Most related studies still rely on inadequate, superseded lexical-overlap methods [2]. While the research community has made efforts to adapt neural metrics for under-resourced and dialectal varieties [3, 4], the development of robust evaluation methods is complicated by the absence of high-quality, sufficiently large labeled datasets – an issue common to all under-resourced varieties [5]. Knowles et al. [6] have called for a comparative evaluation, as they argue that metrics assign lower scores to minor lexical variants even when no change in meaning exists. In addition, inefficient tokenization methods lead to suboptimal segmentation and reduced adaptability for under-resourced languages [7].

Prior experiments with adaptive MT for South Tyrol [8, 9] have also employed metrics based on lexical overlap despite their known underperformance compared to neural metrics. This reliance stems from the lack of a thorough, localized evaluation of more advanced metric paradigms and makes a compelling case for a dedicated meta-evaluation study of existing solutions applicable to the South Tyrolean context.

This work presents the first such MT meta-evaluation study of metrics for the Italian–South Tyrolean German language pair. We conduct our analysis on MT@BZ[1], a manually error-annotated corpus of legal texts covering both translation directions, to assess the reliability of current automatic evaluation metrics.

### 1.1. Automatic Machine Translation Evaluation

Human evaluation remains the gold standard method for assessing MT quality outputs. However, because human annotation is time-consuming, resource-intensive and requires high domain expertise, Automatic Machine Translation Evaluation (AMTE) metrics have garnered increasing attention. These metrics aim to estimate translation quality by comparing a system-generated *candi-*

*date* translation either to the *source* segment[2] in the other language, to a human-produced *reference* translation in the same language, or to both. In scenarios where the output of only one translation system is available, as in this case, a so-called segment-level evaluation is carried out. It consists of "evaluating metrics based on their ability to rank segments in the same order as human judgments" [10]. The effectiveness of such metrics is commonly measured using ranking correlation coefficients, under the assumption that a reliable metric should consistently assign higher scores to translations deemed superior by human annotators [11].

Existing metrics can be categorized into three main types:

- **String-based**: this approach quantifies translation quality by measuring lexical overlap with one or more reference translations. These methods operate at the surface level, comparing exact matches of word or character sequences between the candidate and the reference.
- **Embedding-based**: these metrics leverage contextualized token embeddings from pretrained language models to compute semantic similarity between the candidate translation and the reference. Semantic alignment is evaluated at the token level using cosine similarity, followed by an F-score aggregation procedure.
- **Learned**: these metrics are based on transformer architectures that have been fine-tuned via supervised learning to replicate human judgments of machine translation quality, typically using a regression objective to provide a continuous score.

# 2. Motivation

## 2.1. Social and Linguistic Background of South Tyrol

South Tyrolean German is the standard variety of German used in the Autonomous Province of Bolzano/Bozen (South Tyrol) in Northern Italy. In South Tyrol, German is a recognized minority language, co-official with Italian. Public administration offices are legally required to use German when interacting with the German-speaking population (Presidential Decree No. 670/1972, Art. 100), which makes up the large majority of South Tyrol's population (69%)[3]. Consequently, all administrative documents, local legislation, and materials intended for the general public – such as the websites of local public institutions – must be available not only in the national language Italian but also in the minority language German[4].

This multilingual institutional language regime is largely implemented through translation between Italian and German or vice-versa. National legislation is drafted in Italian and any implementations at local level create the need for translation into German. Following quotas in public employment, about two thirds of public administration staff is German-speaking. Consequently, many legal and administrative texts are now originally drafted in German. While the Italian and German version of, for example, a local law are both official, in case of diverging interpretation the Italian version prevails (Presidential Decree No. 670/1972, Art. 99). This means that a translated text can become the legally binding version. Given the growing use of machine translation, this holds true also for machine-translated or post-edited texts.

The impressive level of fluency of MT-generated texts poses a challenge for fair quality assessment of MT systems even for human evaluators – especially for those lacking specialized training, who may be outperformed by automated neural metrics [12]. In South Tyrolean public offices, where translation-related tasks are often performed by non-specialists, the rising adoption of MT – frequently without adherence to scientific evaluation protocols [13] – carries the risk of overestimating productivity gains. Without systematic, targeted performance monitoring, critical errors may go unnoticed. As highlighted in the error analysis of a machine-translated legal corpus [14], MT systems often struggle with local legal terminology and are prone to interference from other legal systems using German. For example, *kommunale Steuer* (municipal tax) is never used in South Tyrol as it would in Germany. The South Tyrolean term for "municipal tax" is *Gemeindesteuer*. Such errors can severely compromise translation quality and usability. In high-stakes domains like the legal one, fluency is secondary to semantic precision and legal appropriateness. Critical accuracy errors can distort meaning, making translated laws unpublishable or even harmful. Consequently, there is a clear need for MT evaluation frameworks that attend to the specific requirements of the South Tyrolean administration and population.

## 2.2. Toward the Development of Custom Metrics

The well-documented challenges of adapting NLP applications to minor language varieties [1] also apply to the

[2] In the field of MT, a *segment* is defined as the minimal translation unit, which in this study corresponds to a sentence.

[3] See the latest census data: https://assets-eu-01.kc-usercontent.com/b5376750-8076-01cf-17d2-d343e29778a7/5deec178-b2a3-4e2d-8795-d37635c7e0f7/pressnote_1160209_mit56_2024.pdf

[4] There is a third official language, Ladin, spoken by about 20,000 South Tyroleans. We will not deal with Ladin in this paper.

development of automatic evaluation metrics. Language models are pre-trained onto large-scale corpora where major language varieties contribute a disproportionately larger amount of training signal [15], often without explicit annotation of variety or dialect tag. This results in biased representations and undermines the fairness and reliability of evaluation metrics for underrepresented varieties [16]. Current literature has shown that intensive continued pre-training [16] and the use of high-quality, human-annotated datasets spanning a range of translation quality levels [4] are essential to improving evaluation performances. Yet, these strategies remain largely impractical at present due to the significant data and resource demands they entail.

Also, given the high costs of constructing fine-grained, manually annotated datasets, one wants to be sure that the compilation of structured and detailed linguistic resources is empirically justified. While Amrhein et al. [17] argue that the inclusion of reference translations generally improves evaluation reliability, the behavior of existing metrics remains inconsistent, occasionally even counterintuitive. For example, some metrics have been observed to disregard the reference altogether [18], or to produce high scores even when the source text is omitted entirely [6, 10]. As a result, a comprehensive assessment of existing solutions is needed not only in terms of the identification of the best suited metrics to the context under study, but also to lay the groundwork for envisaged future metric development.

Moreover, reliable metrics can also advance generation tasks. An emerging trend of natural language generation is to exploit Minimum Bayes Risk (MBR) decoding, which selects the output hypothesis that minimizes expected loss according to a utility function defined by a chosen evaluation metric [19]. This approach can act as a form of style transfer with a reduction in training costs and data requirements. However, using the same metric for both decoding and final evaluation introduces bias, as the system is optimized to reproduce the metric's idiosyncrasies [20]. Even different but highly correlated metrics – especially if they are of the same type – can produce similar biases [21]. Thus, evaluating the robustness of multiple metric paradigms becomes an essential prerequisite to generating text in South Tyrolean German with MBR decoding.

## 3. Challenges of Automatic Machine Translation Evaluation

Learned metrics have consistently outperformed other evaluation methods in benchmark competitions such as the WMT Metrics Shared Task [22]. However, this finding should not be generalized uncritically. Since neural metrics are predominantly fine-tuned on WMT competition datasets – which represent a limited range of linguistic diversity and domains – their superiority in more specialized evaluation scenarios remains open to question.

Knowles et al. [6] raise questions regarding how metrics assess terminological variation within language varieties and call for more thorough research on the subject. Since larger language varieties contribute more training signal during metric development, studies have observed that major linguistic variants tend to be rated more favorably than minor linguistic variants, potentially leading to biased evaluations [16].

Furthermore, analyses of neural metric performance on non-English language pairs remain limited. As a result, the superiority of neural metrics cannot be indiscriminately generalized to all language combinations [23], with some evidence suggesting that performance may degrade when English is excluded from the evaluation [24].

Among the major limitations highlighted in the literature is the lack of interpretability inherent to many neural evaluation metrics, largely due to their opaque scoring mechanisms. Their black-box nature hinders an assessment of which metrics are best suited for capturing specific linguistic phenomena and complicates the selection of appropriate metrics for targeted evaluation tasks [25]. In response, recent research has increasingly emphasized evaluation methodologies grounded in human error annotations – particularly those following the MQM (Multidimensional Quality Metrics) framework – which offer fine-grained information on translation quality [12]. These span-level annotations have also been leveraged as a standardized method for deriving quality scores (eliminating the need for direct human scoring in evaluation tasks) [26], and training more interpretable quality metrics.

Parallel efforts have also turned to linguistically motivated meta-evaluation test suites and controlled experiments designed to probe metric sensitivity to specific language phenomena [27, 28].

The specialized nature of the legal domain also raises concerns about the reliability of existing evaluation metrics. Zouhar et al. [29] highlight that learned metrics exhibit a performance drop when applied to out-of-domain data, largely due to their final-stage fine-tuning process. This suggests that current training data effectively optimizes metrics for specific domains but does not generalize well beyond them. As a result, extending these evaluation metrics to other domains – such as the legal domain – may lead to performance degradation compared to the base model.

# 4. Methodology

## 4.1. Problem Definition

We establish two criteria to characterize an effective metric for our use case: the first is *absolute agreement*, defined as ranking correct translations higher than incorrect ones. We also define *relative agreement*, that is the capability to rank translations containing critical mistakes lower than those with milder ones [11].

To operationalize the differentiation, we partition the dataset for analysis. *Absolute agreement* is measured on the Whole Dataset – comprising all segments available. To measure *relative agreement,* we subsample only the segments annotated with at least one mistake, the Mistake-only Dataset.

## 4.2. Dataset and Human Scoring

We use the MT@BZ corpus [8], a corpus of machine-translated decrees. It comprises source, reference and candidate translations in both language directions (IT→DE and DE→IT). Each segment has been manually annotated for translation errors using a custom error taxonomy. Table 1 offers a glance into the composition of the corpus for each language direction. We notice that around 60% of all segments is correct for both language directions. To gain further insight, we compute the BLEU score between reference and candidate sentences. Notably, we find that a very high number of segments labeled as correct receives a perfect BLEU score of 100, indicating exact matches with the reference translations. This outcome has also been observed by Oliver et al. [9] in similar experiments on the same data, and is attributed to the repetitive and formulaic nature of legal language, which often leads to low lexical and syntactic variability.

To measure correlation across a range of quality levels (as defined in Section 4.1) in the absence of numerical quality scores, we assign severity weights to each error type annotated in the original dataset (see Appendix A). Given the highly specialized nature of the domain, experts with competence in the South Tyrolean legal framework and German language varieties were consulted to define severity levels for each error type. These levels were established based on both linguistic adequacy and legislative drafting requirements[5]. For a detailed qualitative analysis of the corpus mistakes, refer to De Camillis and Chiocchetti [14].

In this manner, we can lay out a hierarchy of type-of-error severity and derive a more granular quality ranking. We apply a penalty for each error in a segment, equal to the severity weight assigned to that error type, according to the Linear Raw Scoring Model presented by Lommel et al. [30]. The sum of penalties is then deducted from a total of 100 and becomes the human score. This score reflects both the presence and severity of translation errors, thereby enabling the computation of rank-based correlation indices between human judgments and automatic metric outputs.

| **Segments** | **IT→DE** | **DE→IT** |
|---|---|---|
| Error-annotated | 639 | 622 |
| Exact matches | 741 | 412 |
| Other correct | 129 | 475 |
| Total segments | 1,509 | 1,509 |

**Table 1**
Composition of MT@BZ dataset. *Error-annotated* segments indicate the number of translations that have been labeled as containing at least one mistake. *Exact matches* indicate the number of correct translations that are identical to the reference. *Other correct* segments indicate the number of correct translations that are different from the reference.

## 4.3. Setup of Selected Metrics

This section presents the evaluation metrics employed in our study, with details on the tested methods and models provided in Table 2. Following best practices for replicability as recommended by Zouhar et al. [42] for Comet-suite metrics, we include hash codes and model identifiers in the footnotes of the present section.

### String-based Metrics

**BLEU** [31] measures modified n-gram precision with a brevity penalty. **chrF** [34] computes overlap over character-level n-grams, offering sensitivity to morphological and orthographic variation. Finally, **TER** [39] estimates the minimum number of edit operations required to transform the candidate into the reference, approximating post-editing effort.

### Embedding-based Metrics

We utilize the BERTScore framework[6] [33], which uses contextual embeddings from pre-trained language models to compute semantic similarity. The framework allows for model selection. Hash identifiers have been

[5] For example, the South Tyrolean public administration is bound by law to use the terminology that is being officially validated by a dedicated Terminology Commission (Presidential Decree No. 574/1988, Art. 6) and to adopt gender-neutral language (Provincial Law No. 51/2010). These constraints are therefore essential quality aspects when translating official documents into this minor language variety of German.

Details about the evaluation models and methods considered in the study, in alphabetical order.

generated together with the scores and are provided in the footnotes. In our experiments, we evaluate four encoder backbones: **bert-base-multilingual**[7] (which is the default model), **roberta-large-mnli**[8], **deberta-xlarge-mnli**[9] and **bart-large-mnli**[10].

In Table 3, we report the results under their respective model denominations, matched with the aggregated F1 score. We also compute *precision* and *recall* individually to highlight asymmetric contributions to the similarity assessment, which will be commented in Section 5. *Precision* measures how many of the candidate's tokens are present in the reference, while *recall* captures how well the reference tokens are matched by the generated candidate.

### Learned Metrics

We choose learned metrics trained under different input configurations.

We begin with *reference-based* metrics, which incorporate the reference translation during both training and inference. We select **COMET-22-DA**[11] [35] and **BLEURT** [32], which have been fine-tuned simply using quality scores from human annotators.

We also consider *source-based* metrics (also called Quality Estimation or QE metrics), which are trained without access to reference translations. Instead, they learn to predict human quality scores solely from the source sentence and the machine-generated output. We include both **COMET-Kiwi-DA**[12] [36] and its larger variant **COMET-KiwiXL-DA**[13] [37], which builds on the same architecture but differs in model capacity.

The *unified* approach combines both the source and the reference to exploit multi-task interaction. We assess **UNITE**[14] [40]. It jointly leverages the source and the reference as separate input streams during training, then incorporating a last layer to fuse the decomposed scores into the holistic one. We report scores for source (*src*) and reference (*ref*) decompositions.

We also include *error-span* metrics, namely **XCOMETXL-DA**[15] [41], **MetricX-24-Hybrid-Large** and its larger configuration **MetricX-24-Hybrid-XL** [38]. These metrics include a training phase based on error-span labels, according to the MQM error taxonomy. They are trained to predict error spans alongside a penalty score. XCometXL-DA is a hybrid metric that provides additional scores based on four decomposed dimensions: *src*, *ref*, *unified* approach and *MQM* annotations. The holistic score is then produced by ensembling the four sub-scores via a forward pass that establishes aggregation weights. Instead, the MetricX model suite only provides a single additional decomposed score which includes only the source in the evaluation.

Finally, we explore a variant of XCOMETXL quantized to **8 bits**[16], motivated by the hypothesis put forward in Zouhar et al. [42] that lower precision approximations of large metrics can maintain correlation with human judgments while significantly reducing inference costs.

## 4.4. Meta-Evaluation

In Table 3, we report Accuracy *(Acc)* [11], a measure computed through pairwise comparisons across the test set. It quantifies the proportion of pairs for which the

[16] Python3.8.10|Comet2.2.2|qint8|Unbabel/XCOMET-XL|1

evaluation metric produces the same relative ordering as the human gold standard (concordant), versus those where the ordering is incorrect (discordant). We follow Deutsch et al. [43] by using a variant of Accuracy adjusted for tie calibration by artificially creating ties from continuous scores. This procedure is needed in the light of the high number of rank ties stemming from human score fabrication. The *Acc* value ranges from 0 to 1.

We also adopt Spearman's correlation (*Rho*) (ranging from -1 to 1). It offers robustness to outliers and allows to capture rank-based monotonic relationships even across the markedly different score distributions observed in the metrics evaluated [3].

We decide not to use Pearson's correlation because it assumes a linear relationship between the distributions of the two score groups [43]. The proportional severity weights we assign to different error types are not expected to be linearly replicated by metric outputs.

## 5. Results

We apply meta-evaluation measures on both the Whole Dataset and the Mistake-only Dataset. This addresses the need to adequately test the metrics on the two criteria that have been established when defining the problem in Section 4.1: *absolute* and *relative* agreement. In Table 3, results are accordingly structured under two main sections, which separately report metric performance under each evaluation criterion. For metrics that generate holistic scores by aggregating subscores algorithmically, we report the holistic score in bold, while single decomposed scores are provided in regular font.

**Metric paradigm performance varies across quality ranges.** Our results reveal a widely different performance pattern across metric paradigms when evaluated on the Whole Dataset versus the Mistake-only Dataset. Surprisingly, both string-based and embedding-based metrics outperform learned metrics when evaluated on the Whole Dataset. We explain this with the argument that string-based metrics – being rule-based – can reliably detect and reward the high sample of exact matches with the reference. Embedding-based metrics also benefit from their ability to capture lexical overlap at a subword or token level, recognising meaning even when the wording differs. We attribute the underperformance of learned metrics primarily to the inherent nature of their regression-based scoring. Unlike rule-based metrics that produce deterministic outputs, learned metrics rely on regression functions that approximate scores based on distributional patterns in the training data. This can result in unexpected behavior – for instance, candidate translations identical to the reference may not receive the maximum score, or scores may fall outside the valid range of 0 to 1 as in Comet models (requiring post-hoc clipping). This behavior is consistent with prior observations about learned metrics' underperformance on high-quality translations, as noted by Agrawal et al. [44].

However, the trend reverses in the Mistake-only Dataset: here, when including the reference, learned metrics consistently outperform other metric types, regardless of the statistical measure used. This suggests that their modeling power becomes more effective in lower-quality bands, where surface-level matches are less common and mistakes have to be properly identified and penalized. Despite this regained advantage in the Mistake-only setting, the overperformance margins of most learned metrics remain tight and agreement levels insufficient for a reliable quality evaluation. This suggests that there is still room for improvement – especially as far as smaller-size metrics are concerned.

**Mind the reference.** Disaggregating the performance of learned metrics by input type offers valuable insights into which linguistic resources most effectively contribute to accurate evaluation. Considering the Mistake-only Dataset, *reference-based* scores surpass both *source-based* and *error-span* counterparts for COMET, UNITE and MetricX families. Interestingly, for metrics built on the *unified* approach (such as UNITE and XCOMETXL), the inclusion of both source and reference appears beneficial. While the reference remains the primary driver of correlation, incorporating the source provides a modest boost to overall score agreement. This suggests that *unified* models, which incorporate additional layers to weigh and integrate information streams from both inputs into the holistic score, may be better suited to capture certain error types that are only apparent when the source is considered.

In general, while *source-based* metrics trail behind other learned metric types, they can outperform embedding-based metrics counting on reference translations, especially if we consider models with larger capacity (MetricX-24-XL-QE, COMET-KiwiXL-DA and XCOMETXL-src).

**Error-span metrics are misaligned.** We assess the usefulness of error-span annotations in comparison to other linguistic signals. XCOMETXL-DA-mqm is the only available decomposed score based exclusively on MQM error span identification. Considering the Mistake-only Dataset, we observe a drop compared to related subscores of the same metric as well as to the smaller configuration of the same metric (COMET-22-DA). This failure may be attributable to a misalignment between the MQM

**Table 3**

The **Metric** columns shows the name of the metric: metrics in bold represent holistic scores, while metrics in regular font show decomposed scores. The **Whole Dataset** section denotes results obtained on all segments available in the dataset. The **Mistake-only Dataset** section indicates the results obtained onto a subset of the whole dataset comprising only segments containing at least one mistake. *Acc* denotes the tie-adjusted Accuracy measure, while *Rho* stands for the Spearman's correlation measure. The strongest statistical correlation for every column is underlined.

annotation framework used for training such metrics and our custom error taxonomy used for evaluation. Striving for consistency over error label criteria across training and evaluation is thus fundamental for fair assessment.

Looking at Whole Dataset, we likewise highlight that *error-span* metrics (MetricX and XCOMETXL) are surpassed by learned metrics that are optimized only for direct scalar prediction of sentence-level quality, such as COMET-22-DA, BLEURT and UNITE. As the training objective of *error-span* metrics is to regress over error annotations to estimate penalty weights accordingly, they may show a proneness for over-correction even in high-quality segments.

**Precision or Recall?** In Appendix B, we collect decomposed subscores for embedding-based metrics: *recall* and *precision*. We notice that *recall* tends to correlate more strongly with human judgments than the holistic score and the *precision* subscore. This trend may corroborate the importance of the reference translation: gauging how much of semantic and syntactic information contained in the reference transfers to the candidate may generally serve as a predictor of legal text quality as conceived of by expert evaluators. Yet, the negligible edge in the correlation measure is neither strong nor consistent enough to draw definitive conclusions. An informed interpretation of the results would require a qualitative analysis on the amount of semantic explicitation commonly expressed in the legal texts of both languages.

**Minor varieties remain penalised.** Focusing on the target language, we observe that correlations on the Mistake-only Dataset are generally higher for Italian than for German. This result is noteworthy given that German benefits from a larger pool of training data due to the fact that it is a more regularly featured language in WMT shared tasks, which contribute most of metrics training data. We posit that this discrepancy supports the argument that generic models tend to embed biases toward dominant language varieties. In the case of German, it is likely that the datasets used to train evaluation metrics predominantly feature standard varieties such as those used in Germany and at the EU level.

Moreover, we caution against drawing conclusions based on the Whole Dataset, where Italian-to-German translations include nearly twice as many full matches between reference and candidate as the reverse direction. This makes the datasets not comparable to each other, inflating metric performance and simplifying evaluation for German as the target language.

**Size matters.** When comparing learned metrics of increasing model size on the Mistake-only Dataset, we observe a general trend where scaling up benefits evaluation performance. This is evident in the case of COMET-Kiwi, where the XL variant consistently outperforms its smaller counterpart, and for *reference-based* scores of XCOMETXL-DA-ref, which shows stronger results compared to COMET-22-DA. A more nuanced picture emerges with MetricX, where the XL versions outperform the Large models only in evaluations into Italian, suggesting that scaling effects may vary across language directions, presumably due to the language variety provenance of additional data.

The quantized version of XCOMETXL-DA, though slightly lowering correlation measures compared to its full-precision counterpart, still outperforms all other metrics, which confirms previous findings that quantization can be a viable strategy for reducing computational costs.

## 6. Conclusions

As an indication for future metric development, we conclude that reference translations are most crucial for enhancing evaluation reliability, while source sentences may contribute marginally but are not essential. We advise against embarking on the effort of error-span annotation of large corpora with the aim of training new metrics: it has notable human and resource costs but results offer no evidence that they determine commensurate metric improvements. Instead, targeted extensions of the existing MT@BZ dataset may provide more cost-effective support for evaluation purposes.

Given the underperformance of metrics when evaluating South Tyrolean German as a target language, future metric adaptation would likely benefit from applying continued pre-training to generic encoder models on South Tyrolean German data. This would provide a more suitable backbone for further fine-tuning learned metrics. To this end, efforts should be made to compile legal text corpora in South Tyrolean German and including relevant terminology.

Also, we recommend exploring training strategies that integrate the strengths of embedding-based and learned metrics, with the goal of developing evaluation systems that perform robustly across the full quality spectrum of machine translation output.

From a broader perspective, we suggest that metric selection in natural language generation tasks should be guided by a clear definition of the evaluation objective and the nature of the task. Learned metrics are more effective when the task involves detecting and weighing complex linguistic phenomena that may surface in diverse forms – such as in summarization or question-answering tasks. In such cases, the fine-tuning and validation of a custom metric may be a further convenient step. Conversely, more naive evaluation methods like the string-based ones are often appropriate when low variance from a reference is expected, such as in the presence of named entities. As our findings show, the two metric paradigms can even be complementary: embedding- and string-based metrics are well-suited for evaluating accuracy-related aspects, while learned metrics can offer global insight into the overall fluency of the generated text and meaning preservation.

# A. Custom error weights

| Type of Error | Penalty Weight |
|---|---|
| **Accuracy errors** | |
| Mistranslation: | |
| Multiword expressions | 20 |
| Part of Speech | 20 |
| Word Sense Disambiguation | 25 |
| Partial | 20 |
| Semantically Unrelated | 20 |
| Addition | 15 |
| Omission | 15 |
| Untranslated | 20 |
| Mechanical | 15 |
| Bilingual terminology | 25 |
| Source error | 15 |
| **Fluency errors** | |
| Grammar: | |
| Multiword syntax | 15 |
| Word form | 15 |
| Word order | 15 |
| Extra words | 15 |
| Missing words | 20 |
| Lexicon: | |
| Lexical choice | 15 |
| Non-existing or Foreign Word | 20 |
| Orthography: | |
| Spelling | 12 |
| Punctuation | 12 |
| Capitalization | 12 |
| Gender | 5 |
| Inconsistency | 5 |
| Coherence | 5 |
| Multiple fluency errors | 10 |
| Other | 5 |

**Table 4**
The left-hand column lists the error types defined in the custom annotation scheme, while the right-hand column shows the corresponding penalty weights applied to the segment's quality score when each error type is present. The SCATE taxonomy differentiates between fluency and accuracy errors. Some error types are grouped under higher-ranking categories (shown in underlined font), which serve only as structural labels and do not carry additional penalty weights.

## B. Subscores of Embedding-based Metrics

| | WHOLE DATASET | | MISTAKE-ONLY DATASET | |
|---|---|---|---|---|
| **Model** | **IT→DE** | **DE→IT** | **IT→DE** | **DE→IT** |
| **bert-base-multilingual** | 0.781 | 0.715 | 0.527 | 0.549 |
| precision | 0.778 | 0.721 | 0.517 | 0.546 |
| recall | 0.781 | 0.699 | 0.530 | 0.554 |
| **bart-large-mnli** | 0.780 | 0.755 | 0.529 | 0.530 |
| precision | 0.778 | 0.757 | 0.521 | 0.540 |
| recall | 0.780 | 0.738 | 0.530 | 0.544 |
| **deberta-xlarge-mnli** | 0.779 | 0.739 | 0.526 | 0.533 |
| precision | 0.777 | 0.741 | 0.520 | 0.536 |
| recall | 0.782 | 0.733 | 0.533 | 0.539 |
| **roberta-large-mnli** | 0.771 | 0.760 | 0.524 | 0.524 |
| precision | 0.766 | 0.757 | 0.518 | 0.534 |
| recall | 0.775 | 0.754 | 0.526 | 0.536 |

**Table 5**
Accuracy (*Acc*) correlation for the decomposed scores of the embedding-based metrics. The name of the model is in bold font, while *precision* and *recall* decompositions are written in regular font.

**Abstract**

The growing interest in analysing emotions in Italian texts has led to the development of various affective resources, often independently constructed and lacking interoperability. To address this fragmentation, we adopt a Linked Open Data (LOD) approach. This paper presents three main contributions: (1) the release of Sentix 3.0, a revised and enriched polarity lexicon for Italian, together with two derivatives (MAL and WMAL) that address morphological and word frequency variation issues; (2) a new quartile-based methodology to discretize continuous polarity scores; and (3) the linking of Sentix 3. 0 and ELIta, an annotated emotion lexicon with categorical labels, to the LiITA Lemma Bank using standard ontologies (OntoLex-Lemon, MARL) and the newly introduced elita ontology for categorical emotion representation based on Plutchik's Wheel. At the heart of the linking is the word, the central node for aligning different lexical resources.

**Keywords**

Italian, Linguistic Linked Open Data, Emotions, Sentiment, Language Resources

## 1. Introduction

The increasing interest in analyzing emotions from Italian text has led to many specialized linguistic resources, such as lexicons and corpora. However, these resources are often independently built, with varying annotation methods, severely limiting their interoperability.

To address these challenges, we propose a Linked Open Data (LOD) approach. Inspired by projects such as LiLa [1], our work aims to integrate and formalize two Italian affective lexical resources, making them interoperable through linking to the LiITA project's lemma bank [2].

This article presents three original contributions:

- Resource linking and ontology development: we align ELIta, a lexicon annotated with categorical emotions, and the updated Sentix 3.0 with the LiITA project's lemma bank, using the MARL ontology to formally represent affective relations. Linking is achieved through the use of `ontolex:CanonicalForm`, and we introduce the new *elita ontology*, specifically designed to model categorical emotions based on Plutchik's Wheel, as applied to lexical entries.
- Release of Sentix 3.0: we introduce a revised and enriched version of the Sentix affective lexicon for Italian, along with two derivative resources, MAL and WMAL, designed to improve sentiment analysis by addressing morphological and frequency-based challenges.
- New polarity discretization methodology: we propose a novel approach to discretizing continuous polarity scores using quartile-based thresholds. This technique, initially introduced in Vassallo et al. [3], enables a more robust and interpretable classification of polarity levels.

The paper is structured as follows: Section 2 provides an overview of existing resources for Italian and introduces the Linked Open Data (LOD) paradigm, with a focus on its affective application in the LatinAffectus resource, developed as part of the LiLa (Linking Latin) project. Section 3 presents Sentix 3.0 along with its derivative resources, MAL and WMAL. Section 4 details the methodology adopted for polarity categorization and the ontological framework used. Section 5 outlines the LOD-based linking process, while Section 6 offers example queries that demonstrate how the linked data can be explored. Finally, Section 7 discusses future research directions and potential developments.

## 2. Related Works

In recent decades, the analysis of emotions has led to the development of numerous linguistic resources, particularly affective lexicons and annotated datasets. Despite the pervasive impact of extensive end-to-end language models (LLMs), affective and other annotated lexicons remain a dynamic area of research within computational linguistics, maintaining its vitality.They are particularly effective in the development of hybrid approaches [4], especially suitable for small or domain-specific corpora or low-resource languages [5, 6], where they ensure greater effectiveness and interpretability.

These lexical resources are designed to be FAIR (Findable, Accessible, Interoperable, Reusable) and transparent: as every system decision based on a lexicon can be traced back to specific entries, ensuring interpretability. Moreover, unlike computationally demanding large language models, lexicons are accessible to a broader research community, promoting the democratization of research.

For the Italian language, several lexicons [7, 8] and corpora [9, 10] annotated according to the sentiment [11] or emotion associated with the words or texts have been created and published, created by both automatic [12, 13] and manual methods [14]. However, much like the broader landscape of digital resources, there is a significant lack of clear, standardized guidelines for affective resources, resulting in poor interoperability. Each lexicon or corpus is typically developed independently, and although they often share similar objectives, such as sentiment analysis or emotion detection, they differ widely in terms of annotation categories, selected lemmas, and annotation methodologies.

In addition, the availability of these resources is highly fragmented. They are typically hosted on disparate platforms and, even when co-located within a shared repository infrastructure, interoperability between them remains limited or nonexistent.

A notable attempt to address these issues can be found in the LiLa project [15], which pioneered a new model of interoperability for Latin linguistic resources. This vision has since been adopted for Italian by the LiITA project [2]. Both initiatives share an ambitious goal: to build an interconnected system where the lemma acts as the central node linking multiple knowledge bases. The lemma becomes the foundation for connecting diverse databases through the use of shared vocabularies. At the heart of both projects lies the principle of Linked Open Data [16], enabling integration and reuse across resources.

Central to the LOD paradigm is the Semantic Web, which promotes the use of interoperable and interlinkable data schemas for online information. These schemas, commonly referred to as ontologies or vocabularies, support consistent data representation and semantic integration. To this end, the W3C has introduced foundational technologies such as RDF and OWL. Building upon these standards, the MARL ontology has been developed to formally describe opinions and to associate them with contextual information(such as opinion topic, features described in the opinion, etc.).

This infrastructure underpins the design of LatinAffectus [17], a polarity lexicon originated within the LiLa project that adopts a multi-ontology framework for formal representation. Specifically, three standards are used: Lemon and Ontolex [18] to describe lexical data, and MARL [19] to encode sentiment information. In this schema, the lexicon itself is modeled as an instance of class E31 Document13 from the CIDOC Conceptual Reference Model (CRM), an ontology designed to represent entities and relationships in the cultural heritage domain. In parallel, LatinAffectus is also declared as a lexicon-type object following the LInguistic MEtadata (lime) module of Ontolex.

Lexical entries in the resource are connected to the lexicon through the `lime:entry` property and are instantiated as objects of the class `ontolex:LexicalEntry`. Each lexical entry is associated with a label, an `ontolex:canonicalForm` (linking it to the lemma in the LiLa Knowledge Base), and an `ontolex:sense`, which captures its meaning. Since LatinAffectus is concerned with prior polarity, each lexical entry has only one sense, modeled as an instance of the class `ontolex:LexicalSense`. This sense is further described by a label, the relation `marl:hasPolarity`, and the property `marl:polarityValue`. The `marl:hasPolarity` relation links the sense to a category within `marl:Polarity` (namely positive, negative, or neutral) while `marl:polarityValue` assigns a numerical sentiment score from the predefined set: 1.0, 0.5, 0.0, -0.5, or -1.0.

The integration of emotions with Linked Open Data is not a new challenge. Relevant contributions in this area include Iglesias et al. [20] and Sanchez-Rada et al. [21]. These works introduced Onyx, that is an RDF ontology designed to represent emotions in textual content within the framework of the Semantic Web and Linked Open Data. It builds upon and aligns with standards such as EmotionML [22], the NLP Interchange Format (NIF), and lemon (Lexicon Model for Ontologies) [18], providing a flexible yet structured approach to annotating emotional content. Central to Onyx is the concept of an `EmotionSet`, a container for one or more `Emotion` instances, each representing a specific emotional state. These emotions are linked to standardized `EmotionCategory` resources, which can reflect different psychological models, and may include numerical values for emotion intensity and affective dimensions such as arousal and valence. Onyx also enables the asso-

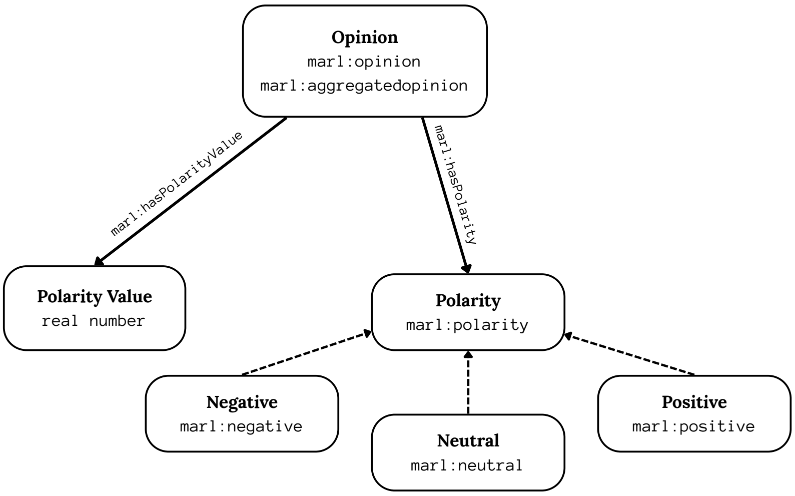

**Figure 1:** Marl Ontology [19]

ciation of emotional annotations with external resources or entities.

While Onyx is conceptually rich and expressive, its structure is relatively complex, as it is designed to represent the emotional content of texts.

**LiITA** LiITA (Linking Italian) is a Knowledge Base (KB) designed to foster interoperability among various Italian linguistic resources by leveraging the principles of Linked Open Data (LOD).

The core component of the LiITA KB is its Lemma Bank, a comprehensive collection of Italian lemmas. These lemmas, which are conventional lexical citation forms used across linguistic resources, serve as the central connection point for interlinking both lexical and textual data. The architecture of the LiITA KB mirrors that of the LiLa KB for Latin[1], operating under the assumption that all interoperable (meta)data sources within the KB are word-related.

Following the Linked Data paradigm, LiITA achieves conceptual interoperability among its distributed resources by applying vocabularies commonly used within the Linguistic Linked Open Data (LLOD). For the Lemma Bank specifically, this means adopting the vocabulary defined by OntoLex-Lemon [18], one of the most widely used models for representing and publishing lexical resources as Linked Data. The Lemma Bank of LiITA is a collection of canonical forms as intended by the Ontolex-Lemon ontology (`ontolex:canonicalForm` property, the conventionally chosen representation for the entire set of inflected forms belonging to a particular lexical entry), modeled as individuals of the Class `lila:Lemma`[2], which is a subclass of `ontolex:Form`, originally created for the LiLa project, and adopted in the LiITA Lemma Bank accordingly.

The Lemma Bank was initially populated with approximately $94,000$ lemmas derived from the online version of the Nuovo De Mauro dictionary, after excluding about $13,000$ multi-word expressions.

**ELIta** ELIta [23], a recently introduced linguistic resource, comprises a lexicon annotated via crowdsourcing. This annotation scheme incorporates both basic emotions, based on Plutchik's model [24] with corresponding association degrees, and the VAD (Valence, Arousal, Dominance) emotional dimensions, thus including sentiment (valence) [25]. The lexical items, primarily sourced from the De Mauro dictionary [26], were annotated in isolation. To date, four distinct versions of this lexicon have been released [8]:

- **RAW**: Full annotations with demographic data.
- **GOLDEN**: Selection of 5 consistent annotations + majority-vote golden label.
- **INTENSITY**: Aggregated intensities from GOLDEN; includes auto-generated "love" and "neutral".
- **BINARY**: Binary version of INTENSITY using 0.50 threshold.

## 3. Sentix 3.0 and two derived resources

Sentix is an affective lexicon for the Italian language created in 2013 by aligning several lexical resources, namely SentiWordNet [27] and MultiWordNet [28] through WordNet [29, 30].

The first version [11] was built by transferring the *synset* annotations from SentiWordNet to the respective Italian *synsets* of MultiWordNet, using an automatic mapping [cf. 31] to resolve the partial alignment of SentiWordNet's indices (based on WordNet 3.0), and those of MultiWordNet (based on WordNet 1.6) [cf. 32]. The performance of the lexicon was evaluated with data manually annotated by independent human judges.

The subsequent version, Sentix 2.0, aggregated the polarity scores of the different senses of a lemma into a single score (-1 to 1), using a weighted average with the sense frequencies calculated on the annotated SemCor corpus [33, 34]. This version, which includes 41,800 different lemmas, has been available on GitHub in the R package *sentixR* since 2019 [35], and has been used in various research projects over these years.

Other lexical resources have been developed from Sentix. The first derived lexicon was MAL [36], created by expanding Sentix 2.0 with inflected forms derived from *Morph-it!*, a morphological lexicon for the Italian language [37]. This was intended to address the inherent difficulties of lemmatization in Italian sentiment analysis - stemming from the language's morphological complexity and the limitations of available NLP tools - which are particularly exacerbated when analyzing user-generated content from social networks (often containing spelling errors, jargon, irregularities, and non-standard syntactic structures). MAL - which inherits Sentix 2.0's scores - has shown to achieve an improvement in overall sentiment analysis performance.

A second derived resource is WMAL [34], a dictionary of inflected forms like MAL, where MAL's scores were recalculated by weighting the original scores inversely with respect to their words frequencies in the TWITA corpus [38] by using the inversed version of the Zipf scale measure [39] that consists in a logarithmic scale based on the well-known Zipf law of word frequency distribution [40]. The two main WMAL lexical and methodological speculations were respectively to give more weight to low frequent terms and to reduce the polarity imbalance when using parametric threshold values to assign polarity classes: even small variations in these values in fact showed to have an opposite impact on the ability to correctly predict negative versus positive polarity [4]. WMAL has achieved better results in polarity classification, especially for negative messages.

On the occasion of WMAL's update, driven by the enrichment and update of the TWITA corpus to 2022, it was decided to harmonize all three resources, which were developed years apart; this involved not only updating WMAL's weights but also rectifying the interconnections among the three to ensure overall consistency. In particular, during the transition from Sentix to MAL, i.e., from lemmas to inflected forms, new identical forms with different scores and different senses are inevitably created. It was decided to manage these in a coordinated manner, primarily by revising Sentix.

A key part of this harmonization involved a deeper re-examination of the foundational Sentix lexicon. This specific effort, working backwards from the original Sentix version, led to an expansion in the number of linkable synsets between SentiWordNet (SWN) and MultiWordNet (MWN), which will be made available[3].

The revision subsequently involved external resources and supervised phases to identify forms present in Sentix that could generate unexpected duplicate entries in MAL (i.e., entries that could be either base forms or inflected forms), and to expand Sentix itself by back-linking lemmas present in *Morph-it!* traceable to pre-existing entries (717 entries). Finally, neutral terms from SentiWordNet not already present in Sentix were added ($22,117$ entries). The new lexicon ultimately contains $63,660$ lemmas [41].

The resources used for the update were: SentiWordNet and MultiWordNet, using the *Open Multilingual Wordnet* (https://omwn.org/) [42, 43], the TreeTagger library [44], and, of course, *Morph-it!* itself.

## 4. Methodology

Following the methodology established for the affective lexicon of Latin within the LiLa project, LatinAffectus, the same approach was adopted for the ELIta and Sentix 3.0 lexicons by using the MARL ontology [19] to represent polarity properties.

In this context, neutrality thresholds for polarity labels were defined within the range between the first and third quartiles of the lexicon. The weighting methodology and polarity calculation based on the new updated version of WMAL are key to Sentix 3.0's polarity categorical classification. In this respect, the first and the third quartile-based interval $[Q1; Q3]$ was calculated on the WMAL scores to better individualize the neutral thresholds and consequently the positive and negative polarity values outside. The quartile-based strategy to detect neutral scores has already provided promising results

[3] Discrepancies between numerical IDs and verbal labels of numerous Italian *synsets*, due to changes between subsequent versions of Wordnet [cfr. 32], often prevents their retrieval when attempting to map from SWN to MWN through standard tools, such as the OMW Python package

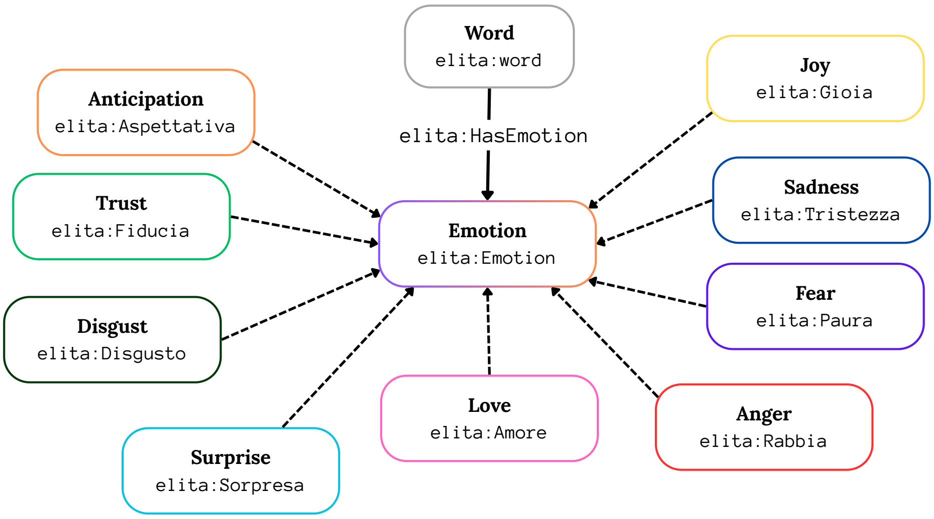

**Figure 2:** *elita ontology*

across annotated corpora[3]. The obtained polarity classification (Table 1) was used to assign categories within `marl:polarity` for bot h Sentix 3.0 and ELIta.

**Table 1**
Polarity classification thresholds based on numerical polarity values.

| Polarity Label | Polarity Value Range |
|---|---|
| Negative | $x < -0.1646$ |
| Neutral | $-0.1646 \leq x \leq 0.1250$ |
| Positive | $x > 0.1250$ |

The other relationship used to describe Sentix 3.0 data is `marl:hasPolaritValue` in which values are continuous from -1 to 1.

For example, the lemma in ELIta "abbandonare" was annotated as `marl:hasPolarity` "Negative", and `marl:hasPolarityValue` "$-0.833$".

However, since the MARL ontology does not provide specific properties for representing categorical emotions, and the structure of Onyx is relatively complex, the *elita ontology* is introduced to fill this gap with a simpler and more transparent model, specifically designed for annotating individual words with emotion categories.

The *elita ontology* has been developed to represent categorical emotions in a structured and interoperable manner, with a particular focus on applications in linguistic and sentiment analysis. In contrast to the MARL ontology, which primarily addresses sentiment polarity (positive, neutral, negative), and Onyx, which incorporates multiple emotion models for text descriptions, *elita ontology* introduces explicit classes and properties for representing discrete emotional categories. These categories are based on Plutchik's Wheel of Emotions [24], and also include the dyad "Love," formed by the combination of "Joy" and "Trust".

At the core of the ontology is the `owl:class` defined `elita:Emotion`, which serves as the general category for all emotion instances. Specific emotions, such as *Gioia* (Joy), are modeled as individuals (instances) of this class.

To associate a resource, such as a lexical item, sentence, or document, with an emotion, the ontology defines the object property `elita:HasEmotion`. This `owl:ObjectProperty` links a subject (e.g., a word or expression) to an instance of `elita:Emotion`, thereby expressing the emotional content attributed to that element (Fig. 2).

Despite its simplicity, the ontology maintains conceptual continuity with Onyx through the use of the `elita:HasEmotion` property, which functionally corresponds to `onyx:hasEmotionCategory`. Moreover, the emotional categories defined in *elita* reflect the annotations present in the ELIta lexical resource, ensuring alignment with existing linguistic data.

This design enables the annotation and querying of resources using fine-grained emotional categories, effectively complementing polarity-based approaches in the representation of lexical entries. At the same time, it ensures interoperability with existing emotion ontologies while providing a lightweight, application-oriented model specifically tailored to lexical annotation.

# 5. Linking

After selecting the ontologies for the Linked Open Data representation of the lexical resources, the lexicons were converted into RDF format. The linking procedure involved mapping lexical entries, each associated with a unique URI, to their corresponding lemmas within the LiITA's Lemma Bank. The results of this linking process are presented in the following sections (an example of a linked entry is shown in Figure 3).

## 5.1. Linking ELIta

The ELIta lexical resource comprises $6,905$ entries, encompassing lemmas (as defined by LiITA), emojis, and multi-word expressions like "a malincuore" (reluctantly). Notably, ELIta's lexical entries include in some cases both masculine and feminine forms of adjectives and nouns. This inclusion aimed to facilitate the assessment of gender-based perceptual differences, particularly when morphological gender is the sole distinguishing factor.

To align ELIta with LiITA's Lemma Bank, emojis were initially removed. The remaining lexical entries were then compared and linked to LiITA's lemma URI where feasible. This process yielded $4,705$ ELIta words that exhibited a one-to-one match with lemmas or hypolemmas in LiITA (as shown in Table 2). The remaining approximately $2,000$ entries, however, matched multiple lemmas within the lemma bank, or none, necessitating further processing.

The lexical entries that presented a one-to-one match were associated with the lemmas in the Lemma Bank using the Ontolex ontology and the relation `ontolex:CanonicalForm`.

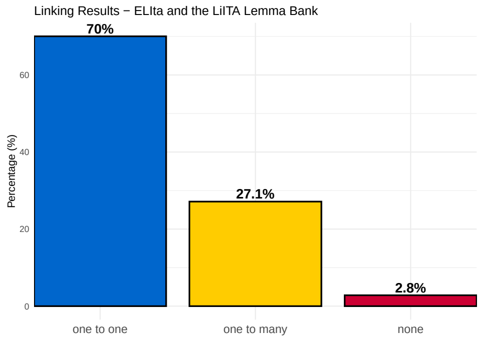

**Figure 4:** Percentages of linking between ELIta and LiITA Lemma Bank.

The high percentage of matches between ELIta and LiITA (shown in Fig. 4) is mainly due to the use of the same lexical source as the backbone of both resources. In particular, both rely heavily on the Nuovo De Mauro dictionary: about 70 percent of ELIta's entries come from the Nuovo Vocabolario di Base [26], while LiITA's Lemma Bank is based on the lexical base of an online version of

**Table 2**
Number of ELIta lexical entries (no emoji) with one link, multiple links, or no representation in the LiITA Lemma Bank.

| One to one | One to many | No one |
|---|---|---|
| 4705 | 1823 | 190 |

the dictionary Nuovo De Mauro[4]. The 190 lexical entries in ELIta that do not have a match in LiITA are mainly multi-word expressions or idiomatic phrases, which were not included in the construction of the LiITA lemma bank.

In addition, some entries without correspondence correspond to feminine forms that were explicitly annotated in ELIta. These forms often carry different affective annotations than their male counterparts, which are usually used as the canonical form of the lemma in LiITA. Consequently, these female variants were not included in the linking process.

One-to-many correspondences, accounting for 27.1 percent of the total, are largely attributable to words that correspond to multiple parts of speech (PoS) in LiITA, and thus correspond to multiple lemmas. In ELIta, the annotation process, following the methodology described in [14], did not specify the part of speech for each entry. As a result, PoS-based disambiguation is not possible in the current version of the resource.

## 5.2. Linking Sentix 3.0

The same procedure was applied to Sentix 3.0, with each entry linked to a lemma from the lemma bank whenever possible. The results revealed that most entries were new to the lemma bank and therefore had no matching lemma. This is primarily because the lexicon contains a large number of multi-word expressions, such as "oggetti per la casa" (household items), "vedova nera" (black widow), "difficoltà di apprendimento" (learning difficulties). As in the case of ELIta, the one-to-many links are due to the presence of lemmas in Sentix that may belong to different parts of speech in LiITA Lemma Bank. To address the one-to-many mappings, a possible solution would be to disambiguate entries based on part of speech. However, the current version of Sentix consists of isolated lexical entries, and PoS tagging typically relies on contextual information. Since such context is not available in the lexicon, it is not currently possible to assign PoS labels reliably. While previous versions of Sentix included some PoS information, this is not present in the current release. As a result, any attempt at disambiguating part of speech would be arbitrary.

Nevertheless, successful linking was achieved in 36% (as shown in Fig. 5) of cases, with 22,946 lemmas matched on a one-to-one basis (see Table 3).

**Table 3**
Number of Sentix 3.0 lexical entries with one link, multiple links, or no representation in the LiITA Lemma Bank.

| One to one | One to many | No one |
|---|---|---|
| 22946 | 6244 | 34497 |

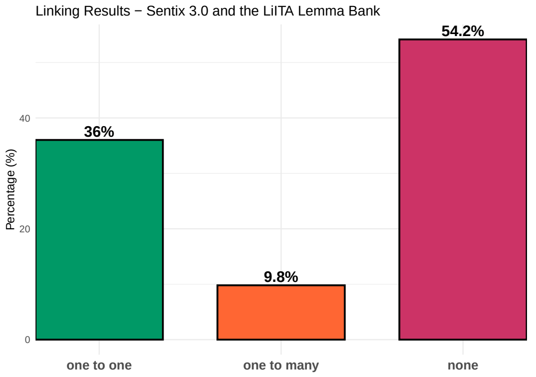

**Figure 5:** Percentages of linking between Sentix 3.0 and LiITA Lemma Bank.

# 6. Query

One of the cardinal principles of Linked Open Data as mentioned above is also the use of standards such as RDF and SPARQL to provide useful information on what is identified by a URI, for the purpose of (meta)data representation and retrieval. If RDF (Resource Description Framework) [45] is the data model underlying the Semantic Web, SPARQL[5] is a query language for (meta)data represented in RDF.

Integrating affective resources into LiITA significantly enhances its query capabilities, allowing for advanced SPARQL interrogations across LiITA's own data and its linked lexical and textual resources.

For instance, it is possible to[6]:

**Query 1. Retrieve the Distribution of Emotions in ELIta** It's possible to query the distribution of emotions as defined within the ELIta lexicon. the SPARQL query counts the number of lemmas associated with each emotion label in the ELIta resource. By linking lemmas from the LiITA Lemma Bank to their corresponding emotion annotations in ELIta, the query retrieves the textual label of each emotion and aggregates the lemmas accordingly. The results are grouped by emotion label and sorted in descending order based on lemma count.

[4] https://dizionario.internazionale.it/

[5] https://www.w3.org/TR/rdf-sparql-query/

[6] The SPARQL queries used to generate these examples are available in the appendix and can be executed via the LiITA endpoint.

Table 4 shows the result of such distribution, with "Aspettativa" (Anticipation) being the most frequent emotion.

**Table 4**
Distribution of lemmas across different emotions.

| Lemmas | Emotion |
|---|---|
| 1257 | "Aspettativa" |
| 1030 | "Gioia" |
| 787 | "Amore" |
| 765 | "Paura" |
| 745 | "Fiducia" |
| 710 | "Rabbia" |
| 645 | "Tristezza" |
| 597 | "Sorpresa" |
| 360 | "Disgusto" |

**Query 2. Retrieve Polarity Distribution in Sentix 3.0:** The SPARQL query counts the number of lemmas associated with each polarity label (e.g., "Positive", "Negative", "Neutral") in the Sentix 3.0 resource. By linking lemmas from the LiITA Lemma Bank to their corresponding polarity annotations in Sentix 3.0, the query retrieves the textual label of each polarity and aggregates the lemmas accordingly. The results are grouped by polarity and sorted in descending order based on lemma count.

This query type helps determine the count of Italian words marked as positive, negative, or neutral based on lemmas shared between Sentix 3.0 and LiITA. Table 5 provides the result, indicating a higher number of neutral lemmas.

**Table 5**
Distribution of lemmas across different polarities.

| Lemmas | polarityLabel |
|---|---|
| 15058 | "Neutral" |
| 3730 | "Negative" |
| 2780 | "Positive" |

**Query 3. Return the average Sentix polarity score for each emotion annotated in ELIta:** Another possible query can be used to identify the most negative emotion in ELIta based on Sentix 3.0 Polarity Value.

The query retrieves the average Sentix polarity value for each emotion label found in the ELIta resource. It does so by:

1. Linking lemmas from LiITA (via lila:lemma) to their associated emotions in ELIta.
2. Retrieving corresponding polarity values from Sentix.
3. Grouping the results by emotion label and calculating the average polarity for each.
4. Sorting the results in ascending order of polarity, so the most negative emotions appear first.

The results indicate that Disgust, rather than Sadness, consistently emerges as the most negative emotion when analyzing average polarity scores for emotions based on Sentix 3.0 annotations. This is visualized in Figure 6, where the color gradient reflects polarity intensity.

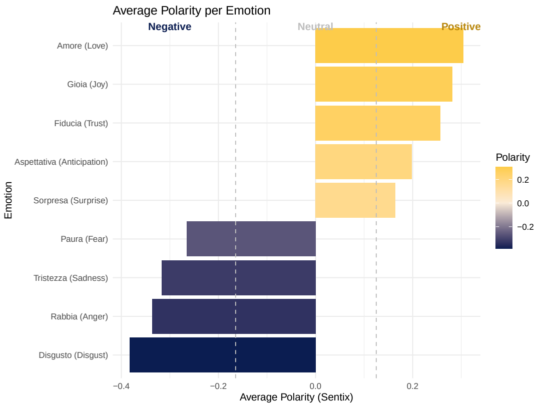

**Figure 6:** Average polarity scores for different emotions based on Sentix annotations. The color gradient represents polarity intensity, with dark blue indicating strong negative valence, dark gold indicating strong positive valence, and pale shades indicating neutrality. Dashed lines mark the thresholds separating negative, neutral, and positive polarity regions.

**Query 4. Determine the polarity of lemmas annotated with contrasting emotions:** Since words in ELIta can be associated with multiple emotions, we explored instances where Joy and Sadness, two emotions of opposing polarities, co-occurred in the annotation of the same lemma.

As a first step, we queried the number of words in ELIta that are simultaneously associated with both Joy and Sadness, grouped by their Sentix polarity label.

More specifically, the query:

1. Selects lemmas from the LiITA Lemma Bank that are linked to ELIta entries.
2. Filters for those lemmas tagged simultaneously with the emotions `elita:Gioia` (Joy) and `elita:Tristezza` (Sadness).
3. Matches these lemmas to their corresponding Sentix 3.0 polarity labels (Positive, Negative, or Neutral).
4. Counts how many lemmas fall into each polarity category.

5. Sorts the output by descending frequency.

We found that in most instances the simultaneous presence of Joy and Sadness corresponded to a neutral polarity. The second most common polarity observed was positive (as shown in Table 6).

**Table 6**
Distribution of lemmas in ELIta associated with both Joy and Sadness, by Sentix polarity.

| Polarity | Lemmas |
|---|---|
| "Neutral" | 24 |
| "Positive" | 18 |
| "Negative" | 2 |

Interestingly, only two words, "invocare" (to invoke) and "umore" (mood), identified through a dedicated query[7], consistently exhibited a negative polarity according to Sentix 3.0. Their respective polarity values are shown in Table 7.

The examples showcased a range of queries that extract information not only from individual resources but also by integrating data from both Sentix 3.0 and ELIta, highlighting how interoperability enables more comprehensive analysis of affective lexical information.

## 7. Conclusions and Future Works

This paper introduces, for the first time in Italian, two affective lexical resources, Sentix 3.0 and ELIta, published according to the Linked Open Data (LOD) paradigm. It also presents the new version of the Sentix 3.0 resource and its derivatives, MAL and WMAL, now available on GitHub. Additionally, the ontology developed for rendering the ELIta emotional lexicon within the Linguistic Linked Open Data (LLOD) framework is introduced.

Both resources have been linked to the LiITA Lemma Bank, thus contributing to and enriching the possibilities of investigation and promoting interoperability among LLOD resources.

Through the LOD paradigm, these resources also support interdisciplinary applications, particularly within the digital humanities (e.g., cultural heritage, social sciences), where linguistic knowledge graphs find practical applications (e.g., through frameworks like CIDOC CRM or LiLa).

Nonetheless, this work represents only the initial phase of fully aligning these affective resources with LiITA. Future efforts will focus on resolving one-to-many mappings and incorporating new lemmas into the LiITA Lemma Bank where applicable.

**Table 7**
Lemmas associated with both Joy and Sadness in ELIta that exhibit negative polarity in Sentix 3.0.

| Lemmas label | Polarity Value |
|---|---|
| "invocare" | $-0.25$ |
| "umore" | $-0.5$ |

Further challenges, such as the emotion analysis of literary texts or interlingual evaluations between regional variants of Italian, can be addressed through interoperability in an ecosystem where the word is the basis of knowledge.

# Appendix

This appendix reports the SPARQL Queries illustrated in 6.

## Query 1

Retrieve the distribution of emotions:

```
PREFIX lila: <http://lila-erc.eu/
    ontologies/lila/>
PREFIX elita: <http://w3id.org/elita
    />
PREFIX ontolex: <http://www.w3.org/ns
    /lemon/ontolex#>
PREFIX rdfs: <http://www.w3.org
    /2000/01/rdf-schema#>

SELECT ?emotionLabel (COUNT(*) as ?
    count)
WHERE {
    ?lemma a lila:Lemma .
    ?elitaLemma ontolex:canonicalForm
          ?lemma .
    ?elitaLemma elita:HasEmotion ?
        emotion .
    ?emotion rdfs:label ?emotionLabel
}
GROUP BY ?emotionLabel
ORDER BY DESC (?count )
```

## Query 2

Return the distribution of polarity:

```
PREFIX lila: <http://lila-erc.eu/
    ontologies/lila/>
PREFIX marl: <http://www.gsi.upm.es/
    ontologies/marl/ns#>
PREFIX ontolex: <http://www.w3.org/ns
    /lemon/ontolex#>
PREFIX rdfs: <http://www.w3.org
    /2000/01/rdf-schema#>

SELECT ?polarityLabel (COUNT(*) as ?
    count)
WHERE {
    ?lemma a lila:Lemma .
    ?sentixLemma ontolex:
        canonicalForm ?lemma .
    ?sentixLemma marl:hasPolarity ?
        polarity .
    ?polarity rdfs:label ?
        polarityLabel
}
GROUP BY ?polarityLabel
ORDER BY DESC (?count )
```

## Query 3

Return the average Sentix polarity score for each emotion annotated in ELIta:

```
 PREFIX lila: <http://lila-erc.eu/
    ontologies/lila/>
PREFIX elita: <http://w3id.org/elita
    />
PREFIX ontolex: <http://www.w3.org/ns
    /lemon/ontolex#>
PREFIX rdfs: <http://www.w3.org
    /2000/01/rdf-schema#>
PREFIX marl: <http://www.gsi.upm.es/
    ontologies/marl/ns#>
PREFIX xsd: <http://www.w3.org/2001/
    XMLSchema#>

SELECT ?emotionLabel (AVG(?
    polarityValue) AS ?avgPolarity)
WHERE {
  ?lemma a lila:Lemma .
  ?elitaLemma ontolex:canonicalForm ?
      lemma .
  ?elitaLemma elita:HasEmotion ?
      emotion .
  ?sentixLemma ontolex:canonicalForm
      ?lemma .
  ?sentixLemma marl:hasPolarityValue
      ?polarityValue .
  ?emotion rdfs:label ?emotionLabel .
}
GROUP BY ?emotionLabel
ORDER BY ASC(?avgPolarity)
```

## Query 4

Determine the polarity of lemmas annotated with contrasting emotions (Joy and Sadness):

```
PREFIX lila: <http://lila-erc.eu/
    ontologies/lila/>
PREFIX elita: <http://w3id.org/elita
    />
PREFIX ontolex: <http://www.w3.org/ns
    /lemon/ontolex#>
PREFIX rdfs: <http://www.w3.org
    /2000/01/rdf-schema#>
PREFIX marl: <http://www.gsi.upm.es/
    ontologies/marl/ns#>

SELECT ?polarityLabel (COUNT(*) as ?
    count)
WHERE {
    ?lemma a lila:Lemma .
    ?elitaLemma ontolex:canonicalForm
        ?lemma .
    ?elitaLemma elita:HasEmotion
        elita:Gioia .
    ?elitaLemma elita:HasEmotion
        elita:Tristezza .
    ?sentixLemma ontolex:
        canonicalForm ?lemma .
    ?sentixLemma marl:hasPolarity ?
        polarity .
    ?polarity rdfs:label ?
        polarityLabel
}
GROUP BY ?polarityLabel
ORDER BY DESC (?count )
```

Retrieve the polarity value and label of lemmas that are identified in LiITA, annotated in ELIta with both Joy and Sadness, and are associated with a negative polarity according to Sentix 3.0:

```
PREFIX lila: <http://lila-erc.eu/
    ontologies/lila/>
PREFIX elita: <http://w3id.org/elita
    />
PREFIX ontolex: <http://www.w3.org/ns
    /lemon/ontolex#>
PREFIX rdfs: <http://www.w3.org
    /2000/01/rdf-schema#>
PREFIX marl: <http://www.gsi.upm.es/
    ontologies/marl/ns#>

SELECT ?label ?value
WHERE {
    ?lemma a lila:Lemma .
    ?elitaLemma ontolex:canonicalForm
         ?lemma .
    ?elitaLemma elita:HasEmotion
        elita:Gioia .
    ?elitaLemma elita:HasEmotion
        elita:Tristezza .
    ?sentixLemma ontolex:
        canonicalForm ?lemma .
    ?sentixLemma marl:hasPolarity ?
        polarity .
    ?sentixLemma marl:
        hasPolarityValue ?value .
    ?elitaLemma rdfs:label ?label .
    ?polarity rdfs:label "Negative"
        @en .
}
```

## Declaration on Generative AI

**Abstract**

This paper presents a comparative multi-modal analysis of Italian and Romanian brain rot memes, investigating the factors that contribute to its appeal and the linguistic and cultural distinctions between the two versions. To conduct this analysis, we introduce a multi-modal brain rot dataset named CRIB (**C**ollection of **R**omanian and **I**talian **B**rain rot), a manually curated collection of 240 TikTok videos stratified by language (Italian, Romanian) and popularity, on which we examine textual, acoustic, and visual features. Our findings indicate that popularity is not significantly correlated with textual elements like sentiment, absurdity, or rhyme, or acoustic elements such as vocal features or sentiment of the sound. Instead, in Romanian language, video-level dynamics, specifically faster cutting speeds and a more rapid overall pace, are strong predictors of a video's success. The cross-linguistic analysis reveals significant differences. Italian brain rot is textually more negative, exhibits higher perplexity, and uses more rhyme, while its sound is characterized by higher melodic range and loudness. Romanian audio is spectrally brighter with more erratic pitch variations.

**Keywords**

data set, brain rot, multi-modal, Italian, Romanian

## 1. Introduction

The first recorded use of 'brain rot' is in Henry David Thoreau's book *Walden*, published in in 1854, which criticizes society's tendency to devalue complex ideas in favor of simple ones, indicating a general decline in mental and intellectual effort: "While England endeavors to cure the potato rot, will not any endeavor to cure the brain-rot – which prevails so much more widely and fatally?" [1].

Brain rot was the Oxford word of the year 2024.[1] Its primary sense is the supposed deterioration of a person's mental or intellectual state as the result of overconsumption of low-quality, trivial, or non-challenging online content. Its secondary sense, acquired over the last year, is the online content itself likely to lead to such deterioration. In particular, the term came to be used in the last months to refer to a certain type of multi-modal short content, intentionally created to be absurd, nonsensical, dissonant and funny, by content developers using generative AI. One of the earliest examples is *Nothing, Forever* in December 2022[2] (shortly after the launch of ChatGPT), while Italian brain rot is a more recent trend that gained popularity in early 2025. As a side note, short animations like *Skibidi toilet* series or *only in Ohio* memes series are not usually created using generative AI, though they are also considered a form of brain rot.

The creator of some of the first Italian brain rots, like Ballerina Cappuccina, supposedly a Romanian,[3,4] describes them as a satiric artistic experiment that both mocks and celebrates pop culture and kitsch. The characters in these creations are childlike, weird, and often grotesque blends of humans, animals, plants and various objects, named with Italian-sounding names, like *Ballerina Cappuccina* in figure 1. The Italian brain rot phenomenon gained traction especially among Gen Z and Gen Alpha communities by means of social media platforms like TikTok and Instagram and has quickly spread to other languages, including Romanian, with characters such as *Morcoveață* in figure 2, a human-like carrot character adapted from Romanian nursery rhymes.

A common trait of brain rot is the uncertain or lack of authorship. As Roland Barthes argued in *The Death of the*

*Author* [2], removing the author takes away a traditional source of authority and shifts the focus to the reader and their interpretation. In a similar way, brain rot content is mostly anonymous or pseudonymous, remixed and layered, reflecting an anarchic and collective form of creation.

Moreover, brain rot has many common traits with the Dadaism movement, which was on the same path of anti-art and anti-meaning, it mocked the art rules and traditions, and it embraced nonsense and absurdity. It celebrated chaos and irrationality, at the same time being psychedelic in the sense of artistic production from the 70s and 80s when using vivid colors, fractals, surreal images, and neon gradients. Both forms of art were born in an age of post truth and information overload.

Finally, the brain rots' original purpose seems to be primarily amusement, but some of them were also used for manipulation, commercial purposes or even political propaganda.

This study aims to explore whether brain rot manifests differently across cultures and languages. We chose to begin with Italian brain rot, as it represents one of the most visible and influential starting points for this phenomenon. The decision to compare it with Romanian brain rot is based on both similar and contrasting historical, linguistic, and cultural characteristics. The main common grounds between the two languages and cultures are that they both belong to the Romance language family, and that they have experienced authoritarian regimes in the 20th century that shaped their collective imagination, creative approaches and imagery. The differences between the two lie in their geopolitical contexts, religious traditions (Catholic and Greek Orthodox), and features of cultural production, which influence the tone, style, and content of their digital aesthetics. At the same time, both Italian and Romanian online cultures remain underrepresented in cultural and computational studies, which represents an opportunity to examine how the upper similarities and differences are reflected in brain rot popular manifestation.

The main research questions are: (1) What makes a brain rot go viral (besides algorithm recommendation/-manipulation or pure chance)? and (2) Are there any cultural or language differences between the form or content of brain rots in these two languages?

## 2. Related Work

Numerous studies are currently interested in understanding what are the effects of digital content overconsumption. Most of them focus on psychological, neuro-biological, or meta-analytical perspectives [3, 4].

This type of digital content certainly breaks conventional norms of art, narrative, and symbolism, aligning well with both surrealism and absurdism, while also embracing the chaos and disjuncture of postmodernity. The chimera-like mixing of humans, animals, plants, and objects is not a new phenomenon, since anthropomorphism can be traced back from Egyptian, Greek, and Roman antiquity, going through Medieval art, all the way to the surrealist movement at the beginning of the 20th century (Max Ernst, Salvador Dali, or René Magritte).

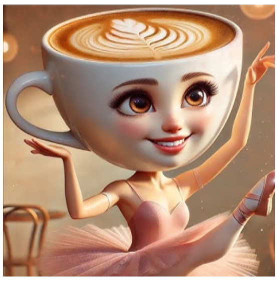

**Figure 1:** Example of Italian brain rot character *Ballerina Cappuccina*

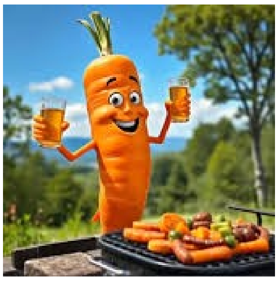

**Figure 2:** Example of Romanian brain rot character *Morcoveață*

To the best of our knowledge, no computational research has been conducted specifically on Italian brain rot. However, internet culture, including memes and viral content received a significant amount of attention. The detection of meme toxicity was investigated in [5]. Multimodal sentiment analysis was conducted by integrating text, image, and audio for improving sentiment detection from vlogs, spoken reviews, and human-machine interactions in [6]. A comprehensive survey which categorizes advances in multimodal sentiment analysis can be found in [7]. [8] introduced a new benchmark for detecting hate speech from multimodal memes. [9] combined LLM-generated debates and fine-tuned judge models to detect harmful memes with improved interpretability and performance. [10] proposed a template-based approach for meme clustering by employing multi-dimensional similarity features.

# 3. Data

The data set was constructed manually from TikTok videos by searching for candidate examples through various methods: direct search queries, tags, the *discover* feature, trending pages, compilation and analysis of video clips, related videos (*You may like*), and the *For You* recommendations. This process cannot be reliably automated due to misleading tags being frequently used to influence the recommendation algorithm.

The extracted samples are stratified across two dimensions: language (Italian and Romanian) and popularity (popular and unpopular). The dataset is well balanced: 120 brain rots per language, with 60 viral examples and 60 less viewed examples, the typical threshold between them being 100k views or at least 10k likes.

Given that we are interested in all aspects of communication, especially creative language use, we filtered out posts with extremely low lexical diversity, as well as re-uploads, translations, and repetitive songs.

Moreover, some of the tools used to generate these videos can be traced by watermarks, although we note that some users specifically crop the content or blur such indicators. In alphabetical order, clips have been created or adjusted with: CapCut, ChatGPT, Hailuo AI, Kling AI (version 1.6), PixVerse.ai, Runway, VEED. TikTok also offers its own tools for video creation.

We collected four subcategories of brain rots for each language. The general category in each language includes the notorious Italian brain rot characters with local adaptations (with 60 examples per language). For Italian, the *skeleton* category consists of 20 videos with a poignant tone. The *Matteo* category comprises 20 memes that exhibit more positive attitudes, and the *Politicians and Celebrities* class consists of 20 political satire videos. For Romanian, we followed the same count and structure. We have selected *schelet*, the corresponding category of Italian *schletro*, *Regina brain rot* (brain rot queen), featuring longer stories, and conversely *Morcoveață*, consisting of very short clips. Throughout this process, we have extracted a total of 240 videos with subtitles and metadata.[5] We name the dataset CRIB (**C**ollection of **R**omanian and **I**talian **B**rain rot).

# 4. Text

## 4.1. Sentiment Analysis of Text

To obtain sentiment analysis scores for the textual transcripts of the brain rots, we employed cardiffnlp/twitter-xlm-roberta-base-sentiment pre-trained model [11], which returns a percentage of negative, neutral, and positive sentiments associated with each text in both languages, for optimal comparison. We used ChatGPT4o for coding assistance and Python in Google Colab to obtain the graphical illustrations and to perform statistical tests.

Overall, for all brain rots, the negative sentiment was predominant. There were minimal variations in sentiments in popular versus unpopular brain rots in both languages, as we can see in figures 3a and 3b for Romanian and in figures 3c and 3d for Italian. However, the Italian ones contained more negative sentiments than their Romanian counterpart.

We tested for statistical significance of these findings and the results are listed in table 1 from the Appendix.

For Romanian differences of positive, neutral, and negative sentiments between popular and unpopular texts, we performed a multivariate analysis of variance (MANOVA). The results indicate no statistically significant multivariate effect. To further investigate potential differences at the level of individual sentiments, given potential concerns about normality and homogeneity of variance, Mann-Whitney U tests were performed for each emotional score. The results confirmed that there are no statistically significant differences.

The same tests on the Italian brain rots obtained the same results: no statistical differences between the sentiments of popular and unpopular texts.

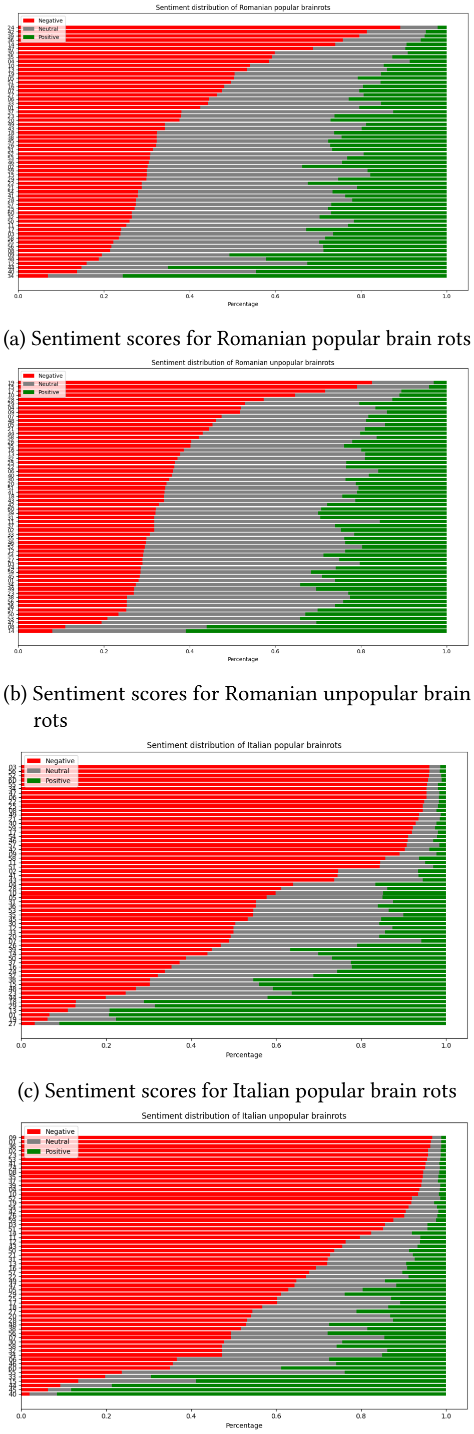
We further performed, for each language, the same statistical tests only on the *general* category of brain rots, which varies less than the combination of all four brain rot categories (*general*, *regina brain rot*, *morcoveață*, and *schelet* for Romanian, and *general*, *matteo*, *politicians and celebrities*, *scheletro* for Italian) to test the differences between popular and unpopular categories. The results showed again no significant differences.

Finally, a multivariate analysis of variance (MANOVA) was conducted to examine whether the distribution of emotional sentiment scores (positive, neutral, and negative) differed between Romanian and Italian brain rots. This time, results were statistically significant, indicating a robust multivariate effect of language on sentiment composition. To further explore individual sentiment differences between languages, Mann-Whitney U tests were applied separately for each sentiment category. Results revealed that positive sentiment was significantly higher in Romanian brain rots ($p < 0.0001$; mean: 0.377 vs. 0.159), that neutral sentiment was also significantly higher in Romanian memes ($p < 0.0001$; mean: 0.385 vs. 0.171), and that negative sentiment was significantly higher in Italian ones ($p < 0.0001$; mean: 0.670 vs. 0.238).

## 4.2. Semantic Similarity and Perplexity

To measure the degree of “absurdity” or “unpredictability” of the brain rots, we employed two complementary measures: semantic similarity and perplexity. Seman-

[5] Using yt-dlp version 2025.04.30.



(a) Sentiment scores for Romanian popular brain rots

(b) Sentiment scores for Romanian unpopular brain rots

(c) Sentiment scores for Italian popular brain rots

(d) Sentiment scores for Italian unpopular brain rots

**Figure 3:** Sentiment scores (Negative, Neutral, Positive) for each language and popularity group of the brain rot texts

tic similarity was computed for a given text of a brain rot as the average pairwise cosine similarity between all word embeddings obtained with the sentence transformer *paraphrase-multilingual-MiniLM-L12-v2* [12]. This reflects how semantically cohesive the vocabulary is — higher values indicate that the words tend to belong to similar semantic fields or contexts, suggesting internal consistency or coherence, while lower values indicate some incoherence or inconsistencies. Perplexity quantifies how unpredictable a text is from the perspective of a pre-trained language model (GPT-2 [13]). Lower perplexity values indicate that the model finds the sequence more predictable and fluent, while higher values suggest syntactic or lexical irregularities, or content that deviates from typical language patterns.

For both semantic similarity and perplexity scores, we tested the differences in means between popular and unpopular brain rots per language and we also tested the difference in mean between the two languages. We used one-way ANOVA and we also conducted non-parametric Mann-Whitney U tests. The results of the statistical tests are summarized in table 2 from the Appendix.

For Romanian brain rots, we evaluated whether the two metrics, semantic similarity and perplexity, differ significantly between brain rot texts categorized as popular versus unpopular. The results of the ANOVA test revealed no statistically significant differences.

The Mann-Whitney tests results also show that there is no significant difference between popular and unpopular brain rot texts for neither semantic similarity or perplexity scores. However, the p-value for semantic similarity was very close to the significance threshold (0.068), indicating a slight preference for more irregular/nonstandard language in popular brain rot texts (M = 168.59 for popular, M = 159.22 for unpopular).

We also performed statistical tests on the Romanian *general* subcategory of brain rots that varies less than the whole Romanian dataset. The ANOVA results confirmed the ones obtained with the the same statistical tests on all the data, with similar p-values that did not surpass the 0.05 threshold. This time, the semantic similarity p-value of the Mann-Whitney test revealed a statistically significant difference in semantic similarity ($p < 0.05$), suggesting that popular brain rots are slightly more semantically coherent (with a difference in mean of 0.002) than unpopular brain rots.

For Italian, the statistical test results suggest that neither semantic similarity, nor perplexity differs significantly across the popular and unpopular brain rot texts. As in the case of Romanian, we also tested the statistical significance of the differences between popular and unpopular texts w.r.t. semantic similarity and perplexity scores, for Italian *general* category of brain rots, but the results were not statistically significant.

Cross-linguistically, we tested whether semantic similarity and perplexity differ significantly between Romanian and Italian brain rot texts. The difference in mean semantic similarity score between Italian (M = 0.59) and Romanian (M = 0.58) was very small. The perplexity scores that reflect language uncertainties or language inconsistencies were substantially higher for Italian brain rot texts (M = 218.74) than for Romanian ones (M = 163.91). While one-way ANOVA test revealed no significant difference in semantic similarity between Italian and Romanian, for perplexity it yielded a statistically significant effect of the language category with a p-value < 0.001, suggesting that the Italian brain rot texts are indeed more language-unpredictable than their Romanian counterparts. The Mann-Whitney tests confirmed the ANOVA results showing no significance for semantic similarity (p = 0.06), and a highly significant difference between the two groups for perplexity (p < 0.0001).

### 4.3. Rhyme

We estimated the rhyme density by the following methodology. We employed a computational method based on sub-string similarity at word endings in two and three letters. Since the speech to text automatic transcription did not identify correctly the verses with end-line, we checked for all rhyme pairs locally, within a distance of two verses. The rhyme coefficient was calculated as the ratio between the total number of distinct, non-adjacent word pairs that share the same suffix of 2 or 3 letters and the total number of words in the text.

We tested the differences in rhyme scores of popular versus unpopular brain rot texts for both languages, and also the differences in rhyme scores between the two languages with Mann-Whitney tests. The results are shown in table 3 from the Appendix.

The difference of the means between Romanian popular (M = 0.19) and unpopular (M = 0.16) brain rots suggests a slight preference towards more rhymed ones in the popular group. However, for our sample of 60 (30 popular and 30 unpopular brain rots), this difference is not statistically significant ($p = 0.135 \geq 0.05$).

For Italian, there is also no statistical difference between the rhyme coefficient of the popular and unpopular groups, since their means are very close (0.215 vs. 0.228) and the p-value is 0.6880 (>0.05).

We also compared Romanian and Italian rhyme coefficients (120 each). The mean for Italian rhyme coefficient is 0.221, higher than the mean for Romanian which is 0.177. This time, the Mann-Whitney test returned the p-value of 0.0001 (<0.05), which means that Italian brain rots do rhyme more than their Romanian counterparts.

## 5. Sound

### 5.1. Audio Processing and Separation

We developed a multi-stage audio pipeline to isolate and characterize the vocal component of Italian and Romanian brain rot, with the goal of quantifying attributes that may influence their popularity, as well as perform comparisons between the two languages. First, each video file was converted to a high-resolution WAV format and processed with a state-of-the-art source-separation model (Demucs) [14] to obtain separate vocal and music stems. Vocal tracks were then normalized for consistent loudness, ensuring that subsequent analyses would not be affected by variations in recording level.

### 5.2. Speech Features

After isolating the vocal stems, we computed a comprehensive set of acoustic descriptors. Pitch contours were extracted via *librosa*'s [15] `pyin` algorithm, yielding mean F0, F0 variance, 95th–5th percentile range, and slope-entropy to quantify melodic movement. On 25 ms/10 ms-hop frames, we computed Mel-frequency cepstral coefficients (MFCCs) 1–13 (means and variances), spectral centroid, bandwidth, roll-off, zero-crossing rate, and spectral-flux (means and variances) to capture brightness, noisiness, and timbral dynamics. Rhythmic patterns were quantified by onset detection—calculating syllable-rate and pause-duration statistics—and by RMS (root mean square) energy envelopes (temporal centroid, mean, and variance). Each clip's features formed one row in a master data matrix.

We then compared these matrices in two ways: within each language (popular vs. unpopular memes) and across languages (Italian vs. Romanian). All continuous features were tested with Mann–Whitney U and corrected for multiple comparisons using the Benjamini–Hochberg procedure at $q < 0.05$ [16].

After correction, for the analyses of the popular vs. unpopular groups within each language, no features remained significant, likely due to modest sample sizes and the number of comparisons. Reporting raw $p < 0.05$ findings (visible in Table 5 from the Appendix) highlights, though, that in the Italian dataset, popular brain rots exhibited significantly greater fundamental-frequency variance (var_f0) and a wider pitch range (range_f0) than their unpopular counterparts. These results suggest that a more expressive, melodic content, characterized by larger and more varied pitch intervals, is associated with higher popularity in Italian clips. In the Romanian corpus, popular audios differed from unpopular ones in three respects: they featured a marginally faster onset rate (syllable_rate), a more stable mid-high spectral texture (mfcc_9_var), and a darker high-frequency timbre (mfcc_11_mean). These patterns imply that a slightly quicker rhythm, smoother structure in the mid-high band, and less pronounced very high frequencies tend to cooccur with popularity. None of these comparisons survived false discovery rate (FDR) correction at q < 0.05, reflecting exploratory sample size considerations.

In addition to our broad comparisons, we also examined popular versus unpopular clips within each thematic category—namely *general*, *scheletro*, *matteo*, and *politicians and celebrities* in Italian and *general*, *schelet*, *morcoveață*, and *regina brain rot* in Romanian. After applying Benjamini–Hochberg correction, only the Romanian *general* subset yielded features that remained significant. In those 60 clips, one clear acoustic hallmark of popularity is a smoother timbre in the mid-to-high frequencies. Specifically, popular memes have a noticeably lower mfcc_9_var (181 vs. 232 in unpopular clips), meaning the shape of the spectrum around 3–4 kHz stays more consistent rather than flitting up and down. This steadiness makes the audio feel more even and less "choppy". There is also a trend toward lower mfcc_11_var (170 vs. 193), which means fewer abrupt jumps in the very high frequencies (around 5–6 kHz), so sibilance and hiss are kept under tighter control. These findings suggest that Romanian *general* brain rots become more engaging when their soundtrack maintains a steady, coherent tone.

When we examine the full set of 120 Italian and 120 Romanian brain rots side by side (as can be seen in Table 4 from the Appendix), a clear pattern of prosodic contrast emerges. Italian vocals move through a broader and more dynamic pitch range, peaking and dipping over a span that is markedly larger than in the Romanian samples, which makes them feel more melodically engaging. Romanian clips, on the other hand, swing their pitch contours in a less predictable fashion, with higher entropy of slope suggesting sudden twists in intonation that can come across as more spontaneous or volatile. In the spectral domain, Romanian brain rot tracks push energy into the upper frequencies: their average spectral centroids, bandwidths, and roll-off points all sit higher than in Italian. Yet these high-frequency bands in Romanian audio are less stable over time, fluctuating more from moment to moment and lending a grainier, more restless timbral texture. Italian clips display a darker, more subdued high-end, but they deliver their muted tones with greater consistency and, at the same time, add sharp bursts of change, especially in those same upper bands, so that the audio doesn't feel monotone. They also sound uniformly louder, amplifying their broad, dramatic pitch gestures and deep spectral shifts, whereas Romanian tracks embrace a leaner, quieter tone. These findings point to two distinct audio "signatures" that likely reflect both the underlying voice synthesis models and the cultural styles of meme production in each language.

### 5.3. Sentiment Analysis of Sound

Full-audio (voice + music) sentiment was assessed using the pretrained speech-emotion classifier superb/wav2vec2-base-superb-er [17]. It categorizes short audio clips into four emotion labels (*angry*, *happy*, *neutral*, *sad*). Each brain rot's waveform was resampled to 16 kHz and fed into the model, after which we captured the full probability distribution over three coarse categories, Negative (-1), Neutral (0), and Positive (+1). These labels were mapped from the original model outputs as such: Negative (-1) for any emotion other than *happy* or *neutral* (i.e. *angry* and *sad*), Neutral (0) for labels predicted as *neutral*, and Positive (+1) for labels predicted as *happy*. This mapping yields a better comparison point for our study, in alignment with the sentiment analysis performed for the brain rots' texts. Separate sentiment files were generated for four groups: Italian-Popular, Italian-Unpopular, Romanian-Popular, and Romanian-Unpopular. The distributions for each audio in the corresponding groups is shown in Figure 4.

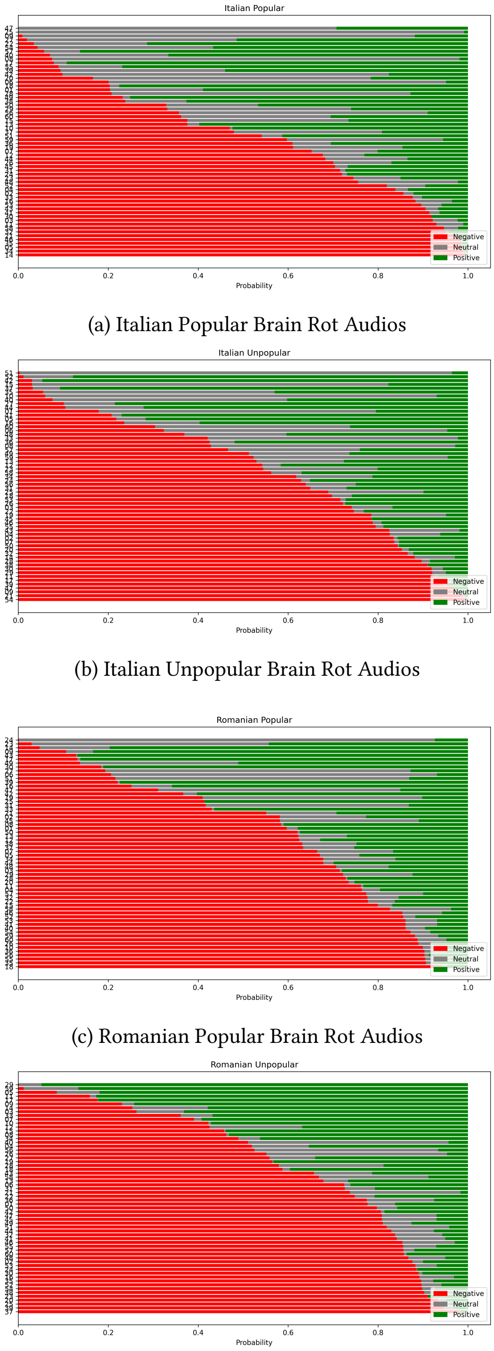
When we treat the three sentiment probabilities (Negative, Neutral, and Positive) as a multivariate outcome, neither Italian nor Romanian shows a significant difference between popular and unpopular brain rot audios. A MANOVA on the Italian data yields Wilks' $\lambda$ = 0.992 (F(3,116) = 0.30, p = 0.826), and the same test on Romanian returns Wilks' $\lambda$ = 0.966 (F(3,116) = 1.37, p = 0.257).

However, comparing Italian versus Romanian clips reveals a modest but statistically significant language effect on the combined sentiment vector (Wilks' $\lambda$ = 0.965, F(3,236) = 2.87, p = 0.037). In other words, the full-audio sentiment differs more by language than by popularity within a language.

We also used Mann–Whitney tests to look at each sentiment dimension in isolation and to account for potential concerns about normality and homogeneity of variance. Comparing Italian against Romanian across all 240 clips, the sentiment score distributions show however no robust separation: Negative (U=6,536; p=0.217), Neutral (U=8,088; p=0.099), and Positive (U=6,878; p=0.550) all lie above the conventional 0.05 threshold. The Neutral score comes closest (p $\approx$0.10), hinting at a possible tendency for Italian memes to register slightly higher neutral-vibe probabilities than Romanian ones, but this trend remains statistically inconclusive.

## 6. Video

To analyze the visual content of the 240 videos, we employed the Gemini Flash 2.5 multimodal model. Each video was individually processed by the model with a prompt instructing it to perform a visual-only analysis and extract a series of predefined attributes. The model returned its analysis for each video as a structured JSON



(a) Italian Popular Brain Rot Audios

(b) Italian Unpopular Brain Rot Audios

(c) Romanian Popular Brain Rot Audios

(d) Romanian Unpopular Brain Rot Audios

**Figure 4:** Continuous-sentiment distributions (Negative, Neutral, Positive) for each language and popularity group of the brain rot audios

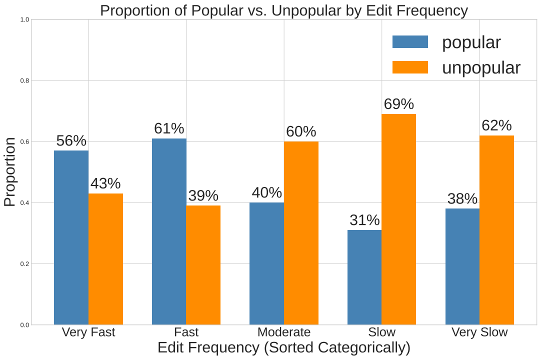


**Figure 5:** Faster video editing speeds show a stronger correlation with popularity than slower editing speeds

object, which allowed for the systematic collection of data for our study. In an initial test, the model demonstrated a notable capability in discerning the language of origin from visual cues alone, achieving an accuracy of 71.67% (Romanian vs. Italian) by identifying culturally specific items (e.g., the Carpathian Mountains). However, it struggled significantly to predict a video's popularity, achieving an accuracy of only 47.92% (random chance). This initial finding suggests that a video's success is not determined by straightforward, immediately classifiable visual markers of appeal. A deeper statistical analysis was therefore performed to uncover more subtle visual attributes that may correlate with popularity (Table 6 in the Appendix).

A key finding emerged from the analysis of the videos' dynamic properties, specifically the rate of the shot transitions. The data indicates a clear and statistically significant tendency for popular videos to feature a much faster cutting speed. Videos categorized with *Very Fast* or *Fast* transitions were substantially more prevalent among popular content, as it can be seen in figure 5. This observation is supported by a positive Pearson correlation of 0.1712 between cutting speed and popularity, which was found to be statistically significant (p=0.0231). This suggests that as the frequency of cuts increases, so does the likelihood of a video being popular, pointing to a dynamic, high-energy visual style as a key component of audience engagement.

Further reinforcing the importance of dynamism, the overall pacing of the videos also proved to be a significant differentiator. A statistically significant difference was found in the distribution of pacing levels between popular and unpopular videos, as confirmed by a Mann-Whitney U Test (p=0.0492). Popular videos were most frequently described as having a *Fast* overall pace. Moreover, when the correlation between pacing and popularity was analyzed by language, a significant difference was observed.

For the Romanian videos, we found a positive Pearson correlation of 0.2791, indicating that as overall pacing increases, videos in Romanian tend to be more popular. In stark contrast, the Italian videos showed a negligible correlation of 0.0047, revealing virtually no linear relationship between pacing and popularity. This language-specific finding suggests that the overall positive trend observed in the combined dataset is almost exclusively driven by the Romanian-language content. While the perceived tempo is an important factor, its influence on popularity appears to be culturally moderated.

In contrast to the clear influence of dynamism, thematic elements such as absurdity and narrative structure showed no significant correlation with video popularity. Although it was hypothesized that surreal, chaotic, or illogical content might be a good indicator of popularity, the analysis did not bear this out. Perceived absurdity levels yielded very low Pearson correlation coefficients and statistically insignificant p-values in the Mann-Whitney tests. For instance, the overall absurdity level, despite being *High* in the majority of videos, had no discernible statistical relationship with popularity (p=0.2937).

In conclusion, the image-level analysis indicates that while the kinetic and rhythmic aspects of a video's construction are influential, their effect on popularity is not universal. The visual dynamism, characterized by rapid cutting and a fast overall tempo, appears to be a powerful element in capturing and retaining audience attention, but this trend is highly dependent on the cultural context of the video. Our data shows this relationship is strong for Romanian-language content but non-existent for Italian-language content, suggesting that the preference for such a style is culturally specific rather than a general driver of engagement.

## 7. Manual Analysis

One of the most striking brain rot characteristic revealed by the manual scrutiny of all the brain rots represents their core element: the dissonance between the tone, the music and the content. The tone is neutral - an AI generated voice- but the text is often deviant, triggering some extreme emotions. There is no harmony or coherence whatsoever between text, speech, music and image. Another notable trait is the unsettling blend of baby talk, nursery rhymes, and children inappropriate content (topics) and language (slang, pejorative jargon, NSFW words).

Overall, the brain rots seem a good example of E(xtended)-creativity, rather than of F(ixed)-creativity, since they tend to break the rules and not only to create new content using existing ones [18].

The manual analysis of the textual content revealed the prevalent topics and characters used in both languages. Some Romanian brain rot content includes political propaganda related to the presidential elections, often carrying extremist nationalist undertones. This suggests that such content goes beyond seemingly harmless absurdist humor and may serve as manipulative material.

The Romanian characters are inspired from the Romanian folklore, such as the Balaur (a dragon-like creature), Morcoveață (a carrot shaped boy inspired by Jules Renard's Poil de Carotte), from Romanian historical figures such as rulers or poets (Mihai Viteazul, Ion Creangă, Mihai Eminescu), or from global pop culture such as Hatsune Miku, Sonic the Hedgehog, or Disney characters, portrayed in explicit real-life situations like relationship with siblings or modern dating.

The topics in Italian brain rot also revolve around daily routine and politics, with celebrity characters such as Volodimir Zelensky or Emmanuel Macron, portrayed in funny and ironical ways, frequently with misspelled names in order to undermine their authority and to deglamorize them. There are also very popular characters like Ballerina Cappuccina, a tragic but very graceful figure featuring sometimes grotesque ballet poses, the ironical and dreamy Skeletro, with emo fragility and self deprecating depression and out dated romanticism.

The music is mostly depressive both in popular and unpopular Italian or Romanian brain rot, written in minor tonality which gives to the brain rots a serious, sad and dark sounding. We identified with the Shazam tool a variety of musical pieces, from classical music by Frederic Chopin or Max Richter, through very popular tunes by Ennio Morricone or Bobby McFerrin all the way to some trap and rap pieces. Most of the titles of these pieces include the words *spooky*, *scary*, *depressive*. We noticed that for the popular category the music is slightly less dark than for the unpopular. Italian popular brain rots showcase a wide array of soundtracks from various genres, while unpopular ones typically feature the same three most used tracks used by viral brain rots. At the same time, the Romanian unpopular samples contain diverse soundtracks from obscure sources and underground artists. Conversely, a single track is present in more than half of all Romanian popular brain rots. This suggests that more effort was required at the beginning of this trend in Italy, but after gaining notoriety, the key to viral clips was to exploit the same soundtracks as established by the initial wave, making them more recognizable.

The visuals are overloaded, kitschy, anti-narrative, absurd, over-sized, ironic, cynical, and, in a way, self-destructive. The popular ones are more animated, present more complex and colorful imagery, the cutting is obviously more dynamic, full of narrative.

## 8. Conclusion

This study conducted a multi-modal analysis of Italian and Romanian brain rot, seeking to identify the factors driving popularity and to map the cultural and linguistic differences between the two languages. Our findings show that the popularity of these memes is not primarily determined by their textual content. Features like sentiment, narrative absurdity, or rhyme density showed no significant link to a video's success. The same can be said about standard audio features and speech sentiment. Instead, the analysis revealed that popularity is strongly correlated with visual dynamics, specifically a faster cutting speed and overall pace (for Romanian language).

The research also uncovered clear distinctions between the Italian and Romanian versions of brain rot. Italian brain rots were textually more negative, more unpredictable, and used rhyme more frequently. Acoustically, their vocals were characterized by greater melodic range and loudness. Conversely, Romanian content was more neutral, while its vocals were spectrally brighter and showed more erratic pitch changes. These differences extend to thematic content, with each language favoring culturally specific characters and references.

As this is a global phenomenon, we plan to extend this study to other Romance languages in future work. Regarding the small sample size, we intend to include samples that would not fit in either popular or unpopular categories, thus rephrasing the popularity aspect as a continuous problem rather than as binary classification.

In essence, the success of brain rot appears to depend on a combination of universal and culturally-specific elements. While fast-paced, dynamic visuals serve as a universal driver for engagement, the content itself is distinctly shaped by the linguistic, acoustic, and thematic norms of its target culture. What makes the genre unique is the strange mix of message, image and sound.

## 9. Limitations

One limitation of this study is that the dataset, while carefully curated, is relatively small and manually collected, focusing only on Italian and Romanian content. This may limit the generalization possibilities of our findings to brain rot in other languages or on a larger scale. Secondly, our analysis identifies strong correlations, such as the link between cutting speed and popularity, but does not establish causation. Other confounding factors not examined here may be at play. Finally, brain rot is a rapidly evolving digital phenomenon, and the features that define it today may change over time, potentially dating our specific observations.

## Abstract

This paper falls within ongoing research aimed at enhancing the human interpretability of neural language models by incorporating physiological data. Specifically, we leverage eye-tracking data collected during reading to explore how such information can guide model behavior. We train a multilingual encoder model to predict eye-tracking features from the Multilingual Eye-tracking Corpus (MECO) and analyze the resulting shifts in model attention patterns, focusing on how attention redistributes across linguistically informed categories such as part of speech, word position, word length, and distance from the syntactic head after fine-tuning. Moreover, we test how this attention shift impacts the representation of the interested words in the embedding space. The study covers both Italian and English, enabling a cross-linguistic perspective on attention and representation shifts in multilingual encoders grounded in human reading behavior.

## Keywords

Eye-tracking, Neural Attention, Multilingual models, Embedding space, Interpretability

## 1. Introduction and Motivation

Neural language models (NLMs) now match or even surpass human benchmarks on many NLP tasks, yet the logic behind their predictions remains largely hidden behind billions of parameters. To make these systems more transparent and data-efficient, researchers are increasingly borrowing ideas from cognitive science, grounding both training and evaluation in how people actually learn and process language (e.g. [1, 2, 3]). Among the most informative cognitive signals of human language processing is eye-tracking (ET). Decades of psycholinguistic work show that fixation times, regressions, and skips mirror both early lexical access and later integrative processes underlying text comprehension [4, 5]. Leveraging these signals has already boosted model accuracy on a variety of downstream tasks ranging from core linguistic tasks [6] to more applied tasks like sentiment analysis [7], language proficiency assessment [8], machine reading comprehension [9], while also giving us a new lens on model interpretability. Studies by Sood et al. [10] and Eberle et al. [11] found that transformer attention does not always line up with human gaze, whereas Bensemann et al. [12] and Wang et al. [13] revealed stronger links in specific layers, hinting at a layered correspondence between reading behavior and neural representations. Extending this direction, Dini et al. [14] investigate how injecting reading-related information into NLMs through different fine-tuning strategies on ET data affects their attention patterns, as well as their performance on downstream tasks and representation space. Their findings show that this intermediate process increases the correlation between model attention and human attention and it leads to a compression of the embedding space, without generally degrading performance on downstream tasks.

Building on this foundational framework, this paper aims to further highlight the effects of **incorporating information about human reading behavior in a NLM** from a **linguistically informed perspective**. Specifically, we examine how fine-tuning on eye-tracking signals leads to **shifts in model attention**, and how these shifts affect the **structure of word representations**. To explore this, we extract a set of linguistic features, capturing progressively more complex language phenomena, from the input text and analyze how attention is redistributed across word classes defined by these features. In parallel, we assess how these attention shifts influence the embedding space, both at a global level and within the local representational geometry of specific word classes.

The code for our experiments is publicly available on GitHub.

## 2. Related work

Our study intersects two complementary lines of research within NLMs interpretability. The first investigates ET data as a diagnostic signal to evaluate the alignment between model behavior and human cognitive processing, particularly through the lens of attention mechanisms. The second focuses on analysing model's attention mechanisms (Section 2.2) and representational space (Section 2.3) in relation to linguistic structure.

## 2.1. Eye-tracking and NLMs

In recent years, eye-tracking has emerged as a prominent physiological signal in NLP research due to its affordability and ease of collection compared to methods like fMRI or MEG. Public resources such as the GECO corpus [15], the MECO corpus [16], and the WE-RDD dataset [17] now let researchers probe gaze behaviour at scale across languages and reading paradigms.

Work with these corpora has split in two directions. The former injects gaze-derived features, into neural architectures, typically lifting accuracy on downstream tasks. The latter, which motivates our study, treats ET as a diagnostic for a model's internal workings.

The first systematic comparison came from Sood et al. [18], who matched attention maps from CNNs, LSTMs and Transformers against human fixations. Their findings reveal that while transformers performed the best, they showed the weakest alignment with gaze. Eberle et al. [11] confirmed that even after task-specific fine-tuning, large Transformers stayed distant from human reading patterns. Conversely, Bensemann et al. [12] reported that raw dwell times correlate strongly with the earliest BERT layers, a relation that persists as model size grows. Morger et al. [19] extended the inquiry cross-lingually and found robust correlations, especially for monolingual encoders, between human word-importance rankings and model saliency. Most recently, Wang et al. [20] showed that deeper layers of NLMs once again echo fixation metrics, hinting at a layered, non-monotonic link between model depth and cognitive fidelity.

## 2.2. Model Attention Dynamics

The role of attention mechanisms in NLMs has been a subject of extensive research and debate. While attention weights are often interpreted as providing insight into model reasoning, a growing body of research has questioned their reliability as faithful explanations of model decisions. Some studies suggest that attention can highlight important input elements, yet others argue that attention distributions can be manipulated without significantly affecting predictions, casting doubt on their explanatory power [21, 22]. In response to these concerns, alternative attribution methods have been proposed—such as attention rollout [23] and gradient-based techniques [24]—which aim to better capture the pathways through which information influences predictions. As part of this debate, a parallel line of work has explored whether attention aligns with known linguistic structures, such as syntactic dependencies or PoS categories, offering a complementary perspective on its interpretability. The foundational study by Clark et al. [25] showed that certain attention heads in BERT consistently focus on syntactic phenomena, such as attending to an entity's determiners or subjects attending to their verbs. However, fine-tuning on syntactic or semantic tasks had minimal effect on altering self-attention patterns. Vig and Belinkov [26] conducted a comprehensive analysis of attention head interpretability in GPT-2 using both visualization and quantitative measures. Their results indicate a layer-specific linguistic sensitivity, with different types of linguistic information—such as PoS and syntactic dependencies—being more salient in particular layers. They also found stronger alignment with syntactic dependencies in the model's middle layers. Htut et al. [27] directly evaluated the extent to which attention aligns with gold-standard dependency parses. By computing the correspondence between attention distributions and syntactic head-dependent pairs, they showed that BERT's attention does not systematically reflect syntactic dependency structures, particularly in deeper layers.

Taken together, these studies suggest that while attention mechanisms can exhibit linguistically meaningful behavior in isolated cases—especially in specific layers or individual heads—they do not consistently encode syntactic or morpho-syntactic structure.

## 2.3. Geometry of the embedding space

Transformer models learn a high-dimensional *embedding space* in which every token is represented by a dense vector that encodes both meaning and syntax. A consistent finding is that these vectors occupy only a narrow cone of the space, an *anisotropic* layout sometimes called the representation degradation effect [28, 29, 30]. In NLP, such behaviour is often viewed as harmful because it can hide fine-grained linguistic cues [31, 32, 33]. Yet theory and broader machine-learning evidence show that anisotropy can arise naturally under stochastic gradient descent and may even aid generalization, especially when models project data onto low-dimensional manifolds [34, 35, 36, 37]. In this respect, studying the impact of various fine-tuning objectives and downstream tasks provides important insights into how they shape the geometry of the embedding space [34, 35, 36]. While still relatively limited, a growing body of work has begun to examine the relationship between embedding space properties and linguistic phenomena. For example, Hernandez and Andreas [38] show that linguistic features tend to be encoded in lower-dimensional subspaces in the early layers of both ELMo and BERT and that relational features (like dependency relations between pairs of words) are encoded less compactly than categorical features like part of speech. More recently, Cheng et al. [39] analyzed representation compression in pre-trained language models from both geometric and information-theoretic perspectives. Their findings reveal a strong correlation between these two views and show that the intrinsic geometric dimension of linguistic data is predictive of its coding length under the language model.

To the best of our knowledge, no systematic study has examined how eye-tracking fine-tuning affects attention patterns and the resulting embedding representations across different linguistic phenomena. Moreover, cross-linguistic analyses of these changes following cognitively motivated fine-tuning remain scarce.

# 3. Dataset

For our analysis, we leverage two distinct datasets: the Multilingual Eye-tracking Corpus (MECO) to finetune the model on human gaze modeling and treebanks from the Universal Dependencies (UD) project to extract linguistically motivated features and compute model attention shifts and representation structure induced by fine-tuning on ET data.

## 3.1. Eye-tracking data: The MECO Corpus

MECO [16] is a multilingual collection featuring reading behavior from both native (L1) and second-language speakers across 13 languages. We focus on the L1 subsets for English and Italian, chosen for their typological diversity and data completeness, allowing for a controlled yet cross-linguistic perspective on gaze modeling.

Each participant in MECO read 12 encyclopedic-style texts, covering general knowledge topics. To ensure consistency and limit computational costs, we selected the largest subsets of users who had read the majority of sentences. For Italian, we included 9 participants who read all sentences. For English, since no participant completed the full set, we selected 25 participants who all read the same set of sentences, missing only two in common.

We used five ET features intended to represent early, late and contextual signals of human reading processes: **First Fixation Duration**: the duration of the first fixation landing on the word; **Gaze Duration**: the summed duration of fixations on the word in the first pass, i.e., before the gaze leaves it for the first time; **Total Reading Time**: the cumulative amount of time spent reading a word, capturing both fixations and potential interruptions (e.g., regressions or pauses); **First-run Number of Fixations**: the number of fixations on a word during the first pass; **Total Number of Fixations**: the number of discrete fixations on areas of interest overall.

## 3.2. Universal Dependencies Treebanks

To analyze how model attention weights and embedding space shift following fine-tuning on eye-tracking data, we relied on linguistically annotated corpora from UD treebanks [40]. Specifically, for Italian, we employed the subsection corresponding to the training set of the Italian Stanford Dependency Treebank (ISDT), which contains $\approx 13,000$ sentences drawn from a variety of textual genres. For English, we used the training set of the English Web Treebank (EWT) [41], including $\approx 12,000$ sentences , also multi-genre. UD corpora were chosen due to their gold-standard syntactic and part-of-speech annotations, which provide a reliable foundation for our fine-grained linguistic analyses. Additionally, the cross-linguistically consistent annotation schema offered by UD enables meaningful comparisons across typologically distinct languages.

# 4. Our Approach

We propose a **linguistically informed framework** to investigate the impact of injecting human reading behaviour into a pre-trained NLM, focusing on its effects on attention and word representations. The approach consists of two main stages: first, we fine-tune the model on predicting several ET features; then, we compare the pre-trained and fine-tuned models along three axes: i) Correlation between model attention and human attention; ii) Attention distribution over input tokens; iii) Sentence representations in the embedding space.

To enable a more fine-grained analysis of how ET fine-tuning affects word representations, we condition our evaluations on the following linguistic features extracted from the UD treebanks: **word length** in characters, **part of speech** category, **position** in the sentence, and **distance** from the syntactic head.

For our experiments we used XLM-RoBERTa-base, a 12 layer multilingual encoder-based model. In what follows, we outline the methodological choices and implementation details of our experimental setting.

## 4.1. ET injection into the Model

To inject reading-related information into the model, we leverage the set of eye-tracking features from MECO described in Section 3.1. Unlike most prior work—which typically aggregates eye-tracking data across participants, with few exceptions [42]—we treat each reader individually, conducting experiments separately for each subject. This design choice is motivated by the intrinsic variability observed in reading behavior, even among skilled readers [43, 44, 45], and enables a more accurate modeling of reader-specific dynamics.

After a hyperparameter tuning phase using 5-fold cross-validation, we **fine-tune the model to predict five word-level eye-tracking features**, training a separate model for each individual reader.

Since the MECO dataset provides annotations at the word level, while the model's tokenizer splits some words into subword units, we follow standard practice [46] and assign eye-tracking features only to the first sub-token of each word, ignoring the rest during training[1].

To examine whether the fine-tuned model develops a more human-like attention pattern, we compute the **correlation between model attention and human attention** before and after fine-tuning. For model attention, we consider the attention weights received by each word when computing the representation of the beginning-of-sentence token (<s>), which is the only token used during the eye-tracking prediction phase and serves as a global summary of the sentence. To account for subword tokenization, we follow the same approach used during fine-tuning and associate attention scores to the first sub-token of each word. As a proxy for human attention, we choose the *Total Reading Time* feature (see Section 3.1). For each reader, we thus compute the correlation between their eye-tracking data and the attention patterns of both the pre-trained and the fine-tuned model across all layers, allowing us to assess whether the latter aligns more closely with human reading behavior.

## 4.2. Assessing the Role of ET fine-tuning on Word Representations

To assess how fine-tuning on ET affects the model's internal dynamics for attention and embedding space, we leverage the linguistic features from the treebanks described in Section 4.

Specifically, to compute the **attention shifts**, for each value of these features, we analyse the amount of attention the corresponding words receive before and after fine-tuning. This allows us to characterize shifts in attention distribution across different linguistic phenomena and across all layers of the models. Firstly, we normalize the attention scores for each sentence (excluding BOS and EOS tokens) so that their sum is 1. Attention shifts are quantified as the percentage change in the average attention received by tokens with a given feature value, before fine-tuning. A positive shift indicates increased attention to these tokens after fine-tuning, while a negative shift reflects a decrease. This allows us to identify which linguistic categories gain or lose prominence after incorporating eye-tracking supervision.

To analyze the **shifts in the embedding space**, we rely on two complementary metrics. *(i) IsoScore* [47] offers a scale-invariant measure of isotropy: lower scores indicate that the embedding variance is concentrated along fewer directions, pointing to a more anisotropic space. *(ii) Linear Intrinsic Dimensionality (Linear-ID)* [48] estimates the dimensionality of the smallest linear subspace that captures the embeddings, providing a proxy for their geometric complexity.

The two metrics were computed on the first sub-token of each word in the UD treebanks. In line with the other analyses, we compare the embedding spaces of the pre-trained and fine-tuned models to assess whether ET fine-tuning leads to more compact or more isotropic representations, as reflected by changes in these metrics.

All reported scores are first computed for each user individually and then averaged across all users.

# 5. Results

## 5.1. Correlation between model and human attention

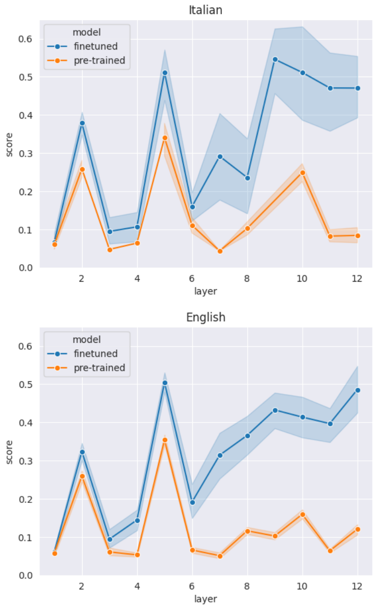

**Figure 1:** Correlation between model attention and human attention (p-value < 0.05).

As a first evaluation step, we computed the correlation between human attention and model attention, both before and after fine-tuning on eye-tracking data. As we are interested in the strength rather than the direction of the association, we considered the absolute values of the correlation coefficients. For the fine-tuned models, we computed the correlation between the model's attention weights and the Total Reading Time of the specific user on which each model was fine-tuned. For the pre-trained model, which is not finetuned to any individual reader, we calculated the correlation between its attention weights and the Total Reading Time of each user independently, and subsequently averaged the resulting coefficients. Figure 1 reports the comparison of Spearman correlation coefficients, averaged across all users.

[1] The fine-tuning is run for 50 epochs, using a learning rate of $5e-05$, a weight decay of $0.01$, and a warm-up ratio of $0.05$.

In line with results reported in [14, 49], **fine-tuning on ET data consistently leads to stronger correlation coefficients between model and human attention, particularly in the deeper layers** of the model. This effect is evident in both Italian and English. The overall patterns are remarkably similar across the two languages, although the correlation scores for Italian are slightly higher on average.

## 5.2. Analysis of the Attention Shifts

This section reports the analysis of the attention shifts induced by fine-tuning on ET data. We grouped tokens into classes for the values of the linguistic features detailed in Section 4. To enhance readability and interpretability, for each linguistic feature we visualised only the most representative values. Rather than applying a strict frequency threshold, we heuristically excluded rare or degenerate cases (e.g., for token length, extremely long tokens such as URLs), retaining typical and frequent values that better reflect standard linguistic patterns. Each figure also includes an "AVG" column summarizing the average shift across all layers, offering a high-level view of the attention reallocation patterns.

**Figure 3:** Attention shift for UD Parts of Speech.

Figure 2 reports the results of the attention shift analysis for word length, showing three distinct patterns. First, **single-character words consistently lose attention after fine-tuning**, with particularly sharp drops observed in layers 5, 7, and 10. An exception appears in Italian, where these short words receive a notable increase in attention in layer 9. Second, **short words** (2-3 characters) **exhibit a general increase** in attention across most layers, especially pronounced in layer 9 and 11, suggesting that the fine-tuned model places greater importance on these short words. Finally, **longer words** (4+ characters) **show a more complex pattern, with attention picks and decreases alternating across layers**. Interestingly, layers 5 and 10 display a gradual increase in attention starting from 6-tokens long, suggesting that it may encode length-sensitive distinctions post-fine-tuning.

Figure 3 shows the attention shift analysis across Parts of Speech. Overall, we observe a reduction in attention to punctuation marks (PUNCT) across layers, reinforcing the word length analysis and suggesting that the **model learns to down-weight non-lexical tokens after fine-tuning on eye-tracking data**. In contrast—and somewhat unexpectedly, given existing psycholinguistic evidence on human reading behavior—, **functional words** like adpositions (ADP), determiners (DET), and auxiliary verbs (AUX) **receive increased attention**, likely reflecting their importance in building the syntactic structure

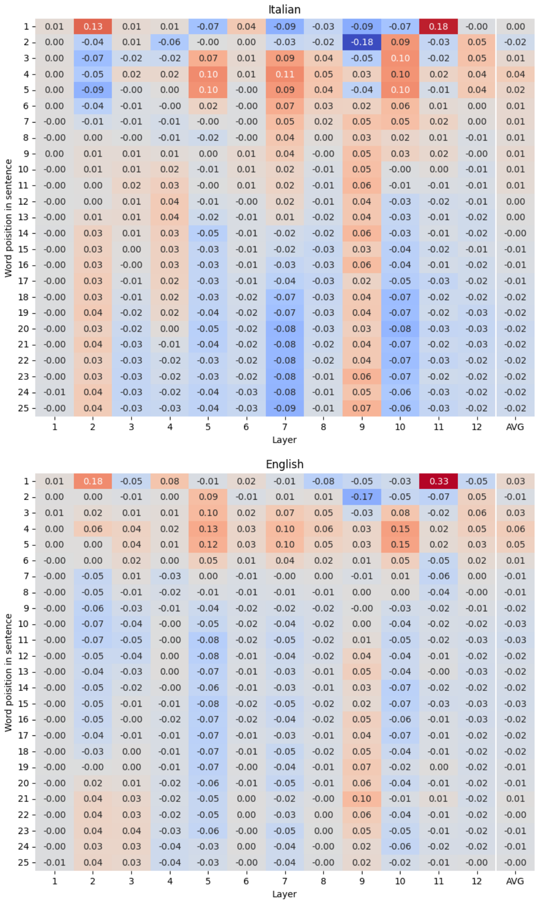

**Figure 4:** Attention shift for word position in sentence.

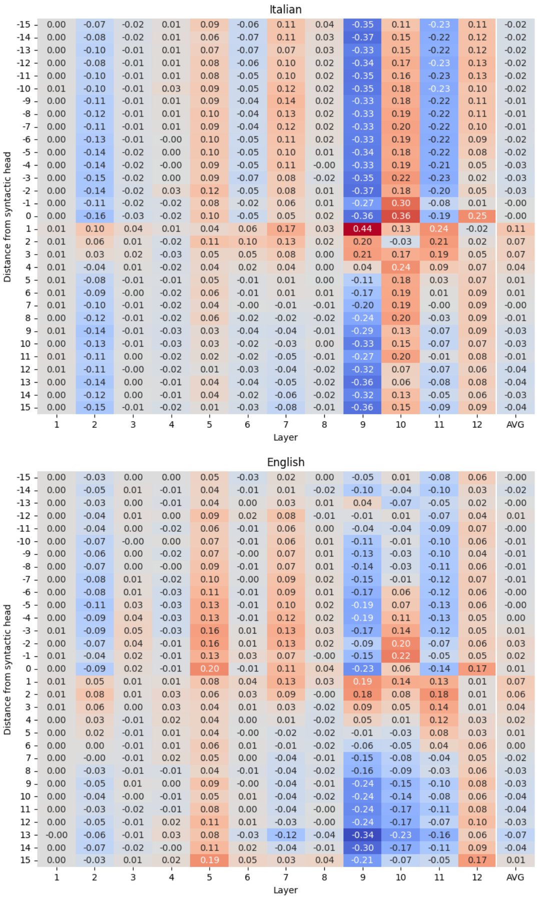

**Figure 5:** Attention shifts for distance from syntactic head.

and sentence interpretation. Additionally, a language-specific effect is visible in Italian, where coordinating conjunctions (CCONJ) gain notable attention across several layers. While similar shifts occur sporadically in the English model, they are less consistent and often offset by decreases in other layers.

As regards the attention shifts based on the word's position within the sentence (Figure 4), we noted that for both languages **tokens appearing earlier in the sentence generally receive slightly more attention after fine-tuning**, whereas those occurring later receive less. An exception is observed for the first two tokens, which deviate from this trend. Layer-specific behaviors also emerge: for instance, layers 2 and 9 tend to increase attention toward later tokens, while most other layers show the opposite effect, emphasizing earlier positions. Notably, layer 2 and layer 11 both show sharp increases in attention to the first token, suggesting a potential reweighting of sentence-initial information after exposure to human reading patterns. Interestingly, quantitative data from the used UD treebanks show that early sentence positions largely correspond to syntactically central elements—particularly the root, which anchors the clause and governs the structure of major complements. The observed shift in attention may therefore reflect the model's increased sensitivity to syntactic organization cues at sentence onset, especially in specific layers. This behavior is also well-documented in psycholinguistic studies and indicative of incremental parsing, where early elements guide syntactic and semantic expectations during sentence comprehension.

Figure 5 shows the attention shifts for the head-dependent distance parameter. A positive value indicates that the head follows the dependent, while a negative one that the head precedes it. The special value 0 is assigned to the root of the sentence. On average, it emerged that **tokens that are syntactically closer to their head tend to receive more attention after fine-tuning, particularly when the head follows the dependent**. This suggests that **fine-tuning on ET data encourages**

**the model to prioritize syntactic dependencies that align with typical reading dynamics**, where upcoming heads may draw anticipatory processing effort.

### 5.3. Shifts in the Embedding Space

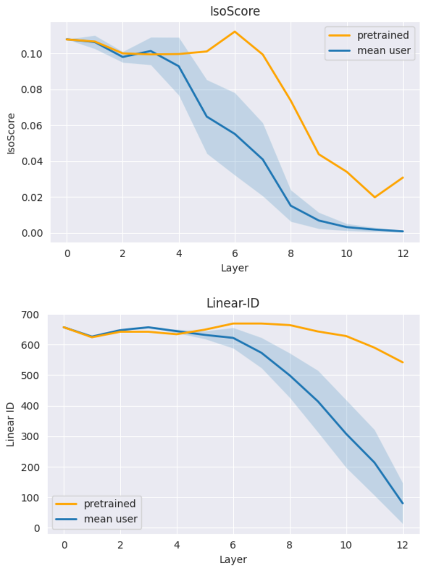

**Figure 6:** IsoScore (Top) and Linear Intrinsic Dimensionality (Bottom) of word embeddings from all model layers, before and after fine-tuning, averaged across users.

For space reasons, this section is limited to results for Italian; results for English show comparable trends and are provided in Appendix B. In the pre-trained model, IsoScore stays flat at $\approx 0.10$ through layer 6 and drops only in the final layers. After ET fine-tuning, the decline starts at layer 4, leaving layers 1–3 unchanged but rendering the upper layers markedly more anisotropic (Fig. 6, top). Linear-ID mirrors this pattern: the pre-trained model sustains $\approx$ 650 effective dimensions across all layers, whereas the fine-tuned one contracts from layer 4 onward and collapses to $< 100$ dimensions by layer 12 (Fig. 6, bottom). For these phenomena, as well as the ones to follow, the reduction of IsoScore and Linear-ID after fine-tuning is statistically significant (p<0.05 based on the Wilcoxon signed-rank test).

These results align with findings reported in [14] on how ET fine-tuning influences the embedding space shift. The linguistically informed analysis provides additional insights. Considering words grouped by *part of speech* and *head-dependent distance* (analyses for the remaining features are given in Appendix B), some main trends emerge. For POS (Figures 7 and 8), **the pre-trained model assigns content words (NOUN, VERB, PROPN) the highest-dimensional, most isotropic subspaces, with functional words and punctuation confined to lower dimensions**. Since content words exhibit high semantic diversity, the model tends to distribute their embeddings across many nearly orthogonal directions, resulting in broader and more isotropic subspaces. Function words, being few but very frequent and semantically uniform, collapse into a tight, anisotropic region, yielding lower IsoScore and Linear-ID. **Fine-tuning compresses all POS categories in the upper stack**, erasing the hierarchy above layer $\sim$ 6 while retaining it below; content words still display slightly greater variability. The observed contraction of the embedding space and loss of isotropy mirror the new optimization objective imposed during fine-tuning: to solve the ET task, the model no longer requires highly granular lexical representations, even for content words, so the latent geometry collapses accordingly. Turning to syntactic structure as captured by dependency distance (Figures 9 and 10), we observe **a notable asymmetry already in the pre-trained model based on the position of the dependent**: right dependents (and specifically within $d \in [-3, -1]$ of the head) display higher Linear-ID and isotropy, while left ones are confined to lower-dimensional and less uniform subspaces. This phenomenon appears highly interesting and, to the best of our knowledge, has not been previously reported, warranting a more in-depth investigation. **After fine-tuning, the model applies a uniform compression across all distance bins in the upper layers** (from layer 8 onward), while preserving the strong distinction between left and right dependents in earlier layers.

## 6. Conclusion

In this paper, we proposed a linguistically informed approach to study the impact of incorporating human reading behavior into a NLM. Our main findings reveal systematic and interpretable changes across both attention patterns and the representation space. Fine-tuning on eye-tracking shifts attention toward syntactic cues and sentence-initial elements, while reducing focus on non-informative tokens like punctuation, especially in middle and upper layers. Some of these trends partially mirror human reading dynamics and warrant further investigation. At the representational level, we observe substantial compression and increased anisotropy, especially for functional words and tokens close to their syntactic heads. We believe these preliminary findings confirm the value of analyzing attention and representation spaces through a linguistic lens, and open several avenues for future research, including how compression effects and cognitively grounded attention patterns may support the development of smaller, more efficient models through human-inspired inductive biases.

# A. Shift in the embeddings space - Extra features

This Appendix section contains the analysis of Section 5.3 conducted on the remaining linguistic features: word length, Figures A.1 and A.2, and word index in sentence, Features A.3 and A.4. As in Section 5.3, a clear hierarchy emerges among the new feature classes. For *word length*, tokens 6–10 characters long retain the highest IsoScore and Linear-ID before collapsing, like all other bins, under fine-tuning.

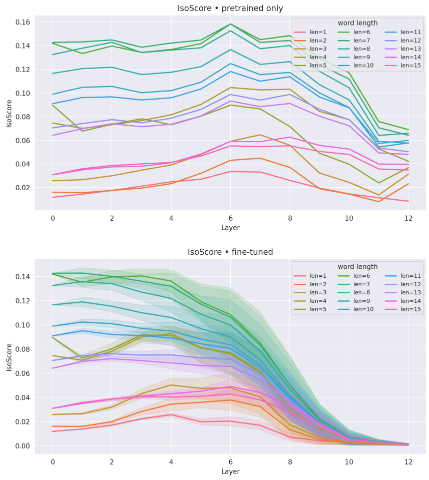

**Figure A.1:** Isotropy before (left) and after (right) fine-tuning, shown for word length (up to 15 tokens).

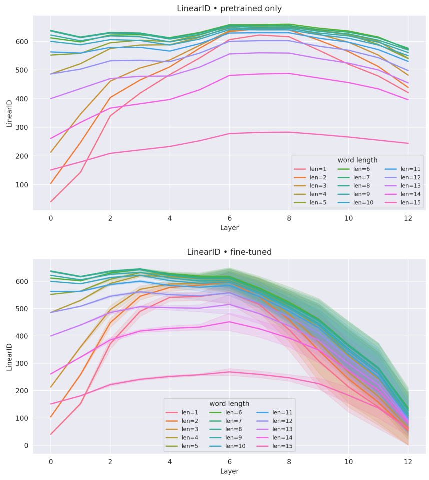

**Figure A.2:** Linear-ID before (left) and after (right) fine-tuning, shown for word length (up to 15 tokens).

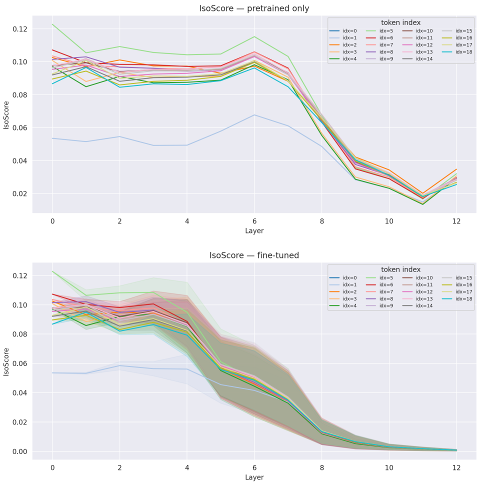

**Figure A.3:** Isotropy before (left) and after (right) fine-tuning, shown for word index (up to index 18).

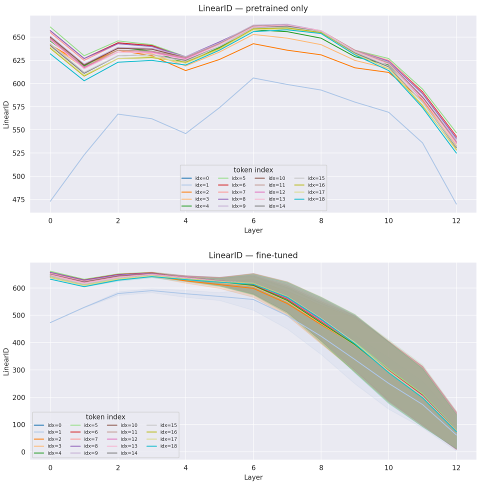

**Figure A.4:** Linear-ID before (left) and after (right) fine-tuning, shown for word index (up to index 18).

For the *word-index* feature, position 1 is the most distinctive. Lexical composition of these classes will be addressed in future work.

# B. Shift in the embedding space - English dataset

We report the scores on the English word embeddings. The results are comparable to those on the italian dataset. Further exploration of parallels and differences will be the focus of future work.

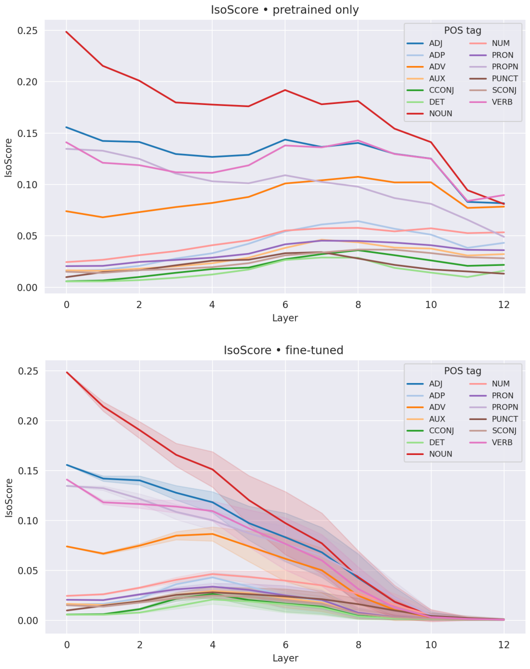

**Figure B.1:** Isotropy before (top) and after (bottom) fine-tuning, shown for the 13 most frequent POS classes.

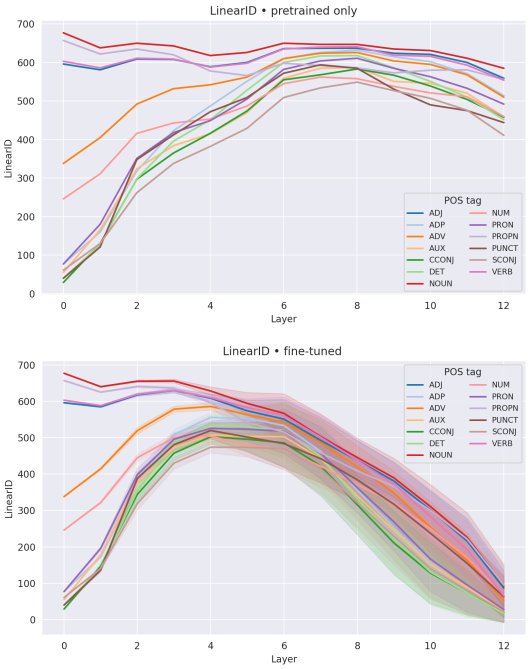

**Figure B.2:** Linear-ID before (top) and after (bottom) fine-tuning, shown for the 13 most frequent POS classes.

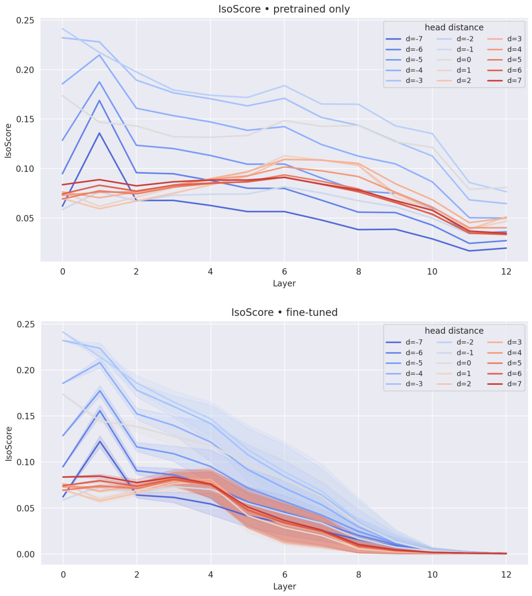

**Figure B.3:** Isotropy before (top) and after (bottom) fine-tuning, grouped by syntactic head distance (up to 7 words of distance).

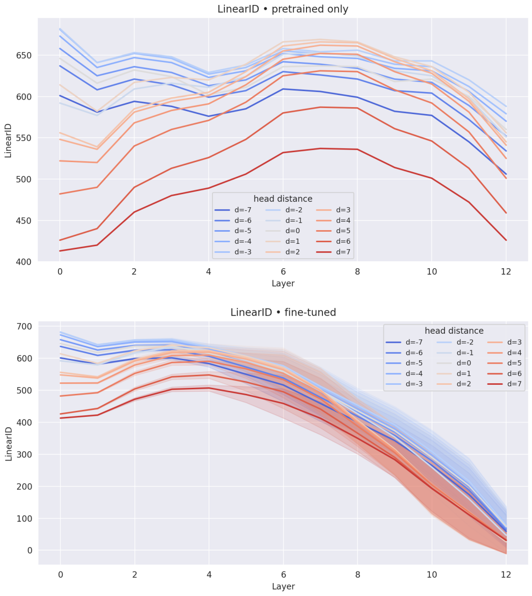

**Figure B.4:** Linear-ID before (top) and after (bottom) fine-tuning, grouped by syntactic head distance (up to 7 words of distance).

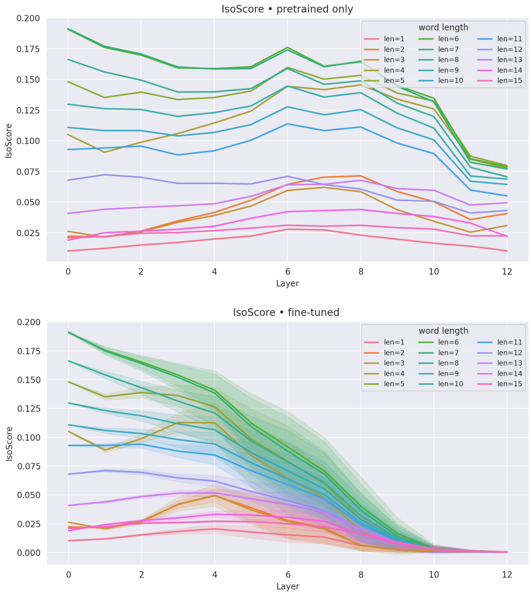

**Figure B.5:** Isotropy before (top) and after (bottom) fine-tuning, shown for word length (up to 15 tokens).

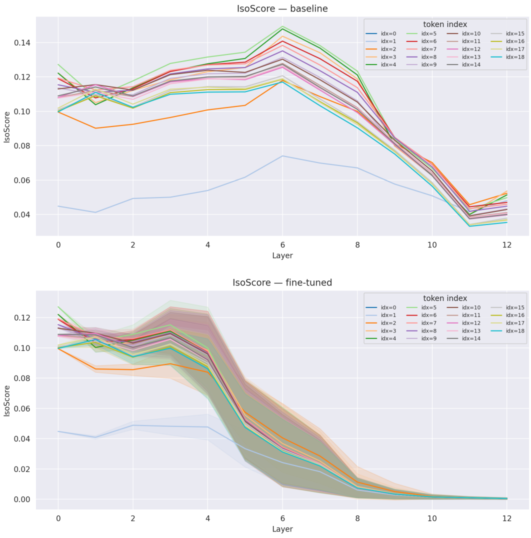

**Figure B.7:** Isotropy before (top) and after (bottom) fine-tuning, shown for word index (up to index 18).

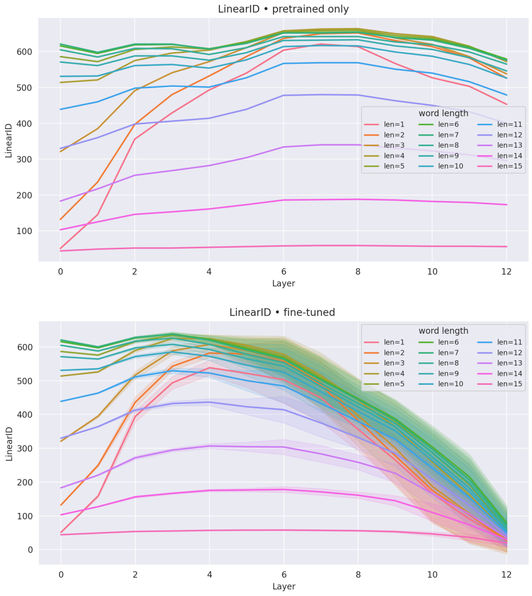

**Figure B.6:** Linear-ID before (top) and after (bottom) fine-tuning, shown for word length (up to 15 tokens).

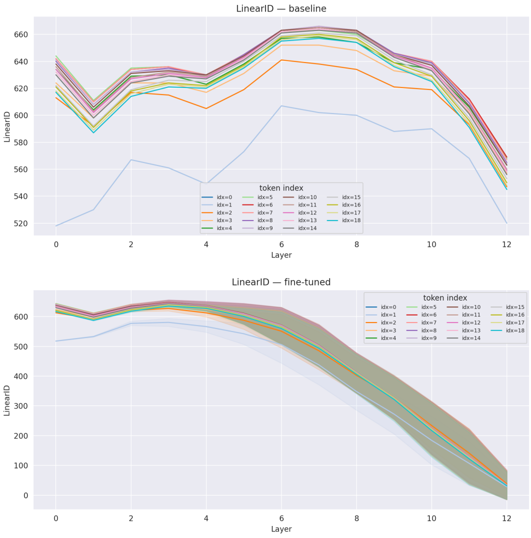

**Figure B.8:** Linear-ID before (top) and after (bottom) fine-tuning, shown for word index (up to index 18).

# Seeing Cause and Time: a Visually Grounded Evaluation of Multimodal Models

Salvatore Ergoli[1,*], Alessandro Bondielli[1,2,*] and Alessandro Lenci[1]

[1]CoLing Lab, Department of Philology, Literature and Linguistics, University of Pisa
[2]Department of Computer Science, University of Pisa

**Abstract**

Reasoning about causal and temporal relationships is fundamental to human intelligence but poses a persistent challenge for AI. Vision-Language Models (VLMs) offer a promising path towards more robust conceptual understanding by grounding language in perception. However, it is unclear if this grounding enables genuine, human-like reasoning. We investigate this question by focusing on the causal and temporal abilities of two leading VLMs using a novel multimodal dataset derived from the ExpliCa dataset. Through a series of carefully designed tasks, we isolate their performance on visual-only input versus combined visual-textual inputs. Our results show that while models exhibit some reasoning capability, they are hindered by a marked "iconicity bias": their performance degrades on relations where the perceptual sequence of images mismatches the logical event order (i.e., anti-iconic). This reliance on simple visual heuristics suggests that their high-level reasoning failures may be symptomatic of a more fundamental, fragile visual understanding.

**Keywords**

Multimodality, Causal Reasoning, Temporal Reasoning, Vision Language Models

## 1. Introduction

The ability to comprehend and reason about causal and temporal relationships is a cornerstone of human cognition, underpinning our capacity to understand narratives, predict outcomes and navigate the complexities of the world. We effortlessly discern why an event occurred and the sequence in which events unfolded, integrating information from various modalities. While Large Language Models (LLMs) have demonstrated remarkable fluency in generating text that describes such relationships, a critical question remains: do they possess a genuine, human-like understanding of these fundamental concepts or do they primarily rely on sophisticated pattern matching learned from vast textual corpora [1, 2]? This distinction is crucial, as linguistic proficiency can sometimes obscure deeper cognitive limitations, a phenomenon known as the "fallacy of language as thought" [3].

Recent advancements have led to the development of Vision Language Models (VLMs), which are trained on both textual and visual data [4, 5]. This multimodal grounding offers a potential pathway to richer, more robust representations of concepts, potentially bridging the gap between linguistic competence and conceptual understanding, as human meaning representation itself relies on multiple modalities [6, 7]. However, the extent to which this enriched inputs translate to superior causal and temporal reasoning capabilities remains an area in need of investigation.

This paper contributes to this line of inquiry by conducting a focused analysis of the causal and temporal reasoning abilities of two distinct, current generation multimodal models: `Llama-11b-vision` and `Gemini-flash-2.0`. We explore their performances with a series of carefully designed tasks on a multimodal version of the ExpliCa dataset, which explicitly combines causal and temporal relations [8]. Our objective is twofold: first, we aim to assess the models' capacity to infer these relations from visual input alone; second, we want to address how their performances change when the visual stimuli accompany the textual captions. We do so by comparing models with differing architectures and parameter counts and varying the input modalities.

Our experimental methodology involves i) constructing a novel image dataset, that we name **Visual-ExpliCa**, aligned with the ExpliCa dataset,[1] and ii) evaluating the models on five distinct tasks of increasing difficulty. The tasks range from directly identifying the type of relationship (causal vs. temporal) and specifying the antecedent and consequent from image-only input, to selecting the correct linguistic connective and judging the overall acceptability of an event when both images and textual descriptions are provided. Through this graduated approach, we seek to disentangle the models' visual inferencing capabilities from their ability to integrate multimodal information.

Our findings reveal that while both models demonstrate capabilities beyond chance in interpreting visual

[1] https://github.com/Unipisa/explica

sequences, they exhibit distinct strengths, weaknesses and biases, particularly struggling with anti-iconic relations (i.e., when the sequence of events is inverted compared to their chronological and/or logical-causal order) when relying solely on visual input. This suggests that current VLMs, despite their multimodal training, may still heavily favour direct, sequential interpretations of visual information for complex reasoning tasks.

## 2. Related works

A growing body of work focuses on assessing the reasoning abilities of pre-trained models, particularly in the domain of causality. LLMs have been evaluated on various causal tasks which reveals that their grasp of formal causality is often superficial and prone to heuristic-based errors. A key development in rigorously probing these limits is the CLADDER dataset [9], which moves beyond commonsense questions by grounding them in symbolic queries derived from an oracle causal inference engine. By evaluating models against the formal rungs of Pearl's Ladder of Causation [10], the authors found that even with bespoke prompting strategies like CAUSALCOT, LLMs struggle significantly with formal, rule-based inference. This concern over the fallibility of LLMs causal understanding is echoed by other research, which shows models are susceptible to inferring causality from simple positional cues or temporal precedence (*post hoc fallacy*) and struggle to infer causal links from counterfactual evidence, suggesting a reliance on memorized heuristics rather than deep reasoning [11]. In another work was proposed a novel architecture (CARE-CA) [12] that integrates explicit causal knowledge from resources like ConceptNet with implicit reasoning patterns from LLMs, enhanced by counterfactual analysis.

This susceptibility to temporal fallacies underscores a critical prerequisite for robust causal reasoning: a coherent understanding of time itself. However, research demonstrates that LLMs' internal model of time is fragile. Authors in [13] identify several key failure modes, including temporal shifts, invariance and inertia, where models either disregard the specific time in a query or fail to update long-held facts. Recognizing that direct reasoning over unstructured text may be the source of this fragility, some approaches focus on actively mitigating these flaws. The TG-LLM framework, for instance, proposes a two-step process: first translating unstructured text into a formal temporal graph and then fine-tuning the LLM to perform Chain-of-Thought reasoning over this explicit structure [14]. This methodological shift from implicit to explicit representation significantly improves performance, highlighting that the reasoning deficit may lie more in parsing complexity than in logical inability.

The challenge of causal reasoning becomes even more pronounced when extending from the linguistic to the multimodal domain, where models must integrate visual evidence with abstract knowledge. Recent benchmarks reveal that the performance of state-of-the-art VLMs is often no better than random chance. The MuCR benchmark [15], designed to test the inference of cause-and-effect from visual cues alone, found that models either suffer from inadequate visual perception or are biased by their language priors to the point of ignoring contradictory visual evidence. This deficiency is not merely about identifying simple causal chains. The NL-EYE benchmark, which frames abductive reasoning as a visual entailment task, found that VLMs perform at or below random baselines on a task humans find trivial [16]. Crucially, the failure was not one of logic—when given textual descriptions of the scenes, the models succeeded. The breakdown occurs in visual interpretation, where models are distracted by superficial cues and fail to grasp the underlying commonsense relationships. This points to a fundamental gap between a model's linguistic reasoning capabilities and its ability to ground that reasoning in the perceptual world. Similarly, the TemporalVQA benchmark tests models on temporal order understanding and time-lapse estimation between images [17]. Their conclusions reveal that even top-tier models perform at or below random chance, are highly sensitive to image layout and rely on superficial spatial cues rather than genuine temporal comprehension.

## 3. The Visual-ExpliCa Dataset

The empirical investigation presented in this paper relies on a carefully constructed dataset, specifically created to align visual stimuli with textual ones from the ExpliCa dataset [8]. ExpliCa features 600 unique events, each represented by a pair of sentences. These pairs are linked by an explicit connective that establishes one of three relationship types: causal (so, because), temporal (then, after) or unrelated. The connectives define the nature and directionality of the relationship between the two sentences. Specifically, this directionality distinguishes between iconic relations, where the order of sentences reflects the chronological or causal sequence of events (i.e., with connectives *so* and *then*), and anti-iconic relations, where the presentation order is inverted relative to the logical flow (i.e., with connectives *because* and *after*). Explicit connectives for sentence pairs where selected via crowdsourcing experiments [8]. Additionally, ExpliCa is controlled for potential confounding biases, such as Lexical Association Bias (ensuring that word co-occurrences within sentence pairs do not disproportionately favor certain relationship types) and Frequency Bias (ensuring that the linguistic structures representing different relations are comparably frequent in natural language).

This makes it a robust resource for evaluating genuine reasoning rather than statistical shortcuts.

In building Visual-ExpliCa, we focused exclusively on the causal and temporal relations, excluding the *unrelated* category of the original dataset. In order to collect visuals matching sentences in the dataset, we first conducted some pre-processing steps. These involved i) lemmatisation, to mitigate data sparsity issues and to alleviate issues with VLMs struggling with temporal dimensions encoded in verb conjugations [18], and ii) NER, specifically to replace people NEs with generic placeholders (e.g., "Matteo" is replaced by "[PERSON]"), and prevent image retrieval to focus on specific individuals rather than the core actions and concepts of the sentence. For pre-processing, we used SpaCy.[2]

## 3.1. Images Collection

Images to match sentences of ExpliCa were mostly collected from the Fondant-CC-25M dataset. [3] It is a large-scale image corpus derived from CommonCrawl, composed exclusively of images with Creative Commons licenses. This choice ensures ethical usage and avoids copyright issues prevalent in many traditional image datasets. To retrieve images, we used the *clip-retrieval* library.[4] This tool leverages CLIP (Contrastive Language-Image Pre-Training) [19] to find images whose embeddings are semantically closest to the text query's embedding. For each sentence, we selected the 10 images with the highest CLIP score. Then, to ensure a reasonable degree of semantic alignment between the visual and textual components, we conducted a further manual review to select the final image for each single sentence.

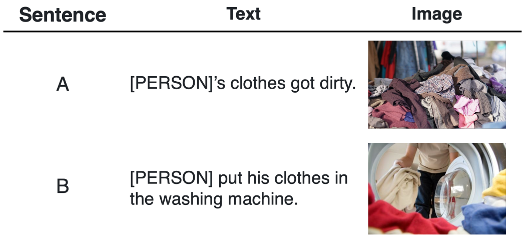
For a small number of sequences we were not able to retrieve high-quality descriptions. To address these cases, we resorted to text-to-image generation. Specifically, we used the Segmind Stable Diffusion model[5] to create visual representations for captions that were too abstract or specific for the retrieval process. The generative approach was required for 39 individual captions (out of the 778 total captions in the final dataset).

Nevertheless, a smaller subset of captions proved intractable. Specifically, for 12 sentence-pairs of the original dataset, it was not possible to obtain a suitable image for at least one of the two descriptions, either through retrieval or generation. We chose to exclude the entire sentence-pair from the final analysis to ensure the quality and coherence of the dataset. Consequently, the final curated multimodal dataset used for our experiments consists of 388 event pairs. Table 1 shows the distribution of categories in the dataset.

| Connective | Relation, Direction | Count |
|---|---|---|
| *so* | Caus., Ic. | 106 |
| *then* | Temp., Ic. | 105 |
| *because* | Caus., A-Ic. | 99 |
| *after* | Temp., A-Ic. | 78 |
| **Total** | | **388** |

**Table 1**
Distribution of event pairs in the final curated dataset, categorized by connective type. Causal and Temporal are abbreviated with Caus. and Temp. respectively. Iconic and Anti-Iconic are abbreviated with Ic. and A-Ic. respectively.

Figure 1 shows an example of a sentence-pair for a Causal, Iconic (Caus., Ic.) including visuals from the final dataset.



| Sentence | Text | Image |
|---|---|---|
| A | [PERSON]'s clothes got dirty. | |
| B | [PERSON] put his clothes in the washing machine. | |

**Figure 1:** An example of a sentence pair with images; the relation in this case is Causal, Iconic.

# 4. Experimental Setup

## 4.1. Models

To evaluate the capabilities of current VLMs in causal and temporal reasoning, we selected two prominent models representing distinct architectural families and development origins: `Llama-11b-vision` from Meta AI [20] and `Gemini 2.0 Flash` from Google DeepMind [21].

`Llama-11b-vision` is part of the Llama 3.2-Vision family of models. It was released by Meta in September 2024. These models are designed to be natively multimodal, capable of processing paired image and text inputs to generate textual outputs. Its architecture builds upon the Llama 3.1 LLM family. The instruction-tuned versions of Llama-3.2-Vision, including the variant used here, are optimized through a combination of Supervised Fine-Tuning (SFT) and Reinforcement Learning from Human Feedback (RLHF) [20]. Authors argue that this alignment process aims to enhance the model's utility, safety and ability to follow instructions. The vision component was pre-trained on a dataset of 6 billion image-text pairs.

`Gemini 2.0 Flash` is a multimodal large language model (text, image, audio, video) with a 1M-token context

[2] spacy.io
[3] https://huggingface.co/datasets/fondant-ai/fondant-cc-25m
[4] https://github.com/rom1504/clip-retrieval
[5] https://huggingface.co/segmind/SSD-1B

window, positioned as an upgrade over Gemini 1.5 Flash. It is reported to achieve improved efficiency and benchmark performance through a refined Mixture-of-Experts Transformer architecture and supports real-time multimodal interactions [22]. It inherits the general Gemini philosophy of deep interweaving of modalities.

We chose these models to reflect two contrasting trends in multimodal AI: Llama, an open-source and relatively small model accessible for research at modest computational cost, and Gemini Flash, a closed but comparatively compact commercial system optimized for efficiency and lower inference costs. This contrast highlights differences in openness, scale, and resource demands, providing a balanced testbed for evaluating causal and temporal reasoning.

## 4.2. Tasks design

To systematically probe the models' reasoning capabilities, we designed five distinct experimental tasks grounded in the Visual-ExpliCa dataset. These tasks are structured to progressively increase in complexity and are organized into two primary conditions that directly address our research objectives: assessing reasoning from visual-only input (Tasks 1 to 3) and evaluating multimodal integration (Tasks 4 and 5).

We employ a **Multimodal-Chain-of-Thought (Multimodal-CoT)** strategy for prompting in visual-only tasks. This strategy is inspired by [23], and is aimed at addressing one of the most critical failure modes in prompting VLMs, i.e. their tendency to rely on superficial visual processing and get distracted by irrelevant cues. In contrast, using Multimodal-CoT we structure the prompt to first elicit a description and interpretation of the visual information before attempting further reasoning, to establish a grounded rationale. This visual analysis then serves as the foundation for the reasoning steps needed to derive the final conclusion, effectively creating a reasoning chain [24].[6]

The first three tasks are designed to isolate the models' ability to infer causal and temporal relations relying solely on visual evidence. The model is first prompted to describe the visual content of the two images before being asked to perform the specific reasoning step. The final two tasks assess how performance vary given the support of textual data, thus evaluating the models' capacity to integrate information from both modalities. In the following, we detail each task.

**Task 1. Relation identification** In the first task, the model's goal is to classify the fundamental relationship between the two visual depictions of events as either *causal* or *temporal*, regardless of the order they are presented in.

**Task 2. Directionality Specification** In the second task, the model's goal is to determine the logical order of the event, identifying which image represent the *antecedent* and which the *consequent*, regardless of their causal or temporal relation.

**Task 3. Connective Selection** In the third task, the model's goal is to provide the most appropriate linguistic connective (among *so*, *because*, *then*, and *after*) given the pair of images representing the events, in a specific order. Recall that each connective is directly associated with a Relation (*causal* or *temporal*) and a Direction of such relation (*iconic* or *anti-iconic*).

**Task 4. Connective Selection With Captions** The fourth task is analogous to the third task. However, in this case the model is provided with both the images and their corresponding textual description of the events from ExpliCa. This allows for a direct comparison of performance with and without linguistic context.

**Task 5. Acceptability rating** In the fifth and final task, we replicate one of the experiments conducted on ExpliCa in [8]. Here, the model must perform a holistic evaluation of a complete multimodal input (two images, two captions and a human-provided connective). It is tasked with providing a numerical plausibility rating from 1 to 10, simulating a human-like judgment of coherence. We chose to exclude `Llama-11b-vision` from this specific task, as preliminary tests revealed it was unreliable in consistently generating ratings in the required numerical format. This is a known issue also reported in [8]. We can speculate that it is probably due to the limited model size. Conversely, to robustly assess `Gemini-2.0-Flash` and account for output variability, we prompted it to generate five distinct ratings for each event. This was achieved by querying the model five times, each with a different temperature setting to modulate the randomness of the output. We used the average of these ratings as the final score.

## 4.3. Evaluation

Our evaluation strategy was designed to measure the multifaceted nature of the models' causal and temporal reasoning across the five experimental tasks. The metrics

[6] We report examples of prompts in the Appendix.

| Model | Overall Acc. | Caus. Acc. | Temp. Acc. |
|---|---|---|---|
| Gemini | 0.72 | 0.58 | **0.87** |
| LLaMA | 0.63 | **0.86** | 0.40 |

**Table 2**
Results for Task 1.

were chosen to reflect the nature of each task, ranging from categorical decisions to graded plausibility judgments.

For tasks requiring a categorical decision (Tasks 1-4), we employed a "cloze test" paradigm, mirroring the evaluation approach often used for the ExpliCa dataset [8]. In this setup, the models were presented with the input (either images-only, or images and partly-hidden captions) and asked to "fill in the blank" by choosing the most suitable option from a predefined list of candidates. A response was considered correct only if it exactly matched the designated ground truth; both incorrect choices and responses that did not conform to one of the choices were marked as an error. The primary evaluation metric for these tasks was **Accuracy**. However, for Tasks 3 (Connective Selection) and 4 (Connective Selection with Captions), which involve a multi-class classification among four connectives, we also computed the F1-score. This metric provides a more balanced assessment than accuracy alone, as it considers both precision and recall for each connective class. This is particularly useful for identifying whether a model's performance is uniform across the different logical relationships or if it excels at some at the expense of others.

For Task 2 (Directionality Specification), correctness was determined by the alignment between the event order identified by the model and the iconicity status (iconic/anti-iconic) of the original pair. For example, if the model identified Image A (presented first) as the antecedent and Image B as the consequent, the answer was deemed correct only if the ground-truth connective for the original pair was iconic (i.e., "so" or "then").

Finally, for Task 5 (Acceptability Rating), evaluation was based on the Pearson correlation between the scores generated by the model and the human-provided acceptability judgments for the highest-rated connective. To ensure the values were comparable on a common scale, both the model ratings and the human judgments were first normalized using min-max technique. This allowed us to quantify the degree of alignment between the plausibility assessment of the model and of humans.

## 5. Results and Discussion

In this Section, we outline and discuss the results obtained by the models on all tasks. In the presentation of the results, we abbreviate Causal and Temporal Caus. and Temp. respectively, and abbreviate Iconic and Anti-Iconic with Ic. and A-Ic. respectively.

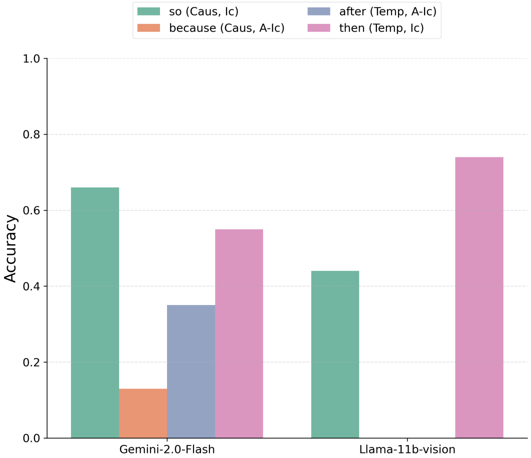


**Figure 2:** Results for Task 2 on each connective.

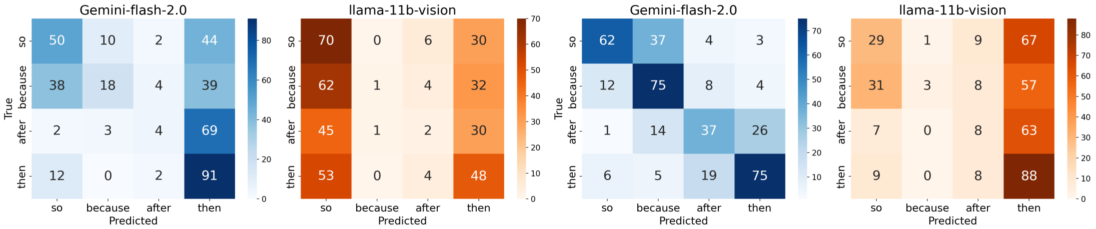
First, we evaluate the performance of the VLMs on causal and temporal reasoning tasks using only visual inputs. Results from Task 1 (Relation Identification) are reported in Table 2, while results on Task 2 (Directionality Specification) are shown in Figure 2. We observe a two-tiered competency. The models can broadly classify the type of relationship (causal vs temporal) with above-chance accuracy. However, they largely fail to determine its underlying structure and directionality. In Task 1, both models perform significantly better than the random baseline, indicating that they can extract relevant signals from the image pairs. A closer look at the results in Table 2 reveals `Gemini-flash-2.0` shows a clear proficiency on temporal relations (87% accuracy), suggesting a default tendency to interpret visual sequences as a chronological progression. In contrast, `Llama-11b-vision` demonstrates the inverse pattern, excelling at identifying causal relations (86% accuracy), implying a strong prior to infer cause-and-effect. This superficial competence however breaks down when models are required to identify the directionality of the relationship in Task 2 (Figure 2). The performance plummets for both models and this failure is almost entirely attributable to an inability to process anti-iconic relations, thus revealing a noticeable "iconicity bias". This bias manifests as a dependency on the perceptual order of visual events to infer their logical structure. `Llama-11b-vision` excels at identifying the direction for the Temporal Iconic connective *then*, but its performance on the anti-iconic connectives is non-existent. `Gemini-flash-2.0` appear more robust, but displays a similar pattern, with a moderate accuracy on iconic relations but a sharp drop in performance for anti-

| Task | Model | Accuracy | Causal Relations (F1) | | Temporal Relations (F1) | |
|---|---|---|---|---|---|---|
| | | | *so* (Ic.) | *because* (A-Ic.) | *then* (Ic.) | *after* (A-Ic.) |
| Task 3 | `Gemini` | 0.42 | 0.48 | 0.28 | **0.52** | 0.09 |
| | `LLaMA` | 0.31 | **0.42** | 0.02 | 0.39 | 0.04 |
| Task 4 | `Gemini` | 0.64 | 0.66 | 0.65 | **0.70** | 0.51 |
| | `LLaMA` | 0.33 | 0.32 | 0.06 | **0.46** | 0.14 |

**Table 3**
Model performance with accuracy and F1 Score for connectives on task 3 and task 4



(a) Task 3

(b) Task 4

**Figure 3:** Comparison of Confusion Matrices for Tasks 3 and 4.

iconic relations (connectives *because* and *after*).

Table 3 reports result on Tasks 3 (Connective Selection) and 4 (Connective Selection With Captions). Task 4, which provides both images and their corresponding textual captions, offers an ideal setting to assess the practical utility of visual grounding in multimodal models. Here, the models receive both images and their corresponding textual captions and their performance can be directly compared to that of the text-only LLMs evaluated on the same cloze task in the original ExpliCa study [8]. The multimodal models, particularly `Gemini-flash-2.0` achieve overall comparable or slightly better results (0.64 vs 0.62 accuracy) than strong text-only proprietary models. This suggests that the visual input may actually provide effective grounding, reinforcing or clarifying the relationship expressed via text without being a hindrance. Similarly, `Llama-11b-vision`'s multimodal performance aligns with text-only open-source LLMs (0.33 vs 0.34 accuracy). Nevertheless, if we look at Confusion Matrices in Figure 3 we observe that they reinforce the findings from previous tasks: the models' performance are in general dictated by the iconicity of the underlying relation, even more so than in the original study. This may suggest that, while visual inputs can prove beneficial on a surface level, their order of presentation may strongly affect and bias the models' ability, especially in anti-iconic cases. This may also be taken as indication that the models' training data contained a significantly larger number of "iconic examples".

Finally, results for Task 5 are shown in Figures 4 and 5 and Table 4. Recall that the objective of the task 5 is is to provide a numerical plausibility rating from 1 (completely incoherent) to 10 (perfectly coherent) for the complete multimodal event: both images, their corresponding textual captions, and the human-provided connective linking them. Also recall that Task 5 was evaluated only on `Gemini-flash-2.0`. To enable a direct comparison between the model's output and the human judgments, both sets of scores were first normalized to a common scale using a *min-max scaler.* The density plots in Figure 4 reveal both a promising alignment and critical divergences. For the iconic connectives, the model's scores show a distribution that closely resembles the human distribution of the connective with the highest rating. Both distributions are heavily skewed towards higher values (0.8-1.0), indicating that the model, like humans, find these iconic constructions highly plausible. Conversely, a significant discrepancy emerges for the anti-iconic connectives. For *because* and especially *after*, the human ratings show a much broader distribution with a notable peak in the mid-to-low range, indicating greater uncertainty and lower acceptability in general. To quantify this alignment, we computed the Pearson correlation between the model's ratings and human judgments (see Table 4). The results confirm the visual trend: We observe a moderate and statistically significant correlation for the iconic connectives *so* and *then.* The correlation is weaker for the anti-iconic connective *because*, and becomes statistically insignificant for *after.*

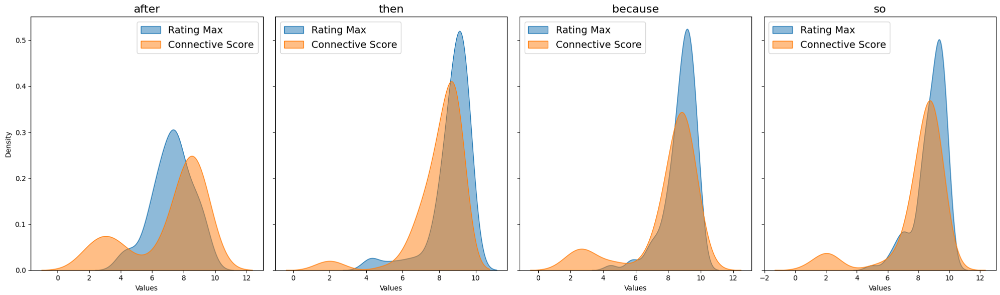


**Figure 4:** Density plots comparing model-generated acceptability ratings with human plausibility judgments

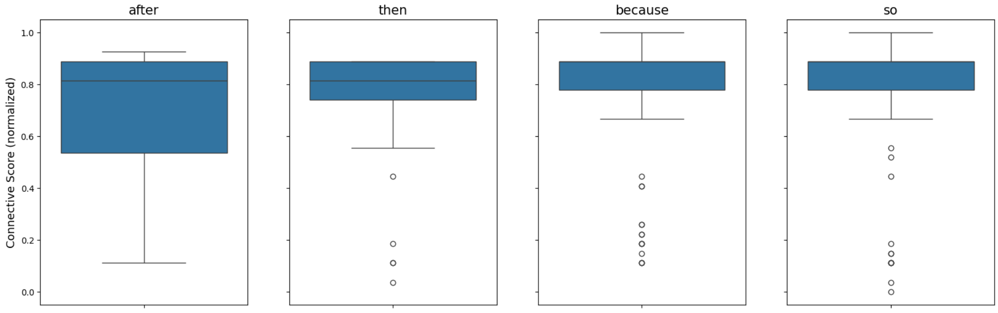

**Figure 5:** Box plots illustrating the distribution of model-generated acceptability ratings for each connective.

| Connective | Pearson $\rho$ |
|---|---|
| *so* (Caus., Ic.) | 0.55* |
| *then* (Temp., Ic.) | 0.53* |
| *because* (Caus., A-Ic.) | 0.39* |
| *after* (Temp., A-Ic.) | 0.21 |

**Table 4**

Pearson correlation between model acceptability ratings and human judgments, grouped by connective type. *Indicates a statistically significant correlation ($p < 0.05$).

To better understand the sources of divergence between the model's and human judgments, particularly for the cases that the model rated as highly implausible, we performed an outlier analysis. We specifically focused on low-scoring outliers, which we formally identified using the interquartile range (IQR) rule: any data point falling below the first quartile (Q1) minus 1.5 times the IQR was flagged. As noted in the original ExpliCa dataset, a subset of sentences were intentionally designed to be *socially challenging*, touching on sensitive topics like religion, immigration, drug abuse or sex. Our analysis (Figure 5) reveals that a significant portion of the outliers are directly attributable to this subset. Specifically, 13 out of the 31 most prominent low-scoring outliers correspond to these socially challenging sentences. This finding suggests that the model's performance may be influenced by its internal bias-mitigation and safety alignment protocols. When confronted with sensitive content, the model appears to override its linguistic and logical assessment, assigning a very low acceptability score regardless of the sentence's grammatical or causal coherence. This highlights a potential conflict where safety-driven heuristics can interfere with and ultimately degrade the model's core reasoning capabilities on specific types of content.

## 6. Conclusion and future works

This paper investigated the capacity of modern Vision-Language Models to reason about the structure of events. We augmented a curated dataset on causal reasoning with visual stimuli, and designed five tasks of increasing difficulty to asses how well the evaluated systems handle causal and temporal relationships, particularly when the logical flow of events diverges from their visual presentation. The central finding of our experiments is a profound vulnerability of the tested VLMs to an "iconicity bias." This manifests as a sharp decline in accuracy for anti-iconic relations, revealing a dependency on perceptual order over abstract logic. This weakness in abstract reasoning is likely rooted in an equally fragile foundational visual understanding. Recent studies using controlled evaluation frameworks [25], have in fact shown that VLMs struggle to robustly identify even fundamental object properties (like color or shape) and their basic spatial relations. Indeed, their performance is heavily dependent on positional biases, with objects at the center of an image being recognized more reliably than those at the periphery. If models fail to build a stable and reliable representation of a single scene, their ability to infer complex causal and temporal relationships across multiple scenes becomes inherently compromised. The macroscopic failures we observed (e.g., the iconicity bias) can therefore be seen as a direct consequence of these microscopic weaknesses. Furthermore, our analysis indicates that this reasoning is not purely logical; it may also be modulated by the models' safety training, which can produce inconsistent evaluations of causally coherent but sensitive content. Taken together, these results challenge the notion that scaling and multimodal pre-training are sufficient for achieving robust, human-like reasoning. The models' reliance on perceptual heuristics points to a fundamental gap between their pattern-matching prowess and their ability to model the more complex, non-sequential nature of real-world events.

A crucial next step is to investigate whether these behavioral failures reflect a deeper deficit in the models' underlying competence. A more direct evaluation, drawing on the framework of Hu and Levy [26], would involve measuring the log-likelihood that models assign to different event structures. However, this approach faces a significant technical barrier: the public APIs for state-of-the-art multimodal models, including Gemini 2.0 Flash, do not currently provide access to token-level log-likelihoods. This constraint makes it impossible to directly probe their internal probability distributions. Future work should therefore seek to replicate this study using open-source VLMs where such access is possible.

## Limitations

While the present work provide some interesting insights, it is fundamental to point out several of its limitations. First, the two models chosen for the analysis can be considered as good representatives of open-weights and closed-weights models in the small to medium-sized model range; we purposely avoided using larger VLMs as they tipically come with a high computational (or monetary) cost. However, we must acknowledge that the paper's results may not hold for other VLMs.

Second, we leverage CoT prompting, but do not present here an analysis of the results from the CoT; these could be point to additional insights. In addition to this, we must note that we did not perform any prompt-level optimization to improve the performances of each model individually.

Third, we do not account for the abstractness of the stimuli. While the ExpliCa dataset contains mostly concrete, everyday scenarios, searching for relations between their abstractness and the performances of the model may yield more robust findings.

# A. Prompts

Task 1. Relation Identification (Causal)

```
The image above contain two separated
     images: Image a (on the left) and
      Image b
(on the right). Describe the elements
     in both images. Now, think
     abstractly
about the relationship between the two
      images. Focus on the general
     cause-
and-effect pattern rather than
     specific details. The antecedent
     is the event that
happens first and directly causes
     another event (the cause). The
     consequent is
the event that happens as a result of
     the antecedent (the effect). If
     Image a is
the consequent and Image b is the
     antecedent, respond with Image a.
      If Image b
is the consequent and Image a is the
     antecedent, respond with Image b.
      Do not
provide explanations, additional text
     or commentary.
```

### Task 1. Relation Identification (Temporal)

```
The image above contain two separated
     images: Image a (on the left) and
      Image b
(on the right). Describe the elements
     in both images. Now, think about
     the
temporal relationship between the two
     images. Focus on the sequence of
     events
rather than specific details. If Image
      a follows Image b, respond with
     Image a.
If Image b follows Image a, respond
     with Image b. Do not provide
     explanations,
additional text or commentary.
```

### Task 2. Directionality Specification

```
Analyze the relationship between Image
      A (left) and Image B (right).
     Determine
whether the connection is temporal (
     one event happens before or after
      the other)
or causal (one event directly causes
     the other). Respond with only one
      word,
either ’temporal’ or ’causal’. Do not
     provide explanations, additional
     text or
commentary.
```

### Task 3. Connective Selection

```
Your task is to select the most
     appropriate word to connect the
     two images. There
are four words:
- So: causal relation in which IMAGE A
      causes IMAGE B;
- Because: causal relation in which
     the IMAGE B causes IMAGE A;
- Then: temporal relation in which
     IMAGE A precedes IMAGE B;
- After: temporal relation in which
     IMAGE A follows IMAGE B;
Answer only with the connective that
     best expresses the relationship
     between the
two images. Do not provide
     explanations or additional
     details. Your answer has
to be coherent with your previous
     reasoning.
```

### Task 4. Connective Selection With Captions

```
You are given two sentences: Sentence
     A and Sentence B and a couple of
     images
(Image A refers to Sentence A and
     Image B refers to Sentence B).
     Your task is
to select the most appropriate word to
      connect the two sentences
     logically and
coherently. The chosen word should fit
      grammatically and contextually
Format:
Sentence A: Sentence A
Sentence B: Sentence B
There are four words:
- Then;
- After;
- So;
- Because;
Thinks about the two sentences and
     answer only with the word that
     best expresses
the relationship between the two
     sentences.
```

Task 5. Acceptability Rating

```
Evaluate the acceptability of
     sentences that describe two
     events linked by connectives: ’so
     ’, ’because’, ’after’, and ’then
     ’. Rate each sentence on a scale
     from
1 to 10 based on how well the
     connective expresses the
     relationship between
the events. Each event is also
     visually represented by an image:
      the left image
corresponds to the first sentence and
     the right image corresponds to
     the second
sentence. Sentence: sentence a
     connective sentence b. Provide
     only a numerical
rating between 1 and 10, without
     explanations.
```

# Mapping Meaning in Latin with Large Language Models: A Multi-Task Evaluation of Preverbed Motion Verbs and Spatial Relation Detection in LLMs

Andrea Farina[1], Andrea Ballatore[1] and Barbara McGillivray[1]

[1]*King's College London, Strand Campus, Strand, WC2R 2LS, London, United Kingdom*

**Abstract**

This paper evaluates the capabilities of Large Language Models (LLMs) on three interrelated linguistic tasks in Latin: preverbed motion verb identification, spatial relation (SR) classification, and SR type disambiguation. We evaluate GPT-4, Llama, and Mistral under zero-shot and few-shot settings, using a manually annotated dataset of Latin sentences drawn from different authors, text types, and historical periods (3rd century BCE – 2nd century CE) as our gold standard. Results show that GPT-4 consistently outperforms open-weight models, particularly in zero-shot scenarios, likely due to its substantial pretraining exposure to Latin. However, even GPT-4 struggles with syntactic disambiguation, especially in linking proper nouns to their governing verbs. SR classification performance is skewed by dataset imbalance, and SR type disambiguation errors often stem from over-reliance on salience over syntax. Qualitative analysis reveals common patterns of overgeneration and uncertainty across tasks. Our findings underscore the potential of LLMs for historical language processing while highlighting persistent challenges related to ambiguity, entity linking, and syntactic reasoning. This study represents the first evaluation of SR recognition in historical languages and lays the groundwork for future domain-adapted fine-tuning approaches in Computational Humanities.

**Keywords**

Large Language Models, Latin, motion verbs, spatial relation classification, SR type disambiguation

## 1. Introduction

The central aim of this study is to evaluate the ability of Large Language Models (LLMs) to analyse spatiality in Latin texts, with a focus on motion events and their syntactic and semantic environments. In Latin, motion verbs, i.e., verbs denoting movement (cf. class 51 in [1]), often combine with *preverbs* — prefixes that attach onto verbal bases to express (among other things) nuanced spatial meanings (cf. Section 4.2). For example, the Latin motion verb *eo* 'go' can be prefixed with different preverbs, which deeply modify its semantics (e.g., the preverbs *ex-* 'out of' and *in-* 'into' generate *exeo* 'exit' and *ineo* 'enter'). This preverbal modification is crucial for encoding spatial relations (SRs) in Latin, as directionality and argument structure are frequently expressed jointly by the verbal root and its preverb. Motion events [2] involve an entity $E$ moving from a *Source* (the starting point of motion) to a *Goal* (the ending point of motion), and along a *Path* (the set of continuous locations crossed by $E$ while moving from the *Source* to the *Goal*) [3]. This usually happens both in literal and non-literal contexts [4].

This paper explores to what extent LLMs can handle such constructions in Latin, taken as an example of a historical and morphologically complex language. We focus on preverbed motion verbs as an area that demands the integration of lexical, syntactic, and spatial information. To evaluate the models' performance, we design three linguistic tasks targeting different layers of interpretation relevant to motion events (Section 3). Preverbs often provide crucial cues to argument structure and directionality (e.g., *abeo* 'go away' vs. *adeo* 'go toward/to'), which may pose significant challenges for automatic disambiguation with LLMs. This allows us to assess the extent to which LLMs are able to perform linguistic annotation on challenging verbal constructions such as preverbed motion verbs, which are structurally more complex than their non-preverbed counterparts.

## 2. Related Work

The application of NLP techniques to Latin has advanced significantly in recent years, driven by developments in neural networks, transformer-based architectures, and the increasing availability of large-scale digital corpora. A key benchmark in this area has been the EvaLatin shared tasks, held annually since 2020, which provide a structured evaluation framework for a range of Latin

NLP tasks [5]. Among the most influential recent developments in Latin NLP is the introduction of contextualised language models. LatinBERT [6], a contextualised model trained on a substantial corpus comprising 642.7 million words spanning from Classical Antiquity to the contemporary period, has been shown to perform well in tasks such as lemmatisation, part-of-speech (POS) tagging, and syntactic parsing. LatinBERT has also shown promise in word sense disambiguation [7, 8] and named entity recognition [9].

Generative LLMs have demonstrated impressive performance across several NLP tasks [10, 11]. However, their success relies on vast amounts of data [12, 13], which is not typically achieved by most historical corpora. The potential of LLMs for Latin is beginning to be systematically evaluated. Volk et al. [14] showed that GPT-4-based machine translation substantially outperforms previous approaches when tested on 16th-century correspondence written in Latin and Early New High German. In addition to translation, they also evaluated GPT-4 for paragraph-level summarisation of Latin texts, with its output compared against human-generated summaries.

Parallel to these developments, efforts have been made to extract SRs from text, not only in computational linguistics, but also in information retrieval and geospatial analytics. Early approaches relied on rule-based methods and regular expressions, which have since evolved into more flexible ML methods. SRs labelling can be characterised as an ML classification task to identify combinations of *trajectors* (e.g., “ball”), *indicators* (“on”), and *landmarks* (“the ground”) [15]. More recent work leverages deep learning for this task, including convolutional neural networks for relation extraction [16].

A related task consists of detecting toponyms in text, usually as part of Named Entity Recognition (NER). A further step associates toponyms with spatial extensions, such as georeferenced points or polygons, to facilitate data integration and analysis — this process is known as geoparsing, geocoding, toponym resolution, or georeferencing. The integration of SR detection with NER has also been explored, estimating the spatial extent of expressions such as “North Milan” and “10 km from the French border” [17]. Recently, LLMs have begun to be evaluated for their effectiveness in NER for place detection and geoparsing. Initial research shows how GPT-based models can achieve high accuracy in multiple domains, including geography [18].

Toponyms exhibit strong temporal variation and require dedicated semantic resources to connect place names to appropriate spatial scopes. The World Historical Gazetteer (WHG)[1] gathers records from multiple sources to identify place names across temporal contexts, such as Byzantium, Constantinople, and Istanbul, using a linked data approach.[2] Historical geoparsers must balance precision with historical sensitivity and domain-specific training [19]. For Latin, NER faces more challenges than for English, including orthographic and diachronic variation, as well as limited and sparse training data [20, 21]. To date, the majority of research and tools focus on contemporary languages, and no Latin evaluation exists for the extraction of SRs and geoparsing.

While the studies briefly reviewed in this section mark important progress in both Latin NLP and SR extraction, systematic evaluation of LLMs on spatial language understanding in Latin remains largely unexplored. Building on this foundation, our study investigates whether LLMs can interpret spatial constructions in Latin with a level of accuracy that approximates human linguistic analysis.

## 3. Research Questions and Evaluation Tasks

We examine whether LLMs can identify and interpret spatial constructions in Latin in ways that approximate human linguistic judgment. Specifically, we investigate three tasks that collectively test the models’ capacity to perform SR extraction and identification in Latin. This study is guided by the following research questions:

**RQ1:** To what extent can LLMs accurately identify preverbed motion verbs in Latin sentences?

**RQ2:** To what extent can LLMs detect place expressions that co-occur with preverbed motion verbs — regardless of their syntactic form — and classify them as indicating the Source, Goal, or Path?

**RQ3:** To what extent can LLMs correctly perform SR type disambiguation in Latin, especially in cases where the distinction between common nouns, proper nouns (toponyms), and adverbs is ambiguous?

These questions target key linguistic phenomena involved in spatial language understanding and test the applicability of LLMs to historical languages. Motion verbs are highly relevant for tasks involving spatial semantics and argument structure, particularly in Latin, where directional meaning is often distributed across both the verb and its preverb. Secondly, motion verbs frequently occur with locative or directional expressions (e.g., accusative or ablative prepositional phrases), providing rich ground for testing whether models can correctly associate verbs with SRs. Finally, the variability in motion verb semantics (e.g., goal-directed vs. manner-of-motion)

[1] https://whgazetteer.org. Last accessed: 26 July 2025.

[2] https://whgazetteer.org/places/12345979/portal/. Last accessed: 26 July 2025.

allows us to probe whether models distinguish different types of motion events. Preverbs play a central role in encoding directionality and spatial modification in Latin motion constructions. The distinction between proper and common nouns (*Roma* 'Rome' vs. *domus* 'house') is important from a cultural perspective to map how motion verbs relate to the geographical imaginary of the Roman world. Technically, it also provides more detail about the ability of LLMs to detect and interpret spatial references.

To operationalise our research questions questions, we define three corresponding annotation tasks:

1. **Motion Verb Identification** (RQ1): Determine whether a given Latin sentence contains a preverbed motion verb.
2. **SR Detection and Classification** (RQ2): Identify the presence of place expressions that co-occur with preverbed motion verbs and classify their semantic role in the motion event as *Source*, *Path*, or *Goal*, regardless of syntactic realization.
3. **SR Type Disambiguation** (RQ3): Perform SR type disambiguation with particular attention to expressions relevant to motion contexts, including disambiguation between common nouns, proper nouns (toponyms), and adverbs.

# 4. Corpus, Annotation, Dataset

## 4.1. The Usual Dilemma: Choosing a Representative Corpus for Latin

Given the fragmentary nature of the surviving material and the uneven transmission of texts across time, genre, and register, a fully representative corpus of Latin, as for historical languages in general, is ultimately unattainable [22]. Nevertheless, the Latin corpus used in this study is constructed specifically to address the limitations of existing resources and to meet the needs of historical corpus linguistics [23, 24]. Standard annotated corpora, such as the Latin Dependency Treebank (LDT) [25, 26], offer valuable syntactically annotated material but are limited in scope and uneven in their coverage. Many important authors — such as Plautus, Seneca, and Petronius — are entirely absent, and key texts like Caesar's *De bello Gallico* and Virgil's *Aeneid* are only partially included. To support quantitative and diachronic analysis, we constructed a custom corpus that is sensitive to linguistic diversity across time and genres. The corpus includes 16 Latin texts by 13 authors, and 265,707 tokens in total.[3] The corpus texts span from the 3rd century BCE to the 2nd century CE. This temporal range captures the major phases of Latin's development, across Early, Classical, and Late Latin [27]. Genre was a key consideration in corpus design. To avoid the so-called "God's truth fallacy" [23] — the mistaken assumption that a single text type or genre can represent the full linguistic reality of a historical period — we included a range of genres that reflect different stylistic and communicative registers. The corpus contains texts from a wide range of genres: historiography, poetry, theatre, philosophy, novel, oratory. [4] This selection allows us to investigate genre-conditioned variation while also providing a broader basis for generalisations about Latin syntax. Texts were sourced primarily from the Perseus Digital Library[5] [29], except for Ennius' *Annales*, accessed via PHI Latin Texts [6] [30].

Prose is more represented (61.7%) than poetry (38.3%), reflecting both textual availability and our aim to balance stylistic registers. Comedy and satire, often considered closer to spoken Latin, were included despite their underrepresentation in standard corpora. Inscriptions and epistolography were excluded due to limited data on preverbs. Text selection also accounted for varying author productivity, with prolific authors like Cicero and Seneca represented by more than one text, while preserving balance across genres.

## 4.2. Selecting Motion Verbs and Preverbs

The study requires a representative sample of motion verbs exhibiting diverse syntactic behaviour and frequently co-occurring with place expressions in Latin texts. We select eight verbal bases denoting different motion domains, and 16 preverbs. This results in a combinatorial space of 128 verb–preverb combinations (though not all are attested). The selection is based on the PREMOVE dataset (cf. Section 4.3), which provides gold-standard annotations for these verbs and preverbs, ensuring both linguistic coverage and empirical grounding. The verbal bases are: *eo* 'go', *venio* 'go, come' (all referring to generic motion), *fugio* 'flee', *gradior* 'walk', *curro* 'run', *volo* 'fly', *no* 'swim' (manner-of-motion verbs denoting specific types of movements along different media: ground, sky, water), and *navigo* 'sail' (motion by water via vehicle). These bases are selected to ensure coverage of different spatial event types and to test model performance across varying lexical, morphological, and syntactic profiles. Apart from the comitative preverb *cum-* 'together', denoting accompaniment, all preverbs possess an inherent spatial meaning. They can be categorised into four classes, based on the SR they inherently focus on:

- **Source**-preverbs: *ab-* 'away, away from', *de-*

[3] Since punctuation is not present in the original Latin texts, punctuation marks are excluded from the token count.

**Table 1**
Overview of Latin Texts in the Corpus.

| Author | Text | Century | Genre | Token Count |
|---|---|---|---|---|
| Ennius | Annales | 3rd cent. BCE | Poetry, epic | 1,194 |
| Plautus | Amphitruo | 3rd cent. BCE | Theatre, comedy | 9,988 |
| | Mostellaria | 3rd cent. BCE | Theatre, comedy | 9,988 |
| Caesar | De bello Gallico 1-4 | 1st cent. BCE | Historiography | 20,498 |
| Cicero | In Catilinam 1-3 | 1st cent. BCE | Oratory | 11,625 |
| | De amicitia | 1st cent. BCE | Philosophy, dialogue | 9,471 |
| Sallust | Bellum Catilinae | 1st cent. BCE | Historiography | 10,655 |
| Livy | Ab Urbe condita 1-2 | 1st cent. BCE | Historiography | 39,913 |
| Virgil | Aeneid | 1st cent. BCE | Poetry, epic | 63,719 |
| Propertius | Elegies 1.1-1.22 | 1st cent. BCE | Poetry, elegy | 4,384 |
| Horace | Satires | 1st cent. BCE | Poetry, satire | 7,048 |
| Seneca | De ira | 1st cent. CE | Philosophy, treatise | 22,614 |
| | Medea | 1st cent. CE | Theatre, tragedy | 5,639 |
| Tacitus | Historiae 1 | 1st–2nd cent. CE | Historiography | 11,852 |
| Suetonius | Life of August | 2nd cent. CE | Historiography, biography | 13,915 |
| Apuleius | Metamorphoses 1–5 | 2nd cent. CE | Novel | 23,358 |

'down from', *ex-* 'out, out of';

- **Goal**-preverbs: *ad-* 'to, towards', *in-* 'into' (in contexts entailing motion), *intro-* 'within, inside of', *pro-* 'forward', *sub-* 'under' (in contexts entailing motion);
- **Path**-preverbs: *per-* 'through', *trans-* 'across';
- **Location**-preverbs: *circum-* 'around', *inter-* 'between, among';

### 4.3. Gold Standard

To create the gold standard for evaluation, we manually annotate occurrences of motion verb constructions in the Latin corpus described above. The annotation is carried out using the INCEpTION platform [31, 32, 33, 34]. INCEpTION's user-friendly interface and extensible architecture proves essential for this study. All annotations are carried out by a single expert annotator (the first author). To verify task clarity, we conducted an Inter-Annotator Agreement (IAA) test on a random sample of 10 sentences, independently annotated by two additional historical linguists. The test yielded perfect agreement (IAA = 1.0), confirming that the task is sufficiently clear and unambiguous to justify relying on a single expert annotator for the full dataset. The annotation follows the guidelines described in [35]. Each sentence containing a preverbed motion verb is analysed to determine the presence of SRs, following a multi-layered annotation scheme (cf. Section 3):

1. **Motion Verb Identification (Task 1)**: Identify whether the sentence contains a target motion verb.
2. **SR Detection and Classification (Task 2)**: If a motion verb is present, determine whether it co-occurs with a SR. When a SR is present, classify its type as *Source*, *Goal*, or *Path*. Prepositions, case morphology, and preverb semantics are used to guide this decision, making the task unambiguous (e.g., *ex urbe* 'from the city' = *Source*; *in urbem* 'to the city' = *Goal*; *per urbem* 'through the city' = *Path*).
3. **SR Type Disambiguation (Task 3)**: Annotate the SR type of spatial expressions, i.e. distinguish between proper nouns (e.g., *Roma* 'Rome'), common nouns (e.g., *domus* 'house'), and adverbs (e.g., *hinc* 'from here').

These annotations form part of the PREMOVE dataset [36], which also contains additional annotation layers as it is developed within the context of a broader research project [37].

## 5. Experimental Setup

### 5.1. Dataset and Models

**Dataset.** The experiments are conducted on the dataset described in Section 4.1, which consists of 1,483 Latin sentences. Since our focus is on spatial semantics, we filter out sentences that lacked SR annotations. The resulting dataset used for experimentation comprises 649 sentences (cf. Section 4.1).

SRs are unevenly distributed across the data: *Goal* relations appears in 68.4% of the occurrences, while *Source* and *Path* occur in only 19.6% and 12.0%, respectively. This is in line with the Goal-over-Source principle, according to which languages express the Goal more frequently because it plays a more central role in the conceptualisation of motion events, making the event appear complete and cognitively salient [38]. Moreover, Goal-oriented motion is often perceived as more intentional and purposeful, while Source expressions suggest less human agency [39, 40]. To mitigate this imbalance and ensure a fairer evaluation of model behaviour across relation types, we also construct three distinct, balanced subsets of the dataset (cf. Sections 5.2, 6.1). Each subset isolates a single SR and balances positive and negative examples for that relation. The resulting subset sizes are as follows:

- *Goal* subset: 394 sentences
- *Source* subset: 256 sentences
- *Path* subset: 150 sentences

The total number of sentences across the subsets exceeds the total number of sentences in the dataset (649), as individual sentences can encode more than one type of SR.

**Models.** We choose two open-weight LLMs (Mistral and Llama) and one proprietary model (OpenAI's GPT) to compare performance across different architectures and accessibility levels. Open-weight models are LLMs whose trained parameters (weights) are publicly released, allowing researchers and developers to run, fine-tune, and deploy them independently. In contrast, proprietary models like GPT are closed-source and accessible only via API or controlled platforms. We use `Mistral-7B-Instruct-v0.1`, Meta's `Llama-3.2-3B-Instruct`, and OpenAI's `GPT-4`. We did not perform any fine-tuning on the open-weight models. We used the pre-trained versions of the models as provided on Hugging Face, without further adaptation or training. The prompts are described in section 5.2. In few-shot settings, manually annotated examples from our corpus (section 5.1) are randomly added to the prompts. We evaluate model performance under zero-shot, one-shot, and five-shot conditions. In the zero-shot setting, the model is given only the task instruction without any examples. In the one-shot and five-shot settings, we include respectively one or five manually annotated examples from our corpus (Section 5.1) to the prompt. These examples are selected at random and aim to reflect typical structures found in the corpus. This design allows us to test how much model performance improves with limited supervision. We intentionally selected models that were not specifically fine-tuned for Latin to ensure a fair comparison across general-purpose architectures. Our aim is to evaluate how LLMs trained primarily on large multilingual or general corpora perform out of the box on Latin. All experiments are performed locally, with a machine comprising 8 CPU cores and 8 GB of RAM. The experiments are implemented in `Python 3.9.13`, using the `PyTorch` and `Hugging Face Transformers` libraries. To run the Mistral and Llama models, we use an `A100 GPU` (purchased) and a `T4 GPU` via `Google Colab`. Our code is freely available on GitHub[7].

## 5.2. Prompt Engineering

**Task 1.** Task 1 consists in identifying all inflected forms of a given Latin verb in one or more input sentences. The core prompt includes the verb lemma, a linguistic framing, and clear task constraints. Importantly, the input to the models consists of individual sentences rather than full passages. These are extracted directly from PREMOVE (cf. 4.3), in order to isolate sentence-level syntactic and semantic behaviour and reduce computational cost during inference. The prompt is given below:

```
This is a task of Latin linguistics. Given the following Latin sentences, identify all the forms of the verb '{verb}' across all sentences. Note that verbs may occur more than once and in more than one sentence, so PROVIDE ALL THE FORMS YOU DETECT.
```

This task is designed to evaluate models' ability to identify all inflected forms of a given Latin verb, not to test their recognition of motion semantics per se. While the target lemmas are motion verbs, they are explicitly provided in the prompt to ensure clarity and task focus. This approach also avoids ambiguity in cases where multiple motion verbs may occur in the same sentence, some of which fall outside the scope of annotation. Testing the models' ability to detect motion verbs without guidance would indeed be a valuable direction for future work, but lies beyond the controlled objectives of this task.

**Task 2.** The base prompt includes a task explanation and binary labels for each SR. A representative zero-shot version is shown below:

```
This is a task of Latin linguistics. Given the following Latin sentence, identify all the forms of the verb '{verb}'. Then, additionally answer: Does the sentence contain a source expression? True or False; Does the sentence contain a goal expression? True or False; Does the sentence contain a path expression? True or False
```

**Task 3.** This task consists of classifying a spatial token linked to a motion verb as either an adverb, a common noun, or a proper noun. Initial prompts list classification labels and provide a target token. As early outputs show

[7] https://github.com/farina-andrea/latin-spatial-relations-llms. Last accessed: 26 July 2025.

that the models confuses proper nouns and their association with the target verbs (cf. 6.2), we implement the prompt to increase specificity:

```
  This is a task of Latin linguistics.
Given the Latin sentence below, and focusing
specifically on the verb ‘{verb}’, identify
the noun or adverb in the sentence governed by
‘{verb}’ and expressing the spatial relation
‘{relation type}’ (Source, Goal, or Path).
Classify this token as one of the following:
- An adverb (e.g., ‘hinc’)
- A common noun referring to a place (e.g.,
‘domus’, ‘forum’)
- A proper noun referring to a place name (e.g.,
‘Roma’, ‘Carthago’).
Sentence: ‘{sentence}’
Answer with exactly two lines, no extra text:
Token: <token>
adverb | common noun | proper noun
```

# 6. Results

## 6.1. Quantitative Evaluation

**Task 1.** The results of Task 1 are given in Table 2.

| Model | Setting | Precision | Recall | F1-score |
|---|---|---|---|---|
| ***Mistral-7B*** | Zero-shot | 0.09 | 0.23 | 0.13 |
| | One-shot | 0.08 | 0.19 | 0.11 |
| | Five-shots | 0.04 | 0.10 | 0.06 |
| ***Llama-3.2B*** | Zero-shot | 0.33 | 0.12 | 0.05 |
| | One-shot | 0.03 | 0.10 | 0.05 |
| | Five-shots | 0.01 | 0.06 | 0.02 |
| ***GPT-4*** | Zero-shot | **0.95** | **0.98** | **0.96** |
| | One-shot | **0.91** | **0.98** | **0.94** |
| | Five-shots | **0.85** | **0.97** | **0.91** |

**Table 2**
Task 1. Model performances across different shot settings on all 649 sentences. Highest scores per shot setting are highlighted in bold.

GPT-4 strongly outperforms both Llama-3.2-3B-Instruct and Mistral-7B-Instruct on all 649 sentences. Its precision, recall, and F1-scores remain consistently high across all prompt settings, indicating robust zero- and few-shot generalisation. The open-weight models perform poorly and also degrade in performance as shots increase, suggesting that additional examples may introduce noise rather than aid in disambiguation.

**Task 2.** Results for Task 2 on all 649 sentences are shown in Table 3. Performance varies significantly between GPT on the one hand, and Mistral and Llama on the other. Mistral and Llama achieve near-identical results across almost all task conditions. This suggests that both are relying on similar simplistic prediction strategies, as seen in the uniformly perfect (1.00) or null (0.00) recall, and very low precision values across categories. The deceptively strong F1 scores (0.82) for *Goal* likely reflect an overgeneralisation strategy: the models tend to label nearly all inputs as positive, which inflates recall and leads to misleadingly moderate F1 scores, especially when the positive class *Goal* is frequent (cf. Section 5.1).

GPT-4 demonstrates a more balanced performance, with better alignment between precision and recall. It shows consistently strong results for *Source* and *Path*, with F1 scores stable across prompting conditions. In contrast, *Goal* shows unexpectedly low performance in one- and three-shot settings, likely due to example sampling variability — none of the randomly selected few-shot prompts included a *Goal* instance, which may have misled the model (cf. 6.1 below).

**Literal motion.** We evaluate Task 2 on a subset annotated exclusively for literal motion verbs, focusing on physical movement and excluding figurative uses. This dataset includes *Source*, *Goal*, and *Path*, but is unbalanced across SRs. Mistral, Llama, and GPT are tested under zero-, one-, and six-shot settings, with the latter including one positive and one negative example per relation.

As shown in Table 4, Llama's and Mistral's performances remain identical and unreliable, marked by low precision and F1-scores, particularly for *Path*, which is never correctly identified. While slight improvements can be seen for *Source* under six-shot prompting (F1 = 0.67 for Mistral), overall performance remains inconsistent and largely unchanged compared to the mixed dataset (cf. Table 3). For this reason, both models were excluded from further experiments on Task 2 and the entirety of Task 3, as it builds upon SR classification performed in Task 2.

GPT-4 performs considerably better. The *Goal* relation continues to be the most robust, reaching an F1-score of 0.83 in the six-shot setting. Performance for *Source* and *Path*, however, remains more variable and consistently lower, with best F1-scores of 0.61 and 0.54 respectively. This suggests that even in literal motion contexts, *Source* and *Path* relations are harder to detect reliably — possibly because *Goal* is more commonly and overtly expressed in motion events, giving the model stronger and more consistent lexical or structural cues to rely on.

**Controlled SRs.** To check whether the imbalance between *Goal*, *Source*, and *Path* is contributing to GPT-4's lower performance on the *Goal* class, we test the model on a three separate subsets of the data. The Task was split into three separate sub-tasks, each focused on a sin-

|  |  | Source |  |  | Goal |  |  | Path |  |  |
|---|---|---|---|---|---|---|---|---|---|---|
| Model | Metric | 0-shot | 1-shot | 3-shots | 0-shot | 1-shot | 3-shots | 0-shot | 1-shot | 3-shots |
| ***Mistral-7B*** | Precision | 0.19 | 0.00 | 0.19 | 0.69 | 0.69 | 0.69 | 0.12 | 0.00 | 0.00 |
|  | Recall | 1.00 | 0.00 | 1.00 | 1.00 | 1.00 | 1.00 | 1.00 | 0.00 | 0.00 |
|  | F1-score | 0.33 | 0.00 | 0.33 | **0.82** | **0.82** | **0.82** | 0.21 | 0.00 | 0.00 |

| ***Llama-3.2B*** | Precision | 0.26 | 0.26 | 0.26 | 0.65 | 0.00 | 0.00 | 0.14 | 0.00 | 0.00 |
|  | Recall | 1.00 | 1.00 | 1.00 | 1.00 | 0.00 | 0.00 | 1.00 | 0.00 | 0.00 |
|  | F1-score | 0.41 | 0.41 | 0.41 | 0.79 | 0.00 | 0.00 | 0.24 | 0.00 | 0.00 |
| ***GPT-4*** | Precision | 0.59 | 0.37 | 0.40 | 0.71 | 0.70 | 0.73 | 0.35 | 0.22 | 0.41 |
|  | Recall | 0.62 | 0.87 | 0.78 | 0.98 | 1.00 | 0.96 | 0.84 | 0.95 | 0.78 |
|  | F1-score | **0.61** | **0.52** | **0.53** | **0.82** | **0.82** | **0.83** | **0.49** | **0.35** | **0.54** |

**Table 4**
Task 2. SR classification results on literal motion verb subset (unbalanced). Highest F1-score values per shot setting are highlighted in bold.

gle SR, with corresponding dataset subsets (cf. 5.1). We restrict this analysis to GPT-4, as it seems to be the only model to produce SR predictions that are not effectively random (cf. 6.1 above).

|  | Relation | Setting | Precision | Recall | F1-score |
|---|---|---|---|---|---|
| ***GPT-4*** | Source | Zero-shot | 0.85 | 0.57 | 0.68 |
|  |  | One-shot | 0.70 | 0.85 | **0.77** |
|  |  | Two-shots | 0.64 | 0.79 | 0.71 |
|  | Goal | Zero-shot | 0.58 | 0.95 | **0.72** |
|  |  | One-shot | 0.57 | 0.97 | **0.72** |
|  |  | Two-shots | 0.57 | 0.94 | 0.71 |
|  | Path | Zero-shot | 0.70 | 0.84 | 0.76 |
|  |  | One-shot | 0.59 | 0.92 | 0.72 |
|  |  | Two-shots | 0.70 | 0.91 | **0.79** |

**Table 5**
Task 2 (GPT-4). SR classification results after the dataset splitting (balanced). Highest F1-score per shot setting is highlighted in bold.

The results on the split dataset show more stable performance across relations (Table 5). For *Source*, the best F1 is 0.77 with one-shot prompting; for *Goal*, recall remains high (0.95) with moderate precision (0.57); and for *Path*, the best F1 (0.79) is achieved with two-shot prompting.

**Task 3.** Table 6 summarises the performance of GPT-4 in classifying parts of speech in sentences related to motion. We exclude the other two models because of their poor performance on the previous two tasks, on which Task 3 relies on (cf. 6.1). Zero- and one-shot prompting achieve the highest F1 score for common nouns, followed by adverbs. For proper nouns, recall is high, while precision is low. This discrepancy between high recall and low precision for proper nouns suggests that while GPT-4 reliably detects their presence, it often overpredicts and misattributes them within the sentence structure (cf. 6.2).

| | Setting | SR Type | Precision | Recall | F1-score |
|---|---|---|---|---|---|
| ***GPT-4*** | Zero-shot | adverb | 0.90 | 0.68 | 0.77 |
| | | common noun | 0.91 | 0.83 | **0.87** |
| | | proper noun | 0.47 | 0.92 | 0.62 |
| | One-shot* | adverb | 0.87 | 0.76 | 0.81 |
| | | common noun | 0.92 | 0.79 | **0.85** |
| | | proper noun | 0.42 | 0.83 | 0.55 |

**Table 6**
Task 3 (GPT-4). SR type disambiguation: adverbs, common nouns, proper nouns, under zero-shot and one-shot prompting. The one-shot (*) is given on a proper noun instance. Highest F1-score per shot setting is highlighted in bold.

## 6.2. Qualitative Evaluation

**Task 1.** Mistral and Llama show high confusion for verb identification, with an overgeneration of predictions that do not include the correct value. They often include forms that are morphologically or semantically related to the correct one (e.g., *conveniens* instead of *conveniunt*, *subeo* instead of *subit*), though in some cases the forms are entirely unrelated (e.g., *advena, adgredior, excolui* instead of *aggressus*). A qualitative inspection of the (few) mismatches for GPT-4 reveals that the model occasionally produces multiple verb forms within its output for a single sentence. Examples include cases such as *transierat, traduxisse* and *evolo, evigila*, where multiple words are listed. In these cases, the words are not different inflected forms of the same lemma, but rather distinct verbs or nouns. Nonetheless, the correct verb form is always present among these outputs (*evolo*, *transierat*), indicating that these are instances of overgeneration or model uncertainty. This behaviour persists despite prompt engineering efforts to constrain the output format, suggesting a tendency of the model to hedge its predictions in ambiguous cases. Interestingly, increasing the number of shots does not improve performance, suggesting that additional examples for verb identification may introduce noise or ambiguity rather than reinforcing the model's task-specific behaviour [41].

**Task 2.** Mistral's and Llama's predictions show that the models randomly assign a positive or negative value to a specific SR. For *Goal*, F1 is high as *Goal* is mostly present in the examples, due to the Goal-over-Source principle [38]. GPT-4 has a different performance depending on the relation type and prompt format. For the *Goal*, performance drastically drops under the one-shot and three-shot settings with an unbalanced dataset. In these cases, the prompt examples possibly do not include a representative positive instance of *Goal*, causing a steep drop in its recognition. Balancing the dataset improves consistency across SRs, but qualitative errors remain. For instance, the model often confuses *Source* and *Path* when the contextual cues are subtle or ambiguous. On the subset limited to literal motion verbs, the model demonstrates relatively strong recognition of *Goal*, but struggles more with *Source* and *Path*.

**Task 3.** The SR type disambiguation task (GPT-4 only) displays different levels of the models' accuracy across parts of speech. While common nouns are identified with high confidence and accuracy, proper nouns pose some challenges, as reflected in lower precision and F1 scores. This finding reinforces the need to treat them separately. Even after prompt engineering (which yielded a slight performance improvement), a consistent pattern of error persists: whenever a proper noun appears in the sentence but is not governed by the target motion verb, the model still annotates it as the relevant argument. Although this is technically a correct identification of a proper noun, it is incorrect in the context of the task. For instance, in the sentence:

> *Nam, ut scis optime, secundum quaestum* ***Macedoniam profectus***, [...] *per transitum spectaculum* ***obiturus****, in quadam avia et lacunosa convalli a vastissimis latronibus obsessus atque omnibus privatus tandem evado*
>
> 'So, as you well know, I had set out for Macedonia to earn a living. On the way, planning to take in some sights, I was ambushed in a remote and marshy valley by a band of enormous robbers. Stripped of everything, I finally managed to escape.' (Apul.Met.1.7)

the model correctly identifies *Macedoniam* as a proper noun but incorrectly links it to the motion verb *obeo* (in the form *obiturus*), instead of recognising that it belongs to a different motion verb (*profectus*, from *proficiscor*), which is not among the verbs considered for annotation. This may suggest that in the context of proper nouns, the model relies heavily on their salience and tends to overlook verb-governance constraints. In other words, the model appears to prioritise SR type recognition and semantic prominence over syntactic dependencies when proper nouns are involved. In other cases, the model occasionally misclassifies common nouns as proper nouns. Examples include words like *fines* 'borders' or *urbs* 'city', which are common nouns, but are mistakenly labeled as proper nouns.

# 7. Discussion and Conclusion

This study evaluates LLMs across three interconnected tasks in Latin linguistic analysis: motion verb identification, SR classification, and SR type disambiguation. Our results are encouraging, but they also highlight the significant differences in performance between models — particularly the stark contrast between GPT-4 and open-weight models such as Llama and Mistral.

GPT-4 achieves high performance across all tasks, already in zero-shot settings. This is likely due to the substantial presence of Latin data in its pretraining corpus. While the precise contents of GPT-4's training data remain undisclosed, estimates based on GPT-3 suggest at least 339 million Latin tokens were included [42], and GPT-4 was trained on significantly more data. This makes it plausible that GPT-4 has substantial exposure to Latin, unlike models such as Llama and Mistral, which likely lack such training data and perform accordingly worse — often failing completely in zero-shot settings.

For preverbed motion verb identification, GPT-4 achieves strong performance, particularly under zero-shot settings [41]. SR classification exposes challenges due to data imbalance, with *Goal* relations dominating the dataset. Creating balanced subsets helps obtain more reliable and interpretable results. SR type disambiguation proves the most difficult task, with the model frequently misclassifying proper nouns and failing to correctly link them to relevant motion verbs. This highlights a gap in the way the models can use contextual reasoning to disambiguate entities. This may be mitigated by expanding the length of the input text so to offer more context to the models. Error analysis suggests that the model's dependence on lexical familiarity and world knowledge, which may not perfectly align with classical contexts, limits its accuracy.

These findings demonstrate that while LLMs show promising semantic understanding in Latin, syntactic and contextual challenges persist. Balancing datasets and employing few-shot prompting improve performance, but do not fully resolve issues related to ambiguity and entity linking.

Future work should focus on domain-specific fine-tuning with classical corpora, possibly integrating external knowledge sources to enhance disambiguation and semantic grounding. This combined approach can better support the complex linguistic features of Latin and ultimately advance computational tools for classical language research. In parallel, similar experiments should be conducted on other languages to assess how especially open-weight models handle spatial relations in languages for which they have broader coverage. Such comparisons can clarify whether the poor performance observed in Latin stems from language-specific limitations or from more general architectural and training differences. Additionally, future studies could isolate prose texts to control for syntactic regularity, as poetic language often introduces greater structural variability and long-distance dependencies that may challenge model performance.

Our study — the first on LLMs' SR recognition in historical languages — clarifies their performance and limits in this area. It lays the groundwork for more specialised computational methods in Computational Humanities and Historical Linguistics, with potential applications to other historical languages where preverbs are vastly employed, such as Ancient Greek [43].

## Author contributions

AF was responsible for conceptualisation, methodology, formal analysis, software implementation (including all code used for analysis), and manual annotation of the dataset; he wrote the original draft for Sections 1, 3-7, and edited the final manuscript. AB and BMcG contributed to the conceptualisation and methodology of the project, drafted Section 2, and participated in review, editing, and supervision of the research.

# MAMITA: Benchmarking Misogyny in Italian Memes

Elisabetta Fersini, Francesca Gasparini, Giulia Rizzi and Aurora Saibene

*University of Milano-Bicocca, Milan, Italy*

## Abstract

This paper introduces **MAMITA**, a novel Italian multimodal benchmark dataset developed for the automatic detection of misogynistic content in online media, with a specific focus on memes. The dataset comprises 1880 memes sourced from popular social platforms—Facebook, Twitter, Instagram, Reddit—and meme-centric websites, selected using misogyny-related keywords covering a wide range of manifestations including body shaming, stereotyping, objectification, and violence. A key feature of this benchmark is its dual annotation strategy: all memes were independently labeled by both domain experts and a pool of 232 crowd annotators. This approach resulted in two parallel sets of annotations that reflect differing labeling perspectives. For each meme, labels include a binary classification (misogynistic or not), the type of misogyny, and its intensity. Beyond categorical labels, the dataset incorporates perspectivist metadata, capturing individual annotators' perceptions of misogyny along with their demographic and socio-cultural background, including age, level of education, and social status. Each meme's textual content was also automatically transcribed to enable multimodal analysis. This enriched benchmark enables nuanced research on the automatic detection of misogynistic content in online social media and supports investigations into how perceived misogyny varies across annotator profiles, allowing us to address the urgent challenge related to the diffusion of hateful content against women.

**Warning: this paper includes examples that may be offensive or harmful.**

## Keywords

Misogynous Memes, Italian Benchmark, Expert vs Crowd Annotation, Perspectivism

## 1. Introduction
