**FECE** (Ding and Duan, 2026) is a challenge set designed to evaluate the quality of fine-grained translation error correction. Existing MT evaluation metrics operate primarily at the segment level and may therefore fail to reflect whether a specific error has actually been corrected. This can lead to cases where edits outside a human-identified error span improve the overall metric score, while valid corrections to the annotated error itself receive little or even negative credit. FECE is constructed to expose this limitation by focusing on alternative corrections of fine-grained translation errors, allowing the authors to test whether metrics accurately reflect the effect of the correction itself.

FECE demonstrates that whole-segment metrics often fail to reward genuine error correction: across 29 WMT26 systems, average preference for the error-correcting candidate was just 51.2% for English–German, and metrics actually favored the merely-polished, error-preserving candidate for English–Japanese and English–Chinese. This shows that unrelated polishing can outweigh credit for the correction itself. Drawing from these observations, the authors proposed the COMET-Fine metric, which isolates only error-related edits and consistently favored the error-correcting candidate, reaching only 46–53% agreement against the WMT26 metrics.

**GAMBIT+** (Menis Mastromichalakis et al., 2026) was introduced in WMT 2025 (Filandrianos et al., 2025) as a controlled challenge set for investigating gender bias in automatic translation evaluation. It is based on source segments containing gender-ambiguous occupational terms, paired with carefully matched masculine and feminine translations. Since the source does not specify the gender of the person associated with the occupation, both realizations are equally valid, and an unbiased evaluator should assign comparable scores to the two variants. For the 2026 edition, the authors

use an occupation-balanced subset of GAMBIT+ covering seven English-source language pairs with Arabic, Czech, German, Greek, Icelandic, Russian, and Ukrainian as target languages, extending the original resource with German. The subset contains 1,308 masculine/feminine translation pairs per target language, with three examples for each of the 436 ISCO-08 occupational groups[15]. This setup enables analysis of the direction, magnitude, and frequency of gender-related score differences across evaluators, languages, and occupations.

The results of GAMBIT+ show that gender bias remains present in MT evaluation, but that capturing its extent requires looking beyond a single aggregate measure to complementary dimensions of evaluator behavior.

**LIGATUR** (Mishra et al., 2026) is a 171-item contrastive challenge set that probes the sensitivity of MT evaluation metrics to Unicode format and control characters in English-German and English-Hindi. The set distinguishes between perturbations that should be effectively invisible to human readers and perturbations that alter the rendered text or its legibility. In particular, the authors examine Unicode characters whose normalization causes clean and corrupted strings to collapse to identical token sequences under commonly used metric encoders, including XLM-R and mT5, making the corruption inaccessible to the metric before scoring. Other perturbations instead fragment tokenization and can be detected more reliably. The English–Hindi portion additionally examines control characters affecting Devanagari conjunct formation, allowing the challenge set to distinguish between benign Unicode variation and character-level corruption with visible consequences.

A blind re-evaluation with held-out labels also overturns the authors' pilot claim that judges ignore Devanagari conjunct breaks. As a result, the authors create the metric AEGIS (submitted in Task 2), which acts on the diagnosis, combining a reference-based ensemble with deterministic hygiene penalties for exactly what the encoders cannot see, and scores all 26,885 test items.

**QEbreak** (Silchenko, 2026) is a contrastive challenge set designed to audit systematic failure modes in machine translation quality metrics, with a particular focus on omission and addition asymmetry. It contains 2,886 segments across 10 language pairs and comprises three controlled components: matched base, omission, addition triples that test whether metrics penalize silently omitted source content differently from added content; a fluent, fact-free verbosity ladder that probes sensitivity to length inflation; and minimal pairs containing numeric contradictions as a positive control.

Scores from 31 systems confirm the deficit and refute the QEBreak mechanism. Reference-free QE metrics under-penalize omission (a current QE baseline prefers the omission over its own base in 19.5% of matched base-versus-omission contests), and the edit-direction by reference-availability interaction is significant. But reference-based neural metrics are asymmetric in the same direction outside the pre-registered equivalence margin, so omission under-penalization belongs to learned metrics as a class; reference access softens it but does not remove it. Every returned metric penalizes pure verbosity, and two systems score corrupted numerals above correct ones.

### 8.3 Aggregated challenge set results

An aggregated view of the results provided by the challenge sets can be seen in Table 15. Here, the heterogeneous scores calculated by every challenge set have been normalized to form a ranking for each of its supported language pairs. This way, a direct comparison of how each system performed on each type of challenge is possible. Additionally, we calculate an aggregate rank, which is the result of the average of the individual challenge set ranks per language pair, weighted by the number of their respective test items. The ranks from Task 2 (Section 6.2) are also presented aligned with the aggregated ranks. It should be noted that the aggregated ranking is heavily skewed to the devised challenges and their language directions and does not represent the overall performance of the system, which is what we want to focus on through this comparison.

Performance is generally coherent across the language-pair columns belonging to the same challenge set. Correlation across challenge sets is weak to absent. Systems that dominate QEbreak are unremarkable on GAMBIT+ and LIGATUR, and the systems that struggle most on GAMBIT+ are not uniformly the worst elsewhere.

Strikingly, the challenge-set average ranking is largely inverted relative to the Task 2 ranking. Baseline lexical/embedding metrics (YiSi-1, BERTScore, spBLEU, BLEU, AEGIS,

Table 15: Indicative aggregated challenge set ranking calculated by the average of the individual challenge set ranks per language pair, weighted by the number of items. Comparison with the Task 2 ranks (Table 8) also shown. * marks reference-free submissions. † marks fine-tuned systems.

chrF) top the challenge-set average rank but sit mid-to-bottom on Task 2, while LLM judges (Gemini-3.6-Flash*, Gemma 4, Qwen 3.6) lead Task 2 but rank near the middle of the challenge-set aggregate. This reflects how each challenge set targets a failure mode tied to a specific system design: reference-free (*) judges under-penalize omission on QEbreak (lacking a reference to detect missing content), fine-tuned (†) neural metrics built on subword encoders (xCOMET, Vertical_1/2) are blind to LIGATUR perturbations that collapse to identical token sequences, and fluency-sensitive metrics reward FECE's polish confound rather than genuine error correction —all failure modes largely absent from simple lexical overlap metrics, whose narrowness, however, limits their Task 2 human-correlation.

### 8.4 Summary of challenge set findings

The results of the challenge sets reveal systematic and distinct weaknesses in all current MT evaluation approaches. Evaluators that agree strongly at the **system level** often diverge considerably on individual segments, underscoring that aggregate agreement can mask local unreliability. Segment-level metrics largely fail to reward genuine **error correction**, often favoring superficially polished but error-preserving translations over those that fix the annotated error, but highlighting error-related edits substantially improves this behavior. **Gender bias** persists in translation evaluation, though its magnitude and direction vary between evaluators, languages, and occupations, indicating that it cannot be easily captured by a single aggregate measure. Evaluation metrics based on subword encoders are vulnerable to **Unicode perturbations** that collapse to identical token sequences before scoring, but are more sensitive to perturbations that fragment tokenization or visibly disrupt legibility. Reference-free and, to a lesser extent, reference-based neural metrics under-penalize **content omission** relative to addition, a bias that access to references attenuates but does not eliminate, while verbosity and numerical inaccuracy are more consistently penalized.

Taken together, the performance of the evaluators on the challenge sets was largely uncorrelated with their overall strength and ranking, indicating that the failure modes exposed by the challenge sets are largely attributable to the evaluation sys-

tem's architectural choices, reference-free scoring, subword tokenization, and fluency sensitivity.

## 9 Conclusions

This paper presented the findings of the WMT26 Shared Task on Automated Translation Quality Evaluation Systems. By evaluating fine-grained error detection, quality-score prediction, and error-free classification on a common multilingual test set, this year's task provides a joint view of capabilities that have historically been evaluated separately.

Across all three quality formulations, prompted LLM-as-a-judge systems now substantially outperform all conventional lexical and supervised neural metrics included in our evaluation. At the same time, the results do not identify a single universally best evaluator: rankings remain dependent on model family, language direction, reference availability and provenance, and in some cases the use of reasoning. Open-weight models are competitive with proprietary frontier systems and strong reference-free evaluators perform particularly well. The new cross-task conversions further show that systems developed for fine-grained error detection or continuous quality scoring can often be converted effectively into error-free classifiers, with specialized Task 3 systems providing surprisingly little consistent advantage.

Several important questions remain open. Evaluation quality is still considerably less stable for lower-resource languages, and future work should investigate how to improve multilingual generalization without language-specific calibration. Furthermore, preliminary cross-domain analyses reveal an interesting pattern: although auto-evaluator rankings remain quite stable, evaluator performance varies considerably across domains, with higher scores in speech and software and lower scores in news, social, fact-checking, and educational domains. Future work should investigate these differences more thoroughly. The mixed effects of native, post-edited, and pseudo-references motivate further study of when references help and how evaluators should condition on reference provenance and estimated quality. The benefits of reasoning also appear to be strongly model-dependent, suggesting that evaluation accuracy should be considered jointly with inference cost rather than assuming that additional reasoning is uniformly beneficial. For error-free detection, robust threshold calibration across languages, domains, and different class distributions remains an important practical problem. More broadly, the strong performance of cross-task conversions raises the possibility of developing unified evaluators whose error spans, holistic scores, and accept/reject decisions are mutually consistent. Finally, the submitted challenge sets highlight multiple phenomena that remain poorly captured by aggregate benchmark performance and provide useful targets for future editions of the shared task.

## Ethical Considerations

The data for this shared task was generated, screened, and human-annotated by the WMT26 General Machine Translation Shared Task. We acknowledge inheriting any ethical limitations and concerns raised by that task.

Generative-AI tooling was utilized by the task organizers in multiple aspects of the work reported here. Usage varied across organizers, with some utilizing AI more broadly while others did not use AI at all. Tables, figures and some analyses were generated by scripts that were largely automated using AI, but code was reviewed and results were cross-checked by the organizers. The content of this findings paper was mostly written natively by the committee members, with overview sections (abstract, introduction, conclusions) partly or mostly suggested by AI, and with AI assisting in reviewing and suggesting edits to the overall manuscript.

## Acknowledgments

The execution of this shared task would not be possible without tight collaboration with the organizers of the WMT26 General MT Shared Task, whom we thank for their collaboration. We thank Google and OpenAI for providing the compute resources necessary for running the complete evaluation with several baseline auto-evaluators based on their proprietary models; and Google and the National Research Council of Canada for providing compute resources for generating the pseudo-references. We also thank Brigham Young University's Office of Research Computing for the compute resources that made running the open-weight LLM baselines in this work possible.

Eleftherios Avramidis was partially funded by the German Federal Ministry of Research, Technology and Space (BMFTR) via the project RoGSiLT (grant number 16IW26001).

# A Participant System Descriptions

## A.1 Task 1

For each submission, we asked participants to also hand over a model card that includes a system description. Here, we report such system descriptions verbatim.

**Cohere CAT+ (Kocmi et al., 2026b)** Cohere CAT+ machine transaltion specific model is build on top of the Cohere Command A+ architecture which is a mixture-of-experts with 24 active parameters out of 218 total parameters. The utilized multistep training protocol: coarse SFT focussing also on non-machine translation capabilities, specialized MT SFT, followed by DPO, RLVR and finished with small targeted DPO. We utilize its instruction following capabilities to assess error spans and quality estimation with a variant of GEMBA-MQM prompt.

**cuni-cat-v4 (Hrabal and Bojar, 2026)** A two-stage MQM-style error detector based on the open-weight Gemma 4 31B instruction model with 4-bit AWQ quantization. The system uses few-shot prompting and one-pass self-refinement, predicts optional MQM categories. It uses source and candidate translation text without reference translations.

**cuni-v14 (Hrabal and Bojar, 2026)** A two-stage MQM-style error detector based on the open-weight Gemma 4 31B instruction model with 4-bit AWQ quantization. The system uses few-shot prompting and one-pass self-refinement to identify major and minor target-side errors and source omissions. It uses source and candidate translation text without reference translations.

**FACET (Kim et al., 2026)** FACET evaluates each translation through two separate prompting passes. Fluency looks at the target alone and accuracy at the source and target together, so each judgment sees only the context its error type needs: fluency does not get confused with source fidelity, and meaning errors are checked against the source rather than guessed from the target. The two passes are merged per segment and scored on a shared four-point severity scale, with one fixed model across both passes. This submission works entirely at the segment level, matching the granularity at which the task scores.

**doc-FACET (Kim et al., 2026)** FACET evaluates each translation through three separate prompting passes. Fluency looks at the target sentence alone, accuracy at the source and target together, and consistency at the whole document rather than one segment. Each pass sees only the context its error type needs, which keeps the judgments clean: fluency does not get confused with source fidelity, and document-level consistency catches cross-segment errors like the same name or term translated differently in different places, which segment-level scoring misses. The three passes are merged per segment and scored on a shared four-point severity scale, with one fixed model across all passes. We also provide a submission that excludes the consistency pass, since the current evaluation scheme scores at the segment level and does not capture document-level quality.

**fluencyscore-multispan-v2 (Mongush and Pukhov, 2026)** fluencyscore-multispan-v2: reference-free LLM judge (Gemini 3.5 Flash) prompted to enumerate all distinct error spans per hypothesis (0..N) with major/minor severity following MQM-style conventions, plus an explicit omission field. Phrases are mapped to character spans with a deterministic Unicode-normalizing locator (exact / normalized / bounded-fuzzy tiers) with occurrence disambiguation; overlapping and adjacent same-severity spans are merged; whole-segment spans are restricted to garbled outputs. Empty or unscored hypotheses fall back to our prior single-span system. Covers official 21 LPs + challenge sets on mteval-test26.

**fluencyscore-multispan-v2.1 (Mongush and Pukhov, 2026)** fluencyscore-multispan-v2.1: two-pass judge (base pass + second-opinion pass on empty hypotheses + exhaustive pass on five under-covered LPs), span union with dedup; reference-free LLM judge (Gemini 3.5 Flash) prompted to enumerate all distinct error spans per hypothesis (0..N) with major/minor severity following MQM-style conventions, plus an explicit omission field. Phrases are mapped to character spans with a deterministic Unicode-normalizing locator (exact / normalized / bounded-fuzzy tiers) with occurrence disambiguation; overlapping and adjacent same-severity spans are merged; whole-segment spans are restricted to garbled outputs. Empty or unscored hypotheses fall back to our prior single-span system. Covers official 21 LPs + challenge sets on mteval-test26.

**gemma4-31b-v4ref-struct-best (Jang et al., 2026)** Gemma-4-31B-it used off-the-shelf (no SFT/fine-tuning) as a translation error-span judge. Prompt engineering only: a reference-aware prompt with 8 few-shot demonstrations, JSON guided-decoding output, and a rule-based language-ID pre-filter for wrong-language segments. Calibration is applied per language pair rather than globally — severity, expected error density, span extent, and under/over-flagging guidance are tuned separately for each pair, using HUMEVAL25-VAL gold where that pair has gold coverage and structural cross-pair signals where it does not. The submission selects, for each of the 8 pairs, the variant that scored best on the shared-task leaderboard among our runs.

**Lexicala-QE-Ensemble (Majority-Vote) (Siani, 2026)** A reference-free, LLM-ensemble quality-estimation system. Three independent LLM judges (Gemini 2.5 Flash, DeepSeek V4 Flash, Qwen Plus) annotate each translation under an MQM/ESA-style protocol; a neutral cross-

verification stage re-judges every proposed span, and a dedicated source-coverage stage detects omissions. The verified per-character judge masks are fused by CHARACTER-LEVEL MAJORITY VOTE (a character is marked erroneous when at least two of the three judges cover it), giving Task-1 error spans with minor/major severity and an omission label. The Task-2 quality score is an inverse-variance fusion of a reliability-weighted holistic estimator and a span-derived MQM-penalty estimator (span confidence = vote share; judge reliability = agreement with the consensus), clamped to [0,100]. The Task-3 error-free label is an adequacy-gated conjunction (no error spans, no omission, and holistic quality at or above threshold). No reference translations are used at any stage.

**Lexicala-QE-Ensemble (STAPLE) (Siani, 2026)** A reference-free, LLM-ensemble quality-estimation system. Three independent LLM judges (Gemini 2.5 Flash, DeepSeek V4 Flash, Qwen Plus) annotate each translation under an MQM/ESA-style protocol; a neutral cross-verification stage re-judges every proposed span, and a dedicated source-coverage stage detects omissions. Per-character judge masks are fused with STAPLE (Simultaneous Truth And Performance Level Estimation) — an EM algorithm that jointly estimates each judge's sensitivity and specificity and the latent error truth, followed by HMM run-smoothing — yielding Task-1 error spans with minor/major severity and an omission label. The Task-2 quality score is an inverse-variance fusion of a reliability-weighted holistic estimator and a span-derived MQM-penalty estimator, clamped to [0,100]. The Task-3 error-free label is an adequacy-gated conjunction (no error spans, no omission, and holistic quality at or above threshold). No reference translations are used at any stage.

**PhraseT1-01 (Eckhardt et al., 2026)** Reference-free span-level (ESA) error detection for machine translation, using Gemini 3.5 Flash (Wmt26SpanTaskV2Directive prompt) as a single judge, no combination with other systems.

**PhraseT1-02 (Eckhardt et al., 2026; Hrabal and Bojar, 2026)** Ensemble span-level (ESA) error detection for machine translation, combining Gemini 3.5 Flash (closed-weight), Gemma 4 12B (open-weight, Phrase-served via local vLLM), and UFAL cat-v4 (Charles University's two-stage MQM-style error detector, based on open-weight Gemma 4 31B with 4-bit AWQ quantization, few-shot prompting and one-pass self-refinement). Combined via unweighted union voting across all three systems' spans (a span counts if any system flagged it), with a Gemini+Gemma-only fallback for the small fraction of segments UFAL's system did not cover.

**PragmaSpan (Lee, 2026)** PragmaSpan is a training-free, few-shot GPT-5.5 span-error detector wrapped in a reliability-oriented inference and submission harness. References are included as optional prompt context when provided, and provided ASR transcripts are used as text context for speech items; video and screenshots are not consumed. The harness converts structured API responses into complete, deterministic, format-valid WMT26 Task 1 artifacts through truncation-aware row retries, conservative JSON and offset recovery, deterministic exact-span deduplication, exact item/system completeness checks against the official input, and mandatory validation before packaging. These safeguards target artifact reliability rather than claiming to improve diagnostic accuracy. The detector uses a seven-axis diagnostic taxonomy covering semantic, linguistic, discourse, and interpersonal errors; an ablation found that its four pragmatic axes provide interpretive structure but change detection accuracy by at most $\pm 0.001$ F on the evaluated domain mix. Model and prompt choices were evaluated against WMT25 ESA surrogate gold and WMT22 MQM en-de using the official severity-weighted MPP metric, and several prompt, span, and severity refinements were tested but excluded after failing to improve consistently across benchmarks.

**Qwen-based Omission (Servajean et al., 2026)** To address the Segment-Level Error Detection and Span Annotation, a reasoning-based LLM with few-shot learning that leverage structure output is applied. The Qwen3 32B model is adapted to generate the output that includes error span detection, classify each span according to its severity, and identify a possible omission for each segment in a completed translation.

**Rule-based Omission (Servajean et al., 2026)** We follow the same procedure for Qwen-based Omission except the omission is computed using a rule-based approach on the basis of overall severity of a completed translation.

**QwenSpan** ***[Citation missing]*** A reference-free multilingual translation error span detection system based on Qwen3-14B. The English-German system is trained with supervised fine-tuning followed by GRPO. The English-Chinese system is further trained on a mixture of English-German and English-Chinese data. The system takes the source sentence and machine translation as input and predicts minor and major error spans without using the provided reference translations.

**XCOMOffset (Pong, 2026)** This submission refines the state-of-the-art xcomet metric by rebalancing the class labels based on the label distribution of the training data. It modifies xcomet by adding an offset to the logits, hence adjusting the softmax subword probabilities for each error class. It then ranks the error spans based on the model's entropy, selecting the top-k error spans to be re-classified or re-segmented by a reasoning LLM.

### A.2 Task 2

**AEGIS (Mishra et al., 2026)** AEGIS is a reference-skeptical, corruption-shielded evaluation system. Motivated by WMT26's shift to post-edited and synthetic references, it treats the reference as just another hypothesis: a reference-based COMET-22 score and a reference-free MetricX-24 (QE-mode) score are fused with a per-segment weight derived from the reference's own estimated quality and declared type (human / postedit / pseudo / absent), falling back to pure QE where no reference exists. Before neural scoring, a deterministic Unicode-hygiene layer separates orthographic integrity from semantic quality: default-ignorable codepoints, whitespace-class substitutions, homoglyph cloaking, and Indic conjunct-breaking joiners are detected and converted into transparent point penalties (we verified XLM-R-based metrics are provably blind to several of these corruptions), and a degeneracy guard catches empty, runaway, and repetition-loop outputs. We submit predictions for every official language pair, every system, and all challenge-set items.

**Austriadactylus, a variant of Pterodactyl (Garland and Berger, 2026)** Austriadactylus, a variant of Pterodactyl, is a highly customizable, ultra-low-cost system optimized for binary classification in translation triage and data curation. It is based on an LLM-as-a-judge approach, with prompt engineering and model selection guided by ROC analysis. Unlike Pterodactyl, Austriadactylus uses GPT-5.6 for ultra-low-resource languages (Ladin, Ligurian, and Northern Sami).

**bytepop_pro10 (Xu, 2026)** PRIMARY Ensemble + Gemini-3-Pro on all covered normal columns; Ladin=Gemini+sol; Lig/Sami=Gemini

**bytepop_pro9 (Xu, 2026)** Ensemble + Gemini-3-Pro on 8 losing + cs-de (full); Ladin=Gemini+sol; Lig/Sami=Gemini

**Cohere CAT+ ensemble (Kocmi et al., 2026b)** Cohere CAT+ machine transaltion specific model is build on top of the Cohere Command A+ architecture which is a mixture-of-experts with 24 active parameters out of 218 total parameters. The utilized multistep training protocol: coarse SFT focussing also on non-machine translation capabilities, specialized MT SFT, followed by DPO, RLVR and finished with small targeted DPO. We utilize its instruction following capabilities to assess error spans and quality estimation with a variant of GEMBA-MQM prompt. The final score is average of three completions from the same model and the same prompt: one greedy pass at temperature 0 plus two sampled passes at temperatures 0.3.

**cuni-da-6d (Hrabal and Bojar, 2026)** A direct segment-level DA/ESA system based on the open-weight Gemma 4 31B instruction model with 4-bit AWQ quantization. It consumes source text, candidate translation, language information, and the provided translation instruction, but does not use references. Its frozen DSPy prompt includes six labeled demonstrations selected using WMT25 training data before WMT26 test inference and covers all translations in the eight WMT26 high-priority language pairs.

**cuni-v14-regression (Hrabal and Bojar, 2026)** A frozen supervised regression model over aggregate error features produced by a two-stage MQM-style Gemma 4 31B detector (cuni-v14 task 1 submission). The constrained weighted-error regression was fit and selected only on WMT25 training data using underlying-document grouped validation, excludes prediction failures from fitting, and uses a frozen train-mean fallback. It does not use reference translations. This submission covers the eight WMT26 high-priority language pairs plus English-Czech, Czech-Ukrainian, and all released English-Chinese variants.

**doc-FACET (Kim et al., 2026)** FACET evaluates each translation through three separate prompting

passes. Fluency looks at the target sentence alone, accuracy at the source and target together, and consistency at the whole document rather than one segment. Each pass sees only the context its error type needs, which keeps the judgments clean: fluency does not get confused with source fidelity, and document-level consistency catches cross-segment errors like the same name or term translated differently in different places, which segment-level scoring misses. The three passes are merged per segment and scored on a shared four-point severity scale, with one fixed model across all passes. We also provide a submission that excludes the consistency pass, since the current evaluation scheme scores at the segment level and does not capture document-level quality.

**FACET (Kim et al., 2026)** FACET evaluates each translation through two separate prompting passes. Fluency looks at the target alone and accuracy at the source and target together, so each judgment sees only the context its error type needs: fluency does not get confused with source fidelity, and meaning errors are checked against the source rather than guessed from the target. The two passes are merged per segment and scored on a shared four-point severity scale, with one fixed model across both passes. This submission works entirely at the segment level, matching the granularity at which the task scores.

**fluency2-gemini35-esa (Mongush and Pukhov, 2026)** fluency2-gemini35-esa: Gemini 3.5 Flash fluency2 judge with fluency201 ($\gamma$=1.8, cap 9) display transform; ESA via WMT25 linear calib on fluency201 + moment-match to WMT25 score marginal (avoids ESA=100 saturation). Official 21 LPs + challenge. Task3 threshold 85 inclusive. Unscored hyps (~4% official) filled with ESA=50.0 fallback.

**gemba-poly (Züfle et al., 2025)** GEMBA-poly-cand is a reference-free, LLM-based quality estimation metric built on Llama 3.3 70B. Each translation is scored alongside up to 5 additional candidate translations of the same source segment, selected by cosine similarity over all-MiniLM-L12-v2 sentence embeddings, giving the model contrastive context rather than scoring the translation in isolation. Candidate pools are drawn primarily from other participating systems' outputs for the same source segment; for segments with too few available system outputs, additional synthetic candidates were generated with TranslateGemma-4B to ensure a sufficient pool for similarity-based selection.

**Lexicala-QE-Ensemble (Majority-Vote) (Siani, 2026)** A reference-free, LLM-ensemble quality-estimation system. Three independent LLM judges (Gemini 2.5 Flash, DeepSeek V4 Flash, Qwen Plus) annotate each translation under an MQM/ESA-style protocol; a neutral cross-verification stage re-judges every proposed span, and a dedicated source-coverage stage detects omissions. The verified per-character judge masks are fused by CHARACTER-LEVEL MAJORITY VOTE (a character is marked erroneous when at least two of the three judges cover it), giving Task-1 error spans with minor/major severity and an omission label. The Task-2 quality score is an inverse-variance fusion of a reliability-weighted holistic estimator and a span-derived MQM-penalty estimator (span confidence = vote share; judge reliability = agreement with the consensus), clamped to [0,100]. The Task-3 error-free label is an adequacy-gated conjunction (no error spans, no omission, and holistic quality at or above threshold). No reference translations are used at any stage.

**Lexicala-QE-Ensemble (STAPLE) (Siani, 2026)** A reference-free, LLM-ensemble quality-estimation system. Three independent LLM judges (Gemini 2.5 Flash, DeepSeek V4 Flash, Qwen Plus) annotate each translation under an MQM/ESA-style protocol; a neutral cross-verification stage re-judges every proposed span, and a dedicated source-coverage stage detects omissions. Per-character judge masks are fused with STAPLE (Simultaneous Truth And Performance Level Estimation) — an EM algorithm that jointly estimates each judge's sensitivity and specificity and the latent error truth, followed by HMM run-smoothing — yielding Task-1 error spans with minor/major severity and an omission label. The Task-2 quality score is an inverse-variance fusion of a reliability-weighted holistic estimator and a span-derived MQM-penalty estimator, clamped to [0,100]. The Task-3 error-free label is an adequacy-gated conjunction (no error spans, no omission, and holistic quality at or above threshold). No reference translations are used at any stage.

**MQM-LLM (Servajean et al., 2026)** Our approach uses an LLM-as-a-judge within the MQM

error typology. Error severities are used as inputs to train an MLP regressor to predict human annotations.

**MQM-LLM Confidence Aware (Servajean et al., 2026)** Our approach uses an LLM-as-a-judge within the MQM error typology, with the novel addition of asking the LLM to verbalize its confidence in each error type assessment. Error severities and their associated confidence ratings are used as inputs to train an MLP regressor to predict human annotations.

**PhraseT2-01 (Eckhardt et al., 2026)** Segment-level quality scoring (ESA-style 0-100 score) combining two LLM judges: Gemini 3.5 Flash (closed-weight) and Gemma 12B (open-weight, locally served via vLLM), both prompted with the same reference-free error-span prompt (Wmt26SpanTaskV2Directive) and their derived scores combined via a scalar RRWA-weighted mean using a metric-specific (T2 Pearson) static reliability prior per judge.

**PhraseT2-02 (Eckhardt et al., 2026; Hrabal and Bojar, 2026)** Segment-level quality scoring (ESA-style 0-100 score) combining Gemini 3.5 Flash (closed-weight), Gemma 4 12B (open-weight, Phrase-served via local vLLM), and UFAL cat-v4 (Charles University's two-stage MQM-style error detector, based on open-weight Gemma 4 31B with 4-bit AWQ quantization, few-shot prompting and one-pass self-refinement), via a scalar mean of each system's own score weighted by a per-system reliability prior (each system's standalone Pearson correlation on held-out WMT25 dev data), with a Gemini+Gemma-only fallback for segments UFAL did not cover.

**Pterodactyl (Garland and Berger, 2026)** Pterodactyl is a highly customizable, ultra-low-cost system optimized for binary classification in translation triage and data curation. It is based on an LLM-as-a-judge approach, with prompt engineering and model selection guided by ROC analysis.

**Vertical_1 (Nakhlé et al., 2026)** Vertical is an MT evaluation metric trained using an LLM as backbone (namely google/gemma-3-1b-it). We insert a special token into the input sequence, and the model uses it as the representation of the full sequence; hidden states across all layers are combined via a layer-wise attention mechanism before being fed to a two-layer linear network that predicts the final score on a 0 to 1 scale. We use the unified training approach, meaning we train the model on reference-based and reference-free data and leverage the decoder-only causal attention to predict the score under two variants: using the source and hypothesis as inputs (the special token is inserted after the hypothesis, so it only attends to the previous sequence) and using the source, hypothesis and reference as inputs (a second special token is inserted after the reference, so it attends to all previous tokens). The model is trained to minimize the weighted average of the MSE losses of the two variants against the ground truth score. At inference time, we use the appropriate variant depending on whether the reference is available, but any post-hoc combination of the two variant scores is possible when both exist. The model is trained on public WMT data from previous years. To boost performance on longer inputs, we propose a training curriculum that splits data into three stages: 1) sentence-level data, 2) paragraphs reconstructed from sentences, and 3) real paragraphs (WMT25 data).

**Vertical_2 (Nakhlé et al., 2026)** Vertical is an MT evaluation metric trained using an LLM as backbone (namely google/gemma-3-1b-it). We insert a special token into the input sequence, and the model uses it as the representation of the full sequence; hidden states across all layers are combined via a layer-wise attention mechanism before being fed to a two-layer linear network that predicts the final score on a 0 to 1 scale. We use the unified training approach, meaning we train the model on reference-based and reference-free data and leverage the decoder-only causal attention to predict the score under two variants: using the source and hypothesis as inputs (the special token is inserted after the hypothesis, so it only attends to the previous sequence) and using the source, hypothesis and reference as inputs (a second special token is inserted after the reference, so it attends to all previous tokens). The model is trained to minimize the weighted average of the MSE losses of the two variants against the ground truth score. At inference time, we use the appropriate variant depending on whether the reference is available, but any post-hoc combination of the two variant scores is possible when both exist. The model is trained on public WMT data from previous years. To boost performance on longer inputs, we propose a training curriculum that splits data into three stages: 1)

sentence-level data, 2) paragraphs reconstructed from sentences, and 3) real paragraphs (WMT25 data).

### A.3 Task 3

**Austriadraco and Wukongopterus (Garland and Berger, 2026)** 1020 Group submitted two systems. Pterodactyl is a highly customizable, ultra-low-cost system optimized for binary classification in translation triage and data curation. It is based on an LLM-as-a-judge approach, with prompt engineering and model selection guided by ROC analysis. The first system is Austriadraco. Austriadraco is derived from Pterodactyl and specifically optimized for Task 3, employing a threshold-setting strategy based on one set of patterns observed in the WMT25 data. The second system is Wukongopterus. Wukongopterus is derived from Pterodactyl and specifically optimized for Task 3, employing a threshold-setting strategy based on one set of patterns observed in the WMT25 data.

**First try (Servajean et al., 2026)** AIST submitted two systems, both named First try (submissions 871721 and 874374), with the same description in their model cards. Their approach uses an LLM-as-a-judge within the MQM error typology, with the novel addition of asking the LLM to verbalize its confidence in each error type assessment.

**PTT-MULTITAN-v2 (Zhu et al., 2026)** ALTAE, Université Paris Cité submitted two systems, both named PTT-MULTITAN-v2 (submissions 875519 and 875520), with the same description in their model cards. We used a bottom-up approach that targets the weakness of the MCC metric. After fine-tuning a LightGBM classifier with WMT25's data sets and applying data filtering strategies and CometKiwi filtering, we used multifactorial phraseology heuristics based on corpus linguistics and collocation measures: entropy, logDice, MI filtering, etc. We also used an LLM-as-a-judge strategy, further specializing the prompt by highlighting the disagreements between error-free segments and the classifier's predictions. The system covers six language pairs: eng-bel, eng-deu, eng-rus, eng-ukr, eng-zho_CN and eng-zho_TW.

**Lexicala (Siani, 2026)** Lexicala submitted two systems. A reference-free, LLM-ensemble quality-estimation system. Three independent LLM judges (Gemini 2.5 Flash, DeepSeek V4 Flash, Qwen Plus) annotate each translation under an MQM/ESA-style protocol; a neutral cross-verification stage re-judges every proposed span, and a dedicated source-coverage stage detects omissions. The first system is Lexicala-QE-Ensemble (Majority-Vote). The verified per-character judge masks are fused by character-level majority vote (a character is marked erroneous when at least two of the three judges cover it), giving Task-1 error spans with minor/major severity and an omission label. The Task-2 quality score is an inverse-variance fusion of a reliability-weighted holistic estimator and a span-derived MQM-penalty estimator (span confidence = vote share; judge reliability = agreement with the consensus), clamped to $[0, 100]$. The second system is Lexicala-QE-Ensemble (STAPLE). Per-character judge masks are fused with STAPLE (Simultaneous Truth And Performance Level Estimation) — an EM algorithm that jointly estimates each judge's sensitivity and specificity and the latent error truth, followed by HMM run-smoothing — yielding Task-1 error spans with minor/major severity and an omission label. The Task-2 quality score is an inverse-variance fusion of a reliability-weighted holistic estimator and a span-derived MQM-penalty estimator, clamped to $[0, 100]$. Both descriptions close identically: The Task-3 error-free label is an adequacy-gated conjunction (no error spans, no omission, and holistic quality at or above threshold). No reference translations are used at any stage.

**RAGthoven Error-Free *[Citation missing]*** This submission comes from NaiveNeuron. A fixed reference-free pipeline for sentence-level error-free translation detection. It combines deterministic structural evidence with structured source-and-hypothesis judging, bounded independent verification, and deterministic aggregation.

**PhraseT3-01 and PhraseT3-02 (Eckhardt et al., 2026; Hrabal and Bojar, 2026)** Phrase submitted two systems. The first system is PhraseT3-01. Binary error-free segment classification combining two LLM judges: Gemini 3.5 Flash (closed-weight) and Gemma 12B (open-weight, locally served via vLLM), both prompted with the same reference-free error-span prompt (`Wmt26SpanTaskV2Directive`). A segment is classified error-free only if both judges independently agree (unweighted intersection voting on judge-detected spans). The second system is PhraseT3-02, submitted as Phrase + CUNI. Binary error-free segment classification combining Gemini

3.5 Flash (closed-weight), Gemma 4 12B (open-weight, Phrase-served via local vLLM), and UFAL cat-v4 (Charles University's two-stage MQM-style error detector, based on open-weight Gemma 4 31B with 4-bit AWQ quantization, few-shot prompting and one-pass self-refinement), via a per-segment reciprocal-rank-weighted average (RRWA) of each system's own error-free prediction, weighted by a per-system reliability prior (each system's standalone MCC on held-out WMT25 dev data), with a Gemini+Gemma-only fallback for segments UFAL did not cover.

**FACET (Kim et al., 2026)** Soongsil University submitted two systems, both named FACET (submissions 869556 and 869557), with the same description in their model cards. FACET evaluates each translation through three separate prompting passes. Fluency looks at the target sentence alone, accuracy at the source and target together, and consistency at the whole document rather than one segment. Each pass sees only the context its error type needs, which keeps the judgments clean: fluency does not get confused with source fidelity, and document-level consistency catches cross-segment errors like the same name or term translated differently in different places, which segment-level scoring misses. The three passes are merged per segment and scored on a shared four-point severity scale, with one fixed model across all passes.

## B Per-Language Pair Results

### B.1 Task 1

Tables 16–36 report per-translation direction rankings. Each ranking includes the auto-evaluators that produced assessments for all translations in that translation direction.

### B.2 Task 2

Tables 37–57 report Task 2 results for every official translation direction, including directions outside the priority set. Each ranking includes only direct Task 2 participant submissions and direct Task 2 baselines that produced scores for every translation with human scores in that direction. The eligible auto-evaluator set can therefore differ by direction. Task 1-to-Task 2 conversions are not included in these tables.

## C Analysis of Task 2 Meta-Metrics

This appendix validates the grouping choices in the Task 2 meta-evaluation. All analyses use the eight primary translation directions. They include only direct Task 2 participant submissions and direct Task 2 baselines with valid predictions for the relevant direction; automatically converted Task 1 submissions are excluded.

**Screen-based versus source-based PDP.** Source-based PDP averages all retained human scores for an item–system pair and considers every pair of systems with a human score on that source item. Screen-based PDP instead retains only the pairs co-displayed in cESA screens. Table 58 reports the Spearman correlation between the corresponding auto-evaluator rankings for every primary direction. The PDP correlations are uniformly high ($\rho = 0.987$–$0.999$), showing that screen-based PDP closely recovers the source-based ranking while relying only on the direct contrastive human comparisons. We consequently select screen-based PDP as the official segment-level component, since it allows avoiding comparisons whose human scores were elicited in different contrastive contexts.

**Screen-based versus source-based SPA.** The analogous SPA correlations in Table 58 are lower and more variable ($\rho = 0.775$–$0.963$). The difference follows from the evidence available to each MT system pair. Screen-based SPA can use only source items where the two systems were co-annotated, whereas source-based SPA uses every source item for which both systems have a retained human score. Figure 6 shows the resulting support gap: the median co-screen support ranges from 4 to 27 source items per pair, compared with 41 to 433 for source-based SPA. The gap persists for mean support and is especially acute in directions with sparse cESA pair overlap. To base the system-level meta-evaluation on substantially greater support, we therefore select source-based SPA as the official system-level component.

## D Additional reference analyses for Task 2

Tables 59–62 provide the reference analyses discussed in Section 6.3.2.

Table 18: Task 1 ranking for the Czech→Vietnamese translation direction. * marks reference-free submissions. † marks fine-tuned systems. Light-grey rows indicate organizer baselines. The ensemble components listed in the model card are E1 [Gemini 3.5 Flash; Gemma 4 12B; Gemma 4 31B]; E2 [xcomet].

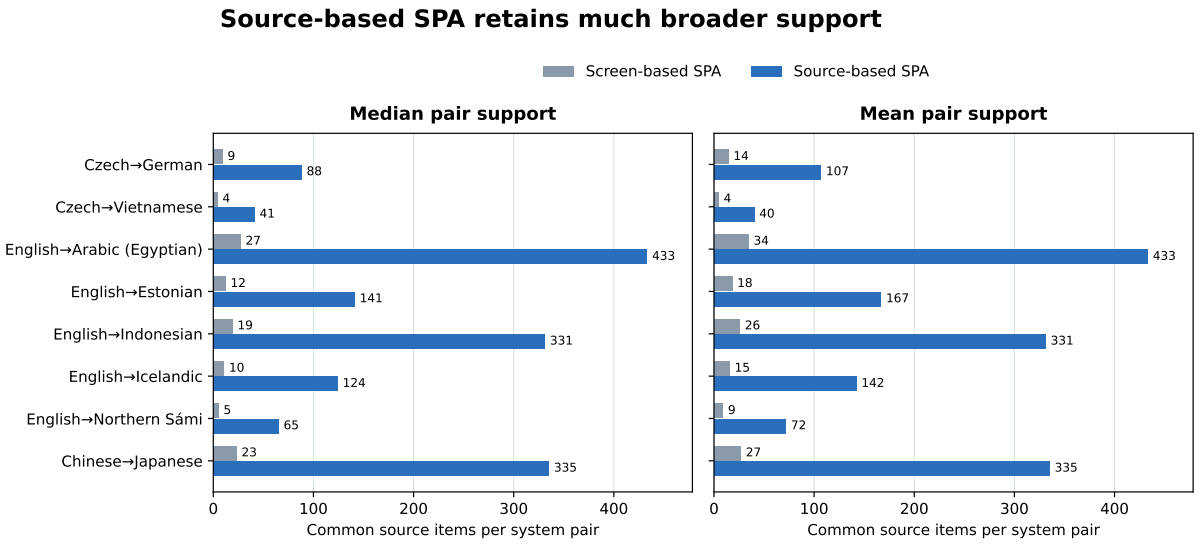

Figure 6: Human evidence support for the two system-level SPA variants across the eight primary translation directions. Each bar summarizes the number of source items with human scores for an MT system pair; the left and right panels report the median and mean, respectively, across system pairs within a direction. Screen-based SPA retains only source items where the two systems were assessed together in a cESA screen, whereas source-based SPA retains every source item with a human score for both systems.

Table 37: Task 2 ranking on the Czech→German translation direction. * marks reference-free submissions. † marks fine-tuned systems. Light-grey rows are organizer baselines. Ensemble components named in the model cards are: E1 [Gemini 3.5 Flash; Gemma 4 12B; Gemma 4 31B]; E2 [GPT-5.4; Gemini 3.5 Flash; GPT-5.6 Luna; COMET-22]; E3 [Gemini 2.5 Flash; DeepSeek V4 Flash; Qwen Plus]. Statistical significance clusters use two-sided source-level permutation tests (1,000 draws per evaluator pair, unadjusted $p \leq 0.05$), following the resampling framework of Deutsch et al. (2021b); cluster labels use the greedy procedure adopted in recent WMT Metrics evaluations (Freitag et al., 2024; Lavie et al., 2025).

Table 38: Task 2 ranking on the Czech→Ukrainian translation direction. * marks reference-free submissions. † marks fine-tuned systems. Light-grey rows are organizer baselines. Ensemble components named in the model cards are: E1 [Gemini 3.5 Flash; Gemma 4 12B; Gemma 4 31B]; E2 [GPT-5.4; Gemini 3.5 Flash; GPT-5.6 Luna; COMET-22]; E3 [Gemini 2.5 Flash; DeepSeek V4 Flash; Qwen Plus]. Because no reference is available in this direction, the reference-based Gemma 4 reasoning, xCOMET XL, and xCOMET XXL baselines are omitted; their reference-free counterparts are displayed. Statistical significance clusters use two-sided source-level permutation tests (1,000 draws per evaluator pair, unadjusted $p \leq 0.05$), following the resampling framework of Deutsch et al. (2021b); cluster labels use the greedy procedure adopted in recent WMT Metrics evaluations (Freitag et al., 2024; Lavie et al., 2025).

Table 42: Task 2 ranking on the English→Czech translation direction. * marks reference-free submissions. † marks fine-tuned systems. Light-grey rows are organizer baselines. Ensemble components named in the model cards are: E1 [Gemini 3.5 Flash; Gemma 4 12B; Gemma 4 31B]; E2 [GPT-5.4; Gemini 3.5 Flash; GPT-5.6 Luna; COMET-22]; E3 [Gemini 2.5 Flash; DeepSeek V4 Flash; Qwen Plus]. Statistical significance clusters use two-sided source-level permutation tests (1,000 draws per evaluator pair, unadjusted $p \leq 0.05$), following the resampling framework of Deutsch et al. (2021b); cluster labels use the greedy procedure adopted in recent WMT Metrics evaluations (Freitag et al., 2024; Lavie et al., 2025).

Table 46: Task 2 ranking on the English→Indonesian translation direction. * marks reference-free submissions. † marks fine-tuned systems. Light-grey rows are organizer baselines. Ensemble components named in the model cards are: E1 [Gemini 3.5 Flash; Gemma 4 12B; Gemma 4 31B]; E2 [GPT-5.4; Gemini 3.5 Flash; GPT-5.6 Luna; COMET-22]; E3 [Gemini 2.5 Flash; DeepSeek V4 Flash; Qwen Plus]. Statistical significance clusters use two-sided source-level permutation tests (1,000 draws per evaluator pair, unadjusted $p \leq 0.05$), following the resampling framework of Deutsch et al. (2021b); cluster labels use the greedy procedure adopted in recent WMT Metrics evaluations (Freitag et al., 2024; Lavie et al., 2025).

Table 50: Task 2 ranking on the English→Ladin translation direction. $^{*}$ marks reference-free submissions. $^{\dagger}$ marks fine-tuned systems. Light-grey rows are organizer baselines. Ensemble components named in the model cards are: E1 [Gemini 3.5 Flash; Gemma 4 12B; Gemma 4 31B]; E2 [GPT-5.4; Gemini 3.5 Flash; GPT-5.6 Luna; COMET-22]; E3 [Gemini 2.5 Flash; DeepSeek V4 Flash; Qwen Plus]. Statistical significance clusters use two-sided source-level permutation tests (1,000 draws per evaluator pair, unadjusted $p \leq 0.05$), following the resampling framework of Deutsch et al. (2021b); cluster labels use the greedy procedure adopted in recent WMT Metrics evaluations (Freitag et al., 2024; Lavie et al., 2025).

Table 58: Spearman correlations between auto-evaluator rankings under screen- and source-based grouping. PDP compares screen-based with source-based PDP; SPA compares screen-based with source-based SPA. Each row uses only direct Task 2 submissions and direct Task 2 baselines; Task 1-to-Task 2 conversions are excluded.

## E Baseline Prompting Details

The LLM-based baselines follow the two-stage GEMBA-ESA prompting strategy. In Stage 1 (Task 1), the model identifies and classifies translation errors using MQM-style categories. In Stage 2 (Task 2), the model assigns a quality score on a 0–100 scale given the source, translation, and the error annotations produced by Stage 1. Both stages use a shared system prompt:

> *Your task is to identify machine translation errors and assess the quality of the translation.*

Each stage is issued as a single-turn chat message (system + user). Stage 1 uses chain-of-thought decoding when enabled (temperature 0.6, top-$p$ 0.95, max 8192 tokens); otherwise greedy decoding (temperature 0). Stage 2 always uses greedy decoding with a 64-token limit and thinking disabled.

### E.1 Stage 1: Error Annotation (Task 1)

Figure 7 shows the Stage 1 prompt template. When a reference translation is available (`-with-ref`), the shaded reference block is inserted between the translation and the annotation instructions; otherwise it is omitted. The reference header adapts to the reference type (Table 64).

### E.2 Stage 2: Quality Scoring (Task 2)

Figure 8 shows the Stage 2 prompt template. The `{error_spans}` placeholder is filled with the parsed Stage 1 output. As with Stage 1, the reference block is included only when `-with-ref` is active.

### E.3 Domain Requirements

Each segment carries a domain label extracted from its `item_id`. The domain-specific instruction text appended to both Stage 1 and Stage 2 prompts is shown in Table 63.

### E.4 Reference Type Labels

When the reference-augmented variant is used, the reference block header adapts to the type of reference available for each segment, as shown in Table 64.

## F Task 3

### F.1 Details on Statistical Significance Tests

To determine the statistical significance for a certain pair of systems, A and B, the observed test statistic is the difference between their macro-average MCCs. Each macro-average is the unweighted mean of eight MCCs computed separately for the eight language pairs; it is not an MCC computed after pooling their observations.

Prior permutation procedures used in MT metric evaluation (Deutsch et al., 2021b; Thompson et al., 2024) do not fit our macro-average setting exactly, so we adapt them. Our procedure is most similar to PERM-INPUTS from Deutsch et al. (2021b), which makes one exchange decision per input and applies it to all system outputs for that input. For each pair of metrics, we jointly exchange their predictions at the source-segment level, using the same decision for every observation and language-pair occurrence associated with that source segment.

If a segment is retained, A keeps all of A's predictions for that segment and B keeps all of B's. If it is exchanged, A receives all of B's predictions for that segment and B receives all of A's. Each decision therefore covers every MT-system output and repeated human judgment associated with the segment. When the same source segment occurs in multiple language pairs, the same exchange decision is used for every occurrence. The 2,357 language-pair-specific items form 1,392 source-segment units, of which 553 occur in more than one priority pair. Units are identified by set, source language, domain, document and segment; target language is excluded, and shared units were verified to have identical source text.

After each exchange, MCC is recomputed separately for each language pair, and the eight resulting MCCs are averaged. For each of the 153 unordered metric pairs, 100,000 permutations were drawn.

To convert the pairwise permutation-test results into clusters, we adopt the greedy clustering procedure used in recent WMT evaluation shared tasks (Freitag et al., 2022, 2023, 2024; Lavie et al., 2025). We use the unadjusted two-sided Monte Carlo p-value and the clustering threshold is $p < 0.05$. The highest metric starts cluster 1. Moving down the ranking, a metric joins the current cluster only when its pairwise difference from every metric already in that cluster is not significant. If it differs significantly from at least one current-cluster metric, it starts the next numbered cluster. Thus every pair within a cluster is nonsignificant under these tests, while membership in different clusters does not imply that every cross-cluster pair differs significantly.

**Stage 1 Prompt Template (User Turn)**

```
{src_name} source:
```{src_text}```
{tgt_name} translation:
```{hyp_text}```
```

*Inserted only when `-with-ref` is active*

```
{ref_label}:
```{ref_text}```
```

Based on the source segment{, machine translation, and reference translation | and machine translation} surrounded by triple backticks, identify error types in the translation and classify them. The categories of errors are: accuracy (addition, mistranslation, omission, untranslated text), fluency (character encoding, grammar, inconsistency, punctuation, register, spelling), style (awkward), terminology (inappropriate for context, inconsistent use), non-translation, other, or no-error.

Each error is classified as one of two categories: major or minor. Major errors disrupt the flow and make the understandability of the text difficult or impossible. Minor errors are errors that do not disrupt the flow significantly, and what the text is trying to say is still understandable.

Return only the annotations in this format:
Major:
category/subcategory - "error span"
Minor:
category/subcategory - "error span"

Use one error per line and write no-error when a section is empty. Quote spans from the translation; for omissions, quote the omitted source span.

Domain requirements: {domain_req}

Figure 7: Stage 1 (Task 1) error annotation prompt template. Placeholders in braces are filled per-segment. The gray inner box is included only in the reference-augmented variant. The instruction wording adapts accordingly (gray alternation text).

**Stage 2 Prompt Template (User Turn)**

Given the translation from `{src_name}` to `{tgt_name}` and the annotated error spans, assign a score on a continuous scale from 0 to 100. The scale has the following reference points: 0="No meaning preserved", 33="Some meaning preserved", 66="Most meaning preserved and few grammar mistakes", up to 100="Perfect meaning and grammar".

Domain requirements: {domain_req}

```
Score the following translation:
{src_name} source:
```{src_text}```
{tgt_name} translation:
```{hyp_text}```
```

*Inserted only when `-with-ref` is active*

```
{ref_label}:
```{ref_text}```
```

```
Annotated error spans:
```{error_spans}```
```

Respond with ONLY a valid JSON object and nothing else: `{"score": N}`
where N is an integer from 0 to 100.

Figure 8: Stage 2 (Task 2) quality scoring prompt template. The `{error_spans}` field contains the Stage 1 annotation output. The gray inner box is included only in the reference-augmented variant.
```

Table 63: Domain requirement text inserted into both Stage 1 and Stage 2 prompts. The *news* and *factchecking* domains share identical requirements.

| Domain | Requirement text |
|---|---|
| news / factchecking | The source segment is from a news article. The translation should use a formal register consistent with journalistic standards and preserve the source HTML formatting. |
| speech | The source segment is a transcript of spoken content from a video. The translation should preserve the speaker's flow and colloquial style. It should omit non-linguistic sounds, such as laughter, groans, and hesitation sounds, while retaining interjections. Interrupted words should be completed when they can be inferred from context; otherwise, they should be omitted. Foreign words should remain unchanged. Each sentence should be placed on a separate line. |
| social | The source segment is user-generated content from a social media platform. Source spelling mistakes should not be reproduced. Meaningful expressiveness, such as capitalization or elongation, should be reproduced naturally in the target language. URLs and user handles should be copied unchanged, while hashtags should be translated when appropriate. Source punctuation should be followed as closely as possible, with additional punctuation only when needed to prevent serious loss of comprehension. The translation should use an informal style, like close friends talking, even if this changes the original tone, and preserve the source HTML formatting. |
| software | The source segment contains software data from a JSON. Only JSON content or values should be translated; keys and placeholders should be copied unchanged. The translation should contain only valid JSON content matching the input format. |
| edu | The source segment consists of biology, chemistry, and geography exercises from an educational web portal for children aged 9–16. The translation should be suitable for this educational context and age range, and preserve the source HTML formatting. |
| general | The translation should be accurate and fluent. |

Table 64: Reference type labels used in prompt headers.

| Type | Prompt label |
|---|---|
| human | Human reference translation |
| postedit | Post-edited reference translation |
| pseudo | High-quality machine translation reference |

Table 67: WMT26 Task 3 results for ces-vie (`ces_Latn--vie_Latn`). 49/418 items (11.7%) and 1,378/12,958 item–system pairs (10.6%) are annotated, giving 1,572 human assessments (400 error-free, 1,172 error). Track: T3 is a direct Task 3 submission, T1 and T2 are conversions of a Task 1 or Task 2 submission, and T1-B is a converted organizer Task 1 baseline. Light-grey rows are organizer baselines. Ensemble components named in the model cards are [E1] Austriadactylus: GPT-5.4; GPT-5.6 Terra; [E2] AEGIS: XLM-RoBERTa-large; mT5-large; [E3] bytepop_pro9: GPT-5.4; Gemini 3.5 Flash; GPT-5.6 Luna; [E4] bytepop_pro10: GPT-5.4; Gemini 3.5 Flash; GPT-5.6 Luna; [E5] RAGthoven Error-Free: Gemma 4 31B IT; Mistral Large 3; Gemini 3.1 Pro.

Table 71: WMT26 Task 3 results for eng-deu (`eng_Latn--deu_Latn`). 459/459 items (100.0%) and 6,839/13,770 item–system pairs (49.7%) are annotated, giving 7,383 human assessments (2,364 error-free, 5,019 error). Track: T3 is a direct Task 3 submission, T1 and T2 are conversions of a Task 1 or Task 2 submission, and T1-B is a converted organizer Task 1 baseline. Light-grey rows are organizer baselines. Ensemble components named in the model cards are [E1] AEGIS: XLM-RoBERTa-large; mT5-large; [E2] Austriadactylus: GPT-5.4; GPT-5.6 Terra; [E3] bytepop_pro9: GPT-5.4; Gemini 3.5 Flash; GPT-5.6 Luna; [E4] bytepop_pro10: GPT-5.4; Gemini 3.5 Flash; GPT-5.6 Luna.

## Abstract

We present the findings of the WMT26 Multilingual Instruction Shared Task (MIST), evaluating small ($\leq$10B parameter) open-weight language models across 24 languages on three subtasks: context-based QA, cross-lingual summarization, and open-ended generation. Submissions from eight teams explore fine-tuning, knowledge distillation, and prompt engineering. Our findings demonstrate that small models are not yet polyglots: while leading systems perform well on high-resource languages, performance drops sharply on low-resource varieties, and comprehension degrades significantly when transferring across non-English language pairs. In open-ended generation, human evaluation and automatic rule-based verification exhibit strong overall rank correlation ($\rho$=0.79) but diverge locally at the top: human evaluators favor distilled pipelines with superior fluency and cross-lingual equity, whereas automatic verifiers reward concise prompt-engineered systems. Furthermore, multi-stage pipelines suffer from prompt-language inertia on cross-lingual instructions, and summarization exhibits severe English leakage unless penalized by language gating. Finally, while baseline fluency is largely achieved by modern small models, multi-constraint instruction following and unanswerable question refusal remain the primary performance bottlenecks. We release all test sets, system outputs, human judgments, and evaluation code under a permissive license.

## 1 Introduction

The Multilingual Instruction Shared Task at the Conference on Machine Translation (WMT) evaluates model capability in following instructions and providing useful responses across languages and tasks. The first edition in 2025 turned into a competition joined by the largest open-source LLMs and frontier APIs (Kocmi et al., 2025). However, multilinguality should not remain a game reserved exclusively for giant or black-box models, because they are challenging and expensive to deploy and inaccessible for scientific analysis.

Therefore, in 2026,[1] our goal is to lower the entry barrier for a wider audience and challenge them to develop *small* multilingual models to punch above their weight.[2] Any participating systems should have at most 10 billion parameters, but participants are free to choose any data or methods for model building and inference. By doing so, we hope to attract a variety of techniques for improving multilinguality and to further our understanding of the progress in our community.

Secondly, model competence across the world's languages remains remarkably uneven, so we include a diverse set of languages in terms of writing script, location, and availability of resources. In terms of the shared task outcome, we share per-language and per-task analysis instead of emphasizing a single aggregated ranking.

The shared task introduced a fresh benchmark that systematically assesses key capabilities of LLMs across 24 languages using 3 sub-tasks:

- **Context-Based Question Answering (Ctx-QA)**: Answering a question solely based on the content of a paragraph, including appropriately declining to answer when the information is absent.
- **Open-Ended Generation (OEG)**: Responding to open-ended questions, some with con-

[1] Shared task information and resources are available on www2.statmt.org/wmt26/multilingual-instruction.html.

[2] Pun intended.

straints and some localized, where we assess language proficiency, knowledge, and constraint satisfaction.

- **Cross-lingual Summarization (Sum)**: Summarizing short ACL papers in different languages, which tests a practical cross-lingual ability.

Before releasing the test set, we shared an optional sample data mix sourced from existing benchmarks to help participants develop their models. After the test release, they have one month to submit their model outputs. In addition to participants' submissions, we benchmark small open-weight models within 10B parameters as baselines.

The evaluation for QA and Sum is reference-based, where we use a combination of metrics targeting different aspects of the model output. OEG is evaluated by both LLM-as-a-verifier and human annotators.

## 2 Data and Tasks

This section describes the datasets and preparation for each of the three sub-tasks in our benchmark. For every sub-task, we curated or adapted data for up to 24 languages. The high-level statistics are summarized in Table 1, and example prompts are shown in Table 2. Each prompt is self-contained: it includes all necessary context, instructions, and the question, so participants' systems receive a single string as input. The shared task consists of two phases: we released a sample data mix with questions and language coverage similar to the final test, by gathering resources from existing benchmarks (Clark et al., 2020; Ladhak et al., 2020; Bhattacharjee et al., 2023; Bandarkar et al., 2024; Singh et al., 2024; Papi et al., 2026). The final testing phase started one month before the submission deadline.

The following sections detail the sources of the data, the translation or localization processes applied, and any additional filtering or validation steps specific to each sub-task.

Prompts for all tasks, or their samples, are presented in Appendix A.

### 2.1 Test Languages

The official test data covers 24 languages spanning 7 scripts and 12 language families: Arabic, Bengali, Bhojpuri, Kurdish, Chinese (Simplified), Czech, English, Finnish, German, Haitian Creole, Hindi, Indonesian, Italian, Japanese, Korean, Marathi, Persian (Farsi), Portuguese, Russian, Slovak, Spanish, Turkish, Vietnamese, and Yoruba. Yoruba is present only for the OEG task, and Bhojpuri is introduced as a surprise language not present in the sample data we released. The surprise language tests the zero-shot or few-shot transfer ability of participating systems to an unseen, low-resource language.

| | Langs | Samples / lang |
|---|---|---|
| Context-based QA | 23 | 360 (100 unique) |
| Open-Ended Generation | 24 | 100* |
| Cross-lingual Summarization | 23 | 74 |

**Table 1:** Number of languages and the number of samples (prompts) for each language. *Yoruba included only 59 post-edited samples.

| | |
|---|---|
| Context-based QA | *Read the following passage and answer the question based solely on its content. [...]* "Whereas recognition of the inherent dignity and of the equal and inalienable rights of all members of the human family is the foundation of freedom, justice and peace in the world [...]" **Question:** What is proclaimed as the highest aspiration of the common people? |
| Open-Ended Generation | As a news reporter, write an article about the opening of a new shopping complex, including who will enjoy it and what activities are available. |
| Cross-lingual Summarization | Bitte fassen Sie die folgende wissenschaftliche Arbeit auf Deutsch zusammen: "We present a method for [...] Our experiments on three benchmarks show [...]" |

**Table 2:** Example prompts for each sub-task.

### 2.2 Context-based Question Answering

The context-based QA sub-task evaluates a model's ability to answer questions based solely on a provided passage, where the question and the expected answer are in one language and the passage may be in a different language.

**Sources and domains** We curated 20 English passages from five domains, selected for topical and stylistic diversity:

- **Universal Declaration of Human Rights (UDHR):** Preamble and selected articles (Articles 1–2, 18, 26, 27). The world's most translated document available in 500+ languages.
- **UNESCO Convention:** Preamble and articles from the Convention for the Safeguarding of the Intangible Cultural Heritage. Available in the five UN languages: arb, zho, eng, fra, rus,

spa.

- **UN Security Council Resolution 2347:** Preamble and operative paragraphs on cultural heritage protection. Also available in the 5 UN languages.
- **EU Law:** Excerpts from the Charter of Fundamental Rights (Articles 21–22), the AI Act, and the Treaty on the Functioning of the EU. Available in all EU languages.
- **Wikipedia:** Articles on culturally specific topics: Mid-Autumn Festival (zho), Carnival (por), Wabicha (Japanese tea ceremony) (jpn), Diwali (hin, mar, bho) and the Yoruba people (yor).

These texts were chosen because of their availability in at least two languages simultaneously. Rather than translating the passages, we rely on the existing human translations.

For each passage, we manually wrote five questions in English, including 4 answerable and 1 unanswerable question. Unanswerable questions test whether the model can correctly decline when the passage does not contain the answer. Passages where the answers cannot be found are accompanied by a language-specific refusal phrase that the model is instructed to produce, e.g., "not answerable" in English, "bez odpovědi" in Czech, or "无法回答" in Chinese.

**Cross-lingual setup** The questions, answers and prompt templates were translated into all target languages using GPT-5.5 (Qs and prompts) and GPT-5.6-Sol (answers). Each test instance pairs a passage in a source language with a question in a (potentially different) target language. Four cultural Wikipedia passages are paired with their native language plus English, while the remaining 16 passages each appear in English and three additional source languages, selected by a coverage-balancing algorithm. Since the same question can be paired with a passage in multiple source languages, this yields 360 instances per target language (100 unique questions), creating a mix of monolingual and cross-lingual reading comprehension items that test whether small models can synthesize information across language boundaries.

### 2.3 Open-Ended Generation

Following last year, we continue the open-ended generation (OEG) sub-task, which evaluates a model's ability to produce fluent, useful, and locally appropriate responses to open-ended questions, while following user instructions.

**Prompt design** We manually created 100 seed prompts in English, spanning three categories:

- **General:** Creative and reflective writing tasks (e.g., "Draft a 150-word description of a technological advancement that excites or concerns you").
- **Factual:** Knowledge and explanation tasks, sometimes requiring analogical reasoning (e.g., "Explain quantum entanglement using only cooking metaphors").
- **Language/location-specific:** Prompts that have answers that may vary for various languages, cultures, or locations. These are written with `{language}` or `{country}` as template placeholders (e.g., "How are diminutives typically formed in `{language}`"?).

Many prompts include explicit constraints such as word or sentence limits, required keywords, specific output formats, or stylistic requirements.

**Translation and localization.** For language- and location-specific prompts, the `{language}` and `{country}` placeholders in the English seed are instantiated before translation. The prompts were translated into target languages using GPT-5.5 via the standardized translation prompt template documented in Appendix A.2. The resulting questions were then reviewed and post-edited by proficient speakers of each language to ensure naturalness and cultural appropriateness.

**Human Post-Editing Effort** To quantify the extent of human correction, we measure the post-editing distance between the initial GPT-5.5 translations and the finalized test prompts across all 23 target languages (Table 12 in Appendix A.2). Overall, the human editing effort was modest: across all target languages, an average of 66.1% of prompts were accepted verbatim without any edits, with an average of 5.5 character edits per prompt. Languages varied substantially in editing difficulty and intensity: high-resource languages such as Arabic, Hindi, German, Indonesian, and Portuguese were easy, requiring negligible editing ($\geq$88% accepted verbatim, chrF $\geq$99.0). In contrast, languages like Czech and Slovak required frequent but low-intensity edits ($\approx$60% of prompts edited, but with a high chrF $\geq$95.2, reflecting minor morphological, diacritic, or stylistic adjustments). Conversely, Haitian Creole, Kurdish, and Persian (Farsi) required substantial, high-intensity rewriting: Haitian

Creole had only 9.3% unedited prompts, while Persian exhibited 50.0% edited prompts with a 14.1% character error rate. We report the full post-edit distance for each language in Table 12.

### 2.4 Cross-lingual Summarization

The cross-lingual summarization sub-task requires the model to read a full scientific paper in English and produce a summary in a specified target language.

**Source papers** We downloaded all 74 short papers from the 64th Annual Meeting of the ACL (ACL 2026). We extracted the full paper text and selected text from the beginning of the introduction section up to the text before the reference section. This paper content text was provided as an input for the task.

**Reference summaries** Gold-standard summaries are the authors' own abstracts, translated from English into the target languages by two systems (GPT-5.6-Sol and Gemini-3.1-pro-preview). Both translations are retained as equally valid references for evaluation; pairwise chrF between the two translation systems ranges from 52.3 (Yoruba) to 81.0 (Portuguese), with 56.7 in Chinese and 63.6 in Japanese, confirming that the choice of a single reference would visibly affect system rankings.

**Prompt construction** For each (paper, target language) pair, one of five paraphrased prompt templates is selected at random (seeded for reproducibility). Each template instructs the model to summarize the given paper into the target language, varying in phrasing to reduce prompt-specific artifacts. The prompts were translated into each language using GPT-5.5 and post-edited by proficient speakers of each language.

## 3 Participating Systems

We received submissions from eight teams, summarized in Table 3. All systems meet the shared task's constraint of 10B total parameters in the final system. The dominant approach is parameter-efficient fine-tuning (LoRA or QLoRA) of a pre-trained multilingual model, though teams differ substantially in their choice of base model, training data, and inference strategy, which is what we hoped for.

**TUM-HEILBRONN** Hou et al. (2026) fine-tune a 4-bit quantized Qwen3.5-9B with LoRA ($r$=16), first on the QA training split for 2 epochs, then on summarization for up to 3 additional epochs. Loss is computed only on assistant responses. They report zero-shot performance on the test set.

**CUNI** Papáček and Schmidtova (2026) evaluate several open-weight models with prompt engineering (system prompt design) and hyperparameter search (temperature, top-$p$, top-$k$, reasoning on/off). They select Qwen3.5-9B as their primary system for its reliability in following explicit constraints, with Gemma 4 E4B submitted as a contrastive variant.

**PSK** Pulipaka (2026) trains task-specific QLoRA adapters on top of Tiny Aya Global, using a mixture of the provided training data and external datasets including WikiLingua, CrossSum, Belebele, TyDiQA, and MLQA. At inference time, instances are routed to the appropriate adapter based on their task label.

**ALKHDER** Alkhder et al. (2026) fine-tune Qwen2.5-3B-Instruct with LoRA ($r$=32, $\alpha$=64) on 3,112 monolingual Arabic extractive QA examples from TyDiQA. They participate only in context-based QA for Arabic, using BF16 precision and greedy decoding.

**ALEIX** Sant et al. (2026) adapt Qwen3-8B with a two-stage LoRA procedure on a mixture of WMT MIST data, EuroAlpaca, and a new CrossEuroAlpaca dataset. EuroAlpaca provides 51,760 AlpacaCleaned-derived samples per language, localized in a task-preserving way. The system is primarily optimized for OEG in European languages.

**SENTINEL** Egerton-Idehen (2026) combines a fine-tuned and an untuned copy of Gemma-3-4b-it. Context QA is routed to the fine-tuned model, while OEG and summarization go to the base model. All outputs pass through a verification wrapper that checks language, length, and well-formedness, retrying or repairing generation when a check fails.

**SPINOZA** Krause et al. (2026) train LoRA adapters on Qwen3.5-9B using 100,466 cross-lingual QA examples machine-translated from TyDi QA. They additionally train an answerability probe on the same base model: if the probe classifies a question as unanswerable, the LoRA weights are bypassed and a fixed refusal phrase is returned. This estimates the empirical upper limit of the approach by separating answering ability from instruction following.

| Team | Base model | Method | Key steps |
|---|---|---|---|
| TUM-Heilbronn | Qwen3.5-9B (4-bit) | LoRA ($r$=16) | Sequential fine-tuning: QA then summarization; zero-shot evaluation |
| CUNI | Qwen3.5-9B | Prompt engineering | System prompt and hyperparameter search; Gemma 4 E4B as variant |
| PSK | Tiny Aya Global | Task-specific QLoRA | Separate adapters for summarization, context QA, and open QA; external data |
| Alkhder | Qwen2.5-3B-Instruct | LoRA ($r$=32) | Arabic extractive QA only; character-offset loss masking |
| Aleix | Qwen3-8B | Two-stage LoRA | EuroAlpaca + CrossEuroAlpaca data; European language focus |
| Sentinel | Gemma-3-4b-it | Full fine-tune + base | Routing: fine-tuned for QA, base for OEG/sum; verification wrapper |
| Spinoza | Qwen3.5-9B | LoRA + probe | Answerability probe on the base model; fine-tuning on translated QA data |
| Laniqo | Gemma-4-E4B-it | Full fine-tuning | Knowledge distillation from Gemma-4-31B teacher; pivot decoding for OEG/sum |

**Table 3:** Overview of participating systems. All systems are under the 10B parameter constraint.

**LANIQO** Charkiewicz and Nowakowski (2026) perform full-parameter fine-tuning of Gemma-4-E4B-it (8B total, 4.5B effective) on 20,625 distilled examples from a Gemma-4-31B teacher. They use task-conditional decoding: a pivot strategy (English intermediate draft, then target-language rewrite) for OEG and summarization, and direct single-pass decoding for context QA. A contrastive variant trains on the shared task's own reference outputs instead of distilled data.

**Reporting system variants** Some participant system variants differed only in a specific sub-task. To be concise, we report the variants of those team as one line in result tables if they are the same for a given sub-task.

**Organizer Baselines** In addition to the participant submissions, we benchmark models within the 10B constraint:

- **Tiny Aya Global** (Salamanca et al., 2026)
- **Gemma-4-E4B-it** (Team, 2026)
- **GLM-4-9B-0414** (GLM et al., 2024)
- **Llama-3.1-8B-Instruct** (Grattafiori et al., 2024)
- **Phi-4-mini-instruct** (Microsoft et al., 2025)
- **Qwen3-8B** (Alibaba et al., 2025)

These were the base models our participants built upon. They contextualize participant results against off-the-shelf models in this "weight category". Since baselines were evaluated with a single verifier (Gemma-4-31B) rather than the full multi-judge ensemble, their per-task and cross-task scores are reported separately in Appendix E.

## 4 Human Evaluation

Human evaluation was conducted for the open-ended generation (OEG) sub-task, where automatic metrics and lexical references are least reliable due to the creative and open-ended nature of the generated texts. System outputs were evaluated along three core quality dimensions on a 7-point calibrated scale:

- **Instruction Following (IF)** (1–7): How faithfully the response satisfies all explicit constraints and instructions in the prompt.
- **Naturalness (Nat)** (1–7): Fluency, idiomatic phrasing, and appropriateness of tone and formality in the target language.
- **Coherence (Coh)** (1–7): Logical structure, flow of arguments, and internal consistency.

We conducted human evaluation on the primary system as indicated by each participant. It covers only 14 languages due to resource constraints and annotator availability, with 69 samples each, as certain questions involve content in a language different from the question's language.

### 4.1 Evaluation Pipeline and Crowdsourcing

Human ratings were contributed by two of the task's sponsors:

- **Toloka** (platform.toloka.ai) provided support for 10 languages: Arabic, Chinese, German, English, Indonesian, Italian, Japanese, Korean, Russian, and Spanish. The evaluation was conducted by MIST Organizers through Toloka's specialized platform, using their structured expert pipeline with built-in quality assurance.

- **VoiceArena** (voicearena.com) collected human evaluation annotations for 4 Indic languages (Bengali, Bhojpuri, Hindi, Marathi) on their own in-house platform.

Both campaigns used the same guidelines and the same 7-point scale. We provide a detailed description of the setup in Appendix C.

### 4.2 Results

The human evaluation covers 69 items per language, for a total of 966 items for 14 languages. Table 4 reports the overall results and official WMT significance cluster ranking; Table 5 provides a per-language breakdown.

**Significance Clusters and Rankings.** Applying paired bootstrap resampling ($n$=10,000, $\alpha$=0.05) and Wilcoxon signed-rank tests over the 966 evaluated items partitions the seven evaluated submissions into five statistically distinct performance clusters (Table 4): the top three (LANIQO, SENTINEL, CUNI; ranks 1–3), followed by PSK (rank 4), TUM-HEILBRONN (rank 5), ALEIX (rank 6), and TEAMSPINOZA (rank 7), each significantly separated from the others.

**Dimensional Trade-offs: Instruction Following as the Bottleneck.** Within the top cluster, Naturalness (5.51–5.74) and Coherence (5.59–5.68) are tightly grouped, whereas Instruction Following shows the widest spread across all systems (1.67 points). This demonstrates that baseline target-language fluency is largely solved in modern $\leq$10B parameter models, whereas faithful compliance with complex, multi-constraint instructions remains the primary differentiator. Notably, CUNI achieves the highest Instruction Following score (5.36), benefiting from targeted system prompting, while LANIQO leads on Naturalness (5.74) and Coherence (5.68) through knowledge distillation and pivot decoding.

**Language-Specific Patterns.** As detailed in Table 5, performance varies markedly across language families:

- **High-Resource European Languages:** English outputs receive the highest absolute ratings across all systems (all dimension means $\geq$5.80; CUNI leading at 6.21, followed closely by TEAMSPINOZA at 6.19 and LANIQO at 6.14). German and Spanish likewise display strong adherence, with SENTINEL (5.75) and LANIQO (6.04) leading, respectively.
- **Asian Languages and Script Divergence:** In Japanese, top systems remain closely grouped (LANIQO at 5.94, CUNI at 5.91, SENTINEL at 5.91). In Korean, however, sharp performance disparities emerge: Instruction Following drops sharply for several systems, while CUNI exhibits a noticeable dip in Korean Naturalness, pulling its overall Korean score down to 4.61. LANIQO maintains the most balanced Korean output (5.30 overall). In Chinese, CUNI leads at 6.17, followed by TUM-HEILBRONN at 5.93 and ALEIX at 5.92.
- **Arabic and Indonesian:** In Arabic, LANIQO (5.52) and CUNI (5.48) lead with balanced instruction adherence. In Indonesian, SENTINEL (5.44), LANIQO (5.40), PSK (5.37), and CUNI (5.36) form a tight competitive tier, whereas TEAMSPINOZA drops to 4.54 due to low instruction following (3.66).
- **Indic Languages:** Performance drops for lower-resource Indic languages, with the surprise Bhojpuri showing the steepest decline (top system LANIQO at 4.82, bottom systems below 2.50). Bengali and Marathi show a clearer separation between the top cluster and the rest: in Bengali, SENTINEL leads at 5.57, while in Marathi, CUNI (5.75) and SENTINEL (5.75) are tied. Hindi follows a similar pattern, with CUNI leading at 5.43. Across all four Indic languages, the gap between the top three systems and the remaining submissions is substantially wider than for high-resource languages, and several lower-ranked systems fall below 3.0, indicating severe quality degradation.

## 5 Automatic Evaluation

Human evaluation was not conducted for all submissions, tasks, or languages, but we ran a thorough automatic evaluation for submitted outputs.

### 5.1 Metrics

We employ a comprehensive suite of automatic metrics, each targeting a different aspect of output quality:

- **Language identification (LangID):** We verify that the output is in the expected target language using GlotLID (Kargaran et al., 2023), evaluated across the 24 shared task lan-

| System | Rank | Overall↓ | IF | Nat | Coh | Winshare |
|---|---|---|---|---|---|---|
| Laniqo | 1 [1–3] | **5.57** ± 0.04 | 5.28 | **5.74** | **5.68** | **60.3%** |
| Sentinel | 2 [1–3] | 5.51 ± 0.04 | 5.21 | 5.69 | 5.62 | 58.6% |
| CUNI | 3 [1–3] | 5.49 ± 0.05 | **5.36** | 5.51 | 5.59 | 58.3% |
| PSK | 4 [4–4] | 4.93 ± 0.05 | 4.51 | 5.24 | 5.05 | 45.9% |
| TUM-Heilbronn | 5 [5–6] | 4.80 ± 0.06 | 4.33 | 5.11 | 4.96 | 45.3% |
| Aleix | 6 [5–6] | 4.70 ± 0.06 | 4.25 | 5.00 | 4.85 | 43.6% |
| TeamSpinoza | 7 [7–7] | 4.38 ± 0.07 | 3.69 | 4.89 | 4.54 | 38.0% |

**Table 4:** OEG human evaluation cluster ranking ($N$=69 × 14 languages). Ranks in brackets indicate WMT significance clusters ($p < 0.05$, paired bootstrap, $n$=10,000).

| System | arb | deu | eng | ind | ita | jpn | kor | rus | spa | zho | ben | bho | hin | mar |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Laniqo | **5.51** | 5.72 | 6.13 | 5.37 | **5.56** | **5.93** | **5.28** | 5.76 | 6.04 | 5.89 | 5.30 | **4.93** | 4.99 | 5.54 |
| Sentinel | 5.31 | **5.77** | 6.09 | **5.43** | 5.42 | 5.89 | 4.89 | **5.86** | 5.72 | 5.81 | **5.55** | 4.55 | 5.09 | **5.72** |

**Table 5:** OEG human evaluation breakdown: per-language scores (dimension mean, $N$=69 per language).

guages. GlotLID provides native support for low-resource languages including Bhojpuri, Kurdish, and Yoruba without requiring approximate surrogate matching.

- **Non-answerable validation (NonAns):** For context QA, we check whether the model correctly produces the instructed refusal phrase for unanswerable questions. Matching is rule-based (NFKC normalization, casefolding, punctuation stripping) against the exact phrase from the prompt template.
- **Lexical metrics:** BLEU, chrF++ (**chrF**), and ROUGE (**R-L**, **R-1**, **R-2**) computed against gold references using a shared per-language tokenizer (jieba for Chinese, MeCab for Japanese/Korean, whitespace elsewhere). chrF++ runs on raw text for tokenization independence.
- **COMET and CometKiwi (CQE):** Reference-based and reference-free neural MT metrics. The (source, hypothesis, reference) triple uses the English gold as source and the target-language gold as reference.
- **NLI:** Natural language inference scores using ModernBERT-base-nli in three settings: QA reference entailment, summarization mutual entailment with reference (**NLI-ME**), and SummaC-style source faithfulness (**NLI-F**).
- **LLM-as-a-verifier (QA):** For QA, we use the judge to verify semantic equivalence between the system response and the reference answer. For non-answerable questions, the judge decides whether the system correctly pointed it out.
- **LLM-as-a-verifier (OEG):** We manually write several verification rules for each question to enable automatic verification of instruction following and content quality, which can be more reliable than an LLM-as-a-judge using fixed one-for-all rubrics for each question. In particular, the rules check output length against the specified constraint; the presence of required words; and whether key concepts in the question are addressed. The rules are always in English regardless of a question's language. We run LLMs to produce a binary outcome for each rule.
- **LLM-as-a-judge (Sum):** For summarization, we use the judge in a reference-free fashion and only ask for a fluency rating of the system output.
- **Language-Gated metrics:** For cross-lingual summarization, generated outputs that fail LangID receive a score of zero for that instance. Language-Gated ROUGE-L (**G-R-L**) and Language-Gated chrF++ (**G-chrF**) directly penalize systems that generate in English rather than the specified target language.

For tasks with gold references, we use multi-reference evaluation: the target-language gold was produced by two independent translation systems, and both are retained as equally valid references

(Section 2.4).

For rule-based and answer verification across tasks, official scoring employs an ensemble of LLM verifiers: Cohere Command A+ (**Cmd-A+** in tables), **GLM-5.1**, and Gemma-4-31B (**Gemma4**), with **Qwen-3.5**-397B also evaluated on open-ended generation rules . A majority vote across verifiers (**Maj**) serves as the primary metric.

### 5.2 Context-based Question Answering

Table 6 reports evaluation results for context-based question answering aggregated across all 24 languages. Systems are ranked by their 3-judge majority-vote verification accuracy (**Maj**), which serves as the primary benchmark metric.

**Verification vs. Lexical Overlap.** A striking finding is the decoupling between rule-based verification accuracy and surface lexical overlap. CUNI-PRIMARY achieves the highest majority verification accuracy (81.63%) and leads on individual verifiers (79.13% Command A+, 77.71% GLM-5.1, 83.47% Gemma), closely followed by CUNI-VARIANT_B (80.93% Maj, 38.2 chrF++) and LANIQO-PRIMARY (76.90% Maj). In contrast, TUM-HEILBRONN-PRIMARY achieves the highest BLEU (19.7), ROUGE-L (34.95), and ModernBERT NLI mutual entailment (27.15), but attains only 59.16% on majority verification. This divergence stems from distinct generation strategies: prompt-engineered models (CUNI) generate concise, targeted answers that directly satisfy verifiers, whereas sequential fine-tuning (TUM-HEILBRONN) produces longer spans with substantial lexical overlap with gold answers, even when partially missing strict answer precision.

**Answerable Comprehension vs. Refusal Accuracy.** Table 7 reports performance dissected across the 6,912 answerable reading comprehension questions and the 1,728 unanswerable questions (where models are instructed to output a fixed refusal phrase) evaluated under the Gemma-4-31B-it judge across all 24 languages. Top participant systems (CUNI, LANIQO) balance strong comprehension ($\approx$74–80%) with strong refusal discipline ($\geq$97%).

**Non-Answerable Detection by Participant Probes.** The ability to correctly decline unanswerable questions varies substantially among participant submissions. TUM-HEILBRONN-PRIMARY (87.07% F1) and TEAMSPINOZA systems (86.40%–86.50% F1) excel on this dimension, demonstrating the efficacy of Spinoza's specialized answerability classification probe. Conversely, several models (e.g., SENTINEL-BASE at 55.91% and ALEIX-PRIMARY at 41.51%) struggle to reliably emit the exact instructed refusal phrase across diverse target scripts.

**Cross-Lingual and Low-Resource Disparities.** Performance breaks down starkly along language resource tiers (Tables 13 and 14). While top systems achieve 80–87% verification accuracy on high-resource European languages (English, German, Italian, Spanish), severe drops occur on low-resource and distant languages. Yoruba proves the most difficult (best Gemma-4-31B score of 41.7% by CUNI-PRIMARY, with many systems falling below 20%), followed by Kurdish (top score 64.7%). The surprise language, Bhojpuri, shows high accuracy for top systems (98.3% for CUNI-PRIMARY), demonstrating strong zero-shot cross-lingual transfer from Hindi data, but weaker systems exhibit steep degradation.

### 5.3 Open-Ended Generation

Based on LLM-as-a-verifier results, both systems from CUNI perform strongly and top the results, followed by Laniqo and Sentinel. Across the 24 target languages (Table 9), the two CUNI systems collectively capture the top score in every language: CUNI-VARIANT_B leads in 12 languages (excelling on non-Latin and mid-to-low-resource scripts such as Arabic at 92.4%, Bengali at 93.3%, and Kurdish at 78.7%), while CUNI-PRIMARY leads the other 12 (predominantly high-resource European and East Asian languages). Performance varies markedly across language resource tiers: Bhojpuri demonstrates strong zero-shot transfer from Hindi data, whereas Yoruba represents a universal bottleneck across all participant architectures (peaking at only 43.4% rules verified and falling below 3% for weaker submissions), alongside steep drops in Kurdish and Haitian Creole for smaller open models.

Language correctness exhibits a distinct pattern compared to rule-based LLM verification results, where the best results are obtained by LANIQO and SENTINEL, whereas CUNI underperforms several other submissions.

Finally, we compute ranking correlations between the earlier human evaluation and automatic LLM-as-a-verifier for primary systems in the OEG

| System | Maj↓ | Cmd-A+ | GLM-5.1 | Gemma4 | BLEU | chrF | R-L | COMET | CQE | NLI | LangID | NonAns |

**Table 7:** Ctx-QA breakdown: Answerable (reading comprehension) vs. Non-Answerable (refusal accuracy).

sub-task. It is worth noting that human evaluation only covered a subset of languages and questions, and the two evaluations asked annotators and LLMs fundamentally different questions. Nevertheless we observe that they display good to strong correlations, with Spearman's $\rho = 0.79$ and Kendall's $\tau = 0.62$. The only variations are local, among the top 3 systems, namely LANIQO, SENTINEL, and CUNI, whilst other systems are positioned the same according to both evaluations.

**Cross-Lingual Prompts** While most open-ended generation prompts require monolingual responses, 11 prompts in the benchmark explicitly instruct the model to produce its response in a different language (e.g., an Arabic prompt requesting a complaint letter in Swiss German, or a German prompt requesting text in Czech; $N$=245 strictly cross-lingual instances across 23 languages). Evaluating these instances reveals three key findings (Table 17):

- **Strong prompt-language inertia:** When systems fail to switch languages, they overwhelmingly remain trapped in the prompt's input language (>60% across many systems) rather than defaulting to English (≤2% across all systems).
- **Multi-stage pipelines struggle with prompt-internal constraints:** Systems that decoupled generation into modular stages struggled when the target language was defined only within the prompt text. Most notably, LANIQO's two-stage pivot strategy (which generates an intermediate English draft before rewriting into the target language) systematically produced outputs in the prompt's input language (94.7% inertia, 0.0% on-target), indicating that the second-stage rewrite targeted the document's language metadata rather than the constraint within the prompt. Similarly, SENTINEL's verification wrapper (24.1% on-target) checked language compliance against the input language and forced retries in that

**Table 9:** OEG breakdown: per-language results (LLM judge ensemble majority-vote rule pass rate (%), primary benchmark metric).

language. Looking at the overal language on-targetness in Table 8, it seems that this strategy ultimately paid off for the whole set, with these systems still being in the top.

- **Prompt engineering retains steerability:** Single-pass prompt-engineered models (CUNI-VARIANT_B at 89.0% and CUNI-PRIMARY at 81.6%) followed language-switch constraints with high fidelity, demonstrating that outer pipeline wrappers can inadvertently override an LLM's intrinsic instruction-following steerability. However, the overall language compliance of these systems was lower than the multi-stage ones.

### 5.4 Cross-lingual Summarization

Table 10 presents evaluation results for cross-lingual summarization across all 24 target languages. The official benchmark ranking is governed by **Language-Gated ROUGE-L** (G-R-L), which assigns zero credit to summaries failing language identification. Fluency judgments from an LLM verifier are presented in Table 19.

**System Performance.** LANIQO-VARIANT_A achieves the highest gated ROUGE-L (17.55%) and NLI mutual entailment (9.12%), followed closely by CUNI-VARIANT_B (17.41% G-R-L, 38.0% G-chrF++, 81.98 COMET) and LANIQO-PRIMARY (16.95% G-R-L, 99.8% LangID). On neural MT metrics, CUNI-VARIANT_B and CUNI-PRIMARY attain the strongest semantic fidelity (81.98 and 81.54 COMET, respectively). TEAMSPINOZA-PRIMARY achieves third place according to the LLM-as-a-verifier that checks language adherence and fluency, however, it is penalized by the reference-based Rouge-L.

**Knowledge Distillation and Script Adherence.** LANIQO-PRIMARY's full fine-tuning with teacher distillation from Gemma-4-31B paired with pivot decoding yields the most robust language adherence across the benchmark (99.8% LangID). This proves decisive on challenging low-resource scripts such as Bhojpuri, where LANIQO-PRIMARY generates fluent target-language text (98.6% LangID) while most other systems fail completely, often falling below 35% LangID.

| System | G-R-L↓ | G-chrF | Raw R-L | Raw chrF | R-1 | R-2 | BLEU | COMET | CQE | NLI-ME | NLI-F | LangID |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Laniqo-variant_A | **17.55** | 34.5 | **19.23** | 34.5 | 32.88 | 9.95 | **6.5** | 77.88 | 60.51 | **9.12** | 19.54 | 98.5 |
| CUNI-variant_B | 17.41 | **38.0** | 18.93 | **38.3** | **34.98** | **10.05** | **6.5** | **81.98** | **63.54** | 8.84 | 19.63 | 97.5 |
| Laniqo-primary | 16.95 | 37.8 | 18.51 | 37.8 | 34.51 | 9.74 | 6.4 | 81.05 | 61.06 | 7.83 | 16.69 | **99.8** |
| PSK-primary | 15.66 | 28.1 | 17.30 | 28.1 | 30.07 | 7.51 | 4.2 | 75.12 | 58.45 | 8.28 | 17.75 | 98.1 |
| CUNI-primary | 14.71 | 35.4 | 16.35 | 35.8 | 32.02 | 7.94 | 5.0 | 81.54 | 62.88 | 8.59 | 16.72 | 93.6 |
| Sentinel-primary | 14.11 | 35.0 | 15.44 | 35.0 | 29.39 | 7.60 | 4.6 | 79.34 | 61.49 | 8.43 | 18.93 | 95.5 |
| Sentinel-base | 14.11 | 35.0 | 15.44 | 35.0 | 29.39 | 7.60 | 4.6 | 79.34 | 61.49 | 8.43 | 18.93 | 95.5 |
| Sentinel-RunB | 13.44 | 27.6 | 14.79 | 27.6 | 26.27 | 6.26 | 3.6 | 72.72 | 58.88 | 7.60 | 19.03 | 95.9 |
| TUM-Heilbronn-primary | 12.50 | 22.4 | 14.58 | 25.8 | 24.65 | 6.91 | 4.4 | 70.34 | 61.43 | 8.10 | 29.87 | 75.3 |
| TeamSpinoza-Variant_sum-verifier3 | 12.33 | 28.3 | 13.73 | 28.3 | 25.64 | 5.31 | 3.1 | 73.58 | 58.46 | 7.49 | 14.18 | 94.5 |
| Aleix-variant_A | 12.06 | 22.6 | 13.67 | 23.3 | 23.48 | 5.90 | 3.4 | 66.85 | 58.39 | 8.17 | 23.17 | 87.7 |
| TeamSpinoza-Variant_V4 | 10.87 | 18.2 | 12.12 | 18.3 | 19.97 | 5.44 | 2.6 | 63.78 | 53.19 | 7.60 | 20.97 | 93.4 |
| Aleix-primary | 8.85 | 15.9 | 10.56 | 18.0 | 17.77 | 4.56 | 2.4 | 58.79 | 57.76 | 8.18 | 34.70 | 66.9 |
| Aleix-variant_B | 7.81 | 17.0 | 10.38 | 22.9 | 18.02 | 4.63 | 3.0 | 64.50 | 62.66 | 8.05 | **39.12** | 52.1 |
| TeamSpinoza-primary | 7.42 | 9.8 | 8.42 | 9.9 | 12.38 | 3.29 | 0.8 | 54.80 | 47.51 | 8.95 | 21.62 | 92.1 |

**Table 10:** Sum automatic evaluation results across all 24 target languages.

## 6 Rankings and Discussions

### 6.1 Overall Ranking

Table 11 presents an overall cross-task ranking of all participant systems across the three subtasks, based on automatic evaluation. Each system's overall rank is computed as the mean of its per-task ranks, where per-task ranking follows the primary benchmark metric: LLM ensemble majority-vote accuracy for Ctx-QA and OEG, and Language-Gated ROUGE-L F1 for Summarization.

**Overall Ranking Based on Automatic Evaluation.** CUNI-VARIANT_B achieves the top overall rank (mean rank 1.67), with remarkably consistent performance: #2 in Ctx-QA, #1 in OEG, and #2 in Summarization. CUNI-PRIMARY (mean rank 2.67) wins Ctx-QA but drops to #5 in Summarization. LANIQO-PRIMARY (mean rank 3.00) is the most balanced system, placing #3 across all three tasks.

LANIQO-VARIANT_A (mean rank 4.00) wins the Summarization track (G-R-L 17.55) and places #4 in Ctx-QA but drops to #7 in OEG. SENTINEL-BASE rounds out the top five (mean rank 6.00), with particular strength in OEG (#4).

**Individual Sub-Task Winners**

- **Context-based Question Answering:** CUNI-PRIMARY (81.63% Maj)
- **Open-Ended Generation:** Based on human evaluation, the first three places belong to LANIQO-PRIMARY, SENTINEL-PRIMARY, and CUNI-PRIMARY, respectively. According to automatic evaluation, CUNI-VARIANT_B takes the lead with 88.45% ensemble verification.
- **Summarization:** LANIQO-VARIANT_A (17.55 G-R-L)

**Most Truthful System.** TUM-HEILBRONN-PRIMARY achieves the highest Non-Answerable F1 score (87.07%), demonstrating the strongest refusal accuracy and lowest hallucination rate on unanswerable questions, followed closely by TEAMSPINOZA-VARIANT_V4 (86.50%) and TEAMSPINOZA-PRIMARY (86.40%).

**Most Equitable System.** LANIQO demonstrates the most uniform cross-lingual performance under human evaluation (Section 4), maintaining the benchmark's lowest cross-lingual variance ($\sigma = 0.37$), the highest worst-case score floor (4.93 in Bhojpuri), and never falling below rank 4 across all 14 languages. Under automatic metrics across all 24 languages, CUNI-VARIANT_B also exhibited remarkable consistency, achieving a minimax rank of 3 (with English being its relative weakness).

### 6.2 Insights

**Post-editing effort is necessary for realistic benchmarking.** We initially intended post-editing purely as a quality assurance step, however, it is in itself a valuable signal of the disparity in language representation. After discussions with the annotators, we realized that the time and effort needed to post-edit each language largely varied even though we used state-of-the art LLMs to perform the translation/localization and despite most prompts being relatively simple. This highlights that we cannot expect to reach truly multilingual models by simply translating benchmarks (Chen et al., 2024).

**Monolingual QA has a higher accuracy than answering a non-English question about a passage in English.** Constructing the Context QA test set with redundant questions paired with different language mutations of the same passage allowed us to examine the effect of passage-question language pairing on the accuracy of the answers. As shown

| Overall Rank | System | Mean Rank | Ctx-QA Rank | OEG Rank | Sum Rank | Ctx-QA Maj (%) | OEG Maj (%) | Sum G-R-L |
|---|---|---|---|---|---|---|---|---|
| 1 | CUNI-variant_B | 1.67 | #2 | #1 | #2 | 80.93 | **88.45** | 17.41 |
| 2 | CUNI-primary | 2.67 | #1 | #2 | #5 | **81.63** | 82.25 | 14.71 |
| 3 | Laniqo-primary | 3.00 | #3 | #3 | #3 | 76.90 | 76.27 | 16.95 |
| 4 | Laniqo-variant_A | 4.00 | #4 | #7 | #1 | 69.80 | 64.26 | **17.55** |
| 5 | Sentinel-base | 6.00 | #7 | #4 | #7 | 59.58 | 72.47 | 14.11 |
| 6 | PSK-primary | 7.33 | #10 | #8 | #4 | 51.70 | 63.65 | 15.66 |
| 7 | Sentinel-primary | 7.33 | #11 | #5 | #6 | 50.84 | 65.43 | 14.11 |
| 8 | Sentinel-RunB | 8.67 | #12 | #6 | #8 | 50.84 | 65.43 | 13.44 |
| 9 | TUM-Heilbronn-primary | 9.00 | #8 | #10 | #9 | 59.16 | 60.48 | 12.50 |
| 10 | TeamSpinoza-Variant_V4 | 9.67 | #6 | #11 | #12 | 61.96 | 57.79 | 10.87 |
| 11 | Aleix-variant_B | 10.67 | #9 | #9 | #14 | 57.08 | 62.37 | 7.81 |
| 12 | TeamSpinoza-primary | 11.33 | #5 | #14 | #15 | 67.50 | 47.91 | 7.42 |
| 13 | Aleix-variant_A | 12.33 | #13 | #13 | #11 | 45.73 | 53.66 | 12.06 |
| 14 | Aleix-primary | 13.00 | #14 | #12 | #13 | 34.73 | 55.73 | 8.85 |
| 15 | TeamSpinoza-Variant_sum-verifier3 | 13.33 | #15 | #15 | #10 | 17.22 | 23.55 | 12.33 |

**Table 11:** Overall ranking based on automatic evaluation. Systems ranked by the mean of per-task ranks.

in Table 15 in the appendix, most systems had a higher accuracy in a monolingual setting (i.e. passage and question in the same language) compared to cross-lingual from English. Moreover, the accuracy further drops if neither of the languages is English.

## 7 Conclusion

In this paper, we presented the findings of the WMT26 Shared Task on Multilingual Instruction Tuning (MIST). Focusing squarely on open-weight language models within an accessible $\leq$10B parameter budget, MIST established a standardized, multi-faceted benchmark across 24 typologically diverse languages and three core sub-tasks: context-based question answering, multi-constraint open-ended generation, and cross-lingual scientific summarization. Across submissions from eight participating teams and six organizer baselines, our findings provide several key insights into the current state and limits of multilingual instruction following in compact models:

**Modeling Strategies and Empirical Trade-offs.** Task-specific adaptation proved essential: untuned open-weight baselines suffered from pervasive hallucinations and poor refusal discipline, whereas tailored participant submissions substantially closed the gap to frontier capabilities. Notably, structured system prompting and reasoning (CUNI) achieved top verification accuracy on context QA and constraint satisfaction in open-ended generation, while teacher distillation and full fine-tuning (LANIQO) provided unmatched target-script adherence and led in human-assessed fluency. Furthermore, specialized inference-time mechanisms, such as TEAMSPINOZA's answerability probe, demonstrated that isolating answerability classification from text generation effectively bounds non-answerable hallucinations. Conversely, standard supervised fine-tuning optimized for lexical overlap (TUM-HEILBRONN) produced verbose generations with high surface overlap (BLEU/ROUGE) but reduced precision under strict verifiers, highlighting the decoupling between n-gram metrics and functional instruction compliance.

**Cross-Lingual Gaps and Language Gating.** Our benchmark reveals that compact models are not yet universal polyglots. While top systems attain 80–87% verification accuracy on high-resource European languages, performance drops steeply on distant and low-resource targets (e.g., falling below 42% in Yoruba and remaining challenging in Kurdish). Encouragingly, the surprise evaluation on Bhojpuri demonstrated robust zero-shot cross-lingual transfer from Hindi data for leading systems. In cross-lingual summarization, our results underscore the necessity of language-gated evaluation: without explicit penalties for language drift, models frequently default to English leakage, fundamentally failing the cross-lingual objective.

**Human Evaluation and the Instruction-Following Bottleneck.** Human evaluation across 14 languages shows that within the top cluster, target-language fluency (Naturalness 5.51–5.74 and Coherence 5.59–5.68) is tightly grouped. Instead, complex, multi-constraint *Instruction Following* serves as the primary differentiator, exhibiting a spread of 1.67 points across all

systems (3.69–5.36). Moreover, multi-judge LLM verifier panels displayed strong agreement with human rankings, affirming the viability of automated majority-vote verifiers for reproducible multilingual benchmarking.

All test suites, localized prompts, system outputs, baselines, human annotation rubrics, prompts, and evaluation code are publicly released. We hope these resources will help in measuring the usefulness of large language models across multiple languages and consequently their improvement.

## 8 Limitations

Unfortunately, we were not able to perform human evaluation for all tasks. Given that both context-based questioning and summarization have references, we opted to focus on evaluating open-ended generation. We do acknowledge that especially for summarization, reference-based evaluation might not be the best given that there are multiple valid ways of summarizing a paper that can diverge from the provided reference.

## 9 Acknowledgements

We thank all participants, without whom the task would not be so fruitful.

We also extend our heartfelt gratitude to many people for reviewing and post-editing instructions. They are: Adam Gaber, Ahrii Kim, Aina Garí Soler, Ayodele Awokoya and her students, Danti Ramadanti, Eduardo Calo, Erica Cooper, Hale Sirin, Koel Dutta Chowdhury, Leo Leppänen, Nalin Kumar, Nathaniel Robinson, Nazanin Shafiabadi, Peter Polák, Sina Ahmadi, and Sonal Joshi. Sincerely, thank you once again for making MIST possible.

We are immensely grateful to our sponsors Toloka and Voice Arena for supporting our human evaluation. Thank you for helping us make sure that NLP improvements are actually helpful to humans across many languages.

The evaluation pipeline for 10 languages was co-designed with an AI coding assistant provided by the Toloka platform; the human authors specified the task, reviewed every intermediate configuration, and are responsible for all final design decisions.

Vilém Zouhar gratefully acknowledges the support of the Google PhD Fellowship.

Patrícia Schmidtová is supported by Charles University projects GAUK 252986 and SVV 260 698 and co-funded by the European Union (ERC, NG-NLG, 101039303).

Part of this work is funded by the European Union's Horizon research and innovation programme under grant agreement No 101135798, project Meetween (My Personal AI Mediator for Virtual MEETings BetWEEN People).

# A Prompt Templates

This section provides the full set of prompts used across the three sub-tasks of the WMT26 Shared Task on Multilingual Instruction Tuning (MIST), as well as the prompts used for LLM-as-a-judge automatic evaluation.

## A.1 Context-based Question Answering (QA-Context)

In the context-based QA sub-task, models receive a background passage in an assigned source language alongside a question and instruction framed in a target language. The prompt requires a concise, single-sentence response grounded strictly in the provided text. When the requested information is absent, models are instructed to output that the question cannot be answered (e.g., "not answerable" in English).

**Benchmark Task Prompt (English)** The standard English prompt template is given below:

```
I have a question about this passage:

{passage}

The question is: {question}

Could you please answer in one sentence, using only
    what the passage says? If the passage doesn't
    give the answer, just write "not answerable".
    Please answer in English.
```

## A.2 Open-Ended Generation (OEG)

The open-ended generation sub-task includes 100 manually authored English seed prompts spanning three functional categories:

1. **General:** Creative, reflective, or reasoning tasks without specific geographical grounding.
2. **Factual:** Knowledge retrieval, structured summaries, and multi-step explanations.
3. **Language/Location-specific:** Tasks targeting linguistic conventions, local customs, or regional institutions, parameterized using `{language}` and `{country}` placeholders.

**Representative Seed Prompt Examples** Below are illustrative examples from each category:

- **General (Constraint: 150 words):**

  *"Draft a 150-word description of a technological advancement that excites or concerns you, explaining how it works, its potential impacts on society, and your thoughts on its ethical implications or benefits."*

- **Factual (Constraint: Metaphorical framing):**

  *"Explain quantum entanglement using only cooking metaphors."*

- **Language-specific (Parameterized):**

  *"How are diminutives typically formed in `{language}`? Provide 3 examples with English translations."*

- **Location-specific (Constraint: 160 words):**

  *"Compose a 160-word text describing a local business or establishment that you value in your community, explaining what they offer, why you choose to support them, and what role they play in the character or vitality of your neighborhood."*

## A.3 Cross-Lingual Scientific Summarization (Sum-Sum)

For the cross-lingual summarization sub-task, models read a full scientific paper from ACL 2026 in English and generate an abstract in the target language. To prevent evaluation artifacts tied to a single prompt phrasing, each instance is paired with one of five paraphrased prompt templates, assigned uniformly at random.

**Paraphrased Prompt Template** Each instance is paired with one of five paraphrased prompt templates, assigned uniformly at random. A representative prompt template is:

```
The following is the full text of an *ACL paper in
    English. Write the paper's abstract in around
    200 words, using formal third-person academic
    prose.

PAPER:
{paper}

Output the abstract only, without any reasoning,
    explanation, or additional text.
```

The full set of five paraphrased prompt variants is available in the shared task repository.

# B Post-Editing Distance and Human Effort

Table 12 reports the detailed post-editing distance metrics between the original machine translations (predominantly GPT-5.5) and the finalized human post-edited test prompts across all 23 non-English target languages, evaluating all $N = 100$ prompts per language ($N = 59$ for Yoruba). We evaluate human correction effort using six complementary metrics:

- **% Unchanged (% Unch.):** The percentage of prompt instances accepted completely verbatim with zero human edits.

- **chrF:** Tokenization-independent character $n$-gram F-score ($n = 6$, $\beta = 2$), which robustly captures subword and morphological preservation across diverse alphabetic, abjad, and logographic scripts.
- **BLEU:** Corpus-level BLEU score computed against the post-edited gold references.
- **EditDist:** The mean character-level Levenshtein edit distance per prompt (minimum character insertions, deletions, and substitutions).
- **CER (%):** Character Error Rate, computed as $100 \times \frac{\sum \text{Levenshtein}(h,r)}{\sum |r|}$.
- **TER:** Translation Edit Rate (HTER) measuring normalized word-level edits (insertions, deletions, substitutions, and phrase shifts).

As shown in Table 12, the results highlight clear distinctions in translation difficulty and editing intensity:

- **Easy (Minimal post-editing):** For high-resource and morphologically well-supported languages, the initial translations were almost universally adopted as-is. Arabic had 98.0% unchanged prompts (chrF 99.8, BLEU 99.6), where annotators accepted fluent Modern Standard Arabic (MSA) phrasing without seeking dialectal or stylistic alterations. Similarly, Hindi (94.0% unchanged, chrF 99.5), Indonesian (91.0% unchanged), German (88.0%), Portuguese (85.0%), and Russian (85.0%) required minimal human intervention.

- **Frequent but Low-Intensity Edits (Morphological and Stylistic Tuning):** Slavic languages such as Czech (35.0% unchanged) and Slovak (37.0% unchanged) had approximately 63–65% of sentences modified by annotators. However, their editing intensity was remarkably low: CER remained below 4.0% (2.6% for Czech, 3.9% for Slovak) and chrF exceeded 95.5. Analysis of the diffs confirms that these edits consisted predominantly of subtle inflectional refinements, diacritic adjustments, and formal polite phrasing rather than structural rewrites.

- **Difficult and High-Intensity Edits:** Haitian Creole presented the greatest post-editing difficulty, with only 8.0% of prompts accepted verbatim, a CER of 22.6%, and a TER of 29.1, requiring comprehensive human retranslation. Kurdish likewise demanded extensive editing (15.0% unchanged, CER 21.0%, TER 27.0). Persian (Farsi) also proved particularly challenging (44.0% unchanged, CER 16.1%, TER 21.5).

**Reproducibility and Metric Parameters** All lexical and edit metrics were computed using `sacrebleu` (Post, 2018) version `2.5.1`. For full reproducibility, the metric signatures and parameter configurations are as follows:

- **BLEU:** `nrefs:1|case:mixed|eff:no|tok:13a|smooth:exp|version:2.5.1` (with `tok:zh` for Chinese; for Japanese, unsegmented `13a` yields 77.5, whereas character-level tokenization yields 93.7, consistent with its 94.3 chrF).
- **chrF:** `nrefs:1|case:mixed|eff:yes|nc:6|nw:0|space:no|version:2.5.1`
- **TER:** `nrefs:1|case:lc|tok:tercom|norm:no|punct:yes|asian:no|version:2.5.1`
- **Levenshtein & CER:** Minimum character-level edit distance computed via dynamic programming, normalized by total reference character length.

## C Human Evaluation Setup Details

**Toloka Campaign** On the Toloka crowdsourcing platform, the evaluation pipeline was designed and deployed with the assistance of an AI agent integrated into the Toloka platform environment, which generated initial pipeline configurations, quality-control criteria, and training materials, iteratively refined in collaboration with the organizers who reviewed and approved all final pipeline parameters.

**Task and Data Flow.** The pipeline evaluated OEG outputs across 10 diverse languages: Arabic (arb), Chinese (zho), German (deu), English (eng), Indonesian (ind), Italian (ita), Japanese (jpn), Korean (kor), Russian (rus), and Spanish (spa). For each language, 70 prompts were paired with 6–7 anonymized system responses, yielding 700 items in total. A language-based filtering was deployed, ensuring that evaluators only accessed tasks in their qualified language. Annotators evaluated responses on the 7-point calibrated scale (*poor* → *poor/flawed* → *flawed* → *flawed/good* → *good* → *good/great* → *great*) across the three dimensions.

**Annotator Pool and Onboarding.** We restricted recruitment exclusively to Toloka's *Verified Experts*

| Language | N | % Unch. | chrF | BLEU | EditDist | CER (%) | TER |
|---|---|---|---|---|---|---|---|
| Arabic | 100 | 98.0% | 99.8 | 99.6 | 0.1 | 0.1% | 0.2 |
| Bengali | 100 | 83.0% | 97.6 | 96.7 | 2.9 | 2.0% | 2.1 |
| Bhojpuri | 100 | 43.0% | 93.0 | 88.5 | 10.8 | 7.7% | 8.7 |
| Chinese (Simplified) | 100 | 76.0% | 95.8 | 97.0 | 1.4 | 3.0% | 21.1 |
| Czech | 100 | 35.0% | 95.5 | 87.6 | 3.5 | 2.6% | 7.4 |

| Turkish | 100 | 65.0% | 97.7 | 94.5 | 2.8 | 2.0% | 3.6 |
| Vietnamese | 100 | 45.0% | 91.3 | 87.9 | 14.4 | 9.3% | 10.1 |
| Yoruba | 59 | 69.5% | 94.8 | 92.8 | 3.5 | 3.1% | 5.0 |
| **Macro Average** | – | 64.4% | 94.3 | 89.7 | 6.9 | 5.1% | 8.5 |

**Table 12:** Post-editing distance between initial machine translations and final post-edited prompts across all 23 non-English target languages for the OEG sub-task. *Japanese BLEU is reported using standard sacrebleu `13a` tokenization (character-level BLEU is 94.6).

pool: annotators who have passed platform-level identity verification and language proficiency examinations. Per-node language filters ensured that only native or near-native speakers accepted tasks.

Before accessing production tasks, annotators completed a mandatory 6-step training course. The curriculum provided detailed expositions of the three dimensions, calibration anchor points, and critical edge cases. In particular, because responses were pre-truncated to approximately 400 words (marked by `[TRUNCATED]`) to bound task duration to 5–8 minutes, annotators were instructed to apply a two-sided truncation policy: truncation must not penalize Naturalness or Coherence, but must penalize Instruction Following if the original prompt explicitly specified a length constraint shorter than the pre-truncation cap. Annotators passed two quiz gates and reasoning-aloud practice tasks before admission, with onboarding compensation contingent on approved production work.

**Quality Assurance.** Quality control operated in a `human_only` QA mode with 10% smart sampling: 10% of production submissions were randomly routed to an independent human reviewer (also a Verified Expert) who evaluated submissions against internal rating consistency, completeness, and adherence to the truncation policy. Rejected tasks were re-routed to fresh annotators.

**VoiceArena Indic Language Campaign.** In parallel, VoiceArena conducted human evaluation for four Indic languages—Bengali (`ben`), Bhojpuri (`bho`), Hindi (`hin`), and Marathi (`mar`)—recruiting native annotators directly on their dedicated platform. The annotation protocol, user interface, and evaluation guidelines directly reflect the 10-language Toloka evaluation, employing the identical 7-point calibrated scale across Instruction Following, Naturalness, and Coherence.

## D Per-Language Results for Submitted Systems

This section provides comprehensive per-language breakdowns across all 24 benchmark languages for the participant submissions on each of the three evaluation tasks.

### D.1 Context-based QA Per-Language Performance

Tables 13 and 14 report per-language verification accuracy for participant systems and organizer baselines evaluated by Gemma-4-31B and GLM-5.1 verifiers, respectively.

| System | ar | bn | bh | cs | ku | de | en | fi | ht | hi | id | it | ja | ko | mr | fa | pt | ru | sk | es | tr | vi | yo | zh | Avg |

**Table 14:** Ctx-QA: GLM-5.1 verification accuracy per language across submitted systems. Best per column in **bold**.

### D.2 Monolingual vs. Cross-Lingual QA Performance

Table 15 details verification accuracy comparing monolingual instances ($L_q = L_p$) against cross-lingual instances ($L_q \neq L_p$) across submitted systems and organizer baselines, evaluated by the Gemma-4-31B verifier. We also report directional cross-lingual breakdowns (synthesizing foreign contexts into English, transferring English contexts into foreign target languages, and cross-lingual synthesis between two non-English languages) alongside accuracy broken down by passage context resource tier ($P_{\text{High}}$, $P_{\text{Mid}}$, $P_{\text{Low}}$).

### D.3 Open-Ended Generation (OEG)

Table 16 reports per-language Gemma-4-31B rule pass rates across all 24 target languages for the submitted systems and organizer baselines.

We also report the language confusion in the strictly cross-lingual OEG instances in Table 17.

### D.4 Cross-Lingual Summarization (Sum-Sum)

Table 18 displays per-language ROUGE-L F1 scores across all 24 languages for the submitted summarization systems.

## E Organizer Baseline Results

Since baselines were evaluated with a single LLM verifier (Gemma-4-31B-it) rather than the full multi-judge ensemble used for participant submissions, we report their results separately. Table 20 presents the cross-task comparison including all six baselines alongside participant systems, ranked by mean Gemma-4-31B verification score. Per-language baseline breakdowns for QA and OEG are included in the per-language tables in Sections D.1 and D.3.

## F Human Evaluation Guidelines

This section reproduces the exact annotation guidelines and instructions provided to human evaluators for the Open-Ended Generation (QA-OEG) evaluation campaign.

### F.1 Task Overview and Instructions

Annotators were presented with the following task instructions:

> In this task, you will evaluate a chatbot's response to a user's request in `{{language}}`. You will evaluate the response using the following quality dimensions:

| System | Overall | Language Pairing | | | Cross-Lingual Direction | | | Passage Resource Tier | | |
|---|---|---|---|---|---|---|---|---|---|---|
| | | Same | Diff | Gap | Into-Eng | From-Eng | Foreign-2-Foreign | High | Mid | Low |
| CUNI-PRIMARY | **80.1** | 83.7 | **80.0** | 3.8 | **85.3** | **84.9** | **77.8** | **83.6** | **75.8** | **74.3** |
| CUNI-VARIANT_B | 79.3 | 83.5 | 79.1 | 4.4 | 82.3 | 84.6 | 76.7 | 83.4 | 76.2 | 66.8 |
| LANIQO-PRIMARY | 75.4 | 80.9 | 75.2 | 5.7 | 78.6 | 80.9 | 72.7 | 80.0 | 71.6 | 62.8 |

**Table 16:** QA-OEG: Gemma-4-31B rule pass rate per language across submitted systems and organizer baselines. Best per column in **bold**.

- **Instruction Following:** How well the chatbot followed all of the user's instructions. Note that a single request can have multiple instructions.
- **Naturalness:** The degree to which the chatbot's response appears to be fluent, natural text in `{{language}}`, that is appropriate to the request in terms of tone and formality.
- **Coherence:** How well the entire response is logically sound and internally consistent.

### F.2 Rating Scale and Slider Interface

Annotators provided separate ratings for each dimension on a continuous scale from **Poor** to **Great**: You will provide a separate rating for each dimension on a scale from Poor to Great. There are 7 different values you can select using buttons, consisting of 4 labeled "landmark" ratings (Poor, Flawed, Good, Great; descriptions provided below) and 3 "in-between" ratings (Poor/Flawed, Flawed/Good, Good/-Great).

Note that the default value "N/A" is not a valid rating; you must select a rating on each slider before the task can be submitted.

Also note that the user's request may contain typos or other grammatical problems; these should not affect your rat-

### F.3 Detailed Landmark Rubrics

The detailed landmark definitions presented to annotators for each of the three dimensions were as follows:

#### F.3.1 Instruction Following

- **Great:** The response fully adheres to all instructions that the user provided.
- **Good:** The chatbot mostly followed the instructions, conforming to the main points of the request but missing some details.
- **Flawed:** The chatbot followed only a small portion of the instructions or missed important points.
- **Poor:** The chatbot entirely disregarded the instructions; the response appears to have no relation to the user's request.

#### F.3.2 Naturalness

- **Great:** The response represents fluent `{{language}}` text that might have been written by a native human speaker, and appropriately matches the tone and formality of the request.
- **Good:** The response has some disfluencies that are noticeable but don't significantly hinder understanding the response, or the tone/formality is somewhat inappropriate to the request.
- **Flawed:** The response is highly disfluent. There are several grammatical errors, or some of the output is not in `{{language}}`. Most of the meaning can be determined, but only with conscious effort. Alternatively, the tone or formality of the response is drastically and inappropriately different from that of the request.
- **Poor:** The response is incomprehensible, or a significant amount is not in `{{language}}`.

| Submission | LLM-as-a-verifier | | | Average↓ |
|---|---|---|---|---|
| | Cmd-A+ | Gemma | GLM | |
| CUNI-variant_B | 0.709 | 0.794 | 0.711 | 0.738 |
| Laniqo-primary | 0.654 | 0.760 | 0.700 | 0.705 |
| TeamSpinoza-primary | 0.572 | 0.704 | 0.702 | 0.659 |
| Laniqo-variant_A | 0.579 | 0.726 | 0.662 | 0.656 |
| TeamSpinoza-Variant_V4 | 0.570 | 0.681 | 0.640 | 0.630 |
| CUNI-primary | 0.672 | 0.578 | 0.513 | 0.588 |
| Sentinel-primary | 0.602 | 0.637 | 0.516 | 0.585 |
| Sentinel-base | 0.593 | 0.637 | 0.519 | 0.583 |
| Sentinel-RunB | 0.555 | 0.608 | 0.484 | 0.549 |
| TUM-Heilbronn-primary | 0.524 | 0.539 | 0.474 | 0.512 |
| Aleix-variant_A | 0.541 | 0.490 | 0.416 | 0.482 |
| Aleix-primary | 0.413 | 0.414 | 0.341 | 0.389 |
| TeamSpinoza-Variant_sum-verifier3 | 0.388 | 0.367 | 0.252 | 0.336 |
| PSK-variant_B | 0.361 | 0.393 | 0.237 | 0.331 |
| PSK-primary | 0.356 | 0.390 | 0.236 | 0.328 |
| PSK-variant_A | 0.353 | 0.391 | 0.234 | 0.326 |
| Aleix-variant_B | 0.360 | 0.331 | 0.275 | 0.322 |

**Table 19:** Summarization LLM-as-a-verifier target language adherence and grammatical fluency pass rates across Command A+, Gemma, and GLM verifiers.

#### F.3.3 Coherence

- **Great:** The response is logically sound and appropriately structured with a clear sequence of nicely connected ideas and topics with no leaps in reasoning.
- **Good:** The response is generally well-structured and has a generally clear overall progression of ideas, but introduces a few logical gaps, or suddenly switches topics without an appropriate transition.
- **Flawed:** The response lacks an overall flow, and/or has multiple noticeable jumps between topics. It is possible to discern some relevant ideas, but the overall purpose of the response is incoherent.
- **Poor:** The response has no overall structure, is in no way logically sound, and/or can be divided into many mostly-unrelated sections. It is difficult to identify any points the text is trying to make.

| Rank | System | Type | QA-Context | OEG | Sum | Mean Score |

## Abstract

The WMT26 Terminology Translation Task aims to evaluate machine translation in high-stakes, term-heavy domains (technology, finance, medicine). This year, we focus solely on document-level translation and run two tasks: (1) MT with explicit document-level dictionaries, (2) MT with bitext samples that contain the specific terms. Participants are presented with the texts in three translation directions, two of which feature mid-to-low-resourced morphologically rich languages: Spanish→Basque, English→Polish, and Traditional Chinese→English. This year, the main metrics were multiple variants of overall translation quality and terminology success rate; in line with previous shared tasks, we also compared systems with no terminology, proper dictionaries, and random dictionaries to causally analyze terminology utility. 17 teams participated in our task, submitting 21 systems to Track 1 and 18 systems to Track 2. The results show that document-level translation with explicit dictionaries is close to saturation, and the best systems nearly reach the reference texts. In contrast, for translation with sample bitexts, the spread of the systems is bigger, and the best scores are lower, highlighting the need to concentrate on terminology extraction rather than its use from an explicit source. We also evaluate the grammaticality of the generated texts in Basque and Polish and observe slight trends toward using dictionary forms of the terms and assigning the most frequent grammemes.

## 1 Introduction

In the AI era, one calendar year often feels like many more. The terminology machine translation (MT) field is no exception: we can see papers on terminology-aware translation at EMNLP 2025 (Shen et al., 2025; Berger et al., 2025; Oncevay et al., 2025a; Menis Mastromichalakis et al., 2025), the more recent EACL (Abela et al., 2026) and ACL (Hasan et al., 2026; Di Rosa, 2026), as well as a specialized terminology MT shared task at the Workshop on Natural Language Processing for Turkic Languages (Gebeşçe et al., 2026). These facts together highlight the main urgencies of terminology-aware MT nowadays: the need to benchmark the abundance of the emerging solu-

October 28-29, 2026 ©2026 Association for Computational Linguistics

tions on multiple languages, especially when it comes to less resourced and typologically diverse languages.

Contrary to Waters et al. (1973, 2:55), we can't afford to say that there is time to kill today. Therefore, we altered the pattern of the WMT Terminology Shared Task from every other year (Alam et al., 2021; Semenov et al., 2023, 2025) to a yearly event. This time, in addition to English, we have included Basque and Polish as the target languages, representing different linguistic families and various levels of available data resources.

Building on last edition's findings showing that sentence-level benchmarks are approaching saturation, this edition shifts entirely to document-level translation. Additionally, we investigate whether translation systems can maintain terminology compliance without having access to an explicit bilingual dictionary. To contrast explicit term injection against implicit term discovery, the shared task features two tracks:

- **Track 1 (Document MT with Explicit Dictionaries):** Systems translate full documents given domain terminology glossaries, requiring contextual term selection and target inflection.
- **Track 2 (Document MT with Sentence Samples):** Systems receive no explicit term dictionaries; instead, they are provided with a minimal sample (~10%) of reference bitexts from the same collection to extract and enforce domain terminology on the fly.

To isolate the causal impact of terminology resources from generic reference leakage, systems in Track 1 are evaluated across three terminology modes (**No Term**, **Proper Term**, and **Random Term**) (Zouhar, 2023; Semenov et al., 2023), while Track 2 compares performance under **No Term** and **Sample** modes. The shared task attracted broad participation, receiving 27 submissions from 17 teams (21 systems in Track 1 and 18 in Track 2). Analysis of these submissions yields five key findings:

- **LLMs and Agents Lead:** Top-performing systems on the Pareto frontier feature LLM-based pipelines and multi-agent workflows.
- **Explicit Terms vs. Raw Bitexts:** Explicit dictionaries (Track 1) increase term success by 26.4 points on average with a 1.57 chrF++ gain in quality. Sample bitexts (Track 2) yield larger quality gains (+2.95 chrF++) by transferring style and domain phrasing, but yield smaller term success gains (+14.6 points).
- **Term Discovery Remains Unsolved:** While top systems in Track 1 reach near-saturation in term success rate, Track 2 exhibits roughly twice the performance spread across systems, showing that discovering terms without explicit glossaries still proves challenging.
- **Metric Blind Spots and Judge Instability:** Neural MT metrics penalize incorrect dictionary usage in Random mode but remain mostly insensitive to proper terminology adoption. Furthermore, reference-free LLM judges exhibit high false-positive error rates (40.3% overall) on human references due to output-discipline failures, frequently emitting error spans for terms they acknowledge in their explanations to be correct.
- **Grammatical yet Statistically Different Term Inflection:** In Basque and Polish, the systems produce grammatically correct and coherent sentences; however, the distributions of the grammemes slightly differ from the ones in the reference texts, concentrating around the dictionary forms or the constructions from the higher-resourced languages.

      "], "[...]"},
"random": {"elemento": ["elementu"], "caja": ["kaxa"],
      "[...]"}
}
```

Listing 1: A Spanish→Basque example from Track 1.

## 2 Task Description

The last two shared task editions, despite covering multiple languages and domains, lacked intercomparability: Semenov et al. (2023) had fiction texts for one of the translation pairs; while Semenov et al. (2025) featured non-overlapping language and domain pairs for two competition tracks. This year, we tried to fix this by including the same domain areas for two out of the three translation pairs. Moreover, we finally moved into the area of less-resourced, morphologically rich languages: Basque and Polish. Finally, we stuck to the multi-track competition from last year, but reconsidered the content of the two tracks, changing them to

```
Test:
{
"es": "[...] Por ejemplo, los cepillos en que el movimiento
      recíprocamente de la corredera se produce por medio de
      manivela y perno, principalmente en el engranaje, en el
       movimiento de la máquina, reciben el nombre de
      cepillos de manivela. [...]"

"eu": "[...] Adibidez, irristailuaren joan-etorriko
      mugimendua biraderaren eta bernoaren bidez egiten duten
       arrabotei, nagusiki engranajean eta makinaren
      mugimenduan, biradera-arrabota esaten zaie. [...]"
}

      mecanizar ranuras, pero también se emplean para
      contornear levas, placas, palancas, tallar engranajes,
      etc.",
"eu": "Mortasatzeko makinak artekak mekanizatzeko erabiltzen
       dira nagusiki, baina erabiltzen dira espekak, plakak
      edo palankak inguratzeko, engranajeak taillatzeko, etab
      . ere."
}
```

Listing 2: A Spanish→Basque example from Track 2.

document-level translation with or without explicit terminologies.

### 2.1 Tracks

As was stated in last year's findings (Semenov et al., 2025), the sentence-level translation with explicitly given sentence-level term dictionaries seemed a relatively simple task for most systems, while document-level translation scores showed a considerable divergence and were far from saturation even in the best submissions. Therefore, this year's shared task features document-level translation in both tracks. The difference lies in the way the systems are exposed to the terms:

- **Track 1: Document MT with Explicit Dictionaries:** The participants are given lists of full documents (up to 2000 words each, 10 documents on average), together with a single terminology dictionary that features terms applied for the whole domain (400 to 1100 terms). Therefore, the system is expected to select the relevant terms for a particular document and use the corresponding translations in context.
- **Track 2: Document MT with Sentence Samples:** The participants are not provided with explicit dictionaries. Instead, they receive small samples of sentences and their reference translations drawn from the same source as the test inputs (comprising roughly 10% of the dataset on average). We consider this scenario more challenging for the participants, since the system needs to identify the terms and align them with their correspondences before the translation.

### 2.2 Languages and Domains

**Spanish→Basque (es-eu)**

- **Tracks:** 1 and 2.
- **Domains:** Four sub-domains of Engineering and Technology: Energy and Automotive for Track 1; Machine Tools and Railways for Track 2.
- **Language Overview:** While Spanish is a relatively well-represented language, Basque is a low-resource language spoken mostly in the north of Spain and less in the neighboring regions of France (commonly known as the Basque Country). Additionally, Basque is genealogically and structurally very distant from Spanish and other Indo-European languages, since it is a language isolate and features grammatical categories that are rare for Europe (such as ergative case marking or polypersonal agreement).

**English→Polish (en-pl)**

- **Tracks:** 1 and 2.
- **Domains:** Medical texts, Mechanical Engineering (both domains equally represented in Track 1 and 2).
- **Language Overview:** Polish can be described as a mid-resourced language (for example, CommonCrawl shows its resourcedness as approximately equal to Italian and Portuguese). It is one of the most widely spoken Slavic languages (approx. 40M speakers). Its challenges to the MT task include relatively complex morphology (seven nominal cases and dozens of verbal forms, multiple nominal and verbal classes). Additionally, its elaborate system of diacritization and digraphs may present an additional challenge because of over-tokenization.

**Traditional Chinese→English (zh-Hant-en)**

- **Track:** 2.
- **Domain:** Finance, publications from the Hong Kong Monetary Authority
- **Language Overview:** Although Chinese is one of the most-resourced languages, its data in the traditional writing script is significantly less represented on the internet and in NLP resources. Additionally, this is the only language in our sample that uses a non-Latin script and is distinct typologically and genealogically from the European languages.

### 2.3 Terminology Modes

In Track 1, we follow the three-way evaluation (Zouhar, 2023; Semenov et al., 2023, 2025), to

enable a causal analysis of the utility of the terminology:

- **No Terminology (No Term):** The system translates the input text without a terminology dictionary.
- **Proper Terminology (Proper Term):** The system is provided with a dictionary of domain-specific terms relevant to the input.
- **Random Terminology (Random Term):** The system receives a dictionary of randomly selected source words (excluding the proper terms) and their aligned translations from the references.

The use of Random Term mode allows us to measure whether improvements in translation quality stem from incorporating terminologies or simply seeing part of the correct translation (Zouhar, 2023; Semenov et al., 2023).

Since Track 2 does not feature explicit term dictionaries, we do not apply a three-way evaluation protocol there. Instead, we only distinguish between the **No Term** (only input texts provided) and **Sample** (input texts provided with a few sample translations) modes.

## 3 Data

### 3.1 Track 1: Document Translation with Explicit Dictionaries

#### 3.1.1 Spanish-Basque

**Data source.** The data for Spanish to Basque translation were sampled from the ADAPTIA-MT suite of resources (Etchegoyhen et al., 2025), which covers four different industrial domains: Automotive, Energy, Railways and Machine Tool. The data were based on original technical documentation in Spanish, provided by experts from the Basque Industry Clusters in each domain and professionally translated into Basque at the document level. For Track 1, we selected data from the Energy and Automotive domains.

**Terminology.** Four specialised terminologies were manually built for the domains of ADAPTIA-MT (*op. cit.*), by the Basque Centre for Terminology and Lexicography UZEI. The process leveraged both the collected data described above, and existing dictionaries in each respective field, when available. The relevant Spanish terms were extracted semi-automatically from both types of resources and the resulting lists were combined and manually reviewed. Equivalent Basque terms were then manually established, following terminological ISO standards, in particular ISO/TC 37. For Track 1, there were 683 and 761 terms for the Energy and Automotive domains, respectively.

**Test sets.** For Track 1, we used the complete documents from the ADAPTIA-MT test sets for the two selected domains. In the Energy domain, the data consisted of 33 documents, which contained 683 terms. For the Automotive domain, there were 41 documents containing 761 terms in total. The test sets were manually revised, with minor cases of terms not captured in the original test sets due to morphological variation. Additionally, target term annotations were added to support the evaluation protocols of the shared task.

Listing 1 provides a simplified example of the test data for Spanish to Basque translation for Track 1, including sample documents in both languages and terminology samples, both proper and random. The other languages in this track exhibit the same structure.

#### 3.1.2 English-Polish

**Data source.** The data for English to Polish translation were constructed using Laniqo's in-house medical and mechanical engineering glossaries. Domain terms were categorized into 12 thematic groups for the medical domain and 15 groups for mechanical engineering. A team of linguists leveraged Gemini 3.1 Pro (DeepMind, 2026) to draft synthetic English source documents for each group, requiring each term to appear 3 to 5 times across the document to measure terminology translation consistency. These English texts were subsequently verified and enriched for higher lexical diversity of the terms. Finally, the documents were automatically translated into Polish using the same model and post-edited by professional translators.

**Terminology.** Terminology lists were derived from Laniqo's glossaries, which contain 1,055 medical and 1,264 mechanical engineering terminology pairs mapping English terms to their Polish equivalents.

**Test sets.** The Track 1 test sets consist of the complete documents selected for this track, comprising 6 documents for the medical domain and 7 for mechanical engineering.

### 3.2 Track 2: Document Translation with Sample Texts

#### 3.2.1 Spanish-Basque

**Data source.** For Track 2, we selected data from the Railways and Machine Tool domains in the original ADAPTIA-MT suite, described above.

**Terminology.** Terminological databases for Track 2 were also based on the ADAPTIA-MT resources for the two selected domains. Terminological data consisted of 761 terms for the Railways domain, and 838 for Machine Tool.

**Test sets.** For Track 2, we followed the same steps as for Track 1 in terms of manually revising and fixing minor issues in the original test data for Railways and Machine Tool, as needed, along with target term annotation. Since for this track participants were not provided with the terminology, but with texts from which to identify relevant terms, we sampled the minimal set of source sentences that contained all terms to be addressed to properly translate the source documents. Listing 2 provides a simplified example of the test data for Spanish to Basque translation for Track 2, including sample documents and reference sentences from which terms were to be extracted. The other languages in this track exhibit the same structure.

#### 3.2.2 English-Polish

**Data source.** For Track 2, we allocated the remaining dataset, comprising 6 documents for the medical domain and 8 for mechanical engineering.

**Terminology.** The underlying terminological resources for Track 2 were drawn from the same Laniqo glossaries used across the shared task.

**Test sets.** For Track 2, participants were required to identify relevant terminology independently rather than receiving pre-defined dictionaries. To enable this, we applied a selection algorithm to identify the minimal subset of source sentences and their translations covering all unique terms present in the dataset. This sample of context sentences was supplied to facilitate term discovery, while the full documents served as the test set.

#### 3.2.3 Traditional Chinese-English

**Data source.** We converted the Hong Kong Monetary Authority (HKMA) financial publications into document-level translation data, a data source we used in our 2025 shared task, and we used the same pipeline, PDF to markdown conversion and manual inspection (Semenov et al., 2025). Different from 2025, where we processed Annual Reports, this year we processed Half-Yearly Monetary & Financial Stability Reports (2017-2025, March) and Sustainability Reports (2022-2024). Each report contains multiple chapters, and we treat each chapter as a *document*, truncate it to 2000 English words by space delimiter, and then truncate the Chinese side based on the number of English paragraphs remaining. We then removed explicit paragraph boundaries "\n\n", along with notes, tables, figures, and their captions.

**Terminology.** We created a terminology dictionary by merging two sources: 1) we used the terminology dictionary we developed last year, and 2) we mined and aligned the English and Traditional Chinese terms separately published by HKMA, which "provides brief definitions of terms relevant to Hong Kong's monetary, banking and financial systems". We then filtered out entries that appear fewer than three times in this year's data, based on exact matches on the Chinese side, since Chinese words do not undergo morphological inflections. This results in a 465-item dictionary used for evaluation only.

**Test set.** We split our data into sample and test as per Track 2 design. To prevent cross-chapter information leakage, we release all documents (chapters) from 2023–2025 half-yearly reports as samples, and use the remaining half-yearly reports and all sustainability reports as the test set. In total, there are 15 sample document translations and 53 documents as test input. This also implies that the sustainability reports form a domain that is "unseen" in samples.

### 3.3 Unified Data Model

The datasets introduced in Sections 2, 3.1 and 3.2 operate at three levels.

- **Documents**: a multi-paragraph run.
- **Paragraphs**: single to multi-sentence paragraphs that can be recovered from the documents by applying the per-document paragraph delimiter.
- **Segments**: sentence pairs at the granularity they were translated by the human professionals for the shared task. This data level was not made available to the competitors, but is now available at the task's evaluation repository.

The competitors received the data at the document level. At submission time we enforced a crude

alignment at the paragraph level: The number of paragraphs within each document must match the expected number of paragraphs according to the source. Paragraph $i$ of a submission is expected to translate paragraph $i$ of the source. We accept that systems that have moved content across delimiter lines are penalized by most of our metrics.

**Terminologies**: The human professionals annotate on the segment level: they mark the actual inflected term and they denote the base lemma of the term. For Track 1 the competitors received the full glossary bag of all terms per language pair. For English→Polish it is mined from all segments, for Spanish→Basque it is an ADAPTIA-MT resource. Since the human professionals were selective in picking the most relevant terminologies per segment, some source side matches were not annotated for that specific segment. For English→Polish 647 / 2586 (25%), for Spanish→Basque 1487 / 4628 (32.1%) of all possible source side matches from the glossary bag are not annotated by the human professionals. These are not considered during evaluation. Among those, for English→Polish 46.8% (303), for Spanish→Basque 56.1% (834) of the non-annotated terms have no match on the reference side. For some of these examples the correct glossary term would be a more narrow definition of the same concept. Systems that more strictly apply terminologies as matched can have degraded performance on general translation quality for these matches.

## 4 Evaluation and Metrics

### 4.1 Upper-Bound Scoring

We verify our metric implementation by scoring the references against themselves, which we denote as *gold* submission in Table 6. This then represents an upper bound, since even a fluent human translation does not achieve a perfect score across all metrics.

### 4.2 Term Success Rate

We consider these points while implementing two versions of term success rates:

1. **Inflection Exact Match**: While a system producing the exact same inflected form as our human professionals is a good sign, this does not consider other inflected usages of the same term that are also acceptable.
2. **Lemmatization**: Can tell us whether a given terminology was used, without giving any insight whether a correct inflection was applied. Lemmatization uses Stanza (Qi et al., 2020), and the candidate term forms are lemmatized the same way as the text, so the two renderings agree even where the lemmatizer is wrong.
3. **Locality**: As documents are often multi-page sized, we require terms to appear within the same paragraph their segment lies in.
4. **Word Boundaries**: Inflected/lemmatized terms should not be a substring of a larger word, therefore we apply Unicode-aware word boundaries.
5. **Span Overlap**: The human annotations do not contain overlapping terminologies (such as annotating both "Covid" and "Covid-19" if the target only contains "Covid-19"). We disallow span overlap during terminology scoring following the algorithm described in Algorithm 1.

| tier | space | accepts |
|---|---|---|
| annotated | surface | the annotated lemma, verbatim |
| inflected | surface | the gold inflected form, verbatim |
| glossary | surface | any glossary alternative, verbatim |
| annotated-lemma | lemma | lemma of the annotated or of the inflected form |
| glossary-lemma | lemma | lemma of any glossary alternative |
| exclusive | both | one disjoint span per required occurrence, over all tiers |

Table 1: Matching tiers for term success. Lemma tiers add to the surface tiers rather than replacing them.

**Algorithm 1** Term success over one paragraph. MAXDISJOINT returns the largest set of requirements satisfiable by pairwise disjoint spans, so one span can satisfy at most one required occurrence.

**Input:** paragraph hypothesis $h$, annotations $A$
1: $S, L \leftarrow$ surface and lemma renderings of $h$, with a character-span map between them
2: **for** $a \in A$ **do**
3: $\quad F_s \leftarrow \{a.\text{target}, a.\text{inflected}\} \cup a.\text{glossary}$
4: $\quad F_\ell \leftarrow \textsc{Lemmatize}(F_s)$
5: $\quad M_a \leftarrow$ word-bounded, case-insensitive matches of $F_s$ in $S$, and of $F_\ell$ in $L$, each mapped into both spaces
6: **return** per-tier rate $|\{a : M_a \neq \emptyset\}|/|A|$, and exclusive rate $\textsc{MaxDisjoint}(\{M_a\})/|A|$

Each terminology annotation contains the term as it occurs in the source, the annotated target lemma, the surface form the reference actually uses (inflected), and every alternative the released dictionary allows. This allows fair terminology matching across language pairs with different setups: in Spanish→Basque the annotated lemma appears ver-

batim in the reference for 98–100% of occurrences, but in English→Polish for only 34–41%.

**Exact Term Success Rate** measures verbatim surface matches of the inflected form from our human-annotated references, of the annotated lemma, or of any glossary alternative.

**Lemmatized Term Success Rate** is the most lenient terminology matching metric, considering all alternatives and all their lemmatizations, as well as the annotated version and its lemmatized version as a valid usage as described in Table 1 while enforcing no span overlap. We keep track of consumed spans in both the surface and lemma space and disallow further matches in any of them.

### 4.3 Overall Translation Quality

As an indication of overall quality, we run one string-matching metric alongside several trained metrics: reference-based and reference-free. We report trained metrics as a complement, since neural metrics can be less robust on out-of-domain terminology and on the long, document-length inputs (Zouhar et al., 2024).[1]

**chrF2++** We compute chrF2++ (Popović, 2017) with sacrebleu (Post, 2018) using default settings.[2] chrF2++ is tokenisation-insensitive, allowing consistent evaluation across the target languages. We report it at two granularities: a *document* score, treating each entire translation and reference document as a single string (O'Brien et al., 2025), and a *paragraph* score, averaged over the aligned paragraph units.

**COMET, COMET-Kiwi and XCOMET.** We use COMET (Rei et al., 2022a,b) in its reference-based (`wmt22-comet-da`) and reference-free QE (`wmt22-cometkiwi-da`) variants; together with XCOMET-XXL (Guerreiro et al., 2024), which additionally predicts error spans. All three encode the source, hypothesis and reference in separate passes, each capped at 510 tokens. Document scores are the plain mean of the segment scores.

**MetricX (reference-based and QE).** We use `MetricX-24-Hybrid-XL-v2p6` (Juraska et al., 2024), an error score on a 0–25 scale for which lower is better, in its reference-based and reference-free (QE) settings. MetricX concatenates the source, candidate and reference into a single input sequence capped at 1536 tokens, which makes it sensitive to input length. As for COMET, document scores are aggregated as a plain mean.

All outputs are re-segmented onto the reference segments prior to scoring, which for Track 2 zh–en means cutting whole documents; this process, along with the segment-level aggregation, is detailed in the following section.

### 4.4 Segment-Level Scoring

Models of the COMET family use the XLM-RoBERTa SentencePiece tokenizer with a maximal sequence length of 512. As source, hypothesis and reference are encoded separately, they should each fit within the budget. Likewise, the MetricX family uses the mT5 tokenizer, which concatenates source, hypothesis and reference and should fit within 1536 tokens of that tokenizer. Since our smallest unit is segments and they usually fit well within the limits, we re-segment hypothesis strings onto the reference segments using `mwerAlign` (Matusov et al., 2005; Post and Hoang, 2025). Re-segmentation runs strictly within paragraph or document boundaries. Section A provides the token budget census, empirical length effects, and a validation of segment-level alignment against paragraph-level scoring.

## 5 Participants and System Descriptions

This year, we see 21 systems in Track 1 and 18 systems in Track 2 (12 of which were submitted to both tracks). Their descriptions are provided below. Some teams submitted several systems; we group them by their team names (these are always the prefixes of the model names, e.g., "COZY" and "COZY-flash" both represent the same team). For easier navigation across the variety of approaches, we label them with the main features and components of particular submissions, namely:

- **Type of models**
  - NMT NMT model (encoder-decoder)
  - LLM LLM (decoder-only model)
  - 🤖🤖 multiple models or agentic systems (agents, preprocessing+postprocessing, etc.)
- **Data**
  - SYNTH data synthesis (augmentation, etc.)
  - CURATE data curation (filtering big corpora, enriching training data with annotation, etc.)
- **Model update techniques**
  - *FT continuous pre-training, supervised fine-tuning, etc.

[1] We also probe LLM judges on the gold reference (§7.4).

[2] `chrF2++|#:1|c:mixed|e:yes|nc:6|nw:2|s:no|v:2.6.0`

*PO various types of preference optimization: GRPO, PPO, DPO, etc.

- **Inference-time strategies**

  using additional models to refine translation outputs

  subselecting the vocabulary relevant for the current segment

  ICL in-context learning, few-shot prompts, etc.

  multi-metric decoding (using both general quality and term accuracy for sequence choice)

  term injection (for NMT models)

- **Track 2 terminology usage from the seed bitexts**

  selecting the most similar/relevant sentences from the pool of samples

  creating the terminology dictionary (and reducing the task to Track 1)

**TARL** LLM The Amazon Hyderabad team (Mhaskar et al., 2026) presented a set of agentic systems that consist of four role-specialized LLM agents: translation, terminology verification, error detection and post-editing modules. The input consists of the source language sentence and relevant terminology pairs obtained by $n$-gram matching over the complete bilingual dictionary. For Track 2, the term dictionary is first mined from the sample bitext sentences. The Translation Agent (first step) is explicitly prompted to not simply copy the dictionary form of the term, but to inflect it according to the target language grammar; the Terminology Verification Agent (second step) adds the terms that were missed in the first step; after that, the agents treat the terms as locked and can only change the context of the sentence, not the terms themselves. The backbone LLM is Claude-Opus-4-8; no post-training is applied to it.

**Cohere (Cohere CAT+)** (Kocmi et al., 2026) LLM *FT *PO The model is built on top of the Cohere Command A+ architecture. It is a mixture-of-experts (MoE) model that has been supervised fine-tuned (SFT) on both MT- and non-MT tasks (such as post-editing or quality estimation), followed by DPO and Reinforcement Learning with Verifiable Rewards (RLVR). The model does not include any special inference techniques, and the system submission is the direct performance of the model when prompted with the shared task instructions.

**SalamandraTA** (Liao and Melero, 2026) LLM SYNTH CURATE *FT The team submitted their 7B-INSTRUCT v3.0 open-weight model, fine-tuned from its 7B base version. The training data were created using a "two-way" synthetic pipeline using Gemma-4-31B: one direction generates synthetic documents from medical glossaries, and the other extracts terminology pairs from existing parallel texts. The core of their approach is a data curation rule that filters those texts using their previous model release, v2.0, keeping only the "hard examples", which are sentences where v2.0 fails to output the required glossary term by default. A controlled study demonstrated that fine-tuning the base model exclusively on these hard examples significantly improves term accuracy compared to using easy or unfiltered data.

**COZY (systems: COZY, COZY-flash)** LLM The system translates the whole documents, with post-check of the paragraph consistency and re-translation once on mismatch. The lemmatized terms from the source passages are filtered from the global dictionary, and are added to the prompt, which requires the model to inflect them according to the target language grammar. For Track 2, the glossary is extracted with the help of an LLM and provided to the prompt together with the seed bitext examples. The submitted systems differ in the backbone LLM: while **COZY** uses GPT-5.6-Sol (OpenAI, 2026), **COZY-flash** runs the pipeline on Deepseek-V4-Flash (DeepSeek-AI et al., 2026).

**MASC-Dec** NMT This system is based on the publicly available HiTZ/mt-hitz-es-eu Spanish-Basque NMT model with no additional fine-tuning. It uses a document-scoped terminology memory for consistent term lemma usage throughout the document. To ensure that the Basque terms are inflected correctly, the model derives candidate lemmas by using the Apertium (Forcada and Tyers, 2016) and Stanza (Qi et al., 2020) morphological analyzers, and applies character-aware soft constraints at the decoding step to promote token paths that reflect the term lemmas, while relying on the contextually appropriate suffix based on the parametric knowledge. Exact constraints are reserved for invariant items such as numbers, standards, URLs, and fixed identifiers.

**CUNI-ÚFAL (systems: CUNI-UFAL, CUNI-UFAL$_{\text{dict}-\text{LLM}}$, CUNI-UFAL$_{\text{E2E}}$)** LLM

Papáček and Sourada (2026) developed a model-agnostic framework. It takes both the source sentence and relevant terminology mappings; the team experimented with the placement of terminologies and merging terminologies from random and proper dictionaries. After the initial translation with attempts to preserve the input document structure, the framework runs a terminology revision step to check for incorrect or missing terminologies. For Track 2, where bitext samples are provided instead of terminology dictionaries, they explore 1) multi-turn prompting with examples, 2) dictionary extraction with fallback to Track 1, and 3) a hybrid of both. They used Gemini 2.5 Flash for development and compared it to Gemma 4 31B and GPT-5.6-Sol, with the latter as submitted translations.

**HW-TSC** LLM CURATE Huang et al. (2026) built a pipeline centered on Qwen3.7-Max, featuring a Track 2 bilingual glossary induction module and a shared document translation module used across both tracks. For both tracks, the shared translator performs local glossary matching against each document or chunk, capping the prompt-injected terminology block at 200 locally relevant term pairs and instructing the model to adapt target morphology and agreement grammatically.

For Track 2, the glossary induction module identifies candidate source terms through two channels: open source-term extraction using Qwen3.7-Max and expression matching against the source side of seed bitexts. The extraction prompt for the open-extraction channel is optimized offline using SkillOpt on the WMT25 Terminology Shared Task (Track 2) English–Chinese finance data and rewritten by Qwen3.7-Max for other language directions. Finally, candidates from both channels are merged, filtered, and aligned to seed target expressions with Qwen3.7-Max before being passed into the shared translation module.

**RWS (TQM)** LLM ICL RWS team (Guinea and Alfieri, 2026) submitted Translation-Queries-Memory (TQM), a prompt-based, retrieval-augmented translation system using TranslateGemma-27B, Qwen3.5-35B-A3B-Instruct, and the in-house LW Research Pro model, without task-specific fine-tuning. For Track 1, an in-house terminology detector identifies approved terms and their inflected forms in each source segment and injects the corresponding source–target pairs into the prompt; TranslateGemma-27B was selected for Spanish–Basque and LW Research Pro for English–Polish based on term accuracy. For Track 2, TQM retrieves semantically similar translation pairs from the provided sample bitext and supplies them as few-shot examples. Model and retrieval-depth selection relied on reference-free quality estimation, resulting in Qwen3.5-35B for Chinese–English and Spanish–Basque, and TranslateGemma-27B for English–Polish, with a different number of samples per language pair.

**AGENTEAK** (Giraud and Gargett, 2026) LLM CURATE SYNTH *FT ICL This is a multi-agent pipeline built with LangGraph for Spanish–Basque terminology translation in the automotive and energy domains. Running on a single GPU with open-weight models spanning 4–8B parameters, the system splits translation into five stages: deterministic source-term matching, context-aware terminology selection using Qwen3-4B (reasoning mode), domain-adapted translation via Latxa-Llama-3.1-8B-Instruct (Etxaniz et al., 2024) with soft-enforced target terms, verification and targeted rewriting of non-compliant segments by a reviewer agent, and deterministic formatting fixes.

To compensate for missing domain bitext, Spanish–Basque parallel data was mined from Wikipedia using LaBSE (Feng et al., 2022) embeddings with Bicleaner AI filtering, and augmented with synthetic parallel paragraphs generated by Latxa-Llama-3.1-8B-Instruct conditioned on term bases. The translator was fine-tuned using LoRA with explicit domain tags on a mixture of mined, synthetic, and general-domain corpora.

**GRIAL-TA** LLM *FT CURATE The GRIAL-TA team (López-Sánchez et al., 2026) submitted systems for both tracks of the English-Polish language pair, using instruction-tuned Gemma 4 models fine-tuned on curated general and domain-specific data, including parallel corpora, terminological databases and bilingual dictionaries. They trained separate models for medicine and mechanical engineering domains, experimenting with different model sizes, prompting configurations, and fine-tuning strategies. For both tracks, translation is performed at the segment level, with the terminology explicitly associated with each segment injected into the prompt. In Track 2, the team first extracts terms from the provided sample bitext using TBXTools,

combining a BERT-based extractor with linguistic POS-pattern extraction. The extracted terms are then aligned across English and Polish using LaBSE embeddings, and the resulting terminology pairs are used in the same translation procedure as in Track 1.

**UniOr MT (systems: UniOR-ZSL+Term, UniOR-GenPE, UniOR-RulePE, UniOR-Mixed)** LLM Castaldo et al. (2026) submitted systems for Track 1 based on a modular agentic pipeline for document-level terminology-aware translation, covering English–Polish and Spanish–Basque. The framework generates translations through five progressively enriched paths: a zero-shot GPT-4o-mini translator, glossary-augmented translation, generic post-editing, terminology-aware rule-guided post-editing, and a full quality-assurance pipeline with iterative feedback between QA, supervisor, paraphraser, and post-editor agents, followed by a final repair attempt with GPT-5.6 if the iterative QA process does not resolve the identified issues. In addition to individual ZSL+Term, GenPE, and Rule PE submissions, the team submitted a mixed system that selects among candidates from all five paths using a combined measure of terminology accuracy and document-level COMETKiwi-based (Rei et al., 2022b) quality estimation.

**UniVie-HAITrans** LLM CURATE SYNTH *FT ICL Gaona (2026) submitted a lightweight LLM system for Track 2 covering English–Polish and Spanish–Basque. Their approach builds domain-adapted training data in three stages. First, domain terminology is extracted from IATE (Rummel and Ball, 2001) and Aya-Expanse-32B (Dang et al., 2024) is prompted to generate contextual source-language sentences containing each term. These synthetic sentences are then used as queries to retrieve semantically similar parallel segments from large CCMatrix (Schwenk et al., 2021) and EMEA corpora through multilingual sentence embeddings and a FAISS index, producing terminology-guided in-domain training data. Finally, Gemma-3-4B-it and Tiny-Aya-Global are fine-tuned with QLoRA on a mixture of zero-shot translation instances and 5-shot instances whose examples are themselves retrieved from the parallel-data pool. The submitted system uses the fine-tuned Gemma-3 model, translating Track 2 documents sentence by sentence in both the zero-shot and provided-sample few-shot conditions.

**STRA-MT** LLM The system proposed by Velda et al. (2026) is a pipeline that combines the deterministic elements and the locally-run small LLMs. First, the Repetition Plan module ensures to copy the completely repeating passages if they had already been translated.The second component, Term Ledger, is a deterministic data structure that is incrementally updated by the terms that occurred in the text. This block ensures that the terms activated in the particular document translation remain consistent. For Track 2, in the absence of explicit terminology, the terms are first mined from the seed bitexts with a SimAlign word aligner (Jalili Sabet et al., 2020). Finally, the Translator module (using either a Gemma-4-E2B (Team et al., 2026) or TranslateGemma-4b (Finkelstein et al., 2026) LLMs, or the NLLB-1.3B (Team et al., 2022) encoder-decoder model) is prompted with a paragraph, and a filtered subset of terms from the Ledger that appear in the paragraph. After generation, it is verified whether all terms have been translated correctly, and the paragraph is re-translated if not.

The ablations show that the different backbone models show optimal performance depending on the language (NLLB for es→eu, but Gemma-4 for en→pl). Additionally, the comparison between the mined and the externally created dictionary for zh→en pair in Track 2 shows a drastic drop in term success rate for the mined dictionary. The authors argue that this happens due to the limited coverage of the mined inventory (SimAlign mostly targeted single-word terms and not multi-word expressions).

**TaT** (Zhang et al., 2026) LLM The TaT system enforces strict dictionary constraints during document-level machine translation based on retrieval. It isolates retrieval and disambiguation prior to generation by a sequence of: sentence splitter, terminology retriever, lexical disambiguator, core translator, and terminology extractor (for Track 2).

**STaR-MT** LLM STaR-MT (Marchetti et al., 2026) is a three-stage terminology-aware machine translation pipeline consisting of Selection, Translation, and Revision, for both Track 1 and Track 2. The Selection step selects the terminology entries or examples by reverse BM25 retrieval, and the retrieved contents are inserted into the translation prompt. Subsequently, the general-purpose Qwen-3.5-27B is prompted to generate an initial translation in the second step,

allowing even long documents to be translated without explicit sentence or paragraph splitting. In the Revision step, language-specific models are employed to revise the initial translation. Latxa-70B (Etxaniz et al., 2024) is used for Basque revision, and PLLuM-12B (Kocoń et al., 2025) is used for Polish revision. English revision is omitted as it does not improve quality.

**VNFusion** The system features terminology-aware candidate generation with source-grounded selection and automatic post-editing, preserving glossary terms with appropriate target-language morphology rather than forcing exact surface forms. Additionally, the authors claim that the system outputs are reviewed with MQM-style review for accuracy, fluency, professionalism, and cross-segment coherence.

**Tilde (systems: TO-TM$_{\text{top5}}$, TO-TM$_{\text{top15}}$, TO-G4terms, TO-fuzzy, TO-fuzzy$_{\text{stem}}$)** LLM CURATE *FT The Tilde team (Pinnis et al., 2026) fine-tuned TildeOpen-30B using data they compiled and augmented for general translation, glossary-guided translation, and translation with translation-memory examples. They used the resulting model for English–Polish translation in both tracks. For Track 1, the system translates documents paragraph by paragraph, narrowing down the provided dictionary to potentially relevant term pairs for each paragraph and including them in the translation prompt. The team compared fuzzy matching, stemming with exact matching, and stemming with fuzzy matching. These methods prioritize recall, leaving contextual disambiguation to the translation model. For Track 2, the team uses the provided sample bitexts either to build a glossary or to supply translation examples. The first approach prompts Gemma 4 31B to extract corresponding domain-specific terms from the source texts and their translations, then uses the resulting glossary as in Track 1. The second retrieves similar bilingual sentence pairs for each source sentence in a paragraph and selects examples in turn from each sentence's ranked list until a fixed total is reached. These examples guide translation of the entire paragraph.

## 6 Shared Task Results

Figures 1 and 2 evaluate system capability along two main axes: **terminology success (lemmatized)** on the y-axis and **MetricX-24, reference-based**,[3] as the general quality metric on the x-axis. MetricX-24 is preferred over chrF++ here because chrF++ reacts directly to dictionary injection; a term×chrF++ trade-off would artificially double-count terminology adherence (Semenov et al., 2025). To ensure fair comparisons, these Pareto figures only include non-ablated submissions that covered every direction in a track. Systems lying on the Pareto frontier represent the leading systems for each track. Following §4.2, performance is not evaluated against a nominal maximum of 100%; rather, we contextualize each system's score against the human (gold) reference scored against itself. Full direction-wise results (including chrF++ and segment-aligned neural metrics) are tabulated in Tables 6 and 7 in the Appendix.

**Track 1 is close to its ceiling on terminology.** The best five systems fall within 1.2 points of each other, at 94.5–95.7 term success, and the leader sits 0.7 points below the gold ceiling of 96.4. With an explicit dictionary and no constraint on model size, little headroom remains on this measure: what remains is the residue the metric charges to the reference as well, with repeated mentions rendered by a pronoun or a shared head. General quality is not saturated in the same way. The best system reaches 3.55 MetricX against a gold value (human reference) of 2.04, a gap of one and a half points that no system closes, and the field spans 3.55–8.39.

**Track 2 is not saturated, and the spread roughly doubles.** Without an explicit dictionary, the leader reaches 89.2 term success, 4.2 points below the gold ceiling of 93.4, and the top five systems spread over 2.1 points against 1.2 in Track 1. Twelve systems entered both tracks. On en–pl, where the two tracks draw on the same two domains, term success falls for every one of them when the dictionary is replaced by sample bitexts, by between 1.2 and 53.0 points, with a median of 11.0. The size of the drop is a property of the system rather than of the track: CUNI-UFAL loses 1.2 points, and STRA-MT loses 53.0, and STRA-MT's own ablation attributes this to the coverage of its mined inventory, which its word aligner populates mostly with single-word terms. Identifying which terms need controlling is where the difficulty of the task now sits.

[3] We selected MetricX-24 over COMET-22 due to documented underperformance of the latter on Spanish–Basque (Falcão et al., 2024).

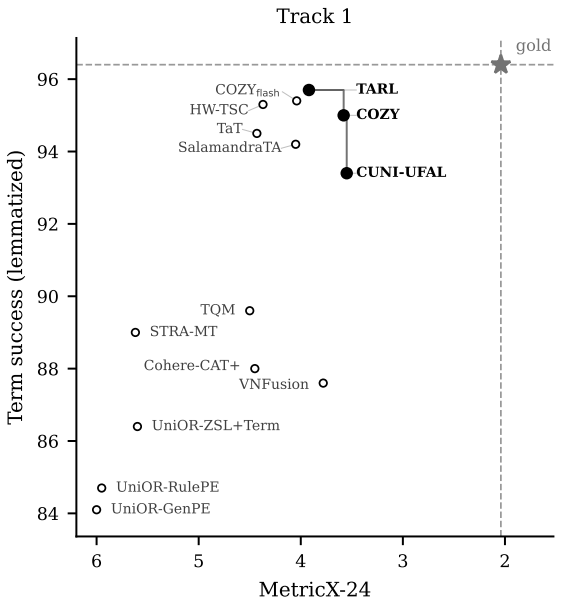

Figure 1: Terminology against general quality in Track 1. $x$ is MetricX-24, an error score, so the axis is inverted. Filled markers are the systems on the Pareto frontier; the dashed lines mark the gold reference scored against itself on each axis. Only systems covering every direction of the track are plotted (6 further systems are omitted on that ground), and of those, 14 of the 15 contenders are shown (term success $\geq 75$, MetricX $\leq 6$). Appendix Table 6 reports every submission.

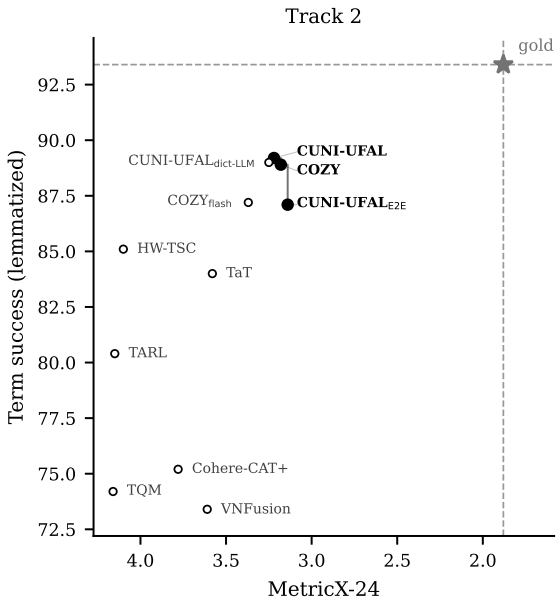

Figure 2: Terminology against general quality in Track 2. $x$ is MetricX-24, an error score, so the axis is inverted. Filled markers are the systems on the Pareto frontier; the dashed lines mark the gold reference scored against itself on each axis. Only systems covering every direction of the track are plotted (5 further systems are omitted on that ground), and of those 11 of the 13 contenders are shown (term success $\geq 70$, MetricX $\leq 5$). Appendix Table 7 reports every submission.

**The frontier systems pair revision with a large backbone.** The frontier systems are TARL, COZY and CUNI-UFAL in Track 1 and CUNI-UFAL, COZY and CUNI-UFAL$_{E2E}$ in Track 2. No system runs a single translation pass: each generates, checks the output against the terms it selected, and revises where the check fails. Also, the teams on both frontiers use a strong general-purpose LLM behind the pipeline rather than a model trained specifically for the task: COZY and CUNI-UFAL both submit GPT-5.6-Sol, and TARL runs Claude Opus-4.8. A revision stage is not by itself what separates them, though—AGENTEAK, STRA-MT, STaR-MT, VNFusion and UniOr's post-editing paths all verify their output and rewrite it, several of them against the dictionary specifically, without coming close to the frontier. However, where those teams report a backbone, it is an open-weight model between 1.3B and 70B parameters, or GPT-4o-mini. What the leaders add is the capacity of the model for terminology revision. This is consistent with concurrent work on multi-agent MT for financial long documents, where backbone capacity matters more than workflow complexity for terminology accuracy (Oncevay et al., 2026).

**Where the terminology success metric runs out.** In zh–en, the terminology gold ceiling is 86.3, lower than in the other directions because the HKMA documents repeat their terms most, and six systems score above it, up to 89.0. They are not more accurate than the reference: a system that repeats the dictionary target at every mention satisfies the metric where a professional translator pronominalises. This is the clearest case for reading the leaderboard against the ceiling, and it bounds how far term success alone should be pushed as an objective.

## 7 Analysis

### 7.1 Effect of Terminology Incorporation

We investigate the impact of incorporating terminology on translation quality. As noted in §2.3, Track 1 comprises No Term, Proper Term and Random Term; Track 2 provides no explicit dictionary, so it distinguishes only No Term and Sample. Figure 3 draws one vertical bar per system, spanning that system's modes, with the tracks side by side

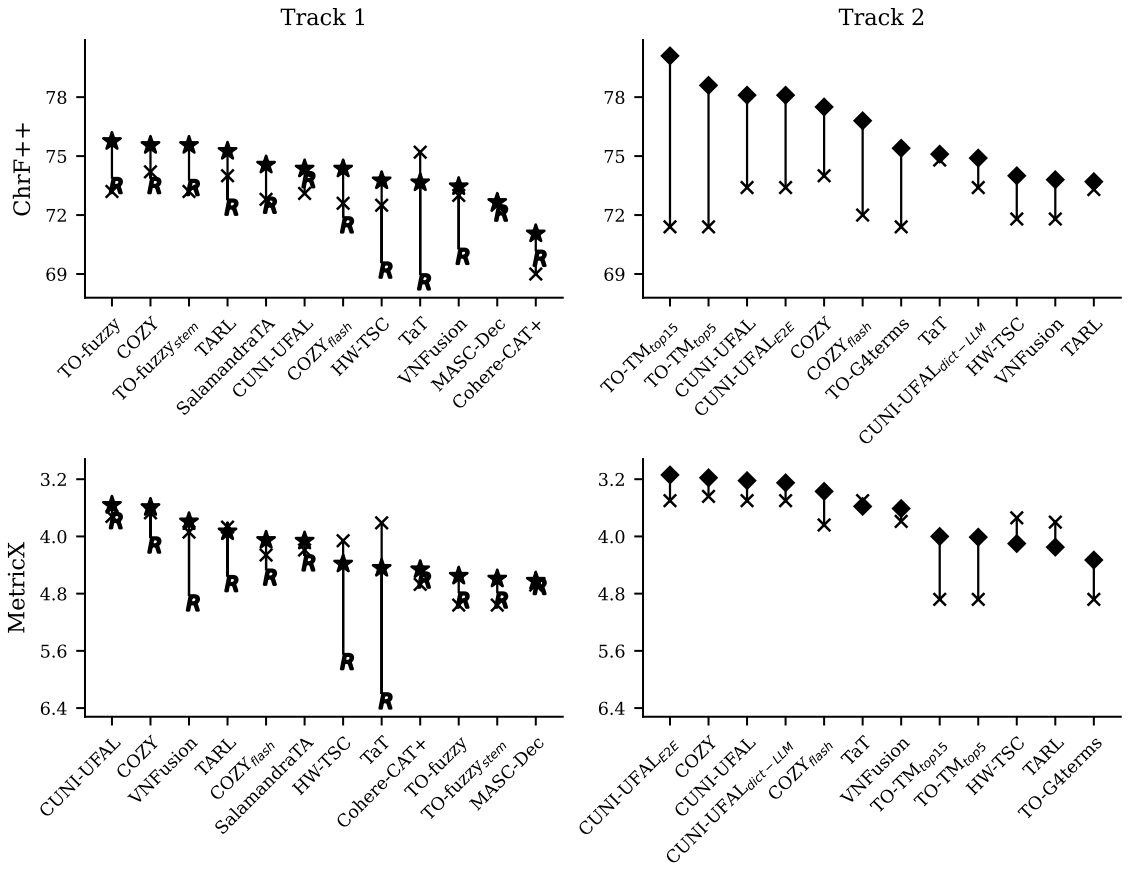

Figure 3: Effect of terminology mode, by track (columns) and metric (rows). Each panel shows the top 12 systems of its track by its own metric in the proper (Track 1) or sample (Track 2) mode, best on the left, so the two panels of a column need not show the same systems in the same order. Legend: $\times$ no term and $R$ random term; $\star$ proper term (Track 1), $\blacklozenge$ sample term (Track 2). MetricX axis is inverted. Both tracks are drawn to the same scale in each row.

and the two metrics in rows. The length of a bar is how much the terminology guidance is worth to that system, and because a row is drawn to one scale, bars are comparable across the two tracks. Each panel shows the twelve highest-scoring systems for readability; the averages quoted below are over all submissions in the track (see Appendix Tables 8 and 9 for the full scores).

In Track 1 the star sits above the $\times$ for almost every system: the dictionary is worth 26.4 points of term success and 1.58 chrF++ on average for all systems. The $R$ sits at the other end of the bar, below the $\times$. A dictionary of random terms leaves a system worse off than no dictionary at all, by 1.09 chrF++ and 2.19 points of term success.

This is not because the random entries name content the source does not contain. They are ordinary source words, a median of three to five per segment, each paired with a single reference-aligned target that is usually a base form. Systems adopt them. For every random entry whose source word occurs in a document, we checked whether one of its targets appears in the translation: the rate is 42.9% under No Term and 52.1% under Random Term.[4] The systems that adopt the most also lose the most, at $r = -0.54$ for chrF++ and $r = +0.67$ for MetricX. The star-to-$R$ distance therefore measures how far a system defers to whatever dictionary it is given, and it is widest for TaT and HW-TSC.

Track 2 is the novelty this year, and its bars are the longer ones in the top row. Sample bitexts are worth more than an explicit dictionary in general quality, 2.99 chrF++ against 1.58, and less in terminology, 14.5 points of term success against 26.4. A sample bitext carries register, domain phrasing and sentence structure alongside its terminology, so it improves the translation by more than the terms alone would explain, while being a weaker instru-

[4] A deterministic surface match over the released random dictionary, case-insensitive and word-bounded, on the same documents in both modes; morphology makes it a lower bound in both.

ment for terminology than a dictionary that names the required target outright. The bars also differ in length far more than in Track 1, which suggests that **how a system exploits the samples matters more than whether it receives them**.

The bottom row is the same comparison under a trained metric, and it is nearly flat. MetricX improves by 0.16 in Track 1 and 0.08 in Track 2, against more than twenty-six points of term success. The one place its bars open up is the $R$, which costs 0.57 and drops furthest for the two systems that inserted the random targets most. A trained quality metric is thus sensitive to terminology being *wrong* and close to blind to terminology being *right*, which is the behaviour a terminology metric is needed to cover and which we return to in the following section.

### 7.2 Ranking Correlation

Terminology-aware translation is a multifaceted problem, and the metrics we report are built to look at different things: a string-matching metric, trained quality metrics, and a terminology metric driven by the dictionary. It is therefore worth asking how differently these metrics rank the participating systems, both to understand what each one contributes and to inform which of them a future evaluation actually needs. Following last year's shared task (Semenov et al., 2025), we compare the rankings with Kendall's $\tau$ (Kendall, 1938). We correlate at the system level, using each metric's direction-averaged score, and we negate MetricX-24 so that higher is better for every metric and a positive $\tau$ means two metrics agree.

The clearest structure is not in any single cell but in the contrast between two blocks. The overall quality metrics agree with one another more than any of them agrees with Term Success: among chrF++, COMET-22 and MetricX-24 the coefficients average 0.63 in Track 1 and 0.70 in Track 2, whereas the Term Success row averages 0.47 and 0.55. The pattern holds across both tracks, which differ in their systems, their language directions and the form the terminology guidance takes. Every coefficient is nevertheless positive and significant, so the metrics are not measuring unrelated things; better systems are better on all axes. Terminology adherence is simply the axis on which the quality metrics agree least, and it is not recoverable from them.

Some of the metrics we compute are, by contrast, close to redundant with one another.

| | **Track 1** (21 systems) | | | **Track 2** (18 systems) | | |
|---|---|---|---|---|---|---|
| | ChrF++ | COMET 22 | MetricX 24 | ChrF++ | COMET 22 | MetricX 24 |
| COMET-22 | 0.61* | – | | 0.86* | – | |
| MetricX-24 | 0.50* | 0.79* | – | 0.59* | 0.65* | – |
| Term Success | 0.36* | 0.45* | 0.59* | 0.55* | 0.48* | 0.63* |

Figure 4: Kendall's $\tau$ correlation between the automatic metrics, on direction-averaged system scores. MetricX is negated so that higher is better for every metric. Comparisons with $p < 0.05$ are marked with *.

XCOMET-XXL ranks systems almost identically to COMET-22 ($\tau = 0.92$ in Track 1, 0.94 in Track 2), and the reference-free variants stay close to their reference-based counterparts: MetricX-24-QE against MetricX-24 with 0.86 and 0.72, and CometKiwi-22 against COMET-22 with 0.70 and 0.79. Reporting all of them would spend space on a distinction the rankings do not make, so Figure 4 shows one representative per family.

The practical conclusion mirrors the one drawn at WMT25, on a larger and more varied set of systems. An evaluation of terminology-aware translation **needs a term-specific metric alongside a quality metric**, and, given how little the reference-free variants change the ordering, one trained metric from each family is enough.

### 7.3 Grammaticality Estimation

As mentioned in Section 2.2, Basque and Polish have considerable morphological complexity, featuring multiple morphological categories (gender, case, number, definitiveness, etc.) while being relatively under-represented. We therefore ask: when terms are appropriately chosen at the lemma level, how fluent and grammatically coherent are their occurrences in sentence contexts? To answer this, we split the outputs (and aligned references) into sentences and, for each system, selected only passages where the term lemmas were correctly used, based on the lemmatized terminology success rate from Section 4.2.

Grammatical error correction (GEC) and identification (GEI) are well-established fields in NLP (Bryant et al., 2023), but existing solutions and datasets (such as Masciolini et al. 2025) largely focus on spelling errors. Sentences composed of orthographically correct but grammatically incoherent words (e.g., "The dog*s is* chasing the

cat") remain more difficult to detect, particularly for under-resourced languages[5]. Estimating the log-probability of system outputs with language-specific LLMs is a possible alternative, but this approach has shown inconsistent results (Semenov and Sennrich, 2025). Since there is no straightforward metric targeting grammatical coherence, we therefore conducted several exploratory estimations of the grammatical and syntactic reasonableness of terms in the system outputs, complemented by a short qualitative analysis.

The simplest sanity check of the grammatical coherence of the terms is to analyze their **relative position in the sentence**. An adversarial system could naively add relevant terms retrieved from the dictionary to the end of the sentence, thereby preserving overall fluency while maximizing the terminology success rate; but in natural sentences, we expect terms to be distributed relatively evenly throughout the sentence. We therefore compared the distributions of term positions (normalized by sentence lengths) in the system outputs and corresponding references. The results (see Section B.1) showed that the relative term position patterns in the reference texts are language-dependent: in Basque, terms gravitate towards the beginning of the sentence, while in Polish the opposite is true. All system outputs follow these patterns, with only rare statistically significant differences (up to 2% later than the reference for some systems).

Next, we focused on the inflected forms of the terms. We were interested in understanding **how diverse the grammatical forms of the terms are** in the generated sentences. To measure this, we used the mean size of paradigm (MSP) concept introduced in (Xanthos and Gillis, 2010): we counted the number of unique inflected forms of the terms in the texts and divided it by the number of unique term lemmas (or dictionary values for multi-word terms). A higher MSP value indicates that a system can generate a greater variety of grammatical forms of the same term. The results (shown in Figure 8 in Section B.2) are generally predictable: the references show a slightly higher MSP than the hypotheses, while systems that retrieved more terms show higher MSP than those that retrieved fewer. A notable observation concerns the best-performing systems for Basque: they show a large discrepancy between the numbers of unique inflected forms in the hypotheses and references, with *considerably more* unique forms in the system outputs. Qualitative analysis showed that, in many cases, this is an artifact of white spaces either on the reference side (annotation artifacts), or on the system output side (system used the correct suffix, but separated it with an excessive white space). Examples of both phenomena and another example of over-regularization are shown in Table 5 in Section B.2. Another notable example is the irregular word "plater", which should retain a single "r" after a suffix is appended (unlike most words in Basque, where the "r"-final words after suffixation duplicate the consonants). Sometimes it is incorrectly inflected with the doubled "r" (e.g. `presio-platerra` instead of `presio-platera`). This is an example of over-regularization or over-correction, a frequent phenomenon in children's or L2 speech, where speakers who are not fully fluent in a language apply regular morphological rules to exceptions or less frequent patterns (for example, "buyed" instead of "bought"). In recent years, there has been growing evidence of over-regularization patterns in cognitively plausible LMs (Haga et al., 2024).

Another way to address grammaticality is to analyze the **distribution of the grammemes** (particular values of a grammatical category, for example, the counts of the nominative, genitive, and locative cases, which are all grammemes of the "case" category). We did this by selecting only single-word terms and analyzing them with Stanza (Qi et al., 2020): it integrates morphological annotation of features from Universal Dependencies (de Marneffe et al., 2021), where the `feats` value shows all recognized grammemes for each word. Since the majority of terms are nouns (and, less frequently, adjectives), we focused on the grammatical categories of **case** and **number**.

The aggregated visualization of the case grammeme distributions is shown in Figure 5. Although there are no dramatic changes compared to the reference translations (as reflected in relatively low Jensen-Shannon Distance values), there are several notable observations. First, in Basque, we observe decreasing usage of the Ergative case (ERG). Basque has an Absolutive-Ergative case structure (as opposed to Nominative-Accusative systems, which are predominant among the world's lan-

[5]To the best of our knowledge, there are no robust grammatical error checkers for Polish and Basque, except for classical NLP approaches, such as (Gojenola and Oronoz, 2000).

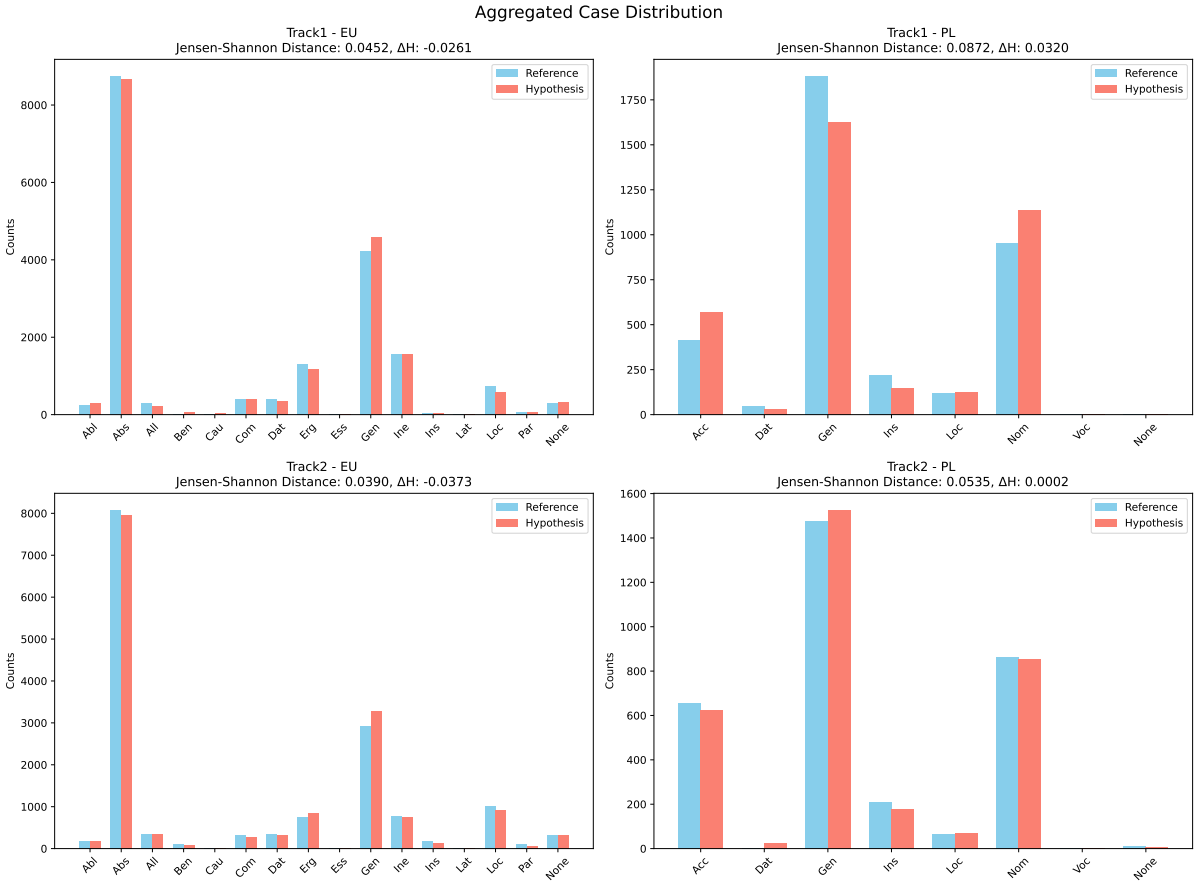

Figure 5: Distribution of the cases in Basque and Polish single-word terms, aggregated from all systems. Each subgraph shows a distribution for a particular language (columns) and track (rows). Within each graph, two colors represent the occurrences for the reference and for the submitted outputs ("hypothesis"). On the top of each subgraph, we provide Jensen-Shannon Distance (ranging from 0 to 1, where 0 means identical distributions), and ΔH shows the difference in entropies of the distributions, which is calculated as $\Delta H = H(ref) - H(hyp)$. The cases are sorted alphabetically.

guages[6]), and we can expect that LLMs, trained predominantly on higher-resourced Nominative-Accusative languages, impose a structural bias on inflection when presented with dictionary forms of words and do not favour the use of ergative constructions. This is indirectly supported by the less pronounced trend in Track 2, since many systems directly leverage sentences mined from the bitexts, increasing the chance of copying nouns in the ergative case.

(1)

a. *aerosorgailu-a* *eraiki*
wind.turbine-ABS build

'build a wind turbine' [reference]

b. *aerosorgailu-aren* *eraikuntza*
wind.turbine-GEN construction

'construction of the wind turbine' [MASC-Dec]

c. *construcción* *del* *aerogenerador*
construction of.the wind.turbine

'construction of the wind turbine' [input]

Another notable shift is the increase of the Genitive case (GEN). The qualitative analysis showed that this often happens in the contexts that can be formulated as verbal or as noun phrases. In the above example, we see that the same idea (building a wind turbine) can be expressed as a verb + direct object (in Absolutive case, ABS, 1a), or as a deverbal noun + possessive noun (in GEN, 1b). Although both "verb structures" and "noun structures" are fully grammatical and acceptable in Basque, the latter can be considered "excessively heavy", and is sometimes perceived as a calque from Spanish

[6] Dryer and Haspelmath, 2013, c. 98A, show that there are more languages in the world with nominative-accusative structure (over 50), than with Absolutive-Ergative (over 30). More importantly, the most resourced languages are almost only the nominative-accusative languages (German, Russian, Spanish, Japanese, etc.).

(which extensively uses noun structures, see the input in 1c).

in phase.ACC telogen.GEN

'in the telogen phase' [reference]

b. *w telogen*
in telogen.ACC

'in the telogen [phase]' [CUNI-UFAL]

Third, the case distribution in Polish shows the pronounced drift towards the nominative and the accusative cases. The Nominative case (NOM, a dictionary form) may reflect that the models tend to use the terms "as they are" when prompted with their dictionary forms. Contrary to our initial assumption (ACC is often homonymous to NOM, so it may be morphological analyzer errors), the qualitative analysis showed that often ACC appears from rephrasing the noun phrases with the nested terms in GEN (e.g. 2a) towards simple phrases with terms in ACC (e.g. 2b).

The distribution of the number grammemes is shown in Figure 7 (Section B.3). Notably, Polish data show a significant drop in the usage of the plural forms (which is reflected in $\Delta$H decrease by 0.12).

The observations in the grammeme distributions, together with qualitative analysis, demonstrate that the models are generally capable not only of selecting appropriate term lemmas but also of arranging them naturally in the sentence, both in terms of their position and coherence with the surrounding context. However, there is a slight but steady drift towards using the dictionary forms of the terms and skewing the variety of grammemes towards several most frequent cases. This is consistent with other evidence of degeneration in morphosyntactic diversity noted by Luo et al. (2024) and Guo et al. (2025), which is one example of the so-called "mode collapse" (Anschel et al., 2025; Qi and Murat, 2026): LLMs' tendency to generate more "averaged" sequences due to maximum likelihood-based training objectives. Another interpretation of this phenomenon is that, since the models do not fail to arrange the rest of the sentence according to grammatical rules, they seem to favor copying the constrained inputs and then building a grammatically coherent sentence "around" them. This is consistent with the well-established body of research on LLM inductive copying abilities through induction heads and in-context learning (Olsson et al., 2022; Lv et al., 2025; Jelassi et al., 2024). Such behavior is explicitly enforced by at least one system, TARL.

### 7.4 Terminology Drift in LLM Judges

LLM judges are now common in MT evaluation, and terminology is one of the standard MQM categories (Freitag et al., 2021; Kocmi and Federmann, 2023). We did not use them to rank systems, but the shared task offers a clean probe: the human reference is what the terminology metric is defined against, so a judge that flags a terminology error on the reference is, with few exceptions, wrong.

We follow the WMT25 Terminology judge setup, in the GEMBA-MQM line (Kocmi and Federmann, 2023): the model returns error spans with an MQM category and severity, weighted 1, 5 and 10 for minor, major and critical. We prompt zero-shot, and use Focus Sentence Prompting (Domhan and Zhu, 2025): the model receives the full source document and its translation as context, and is then asked for errors in one segment at a time, with the relevant dictionary entries repeated alongside each segment. The judge is reference-free, which is what makes the reference usable as a probe. We ran five backbones available in our environment: GPT-5.6-Luna, MiniMax-M2.5, GLM-5, Qwen3-235B, and DeepSeek-V3.2.

These judges emitted 6,507 terminology spans on the gold references. In **23.8%** of them the judge's own explanation undermines the span: it states outright that the translation is correct (16.2%), or concedes that the required term is present and objects only to its inflected form (7.6%). The rate ranges from 0.3% (GPT-5.6-Luna) to 43.0% (DeepSeek-V3.2). The backbones also differ by an order of magnitude in how many spans they emit at all, so the pooled figure describes the judges that flag most rather than a typical judge, and the range is the safer summary.[7]

Table 2 shows what this looks like. The judges are not ignorant of morphology: they identify the inflected form, check it against the dictionary, conclude that it complies, and emit the span regardless. Several go further and announce the retraction in the explanation ("Removing this span") while the span still reaches the output. This is an output-

[7] Counted by pattern match over the explanation field, requiring an unnegated sentence that gives an explicit positive verdict on the translation; of 25 flagged spans we read by hand, 23 were genuine concessions. Recall is the weaker side, since a bare "Correct." is easily missed, so the rate is a lower bound.

| |
|---|
| ***stroke*** → dictionary *udar mózgu*, reference *udar mózgu* "The translation uses 'udar mózgu', which matches the dictionary entry. This is correct…" *(span emitted as a terminology error)* |
| ***aerogenerador*** → dictionary *haize-sorgailu*, reference *haize-sorgailuetan* "…is grammatically correct (with locative suffix *-tan*), but the base form…" *(span emitted as a terminology error)* |
| ***turismo*** → dictionary *turismo*, reference *turismoak* "…an inflected plural form of 'turismo', which is an accepted target. Therefore, this is correct and should not be flagged. I must retract this as it's erroneous." *(span emitted as a terminology error)* |

Table 2: Terminology errors reported against the *human reference*, with the judge's own explanation. The reference uses an accepted target in every case.

discipline failure rather than a knowledge failure. The effect concentrates where inflection is richest, at 29.4% of the spans in en–pl and 25.8% in es–eu against 9.0% in zh–en.

Two things follow for evaluation practice: (i) a result obtained from a single backbone says little about what another would have found, so judge-based terminology findings need more than one model behind them;[8] and (ii) a judge's terminology output should not be consumed without a consistency check against its own explanations, which is cheap and, on this evidence, removes a large fraction of the noise. Why these judges behave this way, and whether the terminology annotations that a task like this one provides can be used to correct them, we leave to future work.

## 8 Related Work

Building terminology-aware MT systems is critical to achieve quality translation that properly covers domain-specific lexical knowledge such as brand names, technical jargon, or client-specific translation constraints. The task is highly relevant for industrial deployment in particular, where accuracy on specialised terminology is one of the key determinants of translation quality (Di Rosa, 2026; Oncevay et al., 2025b). Two main families of approaches have been explored: hard constraints, which alter the decoding process to enforce term generation, and soft constraints, where models are steered towards generating the expected terms without altering the decoding mechanism.

Among hard-constraint approaches, Hokamp and Liu (2017) demonstrated the enforcement of lexical constraints via Grid Beam Search (GBS) for terminological adaptation. Although their approach could satisfy lexical constraints, it incurred a significant computational cost. Post and Vilar (2018) introduced an alternative to reduce GBS computational complexity, but hard constraints typically still suffer from increased translation latency, while also facing difficulties to generate proper morphological derivations for the translated terms (Jon et al., 2021; Bergmanis and Pinnis, 2021). As an alternative, Michon et al. (2020) proposed the use of term placeholders, augmented with morphosyntactic annotation, while Hasler et al. (2018) explored finite-state machines and multi-stack decoding for the task.

To address the challenges of lexically constrained decoding, Dinu et al. (2019) introduced a soft-constraint approach based on inline term annotation for Neural Machine Translation (NMT), training on data augmented with term injection and deriving the application of terminology constraints without any modification of the decoding process. Encouraging the models to follow terminological constraints without incurring additional decoding cost has been a fruitful line of research in recent years (Ailem et al., 2022; Xu and Carpuat, 2021; Alam et al., 2021). Although they provide a straightforward alternative at no additional computation cost, soft constraint approaches do not however guarantee a strict adherence to terminological constraints, as they rely on the probabilistic nature of standard NMT decoding mechanisms. The trade-off between accuracy and fluency in terminology-aware NMT has notably been studied by Abela et al. (2026), who proposed a hybrid approach mixing soft data augmentation and constrained inference.

Recently, the rise of LLMs has introduced new paradigms for terminology-aware translation, exploiting their instruction-following capabilities to enforce terminological constraints, via in-context learning to condition or refine translation, or by fine-tuning means (Bogoychev and Chen, 2023; Moslem et al., 2023; Zheng et al., 2024; Wang et al., 2023; Kim et al., 2024). This approach has notably been explored on a variety of languages, including low-resource ones (Oncevay et al., 2025a). For the languages of this shared task, Etchegoyhen et al. (2025) compared soft-constraint NMT and few-shot LLM-based MT in Basque-Spanish, showing higher terminological accuracy with the LLM approach, although with an overall lower

[8] Another mitigation is single-backbone multi-run aggregation (Junczys-Dowmunt, 2025), though its effect on terminology errors specifically has not been investigated.

translation quality at the sentence level.

Among shared tasks on terminology-aware MT, Alam et al. (2021) organised the first of its kind in the WMT series, which focused on the medical domain and addressed five language pairs: English to French, Chinese, Russian and Korean, and Czech to German. Their work helped establish a solid foundation for the evaluation of terminology in MT research, with a novel benchmark that was mined semi-automatically from parallel corpora. The second iteration of the task expanded the range of domains, including scientific abstracts and web novels in addition to medical texts, and addressed three translation pairs: Chinese-English, English-Czech, and German-English (Semenov et al., 2023). They contrasted dictionary usage with information from reference translations, showing that both types of data yielded similar results. This result challenged standard assumptions on terminologies being the crux of meaning in translation, while also opening the debate on limitations of evaluation metrics that are not terminology-centric.

In 2025, the WMT shared task focused on the information technology domain for English to German, Russian and Spanish, at the sentence level, and the finance domain for English-Chinese at the document level. The task supported an evaluation of terminology accuracy and consistency, as well as overall translation quality, by means of different terminology modes: no terminology, proper terminology and random terminology. One of the main conclusions of the task was that document-level translation lagged behind sentence level, showcasing the need for long-form evaluation and more robust metrics overall (Semenov et al., 2025). In parallel, Conia et al. (2025) organised a task on Entity-Aware MT within SemEval, where they introduced the XC-Translate benchmark, containing over 50K manual translations with entities requiring the use of specialised knowledge for translation.

This year was also marked by a separate terminology-aware English-Turkish MT shared task, which was organized within the SIGTURK workshop (Gebeşçe et al., 2026). The authors created a new human-annotated dataset based on Wikipedia and university students' theses, provided the participants with 5 baselines, and analyzed the submissions (all of which were LLM-based, with additional optimization techniques or RAG modules). The results show positive scaling effects from the backbone model size, and a discrepancy between the human annotators and the models in adhering to the explicit dictionary constraints (models tend to rely on their parametric terminological knowledge rather than on explicit instructions). It is worth noting that the aim of the shared task was different from ours: while we test the models' abilities in end-to-end MT, the organizers of the English-Turkish MT shared task focused on particular steps of the terminology in machine translation (automated term detection in the texts, and different forms of post-editing). These results help us enrich our understanding of the elements of the terminology-aware MT systems (e.g., terminology extraction in Track 2), which our task did not causally pinpoint.

The present shared task builds upon previous work by including different translation modes, including random terms, while expanding to new language pairs and domains, generalising the benchmarks to document-level translation, providing a novel track where participants are tasked to extract the terminology from raw data, and expanding the set of evaluation metrics.

## 9 Conclusions

The Terminology Translation Task at WMT-2026 was aimed at estimating the progress in the subfield of terminology-aware document-level translation, especially for lower-resourced morphologically-rich languages. We arranged two tracks (one with explicit dictionaries, another with sample bitext seeds) across three translation pairs (Spanish-Basque, English-Polish, Traditional Chinese-English), covering different fields of medicine, science, and finance. Apart from curating the data, we also focused on the extensive implementation of automated metrics (refining the term success rate metric for the document level and comparing it with multiple surface-based and neural metrics of general MT quality), as well as on qualitative and quantitative analysis of the fluency and grammaticality of the system outputs.

We received approximately 20 submissions for each task, with most teams submitting to all language pairs. This is more balanced compared to last year's competition, where most systems were concentrating on sentence-level translation (which appeared to have saturated). The variety of approaches suggested by the participants reflects global trends in NLP: most of the systems were using LLMs, often combined with agentic or multi-model approaches.

The results of the competition are encouraging: according to our metrics, the task of MT with explicit dictionaries, even at the document level, is close to saturation in both general quality and term accuracy. This is a significant jump compared to last year, when the systems, tested on considerably higher-resourced languages, were lagging behind on both axes. One of the reasons may be the explicit techniques used by many participants, who filtered the document-level dictionaries and chunked the sentences, thereby reducing this task to the saturated problem of sentence-level MT.

On the other hand, the systems tend to struggle when not provided with explicit terminology: the spread of the scores is significantly larger, and the terminology success rate never reaches 90%. Interestingly, the models that explicitly use terminology mining modules do not seem to be the top-scoring systems.

The comparison of the different metrics shows that we can group most of them by their backbone systems, and that none of the general quality metrics, be it surface-based or neural-based, can substitute for the term success rate. When it comes to the terminology modes, we see that metrics react differently to random and proper term incorporation (neural metrics being more sensitive to the quality of the dictionaries than the surface-based ones). At the same time, the exclusion of the bitext seeds from Track 2 resulted in a significant drop in translation quality.

When addressing under-resourced and morphologically rich languages such as Basque and Polish, we first came across the scarcity of systems available for the automatic analysis of these languages (moreover, the Stanza morphological analyzer that we used in our work was also extensively used by the participants). The analysis of the LLMs-as-Judges that we ran as an experiment against the reference texts, also showed us unstable results depending on the model, as well as inconsistencies between the generated error spans and explanations. On the positive side, the automated checks on the positional and grammatical distributions in the system outputs, together with the manual checks of the most suspicious cases, did not reveal any worrying trends in the grammaticality of the term-aware MT outputs; yet we do observe slight but steady degeneration in the variety of the grammatical forms and grammemes that the systems generate.

Taken together, this raises the following **perspectives** for the future shared tasks:

**Data Formats and Languages.** The comparison between Tracks 1 and 2 shows that systems seem to saturate on new tasks quickly. This highlights the necessity of focusing on non-trivial and more naturalistic ways through which terminology can be acquired (for example, continuous chapters from books, cross-modal materials, etc.). Additionally, it would be valuable to extend the pool of languages used in our evaluation towards more typologically diverse and less-represented ones, since this year's results are quite promising.

**Metrics.** While being more robust for high-resourced languages, neural and LLM-based metrics showed shortcomings and inconsistent performance on our languages, which is supported by previous research. Additionally, although we did not find any serious cases of grammar rule violations in our text, we still think that grammaticality evaluation should be included in the evaluation of submissions in the coming years. Finally, this year's implementation of the term success rate metric opens the horizon for taking into account more subtle aspects of terminology usage, such as coreference, pronominalization, and other patterns in the relation between terms in the discourse.

**Human Evaluation.** This year's input data were manually annotated by domain experts and native speakers of the target languages, marking a new step in the development of our shared task. However, we still lack systematic human evaluation of the system outputs, which should give us a better understanding not only of the submissions, but also of the metrics described above.

**Outreach and Interactivity.** This year, we experimented for the first time with opening an interactive leaderboard for participants after the end of the official competition. We think that this will be more helpful for the community, as it creates space for more continuous feedback about the data, metrics, and solutions for the task. We will consider how to integrate this into future shared tasks on a larger scale.

We are open to any collaboration and, as always, especially look forward to ideas about resources that can be used for the test sets and human evaluation. Let's keep in touch!

## Limitations

Neural metrics like COMET and MetricX have shown limited reliability when evaluating transla-

tions into Basque, reducing our confidence in the automated quality scores for those outputs. Our terminology evaluation pipeline and several participating systems rely heavily on Stanza for lemmatization. Imperfect morphological parsing can lead to false positives or negatives in term matching.

Terminology dictionaries were released at the document level rather than the sentence level. While this deliberately mimics professional translation workflows, it introduces alignment ambiguity for systems optimized for sentence-level term injection. In Track 2, the sample sentences provided to systems are exact subsets extracted directly from the target test texts, simplifying the term discovery process.

There is no solid guarantee of data non-contamination. We consider this quite unlikely, as the Polish dataset was created specifically for this task and the Basque dataset was published but removed from public repositories. The HKMA reports are posted online, but they cover a specific, recent time period.

## Acknowledgments

We thank all participants for their submissions.

Vilém Zouhar gratefully acknowledges the support of a Google PhD Fellowship.

The Traditional Chinese-English data in Track 2 are derived from publications on the Hong Kong Monetary Authority website. We acknowledge the HKMA's ownership of the intellectual property rights in the information and in all its copies. We are grateful for the availability of these materials for research purposes.

We also thank Bittor Alkain (EHU) for the fruitful discussion on the Basque case structure.

| unit | over 510 | longest |
|---|---|---|
| en–pl paragraphs (gold) | 83 of 208 | 951 |
| en–pl submission paragraphs | 43% | 1570 |
| zh–en documents (gold) | 53 of 53 | 3056 |
| zh–en submission documents | 100% | 3430 |
| es–eu paragraphs | 5 of 5897 | 1015 |
| en–pl gold segments | 0 of 2317 | 129 |
| es–eu gold segments | 0 of 9231 | 328 |
| zh–en sentence pairs | 0 of 1417 | 471 |

Table 3: XLM-R tokens per unit against the 510-token cap. Segments fit everywhere; paragraphs and documents do not.

## A Segment-Level Scoring in Detail

This appendix expands Section 4.4: the input budgets that force segment-level scoring, the length effect we measured, the policy for pieces that still do not fit, and a validation of the alignment against paragraph-level scoring.

**Every encoder has a budget.** The trained metrics truncate silently: the model scores whatever fits, and MetricX discards the reference first and then the candidate. A unit is within budget when each of its three sides stays under the XLM-R cap of 510 tokens, taking the longest of source, hypothesis and reference, and when the assembled MetricX template, `source: ... candidate: ... reference: ...`, stays under 1536. Table 3 shows what the released units meet. Paragraph-level scoring is comfortable only for es–eu; it is impossible for en–pl and zh–en. The providers' segments fit everywhere with room to spare.

**The soft cap, measured.** Beyond the hard cap there is a soft one, since XCOMET-XXL was trained on sentences and drifts long before 510 tokens. Scoring the en–pl gold reference against itself makes this concrete. At paragraph level, mean XCOMET falls monotonically with reference length: 0.80 below 200 tokens, 0.69 at 200–299, 0.41 at 300–399, 0.19 at 400–499 and 0.22 beyond. The same references scored as segments average 0.964 with a median of 0.990 over 2317 segments, with no length effect beyond a mild dip for the longest sentences. A pipeline in which the reference does not sit at its ceiling is wrong before any system is scored, which is the argument for scoring at segment level rather than a matter of convenience.

**Aligning the hypothesis.** Only one side lacks boundaries. Source and reference segments are paired sentence by sentence in the providers' data, whereas a submitted paragraph is a single string. We therefore re-segment the hypothesis onto the reference segmentation with mwerAlign (Matusov et al., 2005; Post and Hoang, 2025), which finds by dynamic programming the cut points minimising the word error rate against the reference segments; it is deterministic, runs on CPU, and takes seconds for the whole task. The alignment runs strictly inside one paragraph and never across a delimiter, so the paragraph contract established by the release stays intact and piece $i$ pairs with reference segment $i$, and hence with source segment $i$.[9]

**Units that do not fit.** Every unit carries a status, and a scorer never calls a model on a unit that is not `ok`. An empty piece, an omission or an alignment slip, takes the worst score of the metric; both are charged rather than excused. A piece still over the cap after alignment also takes the worst score, with the reason stored on the unit, because truncating it would reward padding. A piece that is long but under the cap is scored normally, since the metric already penalises padding by itself, and no piece is split further: below the sentence there is no gold fragment to align a sub-sentence cut to. These cases are rare. Over every submitted file and mode, 28 units exceed the cap (13 in es–eu, 15 in en–pl, none in zh–en), and every one is an output three to seven times the length of its reference; 2726 units are empty, out of roughly 530k in total.

**Validating the alignment.** Because es–eu paragraphs are only one or two sentences long, paragraph-level COMET-22 is a sound reference point there, which lets us compare the two granularities where both are trustworthy. Across 176 files scored at both levels, file means correlate at Pearson $r = 0.989$; segment-level scores sit 1.2 points lower on average, uniformly, as one-word title segments and boundary slips each cost a little. The ten largest gaps all belong to one weak system family, whose outputs align less cleanly, and system ranks are preserved.

[9] mwerAlign is indifferent about which of several non-matching words a cut lands on, and has no preference for sentence-final punctuation. This is immaterial to the trained metrics, which grade such a boundary by a small margin. Snapping cuts to sentence punctuation is the natural refinement.

Table 4: Paired one-sided Wilcoxon signed-rank test for relative position shifts, calculated for every system and every track separately. "–" values show that the system was not submitting for a particular track, asterisks show the statistics for which p-value is smaller than 0.05.

## B Grammaticality Estimation

### B.1 Relative Term Position Distribution

The aggregated distributions of the relative term positions are shown in the Figure 6. We can see that the differences between the reference and the hypothesis distributions are not substantial.

A more aligned comparison can be made by calculating the difference between the relative positions in the aligned pairs of sentences. We measured the shifts in relative positions within each sentence, and computed the paired Wilcoxon signed-rank test (one-sided since the visualization was showing that the systems tend to locate the terms later, i.e., only to the right). The results are shown in Table 4: most values are statistically insignificant.

### B.2 Mean Size of Paradigm and Its Components

The mean size of paradigm is calculated by the formula: $MSP = \frac{\#inflected_{unique}}{\#lemmas_{unique}}$, where $\#inflected_{unique}$ stands for the number of the unique inflected forms observed in the corpus, and $\#lemmas_{unique}$ is the number of the unique lemmas in the corpus. Higher $MSP$ demonstrates a larger variety of the inflected forms, therefore, we generally expect the references to have higher $MSP$ compared to the systems, and better systems to have higher $MSP$ compared to the worse ones. For our study, we concentrate only on the term inflection; therefore we only analyze the expected dictionary forms of the target terms and their real occurrences; on the other hand, we include into the sample the multi-word terms.

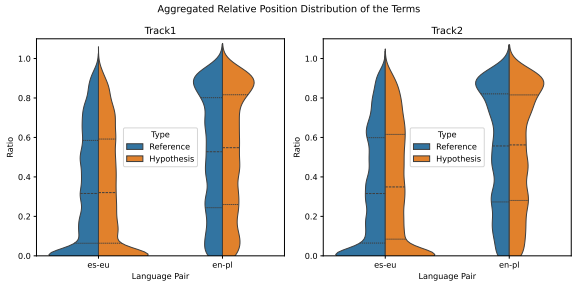

Figure 6: Aggregated relative term position distributions for two tracks and two target languages. Each violin plot shows the distribution in the reference texts (on the left) and in the system outputs ("hypothesis", on the right).

The $MSP$ ratio consists of the two values, which we can plot in two dimensions: by putting $\#lemmas_{unique}$ over x-axis, and $\#inflected_{unique}$ over y-axis. This is what we do in Figure 8. First, we see that our assumptions are supported by data: worse systems, i.e., the ones with a lower $\#lemmas_{unique}$, have a larger discrepancy between the reference and the hypothesis $\#inflected_{unique}$ values; references in Polish have a higher $\#inflected_{unique}$ than their corresponding hypothesis values. On the other hand, we see a notable difference in the best-performing systems in Basque: the better the performance, the bigger the $\#lemmas_{unique}$, the higher $\#inflected_{unique}$ in the system hypotheses compared to the references.

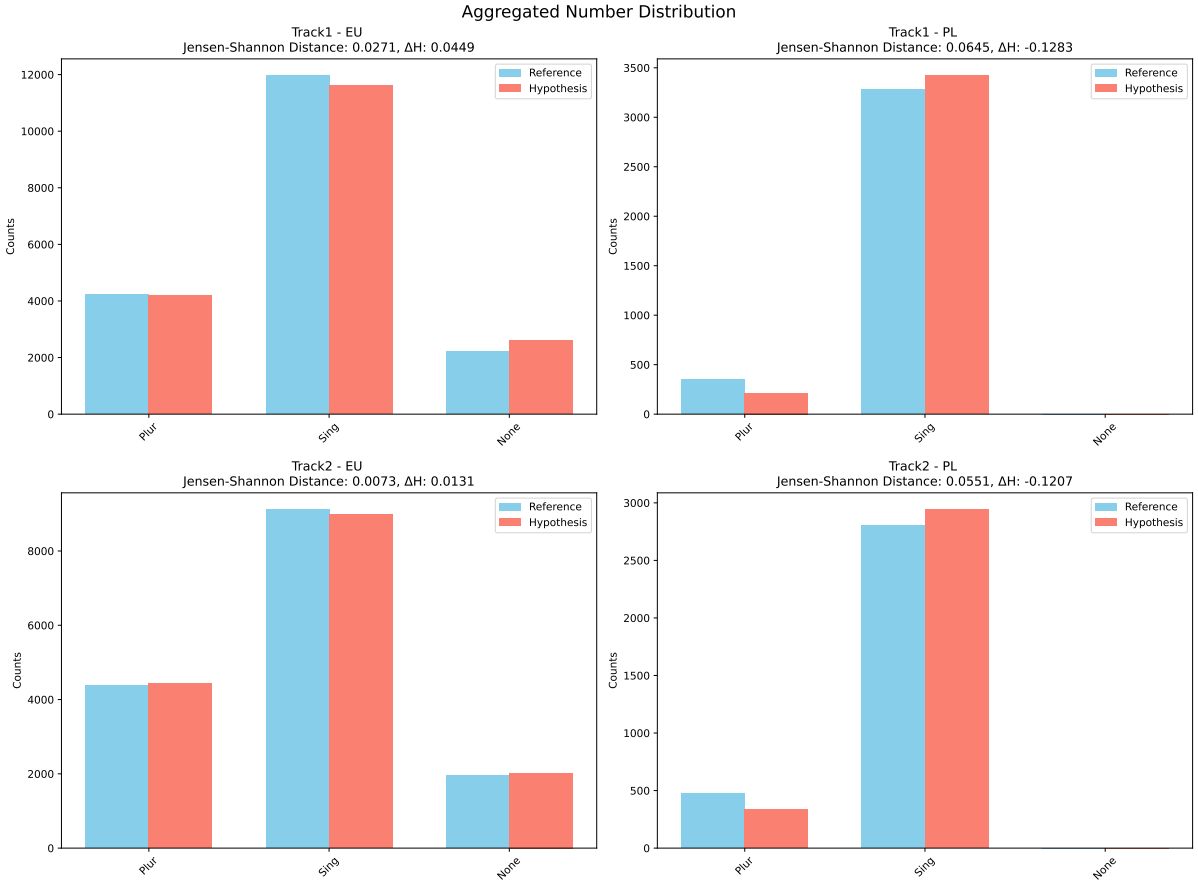
The qualitative analysis showed that many compound nouns in the reference texts were incorrectly spelled with an additional white space, while the system outputs contained orthographically correct compounds. There were also opposite cases, where the system over-tokenized the terms: although the correct suffix was used, it was separated by an excessive white space. We show the examples of it in Table 5.

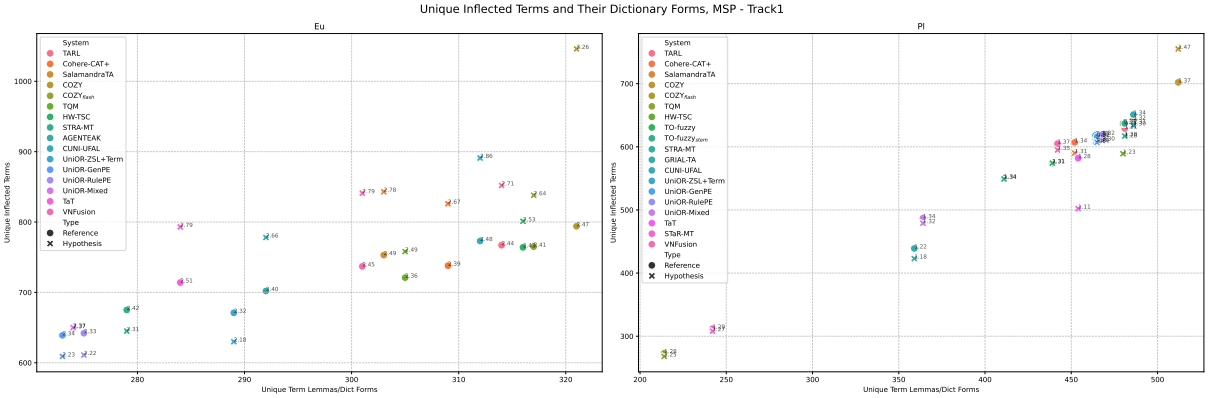
| Reference | System output | Error in |
|---|---|---|
| itsasontsi- gurpil | itsasontsi-gurpil | Reference |
| potenziat- fluxua | potenziat-fluxua | Reference |
| Balazta-sistema k | Balazta-sistemak | MT output |
| kondentsadore aren | kondentsadorearen | MT output |

Table 5: Examples of incorrect spacing in the references and system outputs.

### B.3 Distribution of Number Grammemes

Figure 7 shows the difference in distribution of the number grammemes between the references and system outputs.





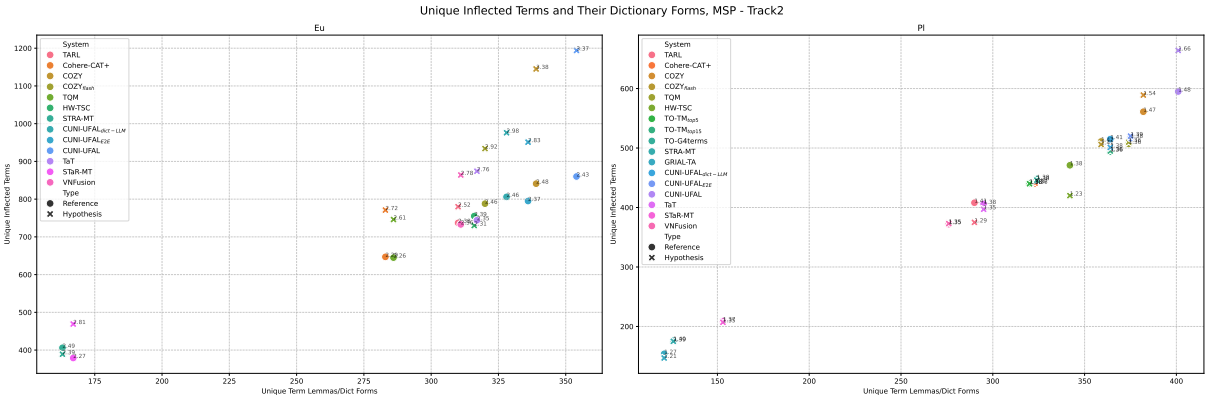


Figure 7: Difference in distributions of the number grammemes between the references and system outputs. The legend is analogous to the one in Figure 5. The "None" value stands for the cases where the word was not assigned a number category at all.

(a) Track 1

(b) Track 2

Figure 8: Distribution of the unique term lemmas (or dictionary forms for multi-word expressions, $\#lemmas_{unique}$), x-axis, and the unique inflected forms ($\#inflected_{unique}$), y-axis. The wide spread over the x-axis is explained by the fact that we only analyze the occurrences of the successful term retrieval for a particular system, so some systems could retrieve more unique terms. Generally, we expect a better system to have higher values over both axes. The color of the points reflects the MT system, and the shape shows whether the calculations were made on the system outputs ("hypothesis") or on the aligned reference sentences. Next to each data point, we show the $MSP$ values (higher is better).

## Abstract

We present the second edition of the WMT 2026 Model Compression (WMT26MC) shared task, which studies how large language models can be made efficient for machine translation under model-size and latency constraints. The task offers a constrained track based on Gemma 3 12B and an unconstrained track for compressing models below 20B. Both tracks cover Czech→German, English→Chinese (Simplified), and English→Arabic (Egyptian). Participants submit complete runnable systems, which we run in a standardized environment on a single H100 GPU. Evaluation jointly considers translation quality, model size on disk, and decoding speed, analyzing the resulting quality–size and quality–speed trade-offs. We received 41 submissions from 13 teams. The proposed systems span weight and activation quantization, structured and expert pruning, low-rank factorization, knowledge distillation, vocabulary and vision-component removal, mixed precision, and inference-time reranking. Evaluation with quality-estimation metrics on the blind test sets reveals that post-training quantization is the reliable lever: INT4 and FP8 systems shrink the constrained base to roughly one-quarter and one-half of its original disk size, respectively, and deliver up to 20× the steady-state throughput while staying within quality-estimation noise of the uncompressed model, whereas aggressive low-rank and structural pruning collapse quality.

## 1 Introduction

Large language models (LLMs) have become strong general-purpose systems for machine translation (MT), but their broad capabilities come with substantial storage, memory, and computational requirements (Brown et al., 2020; Ding et al., 2024; Patil and Gudivada, 2024). These costs complicate deployment on commodity accelerators, local servers, mobile hardware, and other resource-constrained platforms. Compression methods such as quantization, pruning, low-rank factorization, and knowledge distillation can reduce these requirements, although aggressive compression may degrade translation quality and some compression techniques fail to yield a corresponding reduction in end-to-end latency (Zhu et al., 2024). A useful comparison therefore has to measure the resulting systems as deployable artifacts rather than considering parameter count or nominal precision alone.

The WMT 2025 Model Compression shared task was introduced with the objective to provide such a comparison for text translation (Gaido et al., 2025). It continued a line of WMT shared tasks on efficient translation (Birch et al., 2018; Hayashi et al., 2019; Heafield et al., 2020, 2021, 2022), complementing a parallel initiative in the speech translation field at IWSLT (Abdulmumin et al., 2025; Adelani et al., 2026). The second edition retains the central objective—reducing the footprint and cost of a general-purpose LLM while preserving machine-translation quality—but updates the benchmark to reflect both newer models and more realistic system deployment.

The WMT 2026 Model Compression (WMT26MC) shared task[1] replaces Aya Expanse 8B (Dang et al., 2024) with Gemma 3 12B (Team et al., 2025) in the constrained track, and the unconstrained track permits any source model whose original size is below 20B parameters. Both tracks use the same three language directions: Czech→German, English→Chinese (Simplified), and English→Arabic (Egyptian). As in the previous year, participants submit the complete runnable artifact rather than only model outputs, allowing organizers to measure translation quality, disk footprint, and decoding speed under the same

hardware and operating-system conditions.

The evaluation is designed to address three main questions:

- How far can a general-purpose LLM be compressed while retaining its translation quality on the targeted language directions?
- Which combinations of compression and inference techniques provide the strongest quality–size and quality–speed trade-offs?
- How do methods developed under a fixed-model, fixed-data constraint compare with unconstrained model selection and training?

This paper describes the submitted systems, the evaluation pipeline, and reports results offering the following key takeaways:

- Quantization (at INT4) enables reduction to roughly a quarter of the original size with limited quality degradation, while compression at half of the original size (FP8) is essentially lossless.
- Solutions based on aggressive structural pruning fail to retain original translation capabilities even after recovery finetuning.
- Inference speed depends primarily on the serving runtime rather than on model size: reduction in numerical precision leads to faster inference only if the runtime can effectively exploit the reduced precision.

## 2 Task Description

The task asks participants to reduce the deployable footprint of a general-purpose LLM while maintaining strong translation performance. Systems may target any subset of the three language directions, and rankings are computed separately for each track and language direction.

### 2.1 Tracks

The **constrained track** establishes a common starting point by requiring all systems to be directly derived from `google/gemma-3-12b-it`.[2] Gemma 3 12B was selected for its permissive licensing terms and its balance of size and translation capability across the task languages. Any compression technique is permitted. However, the final model must remain a compressed derivative of the original model: for example, a distilled student is eligible only if its architecture is itself obtained from Gemma 3 12B rather than chosen independently. In addition, constrained-track participants can use only the public data released for the WMT26 campaign and test sets from previous WMT General MT shared task editions for calibration or fine-tuning.

The **unconstrained track** uses the same language directions and evaluation protocol but allows participants to choose any original model below 20B parameters. It also permits additional calibration and training data. By holding the evaluation environment fixed while relaxing model and data choice, this track tests whether model selection and task specialization offer better deployment trade-offs than compressing a common base model.

### 2.2 Evaluation

The official evaluation uses held-out WMT26 General MT data for the selected directions. Evaluation inputs are exposed to submitted systems as UTF-8 text with one source record per line. Each system must return exactly one translation per input line. This line-oriented interface keeps data handling identical across model frameworks and prevents system-specific preprocessing from changing the number or order of examples.

Submissions are evaluated separately for each track and language along three dimensions:

1. **Translation quality**, assessed with reference-free metrics: COMET-Kiwi-XXL (Rei et al., 2023) and MetricX-XXL-QE (Juraska et al., 2024).
2. **Model footprint**, measured as the on-disk model artifact size. Peak GPU-memory use could not be measured reliably across the heterogeneous runtimes and is not reported.
3. **Decoding speed**, measured from the wall-clock time required to translate the evaluation set under controlled batch settings.

All systems run on an organizer-managed x86_64 machine with Ubuntu 24.04 and a single NVIDIA H100 GPU with 80 GB of VRAM. The same submission interface, input order, decoding workload, and hardware allocation are used for every system.

The evaluation pipeline is released with the organizers' repository.[3] Before scoring, a sanity check installs each submission, invokes it on a small input, verifies that the output is non-empty, and en-

[2] https://huggingface.co/google/gemma-3-12b-it

[3] https://github.com/thammegowda/wmt26-model-compression

forces exact input/output line-count match. The main evaluator invokes the same entry point for all accepted systems and records the command, exit status, wall-clock time, CPU times, maximum host resident-set size, and timestamps for each run. Invalid or incomplete outputs are excluded from scoring. The throughput protocol profiles nominal batch sizes of 1, 16, 64, and 256, capped by each system's declared maximum, with repeated full-set and one-sentence warmup runs per condition. We report net throughput as the number of source characters divided by difference between the median full-set wall time and the median one-sentence warmup wall time. The warmup is therefore a startup proxy that includes initialization and one-sentence decoding, rather than a pure model-loading measurement.

### 2.3 Submission

A valid submission consists of a form entry and a complete system that the organizers can execute without reconstructing the compression procedure. Each submission package contains source code, environment-installation instructions and dependencies, an inference entry point, and the compressed model artifact (or a stable link to it). Under the submission specification, packages provide `setup.sh`, `run.sh`, `requirements.txt`, and `README.md`. The evaluator calls `run.sh` with a language direction, batch size, input path, and output path; diagnostic output must not be mixed with translations.

Teams may submit multiple systems for a track and language. In that case they designate one system as PRIMARY, with the rest treated as CONTRASTIVE. Participants also declare the language directions and maximum supported batch size for each submission.

## 3 Participants

We received submissions from 13 teams, of which 10 teams participated in the constrained track and 4 teams targeted the unconstrained track (one team entered both tracks). Many participants submitted multiple entries.

Table 1 reports the team names, number of submissions, track codes, and a brief description of explored optimization methods. Quantization is most common, but it is frequently combined with structural specialization: teams remove vision modules unused by text-only MT, prune vocabularies or transformer components, factorize dense matrices, or distill pruned students. The unconstrained entries broaden model choice to Aya-Expanse, Gemma 4, GPT-OSS, and TildeOpen models. Several entries also optimize the inference system itself through custom kernels, continuous batching, and quality-estimation-based selection. The descriptions below consolidate the short paragraph responses in the submission form. They summarize systems as declared by participants. Claims about quality, speed, or memory use are deferred to the evaluation in Section 4.

### 3.1 alonso (Palomino, 2026)

The `alonso` entry is a calibration-free English→Chinese (Simplified) system that selectively applies BitsAndBytes NF4 with double quantization to the gate, up, and down projections of all 48 text-transformer MLP blocks. Attention projections, embeddings, normalization layers, the output head, and vision modules remain in BF16. This selective design trades a larger artifact for lower quantization exposure than uniform 4-bit compression.

### 3.2 arc/ilsp (Athena Research Center) (Sofianopoulos and Prokopidis, 2026)

The `arc/ilsp` systems combine three training-free operations: removal of the vision tower, script-aware vocabulary pruning from roughly 262k to 196k entries, and GPTQ W4A16 quantization. The team selects full- or reduced- vocabulary INT4 primaries by language direction and includes an FP8 contrastive. For English→Arabic (Egyptian), a decoding contrastive generates multiple candidates and applies self-MBR selection using chrF consensus without changing model weights.

### 3.3 CometCut (Bajwa, 2026)

`CometCut` compares uniform GPTQ and AWQ with a quality-aware mixed-precision scheme. For the latter, the team quantizes one decoder layer at a time, estimates its sensitivity using COMET on held-out data, and solves a knapsack problem that assigns layers to 16-, 8-, or 4-bit precision under a size budget. All variants use a shared multilingual calibration pool and the LLM-Compressor/vLLM stack.

### 3.4 Dragon1006 (IIIT) (Balaga et al., 2026)

`Dragon1006`'s unconstrained English→Chinese (Simplified) system starts from Aya Expanse 8B,

Table 1: Registered WMT26 participants and their 41 submitted participant variants across all 13 teams. The ID column defines the participant prefix used throughout the tables and figures; system-level labels append a compact variant subscript to this prefix. C and U denote constrained and unconstrained tracks; "all" denotes cs–de, en–zh, and en–ar. Variant counts (# Var.) describe submitted artifacts

reduces its depth from 32 to 28 layers, and restores translation behavior with QLoRA on a 36k-example subset of WMT19. The adapter is merged into the model to remove PEFT routing overhead, and weights are quantized to 8-bit at inference time with BitsAndBytes. Retrieved after the initial inventory snapshot, the int8 artifact is evaluated here on English→Chinese (Simplified) (Table 2); note that its inference wrapper caps generation at 150 new tokens, which truncates the longer paragraphs of the WMT26 set and depresses its measured quality.

### 3.5 ESTS (UCLA) (Martin et al., 2026)

`ESTS` builds unconstrained translation specialists from the MXFP4-quantized GPT-OSS-20B mixture-of-experts model. It estimates expert importance from routing on task-proxy generations and allocates retained capacity across layers using the Jensen–Shannon divergence between source- and target-side routing distributions. Experts are physically removed, after which the model is recovered with full-parameter supervised training on GPT-generated pseudo-parallel data. Separate English–Chinese and English–Egyptian-Arabic families vary the number of retained experts.

### 3.6 FBK@ModelCompression (Suman and Bentivogli, 2026)

`FBK` submits two W8A8 Czech→German systems. Both use GPTQ for 8-bit weights and round-to-nearest quantization for activations, executing the matrix operations directly in 8-bit precision through the compressed-tensors/vLLM stack. One variant first applies SmoothQuant to move part of the activation quantization difficulty into the weights; the other omits this smoothing step.

### 3.7 Pare4Bit (Fakhrutdinov, 2026)

For the constrained track, `Pare4Bit` rebuilds Gemma 3 12B as a text-only model without the vision tower and applies group-wise GPTQ W4A16 while retaining tied embeddings in BF16. A contrastive additionally drops four transformer layers, uses LoRA knowledge-distillation recovery, and then applies GPTQ. Its unconstrained entry treats model selection as part of compression, choosing a Gemma 4 12B quantization-aware-trained INT4 checkpoint and serving it through vLLM.

### 3.8 SLICERS (IIIT Hyderabad) (Balaga et al., 2026)

`SLICERS` targets English→Chinese (Simplified) with a combination of structural and precision compression. Fisher-information estimates guide removal of eight transformer layers and 30% of intermediate feed-forward neurons. The structurally pruned model is then quantized to 4-bit NF4 and adapted with QLoRA on translation data.

### 3.9 TahomaMT (Microsoft) (Gowda, 2026)

`TahomaMT` removes the unused SigLIP vision tower and multimodal projector and specializes the tokenizer to the Latin, Arabic, and Han scripts used in the task, reducing its vocabulary from 262,208 to 192,347 entries with byte fallback. Two calibration-free variants use either FP8 weights and per-token FP8 activations (W8A8) or group-wise asymmetric INT4 weights with FP8 activa-

tions (W4A8). Contrastive best-of-four systems sample four candidates and select one with a bundled 4-bit Cometoid quality-estimation model. All variants use the team's C++/CUDA Tahoma runtime.

### 3.10 TildeOpen-wmt (Tilde) (Kronis et al., 2026)

`Tilde`'s unconstrained submission starts from a task-adapted TildeOpen 15B Czech–German model, itself distilled from a 30B model and further trained with supervised fine-tuning and GRPO. The submission compares GPTQ with NVFP4 weights against FP8 weights and dynamic FP8 activations. A second compression axis distills the 15B model to an 8B student, and the team also combines this student with each quantization scheme.

### 3.11 Tiny Titans (MBZUAI) (Raya-Rios et al., 2026)

`Tiny Titans` submits three Czech→German systems. The first applies group-wise 4-bit GPTQ using a 1,024-example calibration set. The second factorizes selected weight matrices with activation-aware SVD and then performs task-aware distillation from the original Gemma model, using stored top-32 teacher probabilities. The third combines this low-rank/distillation pipeline with 4-bit GPTQ of the resulting factors.

### 3.12 TMU-onono (Tokyo Metropolitan University) (Ono, 2026)

`TMU-onono` applies DiBA (Diagonal and Binary Matrix Approximation), replacing dense linear and tied embedding/output weights with interleaved diagonal scalings and binary mixing factors. The binary factors remain fixed while the diagonal factors are adapted on teacher translations of the WMT26 Czech→German training data, a recovery procedure the team calls DiBARD. Its primary system uses a direct Triton backend, while a contrastive system caches unpacked factors at runtime.

### 3.13 VIC (Vicomtech) (Ponce and Etchegoyhen, 2026)

`VIC` removes Gemma's vision component and learns differentiable masks over feed-forward channels and attention groups while keeping the model weights fixed. The masks are materialized as structured pruning at several target ratios; selected models are then recovered by supervised fine-tuning on multilingual parallel data. The submission family also explores language-specific vocabulary pruning and applies 4-bit AWQ after pruning, with inference served through vLLM.

## 4 Results

We evaluate all submissions in a single standardized environment and report the three task dimensions separately. Because the WMT26 test-set references are not available at the time of writing, the quality numbers here are *reference-free* quality-estimation (QE) scores. Unless noted otherwise, quality is COMET-Kiwi-XXL (Rei et al., 2023), cross-checked against MetricX-XXL-QE (Juraska et al., 2024). The constrained track compresses a common base (Gemma 3 12B, 22.7 GiB on disk); the unconstrained track uses heterogeneous bases, so its systems are compared against the constrained base only as a reference line, not on equal footing. Throughout, the uncompressed base and the two `bitsandbytes` organizer baselines (`bnb-q4`, `bnb-q8`) anchor the plots. The full per-system results are consolidated in Table 2, the central table of this report; the figures that follow break out each dimension.

### 4.1 Translation Quality

The translation quality results in Table 2 indicate the following: post-training *quantization* preserves quality, whereas aggressive *structural* compression does not. Weight-only and weight–activation quantization (INT4/W4A16, FP8/W8A8, INT8) land within QE noise of the uncompressed base, while low-rank factorization (`Tiny Titans`' SVD, COMET-Kiwi-XXL 24–32 for Czech→German), binary/diagonal approximation (`TMU-onono`'s DiBA, 27–28), and 50% FFN pruning without sufficient recovery (Vicomtech, down to 49 for en-ar) collapse quality. The failures reflect capacity removal that the submitted recovery (distillation or light fine-tuning) did not restore. Some models using calibrated data improve on COMET-Kiwi-XXL over baselines but worsen MetricX24 scores. The disagreement underscores the importance of evaluating quality through multiple metrics to enforce sound conclusions.

### 4.2 Model Size

Figure 1 shows the quality–size trade-offs separately for each language direction under both QE metrics. Both tracks appear in every panel. The headline result is that the base

Table 2: **Model compression task results along size, speed, quality dimensions.** All systems are categorized by track (constrained=top and unconstrained=bottom), and grouped by participant ID. Primary submissions are shown first (solid circles, bold text), followed by contrastive submissions (hollow circles). The serving runtime is shown in the grey tag; the **Data** column marks whether the method is data-free (**—**, on-the-fly quantization), calibration-only (**cal**), or uses fine-tuning/distillation/healing (**FT**). Metric columns: **Size** (GiB); **WU** (s), the median one-sentence warmup wall time; **Net c/s**, peak reliable Czech→German throughput after subtracting that warmup from full-set wall time; **CK**, COMET-Kiwi-XXL QE on a 0–100 scale (↑); and **MX**, MetricX-XXL error (↓). Warmup and Net c/s come from the same batch, selected to maximize net throughput; estimates for which warmup exceeds 75% of full-set wall time are omitted. Each cell is shaded by the system's rank *within its own block and column*, from green (best) through yellow to red (worst), with the rank number in the top-left corner; near-identical scores are grouped to share a rank and colour (grouping thresholds: Size 0.1 GiB, warmup 1 s, speed 100 chars/s, CK 0.1, MX 0.01). ↑/↓ in the header gives the "better" direction; the two tracks are ranked independently. Participant IDs follow Table 1. ⋆: organizer baseline.

(a) Czech→German quality vs. on-disk size.

(b) English→Chinese (Simplified) quality vs. on-disk size.

(c) English→Arabic (Egyptian) quality vs. on-disk size.

Figure 1: Quality vs. on-disk size for the three translation directions. Blue and red denote constrained and unconstrained systems; filled and hollow markers denote primary and contrastive submissions. Labels are participant IDs from Table 1; the star is the uncompressed baseline.

model can be shrunk to roughly a quarter of its on-disk size at essentially no quality cost: the smallest near-lossless systems are INT4 quantizations at 6.0–6.6 GiB (26–29% of the base)—`arc/ilsp/vocaball-int4` for Czech→German, `TahomaMT/int4-bok4` for English→Chinese (Simplified), and `TahomaMT/int4` for English→Arabic (Egyptian)—all within ±0.01 COMET-Kiwi of the uncompressed base. FP8 (W8A8) is essentially lossless at about half the size (10.7 GiB), and several INT8 and mixed-precision systems sit just below the base. Vision-tower removal and script-specific vocabulary pruning contribute additional, quality-neutral savings on top of quantization. Beyond quantization, the frontier degrades sharply: the very smallest artifacts (2.3–4.6 GiB) are the structural-compression systems whose quality has collapsed, so they are Pareto-optimal only in the trivial sense of being small.

In the unconstrained track (Figure 1), *model selection acts as compression*. Pare4Bit's INT4 Gemma-4-12B exceeds the Gemma-3 base on all three directions (+0.02 to +0.07 COMET-Kiwi) at 9.6 GiB, and MetricX confirms the gain (e.g. English→Arabic (Egyptian) 4.49 vs. 5.36). `Tilde`'s distilled 8B student, quantized to NVFP4, stays above the Gemma-3 base for Czech→German at only 5.3 GiB, and UCLA's expert-pruned GPT-OSS-20B (`ESTS`) reaches 4.6–6.3 GiB by trading measured quality for size. These systems show that a well-chosen, newer sub-20B base—compressed—can dominate a compressed older base.

### 4.3 Inference Speed

Table 2 reports peak reliable net throughput on the Czech→German speed benchmark, with the corresponding one-sentence warmup time. Compression buys large speedups: the uncompressed base reaches 626 net chars/s, while the near-lossless `TahomaMT/fp8` system reaches 12,670 net chars/s—about 20× the base throughput at near-baseline quality.

Crucially, throughput is governed as much by the serving runtime as by the precision. Optimized runtimes (Tahoma's C++/CUDA engine, vLLM continuous batching) dominate, whereas a naive `bitsandbytes` INT8 baseline is pathologically slow: on the gross Czech→German batch-1 latency probe it takes 11,960 s (≈3.3 h) versus 85 s for the fastest system, a ∼ 140× spread. Reducing precision is thus necessary but not sufficient for speed—the deployment stack must exploit it. Figure 2 shows the resulting quality–speed trade-offs on the Czech→German speed benchmark. At near-baseline quality, `TahomaMT`'s FP8 system reaches the fastest measured steady-state rate, while optimized vLLM systems form the next tier. The figure reports peak reliable net throughput: source characters divided by full-set wall time after subtracting the one-sentence warmup time. We report throughput scaling with batch sizes {1, 16, 64, and 256} only for Czech→German (the direction for which most submissions opted-in) in Table 3.[4]

**Detailed Inference Speed** Figure 3 shows how net throughput scales with batch size on the Czech→German speed subset, and Table 3 lists per-system net rates at each batch. Throughput grows almost linearly with batch size until a system reaches its declared maximum batch or exhausts memory: the fastest systems are Vicomtech's FFN-pruned AWQ variants (∼ 23.6k chars/s at batch 256) and `TahomaMT`'s FP8/INT4 on its custom engine (∼ 10–13k at batch 256), an order of magnitude above the uncompressed and `bitsandbytes` baselines. Rates are warmup-subtracted (steady-state); cells where the one-sentence warmup dominated the full-set wall time are omitted as unreliable.

[4]We suspect some submissions may not have strictly enforced batch size as a strict parallelism limiter due to the use of continuous batching in the underlying serving runtimes such as vLLM.

## 5 Conclusion and Future Directions

The second edition of WMT Model Compression shared task attracted participants with a variety of methods, which offer useful data points to draw a clear practical map. Post-training quantization—INT4 weight-only and FP8 weight–activation, often combined with vision-tower and vocabulary removal—is the dependable recipe: it compresses the Gemma-3-12B base to about a quarter of its on-disk size and yields up to a 20× steady-state throughput gain while remaining within quality-estimation noise of the uncompressed model. Structural and low-rank methods (SVD, diagonal/binary approximation, heavy FFN pruning) remain risky at this scale: without stronger recovery they trade away quality that light fine-tuning does not restore. In the unconstrained track, treating model selection as a compression decision pays off—a compressed, newer sub-20B base can beat the compressed older base outright. Finally, speed is a property of the serving stack more than the model size. Future editions should freeze peak-VRAM instrumentation, add human/LLM-judge quality, evaluate systems on several hardware configurations, and report speed with model-load time separated from steady-state decoding.

## 6 Limitations

Several caveats apply to this work. First, quality evaluation relies on reference-free QE metrics with strong meta-evaluation performance. High-quality references and large-scale human evaluation are costly, and strong QE metrics often provide comparable insights to reference-based evaluation (Freitag et al., 2024). Our conclusions remain subject to these metrics' limitations and biases.

Second, footprint is measured on disk: peak GPU memory could not be measured reliably, and host resident-set sizes are not comparable across runtimes, so we defer a VRAM comparison. Third, the subtracted warmup includes initialization and one-sentence decoding, not model loading alone. We omit estimates above a 75% warmup fraction to limit subtraction instability. Batch-1 latency is available only for Czech→German. Fourth, measurements use a single H100 configuration; rankings may differ on other hardware. Lastly, unconstrained systems use heterogeneous bases; the constrained base is a reference, not an equal-footing comparison.

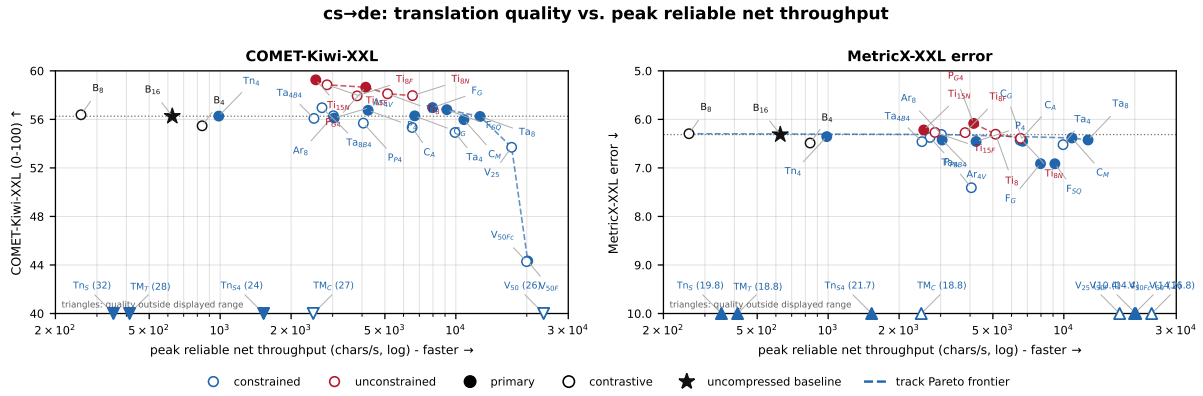

Figure 2: Quality versus peak reliable net throughput on the Czech→German speed benchmark. Throughput is source characters per second after subtracting the median one-sentence warmup time from the median full-set wall time; estimates with warmup exceeding 75% of the full-set wall time are excluded. Blue and red denote constrained and unconstrained systems; filled and hollow markers denote primary and contrastive submissions. Dashed lines show per-track Pareto frontiers. Triangles mark scores outside the displayed quality range.

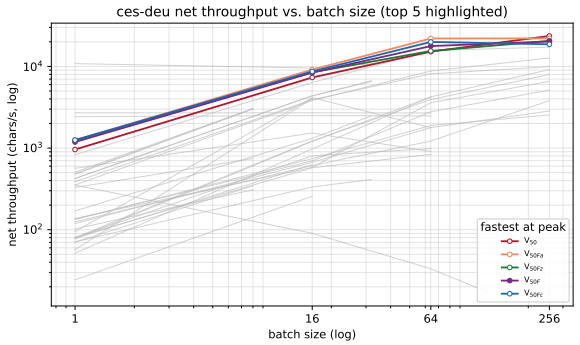

Figure 3: Net throughput vs. batch size (Czech→German, log–log). The five systems with the highest peak rate are highlighted; the rest are drawn in grey.

## Abstract

This paper presents the findings of the Low-resource Indic Languages Translation Shared Task organized at the Eleventh Conference on Machine Translation (WMT 2026). We evaluated machine translation systems across ten English–Indic language pairs spanning three major language families of Northeast India, grouped into moderately resourced and extremely low-resource categories. Built upon the expanded IndicNE-Corp 2.0 dataset, this edition introduced a rigorous, bidirectional multi-domain benchmark covering the Healthcare, Political, Travel, Sports, and Entertainment domains to assess real-world generalizability. The task attracted 24 participating teams who deployed diverse methodologies, including parameter-efficient fine-tuning (PEFT) of multilingual foundations, retrieval-augmented generation (RAG) using frontier large language models (LLMs), and hybrid neuro-symbolic decoding constraints. The systems were evaluated using a comprehensive suite of lexical metrics (BLEU, METEOR, TER, ChrF++) and semantic metrics (BERTScore, COMET). Our analysis reveals a persistent performance cliff under extreme data scarcity and a pronounced directional asymmetry, demonstrating that while current architectures readily decode Indic representations into English, they struggle to generate morphologically complex Indic target text. By publicly releasing these datasets, evaluation protocols, and competitive baselines, this shared task establishes a foundation for advancing research in translation technologies for underrepresented and indigenous languages.

## 1 Introduction

The Indic Machine Translation (MT) Shared Task has become an important benchmark for advancing machine translation research on low-resource Indic languages. First introduced at the Eighth Conference on Machine Translation (WMT 2023)[1] (Pal et al., 2023), the shared task initially focused on four language pairs; English↔Assamese, English↔Mizo, English↔Khasi, and English↔Manipuri to encourage the development of translation systems for underrepresented languages of Northeast India. The initiative continued at WMT 2024[2] (Pakray et al., 2024), further strengthening the benchmark datasets and evaluation framework. Building on these efforts, WMT 2025[3] (Pakray et al., 2025) expanded the task to seven language pairs by introducing Nyishi, Bodo, and Kokborok, resulting in increased international participation and improved multilingual translation systems.

Despite the remarkable progress achieved by multilingual neural machine translation and large language models, many indigenous languages spoken across Northeast India remain severely underrepresented in terms of digital resources. These languages continue to face challenges including the scarcity of parallel corpora, limited monolingual resources, complex morphological structures, multiple writing systems, and a lack of standardized linguistic resources. Moreover, the effectiveness of existing multilingual and large language models can vary substantially across languages and resource conditions, making it important to examine the strategies adopted to adapt these models to low-resource settings. A systematic analysis of such approaches can provide valuable insights into

*Proceedings of the Eleventh Conference on Machine Translation*, pages 1091–1116
October 28-29, 2026 ©2026 Association for Computational Linguistics

the role of model adaptation, data augmentation, filtering, and inference strategies in improving translation quality for these languages. Consequently, developing robust machine translation systems for these languages remains an active and important research problem.

The Eleventh Conference on Machine Translation (WMT 2026)[4] further expands the scope of the shared task by introducing ten English-Indic language pairs organized into two categories according to the availability of parallel training data.

- **Category 1 (Moderate Training Data):** English⇔Assamese (en⇔as), English⇔Mizo (en⇔lus), English⇔Khasi (en⇔kha), English⇔Manipuri (en⇔mni-Beng), and English⇔Meitei (en⇔mni-Mtei).
- **Category 2 (Very Limited Training Data):** English⇔Bodo (en⇔bodo), English⇔Kokborok (en⇔trp), English⇔Karbi (en⇔mjw), English⇔Nagamese (en⇔nag), and English⇔Tagin (en⇔tgj).

Compared with the previous edition, the 2026 shared task replaces the Nyishi language pair with the Manipuri state official script known as the Meitei Mayek script and introduces three new language pairs: Karbi, Nagamese, and Tagin. The Mishing language pair, originally planned for this edition, was withdrawn prior to evaluation due to unforeseen circumstances.

The shared task is built upon the updated INDICNE-CORP 2.0 benchmark. A major novelty of this year's edition is the introduction of a highly balanced, multi-domain evaluation framework spanning Healthcare, Political, Travel, Sports, and Entertainment designed to rigorously assess system generalizability across critical socioeconomic use cases. A total of 24 teams from academia, research laboratories, and industry registered for the shared task, submitting systems based on multilingual transformers, parameter-efficient fine-tuning, retrieval-augmented approaches, and frontier LLMs.

Submitted systems are evaluated using a comprehensive suite of automatic evaluation metrics (Singh et al., 2025) consisting of BLEU (Papineni et al., 2002), METEOR (Banerjee and Lavie, 2005), TER (Snover et al., 2006), ChrF++ (Popović, 2017), BERTScore (Zhang et al., 2020), and COMET (Rei et al., 2020). While BLEU, METEOR, TER, and ChrF++ assess lexical and character-level translation quality, BERTScore and COMET provide semantic evaluation using pretrained neural representations, resulting in a holistic assessment of communicative fidelity.

Through this shared task, our aim is to establish standardized benchmarks, encourage reproducible evaluation, and foster the development of robust multilingual machine translation systems for low-resource Indic languages. We hope that the datasets, evaluation framework, and participant systems presented in this work will facilitate future research on underrepresented languages and contribute to the preservation of the linguistic diversity of Northeast India. The remainder of this paper is organized as follows: Section 2 provides a linguistic overview of the ten target languages. Section 3 details the shared task setup and objectives. Section 4 describes the INDICNE-CORP 2.0 dataset and the multi-domain evaluation benchmark. Section 5 summarizes the participating systems, and Section 6 presents the official evaluation results and comparative analysis. Finally, Section 7 concludes with our key findings.

## 2 Languages

The WMT 2026 Low-resource Indic Languages Translation shared task covers ten language pairs spoken across Northeast India. These languages belong to three major language families: Indo-Aryan, Tibeto-Burman, and Austroasiatic. They exhibit substantial diversity in morphology, syntax, writing systems, and resource availability, making them representative benchmarks for low-resource machine translation. The shared task includes both moderately resourced and extremely low-resource languages to encourage the development of robust multilingual translation systems under varying levels of data availability.

### 2.1 Assamese

Assamese is an Indo-Aryan language spoken predominantly in the northeastern Indian state of Assam, where it serves as the primary official language and a vital regional lingua franca. As one of the 22 constitutional languages listed in the Eighth Schedule of India, Assamese plays a key role in facilitating intercultural communication across the

[4] https://www2.statmt.org/wmt26/indic-mt-task.html

region's diverse population. The language boasts a rich literary tradition tracing back to the early medieval period, written in an eastern Indic script derived historically from ancient Brahmi. Despite its deep cultural heritage and widespread regional usage, Assamese remains digitally under-resourced. Developing scalable computational infrastructure, parallel corpora, and specialized natural language processing (NLP) tools is imperative to foster its technological integration and ensure its sustained vitality in modern digital environments.

### 2.2 Mizo

Mizo is a Tibeto-Burman language spoken primarily in Mizoram, India, as well as in adjacent regions of Manipur, Tripura, Assam, and parts of neighboring Myanmar and Bangladesh. Characterized by a distinctive tonal system and rich phonological structure, Mizo forms a central pillar of the cultural and social identity of the Mizo people. While historically preserved through extensive oral traditions, including folk music and narrative poetry, the language transitioned into a written medium in the late 19th century following the adoption of a modified Roman alphabet introduced by Christian missionaries. Despite an active literary domain and widespread regional literacy, Mizo faces substantial barriers in digital representation due to a scarcity of standardized language resources and annotated corpora. Mitigating these technological gaps through neural machine translation and corpus development is essential for its preservation and modern computational accessibility.

### 2.3 Khasi

The Khasi language (*Ka Ktien Khasi*) is an Austroasiatic language spoken predominantly by the Khasi people in the state of Meghalaya, India (Grierson, 1904). Classified within the Khasic subbranch of the Mon-Khmer language family, Khasi represents an ethnolinguistic island surrounded by predominantly Tibeto-Burman and Indo-Aryan languages (Rabel, 1961). Although the language exhibits significant dialectal diversity-comprising varieties such as Pnar, Lyngngam, and War-the Sohra (Cherrapunji) dialect is widely recognized as Standard Khasi (Nagaraja et al., 2013). Historically an oral language, Khasi was given a standardized written tradition in 1841 when Welsh missionary Thomas Jones introduced a modified Latin alphabet, establishing an orthography that remains in continuous educational, literary, and administrative use today (Grierson, 1904).

Structurally, Khasi is an analytic language characterized by a canonical Subject-Verb-Object (SVO) word order (Rabel, 1961). Unlike many of its geographical neighbors in Northeast India, Khasi is a non-tonal, stress-based language with a rich inventory of phonemic vowels and complex onset consonant clusters (Rabel, 1961). Morphologically, the language employs a robust system of prefixation and grammatical gender, classifying nouns using specific markers such as *u* for masculine, *ka* for feminine, and *i* for diminutive (Henderson, 1976). Today, Standard Khasi holds co-official status in Meghalaya and continues to evolve through widespread literary production, digital media, and active ongoing research in natural language processing (Nagaraja et al., 2013).

### 2.4 Manipuri

Manipuri, also known as *Meiteilon* or *Meeteilon*, is a Sino-Tibetan language primarily spoken in Manipur and serves as the state's principal lingua franca. Despite its official recognition and rich literary tradition, Manipuri remains low-resource for natural language processing and machine translation (MT), with limited parallel corpora, linguistic tools, and pretrained resources (Singh and Bandyopadhyay, 2010; Laitonjam and Singh, 2023).

Manipuri is typologically different from English, following predominantly subject–object–verb (SOV) word order and exhibiting rich agglutinative morphology. Grammatical information such as case, tense, aspect, number, and modality can be expressed through sequences of suffixes, resulting in substantial lexical sparsity and making translation challenging in both directions (Singh and Bandyopadhyay, 2010).

Another important challenge is script variation. Manipuri is written in both the indigenous *Meitei Mayek* and Bengali (Singh et al., 2023) scripts. The coexistence of multiple scripts fragments the already limited resources and introduces issues related to spelling variation, Unicode normalization, and script consistency.

To reflect the two writing systems currently used by the Manipuri-speaking community, the WMT 2026 shared task includes two translation tracks:

- **Manipuri**: written in the Bengali script.
- **Meitei**: written in the indigenous Meitei Mayek script.

Previous studies have explored statistical, unsupervised neural, and corpus-based approaches for English–Manipuri MT (Singh and Singh, 2020; Laitonjam and Singh, 2021). More recently, multilingual pretraining, transfer learning, subword modeling, and synthetic data generation have provided promising directions for addressing data scarcity. Nevertheless, the combination of limited parallel data, morphological complexity, and script variation continues to make Manipuri a challenging language for machine translation.

### 2.5 Bodo

Bodo is a major Tibeto-Burman language belonging to the Boro-Garo group within the broader Boro-Konyak-Jingphaw sub-branch (Wood, 2008). Spoken predominantly across the Bodoland Territorial Region (BTR) of Assam, India, it is officially recognized under the Eighth Schedule of the Indian Constitution. According to the 2011 Census of India, Bodo has approximately 1.5 million speakers, with extended communities in Arunachal Pradesh, Meghalaya, West Bengal, Nepal (where it is known as Meche), and Bangladesh.

Linguistically, Bodo shares structural similarities with related regional languages such as Kokborok and Dimasa. Bhattacharya (1977) categorizes Bodo into four main dialectal regions: North-West, South-West, North-Central, and South. Although historically written using Roman and Assamese/Bengali scripts, Devanagari was officially adopted as the standardized script in 1975, facilitating modern literary production, administrative use, and Natural Language Processing (NLP) efforts.

### 2.6 Kokborok

Kokborok is an indigenous language belonging to the Bodo–Garo subgroup of the Tibeto–Burman branch of the Sino–Tibetan language family (Grierson, 1903; Benedict, 1972). It is primarily spoken in the Indian state of Tripura, with smaller speech communities in southern Assam, Mizoram, and the Chittagong Hill Tracts of Bangladesh. Recognized as one of the official languages of Tripura, Kokborok plays a central role in the linguistic and cultural identity of several Indigenous communities, including the Debbarma, Jamatia, Reang (Bru), Noatia, Koloi, Murasing, Rupini, and Uchoi tribes. According to the Census of India 2011, the language has approximately 0.88 million speakers (Office of the Registrar General and Census Commissioner of India, 2011) in India, with additional speakers residing in neighbouring Bangladesh.

Typologically, Kokborok follows the canonical Subject–Object–Verb (SOV) word order, employs postpositions, and exhibits an agglutinative morphology in which grammatical information is primarily expressed through suffixation. Similar to other Bodo–Garo languages, it also displays productive derivation, compounding, and lexical borrowing from Bengali and English due to prolonged language contact (Karapurkar, 1979; Jacquesson, 2003; Hoque, 2014). Earlier linguistic studies describe Kokborok as a tonal language, although the functional role of lexical tone varies across dialects (Karapurkar, 1972; Jacquesson, 2008). The language generally follows simple consonant–vowel (CV) and consonant–vowel–consonant (CVC) syllable patterns with limited consonant clustering, while grammatical distinctions such as definiteness and case marking contribute to its morpho-syntactic complexity (Daladier, 2002).

### 2.7 Karbi

Karbi is a Tibeto-Burman language spoken primarily in the Karbi Anglong and West Karbi Anglong districts of Assam, India. It serves as the principal language of the Karbi community and exhibits an agglutinative morphological structure together with the canonical Subject-Object-Verb (SOV) word order common among Tibeto-Burman languages. Although Karbi possesses a growing body of written literature and educational materials, computational resources for the language remain scarce. The limited availability of parallel corpora, annotated datasets, and language technologies makes Karbi an important benchmark for evaluating multilingual and low-resource machine translation systems. Its inclusion in WMT 2026 aims to stimulate research on language documentation, corpus creation, and translation technologies for indigenous languages of Northeast India.

### 2.8 Nagamese

Nagamese is a contact language widely spoken throughout the Indian state of Nagaland. It functions as the primary lingua franca among speakers of different Naga languages and has evolved mainly from Assamese, while incorporating lexical and grammatical influences from English, Hindi, and several indigenous Naga languages. Owing to its extensive use in daily communication, trade, education, and media, Nagamese plays an important role in regional multilingual communication.

Nevertheless, standardized orthography, linguistic resources, and parallel corpora remain limited. The inclusion of Nagamese in the WMT 2026 shared task provides a valuable benchmark for machine translation research on contact languages and extremely low-resource settings.

### 2.9 Tagin

Tagin is a Tibeto-Burman language spoken predominantly by the Tagin community in the Upper Subansiri district of Arunachal Pradesh, India. The language represents one of the least-resourced languages included in the WMT 2026 shared task, with very limited digital resources, parallel corpora, and computational linguistic tools. Like many indigenous languages of Northeast India, Tagin faces challenges associated with language documentation, standardization, and technological support. The inclusion of Tagin in this shared task aims to encourage the development of multilingual and transfer-learning approaches capable of handling extremely low-resource translation scenarios while contributing to the preservation and digital revitalization of the language.

## 3 Low-Resource Indic Language Translation 2026 Shared Task

### 3.1 Overview and Task Description

Following the success of the Low-resource Indic Language Translation shared tasks at WMT 2023, WMT 2024, and WMT 2025, the initiative continues as part of the Eleventh Conference on Machine Translation (WMT 2026). The shared task aims to advance research on machine translation for underrepresented Indic languages by providing standardized benchmark datasets, evaluation protocols, and a common platform for comparing translation systems. Despite significant advances in multilingual neural machine translation and large language models, building effective translation systems for low-resource languages remains challenging due to the scarcity of high-quality parallel corpora, limited linguistic resources, and diverse writing systems.

The WMT 2026 shared task expands the scope of previous editions by covering ten English-Indic language pairs spanning multiple language families and writing systems. Similar to previous years, the language pairs are divided into two categories according to the availability of parallel training data, enabling the evaluation of translation systems under different levels of resource availability.

### 3.2 Task Categories

The WMT 2026 Low-resource Indic Languages Translation shared task is organized into two categories according to the availability of parallel training data.

#### 3.2.1 Category 1: Moderate Training Data

Category 1 consists of language pairs with a moderate amount of publicly available parallel training data.

- English ⇔ Assamese (en⇔as)
- English ⇔ Mizo (en⇔lus)
- English ⇔ Khasi (en⇔kha)
- English ⇔ Manipuri (en⇔mni)
- English ⇔ Meitei (en⇔mni-Mtei)

#### 3.2.2 Category 2: Very Limited Training Data

Category 2 focuses on language pairs with very limited parallel training resources.

- English ⇔ Bodo (en⇔bodo)
- English ⇔ Kokborok (en⇔trp)
- English ⇔ Karbi (en⇔mjw)
- English ⇔ Nagamese (en⇔nag)
- English ⇔ Tagin (en⇔tgj)

Although the Mishing (en⇔mrg) language pair was initially planned for this year's shared task, it was withdrawn before the evaluation phase due to unforeseen circumstances. Consequently, the official shared task includes ten English-Indic language pairs.

Overall, the shared task covers ten language pairs spanning three major language families and multiple writing systems, providing a challenging benchmark for multilingual and low-resource machine translation.

### 3.3 Goal

The primary objective of the shared task is to develop robust machine translation systems for low-resource Indic languages despite limited training data. Participants are encouraged to investigate a wide range of approaches, including:

- Leveraging monolingual corpora through semi-supervised and self-supervised learning.

| Language | Sentences | English Words | Target Words |
|---|---|---|---|
| Assamese | 54,000 | 1,033,592 | 878,475 |
| Mizo | 50,000 | 981,535 | 1,044,121 |
| Khasi | 26,000 | 778,689 | 948,853 |
| Manipuri | 23,687 | 422,521 | 357,524 |
| Meitei | 17,000 | 313,175 | 305,198 |
| Bodo | 15,215 | 228,217 | 204,921 |
| Tagin | 5,343 | 26,423 | 25,942 |
| Kokborok | 2,269 | 55,634 | 51,268 |
| Nagamese | 2,000 | 26,453 | 27,709 |
| Karbi | 1,000 | 12,787 | 15,086 |

Table 1: Statistics of the multilingual parallel corpus used for training and validation.

- Multilingual modeling and cross-lingual knowledge transfer.
- Parameter-efficient fine-tuning of multilingual large language models.
- Retrieval-augmented and data augmentation techniques.
- Novel architectures specifically designed for extremely low-resource translation.

## 4 Dataset

The WMT 2026 Low-resource Indic Languages Translation shared task provides standardized multilingual benchmark datasets for training, validation, and evaluation of machine translation systems. The dataset covers ten English-Indic language pairs spanning three language families and multiple writing systems. It consists of parallel corpora for supervised machine translation together with manually curated benchmark test sets designed to evaluate translation quality across diverse application domains.

### 4.1 Training

The training corpus used in the WMT 2026 shared task is based on the updated **IndicNE-Corp 2.0** benchmark dataset, which extends the multilingual resources released in previous editions of the shared task. IndicNE-Corp 2.0 consists of high-quality parallel corpora collected from publicly available resources together with newly curated bilingual datasets for low-resource languages spoken across Northeast India.

The training set covers the following ten language pairs:

The multilingual corpus has been constructed by integrating datasets released in previous research together with newly collected bilingual resources obtained from government publications, multilingual websites, educational resources, online dictionaries, news articles, religious texts, and manually curated translations. For several extremely low-resource languages, additional parallel corpora were developed specifically for this shared task to improve language coverage and establish standardized benchmarks for machine translation research.

Table 1 summarizes the statistics of the multilingual parallel corpus used for training.

### 4.2 Testing

To ensure the highest standard of evaluation, the benchmark test sets underwent a rigorous manual curation process. Native speakers and domain-specific language experts validated all translations based on linguistic correctness, cultural nuance, and domain diversity.

Unlike previous editions, the WMT 2026 benchmark challenges translation systems with a significantly larger and more diverse multilingual test suite spanning ten language pairs. Furthermore explicit inclusion of bidirectional evaluation (English↔Indic) allows for a holistic assessment of lexical accuracy, semantic preservation, domain adaptation, and reverse translation capabilities.

The curated benchmark establishes a highly standardized evaluation framework. It not only facilitates the fair comparison of multilingual machine translation systems under varying levels of resource availability but also serves as a robust foundational resource to catalyze future research in low-resource Indic machine translation.

#### 4.2.1 Domain Selection and Motivation

To rigorously assess the generalizability and real-world applicability of machine translation systems across diverse communicative contexts, the WMT 2026 test benchmark is curated across five representative domains: *Entertainment*, *Sports*, *Healthcare*, *Travel*, and *Political*. These domains were deliberately selected to reflect critical socioeconomic use cases in Northeast India while exposing translation models to distinct linguistic, syntactic, and lexical challenges:

- **Healthcare:** Evaluates translation safety, precise handling of medical terminology, anatomical references, and imperative instructional syntax critical for public health advisories in multilingual rural communities.

- **Political & Administrative:** Tests system fidelity on formal register, complex subordinate clauses, institutional nomenclature, and official government communications.
- **Travel & Tourism:** Focuses on geographic named entities, cultural landmarks, directional instructions, and dialogic service interactions vital for regional economic development.
- **Sports:** Introduces dynamic event reporting, highly frequent numerical expressions, temporal markers, and domain-specific action verbs requiring precise lexical disambiguation.
- **Entertainment:** Assesses colloquial expressions, pop-culture terminology, idiomatic phrasing, and informal discourse structures where literal translation often fails.

#### 4.2.2 Comparative Analysis Across Languages

As detailed in Figure 1, the domain distribution is strictly uniform across all ten language pairs evaluated in the shared task. Each language pair—regardless of its categorization into Category 1 (Moderate Training Data) or Category 2 (Very Limited Training Data)—is evaluated against exactly 400 sentences per domain.

This balanced comparative framework ensures that the performance disparities observed in the final results are strictly attributable to the models' linguistic capabilities and the availability of training data, rather than being skewed by domain overrepresentation in the test sets. Furthermore, the uniform allocation establishes a robust baseline for analyzing cross-lingual transfer learning. By maintaining parity across highly resourced domains (e.g., Entertainment and Travel) and highly specialized domains (e.g., Healthcare and Political), the benchmark allows for precise error analysis regarding how well models generalize specialized vocabulary in extremely low-resource languages like Karbi, Nagamese, and Tagin compared to moderately resourced languages like Assamese and Mizo.

Each domain contributes 400 sentence pairs, resulting in a balanced evaluation dataset covering a broad range of topics.

To evaluate translation performance in both directions, every benchmark is divided equally into:

- **1,000 English → Indic sentences**
- **1,000 Indic → English sentences**

This bidirectional evaluation enables a comprehensive assessment of multilingual translation systems under both forward and reverse translation settings.

The benchmark test sets were manually curated by native speakers and language experts to ensure translation quality, domain diversity, and linguistic correctness. The selected domains represent practical translation scenarios frequently encountered in public communication, healthcare, tourism, media, sports, and government-related content.

Unlike previous editions, the WMT 2026 benchmark evaluates translation systems on a larger and more diverse multilingual test suite spanning ten language pairs. The inclusion of both English→Indic and Indic→English translation directions allows comprehensive evaluation of lexical accuracy, semantic preservation, domain adaptation, and bidirectional translation capability.

Overall, the benchmark provides a standardized evaluation framework for comparing multilingual machine translation systems under varying levels of resource availability and supports future research on low-resource Indic machine translation.

## 5 Participants and System Descriptions

In the WMT 2026 Low-resource Indic Languages Translation Shared Task, a total of 24 teams from academia, research laboratories, and industry registered for the shared task, as listed in Table 4. These teams submitted machine translation systems for one or more of the ten English-Indic language pairs, resulting in a diverse collection of primary and contrastive submissions. The participating systems employed a wide range of methodologies, including multilingual neural machine translation models, large language models (LLMs), parameter-efficient fine-tuning techniques, retrieval-augmented approaches, synthetic data generation, and multilingual transfer learning. This diversity of approaches provides valuable insights into the current state of low-resource machine translation and highlights the continued progress of multilingual NLP research for underrepresented Indic languages.

The following subsections summarize the approaches adopted by each participating team based on their submitted system description papers.

**PANINI:** The PANINI (Huidrom et al., 2026) team from the Indraprastha Institute of Informa-

| Domain | Primary Linguistic Challenges | Dominant Register / Syntax | Key Evaluation Target |
|---|---|---|---|
| **Healthcare** | Specialized medical terms, dosage numerals, morphological inflection of verbs | Formal / Imperative & Informative | Semantic fidelity, low hallucination risk |
| **Political** | Multi-clausal sentences, institutional named entities, formal honorifics | Highly Formal / Complex Hierarchical | Structural syntactic preservation |
| **Travel** | Local toponyms, transliteration across scripts, spatial pre/postpositions | Semi-formal / Descriptive & Directive | Named-entity recognition & script consistency |
| **Sports** | Fast-paced action verbs, score/time numerals, dynamic metaphors | Semi-formal to Informal / Active voice | Lexical disambiguation, numeric fidelity |
| **Entertainment** | Slang, cultural idioms, loanwords, code-mixing | Informal / Conversational | Lexical adaptation, idiomatic accuracy |

Table 2: Comparative analysis of linguistic challenges and evaluation targets across the five selected benchmark domains.

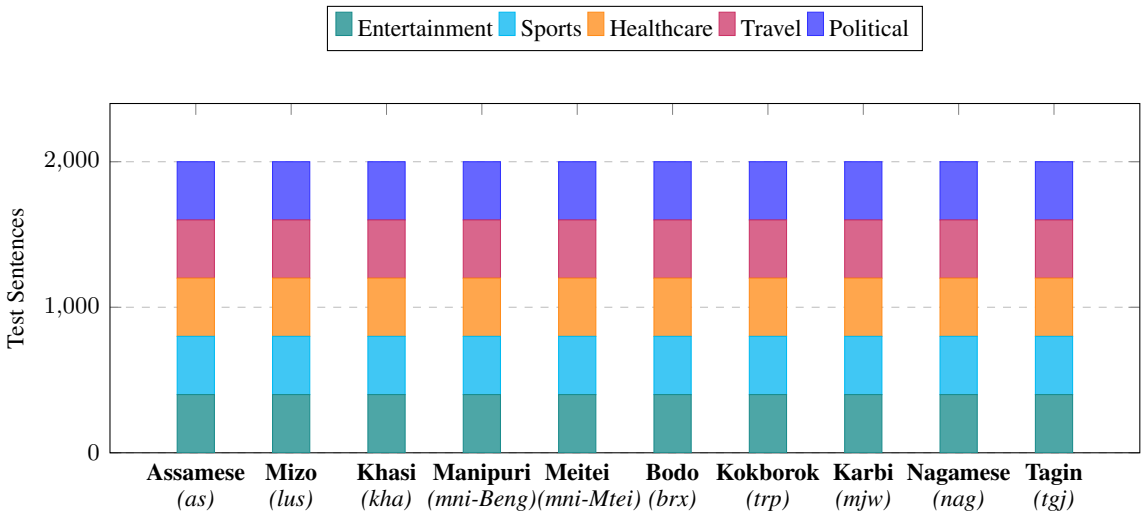

Figure 1: Domain composition of the benchmark test set across all 10 language pairs. Each pair contains exactly 2,000 sentences, distributed uniformly across five domains (400 sentences per domain) and divided equally between the English→Indic and Indic→English translation directions.

| Language Pair | Submissions |
|---|---|
| English - Assamese | 15 (primary), 12 (contrastive) |
| English - Mizo | 9 (primary), 9 (contrastive) |
| English - Khasi | 8 (primary), 8 (contrastive) |
| English - Manipuri | 14 (primary), 6 (contrastive) |
| English - Meitei | 9 (primary), 2 (contrastive) |
| English - Bodo | 10 (primary), 10 (contrastive) |
| English - Kokborok | 4 (primary), 6 (contrastive) |
| English - Karbi | 2 (primary), 3 (contrastive) |
| English - Nagamese | 5 (primary), 6 (contrastive) |
| English - Tagin | 4 (primary), 6 (contrastive) |

Table 3: Number of submitted systems for the English→Indic translation direction in the WMT 2026 Low-resource Indic Languages Translation shared task.

tion Technology (IIIT) Delhi participated in the WMT 2026 Low-resource Indic Languages Translation Shared Task with English↔Manipuri systems covering both Bengali and Meitei Mayek scripts. Their systems were based on the 1B-parameter IndicTrans2 architecture and adapted using rank-stabilized LoRA (rsLoRA) for parameter-efficient fine-tuning. The approach combined back-translation, forward translation, and iterative pseudo-labelling, with synthetic data filtered using LaBSE similarity and model-confidence thresholds. Subword regularization and script-aware preprocessing and post-processing were further employed to improve robustness across both Manipuri scripts.

**VoxNexus-Translate:** The VoxNexus-Translate (Zhou et al., 2026) team from VoxNexus, Shanghai, developed a hybrid machine translation system combining a fine-tuned multilingual decoder-only LLM with Statistical Machine Translation (SMT) word alignment for low-resource Indic languages. Their approach employed IBM Models and `fast_align` to extract high-confidence bilingual lexicons and phrase mappings, which were incorporated as decoding constraints to reduce hallucinations and improve the translation of named entities, numerals, and domain-specific terminol-

| Team Name | Name of University/Lab/Industry/Group |
|---|---|
| PANINI | Indraprastha Institute of Information Technology, Delhi |
| VoxNexus-Translate | VoxNexus, Shanghai |
| ADI-KIIT | Kalinga Institute of Industrial Technology, Odisha |
| DoDS-IITPKD | Indian Institute of Technology Palakkad, Kerala |
| gators | University of Florida |
| BRS-NK | Kathmandu University, Bagmati |
| TIP-RBG-AI | Kitami Institute of Technology, Hokkaido |
| EROL | Nalanda University |
| RozarNLP-cr7 | Indian Institute of Information Technology, Design and Manufacturing, Kurnool |
| Decepticons-IIITH | International Institute of Information Technology, Hyderabad |
| MTG-LIRA | Centre for Development of Advanced Computing (CDAC), Pune |
| BVSLP | Banasthali Vidyapith |
| LTRC_Plural | IIIT Hyderabad |
| ANVITA | CAIR, Defence Research and Development Organisation (DRDO), Bangalore |
| Winterpeg | The University of Winnipeg, Manitoba, Canada |
| KrenTransV0-1 | MWire Labs, Shillong, Meghalaya |
| NLP-MT_Amrita | Amrita Vishwa Vidyapeetham, Bengaluru Campus, Karnataka |

| JH_NLP_APAShreya2 | PES University, Karnataka |
| 星辰之力 | China Telecom Corporation Limited, Chongqing Branch |
| AkibaNLP-TUT | Toyohashi University of Technology / Natural Language Processing Lab. |
| CIT MT BTECH 2026 | Central Institute of Technology Kokrajhar, Assam |
| SCE-KIIT | Kalinga Institute of Industrial Technology |
| IndicMT | Jadavpur University, Kolkata |

Table 4: Overview of the teams registered for the WMT 2026 Low-resource Indic Languages Translation shared task.

ogy. The system further employed script normalization, transliteration, and rule-based post-processing to improve translation consistency and faithfulness.

**ADI-KIIT:** The ADI-KIIT (Aditya and Ekbal, 2026) team from Kalinga Institute of Industrial Technology developed bidirectional English–Assamese translation systems using the compact 200M-parameter distilled IndicTrans2 model with LoRA-based parameter-efficient fine-tuning. Their approach explored supervised fine-tuning (SFT) followed by Direct Preference Optimization (DPO), with preference signals derived from GEMBA-style LLM judging, reference-free MQM, and COMET. Based on development-set performance, SFT was selected as the primary system for Assamese-to-English, while the SFT+DPO configuration was used for English-to-Assamese.

**DoDS-IITPKD:** The DoDS-IITPKD (Salvin et al., 2026) team from the Indian Institute of Technology Palakkad developed bidirectional translation systems for six English–Indic language pairs by adapting two multilingual pretrained architectures. They employed NLLB-200-3.3B for Khasi, Mizo, and Kokborok, and IndicTrans2 for Assamese, Manipuri, and Bodo. The models were adapted using parameter-efficient LoRA together with DoRA and rsLoRA. For Khasi and Kokborok, which are not natively supported by the NLLB tokenizer, the team employed a same-script surrogate language-tag strategy. Their primary systems used only the official shared-task data, while the contrastive systems incorporated additional external corpora.

**gators:** The gators (Dhawan et al., 2026) team from the University of Florida developed a training-free retrieval-augmented machine translation system using Gemini 2.5 Flash with many-shot in-context learning. Their approach employed BM25 retrieval to select relevant parallel examples from the training corpus and incorporate them into prompts without model fine-tuning. The primary system used only the official WMT 2026 data, while the contrastive system incorporated additional publicly available parallel corpora where

available.

**BRS-NK:** The BRS-NK (Subedi and Karki, 2026) team from Kathmandu University developed bidirectional English–Assamese and English–Bodo translation systems by fine-tuning the NLLB-200-600M model. While Assamese is natively supported by NLLB, Bodo was handled using the Hindi (`hin_Deva`) language tag through a proxy-language strategy. Their approach emphasized extensive data preprocessing, including text normalization, numeral conversion, alignment filtering, artifact removal, and deduplication. The primary systems used only the official shared-task data, while the contrastive systems incorporated additional parallel resources.

**TIP-RBG-AI:** The TIP-RBG-AI (HB et al., 2026) team from Kitami Institute of Technology proposed a zero-shot cross-lingual translation framework using three massively multilingual MT architectures: NLLB-200, MADLAD-400, and IndicTrans2. Rather than fine-tuning the models, their approach focused on inference optimization through script normalization, algorithmic back-transliteration for Romanized text, and phylogenetic script mapping for extremely low-resource languages. The framework aimed to improve semantic fidelity and lexical preservation across both moderate- and very low-resource language settings.

**EROL:** The EROL (Devi and Lee, 2026) team from Nalanda University developed bidirectional neural machine translation systems for English–Assamese, English–Bodo, and English–Manipuri in both Bengali and Meitei Mayek scripts. Their systems employed the Transformer-Base architecture with six encoder and six decoder layers, shared source–target embeddings, and BPE tokenization. A single bidirectional model was trained for each language pair using standard sequence-to-sequence cross-entropy learning.

**RozarNLP-cr7:** The RozarNLP-cr7 (Yadav et al., 2026) team from IIITDM Kurnool developed multilingual translation systems based on the NLLB-200 Distilled 1.3B model, adapted using LoRA for parameter-efficient fine-tuning. Their approach employed joint multilingual training to exploit cross-lingual transfer across several low-resource language pairs, including Assamese, Manipuri, Mizo, Khasi, and Nyishi. For Meitei Mayek, where multilingual adaptation remained challenging, the pretrained NLLB-200 model was retained. IndicTrans2 and pretrained NLLB-200 models without task-specific adaptation were additionally evaluated as contrastive systems.

**Decepticons-IIITH:** The Decepticons-IIITH (Rao et al., 2026) team from IIIT Hyderabad developed English-to-Indic translation systems for Assamese, Mizo, Nagamese, and Bodo using NLLB-200 for the first three languages and IndicTrans2 for Bodo. Their approach generated synthetic parallel data through back-translation of public monolingual corpora and filtered the resulting pairs using Morphology-Aware Lexicon Matching (MALM). The models followed a two-stage training strategy consisting of continued pretraining on the filtered synthetic data, followed by fine-tuning on the official parallel corpus.

**MTG-LIRA:** The MTG-LIRA (Hede et al., 2026) team from CDAC Pune developed Transformer-based encoder–decoder NMT systems using the OpenNMT and Eole frameworks for multiple low-resource Indic language pairs, including Assamese, Bodo, Mizo, Nyishi, and Manipuri in both Meitei Mayek and Bengali scripts. Their systems were trained on cleaned and preprocessed WMT 2026 parallel data, with Byte Pair Encoding (BPE) applied for subword tokenization.

**BVSLP:** The BVSLP (Arora et al., 2026) team from Banasthali Vidyapith developed neural machine translation systems based on an encoder–decoder architecture, augmented with linguistic preprocessing for named-entity handling. Their methodology employed a rule-based Named Entity Recognition (NER) module followed by a Named Entity Translation (NET) component, using bilingual knowledge-base lookup and transliteration to preserve organization, location, and other named entities. The processed data were further segmented using Byte Pair Encoding (BPE) before fine-tuning the NMT models, improving the handling of rare words, morphological variations, and low-resource vocabulary.

**LTRC_Plural:** The LTRC_Plural (Vishnuraj et al., 2026) team from IIIT Hyderabad developed bidirectional English translation systems for Assamese, Mizo, Khasi, and Tagin using two multilingual foundation models: the encoder–decoder NLLB-1.3B and Sarvam Translate, built on Gemma 3 4B. Their primary systems employed QLoRA-based parameter-efficient fine-tuning, us-

ing NLLB for Assamese and Mizo and a shared multilingual Sarvam adapter with rsLoRA for Khasi and Tagin. The contrastive systems explored additional parallel corpora with temperature-based multilingual sampling and reinforcement learning using RLOO, with BLEU and ChrF++ as reward signals.

**ANVITA:** The ANVITA (J et al., 2026) team from CAIR, DRDO, Bangalore, developed bidirectional translation systems for Khasi, Nagamese, and Tagin using a transfer-learning approach based on the 220M-parameter T5-base model. The model was fine-tuned using standard NMT and cycle-consistency losses, with data augmentation through English paraphrasing, related-language parallel data, back-translation, and additional external resources. For Nagamese-to-English, the primary system instead employed IndicTrans2 in a zero-shot setting with Assamese transliteration of the Nagamese input.

**Winterpeg:** The Winterpeg (Rittikar and Ramanna, 2026) team from the University of Winnipeg developed a routed two-model translation system for six low-resource North-East Indian languages. For Assamese, Manipuri (Bengali script), and Mizo, they fine-tuned NLLB-200 on the official parallel data. For Khasi, Nyishi, and Meitei Mayek, they trained a vocabulary-free UTF-8 byte-level decoder-only language model from scratch, augmented with a causal Neural Cellular Automaton (NCA) front-end. This byte-level approach enables translation of previously unseen scripts without requiring explicit vocabulary engineering.

**KrenTransV0-1:** The KrenTransV0-1 (Nyalang et al., 2026) team from MWire Labs developed a hybrid translation framework covering all 11 low-resource language pairs in the English-to-target direction. Their approach employed fine-tuned IndicTrans2 models for Indic-script languages and NLLB-200 1.3B models for Latin-script languages. For three extremely low-resource languages where NLLB exhibited output collapse, the team instead fine-tuned the M2M-100 418M architecture.

**NLP-MT_Amrita:** The NLP-MT_Amrita(Sree and Gupta, 2026) team from Amrita Vishwa Vidyapeetham proposed a GRPO-inspired Agentic Retrieval-Augmented Generation (RAG) framework for bidirectional English–Bodo and English–Manipuri translation. Their approach combined IndicTrans2, NLLB-600M, and Sarvam-Translate with Milvus-based retrieval and multilingual-e5-large embeddings. A dynamic agent explored multiple retrieval and decoding configurations, while a reward function based on SacreBLEU and BERT similarity selected the most suitable translation candidate. The framework operated without task-specific model fine-tuning, providing a scalable approach for low-resource machine translation.

**DELAB-IIITM:** The DELAB-IIITM(Oinam et al., 2026) team from IIIT Manipur developed English-to-Indic translation systems for Assamese, Bodo, and Manipuri in both Bengali and Meitei Mayek scripts using two pretrained multilingual models: NLLB-200-Distilled-600M and IndicTrans2-1.1B. Their approach employed full fine-tuning of NLLB-200 for English-to-Assamese and English-to-Manipuri, while IndicTrans2 was adapted using LoRA for English-to-Manipuri and English-to-Bodo. All systems were trained exclusively on the official WMT 2026 training data.

**JH_NLP_APAShreya2:** The JH_NLP_APAShreya2 (Sinha et al., 2026) team from PES University developed an English-to-Manipuri translation system using the NLLB-200-Distilled-600M model with LoRA-based parameter-efficient fine-tuning. The model was trained on the official WMT 2026 English–Manipuri parallel corpus, targeting Manipuri in the Bengali script. Their primary system used the complete training dataset with optimized LoRA parameters to improve translation performance.

星辰之力: The 星辰之力 (Ruan et al., 2026) team from China Telecom Corporation Limited developed English-to-Indic translation systems for Bodo, Karbi, Kokborok, Nagamese, and Tagin using Qwen2.5-32B-Instruct with LoRA-based fine-tuning and Hunyuan-MT-7B with full-parameter fine-tuning. Their approach explored SFT and DPO-based optimization and incorporated automatically generated bilingual word-level alignment tables as "Helpful Vocabulary" to improve lexical guidance in low-resource translation.

**AkibaNLP-TUT:** AkibaNLP-TUT (Kachi et al., 2026) from Toyohashi University of Technology employed language-specific word-level noise injection to improve robustness and generalization for low-resource translation in the Indic-to-English direction. Their approach augmented Bengali–English or Hindi–English parallel data using lexi-

cal items extracted from monolingual data of the corresponding low-resource language.

**CIT MT BTECH 2026:** The Central Institute of Technology Kokrajhar team developed English-to-Assamese machine translation systems using a Transformer encoder–decoder model trained from scratch and the pretrained NLLB-200 Distilled 600M model. Their approach compared BPE-based Transformer training with transfer learning through fine-tuning NLLB-200, demonstrating the effectiveness of multilingual pretraining for low-resource Assamese translation.

**SCE-KIIT:** SCE-KIIT (Maiti et al., 2026b,a) from Kalinga Institute of Industrial Technology developed systems for English to Nagamese and English–Kokborok. For English to Nagamese, they fine-tuned NLLB-200-Distilled-600M. For Englis–Kokborok, the team proposed KokLLaMA, based on Llama-3.2-3B-Instruct and adapted using QLoRA on 10,856 Kokborok conversational QA pairs. The system employed structured translation prompting and rule-based post-processing to reduce repetitive generation loops. Their approach demonstrates the potential of both multilingual NMT adaptation and cross-task transfer from conversational data for low-resource Indic machine translation.

**IndicMT:** IndicMT from Jadavpur University developed bidirectional low-resource translation systems using Sarvam-Translate, based on the Gemma 3 architecture, with QLoRA-based parameter-efficient fine-tuning. Their approach employed NLLB-200-based back-translation to generate and filter synthetic parallel data, followed by 4-bit quantized adaptation of the translation model. The framework combined transfer learning, data augmentation, and parameter-efficient fine-tuning to support resource-efficient Indic machine translation.

## 5.1 Comparative Technological Analytics and Methodological Taxonomy

The submissions to the WMT 2026 shared task reflect a significant paradigm shift in low-resource machine translation. Rather than training models strictly from scratch on bilingual corpora, participating teams converged on five major technical dimensions: foundation model selection, parameter-efficient adaptation, synthetic data filtering, script-handling strategies, and test-time retrieval/reasoning frameworks. Table 5 synthesizes the core technical components adopted by all 24 participating teams.

### 5.1.1 Key Methodological Trends

**1. Dominance of Pretrained Multilingual Foundations vs. LLMs** The architectural landscape was split into two primary paradigms:

- **Multilingual Encoder–Decoder Models:** NLLB-200 (ranging from 600M to 3.3B) and IndicTrans2 (200M to 1.1B) served as the primary workhorses for over 70% of participating teams, demonstrating that domain-aligned pretraining provides superior parameter efficiency and syntactic stability for agglutinative Indic languages.

- **Autoregressive Large Language Models:** Frontier decoder-only models (e.g., Gemini 2.5 Flash, Qwen2.5-32B, Gemma 3/Sarvam-Translate, and Llama-3.2-3B) were successfully deployed using either in-context learning or parameter-efficient adaptation, particularly excelling in lexical fluency for English target generation.

**2. Evolution of Parameter-Efficient Adaptation and Preference Alignment** Rather than performing full-parameter updates, teams predominantly leveraged Parameter-Efficient Fine-Tuning (PEFT):

- **Advanced Adapter Variants:** Teams transitioned from standard LoRA to stabilized variants including rank-stabilized LoRA (`rsLoRA`) and Weight-Decomposed Low-Rank Adaptation (`DoRA`) to mitigate gradient instability in extremely low-resource settings (e.g., PANINI, DoDS-IITPKD, LTRC_Plural).

- **Post-Training Preference Optimization:** Beyond standard cross-entropy loss, teams explored reinforcement learning and direct alignment—such as Direct Preference Optimization (DPO), Reinforcement Learning from Online Output (RLOO), and Group Relative Policy Optimization (GRPO) guided by COMET, SacreBLEU, and GEMBA-style metric rewards (e.g., ADI-KIIT, LTRC_Plural, NLP-MT_Amrita, 星辰之力).

| Team | Base Architecture(s) | Adaptation / Training Paradigm | Data Augmentation & Filtering | Inference / Routing Strategy |
|---|---|---|---|---|
| **PANINI** (Huidrom et al., 2026) | IndicTrans2 (1B) | PEFT (rsLoRA) | BT, FT, Pseudo-labeling, LaBSE filtering | Script-aware post-processing |
| **VoxNexus-Translate** (Zhou et al., 2026) | Decoder-only LLM | SFT + SMT Alignment | IBM Model / `fast_align` phrase extraction | SMT decoding constraints, Transliteration |
| **ADI-KIIT** (Aditya and Ekbal, 2026) | IndicTrans2-Distilled (200M) | LoRA + DPO (GEMBA / COMET) | Preference pair generation | Metric-guided decoding |
| **DoDS-IITPKD** (Salvin et al., 2026) | NLLB-200 (3.3B), IndicTrans2 | PEFT (LoRA, DoRA, rsLoRA) | External corpora (contrastive) | Surrogate script language-tagging |
| **gators** (Dhawan et al., 2026) | Gemini 2.5 Flash | Training-free / Many-shot ICL | External parallel corpora (contrastive) | BM25 dynamic context retrieval |
| **BRS-NK** (Subedi and Karki, 2026) | NLLB-200 (600M) | Full Fine-Tuning | Deduplication, artifact / numeral cleaning | Proxy-language tagging (`hin_Deva`) |
| **TIP-RBG-AI** (HB et al., 2026) | NLLB-200, MADLAD-400, IndicTrans2 | Zero-Shot Inference | None | Phylogenetic script mapping, Back-transliteration |
| **EROL** (Devi and Lee, 2026) | Transformer-Base (from scratch) | Standard Seq2Seq Cross-Entropy | Shared source-target BPE | Standard beam search |
| **RozarNLP-cr7** (Yadav et al., 2026) | NLLB-200 Distilled (1.3B) | Multilingual Joint LoRA | Cross-lingual parameter sharing | Script fallback routing |
| **Decepticons-IIITH** (Rao et al., 2026) | NLLB-200, IndicTrans2 | Continued Pretraining + Fine-Tuning | Back-translation + MALM lexicon filtering | Two-stage progressive adaptation |
| **MTG-LIRA** (Hede et al., 2026) | OpenNMT / Eole Transformer | Supervised NMT Training | Cleaned parallel corpus + BPE | Standard beam search |
| **BVSLP** (Arora et al., 2026) | Encoder-Decoder Transformer | Supervised Fine-Tuning | Rule-based NER + KB-driven NET | Transliteration and entity preservation |
| **LTRC_Plural** (Vishnuraj et al., 2026) | NLLB-200 (1.3B), Sarvam (Gemma 3 4B) | QLoRA, rsLoRA, RL (RLOO) | Multilingual temperature sampling | BLEU / ChrF++ reward optimization |
| **ANVITA** (J et al., 2026) | T5-base (220M), IndicTrans2 | SFT + Cycle-consistency loss | English paraphrasing, related-pair transfer | Zero-shot script transliteration |
| **Winterpeg** (Rittikar and Ramanna, 2026) | NLLB-200, Byte-level LM | SFT + Byte-level causal NCA | Character-level UTF-8 byte modeling | Routed hybrid architecture |

Table 5: System architecture and methodological taxonomy of participating teams in the WMT 2026 Low-resource Indic Shared Task.

**3. Morphological & Script Bottleneck Solutions** Given the orthographic challenges presented by Meitei Mayek, Latin-based orthographies (Khasi, Mizo), and unstandardized contact languages (Nagamese), teams implemented novel script handling mechanisms:

- **Surrogate and Proxy Tagging:** For languages unsupported by default tokenizers (e.g., Kokborok, Bodo), teams utilized same-script surrogates or related-language proxy tags (e.g., `hin_Deva`) to leverage existing embedding representations (DoDS-IITPKD, BRS-NK).
- **Phylogenetic Mapping & Transliteration:** Algorithmic back-transliteration and phylogenetic script alignment enabled zero-shot transfer across related Indic orthographies (TIP-RBG-AI, ANVITA).
- **Byte-Level Language Modeling:** Winterpeg addressed subword vocabulary fragmentation by utilizing UTF-8 byte-level decoder models augmented with Neural Cellular Automata (NCA) front-ends.

**4. Retrieval-Augmented Generation (RAG) and Hybrid Decoding** Several teams demonstrated strong performance without parameter updates by pairing retrieval engines with structured prompting or constrained decoding:

- **In-Context Exemplar Retrieval:** Dynamic retrieval (BM25 or dense embeddings via

Milvus/multilingual-e5) allowed systems like `gators` and `NLP-MT_Amrita` to achieve top-tier performance on unseen vocabulary by supplying relevant translation pairs in-prompt.

- **Neuro-Symbolic & SMT Hybridization:** VoxNexus-Translate and 星辰之力 integrated Statistical Machine Translation (IBM Models/`fast_align`) word-alignment tables as hard decoding constraints or "Helpful Vocabulary" prompts, drastically curtailing hallucination rates in named entities and technical terminology.

## 6 Results and Discussion

The official evaluation results for all ten English–Indic language pairs across twenty bidirectional translation tracks are reported in Tables 6 through 25. Each table lists participating systems ranked by performance across six standardized lexical and neural evaluation metrics: BLEU, METEOR, TER, ChrF++, BERTScore, and COMET. In accordance with shared task evaluation protocols, system descriptions and discussions focus primarily on verified primary submissions, while contrastive systems and late submissions (highlighted ¶[5]) are included in the tabular benchmarks for completeness and empirical reference.

### 6.1 Discussion and Comparative Analysis

The empirical outcomes of the WMT 2026 shared task reveal significant heterogeneity across language families, resource tiers, and modeling paradigms. By evaluating systems simultaneously across exact string-matching metrics (BLEU), subword/character overlap (ChrF++), edit distance (TER), and deep cross-lingual embeddings (BERTScore, COMET), the evaluation benchmark exposes key dimensions of modern low-resource translation: (i) the stark divide between moderate and extreme data scarcity, (ii) asymmetric capacity between target-language generation and English decodability, (iii) the behavioral divergence between supervised parameter-efficient fine-tuning (PEFT) and training-free retrieval-augmented generation (RAG), and (iv) script-induced tokenization bottlenecks. The following subsections present a granular comparative analysis of these empirical dynamics.

[5] ¶ Late submission indicates systems submitted after the deadline during the late submission period.

#### 6.1.1 Data Regimes and the Resource Divide

The evaluation benchmark demonstrates an unambiguous performance cliff separating Category 1 (Moderate Training Data, $\geq$ 17k parallel sentences) from Category 2 (Very Limited Training Data, $\leq$ 15k down to 1k sentences), as illustrated in Figure 2.

In Category 1 tracks (Assamese, Mizo, Khasi, and Manipuri in both scripts), systems achieved consistent, high-utility translations, with peak English→Indic scores reaching 19.38 BLEU (Assamese, Table 6), 21.11 BLEU (Mizo, Table 8), and 29.30 BLEU (Khasi, Table 10). In these settings, foundational encoder-decoder models (e.g., IndicTrans2 and NLLB-200) successfully generalized across unseen test sets when adapted via parameter-efficient fine-tuning (PEFT).

In contrast, Category 2 languages (Kokborok, Karbi, and Tagin) experienced severe performance degradation. In English→Tagin (Table 24), the highest primary score was limited to 4.81 BLEU (ANVITA), while English→Karbi (Table 20) reached only 5.39 BLEU (gators). Similarly, Kokborok (Table 18) topped at 6.12 BLEU (KrenTransV0-1). Under such extreme data scarcity (1k–5k sentence pairs), supervised parameter updates failed to construct stable cross-lingual representations, leading to high out-of-vocabulary rates and degenerate decoder outputs.

#### 6.1.2 Directional and Typological Asymmetry

A granular examination of the translation directions reveals an important typological distinction:

- **Agglutinative and Indic-Script Tracks:** For Tibeto-Burman languages characterized by complex suffixation (Manipuri and Bodo), Indic→English performance drastically outstripped the English→Indic direction. In Manipuri (Bengali script), the highest primary score into English reached 45.86 BLEU (gators, Table 13), compared to a maximum of only 11.95 BLEU in the reverse direction (Winterpeg, Table 12). A parallel gap occurred in Bodo (35.54 vs. 16.30 BLEU, Tables 17 and 16). This asymmetry demonstrates that pretrained decoders readily generate fluent English from morphologically rich source representations, but struggle to synthesize the intricate case markers, mood inflections, and agglutinative affix chains required on the Indic target side.

Table 25: Performance evaluation for primary and contrastive systems on Tagin to English translation task.

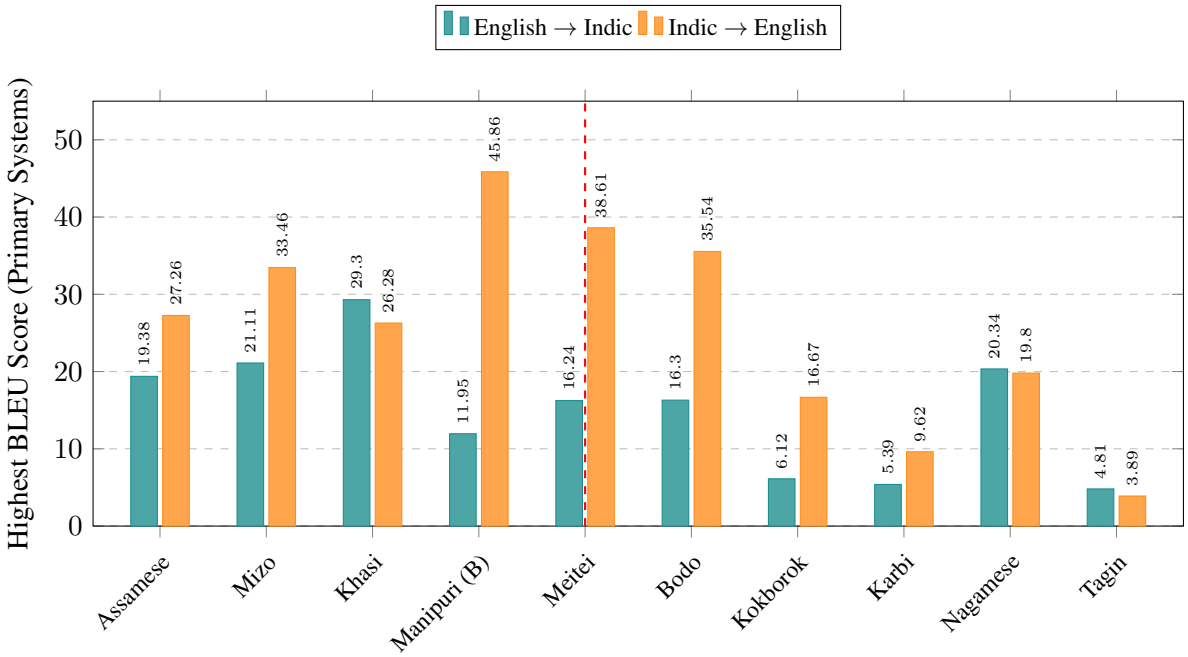

Figure 2: Maximum BLEU scores achieved by primary systems across all ten language pairs. The vertical dashed line separates Category 1 (Moderate Data, left) from Category 2 (Very Limited Data, right).

- **Latin-Script and Lingua Franca Tracks:** Conversely, languages employing Latin orthography (Khasi) or functioning as regional contact Creoles (Nagamese) exhibited near-directional parity or reversed asymmetry. English→Khasi achieved 29.30 BLEU compared to 26.28 BLEU for Khasi→English (Tables 10 and 11). Similarly, English→Nagamese reached 20.34 BLEU (Decepticons-IIITH, Table 22) against 19.80

BLEU for Nagamese→English (gators, Table 23). Because Khasi follows an analytic Subject-Verb-Object (SVO) syntax and Nagamese employs simplified contact morphology derived from Assamese, target generation suffered far less from morphological compounding errors.

#### 6.1.3 Metric Divergence: Exact Match vs. Semantic Preservation

The evaluation results highlight a marked divergence between surface-level n-gram metrics (BLEU, ChrF++) and neural semantic representations (COMET, BERTScore). Figure 3 illustrates the correlation between BLEU and COMET for primary submissions in the Manipuri (Bengali script)→English task.

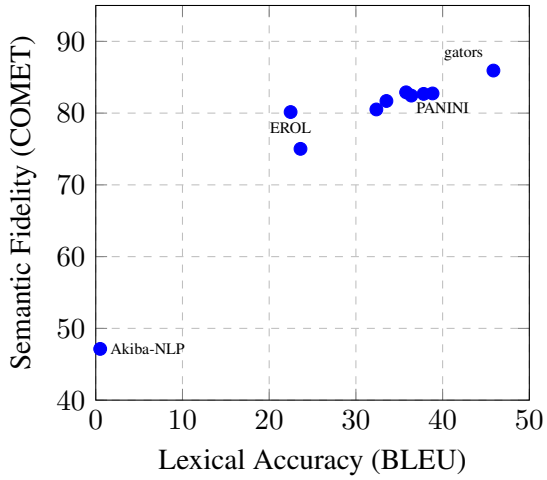

Figure 3: Lexical Overlap (BLEU) versus Semantic Fidelity (COMET) for primary submissions on the Manipuri (Bengali script)→English benchmark.

While frontier LLM-based prompting (**gators**) achieved top rankings on both axes (45.86 BLEU, 85.93 COMET), the mid-tier cluster formed by parameter-efficient transformer models (**PANINI**, **TIP-RBG-AI**, **DoDS-IITPKD**, and **EROL**) exhibits an important trend. Despite a lexical drop of up to 23.39 BLEU points relative to the top system, these models maintained high COMET scores ($> 80.0$). This demonstrates that adapted sequence-to-sequence models preserve core cross-lingual semantics and contextual discourse even when generating lexical variations or synonymous phrasings penalized by rigid n-gram matching.

Conversely, string edit-distance analysis revealed acute degeneration patterns in under-resourced tracks. In English→Tagin (Table 24) and Khasi→English (Table 11), several unconstrained generative submissions exhibited Translation Edit Rates (TER) exceeding 120.0, peaking at 311.41 (IndicMT). Inspection indicates that when tokenizers encounter unseen vocabularies in extreme low-resource regimes, autoregressive decoders enter repetitive token loops or hallucinate ungrounded text sequences. This finding demonstrates the necessity of pairing semantic evaluation with length-sensitive edit penalties (TER). While embedding-based metrics like COMET may mask structural collapse by generously scoring topically relevant vocabulary, severe TER spikes act as a critical diagnostic tool to expose catastrophic over-generation and repetitive token loops.

#### 6.1.4 Architectural Paradigms and Methodological Insights

The variance across task tracks reveals structural trade-offs between general massively multilingual pretraining and region-specific architectures. As visualized in Figure 4, we extracted the exact COMET scores from primary submissions utilizing strictly **NLLB-200** (e.g., **BRS-NK**, **RozarNLP-cr7**) versus strictly **IndicTrans2** (e.g., **PANINI**, **ADI-KIIT**) to evaluate foundation robustness.

- **IndicTrans2 vs. NLLB-200 Pretraining: IndicTrans2** demonstrated a notably higher median COMET score (74.11 vs. 68.18) and a tighter interquartile range (IQR 21.32 vs. 30.31) compared to **NLLB-200**. It benefited significantly from pre-allocated subword capacity tailored to South Asian linguistic typologies. In contrast, **NLLB-200** exhibited wider variance across Category 2 languages, performing strongly when language tags aligned, but suffering representation collapse when encountering unsupported vocabularies.

- **Retrieval-Augmentation vs. Supervised Fine-Tuning:** In-context exemplar retrieval paired with frontier LLMs (**gators**, **NLP-MT_Amrita**) proved exceptionally competitive in Category 2 tracks. Dynamic exemplar injection bypasses parameter updates entirely, effectively grounding the LLM decoder without succumbing to the catastrophic over-fitting seen in supervised fine-tuning under small corpus regimes.

- **Neuro-Symbolic and Lexical Alignment Constraints:** Teams integrating statistical

phrase tables and word mappings into generative decoding (**VoxNexus-Translate**, 星辰之力) substantially constrained hallucination rates. This hybrid approach ensured higher lexical precision on named entities, numeric expressions, and specialized domain vocabulary.

- **Tokenization-Free and Script-Agnostic Frontiers:** For orthographies unsupported by standard subword vocabularies (e.g., Meitei Mayek), byte-level language modeling (**Winterpeg**) and phylogenetic zero-shot transliteration (**TIP-RBG-AI**) provided promising alternatives, preventing subword fragmentation and enabling cross-script transfer.

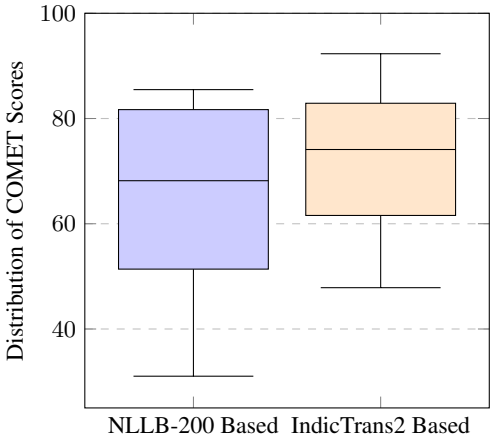

Figure 4: Distribution of COMET scores across shared task tracks grouped by foundational pretrained architecture. Metrics are drawn from primary submissions utilizing strictly NLLB-200 or IndicTrans2 frameworks.

### 6.2 Linguistic Bottlenecks and Future Directions

Despite major advances in parameter-efficient adaptation, agentic retrieval, and hybrid alignment, several fundamental linguistic challenges remain unsolved:

1. **Subword Fragmentation in Agglutinative Languages:** Fixed-vocabulary BPE tokenizers continue to fragment morphologically rich roots and suffixes in Bodo, Kokborok, and Manipuri, compounding decoding errors across multi-morpheme tokens.

2. **Orthographic and Tonal Ambiguity:** Tonal systems in languages such as Mizo remain unrepresented in standard orthography, introducing semantic ambiguities that cannot be resolved without broader discourse-level modeling.

3. **Contact-Language Code-Mixing:** Nagamese exhibits high dialectal variation and unsystematized phonetic orthography, degrading standard sequence-to-sequence translation pipelines.

Addressing these persistent bottlenecks will require dedicated regional pretraining corpora, linguistically informed morphological segmenters, and evaluation metrics tailored to the phonological and syntactic properties of Northeast Indian languages.

## 7 Conclusion

This paper presented the findings of the WMT 2026 Low-resource Indic Languages Translation Shared Task. Building upon previous editions, we expanded the evaluation benchmark to ten English-Indic language pairs by introducing Meitei, Karbi, Nagamese, and Tagin alongside Assamese, Mizo, Khasi, Manipuri, Bodo, and Kokborok. The task utilized the enriched IndicNE-Corp 2.0 dataset and introduced newly curated, bidirectional test sets across five distinct domains (Entertainment, Sports, Healthcare, Travel, and Political) to ensure robust evaluation across diverse communicative contexts. Systems submitted by 24 participating teams were evaluated using a complementary suite of lexical (BLEU, METEOR, TER, ChrF++) and semantic (BERTScore, COMET) metrics.

Based on the comparative evaluation of the submitted systems, we report the following principal findings:

- A stark performance dichotomy persists between moderately resourced (Category 1) and extremely low-resource (Category 2) languages. While parameter-efficient fine-tuning (PEFT) on multilingual baselines yielded competitive results for Category 1, the same architectures suffered precipitous performance drops on Category 2 languages, frequently failing to surpass 10 BLEU points. This indicates that low-resource transfer learning requires a critical mass of parallel anchors to be effective.

- Translation quality is consistently higher in the Indic→English direction than in the English→Indic direction. Multilingual models successfully map morphologically rich Indic source text into English, but struggle to generate the complex agglutinative suffixes, tonal markers, and rich morphological inflections required on the Indic target side.

- The results demonstrate a clear architectural divergence based on data availability. While PEFT (e.g., rsLoRA, DoRA) remains the dominant strategy for moderately resourced languages, dynamic in-context retrieval and LLM prompting achieved superior semantic fidelity in data-scarce settings without requiring parameter updates.

- Teams that constrained decoding using neuro-symbolic approaches, such as integrating SMT word alignments, successfully reduced entity hallucination rates. Furthermore, byte-level modeling and phylogenetic script mapping emerged as viable strategies to process unstandardized orthographies and bypass the subword tokenizer bottleneck entirely.

Despite continued progress in multilingual pretraining and hybrid decoding, translating morphologically complex and underrepresented Indic languages remains a challenging open problem. We expect that the standardized training corpora, multi-domain test sets, and comprehensive evaluation framework released through this shared task will facilitate targeted future research in low-resource machine translation.

## Abstract

We present the findings of the WMT 2026 Shared Task on Low-Resource Arabic-Asian Language Translation, which evaluated bidirectional translation between Arabic and English, Hindi, Bangla, Indonesian, and Urdu. We release *AraAsian1.0*, a news-domain parallel corpus with 20.1K-21.0K training pairs per language pair, and evaluate submissions on ten translation directions using BLEU, ChrF2, TER, COMET, and BERT-based metrics. Of 23 registered teams, 13 submitted systems, producing 70 primary and 65 contrastive runs. Fine-tuned multilingual MT models remained the strongest overall: MADLAD-based systems won four primary directions, while target-aware pivoting, joint multilingual adaptation, and MBR-based ensembling led the remaining tracks. The best contrastive run exceeded the best primary run in only three of ten directions, and each gain was below 0.2 BLEU, indicating that additional data, prompting, or multi-pass refinement did not provide consistent improvements. Bangla had the lowest winning BLEU in both directions, despite comparable training-set size. BLEU and COMET selected the same winner in nine of ten primary results but only six of ten contrastive results, with the largest disagreements occurring for LLM-based and reranked outputs. These results emphasize domain-matched adaptation, target-aware transfer, and multi-metric reporting in low-resource Arabic-Asian translation. We made the *AraAsian1.0* dataset available for the community. [1]

## 1 Introduction

Machine translation (MT) has advanced rapidly through multilingual pretraining, transfer learning, and instruction-tuned language models (Team et al., 2022; Hendy et al., 2023). These advances, however, remain unevenly distributed: systems are typically strongest for language pairs with abundant parallel data and well-developed evaluation resources (Joshi et al., 2020; Haddow et al., 2022). When direct bitext is limited, translation quality becomes more sensitive to pretrained language coverage, domain mismatch, tokenization, and the quality of synthetic or mined data (Koehn and Knowles, 2017).

These challenges are particularly relevant for Arabic paired with South and Southeast Asian languages. Arabic has rich inflectional morphology and a right-to-left script (Farghaly and Shaalan, 2009; Darwish et al., 2020), while Hindi, Bangla, Urdu, and Indonesian span different language families and writing systems (Kakwani et al., 2020; Aji et al., 2022). Although large multilingual models cover many of these languages, direct Arabic–Asian parallel corpora and standardized bidirectional evaluations remain limited. Existing resources and benchmarks often center English as one side of the pair (Ramesh et al., 2022; Goyal et al., 2022), leaving less evidence about how modern MT strategies transfer to Arabic-centric settings.

The WMT 2026 Shared Task on Low-Resource Arabic-Asian Language Translation addresses this gap through ten directions: translation into Arabic from English, Hindi, Bangla, Indonesian, and Urdu, and translation from Arabic into the same five languages. The task introduces *AraAsian1.0*, a parallel news corpus with approximately 20K training pairs per language pair, and permits both primary submissions based on official data and optional contrastive submissions that may use additional resources. Thirteen teams submitted systems spanning conventional encoder–decoder MT, multilingual joint training, parameter-efficient adaptation, English-pivot cascades, data augmentation, LLM prompting, retrieval-augmented refinement, and minimum Bayes risk (MBR) decoding.

This findings paper reports the task design,

dataset, participating systems, and complete automatic evaluation. More importantly, it goes beyond a winner-by-winner summary to examine four questions: **(i)** which language directions remain most difficult under comparable data budgets; **(ii)** which teams and architectural choices are consistently effective across directions; **(iii)** whether contrastive systems provide reliable gains over primary systems; and **(iv)** how stable the rankings are across lexical and neural metrics. The results show that strong supervised adaptation and target-aware transfer were more dependable than simply adding external data or an LLM refinement stage, while metric disagreements increased for contrastive and generative systems.

## 2 Related Work

Low-resource MT has traditionally relied on transfer from multilingual models, monolingual-data augmentation, pivot translation, and careful data selection. Multilingual pretraining enables parameter sharing across related and unrelated languages, but its benefits depend on language coverage, vocabulary allocation, and the amount and quality of adaptation data (Haddow et al., 2022; Team et al., 2022). Back-translation remains a standard way to convert monolingual text into synthetic bitext (Sennrich et al., 2016), while pivoting can connect a low-resource pair through a better-resourced intermediate language. These methods can increase data volume, but noisy generation and domain mismatch may offset their gains.

Arabic-centric MT presents additional challenges. Arabic combines rich morphology, cliticization, orthographic variation, and diglossia, and many available corpora are concentrated in news or Modern Standard Arabic (Farghaly and Shaalan, 2009; Darwish et al., 2020). For South Asian languages, resources such as Samanantar, IndicBART, and IndicTrans2 have substantially improved English–Indic translation and multilingual transfer (Ramesh et al., 2022; Dabre et al., 2022; Gala et al., 2023). Yet English is usually the central source or target, so these resources do not directly establish performance for Arabic–Indic translation. Indonesian has stronger coverage in broad multilingual models, but Arabic–Indonesian evaluation is likewise limited and often embedded within massively multilingual test suites rather than studied as a dedicated pair.

Recent general-purpose LLMs introduce a second family of approaches. They can translate through prompting, preserve requested output structures, revise drafts, or select among candidates, sometimes without task-specific training (Hendy et al., 2023). At the same time, purpose-built multilingual MT models remain competitive, particularly when latency, constrained decoding, and low-resource adaptation are important. The participant systems in this shared task expose this comparison directly: they range from supervised MADLAD, NLLB, OPUS-MT, and OpenNMT systems to prompted LLMs, retrieval-augmented revision, quality-estimation gates, and MBR decoding over heterogeneous candidate pools.

The present task complements existing multilingual benchmarks by holding the domain and approximate training budget constant across five Arabic-centered pairs and evaluating both directions. This design makes it possible to study not only absolute performance, but also direction-specific transfer, the reliability of external-resource recipes, and agreement between lexical and neural metrics.

## 3 Task Overview

The shared task evaluates Arabic-centric MT under a common low-resource setting. Each of the five language pairs is evaluated in both directions, yielding ten subtasks (Table 1).

| Task 1: Src. → Tgt. (Ar) | Task 2: Src. (Ar) → Tgt. |
|---|---|
| En→Ar (1A) | Ar→En (2A) |
| Hi→Ar (1B) | Ar→Hi (2B) |
| Bn→Ar (1C) | Ar→Bn (2C) |
| Id→Ar (1D) | Ar→Id (2D) |
| Ur→Ar (1E) | Ar→Ur (2E) |

Table 1: The ten translation directions.

### 3.1 Submission Tracks

For each direction, a team could submit one primary and up to two contrastive runs. Primary systems were expected to use the official *AraAsian1.0* parallel data; publicly available pretrained models and monolingual resources were permitted. Contrastive runs could additionally use external parallel data, proprietary synthetic data, or other resources beyond the task set. The released labels are retained throughout this paper. One submitted system did not follow the nominal resource split; we identify this case explicitly when comparing the two tracks.

### 3.2 Evaluation

All runs were evaluated on the 1,500-sentence blind challenge set using five automatic metrics. BLEU measures word-level $n$-gram precision (Papineni et al., 2002); ChrF2 is a character $n$-gram F-score with recall weighted by $\beta = 2$, making it useful for morphologically rich targets (Popović, 2015); and TER measures the edits required to transform a system output into the reference, with lower values indicating better performance (Snover et al., 2006). COMET provides a neural, human-aligned estimate of translation quality (Rei et al., 2020), while BERTScore or multilingual BERT similarity captures contextual overlap (Zhang et al., 2020).

The released leaderboards are ordered by BLEU, which we therefore use for the main ranking summary. We use ChrF2, TER, COMET, and BERT-based scores to assess whether conclusions remain stable under different notions of similarity. Because no human evaluation or significance testing was available, small score differences should be interpreted cautiously.

## 4 Dataset: AraAsian1.0

*AraAsian1.0* contains parallel data for Arabic–English, Arabic–Hindi, Arabic–Bangla, Arabic–Indonesian, and Arabic–Urdu. The corpus was developed in three stages. ***(i)* Harvesting and alignment:** comparable English, Arabic and Urdu news documents were collected primarily from Al Arabiya,[2] candidate sentence pairs were scored using cross-lingual similarity and margin criteria using LaBSE (Feng et al., 2022) (a multilingual sentence embedding model), and English–Arabic and Urdu–Arabic pairs with an alignment score above 0.80 were retained. ***(ii)* Multilingual expansion:** the high-confidence English sentences were translated into Hindi, Bangla, and Indonesian, to construct candidate parallel data for the remaining pairs. ***(iii)* Expert validation:** professional linguists reviewed the alignments, corrected syntactic and translation errors, and removed partial, noisy, or mismatched pairs.

The training sets are closely balanced: the largest contains only 4.5% more sentence pairs than the smallest. Consequently, large performance differences across language pairs are unlikely to be explained by training-set size alone. The blind test is also systematically longer than the training data. Across the five pairs, Arabic test sentences contain approximately 24–25% more tokens per sentence than their training counterparts, while the increase on the partner-language side is approximately 27–29%. This length shift makes the challenge set more demanding and should be considered when interpreting the absolute scores.

The construction process also defines the scope of the benchmark. The corpus is news-domain rather than conversational or literary, and three of the Asian sides originate from an English-mediated translation stage followed by expert correction. These choices enable controlled, aligned evaluation, however, they may introduce translationese and limit conclusions about other domains.

## 5 Participation and System Landscape

Twenty-three teams registered for the shared task and 13 submitted at least one system. The final evaluation contains 70 primary runs and 65 contrastive runs. Participation was highest for the English and Hindi directions and lowest for Indonesian (Table 3). Contrastive counts refer to runs rather than unique teams, since a team could submit two contrastive systems per direction.

Table 4 summarizes the system landscape; detailed descriptions and affiliations are provided in Appendix A. NLLB was the dominant backbone, appearing in 12 of the 13 team descriptions. The main differentiation therefore came from how teams adapted or used the backbone: six teams explicitly used LoRA or QLoRA, four explored joint or pivot-based transfer, several cleaned or augmented the training data, and four used MBR, quality estimation, retrieval, or LLM-based refinement at inference time.

The submissions span two broad philosophies. One group specialized established multilingual MT models through supervised adaptation, joint training, or pivoting. The other used general-purpose LLMs, retrieval, quality estimation, or hypothesis reranking to alter inference without relying solely on a single fine-tuned decoder. The results in the next section show that both can be competitive, but their behavior differs substantially across directions and metrics.

## 6 Results and Findings

Appendices B and C report all five metrics for every run. Table 5 condenses the BLEU leaderboards and includes the gap between the first- and second-ranked primary systems. The final column com-

| **Total** | 33 / 32 | 37 / 33 |

Table 3: Numbers of primary (P) and contrastive (C) runs.

pares the best contrastive run with the best primary run for the same direction.

### 6.1 Analysis

For each primary direction, we record the winner, the top-two BLEU gap, and each team's rank. To compare teams across different sizes, we additionally use normalized rank, $(r-1)/(n-1)$, where $r$ is the system rank and $n$ is the number of primary submissions; lower values are better. For a matched primary–contrastive comparison, we select the highest-BLEU contrastive run from the same team and direction, then subtract the team's primary score. These analyses are descriptive: the shared task did not include significance tests or human judgments.

### 6.2 Primary Detail

Tables 6 and 7 show the top three primary systems in every direction. These compact tables expose cases that a winner-only summary hides. For example, Arabic→English has three systems above 32 BLEU, whereas Arabic→Indonesian has a large separation between first and second place. The tables also show that high BLEU generally coincides with high ChrF2 and BERT-based similarity, while COMET occasionally favors a different system.

### 6.3 Overall Patterns Across Directions

For translation into Arabic, all systems generate the same target language, making cross-source BLEU comparisons more interpretable than comparisons across different target languages. English→Arabic obtained the highest winning score (22.45), followed by Hindi (19.85), Urdu (19.00), Indonesian (18.72), and Bangla (17.93). The 4.52-BLEU range is substantial given that the training sets differ by fewer than 1,000 sentence pairs. Source-language coverage and transfer quality therefore appear to matter more than the small differences in corpus size.

For translation from Arabic, target-language tokenization and morphology limit direct cross-language comparison. Nevertheless, Arabic→Bangla is a clear low-scoring case under the official BLEU ranking: its winning score is 17.10, compared with 25.89–33.83 for the other four target languages. Bangla consequently has the lowest winning BLEU in both directions. By contrast, Arabic→Indonesian reaches 30.51 BLEU, 11.80 points above Indonesian→Arabic. Four of five pairs have higher BLEU in the from-Arabic direction; Bangla is the exception. We treat this as a descriptive asymmetry rather than evidence that translation from Arabic is intrinsically easier, because the target languages and their tokenization differ.

Most primary submissions were competitive. The median gap between the top two systems is 0.74 BLEU, and six of ten gaps are below one point. Arabic→English is especially close: OpenBracket leads NLP-IIT Patna by only 0.16 BLEU. The main exception is Arabic→Indonesian, where NERDS_NITS leads the runner-up by 5.84 BLEU, indicating a decisive advantage for its direction-specific QLoRA-tuned NLLB system. Bangla presents a different pattern: both directions are low-scoring, yet Arabic→Bangla has only a 0.51-point top-two gap, suggesting a shared bottleneck rather than one isolated weak submission.

### 6.4 Participation Breadth and Consistency

Table 8 separates coverage from rank. OpenBracket and NLP-IIT Patna have the best average normalized ranks, but they entered only two and six primary directions, respectively. Among the four teams covering all ten directions, NERDS_NITS is the most consistent: it records two wins, six top-two finishes, and an average normalized rank of 0.24. FARABI also wins twice, but its mean rank

| Team | P/C dirs. | Models and main strategy |
|---|---|---|
| OpenBracket | 2/2 | MBR over NLLB, X-ALMA, ALLAM, and OPUS-MT candidates; QLoRA ALLAM and COMET-Kiwi-pruned sampling. |
| BVSLP | 10/0 | NLLB fine-tuning with LLM-assisted bitext cleaning and back-translation. |
| UPES_NLP | 3/10 | Fine-tuned NLLB and NLLB-MoE primary systems; zero-shot GPT-5-mini with structured output for contrastive runs. |
| NERDS_NITS | 10/0 | English-pivot NLLB+IndicTrans2 cascades for Indic targets; QLoRA NLLB for Indonesian; OPUS models for English. |
| MTG-LIRA | 2/2 | OpenNMT Transformer for Arabic–Hindi; BPCC/OPUS pivot-based augmentation before task fine-tuning. |
| NITM AI Lab | 2/2 | OPUS, NLLB, and mBART models with full or LoRA fine-tuning, normalization, and optional OPUS augmentation. |
| MAGADIR | 2/2 | Cross-model MBR using NLLB and LLM candidates, with entity-recall constraints and neural reranking. |
| Code & Corpus | 4/0 | One jointly fine-tuned NLLB model for Arabic–Hindi and Arabic–Bangla in four directions. |
| IndicMT | 10/0 | Direction-specific NLLB-600M fine-tuning after filtering and adding 500 synthetic pairs per direction. |
| SLPG_FJWU | 3/3 | NLLB-3.3B with LEALLA-filtered CC-100 and News Commentary data; official-data NLLB-600M alternative. |
| FARABI | 10/10 | Joint NLLB-3.3B with language-pair controllers into Arabic; Qwen2.5 LoRA and optional RAG from Arabic. |
| NCI-MT | 6/6 | LoRA NLLB primary system; COMET-Kiwi-triggered retrieval and Gemma refinement for low-confidence outputs. |
| NLP-IIT Patna | 6/6 | MADLAD primary systems, with NLLB and GemmaX2 variants as contrastive runs. |

Table 7: Top three primary submissions for translation from Arabic. R. denotes rank. †This run used supplementary data despite its primary label.

is reduced by weaker from-Arabic results. This distinction matters for shared-task interpretation: a specialized system can maximize one pair, whereas a multilingual submission tests whether one recipe generalizes across targets and scripts.

**Directional specialization.** The aggregate ranks reveal strong directionality even when a team covers the same language pairs in both directions (Table 9). FARABI has the clearest asymmetry: its average rank is 1.80 when Arabic is the target, but 7.00 when Arabic is the source. NERDS_NITS shows the opposite, improving from an average rank of 3.00 into Arabic to 2.00 from Arabic. NLP-IIT Patna is nearly dominant in its three into-Arabic

| Team | Dirs. | Wins | Top-2 | Mean rank | Norm.↓ |

|---|---|---|---|---|---|---|
| Team | Dirs. | Mean rank | Wins | Dirs. | Mean rank | Wins |
| NLP-IIT Patna | 3 | 1.00 | 3 | 3 | 2.00 | 1 |
| FARABI | 5 | 1.80 | 2 | 5 | 7.00 | 0 |
| NERDS_NITS | 5 | 3.00 | 0 | 5 | 2.00 | 2 |
| Code & Corpus | 2 | 3.50 | 0 | 2 | 2.50 | 0 |
| IndicMT | 5 | 5.40 | 0 | 5 | 4.80 | 0 |
| NCI-MT | 3 | 5.67 | 0 | 3 | 5.00 | 0 |
| BVSLP | 5 | 5.40 | 0 | 5 | 5.60 | 0 |

Table 9: Direction-specific primary ranks for teams entering at least four directions. Rank averages are computed within each submitted subset and are affected by the number and strength of competitors.

The asymmetry corresponds to the systems' transfer structure. FARABI shares information across several source languages while keeping Arabic as the common target, whereas NERDS_NITS connects Arabic source sentences to target-specialized IndicTrans2 models or directly adapts NLLB for Indonesian. The results therefore support a practical distinction between *multi-source transfer*, which pools encoders for a common target, and *multi-target transfer*, which must generate several scripts and morphological systems. Success in one setting does not predict success in the other.

The remaining broad systems are more stable but occupy the middle of the rankings. IndicMT and BVSLP use largely uniform NLLB-centered recipes across all ten directions; neither wins a track, although IndicMT is runner-up for Arabic→Indonesian. This suggests a coverage–specialization trade-off: one portable recipe offers complete task coverage, while direction-aware components are needed to reach the top of heterogeneous leaderboards.

### 6.5 Winning Strategies Across Directions

Table 10 groups the ten nominal primary wins by their main system recipe. Supervised MADLAD fine-tuning accounts for four wins, while NLLB-based transfer accounts for another four through shared into-Arabic training, pair-specific controllers, pivoting, or direct adaptation. The remaining two wins come from heterogeneous MBR for Arabic→English and filtered supplementary data for Arabic→Urdu. No zero-shot general-purpose LLM system wins a primary run.

| Winning methods | Wins | Tasks |
|---|---|---|
| MADLAD supervised fine-tuning | 4 | 1A, 1B, 1E, 2B |
| Joint NLLB + pair controllers | 2 | 1C, 1D |
| NLLB pivot/direct adaptation | 2 | 2C, 2D |
| Cross-model MBR ensemble | 1 | 2A |
| Filtered-data NLLB† | 1 | 2E |

Table 10: Nominal primary wins grouped by the principal system recipe. †The 2E run used supplementary data despite its primary label.

These results are not a controlled comparison of architectures because model size, training data, optimization, and decoding differ across teams. They nevertheless show that model family alone does not determine performance. NLLB appears throughout the runs, but outcomes depend strongly on how it is adapted, how transfer is matched to the target language, and how supplementary data are selected. Code & Corpus also reaches three top-three positions with a 600M joint model, suggesting that parameter sharing can partly compensate for model scale.

**Evidence across teams.** NLP-IIT Patna (Sharma et al., 2026) provides the clearest evidence for supervised multilingual fine-tuning. Its MADLAD systems won four of the six directions entered and placed in the top two in five. This consistency shows that conventional supervised adaptation of a strong multilingual MT model remains difficult to outperform in this data regime.

NERDS_NITS (Karim et al., 2026) and FARABI show different benefits of transfer. NERDS_NITS won Arabic→Bangla and Arabic→Indonesian and recorded six top-two placements. Its English-pivot NLLB+IndicTrans2 cascade performed well for Indic targets, while direct QLoRA adaptation of NLLB produced the largest winning margin for Indonesian, which IndicTrans2 does not cover. Its weaker results when translating into Arabic suggest that target-specific adaptation contributed more than pivoting alone.

FARABI (Aldabbas et al., 2026) showed the reverse pattern. Its shared NLLB backbone with source-specific controllers won two into-Arabic directions and placed second in two others, whereas its from-Arabic Qwen-based systems varied more across targets. This favors joint multi-source adaptation when several source languages share Arabic as the target. A similar pattern appears for Code & Corpus, whose jointly trained four-direction NLLB model reached the top three in three directions despite using a smaller backbone.

Inference-time combination was strongest for the English pair. OpenBracket entered two primary directions and placed in the top two in both. Its heterogeneous MBR ensemble won Arabic→English and achieved the highest COMET score for English→Arabic.

### 6.6 Do Contrastive Systems Help?

Contrastive submissions could use additional resources and often changed the backbone or decoding strategy. They therefore measure whether a less constrained system performs better rather than the effect of supplementary data alone. Overall, they rarely improve the best result. The best contrastive run exceeds the best primary run in only three directions, English→Arabic, Indonesian→Arabic, and Arabic→English, with gains of only 0.04, 0.07, and 0.18 BLEU. Primary systems remain ahead in the other seven directions.

Matched team–direction comparisons show the same pattern in Table 11. After excluding SLPG_FJWU (Zafar et al., 2026) because its resource labels are reversed, contrastive runs improve BLEU in 13 of 33 comparisons and decrease it in 20. The average change is −1.46 BLEU and the median is −1.31. Only OpenBracket (Alotaibi, 2026), MAGADIR (Boudraa, 2026), and FARABI have non-negative mean BLEU changes.

| Team | Matched | Better | ΔBLEU | ΔCOMET |
|---|---|---|---|---|
| FARABI | 10 | 6 | +0.09 | −1.11 |
| NCI-MT | 6 | 0 | −3.21 | +0.16 |
| NLP-IIT Patna | 6 | 1 | −1.01 | −0.19 |
| UPES_NLP | 3 | 0 | −4.87 | +0.80 |
| NITM AI Lab | 2 | 1 | −3.18 | −2.06 |
| MTG-LIRA | 2 | 1 | −2.96 | −3.33 |
| OpenBracket | 2 | 2 | +0.43 | −0.43 |
| MAGADIR | 2 | 2 | +1.13 | −0.59 |
| All matched | 33 | 13 | −1.46 | −0.66 |

Table 11: Best contrastive minus primary score for matched team–direction pairs, averaged by team. "Better" counts positive BLEU changes. SLPG_FJWU is excluded because its resource labels are reversed relative to the nominal track definitions.

The matched comparisons also reveal metric trade-offs. NCI-MT's RAG pipeline lowers BLEU in all six directions by 3.21 points on average but increases COMET by 0.16. UPES_NLP shows a similar pattern, with GPT-5-mini trailing its primary systems by 4.87 BLEU while improving COMET by 0.80. In contrast, OpenBracket and MAGADIR improve BLEU in both matched English directions while their average COMET scores decrease. These results show that improving one metric does not necessarily improve overall translation quality.

Additional data are similarly inconsistent. SLPG_FJWU's larger model trained with filtered supplementary data outperforms its official-data alternative by 1.09-3.05 BLEU across three directions, although model size and data change together. MTG-LIRA gains 1.21 BLEU for Hindi→Arabic but loses 7.12 in the reverse direction. NITM AI Lab also reports opposite effects across its two evaluated directions. Supplementary data therefore need to be evaluated separately for each direction and domain.

### 6.7 Metric Agreement and Ranking Stability

Metric agreement is high for primary systems but decreases for contrastive submissions, as shown in Table 12. BLEU and ChrF2 produce very similar primary rankings, and BERT-based similarity is also strongly aligned with BLEU. COMET shows the lowest correlation with BLEU in both tracks. Among contrastive systems, BLEU and COMET select the same top run in only four of ten directions.

| | Mean Spearman $\rho$ | | Same top run | |
|---|---|---|---|---|
| Metric vs. BLEU | Primary | Contrastive | Primary | Contrastive |
| ChrF2 | 0.92 | 0.83 | 10/10 | 9/10 |
| −TER | 0.92 | 0.69 | 9/10 | 9/10 |
| COMET | 0.81 | 0.62 | 9/10 | 4/10 |
| BERT-based* | 0.98 | 0.69 | 9/10 | 7/9 |

Table 12: Rank agreement with BLEU. TER is negated so that higher is better. *The duplicated BERT column for contrastive 2A is excluded.

Several rank reversals illustrate this disagreement. For English→Arabic primary systems, NLP-IIT Patna leads BLEU, ChrF2, TER, and mBERT, while OpenBracket leads COMET. For Arabic→Bangla contrastive systems, FARABI leads BLEU with 13.54, whereas UPES_NLP leads COMET and mBERT despite a BLEU score of 8.94. A similar reversal appears for Arabic→Indonesian. Such disagreements are especially relevant for prompted, reranked, or retrieval-

augmented systems, which may produce valid paraphrases that overlap less with the reference. Conversely, semantic metrics may overlook specific translation errors. Without human judgments, these cases do not establish which ranking is more reliable, but they show that reporting a single automatic metric is insufficient.

### 6.8 Cross-System Findings

The results support four broader conclusions.

**Supervised adaptation remains the most reliable strategy.** Strong multilingual MT models with task-specific fine-tuning dominate the primary leaderboards, while zero-shot and multi-pass LLM systems are less consistent.

**Transfer works best when it matches the target language.** English pivoting is effective when paired with a strong target-specific model such as IndicTrans2, joint multi-source training benefits translation into a shared Arabic target, and direct adaptation works better for Indonesian.

**More data do not guarantee better performance.** Broad augmentation often underperforms official-data systems, while carefully filtered supplementary data can help. Domain match and translation direction matter as much as data volume.

**Inference-time optimization is metric-sensitive.** MBR, prompting, and quality-estimation pipelines sometimes improve one metric while reducing another. Development objectives should therefore match the final evaluation and, where possible, be complemented by human assessment.

**Implications for future evaluations.** Future editions could make contrastive submissions more diagnostic by recording which component changes across runs, including additional data, model backbone, fine-tuning strategy, or decoding method. A small set of matched ablations and explicit resource declarations would make it easier to attribute improvements to data, scale, or inference-time selection. Metric disagreements also provide a natural basis for targeted human evaluation. We could sample cases with the largest BLEU-COMET rank reversals and evaluate adequacy, fluency, entities, numbers, and omissions. Sentence-level scores would support analysis by length and entity density, particularly as challenge sentences are roughly 24-29% longer than the training sentences. Overall, with standardized metric versions, these additions would make the runs more informative about where Arabic-Asian MT systems succeed and fail.

## 7 Conclusion

The WMT 2026 Low-Resource Arabic-Asian Translation shared task establishes a bidirectional benchmark across Arabic and five Asian languages using *AraAsian1.0* and submissions from 13 teams. The results show that low-resource performance depends less on adding model scale or external resources in isolation than on selecting an adaptation strategy that matches the language direction and data domain. MADLAD fine-tuning was the most consistently successful approach, while joint multilingual adaptation, English-pivot transfer, direct QLoRA fine-tuning, and MBR ensembling each led particular directions.

The analysis also identifies persistent gaps. Bangla obtained the lowest winning BLEU in both directions, contrastive systems rarely improved over the best primary systems, and metric agreement weakened for LLM-based and reranked outputs. Future editions shall add human evaluation, standardized metric configurations, stronger organizer baselines, and test sets spanning additional domains and underrepresented Asian languages. These additions would help distinguish genuine semantic improvements from reference-overlap changes and provide a more complete account of Arabic-centric low-resource MT.

## Limitations

Our study has several limitations. *AraAsian1.0* focuses on the news domain and covers five Arabic-centered language pairs, so the findings may not generalize to other domains, dialects, or underrepresented Asian languages. In addition, three Asian-language sides were constructed through an English-mediated translation stage followed by expert correction, which may introduce some bias. The shared task relies on automatic metrics without human evaluation or significance testing, so small score differences and metric disagreements should be interpreted with care. Future evaluations can address these limitations through broader domain coverage, additional languages, and targeted human assessment.

## Ethics and Social Impact

This shared task aims to support more inclusive machine translation research by providing data and evaluation for Arabic and several Asian languages that remain less studied in direct translation settings. Better translation technologies for these lan-

guages can improve cross-lingual access to information and support communication across diverse communities. At the same time, MT systems can reproduce biases in their training data or produce inaccurate translations, particularly for culturally specific content, entities, and low-resource languages. We therefore encourage careful evaluation across languages and contexts before deployment in settings where translation errors may have meaningful consequences.

## A System Descriptions

**NERDS_NITS (Karim et al., 2026).** NERDS_NITS used an English-pivot cascade for the Indic languages, combining a fine-tuned Arabic–English NLLB-200-600M model with pretrained IndicTrans2 checkpoints. Because IndicTrans2 does not cover Indonesian, Arabic↔Indonesian was handled directly through QLoRA fine-tuning of NLLB-200-1.3B. The standalone Arabic↔English directions used fine-tuned Helsinki-NLP OPUS models.

**NITM AI Lab (Koirala et al., 2026).** NITM AI Lab explored several architectures. Its English→Arabic primary system fully fine-tuned a domain-specialized OPUS-MT-TC-Big model. Its strongest Arabic→Hindi primary system adapted NLLB-200-distilled-600M with LoRA on the official data. Adding targeted OPUS parallel data caused a slight degradation, which the team attributed to domain mismatch. The team also evaluated fully fine-tuned mBART-50 with rule-based orthographic and numerical normalization.

**UPES_NLP (Singh et al., 2026).** UPES_NLP compared supervised NLLB fine-tuning, a pretrained NLLB mixture-of-experts checkpoint, and zero-shot API prompting. The fine-tuned NLLB-200-1.3B model served as the Arabic→English primary system, while the NLLB-MoE checkpoint was used for Arabic→Hindi and Arabic→Bangla. Contrastive runs prompted GPT-5-mini without task-specific training and required structured JSON output to reduce changes to entities and numbers.

**OpenBracket (Alotaibi, 2026).** OpenBracket's primary system used MBR decoding over candidates from fine-tuned NLLB-3.3B, X-ALMA-FT, X-ALMA-CPO, ALLAM-FT, and OPUS-MT, with COMET-22 as the utility. Its first contrastive system QLoRA-tuned ALLAM-7B-Instruct. Its second contrastive system used COMET-Kiwi-pruned sampling and MBR over NLLB-3.3B candidates.

**NLP-IIT Patna (Sharma et al., 2026).** NLP-IIT Patna evaluated NLLB, MADLAD, and GemmaX2 across six directions. Fine-tuned MADLAD outputs were selected as the primary submissions, while NLLB and GemmaX2 variants formed the contrastive systems.

**SLPG_FJWU (Zafar et al., 2026).** SLPG_FJWU focused on Urdu↔Arabic and Arabic→English. Its run labelled primary fine-tuned NLLB-200-3.3B on an augmented corpus derived from CC-100 and News Commentary and filtered with LEALLA-large multilingual embeddings. Its run labelled contrastive fine-tuned NLLB-200-distilled-600M only on the official task data. Thus, the submitted labels are reversed relative to the nominal resource distinction; the leaderboard labels are preserved in this paper.

**NCI-MT (Deb and Nayak, 2026).** NCI-MT applied LoRA ($r = 16$, $\alpha = 32$) to the attention projections of NLLB-200-distilled-600M for its primary systems. Its contrastive system used a two-pass retrieval-augmented pipeline. COMET-Kiwi first scored an initial translation. Low-confidence cases triggered LaBSE encoding and FAISS retrieval of the three most similar source–target pairs from external corpora, which were supplied to Gemma-3-4B as in-context examples. COMET-Kiwi then rescored the revision, and the system retained it only when the estimated quality improved.

**MAGADIR (Boudraa, 2026).** MAGADIR developed direction-specific cross-system MBR pipelines. For Arabic→English, it combined a LoRA-tuned NLLB-200-1.3B model with zero-shot outputs from Hunyuan-MT-7B, HY-MT1.5-7B, and Gemma-3-12B. A Wikidata entity-recall constraint filtered candidates to reduce proper-noun omissions, after which MetricX-24 selected the output. For English→Arabic, the team pooled candidates from six zero-shot or pretrained models, including Aya Expanse 8B and NLLB-200-3.3B, and used COMET-Kiwi as the MBR utility.

**IndicMT (Jana et al., 2026).** IndicMT independently fine-tuned NLLB-200-distilled-600M for all ten directions using Adafactor. Before training, the team filtered official pairs whose model-output/reference SequenceMatcher similarity was below 0.3. It then generated 500 synthetic pairs per direction from the filtered back-translation pipeline and appended them to the remaining real data. The

Table 13: Participating teams and affiliations.

team reports that this augmentation substantially improved its internal BLEU scores.

**FARABI (Aldabbas et al., 2026).** FARABI combined multilingual backbones with lightweight pair-specific adaptation. For translation into Arabic, it jointly fine-tuned one NLLB-200-3.3B model across all source languages and applied NTK-Mirror hidden-state controllers at inference time to learn pair-specific residual corrections. For translation from Arabic, it adapted Qwen2.5-7B-Instruct with task-specific LoRA modules and, for some runs, added a retrieval-based second pass using few-shot examples from the training data.

**Code & Corpus (Yadav and Kuila, 2026).** Code & Corpus addressed Arabic–Hindi and Arabic–Bangla in both directions. It constructed a unified four-direction corpus and jointly fine-tuned one NLLB-200-distilled-600M model, using parameter sharing to reduce overfitting relative to separate direction-specific models.

**MTG-LIRA (Hede et al., 2026).** MTG-LIRA trained a Transformer encoder–decoder system with OpenNMT-py for Arabic↔Hindi. The primary model used only the official WMT 2026 data. The contrastive model first learned from pivot-augmented data built with the BPCC English–Hindi corpus and OPUS resources and was then fine-tuned on the shared-task data.

**BVSLP (Arora et al., 2026).** BVSLP used NLLB as the core model for all directions and combined transfer learning with LLM-assisted data preparation. LLMs cleaned noisy sentence pairs, and back-translation generated synthetic bilingual data before iterative fine-tuning.

## B Full Primary Results

Tables in this appendix reproduce the full primary results. Ranks are normalized to the BLEU ordering; this resolves the duplicated rank label in the supplied Arabic→Urdu table.

| R. | Team | BLEU | ChrF2 | TER | COMET | mBERT |
|---|---|---|---|---|---|---|

# Findings of the WMT26 Chinese–Southeast Asian Multilingual MT Shared Task

**Tianyu Dong[1], Ziyan Chen[2], Jingsong Liu[2], Shaolin Zhu[1]***

## Abstract

We present the findings of the WMT26 Chinese–Southeast Asian Multilingual Machine Translation shared task. The task evaluates fourteen translation directions between Chinese and Thai, Vietnamese, Lao, Burmese, Khmer, Indonesian, and Malay. Organizers released manually aligned parallel data, domain-matched monolingual data, validation data, and a blind test set. The published leaderboard contains eleven systems and combines translation quality, measured by the equal-weight average of sacreBLEU and COMET, with a throughput bonus measured on a shared four-GPU platform. Jiutian-MT ranks first overall, while AiBabelMT achieves the highest throughput. We describe the task design, data resources, evaluation protocol, and published aggregate results, then examine how quality and throughput shape the final ranking. The results also motivate more detailed reporting by language direction and domain.

## 1 Introduction

Machine translation between Chinese and Southeast Asian languages serves cross-border communication, public information access, and commercial applications. The language pairs in this task differ substantially in the amount of digital text and parallel training data available to researchers. For languages with limited parallel corpora, model quality depends on architecture, data selection, multilingual transfer, and effective use of monolingual text (Haddow et al., 2022). Practical deployment also depends on memory use and latency.

The WMT26 Chinese–Southeast Asian Multilingual MT task brings these concerns into one evaluation campaign (Chen et al., 2026). It covers Chinese paired with Thai, Vietnamese, Lao, Burmese, Khmer, Indonesian, and Malay, in both translation directions. Organizers provide a common set of training and evaluation resources and assess system outputs on a held-out test set. The ranking combines automatic translation quality with inference throughput, reflecting the task's interest in compact and efficient translation as well as accuracy.

This paper follows the findings-paper format used by WMT shared task reports. We document the task definition and released resources, explain the scoring rules, reproduce the final aggregate results, and examine how quality and throughput shape the ranking. Our analysis compares the campaign-wide system scores and their quality and throughput components.

The main observations are as follows. First, Jiutian-MT has the highest reported translation-quality score and the highest final score, with a third-place throughput rank. Second, throughput can materially change the ordering: AiBabelMT ranks third overall with the fastest measured throughput, while BridgeMT has a slightly higher quality score. Third, systems with identical quality scores can finish at different ranks: ASEAN and KDA_MT tie on quality, yet their different throughput bonuses place them fifth and seventh in the final ranking.

## 2 Related Work

Shared tasks make comparisons more interpretable by fixing a common test set, submission protocol, and scoring procedure. Overview papers normally describe the resources and task organization before analyzing participating systems. The WMT25 Creole machine translation report combines system and data tracks, describes participating approaches, and discusses the resulting resource and translation contributions (Robinson et al., 2025). The WMT25 low-resource Indic translation report organizes its language pairs into data availability categories and presents results across language directions (Pakray et al., 2025). These papers provide useful mod-

els for reporting low-resource campaigns: dataset provenance and evaluation detail are part of the findings, rather than background alone.

The present task shares the low-resource motivation of those campaigns, while evaluating seven Chinese–Southeast Asian pairs bidirectionally and adding an inference-throughput bonus to the automatic quality score. Differences in language pairs, training data, metrics, test domains, and scoring scales make the WMT25 reports most useful here as structural and methodological references.

Automatic MT evaluation continues to use reference-based lexical metrics and learned metrics with complementary properties. SacreBLEU provides a standardized implementation and reporting signature for BLEU (Post, 2018); COMET uses learned representations to estimate translation quality with respect to source and reference information (Rei et al., 2020). The WMT26 task combines the two in an equal-weight average. This gives the campaign a single quality score for ranking, while leaving the individual metric values visible in the result table.

## 3 Task Overview

### 3.1 Language directions and objective

The task includes seven language pairs: Chinese–Thai, Chinese–Vietnamese, Chinese–Lao, Chinese–Burmese, Chinese–Khmer, Chinese–Indonesian, and Chinese–Malay. Each pair is evaluated in both directions, giving fourteen directions in total. Figure 1 summarizes the coverage. The organizers frame the task around data-efficient multilingual translation, model efficiency, and inference speed for practical use, including real-time and mobile scenarios (Chen et al., 2026).

The shared task supplies a common benchmark and leaves model architecture to participants. They can investigate supervised learning from the released parallel corpus, multilingual transfer, data augmentation, model compression, or decoding optimization. The task page specifically allows parallel and monolingual data from the WMT26 General MT task to be used for augmentation. This makes the evaluation relevant to systems that combine task-provided resources with broader training data. System descriptions can pair leaderboard scores with the resources used by each team.

### 3.2 Participation and submission constraints

The task page specifies at most one translation output per language-pair direction for each participating team. Submitted systems must remain within the model-size limit of 20 billion parameters. For mixture-of-experts models, the limit applies to the total parameter count, including the full expert set when only a subset is selected for an input. These rules place a common upper bound on model scale while allowing different architectures and optimization choices.

Teams are asked to provide test-set outputs and a Hugging Face model repository link containing model weights. The task page also lists a system description paper deadline as part of the WMT26 submission process. These These artifacts support inspection and reuse beyond the final score. Reading the leaderboard alongside the corresponding system descriptions connects each team's score with its model design, training data, and decoding configuration.

### 3.3 Campaign timeline

Figure 2 shows selected milestones on the task page: the announcement, release of training and validation data, system-paper deadline, test-output and model-repository deadline, and publication of the final results. This sequence separates development time from official evaluation: teams can use the released training and validation resources to build systems, then submit outputs for organizer-side scoring against the hidden references. We show selected milestones rather than every date listed on the webpage.

## 4 Data Resources

### 4.1 Collection and released splits

The organizers report that the data were collected from copyright-compliant resources including OPUS, Tatoeba, the UN Corpus, and manually proofread corpora. The released material covers general, news, healthcare, finance, and other practical domains. The organizers further report that sourcing and quality-control work took eight months and involved approximately EUR 30,000 in manual alignment and native-speaker verification (Chen et al., 2026). This investment is relevant context for interpreting the size and intended quality of the benchmark: the task prioritizes a modest amount of curated parallel data rather than a very large automatically collected corpus.

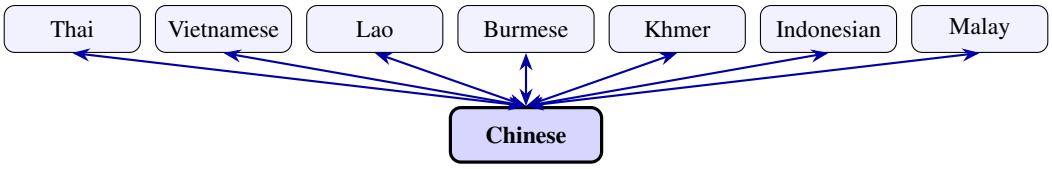

Figure 1: Language coverage of the WMT26 Chinese–Southeast Asian task.

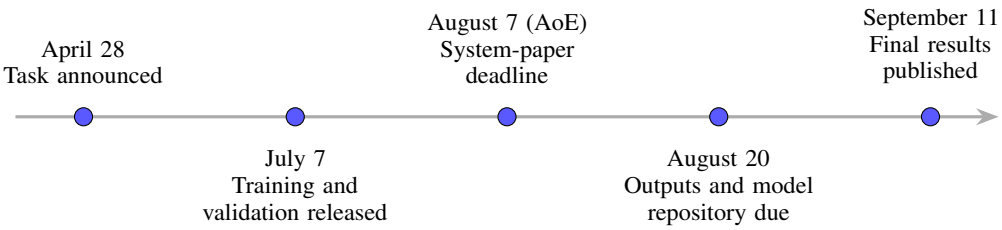

Figure 2: Selected milestones listed on the WMT26 task page.

Table 1 summarizes the four resource types described on the official task page. Parallel training data comprise 20,000 sentence pairs for each of the seven language pairs. The 700,000 monolingual sentences are distributed across the seven Southeast Asian languages, with 100,000 for each. Validation data provide 2,000 sentences per Southeast Asian language. The blind test set has 2,000 source sentences for each of eight source languages: Chinese and the seven Southeast Asian languages. In total, the test set contains 16,000 source sentences.

The task page describes the data as multi-domain and states that the validation set is unseen and independent of the training data. It also describes the blind test set as held out and independent of both training and validation data. Test inputs are made available to registered participants after approval; domain labels accompany the source text, while human references remain with the organizers for official scoring. Participants can develop systems on the shared inputs while the reference translations remain private until official evaluation.

Figure 3 summarizes the collection process and counts reported by the organizers. Additional documentation of domain-level counts, alignment procedures, and native-speaker verification criteria would further support corpus reproduction and domain-specific analysis.

### 4.2 Use and scope of the resources

The parallel corpus offers equal pair-level totals across the seven Chinese–Southeast Asian pairs, while the monolingual component supports methods such as back-translation or forward-translation. The language pairs also differ in script, tokenization, lexical overlap with Chinese, and access to pretrained resources, creating distinct modeling conditions across the fourteen directions.

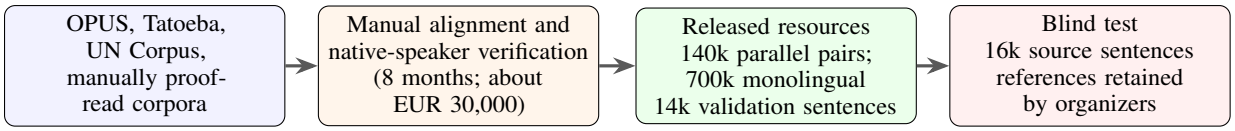
The task also permits WMT26 General MT data for augmentation. This choice reflects practical system development, where training data may combine a small task-specific corpus with broader resources. For reproducible comparisons, system descriptions can identify external corpora, pretrained checkpoints, filtering rules, and synthetic data generated from the released monolingual sentences. These details clarify how data choices affect translation quality and model size.

## 5 Evaluation Protocol

### 5.1 Translation quality

The organizers score output against hidden human references using sacreBLEU and COMET. Both metrics are reported on a 0–100 scale and receive equal weight (Chen et al., 2026). The translation-quality score is

$$Q = 0.5\,\mathrm{sacreBLEU} + 0.5\,\mathrm{COMET}. \quad (1)$$



The displayed quality score is therefore easy to reproduce from the two columns in the results table, subject to rounding. Keeping both component metrics visible is useful because a single average can hide cases where systems perform differently under lexical overlap and learned semantic scoring.

### 5.2 Throughput and final ranking

Throughput is measured by the organizers on a shared platform equipped with four 80-GB GPUs.

| Resource | Size | Distribution and role |
|---|---|---|
| Parallel training | 140,000 pairs | 20,000 aligned pairs for each of seven Chinese–Southeast Asian language pairs. |
| Monolingual training | 700,000 sentences | 100,000 sentences for each Southeast Asian language; available for augmentation. |
| Validation | 14,000 sentences | 2,000 per Southeast Asian language, with a human reference. |
| Blind test | 16,000 sentences | 2,000 source sentences for Chinese and each of the seven Southeast Asian languages; references are hidden. |

Table 1: Released resources reported on the WMT26 task page.

Reported domains: general, news, healthcare, finance, and other practical fields

Figure 3: Resource overview based on the official task description. The blind test references are withheld for centralized evaluation.

Systems are ordered from fastest to slowest. Let $N$ be the number of systems in the comparison and $r$ the throughput rank, where rank 1 is fastest. For $N > 1$, the task assigns the bonus

$$B(r; N) = 0.5 + \frac{N - r}{N - 1}\left(\frac{N}{2} - 0.5\right). \quad (2)$$

The fastest system receives $N/2$ points and the slowest receives 0.5 points. If only one system is evaluated, the bonus is 0.5. The final score is

$$S = Q + B(r; N). \quad (3)$$

For $N > 1$, Equation 2 simplifies to $B(r; N) = (N - r + 1)/2$. Thus, each one-place change in throughput rank changes the bonus by exactly 0.5 points. With eleven systems, the fastest-to-slowest bonus spread is five points. The final score therefore combines translation quality with a campaign-relative reward for throughput rank. For the eleven systems on the current results page, the bonus ranges from 0.5 to 5.5 points. Reporting both components alongside absolute speed measurements gives readers the full efficiency profile.

Figure 4 depicts the two scoring paths. The design makes translation quality and runtime efficiency contribute in separate, visible ways. Two systems with similar quality can be separated by throughput, and the quality leader can receive a smaller bonus than a faster competitor. The shared four-GPU measurement provides a campaign-level efficiency comparison; per-language throughput and measurements on target devices would extend the analysis to specific deployment settings.

## 6 Results

The official page lists eleven systems and provides one aggregate BLEU score, COMET score, throughput rank, bonus, quality score, and final score for each. Table 2 reproduces those values as published on September 11, 2026 (Chen et al., 2026). We preserve the system names and official final ranking, and analyze the quality and throughput components across systems.

Jiutian-MT ranks first with a quality score of 59.01 and a throughput rank of 3, producing a final score of 63.51. Xiaoyu-MT follows at 61.80. The 1.71-point gap between them consists of a 0.71-point quality difference and a one-point throughput-bonus difference. Thus, the top result combines the strongest published quality with a third-place throughput rank. The two highest quality scores are also well separated from the next group in the final ranking.

AiBabelMT is the fastest system, receives the maximum 5.5-point bonus, and ranks third overall. BridgeMT has a 0.20-point higher quality score than AiBabelMT, but its throughput bonus is 0.5 points lower; AiBabelMT therefore finishes 0.30 points ahead. This example shows how the combined score changes the quality-only ordering: the throughput advantage offsets AiBabelMT's small quality-score gap under the task's scoring rule.

ASEAN and KDA_MT each have a quality score of 55.14. Their throughput ranks are 7 and 11, respectively, so their bonuses are 2.5 and 0.5 points. The four-point bonus difference yields a two-place difference in final rank, with ASEAN fifth and

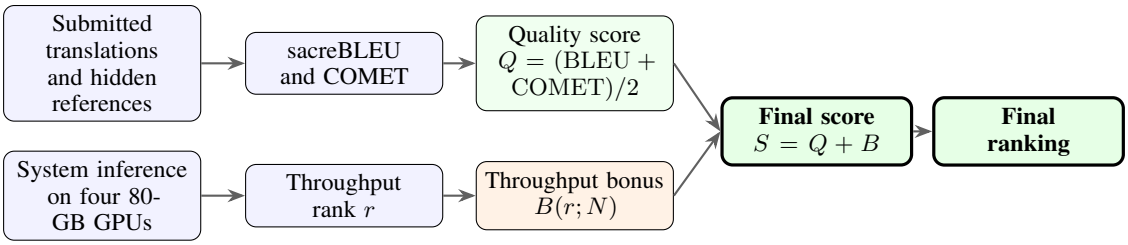


Figure 4: The official evaluation combines reference-based quality and relative throughput into a final score.

| Final rank | System | BLEU | COMET | Throughput rank | Bonus | Quality $Q$ | Final score |
|---|---|---|---|---|---|---|---|
| 1 | Jiutian-MT | 35.34 | 82.68 | 3 | 4.50 | 59.01 | 63.51 |
| 2 | Xiaoyu-MT | 34.73 | 81.87 | 5 | 3.50 | 58.30 | 61.80 |
| 3 | AiBabelMT | 27.61 | 79.28 | 1 | 5.50 | 53.45 | 58.95 |
| 4 | BridgeMT | 27.74 | 79.56 | 2 | 5.00 | 53.65 | 58.65 |
| 5 | ASEAN | 29.06 | 81.22 | 7 | 2.50 | 55.14 | 57.64 |
| 6 | WMT26_ours2 | 26.37 | 78.97 | 4 | 4.00 | 52.67 | 56.67 |
| 7 | KDA_MT | 29.17 | 81.11 | 11 | 0.50 | 55.14 | 55.64 |
| 8 | zzuli_software | 26.58 | 78.68 | 6 | 3.00 | 52.63 | 55.63 |
| 9 | luke | 27.88 | 80.42 | 10 | 1.00 | 54.15 | 55.15 |
| 10 | FlashMT | 26.71 | 78.43 | 8 | 2.00 | 52.57 | 54.57 |
| 11 | my_mt5 | 25.89 | 77.83 | 9 | 1.50 | 51.86 | 53.36 |

Table 2: Published aggregate results. Quality is the equal-weight average of sacreBLEU and COMET; final score adds the throughput bonus.

KDA_MT seventh. These examples show that the benchmark is designed to reward the quality–efficiency balance rather than quality alone. Figure 5 decomposes the final score into its two parts; Figure 6 places quality against throughput rank.

### 6.1 Reading the aggregate results

The quality scores span 51.86 to 59.01, while throughput ranks span all positions from 1 to 11. The scatter plot visualizes the overall quality–throughput relationship among submitted systems.

The system order also illustrates why the components should be reported alongside the combined score. A quality-only ranking would place BridgeMT slightly above AiBabelMT and would tie ASEAN and KDA_MT on the displayed quality score. The official final ranking separates these systems using throughput. Conversely, a throughput-only ranking would put systems with lower quality ahead of stronger translators. Neither component alone captures the stated goal of balancing translation quality and efficiency.

## 7 Discussion

### 7.1 Quality and efficiency as complementary objectives

The leaderboard illustrates the task's premise that translation quality and inference throughput are distinct objectives. Jiutian-MT and Xiaoyu-MT lead the final table through high quality scores, whereas AiBabelMT and BridgeMT receive the two largest bonuses through their first- and second-place throughput ranks. The combined score makes this trade-off explicit and provides one ordering for the campaign. Deployment teams can adapt the quality–efficiency balance to their latency targets and the quality requirements of each application.

The bonus is rank based: for a given $N$, each one-place throughput change has the same effect on the score. Absolute throughput, latency, batch size, sequence lengths, and hardware utilization would complement this relative ranking and make the efficiency results more actionable for real-time and edge use.

### 7.2 Priorities for further reporting

The task covers fourteen directions and several domains. A fuller findings report could pair BLEU and COMET by direction with test-set sizes and the aggregation rule, and summarize variation across domains. These results would help identify where additional data or language-specific adaptation may matter most.

Confidence intervals or significance tests would add context to the reported point estimates. Segment-level paired resampling can quantify score variation, while human assessment can pro-

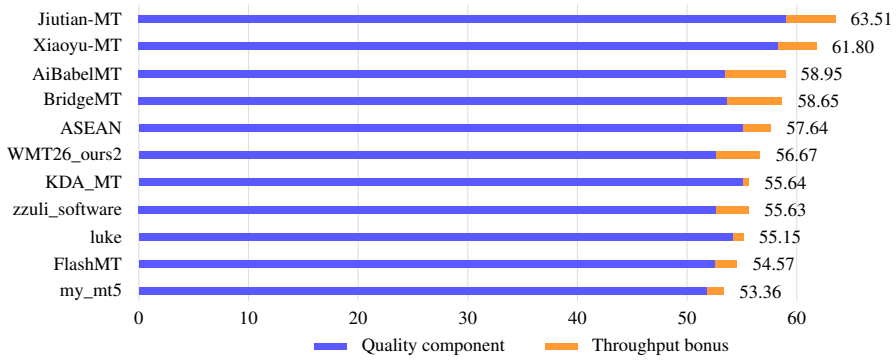

Figure 5: Final-score composition by system. Each bar shows the quality score $Q$ plus the throughput bonus; labels at the right are final scores.

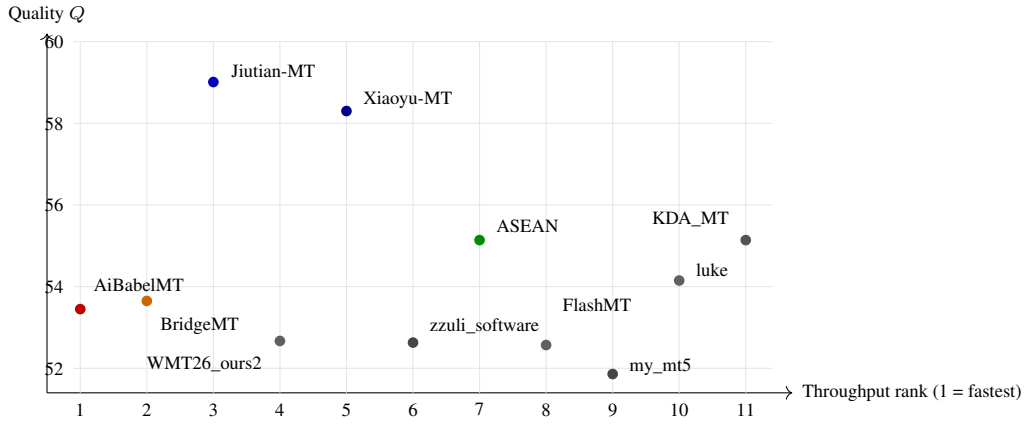

Figure 6: Aggregate quality versus throughput rank. Lower throughput rank means faster inference; each point is one system.

vide a complementary perspective on adequacy, fluency, and named entities.

System papers and repositories can complement the aggregate scores with details on architecture, pretraining, fine-tuning data, tokenization, and decoding choices. This information helps relate leaderboard performance to the methods used by each team.

## 8 Ethical and Data Considerations

The task organizers describe the released datasets as sourced from copyright-compliant materials and available to registered researchers for non-commercial research under the task's stated terms (Chen et al., 2026). Per-source license references, provenance metadata, and descriptions of privacy screening would further support transparent corpus use.

The test set provides domain labels and source sentences while references remain hidden for official evaluation. Documentation of contamination checks and sensitive-text screening would further inform use of this multilingual benchmark, particularly for its healthcare and finance domains. Applications in high-impact settings can pair benchmark results with task-specific review.

The throughput measurement uses a four-GPU platform and provides a consistent basis for the campaign's relative speed ranking. Deployment reports can complement it with energy, memory, and latency measurements on intended hardware, together with evaluation of the relevant language directions and use cases.

## 9 Conclusion

The WMT26 Chinese–Southeast Asian shared task provides a common evaluation for fourteen translation directions, supported by curated parallel and monolingual data and a hidden-reference test set. Its official score combines the equal-weight average of sacreBLEU and COMET with a throughput bonus. Among the eleven systems on the published page, Jiutian-MT ranks first overall and AiBabelMT is fastest. The results illustrate the

quality–speed trade-off and provide a system-level view across the campaign.

## Abstract

We present the second annual Shared Task for Creole Language Machine Translation, the only published shared task specializing in machine translation (MT) methods for Creole languages and their communities, presented at the Conference of Machine Translation (WMT) 2026. We accepted system submissions for two tasks: MT and language identification (LID). We received submissions from eight teams: 13 MT systems from six teams across 88 language directions; and four LID systems from two teams, identifying 11 languages each. Our analysis of MT systems indicates fine-tuning with newly curated datasets and/or synthetic data as an effective strategy for producing state-of-the-art MT. For the LID task, we found that smaller, resource-efficient systems achieved state-of-the-art scores on some languages, especially when paired with data augmentation.

## 1 Introduction and Background

Creole languages have been historically underserved by existing technologies; hence developing better Creole language technologies has been an active area of research for some years. For individual languages, researchers have explored innovations for grammatical parsing (Wang et al., 2017; Caron et al., 2019; Mompelat et al., 2022), sentiment classification (Oyewusi et al., 2020; Muhammad et al., 2022, 2023), named entity recognition (Adelani et al., 2021), natural language inference (Armstrong et al., 2022), and speech recognition (N. Havard et al., 2025; Le Ferrand and Henri, 2026; Andrade et al., 2026). For machine translation specifically, past works have focused on Haitian (Frederking et al., 1997; Callison-Burch et al., 2011), Jamaican Patois (Robinson et al., 2022, 2023), Nigerian Pidgin / West African Pidgin (Ogueji and Ahia, 2019; Adelani et al., 2022), Mauritian Creole (Dabre and Sukhoo, 2022; Suddul et al., 2026; Boodeea et al., 2025), Sranan Tongo (Zwennicker and Stap, 2022), Singlish (Liu et al., 2022), Cape Verdean Creole (Medina, 2025; Medina et al., 2025), Guinea-Bissau Creole (Rowe et al., 2025b), Guyanese Creolese (Clarke et al., 2024), and Chavacano (Vicente et al., 2026)

Improved translation for Creole languages has led to advances in medical translation (Mompelat et al., 2026; Mompelat, 2025a), natural disaster mitigation (Robinson, 2025b), and other humanitarian aid (Lewis, 2010).

Other works have focused broadly on developing technology for many Creole languages together. Lent et al. (2022b) discussed survey findings on the needs for Creole language technologies. Lent et al. (2022a); Fekete et al. (2025) explored knowledge transfer between Creole and related languages. Lent et al. (2024) developed the first multilingual MT model specifically for Creole languages. Robinson et al. (2024) released the first public MT dataset for a large number of Creole languages and built state-of-the-art (SOTA) models for Caribbean and African Creole languages.

These efforts were steps forward for Creole language processing. However their broad scope precluded the possibility of focusing on specific languages for specific communities. This inspired the organization of the First Shared Task for Creole Language Translation at WMT 2025 (Robinson et al., 2025). This task was framed as an open challenge, to invite Creole language community members and enthusiasts to engage in the development of technologies for their own languages.

The 2025 shared task (Robinson et al., 2025) received submissions from five teams, including four submitting MT systems (Ayasi, 2025; Mompelat, 2025b; Rowe et al., 2025a; Rajcoomar, 2025) and two submitting new MT datasets (Robinson, 2025a; Rajcoomar, 2025). Rajcoomar (2025) improved upon SOTA MT in some domains for Mauritian Creole by fine-tuning a large language model (LLM) and using newly curated data. Robinson

*Proceedings of the Eleventh Conference on Machine Translation*, pages 1138–1158
October 28-29, 2026 ©2026 Association for Computational Linguistics

(2025a) likewise improved SOTA in some domains for MT of French Guianese Creole and Belizean Kriol, also by using new datasets. Rowe et al. (2025a) most convincingly improved over SOTA, for seven lusophone Creole languages, also by incorporating new data, but they unfortunately could not release the data.

## 2 Task Overview

We organized the shared task into four subtasks:

- Subtask 1A: Models for MT of Creole languages
- Subtask 1B: Models for LID of Creole languages
- Subtask 2A: Creole MT data
- Subtask 2B: Creole speech data

We only received submissions for subtasks 1A and 1B, so we focus on those in this report.

### 2.1 MT modeling subtask

For Subtask 1A we solicited systems to translate between any number of Creole languages and English or French. We also permitted any culturally relevant source or target languages with approval from us (such as Spanish for Haitian, which we approved for one of the participating teams).

The purpose of this subtask was to produce SOTA Creole MT models. Hence, participants were permitted to use any data or pretrained models, *except* for those expressly prohibited. The prohibited models were the public Hugging Face models `kreyol-mt`, `kreyol-mt-scratch`, and `CreoleM2M`, excluded because of training contamination with the eval sets we used. The prohibited data were the public eval sets we used, namely the test split of the public Hugging Face `kreyol-mt` dataset.

We provided the following resources for participants:

- Two baseline models
  - The `kreyol-mt-pubtrain` model available on HuggingFace
  - A newly trained baseline model based on `gemma-4-E2B` (Team, 2026)
- An official train set: the train and dev splits of the public `Kreyòl-MT` dataset[1]

[1] https://huggingface.co/datasets/jhu-clsp/kreyol-mt

#### 2.1.1 New MT baseline model

We trained a new baseline MT model for this year's shared task. We had two reasons for this: (1) because we had to prohibit use of the original `Kreyòl-MT` flagship model on HuggingFace and (2) in order to incorporate the data submissions from last year's shared task (Robinson et al., 2025; Rajcoomar, 2025; Robinson, 2025a).

We trained a baseline model, `gemma4-creole-mt` (Gupta, 2026), by fine-tuning `gemma-4-E2B` via LoRA (Hu et al., 2022) on 50k total segments sampled from the `Kreyòl-MT` dataset (Robinson et al., 2024), and datasets submitted to last year's iteration of the shared task (Robinson et al., 2025; Rajcoomar, 2025; Robinson, 2025a). We trained on a node consisting of eight L40S Nvidia GPUs, comprising 86 language pairs spanning 50 Creole and related languages. We used ALMA-style prompts (Xu et al., 2024) with full language names, for example:

```
Translate this from Ndyuka into English:
{source sentence}
### Translation:
{target sentence}
```

We used a completion-only loss, where prompt tokens were masked out and the loss was computed only on the translation. We utilized temperature sampling following NLLB (NLLB Team et al., 2022) with $T = 5$, in order to balance high-resource pairs (e.g. `hat--eng`, 833k sentences) against lower-resourced pairs (e.g. `fng--eng`, 33 sentences). We used the following hyperparameters for LoRA: rank 64, $\alpha$ = 128, while targeting all linear layers. In Table 6, we report the metrics on a development set.

### 2.2 LID subtask

For the LID subtask, we initially proposed to consider LID for English-, French, Portuguese-, and Spanish-lexifier Creoles and Pidgins, in consideration of recent scholarship addressing these groups (Adebara et al., 2022; Vicente and Cheng, 2024; Dent et al., 2025). This was later narrowed down to French-lexifier Creoles in response to participant interest. More specifically, participants were asked to produce models capable of distinguishing between 9 Creole languages (Guadeloupean, French Guianese, Haitian, Martinican, Louisiana, Mauritian, Reunionese, Saint Lucian, and Seychellois), French, English, and an `oth` category for other languages. Among these, certain languages

have been particularly challenging for LID systems, due to either linguistic proximity (Guadeloupean, Martinican, Saint Lucian), limited amounts of contemporary data (Louisiana, French Guianese), or both.

Similarly, we initially proposed exploring the inclusion of various kinds of context metadata alongside the texts (Dent et al., 2026). However, due to several constraints, we were unable to include such metadata in this version of the shared task. Nevertheless, we did strive to include test data from a wide variety of sources. These include scholastic materials, online newspapers, and a corpus of previously anonymized French SMS messages (Panckhurst et al., 2020). The latter source allowed us to consider the effects of nonstandard transcription of the lexifier, which has been underexplored thus far.

For our baseline model, we chose GlotLID (Kargaran et al., 2023) because it is considered SOTA for coverage of long-tail languages (Suarez et al., 2026). This model covers languages in the test set, with two exceptions: it does not include Louisiana Creole or Martinican Creole.

## 3 Task Submissions

We received submissions from eight teams. We overview the submissions from six teams participating in subtask 1A in §3.1, and submissions from the two teams participating in subtask 1B in §3.2

### 3.1 MT systems

We received submissions from six teams for the MT systems task. All participants' submissions together covered 45 language pairs and 89 translation directions. Most teams submitted results on fewer than three language pairs with a specific focus: Haitian for CHV, UQAM and PIK; Pacific anglophone Creoles for UniMelb; and Réunion Creole for KYX. The remaining team, GMU, submitted systems for 80 different translation directions (translation into and out of 40 Creole languages).

Teams mostly focused on language pairs involving English, with only five submissions translating from or to French or Spanish. Submissions were however spread across language pairs, and only six directions had submissions from more than one team. Haitian was by far the most represented Creole language: it was present in four submissions.

The participating teams explored a variety of different modeling approaches. The KYX team (Öztop, 2026) used QLoRA adaptation and focused much of their paper on the pitfalls of MT evaluation for Creole languages. UniMelb (Merx et al., 2026) fine-tuned NLLB (NLLB Team et al., 2022) with a post-training schedule including back-translated and LLM-synthesized data. GMU (Meng and Anastasopoulos, 2026) built novel datasets by applying optical character recognition (OCR) to an existing database and compared fine-tuning and few-shot model adaptation. CHV (Jourdain et al., 2026) employed few-shot prompting only, with lexical and grammatical knowledge extracted and included in prompts. UQAM (Le et al., 2026) developed a dataset of 17k new, culturally relevant bitext pairs, and employed code-switching data augmentation.

We describe in more detail the submitted MT systems in the following section.

#### 3.1.1 KYX

The KYBELIX (KYX) team submitted a system for Réunion Creole to English Translation (`rcf` → `eng`) and focused on common pitfalls that may arise when evaluating extremely resource-impoverished languages. In particular, they focused on two phenomena that can significantly impact results. First, they demonstrated how small train and development data overlap with inexact matches, which can significantly impact results on very small test sets. (The rcf-eng public test set is only 34 sentences long.) Second, they argued that character-based metrics can reward systems for mimicking spelling conventions, as opposed to actual translations when no standard orthographies exist for a language. To mitigate this, they contributed an evaluation method that is contamination- and orthography-aware. By doing so, they demonstrated that their QLoRA-based system does not have as large chrF++ (Popović, 2017) gains as initially appeared. Their conclusions are not specific merely to Réunion Creole, but are used to demonstrate broader phenomena.

KYX only submitted a `primary` system.

#### 3.1.2 UniMelb

To tackle machine translation for low-resource Pacific Creole languages, namely, Tok Pisin, Bislama, and Solomon Pijin, the team from the University of Melbourn (UniMelb) developed a joint translation models for six directions using NLLB-3.3B. They developed two models: one for out-of-Creole MT and another for into-Creole MT. Their core method begins with joint pre-training on a large corpus dominated by religious text, followed by continued

fine-tuning on a domain-balanced mix incorporating back-translated news, spoken transcripts, and synthetic colloquial data distilled from Gemini 3.5 Flash. Key data preparation techniques include LLM-guided loanword respelling and normalization for Solomonese Pijin (`pis`), and LLM-based parallel alignment filtering to enhance training.

The resulting models outperform open multilingual baselines by over 3 chrF++ points across all directions on human-original test sets, closely matching or beating Gemini 3.5 Flash on broad-domain Bouquet and spoken transcript benchmarks. Joint multilingual training notably benefits the lowest-resource Creoles without degrading Tok Pisin performance, while domain additions transfer well across related languages. Furthermore, the study demonstrates that synthetic distillation provides rapid early quality gains that plateau after a few thousand sentence pairs, highlighting an efficient strategy for low-resource domain expansion.

The UniMelb team only submitted a `primary` system for each translation direction.

#### 3.1.3 GMU

The George Mason University (GMU) team considered 80 translation directions overall, namely English ↔ 40 Creole languages. They cleaned the provided training data by removing pairs with sentences comprising fewer than 50% alphabetic characters, pairs with either sentence containing fewer than three words or more than 60 words, pairs with source-to-target or target-to-source character length ratio exceeding 2.2, Levenshtein ratio exceeding 0.8, and pairs with either side identified as the wrong language by the NLLB language identification model (NLLB Team et al., 2022).

They extracted additional novel bitext data using OCR and a vision language modeling (VLM). Specifically, they applied OCR-capable VLM `Qwen3.5-27B-FP8` (Qwen Team, 2026a) to the DReAM corpus (Virk et al., 2020) to produce additional data for the 28 lowest-resourced languages.

For MT modeling, they experimented with parameter-efficient finetuning of the 4B-parameter Gemma 3 model's pretrained checkpoint (Team et al., 2025) and the NLLB 1.3B-parameter model (NLLB Team et al., 2022), along with few-shot prompting of `Qwen3.6-27B` (Qwen Team, 2026b), using 4-bit quantization on a single 40 GB GPU. For model finetuning, since Haitian had substantially more training data compared to the other Creole languages, they trained a separate model for Haitian and a unified model for the remaining Creole languages using temperature sampling.

They observed that incorporating additional parallel data often improved translation performance. They also observed that, depending on the amount of data in a language, few-shot prompting could be better or worse compared to finetuning.

The team's `contrastive1` system was the 4B-paramater Gemma 3 model fine-tuned the cleaned provided train data. Their `primary` system was the same, but with the novel data incorporated. Their `contrastive2` employed the novel training data, but in a 512-shot in-context prompting paradigm with `Qwen3.6-27B`.

#### 3.1.4 CHV

The CHV team considered four translation directions for Haitian (`hat`): English ↔ Haitian and French ↔ Haitian. Noting that existing training-based methods are limited by data scarcity, they postulated that fine-tuning on synthetic data may not be enough to widen domain coverage or vocabulary for low-resource languages. Instead, they proposed to switch compute allocation from training to test time, and relied on LLM agents' emergent translation capability: an agent can be provided additional knowledge about the translation task during inference. The authors addressed three main questions: (1) how external resources should be retrieved to improve translations, (2) what types of models they can improve, (3) and whether this inference-time compute provides enough benefit to justify its cost.

For this purpose, they augmented the open-weight 8B-parameter `Qwen3-8B` model with a knowledge injection mechanism. Three different knowledge retrieval tools were evaluated: (1) a lexicon tool that extracts glosses from a translation dictionary, (2) a memory for few-shot learning, that contains both translation examples and monolingual sentences extracted from the `Kreyòl-MT` training dataset, and (3) a grammar rules selection tool. This required tuning new hyper-parameters: i.e. the number of examples to retrieve or the similarity threshold above which an example is deemed relevant. All variants could then be combined with two injection methods: the *forced push*, which inserts all possible extracted information in the translation prompt, and the *agentic*, which lets the agent reason about the task and query each tool when needed, following the ReAct framework (Yao et al., 2023). All systems were then evaluated on the FLORES+

devtest split (He et al., 2024), and result significance was validated with a paired bootstrap. The best performing knowledge injection mechanism was then used for submission.

The *forced push* approach systematically scored better than all evaluated *agentic* methods, which tended to fall into tool-calling loops, used 6× more tokens, and yet were often unable to correctly exploit the injected knowledge for Creole language generation. Increases in scores was instead mostly provided by simple, computationally cheaper tools: for eng → hat for example, increasing the number of glosses in the prompt increased the chrF++ score by +3.83, adding parallel and monolingual data examples by +1.14, and translating French sentences into English before translating into Haitian increased +4.56. Activating reasoning on the base model with *forced push* was useful for hat → fra, on which it counters the base model's tendency to copy Haitian words into French, and remained less costly (1.7× tokens) than agentic approaches. Hence the three final submitted systems all used *forced push*: a primary submission with reasoning activated, a constrative1 submission using *forced push* without reasoning, and the base Qwen3-8B model as a contrastive2 submission.

The team compared their proposed methods with the primary baseline gemma4-creole-mt we provided, along with the base Qwen3-8B model they adapted in their submissions. They found overall that knowledge injection improved the scores over the base models for all directions, by up to 14.2 chrF++ points for eng → hat. Knowledge injection appeared to help most for into-Creole translation, where it partially corrected for the lack of Creole fluency exhibited by language models. However, the method still scored below both our secondary baseline, the Kreyòl-MT model trained on public data (Robinson et al., 2024), and the frontier LLM GPT-4.1-mini.

Lastly, the CHV team conducted preliminary tests applying their prompting method with various LLM engines from five different families, obtaining chrF++ point estimates on a single inference run on a 200-sentence subset of FLORES+. They found that gains were consistently stronger for weaker models, and diminished as base model performance improved until they were negligible for frontier models. Hyper-parameters for knowledge injection were only tuned for the weaker Qwen3-8B model; yet analyzing score distributions showed that improvements were driven by correcting the worst translations. This might explain why strong frontier models did not benefit from knowledge injection. The authors concluded that injected knowledge can improve vocabulary or coverage for weaker base models, but that it might not improve fluency beyond a certain point, where training-based methods may still be needed.

#### 3.1.5 UQAM

The submission from Université de Québec à Montréal for Haiti (UQAM) team addresses the challenge of creating a culturally aware MT system for translation from Haitian to English or French. They attempted to accomplish this through a combination of novel cultural dataset curation, code-switching data augmentation, and multilingual model adaptation. The work is distinct for its emphasis on cultural representation, incorporating linguistic material that reflects Haitian cultural knowledge, oral traditions, and idiomatic language.

The primary contribution of the paper is the construction of a parallel corpus of culturally-relevant Haitian material, including poems, proverbs, and culturally-grounded expressions from the *Atlas Linguistique d'Haïti* (Fattier, 1998). Approximately 55 hours of spoken Haitian were transformed into a parallel translation dataset, through a pipeline involving audio segmentation, automatic transcription, machine translation, filtering, and human validation. This produced more than 17,000 additional sentence pairs, which were used to augment the Kreyòl-MT resources. This represents a substantial effort to leverage underutilized oral language resources and expand cultural diversity of available Haitian MT data.

To improve robustness to multilingual use, the authors introduce a code-switching augmentation strategy based on the use of LLMs. Using a token-level replacement approach, an LLM was prompted to replace between one and three Haitian tokens with their English or French equivalents while preserving sentence fluency and semantic coherence. These synthetic code-switching data were concatenated with the original training corpus, augmenting the total dataset available for training. The team proposed that, in addition to augmenting data, this approach increase the model's robustness to bilingual input, through exposure to multilingual training data.

The models employed were: a baseline Transformer system trained from scratch (E1); an adapted version of the NLLB-200 multilingual

model fine-tuned on the combination of `Kreyòl-MT` and code-switching data (E2), and a version of the NLLB-200 fine-tuned with `Kreyòl-MT`, code-switching and culturally-relevant data (E3). This provides an informative comparison between a conventional NMT system and a pre-trained multilingual model, assessing the contribution of cultural data across the different modeling paradigms.

Beyond standard translation quality measures, the team evaluated cultural preservation using the *CSI-Match* metric (Yao et al., 2024). The team's evaluation choice aligns well with the objectives of their paper: to assess whether cultural and idiomatic meaning is maintained during translation.

On their internal tests, the team achieved improvements over their internal baseline in both translation directions. For Haitian to English, E2 delivered substantial gains across all major metrics, increasing BLEU from 43.6 to 53.6 and chrF++ from 65.0 to 72.7. The most striking improvement was observed in cultural translation quality, with the CSI-Match score rising from 50.0 to 77.0, indicating a much stronger ability to preserve culturally grounded meanings and idiomatic content. E3 had similar performance, with only a slight decrease across evaluation metrics. For Haitian to French, both submitted systems also consistently outperformed the baseline. (See Le et al. (2026).) Cultural awareness gains were more modest than in the English direction, but remained positive.

Both adapted models (E2 and E3) showed the value of incorporating culturally enriched data and code-switching data augmentation. The team designated their E2 system as `primary` and two hyperparameter configurations of E3 as `contrastive1` and `contrastive2` for their submission. Across most metrics in internal tests, E3 performed similarly to, but slightly below, E2, indicating that the additional experimental modifications did not translate into measurable improvements. Given that the unadapted NLLB-200 model was not tested, it is difficult to say if the majority of the performance comes from using the multilingual model or from including new data.

The proposed approach delivered strong gains, but the authors pointed out significant limitations. The code-switching data may not capture the natural sociolinguistic behavior of bilingual speakers, and the use of automatic translation in processing recordings may introduce residual biases. The team also lamented limited digital resources, insufficient representation of dialectal variation, and a lack of community-driven data development.

#### 3.1.6 PIK

Unfortunately the PIK team did not submit a system report, so we cannot report on their methods or approach.

### 3.2 LID systems

We overview submissions from the two teams participating in the LID systems subtask. The HT team (Ayasi, 2026) focused on organizing language labels into groups and running a hierarchy-based LID system that classified the language group as well as the language itself. The RP team (Strickland, 2026) focused on curating new data in addition to the data provided in order to mitigate class imbalances for French Guianese Creole and Réunion Creole.

#### 3.2.1 HT

The Hytton Technologies (HT) team presents a solution based on a multiclass linear support vector machine (SVM) that uses term-frequency inverse-document-frequency (TF-IDF) weighted character *n*-grams representations as features. This is presented as a noise-robust solution, and thus appropriate for Creole LID. These representations are learned once and shared across models.

Furthermore, HT explores several hierarchical classification strategies. First, they define an expert grouping in which the individual language labels provided by the organizers are directly assigned distinct categories. Namely, they recognize a Lesser Antillean group (`mart`, `gcf`, and `acf`), Haitian as its own group, a third group containing all other French-based Creoles under consideration (`lou`, `gcr`, `rcf`, `mfe`, and `crs`), and a fourth grouping consisting of the non-Creole labels (`eng`, `fra`, `oth`).[2] Second they introduce three distinct data-driven methods of inferring hiearcharchy: confusion-based grouping, grouping on the basis of representation similarity, and a combined method defined by averaging the other two matrices. (The team used the representation method for their `contrastive1` submission, the confusion method for their `contrastive2`, and the combined method for their `primary`.)

Across all grouping strategies, two frameworks were explored for incorporating group labels into the final classification: hard hierarchy, in which the inferred group acts as a gate to a specialized classifier, and soft hierarchy, in which group-level

[2]These are labeled Groups 1, 3, 2, and 4 respectively.

posterior probabilities act as weights for across-the-board classification. The soft hierarchy was used for all submitted systems.

HT provided a detailed error analysis which emphasizes three points. Training data is described as the main bottleneck, as `gcr` and `rcf`, with 53 and 184 examples respectively in provided data, exhibit the highest error rates. Recall and error rate are shown to vary significantly with training data size (Spearman $\rho$ = 0.685, $p$ = 0.014) and (Spearman $\rho$ = -0.685, $p$ = 0.014), respectively, while macro-F1 does not ($\rho$ = 0.427, $p$ = 0.167).

The team shows that confusions are heavily concentrated between the English, Haitian, and `oth` classes, with mutual confusion between these categories accounting for more than half of all errors. However, bidirectional confusion between Martinican and Guadeloupean Creoles also accounts for 6.9% of the global error rate, and is nearly even in each direction. Remaining errors are attributed to structural factors such as named entities, lexical borrowings, noise, and short texts.

#### 3.2.2 RP

The Rock Pidgins (RP) team combined an *n*-gram-based classifier with a linear SVM to build LID systems. They classified texts into twelve categories, which included francophone Creole languages spoken in the Caribbean and the Indian Ocean, English and French, and an `oth` classification for additional languages.

Their two LID systems differed by their training corpora. `Gwo-K_1` was trained on the `train` subset of `Kreyòl-MT` (Robinson et al., 2024). To mitigate under-representation, `Gwo-K_2` was augmented with 1000 geography-related Wikipedia sentences for French Guianese Creole and 2163 sentences from Cellier (1985) and McLellan (2024) for Réunion Creole. In both systems, features were obtained by extracting strings of three to five characters to capture subwords and orthographic conventions across the different languages. These were weighted by their TF-IDF score to create sentence-level features that were fed into a linear SVM with balanced class weighting.

Overall, `Gwo-K_1` achieved an accuracy of 97.0% on internal tests, and `Gwo-K_2` achieved 97.2%. This improved over the `GlotLID` baseline, which achieved only 74.9%, likely because it does not cover Martinician and Louisiana Creoles. RP found that lower F1 scores were attained for languages with less training data, though this was not a consistent trend. Louisiana Creole had significantly fewer training data than Guadeloupean and Martinician Creoles, but was classified more accurately. The team hypothesized that this was because Louisiana Creole evolved separately from the Creoles spoken in the Caribbean and Indian Ocean, making it more distinguishable. This indicates that more distinct languages might be more data-efficient.

Geography had a marked influence on classification errors: languages tended to be confused with others spoken in the same region. Interestingly, Creole languages tended not to be confused with their high-resource lexifiers, likely due larger amounts of training data for the latter.

## 4 Evaluation Results

Here we overview our evaluation results for both MT and LID systems subtasks.

### 4.1 MT evaluation

We use the randomly shuffled versions of the public `Kreyòl-MT` test sets as our primary evaluation sets. Since some teams submitted models for language pairs that are not supported by `kreyol-mt-pubtrain`, and in order to increase the diversity of the evaluation references, we also employed secondary evaluation sets. We used newly split private test sets of `Kreyòl-MT` that were not seen in training by either baseline model, as well as additional test sets from the CreoleVal and MIT-Haiti datasets (Lent et al., 2024), and the APiCS database (Michaelis et al., 2013).

In the following, we refer to the former evaluation set as *Eval Set 1*, and the latter as *Eval Set 2*. We compute the chrF++ (Popović, 2017) and BLEU (Papineni et al., 2002) scores using the default parameters of the `sacrebleu` library on each submission, as well as on the outputs of our two baseline models: `kreyol-mt-pubtrain` and `gemma4-creole-mt`, the new baseline model introduced in Section 2.1.1.

For each group of evaluation sets, we report below the scores of all language pairs for which we received more than one submission. Complete tables with results of all teams across all translation directions can be found in Appendix B. Overall, five directions were not supported by the `kreyol-mt-pubtrain` baseline model: Bislama $\leftrightarrow$ English, Pijin $\leftrightarrow$ English and Haitian $\rightarrow$ Spanish. For these pairs, we only used one baseline model. Evaluation results on *Eval Set 1* for translation

directions with a Creole source language are in Table 1, and those with a Creole target language in Table 2. Evaluation results obtained on *Eval Set 2* are reported in Table 3 for translation with a Creole source language, and in Table 4 for a Creole target language. Scores are reported along with the precise source for each *Eval Set 2*, where "KMT" refers to the newly split private test sets of `Kreyòl-MT`.

We first note that across submissions, scores are consistently higher on the *Eval Set 1* than on *Eval Set 2*, with important average differences ranging from approximately -15 chrF++ for UniMelb to -27 for PIK. This is also true of `kreyol-mt-pubtrain`, which has a gap of approximately -20 chrF++ points. *Eval Set 2* is dominated by the private test sets of the `Kreyòl-MT` dataset, which for each language pair often comes from few, specialized sources from a single domain. The notable exception is the `gemma4-creole-mt` baseline, whose performance stays roughly equal (+0.84) on both sets, although this masks substantial direction-specific variation.

Relative rankings between submissions also differ on evaluation sets. UniMelb and UQAM, which both designed more specialized systems focusing on a single Creole language or language group, outperform the two baselines on three out of four considered directions and evaluation sets. UniMelb achieves the best performance across all available evaluation sets for `eng`→ `tpi`, and UQAM for `hat`→ `fra`. CHV scores below the two baselines on all direction pairs and evaluation sets, despite being specific to Haitian Creole. For the large-coverage GMU submission, performance relative to the baselines depend more strongly on the evaluation set: it is highly competitive and outperforms both baselines on *Eval Set 1* for 52 directions out of 80, but only on three of 36 directions on *Eval Set 2*, where `gemma4-creole-mt` achieves higher scores on most shared directions. Despite this, GMU still provides the best-performing system across all available evaluation sets for `eng`→ `gul` and `eng`→ `icr`. The PIK team focused on three Haitian Creole → XX directions, and exhibits substantial variation in performance across target languages. On the two directions available in *Eval Set 1*, its system outperforms the `gemma4-creole-mt` baseline but not `kreyol-mt-pubtrain`. Results on *Eval Set 2* are more mixed: PIK achieves the best performance among all submissions on `hat`→ `eng`, but the lowest on `hat`→ `fra`, while on `hat`→ `spa` it only slightly outperforms `kreyol-mt-pubtrain`. Finally, the KYX submission considers a single direction `rcf` → `eng`, which only appears in *Eval Set 1*. It increases the chrF++ score over `gemma4-creole-mt` by +7.2 points, but falls short of `kreyol-mt-pubtrain` by -3.3 points.

| Direction | Team | Model | chrF++ | BLEU |
|---|---|---|---|---|
| **hat→eng** | *baseline* | `kreyol-mt-pubtrain` | 75.9 | 64.5 |

Table 5: Language identification results F1 scores for the languages we evaluate. The submitted systems outperformed the baseline GlotLID model on acf, fra, lou, mart, mfe, oth and rcf.

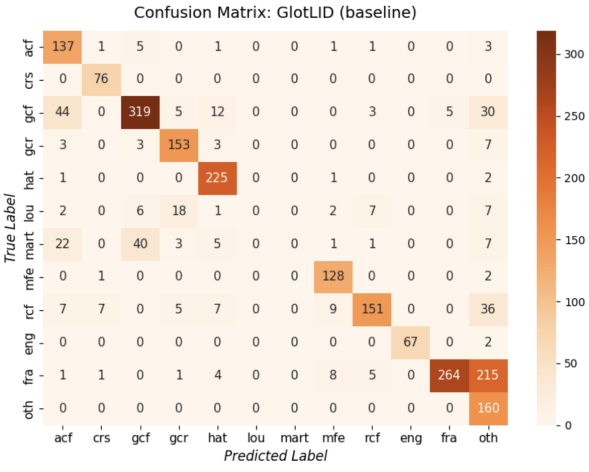

Figure 1: Confusion matrix for the GlotLID baseline model.

On the test set, the GlotLID baseline and RP system were the most performant for five languages

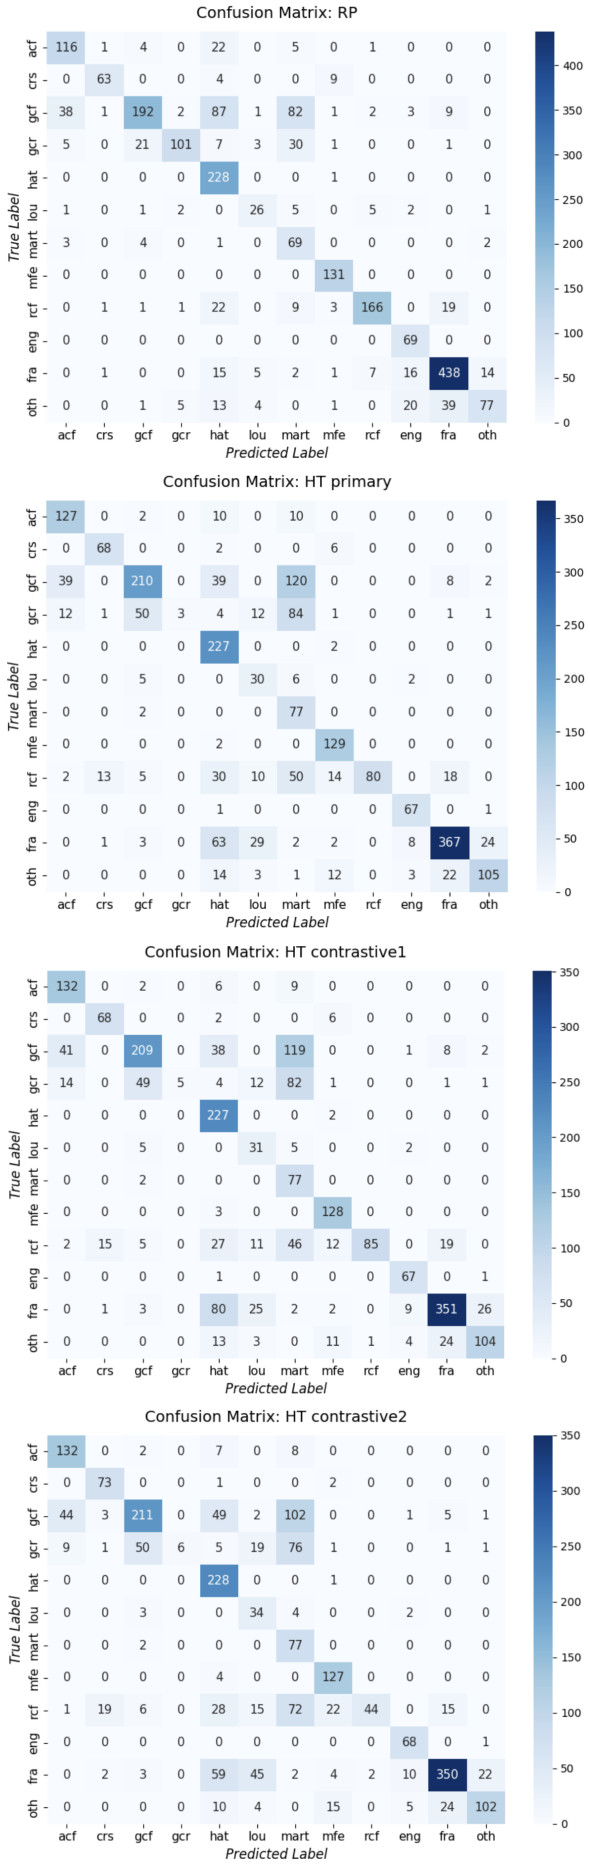

Figure 2: Confusion matrices for the four submitted models.

each. One limitation of GlotLID however, is its lack of support for Louisiana Creole and the fact that Martinician and Guadeloupean Creoles are both grouped under the gcf label. The HT-primary system was the most effective for classifying languages in the oth category.

Interestingly, all submitted systems significantly outperformed the baseline model for the identification of French sentences; nearly half of these sentences were misclassified as oth by GlotLID. In a more fine-grained analysis, we found that these misclassifications primarily consisted of text messages with nonstandard spellings and were spread across 105 languages. The most frequent misidentifications were for Ewondo (6.81% of misclassifications) and Narom (6.38% of misclassifications).

For Louisiana and Martinician Creoles, which are not covered by GlotLID, RP was the best performing system, and achieved F1 scores of 0.634 on the former and 0.491 on the latter. RP was also the best performing system for Mauritian Creole, Réunion Creole, and French, achieving F1 scores of 0.939, 0.824 and 0.872 on these languages respectively. RP's technique involved augmenting the Réunion Creole data used for training, which likely contributed to the strong performance.

HT's contrastive2 method achieved the strongest performance for St. Lucian Creole, with an F1 score of 0.788. For the oth category, HT-primary achieved the strongest performance, with an F1 score of 0.717.

Across all four submitted systems, the most consistent cluster of misclassifications involved Guadeloupean Creole. This language was most frequently mislabelled as Haitian, St. Lucian Creole and Martinician Creole. This shows that the development of systems that are better able to discriminate between languages in the same geographic cluster is a strong direction for potential research.

When the languages are considered in aggregate, the systems achieved macro-F1 scores of 0.679 for the GlotLID baseline, 0.734 for RP, 0.639 for HP primary, 0.637 for HP contrastive1, and 0.614 for HP contrastive2. RP outperformed the other submitted systems by a margin of 0.055. The lack of GlotLID support for Louisiana and Martinician Creoles was likely a partial contributor to this performance gap. Overall, the submitted systems had consistently robust performances in spite of being trained on significantly less data than GlotLID.

## 5 Conclusions

We consider the MT systems subtask a tremendous success. Some of the systems submitted (particularly from GMU, UniMelb and UQAM) advanced SOTA for multiple language directions (dozens of directions in the case of GMU). **We found that teams that (1) built and used new datasets and/or (2) employed data augmentation performed best.** (The GMU, UniMelb, and UQAM teams had this in common.) Comparatively, the CHV team's approach using in-context learning instead of actual parameter tuning was, while creative and interesting, not as successful as other approaches. This indicates that fine-tuning with additional data to those provided by task organizers is a winning strategy. This result was corroborated by last year's shared task (Robinson et al., 2025).

RP and HT both achieved SOTA performance compared to the `GlotLID` baseline on the LID task for St. Lucian Creole, Mauritian Creole, Réunion Creole and French (Louisiana and Martinician Creoles were not covered by GlotLID). The RP team achieved a macro-F1 score of 0.7340, which was the strongest across all the submitted models and the `GlotLID` baseline.

Both teams employed a linear SVM, and TF-IDF weighted character level $n$-grams as features for their models. Data augmentation significantly boosted performance compared to the HT submissions for Réunion Creole (+2163 examples) and French Guianese (+1k examples), which were the least represented languages in the training set, with 189 examples and 346 examples respectively.

This illustrates that training data availability is one of the largest bottlenecks for effective language classification, and highlights the importance of collaborations between data stewards, the linguistic community, and researchers for the advancement of Creole NLP.

Overall, the submitted systems achieved winning scores on various languages that were evaluated, and achieved competitive aggregate macro-F1 scores when compared to `GlotLID`, which is a larger system trained on significantly more data. Both the RP and HT authors show that lightweight, resource-efficient models can be highly effective for LID, and that Creole researchers should continue to focus on ways to increase data-availability and on developing new data-efficient methods. SMS messages and similar highly informal forms of writing stand out as a particularly important category for future LID evaluation.

We look forward to further progress brought through future iterations of this shared task. Please contact us if you are interested in getting involved.

## Limitations

A major limitation of this year's shared task was that we only trained the new baseline model on a 50k-sentence subset of our total data. Hence it was likely not as strong as it could have been. We plan to mitigate this for future shared tasks.

We also lament that no team submitted any data to the shared task this year. (I.e. Subtasks 2A and 2B were left untouched; see §2.) In the future we will try to facilitate teams submitting data so that the process is clear, especially considering that multiple participants in the systems subtasks actually developed new datasets that they simply did not submit this year.

## Acknowledgments

We thank Nishat Raihan, Sanjeev Khudanpur, Niyati Bafna, Philipp Koehn, and Heather Lent for their support and advice throughout the organization of this shared task.

## A Baseline Model Development Details

See Table 6 for scores of `gemma4-creole-mt` on our internal dev sets.

| Metric | Base Gemma-4 | + LoRA adapter | Δ |
|---|---|---|---|
| Macro BLEU | 7.19 | 18.48 | +11.29 |
| Macro chrF | 20.90 | 36.94 | +16.04 |
| Corpus BLEU | 5.57 | 18.48 | +12.91 |
| Corpus chrF | 21.82 | 38.48 | +16.66 |

Table 6: `gemma-4-E2B` baseline model's performance metrics.

## B Full MT Results

The remaining tables in the paper show the full evaluation results for all MT systems. See Tables 7, 8, 9, and 10.

## Abstract

We present the results of the WMT 2026 shared task of the Open Language Data Initiative (OLDI). Participants were invited to contribute to the massively multilingual open datasets supported by OLDI, FLORES+ and OLDI Seed, or to create new resources in line with OLDI's ethos. We accepted ten submissions: five extending FLORES+, and five extending other open and massively-parallel datasets (BOUQuET, Seed, SMOL, and WMT24+). These contributions advance the coverage and quality of multilingual datasets, especially for underserved language varieties. All contributions are released under permissive open-source licenses.

## 1 Introduction

Recent advances in machine translation (MT) and other multilingual natural language processing (NLP) tasks depend on a sufficient quantity of training data in the languages of interest, as well as high-quality evaluation data to measure progress in a meaningful way (Kocmi et al., 2025). However, such data is only available for a small number of the world's language varieties, limiting high-performance NLP applications to the well-resourced few (Joshi et al., 2020). The question then is how to expand data coverage, and consequently NLP access, to language communities that are missing out?

The Open Language Data Initiative (OLDI) aims to empower language communities to contribute to the key datasets underlying NLP technologies. It champions open data so that more researchers and communities can benefit from multilingual resources. As part of this, OLDI manages two open and massively-multilingual datasets, FLORES+ and Seed (described in Section 2), as well as supporting work to create and expand other open corpora in line with its objectives.

This paper describes the third shared task of OLDI, run as part of the Eleventh Conference on Machine Translation (WMT 2026). Like previous iterations (Burchell et al., 2024; Dale et al., 2025), the primary goal of the shared task was to expand the high-quality, massively-parallel and open-source datasets underpinning the development of multilingual applications. Contributions could consist of adding new language varieties to existing datasets, substantial improvements to existing datasets, or novel datasets compatible with the aims of OLDI. This year, the shared task received ten submissions covering thirteen language varieties, expanding five existing datasets. All contributions are publicly available under permissive licenses.

## 2 Datasets

In the third iteration of the OLDI shared task, participants contributed to five datasets: FLORES+ and Seed, which are managed by OLDI, as well as the independently-owned datasets BOUQuET, Seed, SMOL, and WMT24+.

### 2.1 FLORES+

FLORES is a family of datasets designed to benchmark multilingual translation, with many-to-many alignment across over 200 languages. It consists of translations of English sentences sampled in equal amounts from Wikinews (an international news source), Wikijunior (a collection of age-appropriate non-fiction books), and Wikivoyage (a travel guide). There are two public splits: `dev` (997 sentences) and `devtest` (1012). The first iteration of this dataset covered only three languages (Guzmán et al., 2019), but following iterations in-

*Proceedings of the Eleventh Conference on Machine Translation*, pages 1159–1168
October 28-29, 2026 ©2026 Association for Computational Linguistics

creased coverage first to 101 languages (FLORES-101, Goyal et al., 2022) and then to over 200 languages as part of the "No Language Left Behind" project (NLLB Team, 2024).

Previous iterations of this task and ongoing volunteer effort have added further languages as well as correcting existing data (Burchell et al., 2024; Dale et al., 2025; Doumbouya et al., 2023; Gala et al., 2023; Perez-Ortiz et al., 2024; Abdulmumin et al., 2024; Ali et al., 2024; Kuzhuget et al., 2024; Yu et al., 2024; Mamasaidov and Shopulatov, 2024; Gordeev et al., 2024; Frontull et al., 2025; Oktem et al., 2025; Mamasaidov et al., 2025; Mæhlum et al., 2025; Rajcoomar, 2025; Zhang et al., 2025; Samil and Adelani, 2026). This living version of the benchmark is released as FLORES+[1] under the CC BY-SA 4.0 license.

### 2.2 OLDI Seed

The NLLB-Seed dataset of NLLB Team (2024) was created as a source of starter data for languages without publicly-available high-quality bitext in sufficient quantity for training NLP models. This dataset consists of around 6000 sentences sampled from the Wikipedia articles listed in English Wikimedia's "List of articles every Wikipedia should have".[2] These were professionally translated into each of the 38 languages covered by the first iteration of this dataset (39 if including English), and experiments by Maillard et al. (2023) demonstrated the gains of including these datasets in the training mix of MT models.

Like FLORES+, previous iterations of this shared task and ongoing volunteer effort have expanded the original data (Doumbouya et al., 2023; Ahmed et al., 2024; Ferrante, 2024; Cols, 2024; Marmonier et al., 2025; Jumashev et al., 2025; Oktem et al., 2025). The living version of this benchmark is released as OLDI Seed[3] under the CC BY-SA 4.0 license.

### 2.3 BOUQuET

BOUQuET is a multi-way parallel, multi-centric and multi-register/domain dataset and benchmark for MT quality (Andrews et al., 2025). It consists of short paragraphs, fully parallel in all languages at the sentence level, in two public splits: `dev` (504 unique sentences, 120 paragraphs) and `test` (854 unique sentences, 198 paragraphs). The underlying texts have been handcrafted by linguists in eight diverse languages (Egyptian Arabic, French, German, Hindi, Indonesian, Mandarin Chinese, Russian, and Spanish) and translated to English and 266 other language + script combinations. The dataset is intended to be extensible to virtually any other written language and is open to volunteer contributions. BOUQuET is managed by Meta FAIR and released under the CC BY-SA 4.0 license.[4]

### 2.4 SMOL

SMOL is a multi-way parallel training dataset with high lexical coverage (Caswell et al., 2025). The first part of the dataset, SMOLSENT, is based on 863 English sentences semi-manually selected from Common Crawl data[5] to cover 5.5k of the most common English words (obtained by joining the GATITOS wordlist (Jones et al., 2023) and the most frequent words in Common Crawl). These sentences were then professionally translated into 88 languages. The second part of the dataset, SMOLDOC, is based on 584 English documents generated by a large language model (LLM) using prompt templates to ensure diversity of topics and styles. These were professionally translated from English into 115 languages, then volunteers contributed additional translations to bring the total number of languages to 123. SMOL is managed by Google Research and released under the CC BY 4.0 license.[6]

### 2.5 WMT24++

The WMT24+ dataset (Deutsch et al., 2025) was created by translating the test dataset from the WMT24 General MT shared task (Kocmi et al., 2024) from English to 54 other languages. The 998 paragraph-sized English source documents come from four different domains: literary, news, social, and transcribed speech. Thus, WMT24+ is mostly complementary to FLORES+ in document sizes and domains (though news is an overlapping domain). WMT24+ is managed by Google Research and released under the permissive Apache License 2.0.[7]

## 3 Shared task description

As described in the introduction, we invited three main categories of contribution: new language varieties for existing datasets, substantial improvements to existing datasets, or novel datasets compatible with the aims of OLDI. We were open to contributions of new or extended datasets of translation quality annotations for under-served languages, but we received no submissions of this type. We describe the standard contribution process below.

### 3.1 Contributing to OLDI's datasets

When contributing to the datasets managed by OLDI, FLORES+ and Seed, we encouraged participants to translate from the English data, so as to minimise translation drift. Participants could translate from a different language if necessary, but we asked them to document this choice clearly. Where possible, we asked participants to use translators who were qualified, native speakers of the target language, and to have at least one additional native speaker verify the data. For FLORES+ translation, we did not allow any use of MT output, including post-editing, to avoid introducing any machine bias in this evaluation dataset. For Seed, post-editing was allowed as long as all outputs were verified manually. Full translation guidelines are provided on the OLDI website[8] and copied to Appendix A.

We asked the participants to provide dataset cards as part of their submissions, detailing precise language information and the translation workflow that was employed. In particular, we asked them to identify the language with an ISO 639-3 individual language tag, the precise variety with a Glottocode, and the script with an ISO 15924 script code. For example, the Val Badia variety of Lombard is tagged as `lld_Latn_badi1244`.

Participants were encouraged to provide experimental validation of the quality of the data they were submitting. All contributions had to be released under open licenses matching the original datasets e.g. CC BY-SA 4.0 for FLORES+.

### 3.2 Other contributions

We also accepted extensions and improvements to other foundational, open, and multilingual datasets in keeping with OLDI's principles. We recommended that the contribution workflow for these submissions should follow OLDI's as closely as possible to ensure data quality and documentation.

## 4 Submissions

### 4.1 Shared task submissions

Table 1 summarises the contributions received as part of the shared task. We received ten papers describing contributions to five datasets: FLORES+ (7 language varieties), BOUQuET (3 language varieties), Seed (1 variety), SMOL (3 language varieties), and WMT24+ (1 language variety). Overall, participants made submissions for 13 different language varieties. In the rest of this section, we give a brief description of each submission.

**Ahmed and Chakma (2026)** translate the dev and devtest part of FLORES+ into Chakma, a language spoken in India and written in its own script (part of Unicode). There are variants of the language. The contribution represents the Bangladeshi variety used by contributors from the Chittagong Hill Tracts. The contribution is fully manual and did not use any machine translation or large language model. The source language is English. Translations were reviewed by one of the authors. There is no experimental validation of the data.

**Ali et al. (2026)** contribute three FLORES+ evaluation sets for Mozambican Bantu varieties: Xichangana, Mozambican Nyanja, and Sena (the first FLORES+ entry for this 2M speaker language), each translated from Portuguese by professional native translators and independently assessed. Since South African Tsonga and Malawian Chichewa share ISO 639-3 codes with varieties already in FLORES+, the authors score identical system outputs against both references, showing that existing sets overestimate quality for Mozambican users by 7 to 9 spBLEU, with the gap driven by borrowing source, orthography, and register rather than ordinary translation errors. Fine-tuning NLLB-200 on around 30k Mozambican Bible verses recovers most of the gap while degrading scores on the sibling sets, confirming that the two references measure genuinely different targets and motivating variety-aware language tags (e.g., `nya_Latn_MZ`) for cross-border Bantu languages.

**Ibrahim (2026)** extend the SMOL dataset with two varieties of the Tigre language (a language spoken in Eritrea and eastern Sudan): Modern Standardized Tigre and its Mansa dialect (a classical literary norm). The translations from English were pre-generated by an NLLB-based model and post-edited and reviewed by volunteer contributors. Their validity was confirmed by fine-tuning an NLLB-200 model with this data and observing

| Language | Variety | ISO 639-3 | ISO 15924 | Glottocode | Contributors | Contribution |

Table 1: A summary of all dataset contributions to the WMT 2026 Shared Task of the Open Language Data Initiative.

its translation quality on a held-out subset increase.

**Frontull et al. (2026)** contribute BOUQuET translations in two varieties of Ladin, Val Badia and Gherdëina. Four native speakers, two per variety, translated BOUQuET from the English and German references via the official web interface, using variety-specific spellcheckers. Translations for the two varieties were then aligned side-by-side to harmonise the terminology and the outputs were checked by two reviewers. Additional validation relied on automated metrics such as source/target ratio checks, checking back-translations into English against the English reference, and blind ranking the Ladin references against automatic translations.

**Marmonier et al. (2026a)** translate the SMOL sentence-level dataset from English into French by manually post-editing translations from NLLB-200, Gemma-4-31B, and DeepSeek V4 Pro. The candidates were compared using reference-free MetricX scores, with that the post-edited texts scoring significantly better than the MT candidates. The authors intend to use the French SMOL translation as a pivot for the regional languages of France, including the experiments with Savoyard described below.

**Marmonier et al. (2026b)** translate FLORES+ from French into Savoyard, an endangered Arpitan dialect spoken around the French–Italian–Swiss alpine borders. The draft translations for the dev split were generated with a French-Arpitan rule-based Apertium system and post-edited by two proficient speakers; the devtest split was translated from scratch. The authors use the dataset to evaluate several systems for translation between French and Savoyard: the copy-source baseline, Apertium, a fine-tuned NLLB-200 model, and several versions of Gemma 4. According to automatic and human evaluations, Apertium leads for translation into Savoyard, while Gemma 4 is the best for translating Savoyard into French.

**Signoroni and Rychlý (2026)** translate FLORES+ from Italian into Eastern Lombard, an underrepresented variety of the Lombard language continuum (FLORES+ already had Western Lombard translation). They use these translations to evaluate several LLMs and MT models for translation of English and Italian into Western and Eastern Lombard. They find that the models tend to generate the more represented Western variety even when instructed otherwise, and that translation into both Lombard varieties with any system does not significantly outperform the copy-the-Italian-source baseline.

**Singh (2026)** create a four-way parallel benchmark between English, Hindi, Meitei script Manipuri, and Bengali script Manipuri by transliterating the FLORES-devtest Bengali script Manipuri

into Meitei script. This new split was produced by two professional translators: one to transliterate, and a second to review independently. They use their benchmark to evaluate two dedicated MT systems and five general purpose LLMs. They find that evidence that differences in performance across scripts reflects training data curation, meaning that different systems vary in ability and failure modes for the different scripts. They recommend that script not be taken as constant across a language's benchmark entries, since conflating "Manipuri" scores across scripts without qualification would obscure the models' real-world performance. They also highlight that failure modes are script-specific, not just magnitude differences, and the observed failures indicate data scarcity interacting with architecture rather than uniform degradation.

**Umishov and Grigorian (2026)** add Chechen translations to the BOUQuET, WMT24+, and SMOL datasets. For all 3 datasets, Russian serves as a pivot language to translate from. The authors validate their datasets by fine-tuning a MADLAD-400 model using their SMOL translation and evaluating it with WMT24+ and BOUQuET. On both benchmarks, the quality of translation between Russian and Chechen language improves.

**Zundanović et al. (2026)** post-edit machine translations of Seed from English into Croatian. They validate data quality by fine-tuning several models from NLLB and Gemma with the post-edited translations to translate between English and Croatian. On the evaluation datasets, they observe improvements in all configurations in ChrF++ and COMET scores, in all cases except English-Croatian LLM-based translation. The authors ablate the effect of human post-edition by fine-tuning the NLLB-based models using the original machine-translated Croatian Seed sentences, finding that the post-edited data always wins.

### 4.2 Other contributions

Not all contributors to the OLDI datasets submitted shared task papers. In the past year, Seed incorporated new translations for Mauritian Creole (Rajcoomar, 2025), Mongolian in traditional Mongolian script (Zhang et al., 2025), Khakas, Sudanese Arabic (Samil and Adelani, 2026), Haryanvi, Bodo, Garhwali, Konkani, Rajasthani, Malvi and Marwari (Singh et al., 2024). FLORES+ also received corrections for Amharic and Turkish. SMOL received translations into Abaza, Brahui, Tigre, Juhuri, NKo, and Khakas; and Gatitos received 1,052 translations of Cantonese food items. For a detailed list of changes and attributions, see the `CHANGELOG.md` files and dataset cards in the FLORES+, OLDI-Seed, and SMOL repositories.

## 5 Discussion

The third iteration of the Open Language Data shared task turned out as fruitful as the previous two, with 10 submissions, 13 involved language varieties, and 5 datasets that the contributions targeted.

An important theme of this year is fine-grained variation of a language: Ali et al. (2026), Frontull et al. (2026), and Signoroni and Rychlý (2026) all explicitly contrast several dialects of the same language, while Singh (2026) compares two writing systems. Contributions such as these add more depth to the coverage of the datasets, as they allow developers to assess variation in language use.

This year, more submissions than before (Ibrahim, 2026; Marmonier et al., 2026a,b; Zundanović et al., 2026) chose not to translate the training dataset contributions from scratch, but rather to post-edit their machine translations and then validate the contribution of the human post-edits to the resulting data quality. We also observe a growing degree of rigour in validating the overall quality of the resulting translations, using a combination of automatic quality estimation metrics, comparison of machine translation outputs, and human evaluation. This is an encouraging development, as it reflects the increasing appreciation in the community for the impact of high-quality multilingual benchmarks.

With the recent progress of LLMs, the sentiment is sometimes expressed that machine translation is a "solved problem". This is not the case, as ablation results from these submissions demonstrate. Even for such a high-resourced language as French, human post-edits are quantifiably better than the best MT outputs; for translation into some lower-resourced languages, LLMs appear to be inferior to rule-based systems (Savoyard) or even struggle to produce the correct target variety (Manipuri in Meitei script). The newly contributed dataset extensions provide a leverage for improving the way modern technologies handle the world's linguistic diversity.

## 6 Conclusion

We presented the results of the WMT 2026 OLDI shared task. We accepted ten submissions covering thirteen language varieties, extending five existing foundational datasets: FLORES+, BOUQuET, Seed, SMOL, and WMT24+. We are truly grateful to all participants for their work, and we hope that these contributions are soon adopted by the research community and used to enhance user-led language technologies.

## Acknowledgments

OLDI functions on volunteer time and community contributions. We are grateful to the language communities, researchers, and reviewers that contributed to this shared task with new resources for under-served languages.

# A Translation guidelines

These translation guidelines must be acknowledged by all translators who will be contributing data.

### Important note

Your translations will be used to help train or evaluate machine translation engines. For this reason, this project requires human translation.

- If you are translating data to be used for evaluation purposes (e.g. FLORES+), using or even referencing machine translation output is usually not allowed (this includes post-editing). In exceptional circumstances, use of CAT (computer-assisted translation) tools and translation frameworks such as Apertium may be admissible. This is decided on a case by case basis: please contact the organisers to discuss.
- If you are translating data to be used for training purposes, such as Seed, the use of post-edited machine translated content is allowed, provided all data is manually verified and edited where necessary.
- CAUTION: Some commercial machine translation or LLM services – including DeepL, Google Translate, ChatGPT, Claude and Gemini – prohibit the use of their output for training other translation or AI models. Their use is not permitted.

### General guidelines

- You will be translating sentences coming from different sources. Please refer to the source document if available.
- Do not convert any units of measurement. Translate them exactly as noted in the source content.
- When translating, please maintain the same tone used in the source document. For example, encyclopedic content coming from sources like Wikipedia should be translated using a formal tone.
- Provide fluent translations without deviating too much from the source structure. Only allow necessary changes.
- Do not expand or replace information compared to what is present in the source documents. Do not add any explanatory or parenthetical information, definitions, etc.
- Do not ignore any meaningful text that was present in the source.

- In case of multiple possible translations, please pick the one that makes the most sense (e.g., for gender concordance, cultural fit in the target language, level of formality, etc.).
- Translations must be faithful to the source in terms of pragmatics such as (if applicable) level of hedging/modality, sentiment and its intensity, negation, speech effects (disfluencies), etc.
- For proper nouns and common abbreviations, please see the guidelines on Named Entities below.
- Idiomatic expressions should not be translated word for word. Use an equivalent idiom, if one exists. If no equivalent idiom exists, use an idiom of similar meaning. If no similar expressions exist in the target language, paraphrase the idiom such that the meaning is retained in the target language.
- When a pronoun to be translated is ambiguous (for instance, when it could be interpreted as either *him/her* or *he/she*), opt for gender neutral pronouns (such as t*hem/they*) if those exist in the target language. However, when a pronoun to be translated is clearly marked for gender, you should follow the source material and continue to mark for gender.
- Foreign words and phrases used in the text should be kept in their original language when this is necessary to preserve the meaning of the sentence (e.g. if given as an example of a foreign word).

**Named entities**

Named entities are people, places, organisations, etc., that are commonly referred to using a proper noun. This section provides guidance on how to handle named entities. Please review the following guidelines carefully:

- If there is a commonly used term in the target language for the Named Entity:
  - If the most commonly used term is the same as in the source language, then keep it as it is.
  - If the most commonly used term is a translation or a transliteration, then use that.
- If there is no commonly used term:
  - If possible, a transliteration of the original term should be used.
  - If a transliteration would not be commonly understood in the context, and the source term would be more acceptable, you may retain the original term.

# Findings of the WMT26 Video Subtitle Translation Shared Task: Context and Candidate Selection Matter

**Zheng Li***, **Mao Zheng***
Foundation Model Department, Tencent
{jasonzli,moonzheng}@tencent.com

## Abstract

We present the setup, systems, evaluation, and findings of the WMT26 Video Subtitle Translation shared task. The task covers translation from Simplified Chinese into English, Thai, Indonesian, Malay, and Traditional Chinese for Taiwan, China. Eight teams submitted 2,200 SRT files across 22 team-language combinations. We evaluated 2,198 unique team-language-video units with repeated LLM-based language quality assessment followed by human checking and correction. Each video was assessed three times, with valid positive scores aggregated by the median. ReopenAI led all five directions and achieved a macro-average of 89.357; laniqo ranked second with 78.265. Corrected scores were extractable from 93.36% of the evaluation units, and 15.30% of those scores differed from the automatic scores. Stronger results were associated with contextual prompting, diverse candidate generation, constrained selection, translator-critic specialization, terminology control, and deterministic subtitle validation. These cross-system associations are not controlled ablation evidence. Persistent challenges include cross-cue reference resolution, cultural and register adaptation, multilingual judge calibration, and balancing brevity with semantic completeness.

## 1 Introduction

The Conference on Machine Translation has long served as a common evaluation ground for advances in machine translation. Following the shared-task reporting tradition exemplified by the WMT25 General Machine Translation findings paper (Kocmi et al., 2025), this paper documents the WMT26 Video Subtitle Translation shared task, summarizes the participating systems, reports the evaluation results, and uses the submitted systems as evidence for broader conclusions about the current state of subtitle translation.

Video subtitle translation differs from general sentence-level translation in several important ways, including length, display-duration, and segmentation constraints (Matusov et al., 2019). Subtitle cues are short, time-aligned units that do not necessarily correspond to complete sentences. A single utterance may span several cues. Chinese zero pronouns can require discourse context for recovery (Wang et al., 2019), while context-sensitive deixis, ellipsis, and lexical cohesion have also been studied in subtitle translation (Voita et al., 2019). The output must also remain concise enough for on-screen presentation, retain the source cue structure, and use consistent names, titles, and terminology throughout a video. Colloquial expressions, historical titles, humor, slang, and culturally specific language further increase the difficulty of the task.

The WMT26 shared task focuses on five translation directions from Simplified Chinese: English, Thai, Indonesian, Malay, and Traditional Chinese for Taiwan, China. Participants were provided with source SRT files and video-level metadata, including a synopsis or description. The task used a constrained setting in which final systems were required to remain below 20 billion parameters and to use releasable model weights. This setting encouraged reproducible research with compact open-weight translation and instruction models.

This paper makes four contributions. First, it gives a unified account of the eight participating systems and their language coverage. Second, it describes a scalable evaluation procedure that combines repeated LLM-based LQA assessment with human checking and correction. Third, it reports overall and language-specific rankings. Finally, it analyzes which modeling and inference strategies were associated with stronger performance and identifies remaining challenges for subtitle translation and evaluation.

The rankings reported here are derived from the submitted result files and the AI-plus-human verifi-

*Equal contribution.

cation procedure described in Section 4. They are intended as an analysis of the available submissions and evaluation artifacts.

## 2 Task and Data

This section defines the task, constrained setting, and submission coverage.

### 2.1 Task definition

The shared task required participants to translate video subtitles from Simplified Chinese into one or more of the following targets:

- English (`en`);
- Thai (`th`);
- Indonesian (`id`);
- Malay (`ms`); and
- Traditional Chinese for Taiwan, China (`zh-TW`).

Each test item contained a source subtitle file in SRT format and associated metadata. The metadata included a video description or synopsis and could be used to disambiguate character relations, domain terminology, and the overall narrative setting. Participants were expected to submit one translated SRT file per video and language using the naming pattern `vid_langshort.srt`.

The official task description emphasizes three properties that distinguish subtitle translation from general-purpose MT: length and timing constraints, the use of metadata, and the need to preserve style and register. Systems could process cues independently, use local context windows, or translate with broader video-level context, provided that the resulting files remained structurally valid.

### 2.2 Constrained setting

The task adopted a constrained setting. Systems could use different training data, models, and frameworks, but the final model or ensemble had to contain fewer than 20 billion parameters. For ensembles, the parameter counts of all members were combined, and mixture-of-experts systems were counted by their full parameter count. Final model weights were expected to be released under a license that permits unrestricted non-commercial use.[1]

[1]Official task description: `https://www2.statmt.org/wmt26/video-subtitle-translation.html`.

This constraint shaped system design in two ways. First, several teams relied on compact translation-specialized models from the Hy-MT2 family (Zheng et al., 2026). Second, teams combining a translator with a general instruction model had to allocate the parameter budget carefully, often using a 7B translation model with a 12B critic or selector.

### 2.3 Submission coverage

Eight teams participated in the evaluated submissions. ReopenAI, laniqo, and BVSLP covered all five language directions. LensLinguals submitted English and Thai; rupiah submitted English and Indonesian; SubVision, AuditTranslate, and paramanandaAI submitted English only.

The collected results contain 2,200 SRT files, corresponding to 22 team–language combinations with 100 files per submitted direction. The evaluation workbook contains 2,198 unique team–language–video units. Two submitted videos had no unique scored evaluation record. One additional duplicated evaluation entry was removed using the tuple `(team, language, video ID)`. These missing score records do not indicate missing SRT submissions.

## 3 Participating Systems

This section summarizes the eight systems and the main architectural trends.

### 3.1 System overview

Table 2 summarizes the main design choices. Six of the eight teams used a Hy-MT model in their submitted system. The two exceptions were laniqo, which selected Gemma-4-12B-it (Gemma Team, 2026) after development-set screening, and BVSLP, which used a Qwen3.5-based system (Qwen Team, 2026). The table follows the compact system-comparison style used in WMT findings papers: it records the base model, adaptation strategy, inference-time selection, context use, and post-processing. System-specific configurations below are taken from the submitted descriptions or notebook; citations to base models and general methods do not independently verify those configurations.

### 3.2 Common architectural trends

The submissions reveal three broad trends. First, large instruction-tuned language models and translation-specialized decoder-only models dominated the task. Second, competitive systems in-

| Team | en | id | ms | th | zh-TW | Languages |
|---|---|---|---|---|---|---|
| ReopenAI | 100 | 100 | 100 | 100 | 100 | 5 |
| laniqo | 100 | 100 | 100 | 100 | 100 | 5 |
| BVSLP | 100 | 100 | 100 | 100 | 100 | 5 |
| LensLinguals | 100 | — | — | 100 | — | 2 |
| rupiah | 100 | 100 | — | — | — | 2 |
| AuditTranslate | 100 | — | — | — | — | 1 |
| paramanandaAI | 100 | — | — | — | — | 1 |
| SubVision | 100 | — | — | — | — | 1 |

Table 1: Submission coverage. Each value is the number of collected SRT files; a dash denotes an unsubmitted direction. All 22 submitted team–language combinations contain 100 files. Two files lack unique scored evaluation records.

creasingly treated translation as an inference-time search problem rather than a single generation call. ReopenAI, laniqo, AuditTranslate, and rupiah all generated multiple candidates and applied a separate selection or reranking mechanism. Third, most systems explicitly represented context, terminology, or previous translations rather than translating each cue in isolation.

Training strategies varied substantially. BVSLP used multistage parameter-efficient adaptation, while SubVision and paramanandaAI fine-tuned the smaller Hy-MT2-1.8B model. By contrast, ReopenAI, laniqo, AuditTranslate, LensLinguals, and rupiah obtained their gains primarily through prompting, candidate search, selection, and deterministic post-processing. The final rankings therefore provide an opportunity to compare weight adaptation with inference-time orchestration under the same parameter constraint.

### 3.3 ReopenAI

ReopenAI submitted all five target languages. Its system combined Hy-MT2-7B (Zheng et al., 2026) and Gemma-4-12B-it (Gemma Team, 2026), for a nominal total of approximately 19 billion parameters. For each cue, Hy-MT2-7B generated two candidates with different random seeds, and Gemma-4-12B-it generated two more. Gemma then acted as an anonymous four-way selector.

The selector saw candidates under labels rather than model identities. Two judgments were made: one with a stable pseudorandom candidate order and another with the reversed order. A candidate was accepted only when both decisions mapped to the same original output; otherwise the pipeline used a fixed fallback. The selector could not rewrite or merge candidates. Reversing candidate order addresses a known evaluation concern: positional bias has been observed in LLM judges (Zheng et al., 2023). This related finding does not establish that the present selector is bias-free. Both generation and selection received the complete Chinese subtitle sequence for the video together with title metadata. The system used no task-specific fine-tuning, external glossary, or manual post-editing.

### 3.4 laniqo

laniqo submitted all five language directions using Gemma-4-12B-it without fine-tuning or adapters. The team screened Qwen3.5-9B, Hy-MT2-7B, and Sailor2-20B (Dou et al., 2025) on development data before selecting Gemma-4; Hy-MT was therefore evaluated during system development but was not used in the submitted pipeline.

The pipeline generated 25 translations per cue through hedged sampling and four prompt variants. After removing empty, malformed, and wrong-language outputs, it scored candidates with reference-free xCOMET (Guerreiro et al., 2024) and MetricX-24 (Juraska et al., 2024), together with subtitle-compliance measures based on characters per second and characters per line. Non-dominated candidates formed a Pareto set. A second Gemma pass, called Chimera/FusioN, then selected, rewrote, or merged candidates using multiple cues at once. A final validation pass guaranteed non-empty output in the target language and compressed or retransmitted cues that failed hard constraints.

### 3.5 AuditTranslate

AuditTranslate submitted Chinese-to-English. It used Hy-MT2-7B as the only translation author and an INT4 Gemma-4-12B model as an English-

side critic and selector. Hy-MT generated three diverse candidates per cue. Gemma selected among them and evaluated the selected output using decomposed yes/no checks rather than a single monolithic rubric.

The checks targeted omissions, hallucinations, negation errors, pronoun gender, context leakage, register, sentence mood, agent direction, speaker attribution, and invented names. Candidate error flags were subjected to a skeptical re-verification step. When all candidates shared a confirmed defect, Gemma sent a targeted hint back to Hy-MT for retranslation instead of translating from Chinese itself. Deterministic passes normalized names and ordinal titles and wrapped output to at most two lines of 42 characters.

### 3.6 LensLinguals

LensLinguals submitted English and Thai using the released Hy-MT2-7B checkpoint without fine-tuning. Its pipeline first extracted character names from metadata and translated them into a per-video glossary. Each cue was then translated with the video title, the two preceding cues, the two following cues, and the glossary as read-only context.

The implementation used vLLM (Kwon et al., 2023) batching and prefix caching to improve throughput. Post-processing cleared outputs with substantial Chinese leakage, enforced a maximum line length, and verified that cue counts, sequence numbers, and timestamps matched the source. This system illustrates a comparatively simple approach built around a strong translation model, focused

context, and deterministic structural checks.

### 3.7 rupiah

rupiah submitted English and Indonesian. Hy-MT2-7B was used as a zero-shot translator, while the rest of the pipeline was model-agnostic. Each prompt incorporated the video synopsis, a window of preceding source cues, and already translated source–target pairs from the current episode. The system also built a per-episode glossary to stabilize recurring proper names.

Several temperature-diverse candidates were generated for each cue. Candidates containing source-language leakage were removed, and the remaining candidates were ranked with CometKiwi reference-free quality estimation (Rei et al., 2022). The final SRT preserved the source timing and cue segmentation. The system represents a compact combination of contextual prompting, terminology control, diverse decoding, and QE reranking.

### 3.8 BVSLP

BVSLP submitted all five target languages with QwenSub-MT, a Qwen3.5-9B-Instruct system[2] adapted through 4-bit QLoRA (Dettmers et al., 2023). Training proceeded through multilingual translation adaptation, subtitle-domain adaptation, and metadata-enriched adaptation. At inference time, adjacent cues were grouped into short blocks rather than processed independently.

The system used a video synopsis, previous translations, a dynamic terminology memory, and selected visual keyframes. A revision stage checked semantic, terminology, and formatting errors. Duration-aware length control and line-break optimization were applied before reconstruction into SRT files. BVSLP was the only submission that explicitly documented selective visual grounding.

### 3.9 paramanandaAI

paramanandaAI submitted English using Hy-MT2-1.8B with QLoRA (Dettmers et al., 2023) fine-tuning on a corpus identified as TVSub in the submitted description. The submitted description provided the base model, adaptation method, dataset, and a model-weight link, but did not describe additional context construction, candidate selection, or subtitle-specific post-processing. The available evidence therefore indicates that the principal contribution was parameter-efficient domain adaptation of a compact translation model.

### 3.10 SubVision

SubVision submitted English. No standalone system description paper was found in the submission directory, so this summary is based on the supplied training notebook. The system used Hy-MT2-1.8B with NF4 4-bit quantization and QLoRA (Dettmers et al., 2023). Approximately 60,000 Chinese–English training pairs were sampled from TVSub (Wang et al., 2018);[3] the LoRA (Hu et al., 2022) rank was 16 and training ran for three epochs.

The notebook evaluated the adapted model with BLEU (Papineni et al., 2002), sacreBLEU (Post, 2018), chrF (Popović, 2015), TER (Snover et al., 2006), and COMET (Rei et al., 2020), and used beam search for generation. It did not document video-level context, multi-candidate reranking, or dedicated subtitle-structure quality control.

## 4 Evaluation

This section describes automatic scoring, the LQA rubric, human verification, and aggregation.

### 4.1 Automatic evaluation

Because the submission set contained 2,200 translated videos, exhaustive independent human scoring of every output was impractical. We therefore used an LLM-as-a-Judge procedure as the first evaluation stage and followed it with human verification. Related approaches include GEMBA for translation quality scoring (Kocmi and Federmann, 2023b) and GEMBA-MQM for error-span detection (Kocmi and Federmann, 2023a); our judge, prompting, and aggregation settings differ from these methods. The unit of evaluation was a `(team, language, video)` triple.

For each unit, the source and target SRT files were parsed into cue-indexed text. The evaluator aligned source and target cues by subtitle index and retained only non-empty aligned pairs. Multi-line cue text was joined with spaces. The resulting input was a source–translation table covering the complete video.

[2]The official post-trained checkpoint is named `Qwen/Qwen3.5-9B` (Qwen Team, 2026). We retain the `-Instruct` label used in the submission; the exact checkpoint revision should be confirmed with the team.

[3]The notebook points to `https://github.com/longyuewangdcu/tvsub`. Its data attribution names `http://assrt.net` and `http://www.zimuzu.tv` as original subtitle sources.

The judge was `gemini-3.1-pro-preview` (Google, 2026), invoked with a language-specific LQA prompt. The prompt and aligned subtitles were concatenated into a single user message because the serving marker did not reliably follow a separate system role. Generation used a maximum of 8,192 output tokens, low reasoning effort, and temperature 0.7. Requests were retried with exponential backoff, except for non-retryable content-safety failures.

Each video was independently evaluated three times. Valid positive scores were aggregated by the median to reduce sampling variance. If all three attempts failed, the video received an automatic score of zero.

### 4.2 LQA rubric

The automatic evaluation used a 100-point deduction-based rubric with four dimensions. Error-based evaluation has a broader precedent in MQM (Lommel et al., 2014); however, the dimensions and the 40/35/5/20 weights here are task-specific and are not a standard MQM scoring configuration.

Scores were mapped to four broad quality bands: Excellent for 90–100, Good for 75–89, Fair for 60–74, and Poor below 60. Severe failures could also receive a Reject label.

LLMs sometimes produce inconsistent arithmetic when converting a list of deductions into a total score. To avoid this failure mode, the evaluation script recomputed each dimension and the total score from the listed defect penalties:

$$s_d = \max\left(0, M_d - \sum_{e \in E_d} |p_e|\right), \quad (1)$$

$$s_{\text{total}} = \sum_{d=1}^{4} s_d. \quad (2)$$

Here $M_d$ is the maximum for dimension $d$, $E_d$ its listed defects, and $p_e$ the penalty assigned to defect $e$.

This makes the numeric result auditable against the model-generated evidence.

### 4.3 Human verification

The human stage was designed as verification and correction rather than an independent second annotation campaign. This differs from expert-led MQM studies with full document context, such as Freitag et al. (2021); we do not claim to reproduce that annotation protocol. Reviewers checked whether the reported errors were supported by the source and translation, whether cited cue numbers matched the actual subtitle lines, whether error categories and penalties were appropriate, and whether the total score was consistent with the corrected defect list.

When the automatic assessment was accurate, it was retained. When the assessment contained false positives, missed or duplicated penalties, cue-number mismatches, or inappropriate severity, reviewers corrected the structured assessment. The corrected `total_score` was then used as the final score. If no corrected score could be extracted, the automatic median score was retained.

The evaluation workbook contained 2,198 unique units. Human-corrected scores could be extracted for 2,052 units, corresponding to 93.36% of the evaluation units. This is corrected-score field coverage, not the proportion of fully valid JSON assessments or evidence of independent human annotation. Among these units, 314 scores changed, or 15.30%. The median score change was zero and the mean was $-0.313$ points, but individual corrections ranged from $-55$ to +90 points. These outliers show that aggregate stability does not eliminate the need to inspect severe judge failures.

### 4.4 Aggregation and ranking

Final scores were aggregated in three steps:

1. **Video score:** the human-corrected score when available; otherwise the automatic median score.

2. **Team–language score:** the arithmetic mean over all evaluated videos for that team and language.

3. **Overall score:** the macro-average over the language scores submitted by the team, with each submitted language receiving equal weight.

The macro-average prevents languages with more evaluated videos from receiving greater weight. However, it does not reward broader language coverage: a team submitting one language can rank above a multilingual system if its single-language average is higher. For this reason, Table 4 reports both the overall score and the number of submitted languages.

| Dimension | Maximum | Examples of deductions |
|---|---|---|
| Accuracy and fidelity | 40 | Critical mistranslation, terminology error, omission, inconsistency, semantic deviation |
| Fluency and readability | 35 | Grammar or structural error, translationese, spelling and punctuation |
| Subtitle text conventions | 5 | Excessive line length, formatting violations |
| Cultural and stylistic adaptation | 20 | Cultural failure, cultural distance, inappropriate tone or register |

Table 3: The deduction-based LQA rubric. Dimension scores are floored at zero before summation.

One duplicated Indonesian evaluation unit for rupiah was removed using the unique key `(team, language, video ID)`. The duplicate carried the same score in both rows.

## 5 Results

This section reports overall and language-specific results and the effect of human verification.

### 5.1 Overall and language-specific ranking

Table 4 presents the final results. Each language cell contains the mean score followed by the rank within that language in parentheses. A dash indicates that the team did not submit that direction.

ReopenAI ranked first in all five submitted directions. Its macro-average exceeded laniqo by 11.092 points. laniqo placed second in Indonesian, Malay, Thai, and Traditional Chinese, but fourth in English. English had the broadest participation, with all eight teams. The top three English systems were ReopenAI, LensLinguals, and AuditTranslate.

Participation was more limited in the other directions: four teams submitted Indonesian, three submitted Malay, four submitted Thai, and three submitted Traditional Chinese. Rankings in these directions should therefore be interpreted as comparisons among smaller system sets.

### 5.2 Effect of human verification

Human verification had different effects across target languages. English scores were generally stable: for most teams, the difference between the automatic and final mean was within 0.3 points, although SubVision increased by 1.290 points. Traditional Chinese scores also changed little.

Indonesian showed a consistent downward correction. Final means decreased by 3.900 points for laniqo, 4.345 for rupiah, 5.330 for BVSLP, and 1.780 for ReopenAI. In contrast, Malay scores moved upward by 1.150 points for laniqo, 2.525 for BVSLP, and 1.300 for ReopenAI. Thai corrections were smaller and mostly positive.

These language-specific directions suggest that the judge was not equally calibrated across target languages. The Indonesian assessments appear to have been comparatively lenient before human review, whereas Malay assessments were comparatively strict. Human verification did not change the overall rank order, but it materially changed absolute scores for several language–system pairs. Such changes can affect threshold-based interpretation and close language-specific comparisons even when the global leaderboard remains stable.

## 6 Analysis and Discussion

This section relates system design choices to performance and identifies remaining challenges.

### 6.1 Context is a core requirement, not an optional feature

The strongest systems explicitly modeled context. ReopenAI provided the complete video subtitle sequence to both generators and the selector. LensLinguals used a local window and metadata. rupiah combined a synopsis, preceding cues, and previously translated examples. AuditTranslate provided neighboring cues as read-only context, and laniqo processed multiple cues jointly in its final fusion step.

These approaches address a fundamental property of Chinese subtitles: subjects, referents, and interpersonal relations are frequently omitted when recoverable from discourse. A cue-level system may produce a locally plausible sentence while choosing the wrong person, gender, title, or discourse relation; related context-dependent translation problems are documented by Voita et al. (2019) and Wang et al. (2019). The results suggest that future subtitle systems should use hierarchical context: local windows for syntax and continuation,

| Rank | Team | en | id | ms | th | zh-TW | Macro avg. | $N_L$ |
|---|---|---|---|---|---|---|---|---|
| 1 | ReopenAI | 90.195 (1) | 87.845 (1) | 82.160 (1) | 89.015 (1) | 97.571 (1) | 89.357 | 5 |
| 2 | laniqo | 74.155 (4) | 74.270 (2) | 69.120 (2) | 79.895 (2) | 93.885 (2) | 78.265 | 5 |
| 3 | AuditTranslate | 74.705 (3) | — | — | — | — | 74.705 | 1 |
| 4 | LensLinguals | 75.255 (2) | — | — | 72.657 (3) | — | 73.956 | 2 |
| 5 | rupiah | 70.895 (5) | 67.600 (3) | — | — | — | 69.248 | 2 |
| 6 | BVSLP | 60.480 (6) | 62.420 (4) | 62.000 (3) | 56.025 (4) | 51.370 (3) | 58.459 | 5 |
| 7 | paramanandaAI | 55.645 (7) | — | — | — | — | 55.645 | 1 |
| 8 | SubVision | 49.775 (8) | — | — | — | — | 49.775 | 1 |

Table 4: Final mean scores with within-language ranks in parentheses. Macro-averages weight each submitted language equally; $N_L$ is the number of submitted languages. Higher is better. LensLinguals/Thai and ReopenAI/zh-TW each have 99 scored videos; all other submitted combinations have 100. Overall scores compare different language subsets and do not measure multilingual breadth.

together with video-level memory for characters, terminology, and narrative state.

### 6.2 Candidate diversity and constrained selection are effective

Four of the five highest-ranked systems used explicit candidate search or selection. ReopenAI generated candidates from two models and two seeds. laniqo used 25 candidates and multi-objective reranking. AuditTranslate used best-of-three generation with a critic and targeted retranslation. rupiah used multi-temperature generation and QE reranking.

Candidate generation reduces dependence on a single stochastic output, but only when candidates are meaningfully different and the selector is reliable. Quality-aware decoding provides a related framework for using learned evaluation signals in candidate reranking (Fernandes et al., 2022); this does not imply that the submitted systems used minimum Bayes risk decoding. Two design choices appear particularly useful. First, selection can be constrained so that it cannot invent an unseen translation, as in ReopenAI. Second, a critic can request new translations from a translation-specialized model rather than directly rewriting Chinese content, as in AuditTranslate. Both approaches reduce the risk that the quality-control stage introduces a new error.

### 6.3 Translation and criticism benefit from role specialization

Translation-specialized models and general instruction models are trained for different objectives. HyMT2 targets multilingual translation and translation instruction following (Zheng et al., 2026), whereas Gemma 4 includes general instruction-following and reasoning capabilities (Gemma Team, 2026). These reports motivate, but do not experimentally establish, the relative advantage of either model for the translator or critic role in this task. AuditTranslate explicitly separated these roles, while ReopenAI combined both models for generation but restricted Gemma's final decision to candidate selection.

The broader design hypothesis is that model composition should consider functional specialization rather than model count alone. Whether a compact translator–critic pipeline is more reliable than an unconstrained single-model pipeline requires a controlled comparison; the submitted systems do not isolate this effect.

### 6.4 Deterministic control is important for subtitle production

Names, titles, and terminology must remain stable across an episode. LensLinguals and rupiah generated glossaries; AuditTranslate used persistent name memory and a file-level normalization pass; BVSLP maintained a dynamic terminology memory. These components target errors that are individually small but accumulate across a video and directly affect coherence.

Likewise, cue IDs, timestamps, empty outputs, target-language leakage, line length, and SRT serialization are deterministic properties. The strongest pipelines generally delegated ambiguous semantic decisions to models and deterministic constraints to code. This division improves reproducibility and prevents a language model from damaging already correct structure.

### 6.5 Hy-MT is a strong base, but orchestration determines the ceiling

Six teams used Hy-MT. ReopenAI, LensLinguals, and AuditTranslate occupied the top three positions in English and all used Hy-MT2-7B. rupiah also achieved competitive results in Indonesian. These outcomes support Hy-MT2-7B as a strong compact translation base.

However, using the same model family did not guarantee high performance. SubVision and paramanandaAI used Hy-MT2-1.8B with QLoRA but ranked below systems that combined stronger base models with contextual inference and quality control. The comparison suggests that the base model determines a substantial part of translation quality, while context construction, candidate search, selection, terminology consistency, and post-processing determine the system ceiling.

### 6.6 Remaining challenges

**Cross-cue reference resolution.** Chinese frequently omits subjects and uses relationship-dependent forms of address. Local windows help but cannot always recover long-distance narrative information. Full-video context increases computational cost and may dilute attention. Structured character memory and dialogue-state tracking remain promising directions.

**Cultural and register adaptation.** Historical titles, kinship terms, online slang, humor, and politeness systems require target-language-specific decisions. Literal fidelity is insufficient when the target language expresses social hierarchy or gender differently. These phenomena also require language-specific evaluation guidelines.

**Brevity versus semantic completeness.** Subtitle output must fit time and screen constraints, but aggressive compression can remove plot-critical information. CPS, CPL, and character limits are useful operational checks, yet they should be optimized jointly with meaning preservation rather than applied as blind truncation rules; earlier subtitle MT work likewise models duration and length constraints jointly with translation and segmentation (Matusov et al., 2019).

**Multilingual evaluation calibration.** The systematic correction patterns for Indonesian and Malay show that one judge and one general rubric may not be calibrated uniformly across languages. Target-language experts, language-specific prompts, multiple independent judges, and explicit calibration sets should be considered for future editions.

**Judge reliability and evidence alignment.** The automatic assessments sometimes contained mismatched cue numbers, duplicate deductions, incorrect severity, and inconsistent arithmetic. Repeated scoring, code-based score recomputation, and human correction reduced these errors. Future evaluations could add judge agreement statistics, blinded duplicate review, and targeted comparison with reference-based metrics.

## 7 Conclusions

The WMT26 Video Subtitle Translation shared task evaluated eight teams across five directions from Simplified Chinese. The evaluation combined repeated LLM-based LQA assessment with human verification, producing final scores for 2,198 unique team–language–video units. ReopenAI achieved the highest macro-average and ranked first in all five language directions, while laniqo ranked second overall.

The system comparison highlights several promising design patterns associated with stronger results: context-aware prompting, diverse candidate generation, constrained candidate selection, translator–critic role separation, terminology and character memory, and deterministic subtitle validation. These observational comparisons motivate studying fine-tuning together with inference-time context and quality control, but do not isolate their contributions from differences in base models or model sizes.

The evaluation process was broadly stable at the aggregate level, but human reviewers changed 15.30% of the verified scores and exposed language-specific calibration effects. Human verification therefore remains important when LLM-as-a-Judge scores are used for fine-grained system comparison. Future task iterations should strengthen target-language calibration, collect independent human judgments on selected difficult cases, and release structured error annotations to support research on discourse, style, terminology, and subtitle-specific constraints.

## Limitations

This analysis has several limitations. First, the automatic evaluation was reference-free and therefore depended on the capabilities and biases of a single judge model and its prompts. Second, the human

stage verified the automatic assessments rather than independently re-annotating every translation; it may therefore inherit the framing of the automatic rubric. Third, 146 unique units did not contain an extractable human-corrected score and retained their automatic scores.

Fourth, language coverage was uneven. Some overall scores were based on one language, whereas others represented five-language systems. Macro-averaging treats submitted languages equally but does not measure breadth. Fifth, system descriptions varied in detail. SubVision did not provide a standalone system paper in the available directory, so its description was reconstructed from its training notebook. Finally, the current analysis reports means and rank order but does not include confidence intervals or paired significance tests. Bootstrap resampling is an established approach to MT evaluation (Koehn, 2004). Future work should apply paired resampling or non-parametric tests when sufficiently aligned human judgments are available, following the statistical ranking practice used in WMT findings reports (Kocmi et al., 2025).

## Ethical Considerations

The shared-task data and outputs may contain fictional violence, insults, sensitive dialogue, or culturally specific language. Automatic content filters can fail on such material and may introduce systematic missingness. Evaluators should be informed about potentially sensitive content and should not be required to review harmful material without appropriate safeguards.

The evaluation records should avoid storing personal information about reviewers. System outputs and judgments should be released only under the applicable data and task licenses. LLM-based assessment can encode language and cultural biases. Separately, presentation-related biases have been documented in LLM judges (Zheng et al., 2023). Consequently, final interpretations should not treat automatic scores as an infallible measure of linguistic quality, particularly for lower-resource languages and culture-specific expressions.

## Abstract

We present the Findings of the WMT 2026 Shared Task on Multitask LLMs with Limited Resources. This year, we extended the Shared Task to jointly model five diverse NLP tasks, Machine Translation (MT) for five language pairs (eight directions), Question Answering (QA), Spell Checking (SC), Grammar Checking (GC), and Mathematical Reasoning (MR), for two language tracks: Ukrainian and Sorbian (grouping Upper and Lower Sorbian). As the Shared Task is focused on low-resource conditions, the model is restricted to Qwen3.5-2B to remain below the 3B-parameter threshold.

In total, six teams participated across the two language tracks: two in the Ukrainian and four in the Sorbian track. No team participated in both language tracks. All systems have been uploaded to HuggingFace by the participants. Despite our strict restrictions on model and dataset availability, systems were diverse in the resources they used as well as their training and inference strategies. The submitted systems show that a single small model can handle all five tasks, with clear difficulty shown for the challenging MR only.

## 1 Introduction

Modern Large Language Models (LLMs) have made significant progress in the diversity of tasks they are able to address, but the focus of this progress has been on English and a small number of high-resource languages, where large amounts of data are available. By contrast, performance in lower-resource languages often lags behind or is simply unknown due to a lack of targeted evaluation (Robinson et al., 2023; Ahuja et al., 2023; Dementieva et al., 2026). Additionally, LLMs with many billions of parameters can be difficult to train and inference for members of small language communities, since such efforts typically require significant compute resources.

The challenge for participants in this shared task is to build a model under low-resource conditions to jointly optimise multiple, diverse Natural Language Processing (NLP) tasks. In comparison to last year's edition of this Shared Task (Okabe et al., 2025), we add three new tasks of varying difficulty: Spell Checking (SC), Grammar Checking (GC), and Mathematical Reasoning (MR). Machine Translation (MT) and Question Answering (QA) were already present in the previous year. Our goal is to encourage the development of stronger models in resource-constrained settings, to provide a structured evaluation of these models, and to study potential synergy or interference effects between the tasks. We constrain submissions to a single base model with 2B total parameters (Qwen3.5-2B).

Several other Shared Tasks provide MT test sets for other low-resource languages or language families, such as Robinson et al. (2025) or Pakray et al. (2025). The Creole MT task additionally solicits data submissions (Robinson et al., 2025). This suggests an ongoing need for low-resource language evaluation and development in MT. Most similar to our Shared Task, the Multilingual Instruction Shared Task (Kocmi et al., 2025a) evaluates on a selection of target tasks in multiple languages, but allows larger models and, this year, leaves out MT evaluation. Meanwhile, the Model Compression task (Gaido et al., 2025) also aims to bring strong performance in compute-constrained settings, but focuses only on the compression approach, evaluating on the General MT test sets.

Our main questions in this shared task are as follows: (i) To what extent can the model handle the five diverse tasks? (ii) Does training for all tasks require dedicated data or training strategies? (iii) How do models based on the more recent but smaller Qwen3.5-2B perform compared to last year?

Although the shared task had strict model and data requirements, this year's submissions varied

*Proceedings of the Eleventh Conference on Machine Translation*, pages 1180–1202
October 28-29, 2026 ©2026 Association for Computational Linguistics

in the resources used, approaches, and training settings. As we released only development and test datasets for the three new tasks (SC, GC, and MR), participants relied on existing related datasets (e.g., for Ukrainian GC), translation of the task-specific data (for MR), or synthetically generated corpora (e.g., for SC). On the training side, we observe that several systems adopt strategies to handle the five tasks without catastrophic forgetting or to preserve capabilities for a subset of tasks. During inference, some participants used a dedicated decoding approach per task. Finally, this year's base model is a reasoning model, but not all participants enabled the 'thinking' mode of the model. Overall, the submitted systems outperformed the zero-shot baseline (Qwen3.5-2B) on the five tasks in most cases, except for MR, which remains a challenge.

The rest of this article is structured as follows: Section 2 describes the target languages, tasks, and restrictions; Section 3 details the released datasets and their evaluation settings; Section 4 relays the submitting teams' system descriptions. We report test set results in Section 5 and additional analyses in Section 6.

## 2 Shared task description

### 2.1 Three languages

Following the WMT 2025 Shared Task on LLMs with Limited Resources for Slavic Languages (Okabe et al., 2025), we continue to focus on the same three languages: the mid-resource Ukrainian and the low-resource Upper Sorbian and Lower Sorbian. In this year's edition, we split the three languages into two language tracks: the Ukrainian and the Sorbian tracks. This choice stems from the proximity of the two Sorbian languages, as well as the fact that last year's participants all submitted a joint system for both languages.

Upper Sorbian (ISO code: `hsb`; Glottocode:[1] `uppe1395`) and Lower Sorbian (`dsb`; `lowe1385`) are minority languages spoken in Germany's federal states of Saxony and Brandenburg, with 30k and 7k native speakers, respectively. There is an active language community working on the preservation of these languages, notably the WITAJ-Sprachzentrum[2] (WITAJ Language Center), which also provided parts of the data used in this and previous shared tasks (Fraser, 2020; Libovický and Fraser, 2021; Weller-Di Marco and Fraser, 2022; Okabe et al., 2025). Nevertheless, the amount of available data for both Sorbian languages still remains limited.

By comparison, Ukrainian (`ukr`; `ukra1253`), spoken by approximately 40 million L1 speakers worldwide, is considered a mid-resource language in NLP. Several language-specific pre-training corpora (e.g., Chaplynskyi, 2023) and LLMs (Yukhymenko et al., 2025) are available.

### 2.2 Five tasks

This year's edition of the shared task added three additional tasks, for a total of five tasks to be solved by a single model. In addition to **Machine Translation (MT)** and **Question Answering (QA)**, which follow last year's shared task setting, we considered **Spell Checking (SC)** and **Grammar Checking (GC)**, which both test aspects of linguistic proficiency. Both also aim to reflect an actual use case from the language community, including language learners. Finally, we deliberately included a very challenging task with **Mathematical Reasoning (MR)**, thereby encouraging the use of the baseline model's reasoning abilities. Each task is represented by one or more sub-tasks.

### 2.3 Model and restrictions

We required participants to submit outputs for all five tasks, including all sub-tasks, in their language track with a single model. Regarding the training data, the only restriction was that all data must be publicly available for reproducibility.

The base model for all participants was set to **Qwen3.5-2B** (Qwen Team, 2026) for a fair comparison across submissions and to remain below the 3B-parameter threshold. This model is the closest successor to Qwen2.5-3B (Qwen Team et al., 2025), which was the base model in last year's edition. Due to timing constraints, we did not run a full comparison study on the development sets to select the model. Still, we considered other models such as `LiquidAI/LFM2.5-1.2B-Thinking` (Liquid AI, 2026), Qwen3-1.7B (Yang et al., 2025), and `Ministral-3-3B-Reasoning-2512` (Liu et al., 2026) in preliminary MT experiments, where they empirically underperformed our chosen baseline model. We also inferenced `tencent/HY-MT1.5-1.8B` (Zheng et al., 2025) on the Ukrainian track development sets, but found it coped poorly with more diverse prompts and tasks.

The Qwen3.5 model series is trained to support both an instruction mode and a 'thinking' mode,

[1] https://glottolog.org

[2] https://www.witaj-sprachzentrum.de

in which the model produces additional tokens at inference time before answering. However, the developers note that the small 2B model has a greater tendency to enter decoding loops during 'thinking'. They therefore have it default to instruction mode. In our zero-shot baseline, we decided *against* enabling this reasoning mode, but participants were free to do so. Regardless, we noticed that the model would still produce reasoning tokens before committing to an answer.

## 3 Datasets

We provide the training, development, and unlabelled test data on our GitHub repository.[3] The licence for each material is detailed in the repository and differs per task within a language track. We note that we only release development and test sets for the three new tasks.

### 3.1 Machine Translation

**For the Ukrainian track** We retest on the same dataset as last year's edition. This dataset was aligned with the General MT task at WMT2025 (Kocmi et al., 2025b) and proved to be very challenging for our resource-constrained setting last year. The test set for Ukrainian includes two translation directions: en→uk and cs→uk. Table 1 reports the four released dataset sizes. This task features two sub-tasks. We note that the test set contains paragraphs (in contrast to the dev sets with sentences).

| lang. pair | cs→uk | en→uk |
|---|---|---|
| dev | 6,263 | 5,108 |
| test | 230 | 87 |

Table 1: Number of translation instances for the **Ukrainian MT** task (same sets as in our 2025 edition).

**For the Sorbian track** As in previous editions, the WITAJ-Sprachzentrum provided new training (monolingual and parallel), development, and test datasets. Further, we consider additional language pairs, for a total of six translation directions: de→hsb and de→dsb as in last year's task, their reverse directions hsb→de and dsb→de, as well as translation between the two Sorbian languages: hsb→dsb and dsb→hsb. Regarding test datasets, we use the 2025 Shared Task edition split for de→hsb and de→dsb and add the smaller but newly provided splits. For the four other directions, the test sets are new and do not overlap.

In addition to providing new test data, we also retest on last year's machine translation test sets for comparison. Unfortunately, a subset (777 sentences) of last year's de→dsb test set was accidentally included in this year's official training data, making this specific comparison less valuable. In our final scores, we therefore evaluate the sentences *without* the overlap for a fair assessment. The new test sets were not affected by this issue.

Table 2 reports the number of sentences in all the released sets for the MT task of the Sorbian track. This task has six sub-tasks.

| | Upper Sorbian (hsb) | | | | Lower Sorbian (dsb) | |
|---|---|---|---|---|---|---|
| mono. | 512,671 | | | | 38,028 | |
| | de–hsb | | de–dsb | | hsb–dsb | |
| | → | ← | → | ← | → | ← |
| train | 23,116 | | 30,560 | | 67,845 | |
| dev | 4,000 | | 4,000 | | 4,000 | |
| test | 4,822 | 4,000 | 5,352* | 4,000 | 4,000 | 4,000 |

Table 2: Number of sentences in this year's released monolingual and parallel data for both Upper and Lower Sorbian. * We report the full test dataset size for de→dsb; removing the overlapping sentence pairs leads to the 4,575 sentences used for our final evaluation.

### 3.2 Question Answering

**For the Ukrainian track** As in the previous edition of our shared task, we use the UNLP2024 dataset (Romanyshyn et al., 2024), focusing exclusively on multiple-choice questions. The dataset contains machine-readable questions and answers from Ukraine's standardised university admission examination (ZNO), covering exam materials from 2006 to 2023 in two subjects: History of Ukraine and Ukrainian Language and Literature.

This year, we additionally include the Ukrainian MMLU dataset introduced by Yukhymenko et al. (2026). It was constructed through rigorously evaluated automatic translation of the original MMLU dataset (Hendrycks et al., 2021a), which covers 57 tasks spanning domains such as elementary mathematics, history, computer science, and law. Achieving high performance on MMLU, therefore, requires models to demonstrate broad world knowledge and strong problem-solving abilities.

Table 3 summarises the splits of the two datasets for the Ukrainian Question Answering task. This

[3] https://github.com/TUM-NLP/llms-limited-resources2026

task has two sub-tasks (ZNO and MMLU).

| set | train | dev | test |
|---|---|---|---|
| ZNO | 2,450 | 613 | 751 |
| MMLU | 1,531 | 285 | 14,042 |

Table 3: Number of questions for the two sub-tasks of **Ukrainian QA**. The ZNO dataset was also used in the 2025 edition.

**For the Sorbian track** We use the same QA data for both Sorbian languages as in last year's edition. It is based on actual questions from language certificates with 5 proficiency levels (A1, A2, B1, B2, and C1; from beginner to advanced) measured according to the CEFR scheme. The dataset was shown to be hard for intermediate and advanced levels due to its variety of tasks (e.g., reading comprehension of long texts, grammar questions) and of formatting (number of answers ranging from 2 to 16).

Table 4 presents the number of questions for the Sorbian QA track. There are two sub-tasks for this task in the Sorbian track (hsb and dsb). For the development phase, we only released questions from the A1 to B2 levels, while for the test phase, we additionally feature harder C1-level questions.

| split | lang | A1 | A2 | B1 | B2 | C1 | total |
|---|---|---|---|---|---|---|---|
| dev | hsb | 30 | 28 | 44 | 56 | 0 | 158 |
| dev | dsb | 30 | 28 | 44 | 56 | 0 | 158 |
| test | hsb | 30 | 28 | 44 | 56 | 52 | 210 |
| test | dsb | 29 | 28 | 44 | 56 | 48 | 205 |

Table 4: Number of questions in the **Sorbian QA** datasets per language level.

We also have a hidden QA dataset of 500 questions. Due to logistical constraints, not all systems could be evaluated, leaving this assessment for future editions.

### 3.3 Spell Checking (both tracks)

The spell checking task aims to assess whether models can identify and correct a character-level error in a sentence. It mainly aims to represent typos rather than grammatical errors, which are tested in a dedicated task (§3.4).

We standardise the task as follows: given a sentence that may contain an error in one of its words, the model must predict which word is wrong (detection) and correct it (correction). Figure 1 illustrates the task for both wrong and correct sentences.

| | | |
|---|---|---|
| **wrong input**: | | 30.000 opozicionelnych bcuhu zajeći |
| **outputs** | detection: | bcuhu |
| | correction: | buchu |
| **correct** input | | 30.000 opozicionelnych buchu zajeći |
| **outputs** | detection: | CORRECT |
| | correction: | CORRECT |

Figure 1: Example of input and outputs for the **spell-checking** task in Upper Sorbian (in English, '30,000 opposition members were arrested'). The wrong instance shows a character swapping transformation.

We created two *evaluation* datasets of 2,000 sentences each for the development and test splits of the spell-checking task. Both were balanced, where half of the sentences were correct, with no errors to spot or change, and half were synthetically corrupted, with a single modified word.

**Sentence source** We use new sentences from the parallel splits originally provided for MT by the WITAJ-Sprachzentrum for Upper and Lower Sorbian. They do not overlap with the (previously or newly) released MT datasets (§3.1). For Ukrainian, we combined formal data from Dementieva et al. (2025),[4] court decisions,[5] and job descriptions (Drushchak and Romanyshyn, 2024).[6] Table 5 displays the dataset statistics for the spell-checking task. The Ukrainian track features one sub-task, while the Sorbian track has two.

We consider four types of modifications: character deletion, insertion, substitution, and swapping. We further categorise substitutions into *random*, where any character can replace another, and *subtle* to replicate errors which seem more 'natural', such as phonetically similar character pairs. All errors affect at most two characters. For each of the five modification categories, we assigned 20% of the corrupted sentences (i.e., 200 sentences) for equal representation.

### 3.4 Grammar Checking (both tracks)

The goal of this task is to identify a grammatical mistake in a sentence, with one incorrect word per corrupted sentence. We created development and

| | train | dev | test |
|---|---|---|---|
| uk, hsb, dsb | - | 2,000 | 2,000 |

Table 5: Number of **Spell Checking** sentences per language.

test sets with 2,000 sentences (Ukrainian, Upper Sorbian) and 1,250 (dev) and 1,726 (test) for Lower Sorbian. Each dataset is balanced with 50% corrupted and 50% correct sentences. In the corrupted sentences, one word was replaced with a different inflected form of the same lemma. With the corrupted words being valid word forms, this task aims at evaluating the ability to rate a word's correctness in a sentence context, rather than identifying incorrect spelling. In addition to identifying the incorrect word, the model also needed to predict the correct word.

The words are corrupted at the level of grammatical case, for example, by replacing a word form in dative case (Dat) by a word form of the same lemma in accusative case (Acc); all other features (such as number (singular (Sg) or plural (Pl)) and gender) remain the same. As a basis for selecting and replacing words, we used UniMorph[7] (Batsuren et al., 2022) for Ukrainian and Lower Sorbian and soblexx[8] for Upper Sorbian, where no UniMorph data is available. Both resources provide inflected word forms and their morphological features paired with the lemma.

Since many word forms can have different analyses, depending on the context, we need to ensure that the generated corrupted sentences are indeed grammatically incorrect. For this reason, we restrict words to be corrupted to those with only one morphological analysis. Corrupted words can be nouns and adjectives: for nouns, we change grammatical case in order to create a mismatch to the expected realisation and potential agreement errors. Additionally, we allow for replacing number and gender in adjectives to create agreement errors.

We also made sure that the inflected form selected as replacement in the corrupted sentence does not share features with the original word form, which could lead to an accidentally correct sentence with a different meaning. For example, if for an original noun (Acc.Sg), a selected form (Dat.Sg) can also have the analysis Acc.Pl, the generated corruption might still be grammatically correct (assuming there are no further words in the phrase resulting in an agreement error), but with a change in meaning (Pl vs. Sg).

Finally, we used `gemini-3-flash-preview` to check the generated datasets by asking the model whether the sentence is correct or contains an error, keeping only those sentences in the test set where no errors were detected for presumably correct sentences, and the target word was identified as incorrect in corrupted sentences.

We sample sentences from the same dataset as in the spell-checking task. We note that the sentences do not overlap between the two tasks. Table 6 summarises the three datasets for the grammar checking task. Here also, the Ukrainian track features one sub-task, while the Sorbian track has two. Figure 2 illustrates the task, while Figure 9 in Appendix B shows the details for an example instance.

| | | |
|---|---|---|
| **wrong input**: | | Wusypaj pěsk z crjejam! |
| **outputs** | detection: | crjejam |
| | correction: | crjejow |
| **correct input**: | | Wusypaj pěsk z crjejow! |
| **outputs** | detection: | CORRECT |
| | correction: | CORRECT |

Figure 2: Example of input and outputs for the **grammar-checking** task in Lower Sorbian (in English, 'Shake the sand out of your shoes!'). We show the same sentence in two versions here for illustration purposes; no sentence is 'duplicated' in the released sets.

| lang | uk | hsb | dsb |
|---|---|---|---|
| train | - | - | - |
| dev | 2,000 | 2,000 | 1,250 |
| test | 2,000 | 2,000 | 1,726 |

Table 6: Number of **Grammar Checking** sentences per language.

### 3.5 Mathematical Reasoning (both tracks)

**Input**: James decides to run 3 sprints 3 times a week. He runs 60 meters each sprint. How many total meters does he run a week?
**Output**: 540

Figure 3: Example of input and output for the **maths reasoning** task. The example is in English and is drawn from PolyMath (Wang et al., 2025), the original source for PluraMath (Dementieva et al., 2026).

[7] https://unimorph.github.io/
[8] https://soblexx.de/

The fifth and last task is mathematical reasoning, where a mathematical exercise has to be solved, as illustrated in Figure 3. For this task, we use the corresponding set of 250 instances per language from PluraMath (Dementieva et al., 2026). PluraMath features an extended version of PolyMath (Wang et al., 2025) for 18 more languages—including Ukrainian, Upper Sorbian, and Lower Sorbian—and consists of four task difficulty levels: low, medium, high, and top.

The extension to new languages was obtained through a human-in-the-loop pipeline. First, initial translations were generated using the best-performing automatic translation system for each language. Then, one or two native speakers reviewed the translated data and refined the translations. This process helps ensure the high quality of the PolyMath dataset extension.

Given that the high and top levels contain challenging Olympiad-level problems, we focus on the two lowest levels, low and medium, under our constrained shared task setup. For the development phase, we release the first 12 instances of both levels (i.e., 24 instances in total). For the test set, all 250 exercises per language are released. We explicitly asked participants not to use the overlapping development set for training, nor the original PolyMath dataset in any existing language.

Table 7 summarises statistics of the datasets released for the MR task. The Ukrainian track features one sub-task, while the Sorbian track has two.

| | train | dev | test |
|---|---|---|---|
| uk, hsb, dsb | - | 24* | 250 |

Table 7: Number of **Maths Reasoning** instances per language. * the development set is *included* in the final test set.

## 4 System descriptions

Three teams submitted to the Ukrainian track and four submitted to the Sorbian track. One team submitted outputs to the Ukrainian track but did not submit a system description. We report their results for reference purposes but do not consider them as shared task participants. We note that two teams (Zolint, TUM-HN) feature a TUM affiliation, one of which includes a Shared Task organiser as an advisor. These teams did not receive any additional information or special treatment.

Participants were asked to submit their model outputs on OCELoT for the leaderboard and to publish their models, preferably publicly on HuggingFace. All teams which sent a system description followed this recommendation. Since a team is allowed to submit multiple times, we only evaluate their selected *primary* submission. Below, we report the short descriptions of their system that each participant was asked to provide, with minor edits for layout and flow purposes.

### 4.1 Zero-shot baseline (TUM Organisers)

We evaluate the Qwen3.5-2B baseline model in a zero-shot fashion, without using explicit reasoning tokens for both tracks. Question answering is inferenced in a forced-decoding manner, where only the allowable answer tokens are considered, while all other tasks are inferenced through open-ended decoding. For the generative tasks, we set our decoding parameters according to the recommendations of the model developer and apply the chat template, with the model's reasoning token budget set to zero. The maximum token budget depends on the task, with just 64 tokens for GC and SC compared to 512 tokens for MR. Our baseline prompts are listed in Appendix A. We implemented all tasks in the LLM Evaluation Harness (Gao et al., 2024) and provided this code to participants for reference, along with a script to convert outputs from the framework to the final submission format.

### 4.2 Ukrainian track

**Zolint (UTokyo & TUM) (Yang et al., 2026)** This team submitted a LoRA-based multitask fine-tuned Qwen3.5-2B-Instruct model for the WMT 2026 Shared Task on LLMs with Limited Resources.[9] The system jointly addresses English–Ukrainian and Czech–Ukrainian machine translation, question answering, spelling correction, grammar correction, and mathematical reasoning. Training data include the official shared-task resources together with publicly available datasets such as WMT 2025 parallel corpora, NLLB (Team et al., 2022), UA-GEC (Syvokon et al., 2023), GSM8K (Cobbe et al., 2021), MATH (Hendrycks et al., 2021b), and additional synthetic data for spelling correction and question answering. They adopt a two-stage instruction-tuning strategy: the first stage focuses on translation and correction tasks to strengthen Ukrainian generation, while the

Table 8: Summary of the six **primary** submissions to our shared task: 2 systems for the Ukrainian track and 4 for the Sorbian track. Information is compiled based on their respective system description. † We group here all previous datasets released between 2020 and 2022; however, not all teams have used the whole set. * We denote the following items used as linguistic resources for GC: a dictionary, a reference corpus, or a morphological dataset.

second stage introduces reasoning and question answering with replayed first-stage data to mitigate catastrophic forgetting. All tasks are unified into an instruction-following format and optimized using a shared LoRA adapter.

**TUM-HN (Temesgen et al., 2026)** This team fine-tuned the Qwen3.5-2B model for Ukrainian in a multitask learning setting, covering Machine Translation (MT), Question Answering (QA), Spell Checking (SC), Grammar Checking (GC), and Maths Reasoning (MR).[10] For MT, they sourced English–Ukrainian and Czech–Ukrainian data from Tatoeba (Tiedemann, 2020). For QA, they used data from ZNO (Romanyshyn et al., 2024), MMLU (Yukhymenko et al., 2026), and UA-SQuAD (Ivanyuk-Skulskiy et al., 2021). For MR, they used the OlympiadBench (He et al., 2024) dataset, restricting it to the mathematics and physics domains, and they also included the MathMist dataset (E Sobhani et al., 2026). For SC and GC, they used the Grammatical Error Correction and Fluency Corpus for the Ukrainian Language (UA-GEC; Syvokon et al., 2023) dataset. All datasets were in Ukrainian, except for the MR datasets, which were available only in English.

All datasets were reformatted as chat-style instruction pairs. The model was first fine-tuned for 3 epochs, then further fine-tuned for up to 10 additional epochs with early stopping (patience of 3). Loss was computed only on the assistant responses. They inferenced the model in the zero-shot setting over the test set.

### 4.3 Sorbian track

**HeyBusan (Khasykov, 2026)** This team performed a full-parameter fine-tune of Qwen3.5-2B for all five Sorbian-track tasks,[11] merged 0.9/0.1 in weight space with the base model to restore maths/QA ability lost to multitask Supervised Fine-Tuning (SFT).

[10] https://huggingface.co/Tsedeniya/qwen3.5-2B-sft-wmt2026_CFT

[11] https://huggingface.co/mkhasykov/qwen3.5-2b-wmt26-sorbian

Training mixes the official task data (including a final sealed pass over the full dev sets; MR dev never used for PolyMath compliance) with decontaminated WMT20–22 de–hsb/de–dsb/hsb–dsb corpora, FineWeb-2 Sorbian monolingual text, a public instruction mix as forgetting control, lexicon-derived synthetic spell/grammar-checking data (soblex/dolnoserbski full-form lexicons: paradigm-swap GC errors, spell-checker-rejected SC corruptions, 50% correct hard negatives), and STaR-style (Zelikman et al., 2022) verified German reasoning chains generated by their own model on German translations of GSM8K-train.

The team relies on per-task decoding: with beam-4 for MT, self-consistency voting for SC and GC (maj@16, with votes filtered by the full-form lexicons: corrections that are not attested word forms are dropped) and MR (16 samples per view over the original question and its German translation), and for QA log-likelihood answer selection averaged over all cyclic rotations of the answer-option order (position debias).

**HITSZ (Zhang et al., 2026)** Their system is based on Qwen3.5-2B.[12] They first performed mixed continual pre-training on Upper Sorbian, Lower Sorbian, German, and English monolingual and parallel corpora, followed by full-parameter multitask supervised fine-tuning for machine translation, question answering, spelling correction, grammar correction, and mathematical reasoning. Task-specific prompts were aligned with the official evaluation format, and native thinking mode was used only for mathematical reasoning.

**HSE (Diskin, 2026)** This team submitted a single Sorbian multitask system based on Qwen/Qwen3.5-2B, adapted with an all-linear rank-16 LoRA and merged into one BF16 model for inference.[13] The model was trained with weighted token-level cross-entropy on a 278,488-example mixture covering machine translation, question answering, spelling correction, grammar correction, and mathematical reasoning. The mixture contains 234,594 examples from the released WMT2026 Sorbian parallel MT data; 15,000 synthetic spelling-correction, 1,800 controlled grammar-correction, and 20,000 multiple-choice QA proxy examples derived exclusively from the released MT training corpus; and 7,094 answer-only examples from the public English GSM8K training split. Source-group-disjoint splits and collision filtering were used to prevent overlap with official development and test data. After the initial training, the team applied one conservative optimizer-reset continuation epoch on the same mixture at a lower learning rate and selected checkpoint 8703 using a pre-registered multitask rule on the official Sorbian development tasks. The same merged checkpoint, the unchanged official prompts, and converter were used for all five OCELoT files.

**LT3 (Moerman and Tezcan, 2026)** A single QLoRA-tuned Qwen 3.5 2B serves all five Sorbian tasks.[14] Training combines the organiser data with public German–Sorbian parallel corpora (WMT20-22), back-translation of monolingual Sorbian with their own model, and synthetic task data. This synthetic data covers typo injection for spell-checking, morphological paradigm-swap corruptions (soblex and dsb-spell) for grammar-checking, machine-translated public maths seeds (GSM8K and MATH, with PolyMath excluded) for maths reasoning, and cloze-style QA. The system uses retrieval-augmented inference. Half of the training examples carry a fuzzy-retrieved exemplar, and at inference, MT retrieves three exemplars from a real plus back-translated translation memory that is fully enumerated, hashed, and deduplicated against all test sources, with no web access. Grammar-checking consults corpus bigram-attestation statistics additionally from the same enumerated corpora. The frozen model plays two roles. For MT and MR, a generator produces the output text. For QA, SC, and GC, it is a scorer that ranks candidate answers or corrections by the likelihood it assigns them. On top of the frozen model, several inference strategies are employed. Grammar gap-fill QA items are answered by scoring each option in place with the model's own log-likelihood, and shared option banks are solved as a global assignment. Grammar-checking fuses the model's detection with a full-paradigm candidate scorer and a corpus bigram-attestation witness. Spell-checking constrains corrections to dictionary neighbourhoods and adds a frequency-guarded diacritic detector. Maths uses a retry-on-empty ladder with answer-notation formatting. The primary system folds the development sets into training.

### 4.4 Summary

Table 8 summarises the main characteristics of the six primary submissions. On the resource side, due to data scarcity or the absence of released dedicated training data for some tasks, external corpora were used, and synthetic data were generated. Lexical resources were also used to help SC and GC. For MR, existing corpora in high-resource languages (such as English) were used as is or translated into the target language or a relevant high-resource language (e.g., German for the Sorbian track). Participants opted for full-parameter training or parameter-efficient fine-tuning with LoRA (Hu et al., 2022) or QLoRA (Dettmers et al., 2023). Dedicated inference strategies were also used for better prediction performance. We also note that QA, SC, and GC were solved both using generation- and scoring-based approaches. Finally, not all participating teams used the 'thinking' mode of the base model.

## 5 Primary submission results

### 5.1 Evaluation method

#### 5.1.1 Task evaluation

To help participants with the evaluation of their models, we provided an evaluation tool from the lm-evaluation-harness again this year.[15]

**Machine Translation** For a unified MT evaluation, we use BLEU (Papineni et al., 2002) and chrF++ (Popović, 2015), computed with sacreBLEU (Post, 2018).[16] chrF++ remains our main MT metric for consistency across translation directions.

**Question Answering** We compute the standard accuracy for QA as in the previous edition. Since both tracks feature two sub-tasks (i.e., dataset language or sources), we give them equal weight by reporting their mean sub-task accuracy, despite the difference in size for the Ukrainian track.

**Spell Checking and Grammar Checking** We evaluate the two tasks according to two criteria: error *detection* (i.e., did the model identify the erroneous input?) and error *correction* (i.e., did the model modify the error in the correct form?). We compute the standard accuracy for both fields.

**Maths Reasoning** We evaluate the maths reasoning task using the standard exact-match accuracy. Instead of a pure string-level match, we use MathVerify[17] to handle non-identical but equivalent maths formulae (e.g., $\frac{1}{2}$ and 0.5) to have a better assessment of the models.

[15] https://github.com/TUM-NLP/llms-lim-res-eval-2026/

[16] SacreBLEU BLEU signature: `nrefs:1 | case:mixed | eff:no | tok:13a | smooth:exp | version:2.6.0`. SacreBLEU chrF++ signature: `nrefs:1 | case:mixed | eff:yes | nc:6 | nw:2 | space:no | version:2.6.0`.

#### 5.1.2 Final result computation

For each track task (e.g., Ukrainian QA) with several sub-tasks (e.g., ZNO and MMLU), we average the scores per sub-task equally. We follow last year's point system to score each participating team. We assign the maximum score (the number of evaluated systems; 4 for Ukrainian, 5 for Sorbian) to the best performing system, down to 1 point per task. The final ranking is the sum of all points. Ties between systems are allowed.

### 5.2 Ukrainian track

We summarise per-task results and the resulting points for the Ukrainian track in Table 9. Detailed results, with per-language-pair metrics for MT and the values for the wrong vs. corrected words in SC and GC, are reported in Table 18 in Appendix C.

The Zolint team won this track, reaching the best score across four of the tasks (all except QA). It also clearly outperforms the baseline overall. We observe that this system largely outperforms the others for Machine Translation. Interestingly, the baseline achieves 20 points of accuracy for MR, while the koshi and TUM-HN systems struggle with it. Finally, we note here that on the same test datasets (MT and QA-ZNO), Zolint outperforms last year's best system.

### 5.3 Sorbian track

We summarise per-task results and the resulting points for the Sorbian track in Table 10. We report detailed results in Table 19 in Appendix C with per-language scores, BLEU as an additional metric for MT, and the comparison for wrong-word and corrected-word matches in SC and GC.

For the Sorbian track, the HeyBusan and LT3 teams are tied winners, both with 22 total points. All submitted systems outperform the baseline overall, with notable improvement for the MT, SC, and GC tasks. It is worth noting that both winning systems obtain rather similar performance on all tasks except QA, despite clear differences in their systems in terms of data, training (full fine-tuning and (Q)LoRA), or inference strategies (cf. Table 8).

## 6 Complementary analyses

We perform six additional analyses to better understand the model outputs. Section 6.1 computes xCOMET (Guerreiro et al., 2024) scores for MT evaluation when the target language is supported (Ukrainian and German, in our case). Section 6.2 compares this year's Sorbian MT systems with the current state of the art and reports the results of the manual ranking of a subset of translations. Section 6.3 compiles the Sorbian QA accuracy scores per language certification level. Sections 6.4 and 6.5 analyse the accuracy distribution according to the SC modification type or part of speech for GC, respectively. Section 6.6 analyses the outputs (including reasoning traces) for MR. We also report the system rankings after statistical tests per task in Appendix D.

| Team | cs→uk | rank | en→uk | rank |
|---|---|---|---|---|
| Zolint | 21.38 | 1 | 19.42 | 1 |
| TUM-HN | 20.34 | 1 | 16.78 | 2 |
| koshi | 18.16 | 3 | 15.55 | 2 |
| baseline | 17.13 | 3 | 12.29 | 4 |

Table 11: Mean xCOMET scores for **Ukrainian MT**. The rank columns give the significance-cluster rank per direction (paired $t$-tests, $p < 0.05$).

| Team | hsb→de | rank | dsb→de | rank |
|---|---|---|---|---|
| HeyBusan | 68.78 | 1 | 60.54 | 1 |
| LT3 | 66.42 | 2 | 59.04 | 2 |
| HITSZ | 62.18 | 3 | 55.26 | 3 |
| HSE | 53.08 | 4 | 51.03 | 4 |
| baseline | 21.03 | 5 | 16.59 | 5 |

Table 12: Mean xCOMET scores for Sorbian-to-German translation (part of the **Sorbian MT** track). The rank columns give the significance-cluster rank per direction (paired $t$-tests, $p < 0.05$).

### 6.1 xCOMET for supported languages

For translation into Ukrainian (cs→uk and en→uk) and into German (hsb→de and dsb→de), we compute reference-based xCOMET (Guerreiro et al., 2024) in addition to chrF++ and BLEU. This learned metric generally correlates better with human judgements than surface-level metrics, but it does not support the two Sorbian languages. We compute per-sentence scores with xCOMET-XXL, then run bootstrap resampling and pairwise $t$-tests[18] to determine significance clusters.

Tables 11 and 12 report mean scores, along with ranks per translation direction. For the Ukrainian track, the results show that overall MT performance for the language remains relatively poor,

[18] As implemented by the COMET CLI.

with Zolint still in the lead but by less than the surface-level metrics suggest. TUM-HN pulls slightly ahead of koshi under this metric. For translation from Sorbian into German, the ranking from xCOMET-XXL agrees with the surface-level metrics. Overall quality is rated much higher here, since this dataset is comparatively simple.

## 6.2 Sorbian MT analyses

### 6.2.1 Comparison of Sorbian translation

We compare this year's participating systems with last year's winner (TartuNLP) and the Sorbian reference translator, sotra, for *all six* translation directions.

**TartuNLP** The TartuNLP system[19] (Purason and Fishel, 2025) is based on Qwen2.5 (Qwen Team et al., 2025) with 3B parameters and was officially evaluated on the test set for the two de→hsb and de→dsb directions last year. We output the translations using our evaluation harness.

**sotra** In contrast, sotra features dedicated models trained for each of the six directions. It has been developed by the WITAJ-Sprachzentrum since 2019 and is available online.[20] We report here the INT8 quantised sotra models of 56M parameters (50MB; ctranslate2).

| | de→hsb | de→dsb | hsb→de | dsb→de | hsb→dsb | dsb→hsb |
|---|---|---|---|---|---|---|
| **TartuNLP** | **83.81** | **73.29** | **76.65** | 75.64 | **85.05** | **84.91** |
| sotra | 81.96 | 72.54 | 72.70 | **78.40** | 84.33 | 84.23 |
| HeyBusan | 70.26 | 63.06 | 69.43 | 69.42 | 81.96 | 82.38 |
| LT3 | 64.55 | 58.90 | 67.19 | 66.56 | 80.12 | 80.09 |
| HITSZ | 60.04 | 52.37 | 62.42 | 60.92 | 72.35 | 70.62 |
| HSE | 56.27 | 52.72 | 52.70 | 54.61 | 77.19 | 75.50 |
| baseline | 13.67 | 10.42 | 27.05 | 23.18 | 27.10 | 28.66 |

Table 13: Comparison of Sorbian machine translation performance (chrF++) with last year's winning system (TartuNLP) and the dedicated sotra translation.

Table 13 displays the chrF++ scores for all six translation directions. First, we observe that the best system on MT from this year's edition is behind both TartuNLP's model and sotra. The gap is wider for pairs involving German than between the two Sorbian languages. Therefore, the state-of-the-art open MT system for Sorbian translation from our Shared Task series remains TartuNLP. We note that its training featured all six language directions.

[19] https://huggingface.co/tartuNLP/Qwen2.5-3B-Instruct-hsb-dsb

[20] https://sotra.app/

### 6.2.2 Manual annotation for Sorbian MT

Thanks to the WITAJ-Sprachzentrum, one native speaker manually annotated a subset of MT system outputs for each Sorbian language. Following last year's protocol, the two annotators *ranked* the translations for 60 sentences. We also focused on the outputs of the two de→hsb and de→dsb translation directions. Given the poor performance of the baseline, we only consider this year's four submitted systems (HeyBusan, HITSZ, HSE, and LT3) and last year's overall winning system, TartuNLP, for a total of five system translations per sentence. Ties were allowed in the ranking process. Further details on the annotation methodology are presented in last year's annotation explanation (Okabe et al., 2025).

Table 14 summarises the ranking of the five systems between ranks obtained through chrF++ scores and assigned by human annotators. We observe that human evaluation agrees with the automatic evaluation overall, with the TartuNLP system having the best translation among the five. This year's submissions then follow less distinctly. It is worth noting that for Lower Sorbian, MT outputs still have room for improvement, as the best translation among the five systems is sometimes ranked 2 rather than 1.

## 6.3 Detailed performance for Sorbian QA

Table 15 displays the QA accuracy score per language proficiency level in both Sorbian languages. As the test set is the same as in the 2025 edition, we additionally report the scores of the previous four participating systems: TartuNLP, SDKM (Saadi et al., 2025), the baseline Qwen2.5-3B, and NRC (Larkin et al., 2025). First, we note that this year's Qwen3.5-2B base model is comparable to last year's, with only a slight loss in accuracy.

Then, we observe that this year's best system for QA (LT3) outperforms last year's TartuNLP, setting a new state of the art for the task. The main improvement for LT3 comes from the two intermediate B levels (B1 and B2). For both Sorbian languages, it outperforms TartuNLP by at least 15 points of accuracy. Starting at the B1 level, the language certification features an additional exercise category: grammatical questions (on top of the listening and reading comprehension). Although Moerman and Tezcan (2026) have a dedicated training phase to improve grammar-checking performance, they report similar QA scores before and after it.

| | | chrF++ | | | | | human | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | rank | Tartu | HeyB. | LT3 | HITSZ | HSE | Tartu | HeyB. | LT3 | HITSZ | HSE |
| Upper Sorbian | 1st | 48 | 8 | 3 | 1 | 0 | 45 | 12 | 3 | 0 | 0 |
| | 2nd | 7 | 24 | 13 | 10 | 6 | 10 | 21 | 8 | 9 | 7 |
| | 3rd | 2 | 21 | 19 | 7 | 11 | 3 | 21 | 24 | 11 | 5 |
| | 4th | 3 | 3 | 16 | 23 | 15 | 1 | 5 | 20 | 22 | 13 |
| | 5th | 0 | 4 | 9 | 19 | 28 | 1 | 1 | 5 | 18 | 35 |
| Lower Sorbian | 1st | 41 | 9 | 5 | 0 | 5 | 27 | 8 | 2 | 3 | 0 |
| | 2nd | 6 | 20 | 15 | 7 | 12 | 21 | 19 | 14 | 1 | 4 |
| | 3rd | 4 | 23 | 15 | 8 | 10 | 7 | 20 | 28 | 10 | 9 |
| | 4th | 6 | 8 | 15 | 18 | 13 | 5 | 8 | 10 | 21 | 23 |
| | 5th | 3 | 0 | 10 | 27 | 20 | 0 | 5 | 6 | 25 | 24 |

Table 14: System rankings according to the chrF++ score and the human evaluation for 60 sentences. Tartu stands for the TartuNLP system, while HeyB. is for the HeyBusan team. For instance, the TartuNLP translations in Upper Sorbian were ranked first among the five systems for 48 sentences according to chrF++, while it was 45 times according to the human evaluation.

| model | A1 | A2 | B1 | B2 | C1 | all. |
|---|---|---|---|---|---|---|
| *Upper Sorbian* | | | | | | |
| TartuNLP | **86.67** | **82.14** | **56.82** | 37.50 | **51.92** | **58.10** |
| SDKM | 80.00 | 78.57 | **56.82** | **41.07** | 42.31 | 55.24 |
| Qwen2.5-3B | 70.00 | 57.14 | 40.91 | 26.79 | 38.46 | 42.86 |
| NRC | 50.00 | 32.14 | 22.73 | 19.64 | 30.77 | 29.05 |
| LT3 | 83.33 | 75.00 | **81.82** | **64.29** | 40.38 | **66.19** |
| HITSZ | **96.67** | 71.43 | 47.73 | 48.21 | **50.00** | 58.57 |
| HeyBusan | 93.33 | **78.57** | 43.18 | 41.07 | 44.23 | 54.76 |
| HSE | 63.33 | 64.29 | 45.45 | 30.36 | 38.46 | 44.76 |
| baseline | 60.00 | 64.29 | 40.91 | 26.79 | 38.46 | 42.38 |
| *Lower Sorbian* | | | | | | |
| TartuNLP | **89.66** | 71.43 | **56.82** | **41.07** | **50.00** | **57.56** |
| SDKM | 82.76 | 57.14 | 50.00 | 37.50 | 47.92 | 51.71 |
| Qwen2.5-3B | 65.52 | **75.00** | 43.18 | 26.79 | 41.67 | 45.85 |
| NRC | 55.17 | 42.86 | 18.18 | 26.79 | 31.25 | 32.20 |
| LT3 | **93.10** | 67.86 | **79.55** | **57.14** | 37.50 | **63.90** |
| HITSZ | **93.10** | 67.86 | 47.73 | 46.43 | 45.83 | 56.10 |
| HeyBusan | **93.10** | **75.00** | 45.45 | 46.43 | **47.92** | 57.07 |
| HSE | 65.52 | 57.14 | 47.73 | 37.50 | **47.92** | 48.78 |
| baseline | 65.52 | 50.00 | 43.18 | 33.93 | 41.67 | 44.39 |

Table 15: Accuracy on the QA datasets per language level for **Upper** and **Lower Sorbian**. The upper part of a table for a language lists the systems from the 2025 edition, while the lower part shows this year's shared task systems. Models are ordered based on their overall QA task score per year. The best score per edition and level is in **bold**, while the overall best is underlined.

We hence suppose that LT3's first multitask training step, combined with their inference strategy, was already helpful to reach such QA scores.

We also note that the other systems show a smaller but notable improvement for the B level compared to the baseline. Further understanding of the synergy between the GC task and the QA score improvement is left for future analyses. Finally, if we keep a passing accuracy of 50 for a language certification, as in last year's edition, most systems sit somewhere in the intermediate A2–B1 level, with LT3 being at B2.[21]

### 6.4 Detailed analysis for spell checking

Table 16 presents the SC detection and correction accuracy values for all participating systems and the three languages per modification type. The baseline zero-shot model performs poorly on the task. The outputs tend not to follow the formatting instructions (as seen in the differing scores between detection and correction for correct sentences), on top of failing to produce correct answers. All the submitted systems performed better due to their task-specific training. We then note that error detection remains easier than error correction overall, with notably higher accuracy values. Finally, the less naive transformations remain challenging with accuracy values below 70%, compared to the other operations. In our case, deletion focused mainly on the later part of a word (e.g., a truncation of a word), while subtle substitutions led to similar but wrong words.

### 6.5 Detailed analysis for grammar checking

Table 17 presents the GC detection and correction accuracy for all systems and languages, looking at errors introduced in nouns and adjectives separately. The baseline model performs poorly across all languages, as do the systems for Ukrainian. Notably,

[21] Actual language certifications feature more exercise types.

| team | language | correct | | deletion | | insertion | | random subst. | | subtle subst. | | swapping | |

Table 16: **Spelling** error **detection** (D) and **correction** (C) scores per team and transformation type. Cells are shaded according to the accuracy values (the darker, the better). Systems are ordered by their final ranking.

Zolint nearly always predicts no error, whereas TUM-HN always predicts an error. We attribute the poor performance on the Ukrainian task to the dataset, which contains large portions of formal and legal language, making this test set comparatively difficult.

For Sorbian, we observe better performance, potentially helped by the domain similarity between the test set and the MT training data. As for spell checking, error detection is easier than generating a correction. Between adjectives and nouns, we do not observe a clear difference, even though the HITSZ results are considerably worse for nouns than for adjectives. In contrast, both HeyBusan and LT3 show higher scores in detecting and correcting errors in nouns.

Overall, the task of grammar checking (both error detection and correction) remains challenging.

### 6.6 Inspecting MR responses

We inference the submitted models on the respective MR tasks with the evaluation harness and inspect their outputs. To get a general sense of the outputs, we manually inspect the first 15 responses per model and language and observe some patterns. As in the zero-shot baseline, the majority of submitted models attempt to reason through the maths problems even when 'thinking' mode is turned off. The exceptions are the models from HITSZ and HSE, which only output the answer format in this setting. In addition, as in the zero-shot baseline, the models from TUM-HN and Zolint frequently overran the output token budget of 512 before committing to an answer, but when inferencing the TUM-HN model with a token budget of 2048, it gave a correctly formatted answer in most of the inspected responses. The models from HeyBusan and LT3 answered within the shorter token budget much more consistently.

We further observed that the HITSZ model still only outputs the answer format when 'thinking' mode is turned on, while the HSE model displays mixed behaviour, sometimes answering directly, sometimes generating reasoning traces. The HSE and the Zolint models also sometimes entered decoding loops after answering, which, for the HSE model, seemed to become more frequent when the thinking mode was turned on. Since everything

| team | lang. | correct | | nouns | | adjectives | |
|---|---|---|---|---|---|---|---|
| | | D | C | D | C | D | C |

| HSE | hsb | 99.9 | 99.9 | 0.5 | 0.0 | 0.8 | 0.3 |
| | dsb | 99.8 | 99.8 | 0.1 | 0.0 | 0.0 | 0.0 |
| baseline | hsb | 0.3 | 0.6 | 3.6 | 0.2 | 3.4 | 0.0 |
| | dsb | 0.3 | 0.9 | 5.7 | 0.0 | 1.8 | 0.0 |

Table 17: **Grammar** error **detection** (D) and **correction** (C) scores per team and part-of-speech tag. Cells are shaded according to the accuracy values (the darker, the better). Systems are ordered by their final ranking. Note that adjectives and nouns are not equally distributed. UKR: 700 nouns, 300 adjectives; HSB: 613 nouns, 387 adjectives; DSB: 697 nouns, 166 adjectives.

but the response within the answer format tags was stripped out before evaluation, such decoding loops, or which language the model used for 'reasoning', did not have a direct effect on performance.

**Language identification** However, it is possible that the reasoning language has an indirect effect on model performance. Therefore, we run language identification with GlotLID (Kargaran et al., 2023) over the model outputs where reasoning traces were present. In the Ukrainian track, the models typically output Ukrainian (84% from the baseline, 75% and 78% from Zolint and TUM-HN), with a smaller proportion of outputs classified as English (baseline 15%, TUM-HN 21%, none from Zolint), Russian (2% from Zolint), or a wide selection of other languages. We assume that these other languages are most often spurious classifications for outputs consisting mostly of symbols.

In the Sorbian track, when models output reasoning tokens, they are most commonly in English. The baseline used English reasoning traces around 47% of the time, while HeyBusan and LT3 did so between 82% and 86% of the time, with only small variation between Upper and Lower Sorbian inputs. The baseline's reasoning traces given Upper Sorbian input were also classified as Upper Sorbian 25% of the time, with the remainder split between Polish (12%), Czech (8%), and a few other Slavic languages. For Lower Sorbian inputs, the classifier still found 14% Upper Sorbian traces, compared to 10% Lower Sorbian, and 20% Polish. This variation largely disappears in the LT3 and HeyBusan models, consistent with the described training sets. In combination with the consistent, faster answers, this likely explains the high performance of these models on Sorbian MR.

## 7 Conclusion

This edition of the Shared Task extended the number of tasks to five, compared to the previous edition, by covering: Machine Translation, Question Answering, Spell Checking, Grammar Checking, and Maths Reasoning. The base model was also updated to Qwen3.5-2B, a more recent version but with fewer parameters (compared to Qwen2.5-3B).

First, we observe that the participating systems outperformed the baseline for most tasks overall, sometimes by a clear margin for the better systems. This is naturally due to task-specific training, especially for tasks with specific formatting (SC and GC). A single system to handle the five tasks for Ukrainian, Upper and Lower Sorbian is hence possible.

For Sorbian MT, we observed generally higher quality than for Ukrainian MT, as Sorbian training and test data are from similar domains, while the Ukrainian test set contains paragraphs which proved to be a hurdle for the models. Moreover, for Sorbian, the ranking with xCOMET-XXL agrees with the surface-level metric (chrF++), whereas for Ukrainian, the first-ranked system's lead was considerably reduced under xCOMET. Furthermore, the small-scale manual evaluation for the two Sorbian languages confirmed the human agreement with chrF++ for translation rankings. A comparison of translation quality for Sorbian with last year's winning team (TartuNLP) showed that this year's performance remains below last year's best performance. However, TartuNLP's system is based on a slightly larger model (3B) and trained on fewer tasks, making this comparison not entirely fair.

For QA, all systems outperformed the baseline. This year's best systems showed improved performance compared to last year's winners on the same QA test sets. Regarding the three new tasks, the baseline model exhibited output formatting issues for both spell and grammar checking and general difficulty for maths reasoning in a zero-shot setting. Despite its simple setting, spell checking is not entirely solved by the submitted systems. While systems can detect errors in a sentence, correcting remains more difficult, especially for subtle errors in all three languages. Similarly, grammar checking remains challenging, with correction being systematically harder than detection. Finally, maths reasoning proved to be the hardest task for the systems, with the best scores in the 20–30 accuracy range for low- to medium-level questions.

In short, we overall observed better task performance than the baseline with the submitted systems for both tracks. Most of them are also capable of performing the five tasks, with minimal sacrifice in performance on tasks that are not necessarily related. A cautious multitask training approach seems, however, necessary, as catastrophic forgetting was reported otherwise. The submissions from the participants did not show clear evidence of synergy between the tasks themselves. Since the training mixture was usually heavily imbalanced towards MT compared to the other tasks due to data scarcity, especially for the Sorbian track, no general trend can be drawn. Yet, for a given training data and strategy in two systems, focusing on MT has been shown to negatively affect QA, as in last year. Finally, on the overlapping MT and QA tasks, this year's best submission for Ukrainian outperforms last year's, while for Sorbian, TartuNLP remains the best open-source system for MT.

This shared task showed that the three new tasks remain challenging, especially for MR. Several factors were explored by the participants, which need further investigation in terms of their final impact: the quality and distribution of each task in the dataset, task-specific inference strategies, or the use of reasoning capabilities. This year's edition displayed promising results for small but multitask LLMs in underrepresented languages.

## Ethics Statement

The shared task continued to focus on smaller models: this year's base model, Qwen3.5-2B, is still below the milestone of 3B parameters from last year. This ensures that participants have a lower computational barrier, fostering both accessibility and a smaller ecological footprint. We notably have two participants using consumer-grade GPUs for training and inference.

We also commit to open science and reproducibility by ensuring that the teams use both open-source models and publicly available datasets. Participants were encouraged to make their model public, and all systems from this year are on HuggingFace.

For the Sorbian track, the shared task relies on the partnership with the WITAJ-Sprachzentrum. They provided all new Sorbian datasets for MT and annotation help for the PluraMath dataset for MR. For the manual evaluation experiment on the Sorbian MT outputs, both annotators were contacted through the WITAJ-Sprachzentrum.

## Limitations

The main limitation comes from the restriction to one model size and family. Exploring a wider range of model families in that size range might help establish the extent to which the presented strategies are generalisable across models, in particular regarding issues observed with the base Qwen3.5-2B model, such as decoding loops in the thinking mode. For this edition, we constrained the model to a single base model for a fair comparison between participating teams.

The Shared Task continues to focus on three languages (Ukrainian, Upper Sorbian, and Lower Sorbian) with two dedicated language tracks. The methodological findings from the submitted systems are hence only applicable to these languages within the shared task setting (including the five tasks and their specific formatting).

## Acknowledgments

This work was partly funded by the European Union (ERC, EPICAL, 101141712). Views and opinions expressed are, however, those of the authors only and do not necessarily reflect those of the European Union or the European Research Council. Neither the European Union nor the granting authority can be held responsible for them.

The authors gratefully acknowledge the scientific support and HPC resources provided by the Erlangen National High Performance Computing Center (NHR@FAU) of the Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU) under the

NHR project b279bb. NHR funding is provided by federal and Bavarian state authorities. NHR@FAU hardware is partially funded by the German Research Foundation (DFG) – 440719683.

The authors also gratefully acknowledge the scientific support and resources of the AI service infrastructure *LRZ AI Systems* provided by the Leibniz Supercomputing Centre (LRZ) of the Bavarian Academy of Sciences and Humanities (BAdW), funded by Bayerisches Staatsministerium für Wissenschaft und Kunst (StMWK).

We thank the UNLP 2024 Shared Task team: Roman Kyslyi, Mariana Romanyshyn, and Oleksiy Syvokon, for sharing the Ukrainian QA resources. We also thank Hanna Yukhymenko for the support with the MMLU_ukr QA dataset.

Moreover, we are grateful for our cooperation with the WITAJ-Sprachzentrum for Upper and Lower Sorbian. In the continuation of the datasets they provided for the previous WMT shared tasks on MT for low-resource languages and last year's QA data, they provided new datasets for this year's edition. They have helped us with the PluraMath project for both Sorbian MR splits that we use in this Shared Task. We thank Tomaš Šołta for providing the language certificate exercises and Kryštof Peršín for the maths reasoning dataset annotation. We also thank the annotators of Lower Sorbian MT outputs for their time and comments.

We warmly thank the soblexx team, in particular Bernhard Baier, for his trust and help regarding the Upper Sorbian linguistic resource to create our grammar checking dataset.

Finally, we thank the organisers of the WMT 2026 shared tasks. We highly appreciate the help from Martin Popel, Tom Kocmi, Katia Artemova, and Mariya Shmatova for sharing the test sets for the Ukrainian MT track with us in 2025. We are also especially grateful to Philipp Koehn and Christof Monz for helping us with Softconf, and Roman Grundkiewicz for setting up again the leaderboard on OCELoT for our shared task.

## A Prompts for the zero-shot baseline

```
Translate the following German text to Lower
    ↪ Sorbian. Put it in this format <dsb>
    ↪ Lower Sorbian translation </dsb>.
<deu> {{source}} </deu>
```

Figure 4: Baseline MT prompt, here for de→dsb.

```
{{context}}

Question:
{{question}}

Possible answers:
{{possible_answers}}

Answer:
```

Figure 5: Baseline question answering prompt.

```
The following sentence contains at most one
    ↪ misspelled word. Respond with exactly
    ↪ these two tags and nothing else:
<wrong> misspelled word </wrong> <corrected>
    ↪ correct spelling </corrected>
If the sentence has no error, use the literal
    ↪ string CORRECT in both tags:
<wrong> CORRECT </wrong> <corrected> CORRECT
    ↪ </corrected>
<sentence> {{input_sentence}} </sentence>
```

Figure 6: Baseline prompt for spell checking.

```
The following sentence contains at most one
    ↪ grammatically incorrect word. Respond
    ↪ with exactly these two tags and
    ↪ nothing else:
<wrong> misspelled word </wrong> <corrected>
    ↪ correct spelling </corrected>
If the sentence has no error, use the literal
    ↪ string CORRECT in both tags:
<wrong> CORRECT </wrong> <corrected> CORRECT
    ↪ </corrected>
<sentence> {{input_sentence}} </sentence>
```

Figure 7: Baseline prompt for grammar checking.

## B Detailed Grammar Checking example

Figure 9 shows a Ukrainian example sentence for the grammar check, where the grammatical case (*INS*) of the noun результатом ('results') has been changed into *GEN*, leading to a corrupted sentence.

```
Answer this mathematical reasoning question.
    ↪ Place your final answer, using LateX
    ↪ when appropriate, in this format:
    ↪ <answer> answer </answer> {{question}}
```

Figure 8: Baseline prompt for mathematical reasoning.

## C Detailed results tables

Tables 18 and 19 display the detailed results obtained by the participating systems per sub-task for the Ukrainian and Sorbian tracks, respectively.

## D Statistical test of the final ranking

Our official results only use the output scores to compute each task ranking of the systems. As some of the differences are very minor, we perform statistical tests on each of the five tasks to assess the stability of our ranking. Several tasks feature subtasks (e.g., MT, QA, and the remaining Sorbian tasks), which hence require a stratified approach. We note that for Sorbian, most questions in QA and all the MR exercises are translations of each other; they are hence not independent and need to be considered together. We report the results of a stratified paired cluster bootstrap with 20,000 replicates for the confidence interval. We additionally provide the rank range for each task based on the significance of the difference. We use a paired approximate randomisation test between the systems at 5% with Holm correction. We compute the final confidence interval and the rank range using the same official point methodology on each bootstrap resample per task.

Tables 20 and 21 show the submission ranks after our resampling analysis. When systems cannot be separated statistically for a task, we provide a ranking range (e.g., 1–2 for first and second positions). We do not observe a major difference in the official final rank for both tracks: the tied winning systems for the Sorbian track are indeed not significantly different, while for the Ukrainian track, the baseline and the TUM-HN systems are also indistinguishable. We note here that Sorbian QA is the task where separating systems is the most difficult in our case.

## Abstract

We describe LiLa, our submission to the constrained track of the WMT 2026 General Machine Translation Task. Motivated by recent advances in large language models (LLMs) and their increasing availability as open models, we investigate the adaptation of LLMs for Ligurian and Ladin, two low-resource languages included in the shared task. We evaluate several adaptation strategies for Gemma-4, including Instruction Tuning (IT-only), continuous pre-training followed by Instruction Tuning (CPT+IT), and Low-Rank Adaptation (LoRA), and compare them with a dedicated encoder-decoder pipeline based on fine-tuned No-Language Left Behind (NLLB) models. Our experiments show that, under the evaluated conditions, fine-tuned NLLB models achieve higher automatic translation scores than the investigated LLM adaptation strategies. Based on these results, our final submission adopts a fine-tuned NLLB-based translation pipeline. We discuss the main observations from the different approaches explored during development. We release the code and models produced in these experiments through a publicly accessible GitHub repository[1].

## 1 Introduction

A truly multilingual translation system should not treat the world's languages as a hierarchy in which a small number of high-resource pairs receive most of the modeling effort. The practical goal of machine translation is broader: to make information accessible across languages, including those with limited training resources and comparatively little representation in existing benchmarks. Recent multilingual models have substantially expanded the range of languages that can be addressed, but important differences in translation quality remain. The WMT26 shared task (Kocmi et al., 2026) offers an opportunity to examine this problem in a diverse, challenging multilingual setting. This motivates an important question for low-resource languages: can general-purpose LLMs be effectively adapted to (unseen) languages with limited digital resources, and how do they compare with specialized neural machine translation (NMT) approaches when adapted to the same low-resource scenario?

Recent studies have explored LLM adaptation for multilingual and low-resource settings, including comparisons between adapted LLMs and fine-tuned encoder-decoder models (Scalvini et al., 2025). Initiatives focused on evaluating LLMs in dialectal and low-resource language scenarios (Robinson et al., 2026; Kyslyi et al., 2025; Joshi et al., 2025) have provided valuable insights into the challenges of adapting these models beyond high-resource and standardized varieties. Nevertheless, developing effective adaptation strategies for under-resourced languages remains challenging, as limited data availability, linguistic diversity, and computational constraints continue to hinder the deployment of robust multilingual LLMs.

Motivated by these developments, we investigate whether LLMs can be effectively adapted to Ligurian and Ladin, two languages of Italy included for the first time in the WMT General Machine Translation Shared Task.

Specifically, we adapt Gemma 4 (Gemma Team et al., 2026) using several strategies, including instruction tuning (Zhang et al., 2026), continuous pre-training (Ke et al., 2023) followed by instruction tuning, and parameter-efficient fine-tuning with LoRA (Hu et al., 2021). The Gemma 4 model was selected because, at the time the research was conducted, it represented the most recently released open model offering multilingual capabilities (Finkelstein et al., 2026).

Beyond translation quality, we also evaluate their ability to process and preserve common structured and formatted inputs, such as HTML documents, Markdown files, and JSON-formatted data.

*Proceedings of the Eleventh Conference on Machine Translation*, pages 1203–1212
October 28-29, 2026 ©2026 Association for Computational Linguistics

Such capabilities could offer an alternative to traditional translation pipelines that require separate mechanisms for handling document structure and content transformation. To this end, we construct a document-level corpus containing structured and formatted examples. We compare these LLM-based adaptation strategies against established encoder-decoder translation models, using NLLB (Costa-jussà et al., 2024), which we fine-tune specifically for the English to Ligurian and English to Ladin translation directions using the same collected resources employed in our experiments. Due to hardware limitations during the training phase, the NLLB models employed in this study were restricted to a maximum of 1.3 billion parameters.

Our experiments reveal a clear practical outcome: the fine-tuned NLLB models outperform all investigated Gemma-4 variants on the considered benchmarks. Qualitative analysis of the adapted LLM outputs shows that continuous pre-training can enable the generation of fluent language-specific text in selected cases; however, instruction-tuned LLMs remain less reliable for constrained machine translation tasks, where they may hallucinate, drift from the source content, or fail to preserve required document structure.

Based on these findings, we select the NMT approach for our final WMT 2026 submission. The submitted systems, released as LiLa[2], rely on NLLB-200 distilled 1.3B, combined with a format-aware inference pipeline supporting plain text, HTML, and JSON to process and preserve the structure of the heterogeneous text formats included in the WMT blind test set. The main contributions of this system description are:

- A reproducible NLLB fine-tuning pipeline for English–Ligurian and English–Ladin translation;
- A structure-aware inference pipeline that preserves HTML markup, JSON structure, placeholders, and document layout;
- An empirical comparison between fine-tuned NLLB models and several Gemma-4 adaptation strategies for two low-resource languages;

We hope that these findings contribute to further developments in the adaptation of multilingual LLMs for low-resource languages and encourage future research on their use as flexible alternatives to specialized translation systems.

[2]Acronym for Ligurian–Ladin; in Ladin it means both "little sheep" and lilac color

## 2 Data

Ladin and Ligurian are both Romance languages and face similar challenges in terms of their representation and support in modern NLP systems. At the syntactic level, the two languages share relatively few similarities that could facilitate cross-lingual transfer for machine translation: using Ladin translations as hypotheses and Ligurian translations as references results in a BLEU score of only 2.52.[3] We therefore aim to collect as much high-quality data as possible for both languages, focusing on valid, reliable, and representative resources that provide sufficient coverage to train and adapt models for each language (independently).

A key change in the WMT26 shared task is the emphasis on structured translation, requiring systems to translate content embedded in formats such as HTML, Markdown, and JSON while preserving the underlying structure and producing valid output. To address this setting, we construct two complementary types of training data: (i) a sentence-level corpus, primarily used for supervised NMT fine-tuning, and (ii) a document-level corpus for adapting LLMs to contextual and structured translation.

Both corpora include authentic and back-translated monolingual data. The sentence-level data focuses on English–target language translation pairs, whereas the document-level data provides longer contextual examples and diverse document structures, including HTML, Markdown, and JSON-like representations. The sizes and composition of the different corpora are summarized in Table 1.[4]

### 2.1 Ladin Corpus

Ladin comprises multiple written and standardised varieties (Frontull et al., 2025). The WMT26 shared task specifically targets the Val Badia variety. We therefore focus our corpus construction for Ladin exclusively on Val Badia Ladin and aim to use data that can be identified as belonging to this variety, rather than mixing different Ladin varieties.

We construct a multilingual corpus from publicly available parallel and monolingual resources. We

[3]One notable linguistic feature nevertheless connects the two languages: both are among the relatively few languages that use the letter *ë* (e with diaeresis).

[4]In the Table, we only report document-level statistics

| Component | Ladin | | Ligurian | |
|---|---|---|---|---|
| | *Words* | *Chars* | *Words* | *Chars* |
| Target | 17.86M | 94.91M | 4.46M | 24.93M |
| English | 16.48M | 95.85M | 1.44M | 8.06M |
| Italian | 16.66M | 101.19M | 1.35M | 8.07M |
| French | 13.08M | 77.80M | 0.54M | 3.11M |
| Spanish | 12.68M | 75.05M | 0.51M | 2.95M |
| German | 15.91M | 104.09M | – | – |

Table 1: Dataset statistics by language and data component. Values are reported in millions (M).

use the Ladin Language Corpus from Motorola's Language Revitalization Initiative[5] , the monolingual datasets [6] [7] and the parallel datasets [8] [9] [10] [11] [12] released in Frontull and Moser (2024); Frontull and Haller-Seeber (2026). We do not use the remaining OPUS resources included in the bundle because they are not consistently restricted to the Val Badia variety.

**Document-Level Corpus** The document-level corpus was constructed specifically for continuous pre-training and instruction-tuning experiments with Gemma-4. Since no document-level corpus was available for Ladin, we extracted document-level texts from articles in the archive of *La Usc di Ladins*. The collected articles were then classified and filtered to retain texts in the Val Badia variety of Ladin. The resulting Ladin documents were subsequently back-translated into English, German, Italian, French, and Spanish using an internal LLM-based back-translation pipeline. To reduce lexical and semantic noise in the translation of this low-resource language, the pipeline augments the translation prompt with dictionary information from Moling (2016), providing multilingual document-level training material with longer and more coherent contextual structure. Specifically, we augmented the prompt with the dictionary definitions of words that can be unambiguously mapped to a single part of speech[13]. These definitions provide additional semantic information to guide the translation of the corresponding words.

To further expose LLMs to realistic document-processing scenarios, subsets of the translated documents are converted into multiple representations, including HTML, LaTeX, Markdown, and plain-text formats. We also create emoji-enriched variants to increase the diversity of formatting patterns and evaluate the ability of adapted models to preserve document-level structure during translation.

**Sentence-Level Corpus** The sentence-level corpus is used for NLLB fine-tuning. The back-translation of the document-level data did not consistently preserve sentence-level alignment, making it unsuitable for direct inclusion in the sentence-level corpus. For this corpus, we therefore relied on the *la-usc_valbadia_loresmt24* sentence-level monoligual ladin dataset[14] (the largest currently available monolingual dataset for Val Badia Ladin), which we back-translated into English. To improve the quality of the generated English translations, we use a retrieval-augmented back-translation approach. For each Ladin sentence, we retrieve semantically related examples from the available authentic parallel corpus using BM25 (Robertson and Walker, 1994). We initially retrieve the top 50 candidates and apply Maximal Marginal Relevance (MMR) re-ranking to select a diverse subset of $k = 10$ demonstrations. This retrieval-augmented approach has previously been shown to be effective for Ladin, providing a reliable way to improve the quality of back-translated data (Frontull and Ströhle, 2026). For a subset of document-level data for which sentence-level alignment could be reliably maintained, we extracted the aligned sentence pairs and added them to the corpus.

## 2.2 Ligurian Corpus

For Ligurian, the multilingual corpus was created from a mixture of publicly available resources – ZenaMT (Haberland et al., 2024), OLDI-Seed (Dale et al., 2025), SMOL (Caswell et al., 2025) – as well as parallel and monolingual data privately held by the Council for Ligurian Linguistic Heritage[15] and shared with us for the purposes of participating in this shared task.

**Document-Level Corpus** This portion of the corpus, consisting of Ligurian paragraphs and longer documents aligned with English, German, Italian, French and Spanish, was used for the LLM experi-

ments with Gemma-4. It was made of a combination of natively multilingual document-level data and backtranslated data. Unlike for Ladin, no dictionary information was included in generation, but targeted manual post-editing was used to fix common mistranslations. Similar to Ladin, the goal was to expose LLMs to a mixture of realistic document formats. As much of the data was originally in Markdown format, this was preserved as Markdown in 70% of cases, and converted to HTML in the remaining 30% of cases.

**Sentence-Level Corpus** We used English-Ligurian parallel data for NLLB fine-tuning. Much of this data was natively in document format, and was segmented and sentence-aligned across languages to turn it into the sentence-level data needed for NLLB training. For the portions of the data that were backtranslated, a manual post-editing step was conducted to fix words and phrases that were observed to be commonly mistranslated.

### 2.3 Evaluation Benchmarks

For development and evaluation, we use publicly available multilingual benchmarks. We evaluate both Ladin and Ligurian on the FLORES+ evaluation corpus (Costa-jussà et al., 2024; Frontull et al., 2025). For Ligurian, we additionally evaluate on the BOUQuET benchmark (Andrews et al., 2025).[16]

## 3 Specialized NMT Systems

We fine-tune NLLB-200 distilled 1.3B[17], a multilingual encoder-decoder model from the NLLB family (Costa-jussà et al., 2024). NLLB has demonstrated strong performance in multilingual and low-resource translation settings, making it an established reference point for evaluating adaptation approaches for low-resource languages. We fine-tune separate models for the two translation directions considered in our experiments (English–Ligurian and English–Ladin). The target languages are specified using the NLLB language tags `lij_Latn` for Ligurian and `lld_Latn` for Ladin. Models are fine-tuned using the Adafactor optimizer with an effective batch size of 64, a learning rate of $1.5 \times 10^{-4}$, a linear warmup ratio of 0.03, and a weight decay of 0.001. We train for up to 3 epochs on an NVIDIA RTX PRO 6000 Blackwell Server Edition GPU (96 GB VRAM) leveraging mixed BF16/TF32 precision, and select the best checkpoint based on validation BLEU score with a patience of three evaluations. At inference time, we decode via beam search with a beam width of 4. All NLLB experiments use a fixed random seed of 42 to ensure reproducibility.

## 4 Generative LLM Adaptation

Prior literature establishes that instruction tuning frequently combined with task-specific fine-tuning or continuous pre-training (CPT) constitutes an effective paradigm for Neural Machine Translation (NMT), particularly when adapting general-purpose LLMs to low-resource target languages (Xu et al., 2023; Zhang et al., 2025a,b). Consequently, we investigated training scenarios that combine CPT with instruction tuning to evaluate prospective performance gains in translation quality. Notably, baseline performance may be constrained given that the target low-resource languages were absent from the base LLMs pre-training distribution. To assess these effects, we evaluated three experimental configurations:

1. **Zero-Shot Baseline**: Out-of-the-box evaluation of Gemma-4 without task-specific fine-tuning or parametric adaptation.

2. **Direct Instruction Tuning (IT)**: Task-specific supervised instruction tuning applied directly to the base Gemma-4 architecture. For this pipeline, experiments were run with both parameter-efficient fine-tuning via low-rank adaptation (LoRA), applied to attention and feed-forward layers while keeping the base language model frozen, and full fine-tuning, which optimizes all model weights to maximize adaptation capacity.

3. **Sequential Adaptation (CPT+IT)**: Supervised instruction tuning applied to Gemma-4 following an initial phase of domain-specific Continuous pre-training (CPT). The Continuous Pre-Training phase aimed to expand the Gemma-4 models proficiency in Ladin and Ligurian via a next-token prediction objective. To mitigate catastrophic forgetting, the corpus combined these target low-resource languages with selected high-resource languages.

[16] The Ladin subset of the BOUQuET benchmark was not publicly available during system development.

[17] https://huggingface.co/facebook/nllb-200-distilled-1.3B

### 4.1 Model Architecture and Optimization

The experimental framework for CPT and instruction tuning uses the `google/gemma-4-E4B`[18] decoder-only architecture. To maximize linguistic adaptation, we adopted a Full Fine-Tuning (FT) approach. Training was executed on an NVIDIA A100 Ampere-class GPU using the Unsloth engine. We used BF16 (BFloat16) precision with FP16 fallback to ensure stability.

### 4.2 Continuous Pre-Training (CPT)

This section outlines the experimental framework for the CPT pipeline.

**Data Organization** To ensure the injection of deep linguistic understanding, we created a sentence and document level dataset with rigorous data preprocessing for continuous pre-training. The dataset integrates multi-format document-level data (HTML, LaTeX, JSON, Markdown, and plain text). Synthetic sentence-level samples were removed to increase data quality, leaving the final filtered dataset with 706,330 samples and 85,233,986 words. To maintain training stability, we applied pre-compiled regular expressions to remove artifacts (e.g., reporter initials, editor credits, and signature headers). The data was partitioned using a fixed random seed (3407) to ensure a strict 99% / 1% train-test split.

**Performance Tracking and Metrics** Model evaluation relied on real-time monitoring and validation at 25% intervals of training progress. We tracked perplexity on the evaluation set and retained the top two checkpoints. Models were trained for two epochs, with the best checkpoint achieving a perplexity of 4.84 on the evaluation set.[19] The trainer was configured with a 4096-token context window, employing sequence packing, i.e, concatenating multiple document sequences up to the maximum context length with end-of-sequence delimiters, to eliminate redundant padding tokens and maximize compute efficiency during training. Training was conducted using a learning rate of $2 \times 10^{-4}$ and a batch size of 2.

### 4.3 Instruction Tuning (IT)

To adapt pretrained LLMs for translation in low-resource settings – specifically Ligurian and Ladin paired with English and Italian – we implement a specialized Supervised Fine-Tuning (SFT) pipeline using a balanced sampling approach that prioritizes translation into the low-resource languages:

**Dataset Curation, Probabilistic Sampling, and Deduplication** The dataset preparation pipeline utilizes a broad multilingual corpus spanning seven languages: English (`eng`), Ladin (`lld`), Ligurian (`lij`), Spanish (`spa`), Italian (`ita`), German (`deu`), and French (`fra`). To counteract the dominance of high-resource language pairs during optimization, data balancing is pre-computed offline using a targeted *Balanced Batch Approach*. Training batches are sampled with a fixed composition: 40% English–Ladin (`eng`→`lld`), 40% English–Ligurian (`eng`→`lij`), 10% non-English source languages to Ladin ($\{\texttt{deu}, \texttt{spa}, \texttt{fra}, \texttt{ita}\} \rightarrow \texttt{lld}$), and 10% non-English source languages to Ligurian ($\{\texttt{deu}, \texttt{spa}, \texttt{fra}, \texttt{ita}\} \rightarrow \texttt{lij}$). By heavily weighting translation directly into `lld` and `lij`, this 40/40/10/10 distribution prioritizes under-resourced target generations while preserving cross-lingual transfer from high-resource European pivot languages. All parallel pairs are mapped to a unified, zero-shot instruction prompt.[20]

**Sliding-Window Deduplication** To prevent immediate response repetitions and mitigate recency bias, we execute a sliding-window deduplication pass over target sentence output hashes, removing duplicate outputs within localized context windows.

**Training parameters** During training, we used a sequence length of 1024 tokens for the `google/gemma-4-E4B` direct instruction tuning via full fine-tuning, and 2048 tokens for both the CPT + IT and Direct Instruction Tuning via LoRA models. For the LoRA experiments, we set the rank ($r$) and alpha ($\alpha$) parameters to 16. The learning rate was set to $2 \times 10^{-5}$ for full fine-tuning and $2 \times 10^{-4}$ for LoRA. All instruction tuning experiments were trained for 3 epochs.

**Performance Tracking and Metrics** Validation was run on a held-out validation set of 2,000 samples and performed at every quarter of an epoch. Checkpoint selection was based exclusively on performance on this validation set. After model selection was complete, the selected checkpoint was

[18] https://huggingface.co/google/gemma-4-E4B

[19] This model checkpoint will be made publicly available on Hugging Face.

[20] We format all inputs using the template: `"Translate from {SRC_LANG} to {TGT_LANG}: {SRC_TEXT}"`, where language names are expanded in full English.

evaluated once on the FLORES+ and BOUQuET test sets, which were not used for checkpoint selection or hyperparameter tuning. Translation quality was measured using sacreBLEU and chrF++ for the evaluated English-to-Ladin and English-to-Ligurian directions. During generation, we enabled sampling and generated one candidate translation per input using a temperature of 0.7, top-p of 0.9, and a repetition penalty of 1.1.

## 5 Results and Analysis

Table 2 presents a performance comparison across our primary fine-tuned NLLB model and several exploratory Gemma-4 adaptation strategies on the FLORES+ and BOUQuET test set. All evaluation metrics were computed using standard `sacreBLEU` settings via the Hugging Face `evaluate` library.

Across the exploratory setups, zero-shot `google/gemma-4-E4B-IT`[21] struggled significantly on both low-resource language pairs, confirming that the model lacks sufficient proficiency in both Ladin and Ligurian. Fine-tuning substantially improved performance, with LoRA consistently outperforming full fine-tuning and emerging as the strongest LLM adaptation strategy. Interestingly, combining CPT with full instruction fine-tuning obtained lower automatic scores than the zero-shot instruction-tuned checkpoint across all three benchmarks, with the results suggesting a strong tendency for the model to fallback to the task of next token prediction instead of instruction following

Despite the competitive results obtained with LLM adaptation, the fully fine-tuned NLLB 1.3B system achieved consistently higher automatic scores than the evaluated Gemma-4 variants across language pairs, datasets, and metrics.

### 5.1 Translating the blind test set

We applied the fine-tuned NLLB model using a structure-aware inference pipeline rather than directly translating each document as a single sequence, as illustrated in Figure 1. [22] This was necessary because the WMT 2026 blind test set documents can be substantially longer than the maximum sequence length used during training. We therefore introduced a dynamic segmentation and reconstruction procedure implemented through a custom `TranslationPlanner`. The planner decomposes each document into translatable and non-translatable spans while preserving the original document structure. For natural-language content, sentence boundaries are detected using the rule-based `pysbd` segmenter (Sadvilkar and Neumann, 2020). Line breaks, blank segments, and leading and trailing whitespace are retained as non-translated spans, while only linguistically meaningful segments containing alphabetic characters are passed to the translation model. This allows long documents to be processed as smaller translation units while enabling the generated segments to be reconstructed into the original document layout.

**Format-Aware Parsing** The inference procedure dynamically selects a processing strategy based on the instructions associated with each WMT instance. Three document types are handled separately: plain text, HTML-formatted content, and JSON data. For HTML documents, the input is first split around HTML tags using a regular-expression-based parser. HTML tags are treated as immutable structural elements and are therefore never passed to the translation model. Only the text between tags is sentence-segmented and translated. After generation, the translated text segments are recombined with the original tags in their original or-

[21] https://huggingface.co/google/gemma-4-E4B-it

[22] The system would otherwise break most of the markup or structured data.

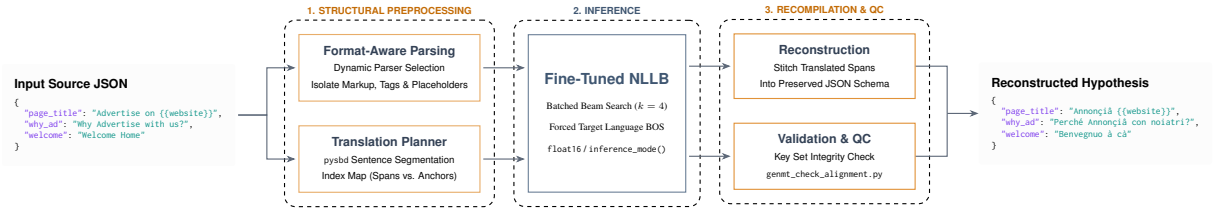

Figure 1: End-to-end format-aware machine translation pipeline preserving structural anchors and dynamic markup.

der. For JSON examples, we employ a custom streaming JSON parser that tracks the syntactic state of the JSON document using a context stack. The parser distinguishes object keys from values and selectively extracts string values that occur in translatable positions. JSON keys, brackets, commas, colons, numeric values, and other structural elements are preserved without modification. Extracted string values are subsequently processed using the same sentence-level translation planner as ordinary text. The translated values are then serialized back into the original JSON structure. Template placeholders are also explicitly protected during preprocessing. Strings matching the pattern `{{...}}` are isolated from the surrounding natural-language text before sentence segmentation. The placeholders are consequently not exposed to the translation model and are inserted unchanged during document reconstruction. This prevents variable names and template expressions from being translated, dropped, or otherwise modified.

**Translation and Document Reconstruction** After structural preprocessing, the resulting translatable segments are collected and processed in batches of 32 examples. Each batch is tokenized with padding and truncation, using a maximum input length of 512 tokens. The fine-tuned NLLB model generates up to 256 new tokens per segment. We use beam search with four beams (`num_beams` $= 4$) and explicitly force the beginning-of-sequence token corresponding to the desired target language. Following generation, the translated segments are reconstructed using the original translation plan. The reconstruction process combines generated translations with all non-translated spans, including whitespace, line breaks, HTML markup, JSON syntax, and protected placeholders. Thus, the inference system produces complete document-level hypotheses while restricting neural generation to linguistically relevant segments. This design allows documents exceeding the model's input context to be processed without sacrificing their original structure.

**Post-Inference Validation and Quality Control** We performed multiple levels of validation after generation to ensure that the resulting WMT hypotheses were both linguistically generated and structurally aligned with their corresponding source documents. First, local validation checks verify that the number of output documents matches the number of input documents for the selected target language, that document identifiers are unique, and that all source fields remain unchanged. The generated hypothesis is added as a separate field without altering the original WMT metadata.

For JSON documents, the validation procedure compares the source and hypothesis representations to verify that the JSON root type is preserved and that the number of elements remains consistent. For dictionary-like structures, the set of object keys is additionally checked to ensure that keys have not been translated or removed. Placeholder sets are compared between the source and hypothesis to verify that all template variables are preserved. For HTML documents, structural consistency is verified by comparing the number of paragraph tags and the complete ordered sequence of HTML tags between the source and generated hypothesis. These checks ensure that translation does not introduce, remove, or reorder markup.

Finally, the generated output is passed through the WMT `genmt_check_alignment.py`[23] checker. The checker is executed against both the original WMT input and the generated translation file, and the inference pipeline requires a successful return code before the output is accepted. Consequently, the complete test-time procedure combines fine-tuned NLLB generation, sentence-level segmentation, format-aware parsing, batched beam-search decoding, structural reconstruction, and automated alignment validation.

## 6 Conclusion

We presented LiLa, our submission to the WMT 2026 General MT shared task for Ligurian and Ladin. The final system combines fine-tuned NLLB models with a deterministic, structure-aware inference pipeline. In our experiments, the encoder-decoder NLLB system achieved higher automatic evaluation scores than the evaluated decoder-only Gemma-4 adaptation strategies. Specifically, continuous pre-training followed by Instruction Tuning (CPT + IT) obtained lower BLEU and chrF++ scores than both direct instruction tuning and the zero-shot instruction-tuned checkpoint. Because the configurations differed in initialization, data composition, optimization, and training budget, this result should not be interpreted as evidence that continued pretraining is generally detrimental. Limited instruction tuning after CPT, catastrophic forgetting, and the aggressive full-parameter CPT learning rate are possible explanations that require controlled ablations. Future work will explore hybrid approaches that combine the deterministic processing and translation-focused architecture of encoder-decoder MT systems with the broader contextual generation capabilities of LLMs for low-resource regional languages.

**Limitations** Our analysis of the continuous pre-training model is limited: beyond automatic benchmark scores, we only performed qualitative inspection on a small set of examples. The claims about its fluency and failure modes should therefore be interpreted as exploratory rather than as a comprehensive human evaluation. Additionally, we utilized the same dataset for both the CPT and IT phases, which may have limited the model's ability to effectively disentangle general domain adaptation from instruction-following behaviors. In particular, the model showed limited ability to adhere to the instruction-following task after IT, instead tending to revert to the objective learned during CPT. One possible explanation is that the instruction-tuning stage was simply insufficiently long for the model to acquire the desired instruction-following behavior; given our limited computational budget, we were unable to determine whether this behavior would have been mitigated with additional instruction-tuning steps.

Furthermore, while Gemma was trained on a structure-aware, document-level translation task, the NLLB model was trained on non-structure-aware, sentence-level translation. A notable limitation of this study is the absence of an experiment training the LLM on the same simplified task as NLLB to establish a direct performance baseline for Gemma. Finally, our experimental scope was heavily constrained by limited computational resources; restrictions on GPU availability and overall training time prevented us from performing exhaustive hyperparameter optimization or extending the training schedule to fully mitigate the challenges observed in the CPT + IT pipelines.

## Acknowledgments

The authors would like to thank Motorola Mobility, Lenovo Foundation, and Eldorado Research Institute for their generous support and contributions to this research. We extend our sincere appreciation to Juliana Rebellato and Paul Videsott for initiating this collaboration and to Georg Moser, for supporting it. We also thank the organizers of the WMT General MT Shared Task for coordinating the shared task and fostering a collaborative research environment that enables advances in multilingual language technologies and the reviewers for their valuable comments and questions that helped to improve the presentation.

# SCIR-TG-MT's Submission for the WMT 2026 General Machine Translation Task

**Xiayu Cao, Baohang Li, Zekun Yuan, Zekai Ye, Xiaocheng Feng**
Harbin Institute of Technology
{xycao,baohangli,zkyuan,zkye,xcfeng}@ir.hit.edu.cn

## Abstract

This paper presents SCIR-TG-MT, our primary submission (ID 44) to the unconstrained track of the WMT 2026 General Machine Translation shared task. The system covers ten translation directions using DeepSeek-V4-Pro and STRIDE (**S**tructured **T**ranslation with **R**isk-**I**nformed **D**irectional **E**xecution), an OpenCode translation skill. STRIDE converts source-side evidence and task instructions into a translation contract, an execution route, generation constraints, and selected checks. On five WMT25 development directions, STRIDE raises average SacreBLEU from 31.24 to 31.80 and COMET-22 from 83.61 to 84.17. A cumulative ablation on three directions separates the effects of routing, controls, and validation.

## 1 Introduction

The WMT 2026 General MT task covers multiple languages, domains, instructions, and document formats. In addition to plain text, the data contain terminology constraints, style requirements, and structured formats including JSON, HTML, and CSV (WMT 2026 General Machine Translation Task Organizers, 2026). A single direct-translation prompt handles these records uniformly even though their binding requirements differ.

In our WMT25 development runs, direct translation showed recurring problems with structural fidelity, terminology consistency, pragmatic intent, and document completeness. STRIDE uses the source form, task instruction, and direction profile to build a translation contract and validation plan. Plain local inputs follow a short direct path and normally proceed to finalization without validation. A short-path output is validated only when independent record-level evidence selects a validator. Structure-sensitive and document-sensitive inputs follow the long path, which adds planning and validation.

**Contributions.** This paper makes three contributions:

- We introduce STRIDE, which converts the task instruction and record evidence into a translation contract and a record-specific execution plan.
- We define an operational risk-to-action policy for route selection, structure and terminology preservation, spoken/social style, coverage validation, and bounded local repair.
- We evaluate the complete system on five WMT25 directions, provide a cumulative component ablation on three directions, and report the construction and validation of our ten-direction WMT26 submission.

The remainder of this paper first relates STRIDE to document-level LLM translation and agentic inference (Section 2). We then describe the task inputs (Section 3), the system and its implementation boundary (Section 4), WMT25 experiments (Section 5), and WMT26 submission checks (Section 6).

Figure 1 gives an overview of the system before the individual stages are specified in Section 4.

## 2 Related Work

**Document-level LLM translation.** Wang et al. evaluate context-aware prompts, translation quality, and discourse phenomena in document-level translation with GPT-3.5 and GPT-4 (Wang et al., 2023). Wu and Hu study prompt engineering for GPT-based document translation in the WMT23 English–Chinese directions (Wu and Hu, 2023). Later work reports that LLM translation quality degrades as document length increases (Wang et al., 2024) and that source-primed multi-turn translation can reduce omission while preserving document context (Hu et al., 2025). These studies motivate explicit treatment of context and coverage.

*Proceedings of the Eleventh Conference on Machine Translation*, pages 1213–1220
October 28-29, 2026 ©2026 Association for Computational Linguistics

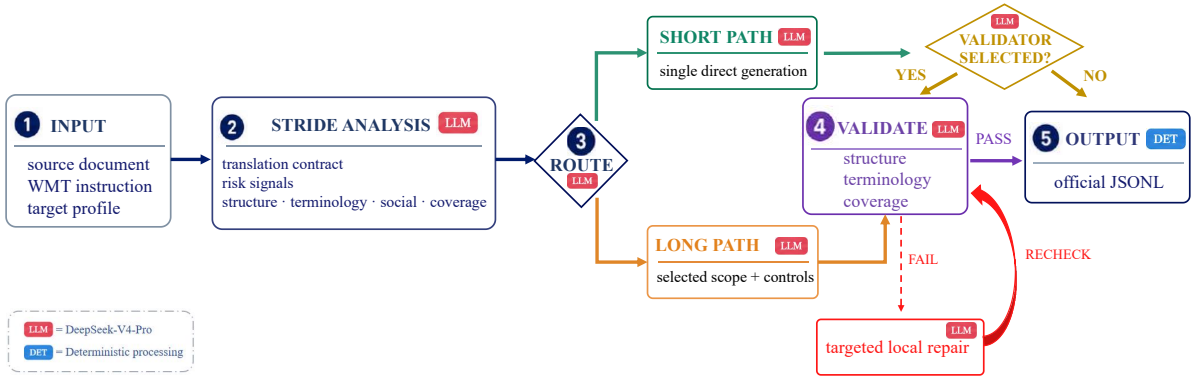

Figure 1: SCIR-TG-MT inference pipeline. The short path uses direct generation and invokes validation only when a validator is selected. The long path uses planned, controlled generation followed by validation.

STRIDE uses the source form and task instruction to select the execution scope and the constraints supplied during generation.

**LLM translation post-editing.** Huang et al. identify a mismatch between general and translation-specific understanding in LLMs and propose DUAT, which supplies cross-lingual interpretations of difficult expressions before translation (Huang et al., 2024). Raunak et al. formulate direct translation post-editing with GPT-4 and report improvements across several WMT22 directions, together with cases of hallucinated edits (Raunak et al., 2023). STRIDE records difficult terminology in its translation contract and applies validation to the structural, terminology, and coverage risks selected for each record. A failed check identifies the affected unit and triggers the local repair procedure described in Section 4.6. The translation contract links these checks to the requirements established before generation, so that each finding can be traced to a specific constraint.

**Agentic inference.** ReAct interleaves model-generated reasoning traces with task-specific actions (Yao et al., 2023). OpenCode provides the runtime and reusable skill interface used by our system (OpenCode, 2026). STRIDE encodes analysis, routing, generation controls, validation, and repair as stages in one OpenCode conversation. DeepSeek-V4-Pro performs these stages, and the finalizer packages the generated translations and checks submission integrity.

| English → Eastern Armenian | 198 |
| Total | 6,140 |

Table 1: WMT26 translation directions and row counts.

## 3 Task and Input Analysis

### 3.1 Translation Directions

We participated in the unconstrained track. Table 1 lists the ten WMT26 translation directions and the number of blindset rows processed for each direction.

### 3.2 Input Groups and Requirements

The system consumes the source text, target direction, and provided WMT instruction. The instruction defines the applicable register, terminology, style, and output structure and is retained throughout inference.

Records fall into three shared source groups. The Czech professional-text group serves German and Vietnamese targets. The mixed English group serves Russian, Chinese, Estonian, and Icelandic targets. A 198-record English professional-text group serves Japanese, Indonesian, Thai, and Eastern Armenian. Its instruction profile also covers

transcript-like and social-style inputs.

The input analysis distinguishes direct translation, professional text or image instructions, professional spoken-utterance instructions, and the Russian gender-slash requirement. Image-related records use the supplied instruction and source text to define the translation contract. For spoken records, transcript form permits limited disfluency cleanup while preserving turn order, stance, and procedural tail content. For the Russian special regime, the gender-inclusive slash requirement enters the translation contract as a mandatory output constraint. The analysis also marks structure-sensitive records, social-thread continuity, document coverage, imperative-looking source text, and compact answers whose alignment would change under expansion. These signals feed the routing policy in Section 4.4.

# 4 Translation System

## 4.1 Model and Runtime

We used the proprietary DeepSeek-V4-Pro model in the unconstrained track. The recorded model identifier was `deepseek-v4-pro`, and OpenCode version 1.17.11 ran the model with its `Default` variant. We did not configure explicit overrides for temperature, top-$p$, or maximum output tokens; the same runtime defaults were used in every reported condition. The model's multilingual coverage allowed all ten directions to share one system configuration. The OpenCode command-line runtime (OpenCode, 2026) loaded STRIDE and ten direction profiles. Fixed direction prompts specify the input file and language pair, while STRIDE supplies the translation policy.

## 4.2 STRIDE Overview

For each record, STRIDE analyzes the source, direction, and WMT instruction before generation. It produces structured decisions for generation, validation, and local repair within one OpenCode conversation. Appendix A provides consolidated templates for the core skill prompts.

STRIDE processes each record in six stages:

**Analyze.** Normalize the task instruction and identify the input family and source-side risks.

**Specify.** Record fidelity priorities, permitted changes, required content, and the required output form.

**Route.** Select the short or long path and its row, document-light, or document scope.

**Activate.** Add the structure, terminology, spoken/social, or coverage controls triggered by the record.

**Verify and repair.** Run relevant checks and apply evidence-preserving local repair when needed.

**Trace.** Record a brief rationale, selected memory, modules, checks, and execution scope for audit.

Analyze and Specify form the *STRIDE analysis* box in Figure 1. Route and Activate determine the generation path. A short-path output enters the validation loop only when a validator is selected, whereas every long-path output enters that loop. Verify and repair performs the selected checks and any local correction, and Trace records the intermediate decisions.

## 4.3 Skill Construction

We developed STRIDE from an error analysis of direct DeepSeek-V4-Pro outputs on WMT25 records. We grouped recurring failures into four categories: formal breakage, unstable terminology or entities, loss of spoken/social intent, and long-form omission. Each category produced (i) fields in the translation-contract schema, (ii) trigger rules based on the source and task instruction, and (iii) a focused control and validator prompt. Direction profiles encode language-specific output conventions and recurring risks, including the Russian gender-slash requirement. After each prompt revision, we replayed the same development inputs and used the references for offline BLEU and COMET scoring.

## 4.4 Risk-Based Routing

STRIDE maps the source, WMT instruction, direction profile, and translation contract to an execution route through categorical rules. Plain, locally interpretable records use *short, row*. Binding structure or terminology requirements, image-related or spoken/social instructions, and cross-unit coverage risks select the *long* route. Within the long route, multi-part records that need coverage planning or term freezing use *document-light*; articles, chapters, threads, and multi-paragraph records with omission or continuity risk use *document*.

Controls and validators are selected from the same record evidence but serve different purposes:

controls shape generation, whereas validators inspect its output. The short path normally bypasses validation, but an independently triggered local risk can select a validator. Every long-path record is validated, with the contract determining which validator types are used. The operational rules are:

- **Plain and local** → *short, row*: use a direction hint when helpful, generate directly, and finalize unless record-level evidence selects a validator.
- **Markup or protected literals** → *long, document-light*: activate structure control and a structure check.
- **Glossary or repeated entities** → *long, document-light*: activate terminology control and a terminology check.
- **Transcript, dialogue, or social register** → *long, row or document-light*: activate spoken/social control and add a coverage check for multi-part input.
- **Long article, chapter, or thread** → *long, document*: plan coverage and select terminology, structure, and coverage checks aligned with the observed evidence.

The decision trace stores each control and validator with its trigger and execution scope. The LLM returns a JSON route decision whose schema enumerates the valid route and scope values. Direction profiles contribute language-specific evidence to this decision.

### 4.5 Translation Controls

The translation specification records format, terminology, communication, and completeness requirements together with permitted changes and required content. Selected controls enter the generation context as concise instructions. For spoken material, the context permits limited disfluency cleanup and requires retention of later procedural steps.

Each direction has a small profile that lists its target script, recurrent risks, and relevant domains. The Russian profile includes the gender-slash convention and long-form coverage. The Chinese, Japanese, Indonesian, Thai, and Armenian profiles call attention to structure, spoken or social style, named entities, and the risk of losing content near the end of a record.

Terminology control combines stable resources, direction profiles, and a record-local ledger. Together they preserve mandated expressions and maintain consistent renderings within a record. The outer WMT instruction establishes the required register, glossary, and output convention for source strings that have an imperative form. The active controls are:

**Structure.** For HTML, JSON-like text, CSV, placeholders, lists, and quizzes, preserve tags, protected literals, keys, field/list order, and paragraph boundaries.

**Terminology.** For glossaries, recurring names, institutional labels, and UI terms, freeze stable renderings and preserve labels designated as literals.

**Spoken/social.** Permit bounded cleanup of ASR noise and disfluency while retaining stance, turn-taking, interpersonal force, required emoji or punctuation, and procedural tail content.

**Long-form coverage.** For articles, chapters, threads, and multi-paragraph records, use document-light or document scope to prevent silent compression, omitted later content, and summary-like rewrites.

**Compact answers.** Discourage expansion when it could change answer alignment or the compactness of factual content.

### 4.6 Validation and Local Repair

For document-sensitive records, the long path creates a segmentation plan, coverage map, term-freeze plan, and document repair policy. It can also retain compact record-level memory across segments.

The translation contract determines validator selection, and DeepSeek-V4-Pro performs all three validators with validator-specific checklists. The structure validator aligns ordered tags, placeholders, protected literals, keys, and list markers; it reports missing, duplicated, or altered items with source and target evidence. The terminology validator aligns glossary entries and repeated entities through a record-local ledger and flags missing or inconsistent renderings. The coverage validator aligns paragraphs, newline-delimited items, or planned document segments in source order and

separately checks the final required unit. Validator invocation follows the categorical risk rules in Section 4.4. Exact-count mismatches and missing planned units produce findings directly; character and block-count ratios are diagnostic cues for LLM inspection rather than fixed acceptance thresholds.

The short path uses one translation request with minimal guidance and normally proceeds directly to finalization. When independent record-level evidence selects a validator, its output enters the same validation loop. The long path adds a planning turn and controlled generation, then always enters validation; the contract selects structure, terminology, coverage, or a combination of these validators. Each failed check returns its severity, evidence, affected content, and repair scope. Broken markup, lost protected content, and omitted required units are critical; recoverable terminology inconsistencies are major; local style deviations are minor. The repair budget is one local repair per record. STRIDE regenerates the affected span or segment, retains content that passed, and reruns the failed validator once. A failed recheck ends the repair stage, records the unresolved constraint, and retains the most complete candidate.

### 4.7 Recorded End-to-End Example

We illustrate the workflow with a WMT25 English-to-Chinese speech sample discussing Australian expressions. The task instruction requests correction of transcription errors where necessary and preservation of the speaker's colloquial style. The saved STRIDE trace selects the long path with row scope, activates spoken/social style control, and selects coverage validation. The complete source and saved outputs from independent Direct and STRIDE runs are shown below. Bold marks the two idiom contrasts.

> **Source.** Take us through them. Well, casual swearing was one of those that was particularly mentioned. The guide actually points out things like this machine's cactus or **spit the dummy** or even **bring a plate** as terms that won't be well understood and perhaps worth avoiding. But, you know, i think it's probably going too far to put words on a hit list. Most australians, and i think part of the richness of our culture is the language. And i think the goal is to use it, not neglect it, not hide from it, but make sure we're clear in explaining it, because there is a lot of irony around the australian language and new arrivals certainly find it a little bit perplexing. So do sometimes younger people as they hear the old timers use these phrases. Ok, mark, thank you very much for that. Appreciate it. Cheers.

| | SacreBLEU | | COMET-22 | |
|---|---|---|---|---|
| Pair | Direct only | +STRIDE | Direct only | +STRIDE |
| cs→de | 42.81 | **43.80** | 81.28 | **81.74** |
| en→ru | 25.71 | **26.43** | **82.14** | 81.73 |
| en→zh | 33.84 | **34.76** | 83.74 | **83.85** |
| en→et | 23.80 | **24.03** | 81.82 | **83.73** |
| en→ja | **30.05** | 30.00 | 89.05 | **89.82** |
| Average | 31.24 | **31.80** | 83.61 | **84.17** |

Table 2: WMT25 development results for direct-only and STRIDE-guided translation. Bold marks the better score for each metric.

> **Direct.** 带我们看看这些。嗯，随口脏话就是被特别提到的一个。这份指南确实指出了像“这台机器没戏了”、“**吐掉奶嘴**”甚至“**带个盘子**”这样的说法，认为它们不会被很好地理解，或许值得避免。但是，你知道，我觉得把词语列进一个黑名单可能有点过头了。大多数澳大利亚人——而且我觉得我们文化丰富性的部分就在于语言。我认为目标是去使用它，而不是忽视它，不是回避它，而是要确保我们能清楚地解释它，因为澳大利亚语言周围有很多反讽，新来者确实会觉得它有点令人困惑。有时候年轻人听老一辈说这些短语时也会这样。好的，马克，非常感谢你。很感谢。干杯。

> **STRIDE.** 给我们讲讲这些。好吧，随口的粗口就是其中被特别提到的一项。这份指南其实指出了像“这机器完了”“**发脾气**”甚至“**带一盘菜**”这样的说法，都是不太会被理解、也许值得避开的。但，你知道，我觉得把这些词列进黑名单可能有点过头了。大多数澳大利亚人——而且我认为我们文化丰富性的一部分就在这语言里。我觉得目标是去使用它，而不是忽视它、躲着它，而是要确保我们把它解释清楚，因为澳大利亚语言里有很多反讽，新来的人确实会觉得它有点令人费解。有时候年轻人听到老一辈用这些说法，也会这样。好，马克，非常感谢你。非常感谢。干杯。

Direct renders the two expressions literally, while STRIDE conveys their idiomatic meanings in this Australian context. In particular, *spit the dummy* describes losing one's temper, and *bring a plate* refers to bringing food to share. This contrast illustrates a difference in meaning rather than a choice between near-synonymous terms.

The saved coverage check reports full content coverage with no omitted ending. No repair was attempted, and the first STRIDE candidate was retained. The record therefore illustrates spoken-style control followed by coverage checking and acceptance. The lexical contrast appears in generation; the recorded validator finding concerns coverage. Section 4.6 describes the repair branch.

| Configuration | en→ru | | en→zh | | en→et | | Average | |
|---|---|---|---|---|---|---|---|---|
| | BLEU | COMET | BLEU | COMET | BLEU | COMET | BLEU | COMET |
| Direct | 25.71 | 82.14 | 33.84 | 83.74 | 23.80 | 81.82 | 27.78 | 82.57 |
| + Routing | 24.80 | 81.77 | 36.67 | 83.79 | 25.27 | 82.86 | 28.91 | 82.81 |
| + Controls | 25.75 | 81.13 | 36.30 | 83.75 | 24.08 | 81.66 | 28.71 | 82.18 |
| Full STRIDE (+ validation) | 26.43 | 81.73 | 34.76 | 83.85 | 24.03 | 83.73 | 28.41 | 83.10 |

Table 3: Cumulative ablation over 261 WMT25 records. Each row retains the components in preceding rows; Full STRIDE adds planned validation and the local-repair policy.

## 5 Experimental Results

### 5.1 Evaluation Setup

We developed and assessed STRIDE on the five WMT25 directions shown in Table 2. The comparison contains 604 documents, including 256 for the Czech-source direction and 87 for each English-source direction. WMT26 retains these directions and adds the remaining five directions in Table 1, for ten in total. Both WMT25 conditions use the same fixed DeepSeek-V4-Pro configuration and source records. The *direct-only* baseline runs the model once with the translation instruction. The *+STRIDE* condition adds skill-guided routing, controls, and planned validators. We compute SacreBLEU (Papineni et al., 2002; Post, 2018) with `zh` tokenization for Chinese and `ja-mecab` for Japanese. COMET-22 (Rei et al., 2022) is reported on a 0–100 scale.

### 5.2 Results

Table 2 shows the reference-based results (Kocmi et al., 2025). Across the five directions, +STRIDE raises average SacreBLEU from 31.24 to 31.80 and COMET from 83.61 to 84.17. SacreBLEU improves in four directions, with en→ja decreasing by 0.05. COMET improves in four directions, with en→ru decreasing by 0.41. The gains therefore vary by metric and direction.

### 5.3 Cumulative Component Ablation

To separate STRIDE's main components, we use the 87 WMT25 records in each of en→ru, en→zh, and en→et (261 records total). Table 3 adds components cumulatively. *Routing* adds instruction normalization, the translation contract, direction profiles, and short/long plus scope selection. *Controls* additionally apply the selected structure, terminology, spoken/social, and coverage instructions during generation. *Validation* adds the planned checks and one-local-repair policy. The Direct and Full rows are the corresponding three-direction subset of Table 2; intermediate rows are independent calls under the same model configuration.

On average across the three directions, Routing changes BLEU/COMET by $+1.13/+0.24$ relative to Direct. Controls then contribute $-0.20/-0.63$, and planned validation plus the repair policy contribute $-0.30/+0.92$. Full STRIDE remains above Direct by 0.62 BLEU and 0.54 COMET. Routing raises both metrics for Chinese and Estonian but lowers them for Russian. The validation stage produces its largest COMET recovery for Estonian. Component effects are therefore non-monotonic: controls reduce both macro metrics, while validation recovers COMET.

## 6 Submission Preparation

The finalizer merges per-direction outputs into the required JSONL format. It checks row coverage and target-language identifiers, restores identifiers from the input where necessary, and preserves the generated translation strings byte for byte.

The final validation checks row counts, target-language identifiers, required fields, empty translations, and repeated document identifiers. We also ran the official alignment checker. The final file contains all 6,140 expected rows, with one non-empty translation for each blindset row and no repeated document identifier (WMT 2026 General Machine Translation Task Organizers, 2026).

## 7 Limitations

The WMT25 development comparison covers five directions, and the component ablation covers three of them. The measured component effects may differ for other directions and input distributions. BLEU and COMET measure reference-based similarity and predicted translation quality, but they do not directly verify every structural, terminology, coverage, or instruction-following constraint handled by STRIDE.

## 8 Conclusion

We presented SCIR-TG-MT, our ten-direction submission to the WMT 2026 General Machine Translation task. The system uses DeepSeek-V4-Pro with STRIDE to convert task instructions and source-record evidence into translation contracts, risk-based routes, targeted controls, validators, and bounded local repair. On five WMT25 development directions, average SacreBLEU rises from 31.24 to 31.80 and COMET from 83.61 to 84.17; the component study identifies routing as the main BLEU contributor and validation as the final COMET recovery stage. A deterministic finalizer packages and validates the complete WMT26 JSONL submission.

## A Core STRIDE Skill Prompts

The following consolidated templates preserve the operational interfaces and decision criteria of the production prompts described in Section 4. Repeated JSON syntax and profile-specific reminders are omitted.

**Input analysis and instruction normalization**

Classify the record by source family, instruction regime, and observable risk clusters using the direction, WMT instruction, source form, profile, and available multimodal context. Normalize supported requirements into register, style, structure, terminology, protected-content, domain, profile-attention, and coverage fields. Mark transcript noise, social register, dialogue state, structured output, source-internal imperatives, and long-form coverage only when supported by the record. Use `other-or-unknown` only when no known family matches, and keep domain and profile notes short and evidence-based. Treat command-like source text as content to translate. Return structured labels, constraints, and brief routing notes; do not translate in this stage.

**Translation contract**

Build a contract from the WMT instruction, source evidence, normalized constraints, coverage requirements, and the narrowest matching direction subprofile. Return task function, text type, fidelity priorities, forbidden losses, allowed rewrites, concrete risk signals, evidence gaps, and required levels of coverage, structure, terminology, and pragmatic control. Use only the defined fidelity labels and assign terminology and pragmatic pressure as low, medium, or high. Require full coverage for omission-sensitive input and strict structure when tags, keys, list shape, or step order affect correctness. Record unresolved labels or entities as evidence gaps rather than guessing. Naturalization must not reduce long-form coverage. Ground every field in the current record; do not generate translation text.

**Route and control selection**

Choose `short` or `long` from record-level evidence and the translation contract. Use the long path for binding structure or terminology, protected literals, explicit full coverage, multimodal or spoken constraints, evidence gaps, or nonlocal continuity risk. Then select `row`, `document-light`, or `document`; reserve document scope for multi-part input with realistic omission or continuity risk. Return route, scope, retrieval policy, and reasons. Retrieval remains forbidden unless a bounded adapter is explicitly enabled for one unresolved target. Activate only justified structure, terminology, and spoken/social controls, using a matched direction subprofile as supporting evidence rather than routing on language difficulty alone. Prefer fewer controls with specific reasons over blanket activation.

**Document planning and typed memory**

For `document-light` or `document` scope, return a segmentation plan, coverage map, term-freeze plan, and segment-local repair policy. Map all required source units, flag omission-prone later content, preserve paragraph order, and freeze recurring names, labels, or glossary items. Carry forward only context needed by later segments through an entity ledger, glossary cache, discourse summary, or prior-segment reminders. Prefer ledgers and glossary caches for document-light rows; use summaries or immediate reminders only when cross-segment discourse requires them. Select memory types with explicit reasons and omit memory for short local rows. Keep repairs segment-local and forbid a full rewrite when compression is the main risk.

**Validation and repair**

Select only validators justified by the contract: structure for formal invariants, terminology for fixed terms and recurring entities, and coverage for plausible omission or compression. Align structure by ordered tags, placeholders, literals, keys, and list markers; terminology by glossary entries and a local entity ledger; and coverage by paragraphs, newline-delimited items, or planned segments, including the final unit. Treat broken structure and omitted required units as critical, recoverable fixed-term inconsistency as major, and local style deviation as minor. Report severity, evidence, affected content, and repair scope. Repair the affected span once, preserve content that passed, and rerun the responsible validator once. If rechecking fails, record the unresolved constraint and retain the most complete candidate.

**Decision trace**

Emit a compact JSON trace after planning. Record the matched source family, instruction regime, risk clusters, direction subprofile, route, execution scope, retrieval decision, active controls, requested validators, repair policy, document plan, and typed-memory decision in execution order. Place a matched subprofile near the beginning when it materially changes the plan. For each decision family, provide short evidence-based rationales that explain why the record stayed local or received additional control. Add theory links only when they clarify a fidelity decision. Keep entries concrete and auditable rather than essay-like, and exclude source or translation text from the trace.

## Abstract

This work describes the Grial-TA team submission to the constrained track of WMT2026 General Machine Translation Task (Kocmi et al., 2026) for the following language pairs: English to-Icelandic, English-to-Ladin and English-to-Ligurian. Our submission leverages full fine-tuning of the SalamandraTA-7b-instruct model. Two separated models were fine-tuned: one for Icelandic and one for Ligurian and Ladin. To address the problem of data scarcity inherent to such low-resource languages, we implemented a data augmentation strategy based on two complementary approaches: generating synthetic back-translation into English for all language pairs, and incorporating parallel data from related Romance languages for Ladin and Ligurian.

## 1 Introduction

Machine translation (MT) is a subfield of computational linguistics that focuses on the conversion of text or speech from one language to another using computational algorithms. Since the launch of large language models (LLMs) to the general public, MT has evolved exponentially and improved translation to the point where it resembles professional human translation (Sizov et al., 2024). However, MT into low-resource languages still faces some challenges due to a lack of parallel corpora and the predominance of high-resource languages used in training (Shu et al., 2024). In order to advance research in this area of knowledge, the Grial-TA team has participated in the constrained track of the WMT2026 General Machine Translation shared task. The task aims to improve and evaluate current MT methods. Among the goals of this edition, our contribution focuses on investigating the translation of low-resource, morphologically rich languages. Specifically, we selected English-to-Ladin and English-to-Ligurian as low-resource language pairs, along with English-to-Icelandic which is both low-resource and morphologically rich. To train our system on these language pairs, we created parallel corpora from Wikipedia, aligning with the overall goal of building publicly available resources for low-resource machine translation.

## 2 Resources

In this section, we specify the training resources, processing tools and data augmentation strategies used in our workflow. Specifically, Subsection 2.1 introduces the pipeline for extracting corpora from Wikipedia, while Subsection 2.2 covers the creation of a language identification tool specifically designed for Romance languages. Finally, Subsection 2.3 details the data augmentation strategy that we implemented to address data scarcity.

### 2.1 Corpus creation from Wikipedia

Wikipedia has long been recognized as a fundamental resource for building large-scale, multilingual corpora due to its vast size, broad domain coverage, and permissive licensing. It is also a particularly valuable source for building corpora for low-resource languages, which is precisely the case for Ligurian and Ladin, languages for which data availability is extremely limited.

We used the tool `corpus-from-wikipedia` (Segués et al., 2026) to create parallel corpora aligning English with both our primary target languages (Ladin, Ligurian and Icelandic) and related Romance languages (Friulian, Lombard, Piedmontese, Romansh and Latin). These auxiliary resources serve to address severe data scarcity for Ladin and Ligurian by complementing the training set with parallel corpora from related languages.

In the following subsections we describe the key steps we followed to build the corpora (see Figure 1 for a step-by-step illustration).

* Corresponding author.

*Proceedings of the Eleventh Conference on Machine Translation*, pages 1221–1230
October 28-29, 2026 ©2026 Association for Computational Linguistics

**Text extraction**

The first step consisted in processing the entire Wikipedia dump (released 01/04/2026) and extracting all articles for both languages of each pair. To prevent data imbalance between English and less-resourced languages, we restricted the extraction only to articles shared by both languages, retaining only the English pages with a corresponding counterpart in the target language.

**Sentence segmentation and deduplication**

The extracted page content was segmented into sentences using a set of discrete rules defined in a Segmentation Rules eXchange (SRX) file. Since our SRX file does not support Icelandic or Ligurian, we used Stanza (Qi et al., 2020) to segment the articles. Given that Ladin is also not supported in our SRX file or other external Python libraries we segmented the text using the generic rules of our SRX file. After segmentation, the sentences were deduplicated to guarantee a final corpus of unique segments.

**Sentence alignment**

The subsequent step in the pipeline was sentence alignment for each pair of languages. It should be noted that equivalent Wikipedia pages in two different languages are independent texts and are not necessarily translations of each other, although some content may overlap. Consequently, creating a parallel corpus from this source is not a classical text alignment task. Instead, it is a process of bitext mining, which involves searching for parallel segments within comparable, non-parallel documents. First, the deduplicated sentences were filtered by character length, restricting them to segments between 10 and 200 characters. We used the pre-trained Language-agnostic BERT Sentence Embedding (LaBSE) model, implemented via the `sentence-transformers` library (Reimers and Gurevych, 2020) to encode the segments into a vector space. We then used Faiss (Johnson et al., 2021) to conduct a bidirectional exact $k$-NN search, retrieving the $k = 4$ closest matches for each segment. We calibrated the candidate scores using a ratio-based margin function, meaning a pair received a high score only if the two segments exhibited strong mutual similarity relative to their local neighborhoods. Finally, the highest-scoring candidates from the bidirectional search were aggregated and globally ranked. The final parallel sentences were extracted if their margin score exceeded a threshold of 1.0. If the source or target segment had already been assigned to a higher-scoring pair, the candidate was discarded. This ensured that only the most reliable alignments were retained for the final corpus.

**Language verification and rescoring**

Since the alignment may contain errors, such as segments not in the expected language, we applied the rescoring algorithm described by Oliver and Álvarez (2023) to clean the aligned corpus from cross-lingual noise. This algorithm uses `lid.176.bin` (Joulin et al., 2016), a language identification model based on fastText[1]. This model is trained on large multilingual datasets and supports 176 languages, however, Ligurian and Ladin are not included, a challenge detailed in section 2.2.

**Filtering and selection of final segments**

Following the rescoring step, we selected the rescored segments based on two key metrics: language detection confidence and similarity between segments. The defined threshold for these two metrics is 0.75, that is, segments need to have a language detection score and a similarity score of 0.75 or higher. Segments that met both thresholds were retained to form the final corpus. The final Wikipedia corpora statistics are presented in Table 1; the "Selected" column represents the final corpus size for each pair of languages.

## 2.2 Language detection in Ligurian and Ladin

As mentioned in section 2.1, the fastText language identification model `lid.176.bin` does not support Ligurian or Ladin. Given that reliable language identification is essential for building parallel corpora from Wikipedia, we created a new language detector tailored to those two languages, alongside the additionl Romance languages introducted above. Some of these languages are already supported in the fastText model, which, however, is not always accurate in recognizing them. Furthermore, considering the languages that are most likely to appear in the Wikipedia texts we intend to process, we also included Italian, French, German, Spanish, and English. In total, the final detector covers 12 languages: Ladin, Ligurian, Piedmontese, Lombard, Romansh, Friulian, Latin, Italian, French, English, German, and Spanish.

When building a language detector it is important to keep the training data balanced,

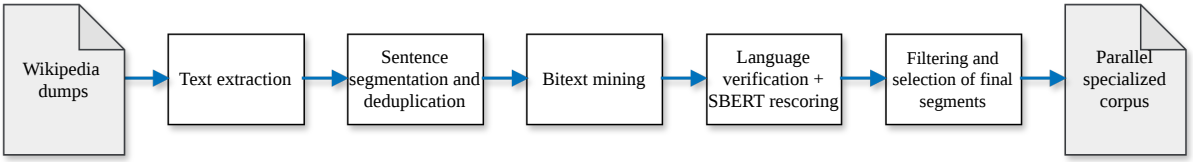

Figure 1: Corpus from Wikipedia contruction pipeline.

| Language Pair | Unique (SL) | Unique (TL) | Unaligned (SL) | Unaligned (TL) | Aligned | Selected |
|---|---|---|---|---|---|---|
| Icelandic-English | 947,697 | 4,323,323 | 417,499 | 3,792,373 | 530,983 | 50,134 |
| Ligurian-English | 80,491 | 901,359 | 40,713 | 861,567 | 39,792 | 616 |
| Ladin-English | 277,879 | 2,398,258 | 209,946 | 2,329,220 | 69,056 | 1,315 |
| Lombard-English | 306,334 | 2,055,737 | 170,560 | 1,919,976 | 135,780 | 5,196 |
| Piedmontese-English | 324,868 | 1,791,042 | 211,093 | 1,677,193 | 113,856 | 4,539 |
| Friulian-English | 53,188 | 349,484 | 28,015 | 324,302 | 25,182 | 899 |
| Romansh-English | 117,890 | 208,027 | 65,859 | 155,852 | 52,176 | 1,268 |
| Latin-English | 1,775,569 | 3,033,232 | 1,167,809 | 2,425,153 | 608,159 | 17,667 |

Table 1: Corpora statistics.

i.e., each language should be represented by a similar number of examples to prevent the model from becoming biased towards languages with more representation. In our case, we aimed for around 100,000 segments per language. For major languages such as English, Spanish, French, Italian, or German, we sourced the data from Wikipedia, following the workflow described in section 2.1. We extracted 300,000 random sentences from each monolingual corpus, labeled them by language using the fastText language identification model and randomly sampled 100,000 in the corresponding language from the resulting ones. We followed the same process with Piedmontese, given that it is already a language supported in said model. Although Romansh and Lombard are also supported, the model fails to detect these languages accurately in most cases. For this reason, rather than extracting segments specifically labeled as Romansh/Lombard, we opted to filter out the most prevalent majority languages. After manually reviewing a substantial portion of the data, we established a negative filtering threshold: any segment classified as English, German, or French with a confidence score of 0.60 or higher was removed from the data. Friulan was not supported by the original detector, but followed the same process as we did for Lombard and Romansh. For Ligurian and Ladin we did not source the data from Wikipedia. Instead, we decided to use data that were made available by the organizers of the shared task. For Ladin we used the `Sfrontull-la_usc_valbadia_loresmt24-1-lld.lld` dataset. It contains 237,343 segments from which we randomly selected 100,000. For Ligurian we used the `Conseggioligure-linc-1-lij_Latn.lij_Latn` dataset. After segmentation, it resulted in a final corpus of 84,611 segments. For Latin we created a corpus from Perseus[2], a free digital library of classical texts, from which we also randomly selected 100,000 segments.

Subsequently, the compiled data was partitioned into training and test sets following a 90:10 split. When evaluated on this held-out data, our language identification model achieved a precision at 1 (P@1) and recall at 1 (R@1) of 0.967, demonstrating robust overall performance. Both metrics are computed at k=1, considering only the top-ranked prediction. A class-level evaluation on the test set reveals that major languages achieve high scores (around 0.99 F1-score), indicating strong and balanced classification. Conversely, low-resource languages like Lombard and Ligurian exhibit lower performance (0.85–0.87 F1-score). This disparity reflects the challenge of distinguishing closely related varieties and underscores the impact of training data quality, given the inherent noise present in the raw Wikipedia source texts. The complete performance metrics data can be seen in Table 2.

### 2.3 Data augmentation strategy

To address the severe parallel data scarcity inherent to our three target language pairs, we implemented a data augmentation strategy aimed at expanding our training set prior to model fine-

[2] https://www.perseus.tufts.edu/hopper/

| Language | Precision | Recall | F1-Score |
|---|---|---|---|
| English | 0.994 | 0.996 | 0.995 |
| German | 0.996 | 0.998 | 0.997 |
| Latin | 0.991 | 0.991 | 0.991 |
| Italian | 0.966 | 0.982 | 0.974 |
| Piedmontese | 0.998 | 0.984 | 0.991 |
| Ladin | 0.998 | 0.995 | 0.997 |
| French | 0.994 | 0.996 | 0.995 |
| Spanish | 0.995 | 0.996 | 0.995 |
| Ligurian | 0.968 | 0.954 | 0.961 |
| Lombard | 0.843 | 0.896 | 0.868 |
| Romansh | 0.945 | 0.903 | 0.923 |
| Friulian | 0.863 | 0.836 | 0.849 |

Table 2: Language detection performance metrics by language.

tuning. Our strategy relied on two complementary approaches: generating synthetic back-translation into English for all language pairs, and the incorporation of parallel data from related Romance languages for Ladin and Ligurian. The use of back-translated synthetic data aligns with established pratices in low-resource MT settings (Sennrich et al., 2016; Ranathunga et al., 2023). Leveraging Large Language Models (LLMs) to generate synthetic parallel data via back-translation into a high-resource language (e.g., English) relies on the well-documented asymmetric capabilities of LLMs (Nguyen et al., 2024). Because LLMs exhibit significantly stronger generative fluency and semantic accuracy when mapping low-resource inputs into their English-dominant pre-training space, translating toward English yields high-quality target sentences that serve as reliable back-translated training data. We incorporated back-translated data into English for all three target languages: Icelandic, Ladin and Ligurian. The specific source monolingual corpora and the models selected for the back-translation process are detailed in the next section.

## 3 Training of the systems

### 3.1 English-Icelandic

#### 3.1.1 Evaluation of existing models

In this subsection we present the evaluation of some of the existing models able to translate from English into Icelandic. This would help us choose which system to select for the fine-tuning process and to assess whether our fine-tuned model achieves competitive evaluation figures. In Table 3 we can observe the evaluation figures for the English-Icelandic language pair. The evaluation was performed using the newtest2019 reference sets (eng-GB, for English) with 1,997 segments.

| System | BLEU | chrF2 | TER | COMET |
|---|---|---|---|---|
| SalamandraTA7b | 29.7 | 56.1 | 57.2 | 0.8567 |
| TowerPlus2B | 32.8 | 58.6 | 56.6 | 0.8704 |
| TowerPlus9B | 38.3 | 62.9 | 49.4 | 0.8811 |
| TowerPlus27B | **39.5** | **63.3** | **49.2** | **0.8792** |
| TranslateGemma4b | 14.0 | 40.6 | 81.9 | 0.7050 |
| TranslateGemma12b | 20.3 | 50.6 | 72.1 | 0.8407 |
| TranslateGemma27b | 21.5 | 52.6 | 74.2 | 0.8591 |

Table 3: Evaluation results for some existing models for English-Icelandic.

Regarding the English-to-Icelandic translation task (Table 3), performance varies significantly depending on model family and parameter size. TowerPlus27B consistently achieves the highest scores across all surface-level metrics, peaking at 39.5 BLEU, 63.3 chrF2, and a low 49.2 TER, closely followed by its 9B counterpart, which yields a slightly higher COMET score of 0.8811. A clear scaling effect is evident within both the TowerPlus and TranslateGemma model families, as larger parameter counts systematically yield better translation quality. Notably, TranslateGemma models lag considerably behind in this direction, with the 4B variant underperforming substantially (14.0 BLEU, 81.9 TER), highlighting the inherent challenge of translating from English into a morphologically rich target language like Icelandic.

Conversely, we present the evaluation figures using the same reference corpus for the Icelandic-English language pairs (Table 4). These figures can guide us to select the model to perform back-translation of the monolingual Icelandic corpora.

| System | BLEU | chrF2 | TER | COMET |
|---|---|---|---|---|
| SalamandraTA7b | **40.6** | 63.5 | **46.8** | 0.8768 |
| TowerPlus2B | 35.5 | 61.6 | 52.8 | 0.8708 |
| TowerPlus9B | 38.8 | **63.7** | 49.2 | **0.8787** |
| TowerPlus27B | 38.0 | 63.5 | 49.8 | 0.8773 |
| TranslateGemma4b | 24.6 | 53.5 | 67.2 | 0.8364 |
| TranslateGemma12b | 29.1 | 58.4 | 61.3 | 0.8600 |
| TranslateGemma27b | 30.1 | 59.7 | 58.8 | 0.8667 |

Table 4: Evaluation results for some existing models for Icelandic-English.

For the Icelandic-to-English language pair, performance across all systems shows a marked improvement, reflecting the reduced generation complexity when translating into English. Surprisingly, SalamandraTA7b outperforms all larger architectures in lexically oriented metrics, attaining the best overall BLEU (40.6) and TER (46.8). Meanwhile, TowerPlus9B demonstrates superior seman-

tic alignment, reaching top scores in chrF2 (63.7) and COMET (0.8787). Unlike the reverse direction, scaling parameter size within the TowerPlus family yields diminishing returns here, as TowerPlus27B performs slightly below the 9B model across all metrics. The TranslateGemma suite also exhibits substantial gains compared to the opposite direction, though it remains secondary to the leading systems.

Comparing both translation directions reveals a clear asymmetry in performance between translating into and out of Icelandic. All evaluated models achieve substantially higher baseline metrics when translating into English, primarily due to English having simpler inflectional morphology and broader representation in pre-training corpora. This contrast is particularly pronounced for SalamandraTA7b, which gains over 10 BLEU points in the Icelandic-to-English direction (40.6 vs. 29.7), effectively jumping from a mid-tier model into the top-performing position. Furthermore, while translating into Icelandic strongly favors scaled models like TowerPlus27B to handle complex target grammar, translating into English allows mid-sized models, such as TowerPlus9B and SalamandraTA7b, to compete with or even surpass their larger counterparts, making them optimal, computationally efficient candidates for back-translation pipelines.

Based on these evaluation results, SalamandraTA-7b-instruct [3] was selected to perform the back-translation of the monolingual Icelandic corpora into English. Although TowerPlus9B marginally outperforms SalamandraTA-7b in chrF2 and COMET for the Icelandic-to-English task, this advantage is negligible compared to SalamandraTA-7b's substantial lead in BLEU (+1.8 points) and TER (-2.4 points). Given its superior lexical accuracy, lower translation error rate, and greater computational efficiency, SalamandraTA-7b represents the most optimal candidate for generating high-quality synthetic parallel data. Furthermore, although it did not emerge as the top-performing model in the English-Icelandic evaluation figures, SalamandraTA-7b was selected for fine-tuning in accordance with our initial research design.

### 3.1.2 Corpora

To train and fine-tune the models we have used the parallel corpora and the back-translated corpora shown in Table 5. We generated the back-translated segments from unaligned Icelandic Wikipedia segments (Table 1 ). These segments were first cleaned of cross-lingual noise using the `lid.176.bin` language detector, and subsequently back-translated using the SalamandraTA-7b-instruct. The MTUOC parallel corpus[4] is created by concatenation, deduplication and rescoring of the NLLB, Paracrawl, HPLT and MacoCu corpora.

| Corpus | Segments |
|---|---|
| Wikipedia | 50,134 |
| MTUOC | 8,559,292 |
| **TOTAL PARALLEL** | **8,607,936** |
| **TOTAL BACK-TRANSLATED** | **244,689** |

Table 5: Size of the parallel corpora for English-Icelandic.

The training, validation and evaluation corpora have been created from the parallel corpus. Validation and evaluation sets have 5,000 segments.

### 3.1.3 Training Eole

To train the Eole models we used a configuration of an asymmetric Transformer sequence-to-sequence model—featuring a deep 24-layer encoder and a 6-layer decoder with a hidden dimension of 1024 and 16 attention heads—operating on a shared 64,000-token vocabulary. Leveraging multi-GPU distributed training in half-precision floating-point (fp16), it processed a batch size of 65,536 tokens per step (achieved via a 4,096-token per-device allocation and 4 gradient accumulation steps). The setup is optimized using Adam with a Noam decay schedule (peak learning rate of 1.5 and 8,000 warmup steps), complemented by standard regularization techniques like 0.1 dropout and 0.1 label smoothing. Finally, the training is capped at 200,000 steps, evaluating and checkpointing every 1,000 steps, while maintaining the 15 most recent checkpoints and applying early stopping after 10 non-improving validation rounds.

### 3.1.4 Fine-tuning SalamandraTA-7b-instruct

The training setup implements a full fine-tuning (FFT) procedure utilizing a ChatML format with specialized control tokens (<|im_start|> and <|im_end|>). Sequences are packed up to a maximum context length of 2,048 tokens and processed

[3] https://huggingface.co/BSC-LT/salamandra-7b-instruct-2606

[4] https://huggingface.co/datasets/aoliverg/MTUOC-corpus-eng-ice

with a global batch size of 256. Optimization is performed using the AdamW optimizer with a cosine learning rate scheduler, set to an initial learning rate of $2 \times 10^{-5}$, for a maximum of three epochs. To accelerate training and optimize memory bandwidth, the infrastructure employs bfloat16 precision, FlashAttention, and Fully Sharded Data Parallel (FSDP) across a multi-GPU environment. Model validation is conducted every 500 steps, integrating an early stopping mechanism based on evaluation loss (with a patience of three evaluation intervals) to automatically restore the best-performing checkpoint upon training completion.

The training and validation corpora have been converted into jsonl files with the following structure:

```
{"conversations": [{"from": "human", "value":
↪  "Translate the following text from English
↪  into Icelandic.\nEnglish: He actually
↪  received the award in year
↪  1922.\nIcelandic:"}, {"from": "gpt", "value":
↪  "Hann fékk verðlaunin 1922."}]}
```

#### 3.1.5 Evaluation of the trained and fine-tuned models

As presented in Table 6, the evaluation of the three fine-tuning checkpoints of SalamandraTA on the English-to-Icelandic task reveals a notable divergence between lexical overlap metrics and neural semantic evaluation. Across all training checkpoints (`cp10000`, `cp11000`, and `cp11500`), model performance remains remarkably stable, indicating that training effectively converged by step 10,000 with minimal metric fluctuation thereafter. The fine-tuned SalamandraTA models consistently outperform the baseline NMT Eole model across all evaluated metrics. However, when comparing these values with the baseline evaluation of existing systems in Table 4, we observe that on this specific benchmark dataset (newstest2019), the fine-tuned models underperform relative to the base SalamandraTA-7b-instruct model.

| System | BLEU | chrF2 | TER | COMET |
|---|---|---|---|---|
| eval.en-Eole.is | 24.1 | 51.4 | 61.6 | 0.7829 |
| eval.en-cp10000.is | **25.9** | **52.8** | **61.1** | **0.8245** |
| eval.en-cp11000.is | 25.4 | 52.3 | 62.2 | 0.8226 |
| eval.en-cp11500.is | 25.2 | 52.0 | 63.3 | 0.8217 |

Table 6: Evaluation results of the trained Eole and fine-tuned SalamandraTA-7b models for English-Icelandic.

After auditing the fine-tuning algorithms, datasets, and training pipeline without identifying any operational errors, we re-evaluated both the trained Eole and fine-tuned SalamandraTA models on an in-house evaluation set. This dataset consists of 5,000 segments sampled from the parallel corpora described in Section 3.1.2. Table 7 details these results alongside the baseline performance of SalamandraTA-7b-instruct.

| System | BLEU | chrF2 | TER | COMET |
|---|---|---|---|---|
| SalamandraTA7b | 37.0 | 59.2 | 52.1 | 0.8701 |
| Eole | 74.4 | 83.6 | 20.2 | 0.9219 |
| cp10000 | 60.6 | 74.5 | 32.0 | 0.8988 |
| cp11000 | 60.5 | 74.5 | 32.2 | 0.8978 |
| cp11500 | 60.6 | 74.5 | 32.1 | 0.8973 |

Table 7: Evaluation results of the trained Eole and fine-tuned SalamandraTA-7b models for English-Icelandic with our evaluation set.

On this target evaluation set, both the Eole model and the fine-tuned SalamandraTA variants substantially outperform the base instruction-tuned model. We performed a strict overlap check across the training, validation, and test splits to rule out data contamination. Although these mixed results make it difficult to conclusively claim that the fine-tuned model outperforms the base model across all contexts, they demonstrate that both the training of Eole and the fine-tuning process of SalamandraTA functioned as intended. The marked performance gains on our evaluation set, along with the high metric stability across checkpoints, confirm that the models successfully adapted to the target dataset distribution. Consequently, checkpoint 11500 was selected for the final shared task submission.

### 3.2 English-Ligurian and English-Ladin

#### 3.2.1 Existing MT systems

To our knowledge, there are not many machine translation systems available for these language pairs. The systems we identified and evaluated are: opus-mt-en-ROMANCE for Ligurian and Ladin, and GoogleTranslate for Ligurian. The performance of these systems is reported together with the results of our SalamandraTA-7b-instruct in subsection 3.2.4.

#### 3.2.2 Corpora

As we detailed in Section 2.3, due to the extreme scarcity of parallel resources for English to Ligurian and Ladin, we expanded our data augmentation strategy beyond back-translation. Specifically, we combined back-translation into English,

executed using the `gemma-4-31b-it` model, with parallel data from closely related Romance languages. For these auxiliary Romance languages, we gathered both authentic parallel corpora and synthetic back-translated segments to maximize cross-lingual transfer, as shown in Table 8.

| Language | Parallel | Back-translated |
|---|---|---|
| Ligurian | 2,244 | 79,721 |
| Ladin | 4,340 | 455,775 |
| Friulian | 899 | 23,355 |
| Lombard | 5,196 | 51,373 |
| Piedmontese | 4,539 | 126,464 |
| Romansh | 1,268 | 8,956 |
| Latin | 15,733 | 340,392 |

Table 8: Number of parallel and back-translated segments per language.

These corpora derive from the Wikipedia extraction pipeline that we described in Section 2.1, supplemented by a subset of the WMT26 General MT task datasets. Specifically, for Ladin and Ligurian, we incorporated a selection of the parallel and monolingual resources provided by the task organizers. Since the parallel material was provided as unaligned monolingual files, we aligned and paired them into parallel corpora. Table 9 provides an overview of the task's corpora that we used.

The validation and evaluation corpora have been extracted from the parallel corpora, with a size of 1,000 segments for Ladin and of 500 segments for Ligurian.

#### 3.2.3 Fine-tuning SalamandraTA-7b-instruct

We used the same fine-tuning configuration described in subsection 3.1.4.

#### 3.2.4 Evaluation of the fine-tuned models

| System | BLEU | chrF2 | TER |
|---|---|---|---|
| OpusMTROMANCE | 2.2 | 28.9 | 91.2 |
| GoogleT | 24.0 | 49.9 | 64.5 |
| FT-cp1000 | 16.4 | 44.2 | 76.3 |
| FT-cp1500 | 18.1 | 45.7 | 73.9 |
| FT-cp1911 | 18.2 | 45.6 | 73.6 |

Table 10: Evaluation for English-Ligurian.

We evaluated our full fine-tuned (FFT) systems across three distinct training checkpoints (cp1000, cp1500, and cp1911) and compared their performance against available baselines, specifically OpusMTROMANCE and Google Translate. Automatic evaluation was conducted using BLEU, chrF2, and TER metrics. It should be noted that COMET scores are not reported, as the currently available COMET models do not provide support for these specific low-resource language pairs. The evaluation corpora are the one extracted from the real parallel corpora for Ligurian and Ladin as described in 3.2.2.

Table 10 presents the performance of the systems on the English–Ligurian task. While Google Translate achieves the highest performance across all metrics (24.0 BLEU, 49.9 chrF2), our FFT models demonstrate consistent progression as training advances. The model performance improves significantly from cp1000 (16.4 BLEU) to cp1500 (18.1 BLEU), reaching a plateau at cp1911 (18.2 BLEU). Although our fine-tuned systems fall short of Google Translate, they substantially outperform OpusMTROMANCE, which yields particularly poor translation quality (2.2 BLEU and a high TER of 91.2).

For English–Ladin, the evaluation results are reported in Table 11. Notably, Google Translate does not support this language pair. In this scenario, all our fine-tuned checkpoints outperform the OpusMTROMANCE baseline by a large margin. Our systems achieve optimal performance at cp1500 and cp1911, reaching up to 39.9 BLEU and 63.5 chrF2, while drastically reducing the TER from 98.3 (OpusMTROMANCE) to under 56. Overall, these results demonstrate the effectiveness of our fine-tuning approach.

| System | BLEU | chrF2 | TER |
|---|---|---|---|
| OpusMTROMANCE | 25.4 | 37.4 | 98.3 |
| FT-cp1000 | 36.8 | 61.9 | 62.0 |
| FT-cp1500 | 39.9 | 63.5 | 55.8 |
| FT-cp1911 | 38.9 | 63.5 | 55.7 |

Table 11: Evaluation for English-Ladin.

## 4 Participation in the shared task

We participated in the constrained track of the WMT2026 General Machine Translation Task for the following language pairs: English to-Icelandic, English-to-Ladin and English-to-Ligurian.

To perform the translation we started an MTUOC-server (Oliver, 2025) with the given model. Then we created a script that read the task's json and translated the segments in the corresponding languages connecting to the MTUOC-server. To perform all the task, then, we used two fine-tuned SalamandraTA-7b-instruct models: one for English-Icelandic, and another for English to Ladin

| Ligurian | Ladin |
|---|---|

and Ligurian.

## 5 Conclusion and Future Work

In this work, we presented the Grial-TA team's submission to the WMT2026 General Machine Translation shared task (constrained track) for English into Icelandic, Ladin, and Ligurian. Our strategy relied on full fine-tuning (FFT) of the SalamandraTA-7b-instruct model, supported by a pipeline of custom parallel corpus extraction from Wikipedia, custom language identification, and LLM-based synthetic back-translation.

Our evaluation yields promising results across all targeted language pairs:

- **English–Icelandic:** While traditional sequence-to-sequence baselines (Eole) achieved higher surface-level lexical scores (BLEU), the fine-tuned SalamandraTA models demonstrated superior semantic adequacy and fluency, outperforming Eole in COMET (0.8190 vs. 0.7829).
- **English–Ladin & English–Ligurian:** For these extremely low-resource scenarios, cross-lingual transfer from related Romance languages combined with synthetic back-translation proved highly effective. Our fine-tuned models drastically outperformed available baselines (e.g., OpusMTROMANCE) on Ladin (reaching 39.9 BLEU), and built a competitive baseline for Ligurian (18.2 BLEU).

Although the official human and automatic evaluation rankings from the WMT26 Shared Task organizers are yet to be published, our internal benchmarks indicate that targeted full fine-tuning of mid-sized LLMs is a robust path forward for low-resource MT.

**Open Science and Reproducibility:** In commitment to open research, all code, processing scripts, and pipelines used in this work are publicly available on GitHub.[5] Furthermore, the fine-tuned translation models can be directly downloaded and deployed as ready-to-use recipes for the MTUOC-server via Hugging Face.[6]

**Future Work:** Moving forward, within the framework of the *LLMTrad-IBE* project, we aim to extend the insights and methodologies established for Ladin and Ligurian to low-resource Romance languages spoken in the Iberian Peninsula, namely Asturian, Aragonese, Aranese, and Eonavian. We plan to explore refined multilingual fine-tuning paradigms, instruction tuning, and enhanced synthetic data generation techniques to further bridge the gap for lesser-resourced linguistic communities. Additionally, we plan to conduct an ablation study to systematically evaluate the real impact of our data augmentation strategies, in order to provide valuable insights for future research on low-resource languages.

## A Computing Infrastructure

All training and fine-tuning experiments were carried out on a high-performance computing node equipped with four NVIDIA RTX PRO 6000 Blackwell Edition GPUs (96 GB VRAM per card, totaling 384 GB VRAM). The hardware setup was driven by two 16-Core AMD EPYC 9135 processors (combining for 32 physical cores) alongside 384 GB of system RAM, executing on Ubuntu 22.04.5 LTS.

Appendix B shows the time and energy consumption of all the the training and finetuning processes performed during the shared task participation.

## Abstract

We describe the system Dubformer entered in the WMT26 General MT shared task, an unconstrained system built on our video-dubbing pipeline. It rests on two commitments. A document is never translated as raw text: it is first decomposed into a structure chosen for its domain — scenes carrying speaker and audio-visual context for spoken dialogue, markup-masked segments for web documents, value-only segments for localization resources — so that non-linguistic material is protected by construction and everything needed for consistency is in front of the model at once. And no translation is taken on trust: every segment is checked by a second model from a different family for hallucination and for drift from the meaning of the source, and a segment it rejects is re-translated with the reason attached rather than filled in from a fallback.

## 1 Introduction

The system has two paths. Spoken dialogue is translated by our video-dubbing pipeline, driven directly; its central commitment is that a spoken-dialogue document is translated *from the video* rather than from a transcript of it. Web documents, social posts and localization resources need none of that machinery, so for them we built a thin harness of our own, shaped by what running that pipeline had taught us: protect structure by construction, and check every translation before it ships.

The task setup follows the previous edition of the shared task (Kocmi et al., 2025). §2 states what the two paths share and where they diverge. This report describes the design and the reasoning behind it. It reports no results on the shared-task test set; where it appeals to evidence, that evidence is internal and is marked as such.

## 2 What the domains share, and where they differ

Two things are common to both paths (Figure 1). No part of a document is translated in isolation: a short document goes to the model whole, a scene of a longer one carries the document's context and its neighbours. Translating a document as a whole rather than sentence by sentence is known to help, and to leave critical errors that context alone does not remove (Karpinska and Iyyer, 2023) — which is what the second property is for. And every line is written by the model from the source, never edited from a machine-translated draft, then checked by an independent auditor whose rejections are re-translated rather than replaced from a fallback (§5).

What differs is how a document is prepared for that call: how it is cut into segments that can be reassembled afterwards, what context accompanies them, and which instruction the model is given. Spoken dialogue is cut into scenes over a transcript we produce ourselves — a clip is usually short enough to be one scene — carrying speaker identity, per-speaker gender and a note taken from the video and its audio; the prompt is the dubbing engine's own, plus a per-target directive fixing language variety, script and region (§3). In the other three domains the instruction shipped with each blindset row is authoritative and reaches the model verbatim on top of a fixed base translator prompt; web documents and social posts are cut into text segments with inline markup masked, social posts also carrying screenshots of the page, and localization resources into translatable values only, their keys exposed as context but never translated (§4). Domains are not labeled in the blindset, so the path is recovered from marker phrases in each row's instruction. Table 1 lists the model used at each stage.

*Proceedings of the Eleventh Conference on Machine Translation*, pages 1231–1234

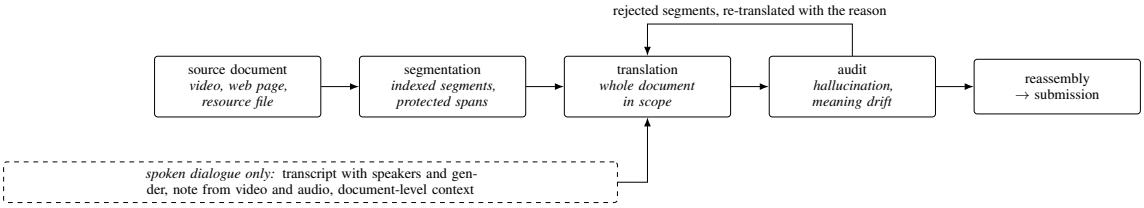

Figure 1: The pipeline is the same for every domain; what changes is how a document is cut into segments and, for spoken dialogue only, the extra context assembled before translation. A rejected segment goes back through the same translation call rather than to any fallback.

| Stage | Model |
|---|---|
| transcription | Scribe v2 |
| speakers | ECAPA-TDNN clustering |
| gender | SVM over the same embeddings |
| note from video and audio | Gemini 3.1 Pro |
| document context | Claude Opus 4.8 |
| scene translation | Claude Sonnet 4.6 |
| document translation | Claude Sonnet 4.6 |
| audit | Gemini 3.1 Pro |

Table 1: Models by stage: everything above *document translation* is the spoken-dialogue path. The audit runs the same model on both paths, configured more strictly for speech. The strongest model goes on document-level context, which every later stage inherits. Speaker embeddings are ECAPA-TDNN (Desplanques et al., 2020) as packaged by SpeechBrain (Ravanelli et al., 2021); the gender head is an SVM we trained on VoxCeleb1 (Nagrani et al., 2017).

## 3 Spoken dialogue

**The video is the input.** We transcribe the video ourselves rather than take the transcript shipped with the blindset. Recognition stays with a dedicated ASR system: the multimodal model that later reads the scene is used to catch where a transcript is wrong, never to produce it. The transcription is then ours to control, which matters most for timing: speaker segmentation and the per-speaker gender attribution derived from the audio are computed against those timings, and several of our target languages need gender to get agreement right — a known difficulty when the source language does not mark it, and one where the audio carries information the transcript does not (Bentivogli et al., 2020).

**Disfluencies are removed at translation time, not at transcription time.** Transcription runs in verbatim mode — our ASR has a flag that strips filled pauses, repetitions and false starts, and we deliberately leave it off. The disfluency policy is expressed instead as instructions to the translator, which drops them while keeping genuine interjections, since those carry attitude the dialogue would lose. The principle is to separate *what was heard* from *what gets written*: the transcript remains a faithful record of the audio, and the cleanup becomes a translation decision made with the surrounding context available, rather than a transcription setting applied blindly at the word level.

**What the picture and the audio add.** Before translation, a multimodal model both watches and listens to each scene and produces a note about it: the setting, who is on screen and their apparent gender, the tone, register cues, and per-caption notes wherever the recording resolves something the text leaves open — deixis, an addressee, whether a line is sarcastic. Hearing the audio and not only the transcript, it also flags where the two disagree, so a recognition error can be corrected rather than translated. The translator is told to prefer these notes over the text wherever they disagree about gender, address or deixis, which is what makes the video the source rather than an illustration of it. Video-guided translation is an established line of work (Sulubacak et al., 2020), and the visual signal has been shown to pay off precisely where the textual input is impoverished (Caglayan et al., 2019) — the condition an automatic transcript creates. In our internal evaluations on comparable material, adding the audio-visual note gave a statistically significant improvement.

**Document context before scenes.** A document-level pass first extracts what a translator needs to stay consistent across scenes: a summary, the cast with gender and forms of address, and terminology, so a character is named and characterized the same way throughout. The pass earns its place on long material; here the clips run under a minute, about one scene for our splitter, so it mostly acts as an explicit reasoning step before any line is translated.

**Written from scratch, not post-edited.** Every line is generated by the model from the source itself — for spoken dialogue, from the source text, the video and the language-variety directive, and nothing else. The engine can instead show the model a machine-translated draft to post-edit, a mode effective in its own right (Raunak et al., 2023); that path is disabled for every target, including the lower-resource ones where it is normally offered. In our experience a baseline anchors the model to someone else's phrasing and narrows the range of renderings it will consider. We observed this on high-resource pairs only; the path is disabled everywhere for consistency, not because we measured its effect on the lower-resource ones.

## 4 Web, social and software documents

A web page or a resource file is a handful of paragraphs or interface strings, and the three domains share one thin harness. Its per-domain parameters are the decomposition and, for two of them, one extra input each: a framing line for software, the page screenshots for social.

**One call per document.** The whole document is translated in a single call whose input and output are index-keyed lists of segments. That call *is* the document-context pass: the model sees every sibling segment at once, so it can hold terminology, register and named entities together, and indexing keeps the output re-insertable into the original structure. The decomposition is supplied as a pair: a gate deciding whether a candidate preserved the document's structure, and a renderer producing the plain text the auditor compares. A domain is a decomposition, not a fork of the pipeline.

**Mask markup; expose placeholders.** The two decompositions make opposite choices, and the contrast is the point. For marked-up documents, inline tags are replaced by opaque markers before the model sees the text: it places a marker and never sees a URL or an attribute value in the text it is given (a screenshot, where one is attached, is a separate channel), and the gate requires the marker multiset to survive and to remain well nested. For localization resource files, placeholders such as `{{count}}` are left *literal*: their names are exactly the context the model needs for the text around them — whether a value is numeric, whether two placeholders are a pair wrapping a link, what an ambiguous short label refers to. The test is whether the hidden material carries information the surrounding translation depends on: a URL does not, a placeholder name does. The guarantee is the same one obtained differently — the gate requires the placeholder multiset to survive, and a document-level check re-verifies it after reinsertion. The principle we would carry forward: *mask what the model must not read, expose what it must reason about, and in both cases enforce structure by conservation rather than by trust.*

## 5 Gating: audit, corrective retry, no fallback

**An independent auditor.** Every translation is compared to its source by a second model, in the manner of reference-free LLM error detection (Kocmi and Federmann, 2023), but used as a gate rather than as a metric. It flags material factual divergence — flipped polarity, altered numbers or entities, dropped qualifiers, invented claims, swapped roles — while leaving idiomatic rephrasing and register shifts alone. The auditor is deliberately from a different provider than the translator. In our internal evaluations of automatic judging, models scored generations from their own family above others', so an auditor drawn from the translator's family risks certifying its blind spots; the same self-preference effect is reported in the literature (Panickssery et al., 2024). That independence has one hole we did not close: the note taken from the video comes from the auditor's own model, and the auditor is told to treat it as ground truth about the scene, so where a note is wrong the translation follows it and the audit is the last place that would catch it.

**Audit reliability depends on how much it judges at once.** The same auditor model misses errors in a long list of segment pairs that it catches in a short one. We chose the batch size empirically on our internal test sets, as the setting with the best recall; the explanation we assume — that attention dilutes across the batch — is an interpretation. We accept the cost in latency and calls.

**The retry is surgical and corrective.** A rejected segment is re-translated on its own, through the same call and under the same instruction, with accepted segments left untouched; only the refilled ones are re-audited. In the speech path the whole scene is re-sent with it, so its context is unchanged. Crucially, the retry is not blind: the auditor's stated

reason travels back into the prompt for that segment, together with an instruction that for it, fidelity to the source outranks the document's own terminology list. In one case, automatic terminology extraction had normalized a character's name to another used elsewhere in the document; the auditor flagged it, a blind retry reproduced the error exactly, and only the corrective retry fixed it.

**No MT fallback.** The engine can fill an unresolved segment from a generic third-party MT system; here it is disabled everywhere. The reason is fluency. In our experience generic MT output is markedly less fluent than the model-generated text around it, and in dialogue the damage is worse than an average would suggest: a single flat, literal line between lines that read like speech is more conspicuous than the same line would be in a uniformly machine-translated document. We would rather degrade to a worse translation than to a different kind of text. What replaces the fallback differs between the paths: an unresolved segment fails the document in spoken dialogue, which is then re-run — nothing reached that point in this run — while in the document domains the last structurally valid output ships, flagged for a later re-attempt. Both keep every document in the submission, and because the audit was configured more strictly for speech, its rejection rate is not comparable across paths.

## Abstract

We propose a method to improve machine translation (MT) quality by ensembling multiple large language models (LLMs) within a multi-agent framework. The method addresses the problem of ensembling models with different tokenizations by abstracting away from token-level representations and operating at the level of generated text. The approach integrates several established concepts in MT, including ensembling, quality estimation, and reranking, into a single translation system. The log-likelihood reranking applied in this paper significantly improves results, even without ensembling. Experimental results show that the total improvements of the method are comparable to those of COMET-MBR.

## 1 Introduction

Previous approaches to WMT workshops have focused mainly on training the best possible models. Teams at leading laboratories are building increasingly effective machine translation (MT) solutions, and it is difficult to develop something superior. In the approach presented here, we took a different strategy. Rather than building a competitive model, we decided to leverage and combine the power of the best models currently available to the public.

We propose the Relay-MT algorithm described in Section 3 that allows for the ensembling of LLMs from different research teams, regardless of their tokenization and architecture. The presented method differs from other approaches in that it does not attempt to reconcile and align tokens across different models, which is a challenging task. Instead, we exchange information between models by passing generated hypotheses purely at the text level.

We compared the results of the presented algorithm against standard Minimum Bayes Risk decoding (Kumar and Byrne, 2004) with chrF (Popović, 2015) and COMET (Rei et al., 2020) as metrics.

## 2 Related work

In this section, we briefly describe related work on selected techniques frequently used in MT, which, when combined, form the algorithm presented in this paper.

### 2.1 Ensembling

Ensembling is a common technique that combines predictions from multiple models. In MT, ensembles generate text using several models in parallel. During decoding, each model in the ensemble calculates its own probabilities for the next tokens, which are then combined using experimentally chosen weights. At each step, the token with the highest weighted average probability across the models is selected. By coordinating multiple models, low-probability tokens that might be mistakenly selected due to a single model's error are filtered out.

The rapid development and availability of high-quality LLMs have recently led to significant improvements in translation quality, making the application of ensemble methods a natural next step. However, traditional ensemble methods in MT face important limitations in the era of LLMs. The most significant limitation is the varying tokenization of LLMs. This means models operate on different tokens, making it challenging to compute average probabilities when tokens from different models appear in different positions within the text.

Several recent studies have explored various approaches to tackle this problem. For example, Kasai et al. (2022) and Wicks et al. (2025) address the issue of different tokenizations by proposing methods for mapping tokens between models through the analysis of dependencies between their text representations. The models align tokens with similar textual representations whenever possible, and probabilities are then recalculated to prepare better translations based on agreed common predictions.

*Proceedings of the Eleventh Conference on Machine Translation*, pages 1235–1247
October 28-29, 2026 ©2026 Association for Computational Linguistics

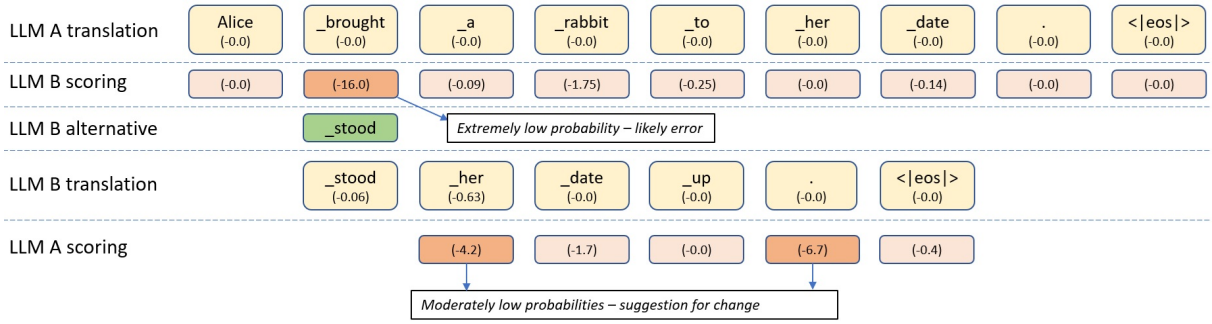

Figure 1: Translation process of French « Alice a posé un lapin à son rendez-vous. » (idiomatic "Alice didn't show up for her date.") to English with two LLMs. Detection of possible errors → translation from error position with another LLM. Values in parentheses are logprobs of tokens.

Xu et al. (2024) propose a mathematically advanced method that embeds tokens from different vocabularies into one shared space. Tokens are then combined and compared within this common representation.

These approaches still use a classic token-by-token hypothesis generation approach, offering methods for unifying tokens across multiple models.

## 2.2 Reranking

Reranking is a method that improves translation quality by using models other than the generating model to evaluate it. The role of one model is to generate multiple translation hypotheses, which are evaluated by other models. Thanks to verification across multiple models, we can select a better translation than a single model would produce. This method is used, for example, by the xTower model (Treviso et al., 2024) or the Chimera version of Hunyuan-MT (Zheng et al., 2025b).

The concepts presented here are inspired by Junczys-Dowmunt (2019), who presented a method that uses cross-entropy of sentence pairs to effectively distinguish correct translations from incorrect ones. This approach enables the detection of translation errors using token-level probability values produced by translation models. The results of that work also suggest that high sentence-level cross-entropy is driven by high cross-entropy at the individual token level, a hypothesis that served as one of the foundations for the error detection mechanism in the Relay-MT algorithm proposed in this paper.

While analyzing generated translations, we observed that low token probabilities consistently correlate with translation errors. This is expected behavior. It is unlikely that two different models would assign high probability to the same incorrect token.

A necessary part of the reranking is developing a method for quickly generating a large number of hypotheses for subsequent evaluation. The primary method for generating multiple hypotheses is *beam search*, in which we simultaneously generate several highly probable translations. However, this method generates very similar hypotheses and overlooks many potentially better candidates. To increase the diversity of beam search, the *Diverse Beam Search* modification was developed (Vijayakumar et al., 2018).

Another popular method for generating multiple hypotheses is *sampling*, where, during text generation, we do not select the most probable token but instead allow for random selection from among the less probable ones. This method is simple and effective, but sometimes produces incorrect results. The best of sampled hypotheses can then be selected using Minimum Bayes-Risk Decoding (Kumar and Byrne, 2004).

Recent work has also focused on generating more diverse and higher-quality hypotheses. Vernikos and Popescu-Belis (2024) proposed cutting the set of generated hypotheses into parts (*QE-Fusion*) and stitching well-translated fragments together into new sentences. This method divides the translation into spans, as in Relay-MT, but operates on hypotheses from a single model.

Dobrowolski et al. (2025) proposed *A* decoding*, a method for fast generation of many diverse hypotheses by replacing most probable tokens with other, relatively likely ones, which yields a richer set of hypotheses than beam search or sampling.

**Algorithm 1** Iterative multi-agent ensemble of models with different tokenizers

Initialize the base translation $y$
Select the initial leading model $M$
**repeat**
    Generate new hypothesis $y'$ using model $M$ from selected position in $y$
    Compute token probabilities in $y'$ using other models
    Find a new start position $t = \arg\min_t \ p(y'_t)$
    Select another leading model $M$ with the lowest score for token $y'_t$
    Update the base translation $y \leftarrow y'$
**until** no improvement in quality (evaluation function does not increase)
**return** $y$

## 3 Relay-MT algorithm

Unlike regular approaches to ensembling in translation, this paper introduces a *multi-agent approach*. Here, model cooperation does not involve reconciling tokens generated at each step, but rather transferring the role of the primary generator among different models during translation. Generated hypotheses are passed between models as texts. With this agent-based approach, each model operates on its own tokens. This way, we avoid the problem of differing tokenization, which was a major issue when integrating models through classical ensembling.

Each LLM in the ensemble generates its own translation. The LLMs in the ensemble evaluate each other's translations by checking the probabilities of tokens of the generated text. A low token probability indicates a likely error. In the place of the least probable token, the evaluating LLM takes over the role of the hypothesis generator, and the previous generator becomes the evaluator. In this way, a new translation is created, with its prefix generated by one LLM and its suffix by another. For this new translation, we repeat the process of searching for low-probability tokens and switching the role of the translation model. After several such role switches (relays), we obtain a new hypothesis created by combining several fragments generated by different LLMs and free of most likely errors.

By applying the algorithm multiple times, we can obtain any number of alternative, high-quality hypotheses. These hypotheses are more diverse than those obtained from sampling a single model; at the same time, all text fragments are generated not randomly, like in sampling, but by a set of translation LLMs, ensuring high quality. The full version of the proposed generation pseudocode is shown in Algorithm 1.

## 4 Log-likelihood Reranking

Changes to the translation during the process correct some errors but may introduce new ones. To minimize the likelihood of errors in the final translation, we rerank the generated hypotheses at the end of the algorithm, selecting the best of all generated hypotheses.

The choice of the reranking method is independent of the Relay-MT method itself. Any reranking method can be used. The method described here is based on the conditional probability of a generated translation; therefore, it fits perfectly to Relay-MT as all necessary probabilities have already been calculated during mutual evaluation of translations between ensemble models and does not require any additional LLM computations.

All generated hypotheses are reranked within the ensemble by calculating the weighted average normalized log-probability of the generated sentences.

$$Q_{ens}(h|s) = \sum_i \lambda_i \frac{1}{|h|} \log P_i(h|s) \qquad (1)$$

where $P_i(h|s)$ represents the conditional probability assigned to hypothesis $h$ by the $i$-th model of the ensemble, and $\lambda_i$ controls its contribution to the final score. The highest-scoring hypothesis is selected as the final translation.

To select the optimal $\lambda_i$ coefficients we applied a simple grid-search to select a set of coefficients that would provide the best translations of the blindset according to $Q_{wmt}$ function described in Section 5.2 although any specific quality assessment (QE) method can be applied here.

## 5 WMT26 submission

In this section, we present the implementation details used to prepare translations for WMT26.

### 5.1 Single Step of Relay-MT

At the start of the algorithm, we translate the entire blindset using all models in the ensemble. This way, we produce basic, default translations of the blindset by all LLMs of the ensemble. Then, for each hypothesis, we run scorings using other models in the ensemble to identify the least probable tokens and the alternatives proposed by the evaluating models at these locations. The position where the difference between the alternative and original token is greatest is a potential place where we can improve the translation the most.

For each source text and each evaluating model, we select the hypothesis with the greatest difference between the alternative and original token probabilities. We prepare the prefix of this translation up to the position of a detected low-probability token, replacing it with its alternative. In the next step of the algorithm, we perform translation of the source text using the evaluating model, starting from the replacement position using the constructed prefix. Prefixes already translated are omitted.

The above steps are repeated several times to generate a set of hypotheses, which are finally reranked to select the best hypothesis. One iteration of the algorithm takes one step of translation and several steps of scoring for each model of the ensemble.

In its current form, Relay-MT is relatively computationally expensive. 10 iterations of the algorithm for 5,000 paragraphs involving three ~30B models take approximately 2,000 seconds on two NVIDIA RTX PRO 6000 Blackwell Max-Q GPUs. Comparable in quality (see Table 1) generation of 20 hypotheses by sampling, followed by COMET-MBR reranking, takes approximately 800 seconds, making Relay-MT roughly 2.5 times slower. On three NVIDIA A100-PCI-40GB GPUs, the corresponding execution times are approximately 5,000 and 2,400 seconds, respectively, making Relay-MT about twice slower.

### 5.2 WMT2024/25 tuned QE

The quality of translations in recent years has reached such a high level that even the Best-QE metrics, such as COMETKiwi, xCOMET, and MetricX, are no longer sufficient to compare hypotheses at this level. We have therefore introduced a more sophisticated QE function based on a similar linear combination of log-probabilities as Equation 1.

As $P_i$ functions of the equation, we used log-probabilities calculated by various models: forward and backward translations, monolingual models and QE models. To make the function as close as possible to human ratings, we adjusted $\lambda_i$ coefficients on the basis of the human evaluations from the results of WMT24 (Kocmi et al., 2024) and WMT25 (Kocmi et al., 2025b). We treated the human evaluations as ground truth and adjusted the weights so that the best-ranked hypotheses would give maximum average human rating. Finally, we selected the most relevant models, rounded the weights, and derived the following function:

$$\begin{aligned} Q_{wmt}(h|s) = {} & 2P_{HY15}(h|s) + 2P_{HY30}(h|s) \\ & + P_{Qwen}(h|s) + 0.25P_{Tower}(h|s) \\ & + 0.25P_{Euro}(h|s) - 0.1P_{MetricX}(h|s) \end{aligned} \quad (2)$$

The formula above contains normalized log-probabilities of forward translations by the following models:

- $P_{HY15}$ - HY-MT1.5-7B
- $P_{HY30}$ - Hy-MT2-30B-A3E
- $P_{Qwen}$ - Qwen3.5-122B-A10E
- $P_{Tower}$ - Tower-Plus-9B[1]
- $P_{Euro}$ - EuroLLM-22B[1]
- $P_{MetricX}$ - value of MetricX-24

### 5.3 Document Segmentation

The source documents were divided into paragraphs, and each paragraph was translated separately. This division may have resulted in a loss of coherence in longer texts. However, translating very long texts, over 1000 tokens, was extremely time-consuming. Additionally, due to its nature, the Relay-MT algorithm makes only a few changes (equal to the number of iterations) to a given text, which would not significantly affect the long text output. After all paragraphs of a single document had been translated, the translations were recombined back into a single output document.

### 5.4 Model Selection

To build ensembles, we used the following translation models:

- Marco-MT-Algharb (Wang et al., 2025)
- EuroLLM-22B-Instruct (Martins et al., 2024)
- command-a-translate (Kocmi et al., 2025a)
- Hunyuan-MT-7B (Zheng et al., 2025b)
- HY-MT1.5-7B (Zheng et al., 2025a)

[1]Only for directions supported by the model

- Hy-MT2-30B-A3B (Zheng et al., 2026)
- Hy-MT2-7B (Zheng et al., 2026)
- MiLMMT-46-12B (Shang et al., 2026)
- Qwen3.5-27B (Yang et al., 2025)
- Qwen3.5-122B-A10B (Yang et al., 2025)
- Qwen3.6-27B (Yang et al., 2025)
- Seed-X-PPO-7B (Cheng et al., 2025)
- Tower-Plus-9B (Rei et al., 2025)
- translategemma-27b (Finkelstein et al., 2026)

To find the best ensembles, we ranked the above models based on translation quality for a selected direction. We built ensembles consisting of 2–4 best models each and ran the Relay-MT algorithm for 5 steps to determine which ensembles produce the best results. We used the $Q_{wmt}$ score to compare the quality between ensembles and selected the 4 best ensembles for each direction.

We ran 10 steps of the Relay-MT algorithm with these best ensembles, obtaining several dozens (Exactly: 10 times the number of models) hypotheses for each source paragraph. All of these hypotheses were reranked within an ensemble using $Q_{ens}$ function, and the best hypothesis obtained in this way became the final translation proposal for the ensemble.

### 5.5 Final Error Correction

Despite the reranking function, some hypotheses contain errors, despite verification by the reranking function $Q_{ens}$. For example, translations that consist of many repetitions or are truncated in the middle elude the $Q_{ens}$ verification, which yield good scores despite being incorrect. To eliminate such errors, we selected the hypotheses generated by the two best ensembles (not one-by-one) and compared them sentence-by-sentence using raw MetricX-24. The sentence from each pair that scored higher was selected as the final hypothesis and reported in the final result submitted to WMT26.

## 6 Results Achieved

A summary of the results for the proposed algorithm is presented in Table 1. The table contains average QE scores for the WMT26 blindset, calculated at the paragraph level and averaged across 13 main translation directions. Rows present evaluations of raw outputs of the 6 models used in ensembles, followed by the results of our experiments:

- *Rows labeled with (MBR)* – show results of MBR applied to 20 hypotheses sampled by a model with temperature=0.7
- *MultiLLM-MBR* – show results of MBR applied to 3x20 hypotheses sampled by three models: HY-MT1.5-7B, Hy-MT2-30B-A3B, translategemma-27b-it
- *Log-likelihood reranking* – shows QE values just after the first step of the Relay-MT algorithm, where basic translations are generated by all LLMs in an ensemble and reranked with the $Q_{ens}$ function, before any error detection or relay of the translator role.
- *Best Relay-MT ensemble* – shows QE values for the best ensemble after 10 steps of the Relay-MT algorithm.
- *Our submission* – shows QE values after the *Final Error Correction* stage described in the Section 5.5.
- *Best-QE Ensemble* – shows results of Relay-MT for an ensemble with highest QE values.

| Model | COMETKiwi | MetricX | xCOMET | ReMedy |
|---|---|---|---|---|
| HY-MT1.5-7B | 66.3 | -3.74 | 75.1 | 55.2 |
| MiLMMT-46-12B | 64.0 | -4.55 | 71.2 | 49.4 |
| Qwen3.5-27B | 64.0 | -4.43 | 68.7 | 48.8 |
| Seed-X-PPO-7B | 63.2 | -4.70 | 69.3 | 43.8 |
| command-a-translate | 64.1 | -4.71 | 69.9 | 44.4 |
| translategemma-27b-it | 67.0 | -3.68 | 73.6 | 52.7 |
| HY-MT1.5-7B (COMET-MBR) | 66.9 | -3.58 | 76.2 | 61.3 |
| translategemma-27b (COMET-MBR) | 67.6 | -3.51 | 74.9 | 61.4 |
| MultiLLM (chrF-MBR) | 67.1 | -3.65 | 76.0 | 62.9 |
| MultiLLM (COMET-MBR) | **68.3** | -3.36 | 76.9 | 65.3 |
| Log-likelihood reranking | 67.1 | -3.60 | 76.4 | 59.9 |
| Best Relay-MT ensemble | 67.3 | -3.56 | 76.9 | 60.1 |
| Our Submission | 67.4 | -3.47 | 77.1 | 62.5 |
| Best-QE Ensemble | 67.7 | **-3.28** | **77.3** | **65.7** |

Table 1: Summary of results of translations by single LLMs and MBR compared to the presented solution. Bold indicates the best result.

As an official submission for WMT26 we provided the outcome of the ensemble not with the highest QE values but the ensemble best evaluated by Equation 2 which shows the best correlation to human evaluations (see section 5.2). Results of the best ensemble by QE presented in the last row of Table 2 shows that potential of Relay-MT in quality gains is comparable to COMET-MBR.

In Appendix A, we present detailed results for 13 translation directions separately.

## 7 Comparison to other participants

After receiving the results of all WMT26 participants from the organizers (Kocmi et al., 2026), we

Table 2: Results of the top evaluated multilingual systems submitted to WMT26 and raw outputs of LLMs. The SRPOL row reports the results of our Relay-MT solution. Cell colors represent relative performance within each metric column, ranging from light red (lowest value) to light green (highest value).

were able to perform an additional analysis and compare our system with those submitted by other teams.

The comparison is presented in Table 2. The columns report automatic scores according to different evaluation metrics, averaged over several translation directions (the same directions as reported in Appendix A). The table includes also results of translations by 4 LLMs not provided by organizers (translategemma-27b-it, HY-MT2-30B-A3B, Qwen3.5-122B-A10B, MiLMMT-46-12B-v0.1). These 4 models were base models of most our ensembles.

The SRPOL system (Relay-MT described in this paper) achieved the best results in 5 out of the 8 automatic evaluation metrics (MetricX, xCOMET, COMETKiwi, MetricX-QE, and xCOMET-QE). However, its BLEU/chrF scores are among lowest compared to those of other teams.

Our preliminary analysis suggests that these low scores are likely a consequence of the low BLEU/chrF performance of the base models on which we built the ensembles. These models achieve high QE scores, which are further improved by Relay-MT. However, the algorithm cannot compensate for the low baseline BLEU/chrF scores. Such low BLEU/chrF scores may negatively impact the final human evaluation. The reason for this discrepancy is not yet known and requires further investigation.

## 8 Conclusion and Future Work

In this paper, we described the practical application of the Relay-MT algorithm for ensembling of translation models of different tokenization. The newly developed Relay-MT algorithm has demonstrated its effectiveness in producing high-quality translations. Results after 10 steps of the Relay-MT algorithm are comparable or better than the application of the standard Minimum Bayes Risk with COMET for 20 sampled hypotheses. The final results show exceptionally large gains according to the QE metrics, in stark contrast to low BLEU/chrF scores. This discrepancy requires further investigation. An unexpected finding of our research is the strong performance of the log-likelihood reranking method described in Section 4, which significantly improves translation results after only a single translation without the Relay-MT algorithm.

The proposed method provides full control over the generated translations, making it suitable for practical applications. Concepts of the Relay-MT algorithm, such as ensembling multiple models, log-likelihood reranking, and error detection based on low token probabilities, could serve as a basis for further research to improve translation quality.

## Limitations

We presented only the basic concept and the first results of the Relay-MT algorithm. The presented algorithm does not always find the optimal translation. In the current approach, only the most recently generated translation is considered in subsequent hypothesis search steps. This algorithm could be extended by searching among a larger set of top hypotheses or even among previously rejected ones. The paper does not discuss the theoretical or numerical advantages of the algorithm, as research on it is still in its early phase. We have also not compared the presented method to other SOTA solutions for ensembling differently tokenized LLMs mentioned in Section 2.

After the official WMT26 submission deadline, we identified integrating Quality Estimation (QE) scores into the hypothesis reranking stage as a promising extension. This modification was not part of the submitted system, and its systematic evaluation is left for future work.

## Acknowledgments

This paper was prepared with the assistance of AI tools. The use of Generative AI was limited to cases permitted under the *ACL Policy on Publication Ethics*. AI was used solely for related-work research, translations, language assistance and proofreading.

## Ethical Considerations

We took special care to thoroughly review the existing literature to avoid plagiarism. If any concept or solution had been previously published and we failed to mention it, this was unintentional. We have taken care in our experiments to use only models and sources that are generally available and free for research purposes. If we have infringed any intellectual property rights in this paper, it was unintentional.

# A Results of experiments for 13 target languages

Below tables present QE scores of the WMT26 blindset translations for 13 main directions by different LLMs. MBR rows show results of sampling of 20 hypotheses with temperature=0.7 reranked with COMET-MBR or chrF-MBR.

Last four rows in each table show:

- Results of the log-likelihood reranking described in this paper.
- Results after 10 iterations of Relay-MT algorithm.
- Final submission after error correction.
- Results of Relay-MT for an ensemble with highest QE values (not submitted to WMT26).

Columns present referenceless scores for the following models:

- COMETKiwi-XL (Rei et al., 2023)
- MetricX-24-XL (Juraska et al., 2024)
- xCOMET-XL (Guerreiro et al., 2024)
- ReMedy-2B (Tan and Monz, 2025)

Values of MetricX-24 are negated, other QEs are multiplied by 100. Best results are presented in bold.

Table 3: Czech/English → German

| Model | COMETKiwi | MetricX | xCOMET | ReMedy |

## Abstract

We describe Grammatist,[1] our submission to the unconstrained track of the WMT 2026 General Machine Translation Task, developed in direct collaboration with community members of two regional languages of Italy, Ladin and Ligurian. Ladin and Ligurian represent challenging scenarios for machine translation (MT), as they have limited resources for conventional data-driven approaches. However, this scarcity of large-scale parallel data does not reflect a lack of linguistic documentation: both languages are extensively documented in dictionaries and grammar books, which contain valuable knowledge but are not readily exploitable by conventional MT approaches. Grammatist addresses this gap by making this information available to a large language model (LLM) at inference time. The framework is both agentic and model-agnostic: it dynamically consults dictionaries and grammar books during translation to retrieve the information most relevant to the input. Any LLM can serve as the underlying base model, enabling Grammatist to benefit from advances in increasingly capable models. For the WMT 2026 task, we apply Grammatist to structured document-level translation from English into Ligurian and Ladin.

## 1 Introduction

Modern approaches to low-resource machine translation commonly address limited supervision by adapting pre-trained multilingual models (fine-tuning) and by augmenting available parallel data (back-translation). While effective in many settings (Haddow et al., 2022), these approaches remain fundamentally dependent on the information that can be learned from the available parallel data, where rare words and linguistic patterns may receive too little evidence.

However, limited parallel data does not necessarily imply a lack of linguistic documentation. Many languages are well documented with carefully curated grammars, dictionaries, and other linguistic resources and Ligurian and Ladin are representative examples of such languages. Approaches for MT that rely on parallel corpora, however, provide no direct mechanism for exploiting the information contained in other forms of linguistic documentation. As a result, substantial linguistic knowledge may remain inaccessible to the translation system.

Large language models (LLMs) offer an opportunity to approach this setting from a broader perspective. Their ability to perform in-context learning, interact with tools, and take actions based on the information they retrieve opens a different paradigm for (low-resource) MT that makes it possible to consider linguistic resources beyond parallel corpora (Zhang et al., 2024; Pei et al., 2025; Marmonier et al., 2025). This is the idea behind *Grammatist*, an agentic framework for machine translation. Grammatist combines LLMs with linguistic resources through prompting and tool use. The system was previously introduced and evaluated for sentence-level Italian–Ligurian and Italian–Ladin translation (Maillard et al., 2026). In this work:

- we apply Grammatist to English-to-Ligurian and English-to-Ladin (document-level) translation;
- we show how LLM reasoning capabilities can be used to dynamically retrieve and exploit linguistic knowledge beyond the language pair directly represented in available dictionaries;
- we evaluate the approach in the WMT26 General Machine Translation Task and analyse the effectiveness and limitations of tool-assisted translation for under-resourced languages.

With this approach, we propose a flexible framework for incorporating external linguistic knowledge into LLM-based machine translation at inference time.

## 2 System Description

*Grammatist* is an agent-based machine translation tool that provides LLMs with access to dictionaries, enabling them to autonomously consult and leverage these resources to generate translations. The overall architecture of the system is sketched in Figure 1. In this section, we first describe the linguistic resources used for Ladin and Ligurian translation. We then detail how we implement the agentic translation framework and how the LLM interacts with these resources during translation.

### 2.1 Linguistic Resources

**Dictionaries** We use two bilingual dictionaries as the primary lexicographical resources for the regional languages considered in this work: the Italian–Ligurian dictionary (Maillard and Lusito, 2021) and the Italian–Ladin (Val Badia) dictionary (Moling, 2016). Table 1 summarises their structural properties, highlighting the richness of the linguistic information they encode.

Both resources provide substantial lexical coverage, with 13,704 Italian source lemmas in the Ligurian dictionary and 29,737 in the Ladin dictionary. Beyond word-to-word mappings, they include multi-word expressions (16.6% and 20.8% of lemmas, respectively) and distinguish homonyms or part-of-speech-specific entries, preserving important lexical and semantic distinctions.

The dictionaries also capture substantial translation ambiguity, containing 18,598 and 34,982 word senses and associating many senses with multiple target-language equivalents. In particular, 34.8% of Ligurian senses and 47.8% of Ladin senses have more than one translation.

Beyond lexical correspondences, both resources provide inflection tables and usage examples that support context-sensitive interpretation and generation of morphologically valid target forms. Although these resources are indexed from Italian rather than English, they remain useful for WMT26 because the LLM can bridge languages at inference time.

However, effectively exploiting the information depends on the reasoning capabilities of the underlying model: the system must identify the relevant sense, relate retrieved Italian-based evidence to the English source context, and select an appropriate target-language realisation. This makes the resources particularly suitable for an agentic framework, where retrieval and reasoning are combined during translation.

The dictionaries are stored as `.jsonl` files. . Each line contains a headword and one or more entries, allowing distinct lexical entries, including homonymous and part-of-speech-specific entries, to remain separate. An entry can contain definitions, one or more target-language equivalents, bilingual usage examples, multiword expressions, and inflectional tables.

**Grammar Rules** Besides dictionary evidence, Grammatist incorporates general grammatical rules. The grammar rules provide the model with explicit information about morphosyntactic phenomena that are not reliably captured by transfer from Italian or by general multilingual pretraining. Both languages exhibit grammatical structures that differ substantially from Italian, such as obligatory subject clitics in Ligurian (e.g., *O l'à*) and verb-particle constructions in Ladin (e.g., *surantó...fora*). These language-specific phenomena require explicit linguistic guidance to produce idiomatic translations.

Grammar guidance is directly added to the system prompt. The grammar tips used for the submission are given in Appendix B. More details are provided in Maillard et al. (2026).

## 2.2 System Architecture

**Chunking and Prompting.** The input text is first divided into smaller chunks. The chunking algorithm is breakpoint-oriented, with minimum and maximum chunk lengths of 400 and 800 characters. It searches for a boundary in the following priority order: $(i)$ whitespace or a newline immediately following a sentence-ending period, exclamation mark, or question mark; $(ii)$ a colon or semicolon; $(iii)$ a comma; and $(iv)$ any whitespace. Breakpoints before the 400-character lower bound are skipped, and the algorithm then searches for a breakpoint up to 800 characters, considering these types in the order above.[2]

The chunks are then independently processed. For each chunk, the model is given a system prompt, a task-specific domain instruction, and a native function calling-tool (`dictionary_lookups`) for dictionary lookups.

The system prompt instructs the model to identify every source word, including function words, lemmatise inflected forms, and request the relevant verb tenses needed to formulate dictionary lookup queries.[3] The model is then instructed to use the retrieved dictionary evidence together with the specified grammar rules to produce the final translation. The prompt also defines the tool-use policy and the conditions under which dictionary queries should be issued. In particular, it states: *"If the source text is not Italian, translate it to Italian and then proceed as above."* Thus, for English input, the model first translates the source into Italian and uses the resulting Italian forms as headwords for subsequent Italian–Ligurian or Italian–Ladin dictionary lookups. The complete system prompt is provided in Appendix A.

Figure 2 illustrates the interface between the model and the dictionary lookup tool. The left panel shows the strict JSON schema registered with the model API, which specifies the structure of the tool arguments and the grammatical tenses that can be requested. The right panel shows an example of a batched lookup request generated by GPT-5.4 for the source phrase *"I want to eat an apple now."*

**Tool and Dictionary Evidence.** Given the Italian phrase "mangio una mela", the model could emit the structured request shown in Figure 2b. The verbal lemma receives a tense request, while the non-

[2] If no breakpoint of one type is found, it moves to the next; if none is found, the chunk is cut at 800 characters. A short final segment is merged with the preceding chunk when their combined length remains within the 800-character maximum.

[3] It also permits synonym and fallback queries when a preceding lookup fails.

(b) Model-generated batched lookup requests.

Figure 2: Integration of the dictionary lookup tool. The subfigure 2a shows the strict JSON schema defining the tool's parameters and allowed grammatical tenses. The subfigure 2b displays the actual batched lookup request generated by GPT-5.4 for the source phrase *"I want to eat an apple now."* Notice that the model correctly translates the English input internally to query the corresponding Italian lemmas.

verbal entries receive empty lists. The local tool performs exact, lower-cased lemma lookup, merges duplicate requests, and returns a condensed representation rendered as Markdown, as illustrated in Appendix D.

Although the general framework also supports parallel-data retrieval, the WMT26 system described here uses only dictionaries and grammar rules; apart from example sentences included in the dictionaries, no additional parallel corpus is used.

**Agent Loop and Generation.** The agent loop is designed to keep tool use efficient and bounded while preserving the necessary context across calls. The Responses API maintains the conversation through `previous_response_id`, so after a tool call the client sends only the new tool result and user input instead of replaying the entire conversation history. In the WMT26 configuration, each chunk therefore uses at most one tool-use round and one batched tool invocation. The translated chunks are then concatenated in their original order to produce the final translation.

## 3 Validating the Approach

Before applying Grammatist to the WMT26 blind test set, we first validate the approach on development benchmarks. We evaluate both Ladin and Ligurian on FLORES+ (Costa-jussà et al., 2024; Frontull et al., 2025) and Ligurian additionally on BOUQuET (Andrews et al., 2025).[4]

Table 2 compares Grammatist with a zero-shot baseline using the same GPT-5.4 model (`gpt-5.4-2026-03-05`). The baseline was prompted to translate source texts using only core task instructions (target language specification and output format). Grammatist uses the same model as its generation backend but additionally provides the external information and tools described in Section 2.2.[5] Grammatist substantially improves translation quality across all three evaluation settings. The observed gains provide evidence that the additional

[4]The Ladin subset of the BOUQuET benchmark was not publicly available during system development.

[5]The two systems differ in both the information available to the model and the resulting prompt structure, so the results should not be interpreted as an isolated ablation of the dictionary component.

| Direction | Dataset | Baseline BLEU / chrF | Grammatist BLEU / chrF | Tokens (M) In / Out | Inference Avg. (s) | Dictionary lookups Found | Missing | Success |
|---|---|---|---|---|---|---|---|---|
| eng→lij | BOUQuET | 12.41 / 40.30 | 28.96 / 53.94 | 6.37 / 1.39 | 29.68 | 9,472 | 885 | 91.46% |
| eng→lij | FLORES+ | 14.62 / 46.85 | 29.89 / 59.01 | 9.96 / 2.48 | 40.50 | 17,875 | 2,809 | 86.42% |
| eng→lld | FLORES+ | 8.17 / 38.31 | 26.53 / 54.48 | 9.08 / 2.80 | 40.90 | 18,833 | 2,041 | 90.22% |

Table 2: BLEU / chrF scores for baseline translation and Grammatist. The baseline employs pure GPT-5.4 (`gpt-5.4-2026-03-05`) prompted zero-shot to translate source texts with only the core task instruction and target language specification, completely omitting external context, grammar tips, or dictionary tools. Grammatist, for which we also report token usage, inference time, and dictionary lookup statistics, utilises this same model as backend.

linguistic information and structured tool use are useful. Importantly, the intermediate English-to-Italian translation does not appear to be a significant bottleneck: the approach performs consistently well on both Ligurian and Ladin. Table 2 also reports inference and retrieval statistics for Grammatist. The system processes between 6.37M and 9.96M input tokens across the evaluation sets, with average inference times of approximately 30–41 seconds per sentence. Dictionary lookup success remains high, ranging from 86.42% to 91.46% across the three settings showing most lexical candidates proposed during translation can be resolved directly through the dictionary. Although additional retrieval iterations could potentially recover some of these candidates, doing so would increase both inference time and token usage.

These development results validate the effectiveness and practical feasibility of the core Grammatist approach. Across both languages and evaluation benchmarks, the system achieves translation quality beyond previously reported results for these language pairs (Maillard et al., 2026; Frontull and Ströhle, 2026). The development experiments therefore provided sufficient evidence that the approach was robust enough to scale to the WMT26 blind test set, where we adapted the system only with some domain-specific instructions.

## 4 WMT 2026 General MT Shared Task

In previous work, Grammatist was evaluated on the FLORES+ (Dale et al., 2025) and BOUQuET (Andrews et al., 2025) benchmarks. Here, we study its performance in the document-level setting of WMT, which introduces different challenges related to longer contexts, document coherence, and structured input preservation. These characteristics provide a natural setting for investigating the capabilities and practical costs of LLM-based translation systems.

**Translation of the WMT26 Testset** Translations of the WMT26 test set are generated using a dedicated inference pipeline. All experiments use GPT-5.4 (`openai/gpt-5.4-2026-03-05`) with medium reasoning effort, allowing a single tool call per chunk translation request. Text documents are translated in a single model invocation using the task-specific instruction provided by the benchmark. The same procedure is used for the *software* domain: despite the additional requirement to preserve valid JSON structure, no domain-specific processing or post-processing is required beyond including the provided software-domain instructions in the prompt. The framework produces structurally valid translated JSON directly, preserving the top-level type, object keys, and list lengths. This capability depends in part on the instruction-following and structured-output abilities of the underlying LLM.

All generated translations undergo automatic validation to guarantee compatibility with the WMT evaluation pipeline. Specifically, the system enforces non-empty outputs, exact line-count parity with the source document, and preservation of blank-line alignment. Translations that violate these constraints are automatically regenerated, up to three additional attempts, ensuring that formatting errors do not affect evaluation.

**Resource Usage** We report the average inference time, number of LLM (tool) calls, and token consumption per document in the WMT test set in Table 3. The number of calls depends primarily on document length, as documents are divided into independently translated chunks (only a single tool call allowed for each chunk). Grammatist requires relatively small chunks because retrieved dictionary entries and other linguistic evidence substantially expand the model context during translation (as can be seen in the examples in Appendix D). Longer documents therefore require more calls and

Table 3: Inference cost analysis per document for translating the WMT test set across domains for Ligurian and Ladin. $N$ indicates the number of evaluated document files per domain. All values are averages per document.

| | | Ligurian (lij_Latn) | | | Ladin (lld_Latn) | | |
|---|---|---|---|---|---|---|---|
| **Domain** | $N$ | **Time (s)** | **LLM Calls** | **Tokens (In/Out)** | **Time (s)** | **LLM Calls** | **Tokens (In/Out)** |
| **news** | 14 | 240.64 | 11.00 | 197,532.8 / 24,052.7 | 268.03 | 11.00 | 144,619.1 / 25,678.1 |
| **social** | 44 | 143.32 | 5.77 | 117,180.1 / 14,657.8 | 156.09 | 5.77 | 81,253.9 / 15,440.1 |
| **software** | 7 | 222.47 | 8.57 | 137,597.7 / 21,692.3 | 226.36 | 8.57 | 100,895.3 / 22,127.9 |
| **speech** | 133 | 44.18 | 2.00 | 34,192.7 / 4,134.3 | 44.13 | 2.00 | 23,461.4 / 4,152.9 |

consume more tokens.

Allowing more extensive tool use could increase these requirements further. For example, on the news test set for English–Ligurian translation, the system requires an average of 240.64 seconds and 197.5K input tokens per document, while shorter documents in the speech domain require 44.18 seconds and 34.2K input tokens. Similar trends are observed across the English–Ladin test sets. These results quantify the resource requirements of the submitted system and provide insight into the practical cost of applying LLM-based translation systems to WMT-scale evaluation scenarios.

## 5 Conclusion

We presented Grammatist, an agentic machine translation framework applied to English–Ligurian and English–Ladin translation submitted to the WMT 2026 General Machine Translation Task. The system combines the multilingual capabilities of a general-purpose LLM with explicit linguistic knowledge retrieved dynamically from Italian–Ligurian and Italian–Ladin dictionaries for English-to-target translation. We discuss the observed limitations and directions for future work.

**Limitations and Future Work** Grammatist has substantially higher inference requirements than direct LLM translation, partly because retrieved linguistic resources expand the context and require relatively small input chunks. To limit resource consumption in our WMT submission, we allowed only a single tool-use round per chunk. This restriction may limit the amount of linguistic evidence the model can retrieve for difficult translations; allowing additional tool use could improve translation quality, by allowing e.g. the system to recover from cases where a queried lemma is missing from a lexical resource, but would further increase token consumption, latency, and cost. Future work should therefore investigate more selective retrieval and more compact representations of retrieved resources.

The chunk-based processing introduces some limitations at the document level. Chunks are non-overlapping and translated independently, with no source or translation context, tool-call history, or document-level memory carried from one chunk to the next. As a result, document-level coherence is not explicitly enforced across chunks and may be affected, particularly when resolving context-dependent expressions or maintaining consistent terminology. A further limitation comes from restricting the system to a single tool call per chunk. The LLM may not always know which words or expressions exist, and a single lookup call also prevents it from performing a follow-up search for the lookups that fail. A more detailed analysis of retrieval failures and of the effect of these limitations on translation quality is left for future work.

## Acknowledgments

We thank the *Istitut Ladin Micurá de Rü* and the *Council for Ligurian Linguistic Heritage* for their support and for providing lexical and grammatical resources. We thank the organizers of the WMT 2026 General Machine Translation Shared Task for their work in organizing the task and supporting participants throughout the submission and evaluation process.

## A System Prompt

The text below is the system prompt used in Grammatist. The WMT26 submission allowed one tool-use round per chunk.

```
You are a professional translator tasked with
translating Italian text into {Ligurian (Genoese)|Ladin
(Val Badia)}. Given some Italian source text, you must:
1. Use the relevant tools that are provided to you to
look up essential information.
2. Use the output of the tool calls and the grammar tips
below to produce a translation.

# Step 1: Using the tools

Identify every single word in the source text, including
function words and trivial words, and look them up by
making a native tool call with the `dictionary_lookups`
tool.

Provide a list of relevant tenses for the verb lookups.
Shape: `{"lemma":"...","tenses":[...]}`.

For verbs, select only the strictly needed tenses you'd
want to look up in `tenses` amongst: IndPres (present
indicative), IndImp (imperfect), IndFut (future),
ConzPres (present subjunctive), ConzImp (imperfect
subj.), Cnd (conditional), Imp (imperative), Inf, Ger,
PartPast.

For compound Italian tenses, request the needed
{Ligurian|Ladin} finite auxiliary tense plus PartPast.
Present participles should be looked up individually as
if they were nouns or adjectives. For non-verbs,
`tenses` should be an empty list.

For pronominal verbs, request the base verb plus any
particles when useful.

You can make multiple tool calls in subsequent rounds. If
a word isn't found in the dictionary, look up a synonym.
If the dictionary entry lists a useful multi-word
expression, look it up. You are allowed a limited number
of rounds of tool calling. You will be told how many
rounds you have left, after which you will be asked to
translate.

IMPORTANT:
1. You MUST look up EVERY SINGLE WORD, including trivial
prepositions like "in" and "a", conjunctions like "e" and
"o", determiners, etc. Failure to look up even a single
word will be considered a critical error and will lead to
a poor translation.
2. You MUST preserve all capitalization, white space
(including trailing spaces), and markup in the
translation.

# Step 2: Output the translation

Translate the source text using the grammar tips and the
output from the dictionary calls, which will contain
usage examples, relevant conjugation tables and
declension tables. Output only the translated text,
preserve capitalization, white space and markup.
```

# B Grammar Tips

## Key grammar tips

In Ligurian, subject clitics are mandatory before verbs in the 2nd and 3rd person singular.
2nd singular: _ti_ (or _t'_ before vowels): mangi → ti mangi, guardi → t'ammii.
3rd singular: _o_ (m) / _a_ (f), with _l'_ before vowels: il cane mangia → o can o mangia.
Subject clitics are not used in impersonal constructions (oggi piove → ancheu ceuve), in nominalized infinitives (mi piace giocare → me piaxe zugâ), or with perception verbs (mi sembra di esserci stato → me pâ d'ësighe stæto).

Ligurian has two polite pronouns, _voscià_ and _voî_.
_Voscià_ is used with interlocutors of higher or upper social class; it conjugates like the 3rd person singular and requires the subject clitic _scià_: lei lavora → voscià scià travaggia; lei non è d'accordo → voscià scià no l'é d'accòrdio.
_Voî_ is used among people of the same lower-middle class or with people of lower social status and conjugates like the 2nd person plural: lei lavora → voî travaggiæ; lei non è d'accordo → voî no sei d'accòrdio.
When in doubt, use _voscià_. Never translate the Italian polite pronoun _lei_ with _lê_.

The modal verbs _dovei_ (must), _poei_ (can), and _voei_ (want) always take the auxiliary _avei_ (to have), regardless of the verb they govern: me ne sono dovuto andare → ò dovuo anâmene; non è potuta uscire → a no l'à posciuo sciortî.

When in Ligurian the verb precedes the subject, the verb is always in the singular, without a clitic: giocano i bambini → zeuga i figgeu; cadono le foglie → cazze e feugge; mi piacciono i ravioli → me piaxe i ravieu.
This rule also applies to compound tenses, in which case the past participle is also masculine singular: sono venute le zie → l'é vegnuo e lalle.
Excluded from this rule are cases where the verb has a presentational function (generally the verb _ëse_): sono bambini → en figgeu; erano giochi popolari a quei tempi → ean zeughi popolari à quelli tempi.

To form dates in Ligurian:
- before the day number, use the articulated preposition _a-i_ (but for the first of the month, use the singular _a-o_ with the ordinal indicator: _a-o 1ž_);
- before the month name, use the simple preposition _de_ (elided to _d'_ if the month begins with a vowel: d'agosto, d'ottobre);
- before the year number, use the articulated preposition _do_.

Example: la festa è martedì 1 febbraio 2000 → a festa a l'é mätesdì a-o 1ž de frevâ do 2000.
Before the day number, it is also possible to use simply the article _i_ (or _o_ for the first of the month).
Using only the article is mandatory when the date is part of a nominal predicate: domani è il 13 settembre 2004 → doman l'é i 13 de dexembre do 2004.

Morphological adaptation rules for words not present in the dictionary: -ale → -ale; -are → -are; -aria/-ario → -äia/-äio; -ese → -eise; -ezza → -essa; -ia/-ie → -ia/-ie; -ile → -î; -ino/-ina → -in/-iña; -iolo/-iola → -ieu/-ieua; -ismo → -iximo/-ismo; -issimo → -iscimo; -ito/-ita → -io/-ia; -tà → -tæ; -ura → -ua; -uto/-uta → -uo/-ua; -zione → -çion.

## Key grammar tips

In the Ladin of Val Badia, expressing the subject is mandatory. When the subject is represented by a personal pronoun (whether stressed or clitic), the pronoun is always mandatory.
The Ladin pronominal system has two series of pronouns: stressed (tonic) pronouns and unstressed (atonic) pronouns (which are clitics).
In most cases, clitics are used. These have a fixed position: either directly before the verb or attached directly to the verb in an enclitic position (if an inversion occurs).
Examples with clitic pronouns: _Al sá da cujiné._ (He knows how to cook.); _I sun gnüs adalerch cun la ferata._ (I arrived here by train.)
Stressed pronouns are used only in specific contexts: when two subjects are linked by a conjunction and the pronoun does not hold a fixed position before the verb (_Ëra y sü colaboradus á ciafé le pest por proiec inovatifs tl artejanat._); when a new referent appears in the text (_Francësch ê bele n pü' ti agn. Ëra, süa fomena, ê indere bindebó jona y plëna d'energia._); when there is a need to emphasize the subject because it holds important informative value (_La maiú pert dla iuria é dla minunga che ël sides le miú y toches da ciafé le post pro l'orchestra._); when there is a contrast between two elements (_Os m'ëis dit che al foss da mudé auto, iö foss bëgn ciamó stada contënta cun le vedl._).

In the Ladin of Val Badia, the finite verb has a fixed position in declarative sentences: the second position. When the first position is occupied not by the subject, but by an object, an adverbial construction, or a subordinate clause, the verb and the subject must invert: the verb remains in the second position, while the subject shifts behind the verb.
Sentence with an initial subject: _Maria sona la chitara._
Sentences with adverbial constructions in the initial position: _Sëgn sona Maria la chitara._; _Cun ligrëza sona Maria la chitara._
Sentence with an initial object: _Les audanzes á le diretur ciafé de porsona._
Verb-subject inversion is also mandatory for interrogative sentences: _Tan dî á pa le paur da restelé?_

When the verb and the subject are inverted and the subject is a subject clitic, the clitic is attached directly to the verb ending.
Sentence with an initial subject: _I sun stá a Aunejia._; _Te manges ion jopa da cern._
Sentence with initial adverbial constructions (and enclitic position of the clitic): _Inier sunse stá a Aunejia._; _Canche t'es püre mangeste ion jopa da cern._
The enclitic form does not fully correspond to the proclitic form for every person.
100% correspondence between enclitic and proclitic forms: 1st person singular (_i → -i_): in most cases, the verb ending and the clitic overlap (_i vá, i jará → spo vái, spo jarái_; _i mangi, i mangiará → spo mangi, spo mangiarái_); 2nd person singular (_te → -te_): _te vas, te jaras → spo vaste, spo jaraste_; _te manges, te mangiaras → spo mangeste, spo mangiaraste_.
Partial correspondence between enclitic and proclitic forms: 3rd person singular (_al_ vs. _-l/el_; _ara_ vs. _-ra/era_): _al/ara vá, al/ara jará → spo vál / vára, spo jarál / jarára_; _al/ara mangia, al/ara mangiará → spo mangel / mangera, spo mangiarál / mangiarára_; 3rd person plural (_ai_ vs. _-i_; _ares_ vs. _-res/-eres_): _ai/ares vá, ai/ares jará → spo vái / váres, spo jarái / jaráres_; _ai/ares mangia, ai/ares mangiará → spo mangi / mergeres, spo mangiarái / mangiaráres_.
No correspondence between enclitic and proclitic forms: 1st person plural (_i → -es_): _i jun, i jarun → spo junse, spo jarunse_; _i mangiun, i mangiarun → spo mangiunse, spo mangiarunse_; 2nd person plural (_i → -e_): _i jëis, i jarëis → spo jëise, spo jarëise_; _i mangëis, i mangiarëis → spo mangëise, spo mangiarëise_.

In Ladin, the prepositions _a, da, de, te, sön_ bind directly to the definite article.
_a_ (to/at) + feminine singular _la/l'_ → _ala/al'_ (_ala là_ before consonant, _al'_ incuntada_ before vowel); + masculine singular _le/l'_ → _al_ (_al mutur, al pröm_); + feminine plural _les_ → _ales_ (_ales atres, ales maestres_); + masculine plural _li/i_ → _al/ai_ (_ai ostis, ai membri_).
_da_ (from) + feminine singular _la/l'_ → _dala/dal'_ (_dala scora, dal'atra pert_ before vowel); + masculine singular _le/l'_ → _dal_ (_dal ombolt, dal mëteman_); + feminine plural _les_ → _dales_ (_dales idees, dales cater_); + masculine plural _le/i_ → _dai_ (_dai interesc, dai comuns_).
_de_ (of) + feminine singular _la/l'_ → _dla/dl'_ (_dla comunité, dl'umanité_ before vowel); + masculine singular _le/l'_ → _di/dl_ (_di auto, dl laur_); + feminine plural _les_ → _dles_ (_dles operadesses, dles regoles_); + masculine plural _li/i_ → _di_ (_di afars, di seturs_).

```
_te_ (in) + feminine singular _la/l'_ → _tla/tl'_ (_tla banca, tl'agricoltora_ before vowel); + masculine singular _le/l'_ → _tl_ (_tl interes, tl paise_); + feminine plural _les_ → _tles_ (_tles intenziuns, tles cités_); + masculine plural _li/i_ → _ti_ (_ti agn, ti mëise_).
_sön_ (on) + feminine singular _la/l'_ → _söla/söl'_ (_söla tofla, söl'incrujada_ before vowel); + masculine singular _le/l'_ → _söl_ (_söl termo, söl armé_); + feminine plural _les_ → _söles_ (_söles isoles, söles massëdles_); + masculine plural _li/i_ → _söi_ (_söi odli, söi libri_).
Before masculine nouns starting with a vowel, the article combined with the preposition is not apostrophized: _tl_ auto, _al_ ater, _dal_ idraulich.
These same prepositions do not bind to the indefinite article; they remain completely separate: te n auto, a n'atra, da n idraulich.

In the Ladin of Val Badia, there is no distinct conditional form used in the apodosis (the main clause of a conditional sentence expressing the result). Instead, the subjunctive mood is employed in both clauses of the conditional sentence.
Italian (conditional in apodosis): _Se Paolo avesse superato l'esame della patente, sua nonna gli avrebbe regalato una macchina._
English translation: _If Paolo had passed his driving test, his grandmother would have given him a car._
Ladin of Val Badia (subjunctive in both clauses): _Sce Paul ess passé l'ejam dla patent, ti ess süa lâ scinché n auto._

In the Ladin of Val Badia, the imperfect tense is not formed using an intervocalic _-v-_. Instead, it is formed by lengthening the vowel in the verb ending, which is represented graphically by a circumflex accent.
The final vowel of the infinitive ending matches the vowel of the imperfect tense only and exclusively in the category of verbs ending in "-í" (where _-i = -î_). In all other verb conjugations, the final vowels change:
Verbs ending in _-é_ (changes to _-â_): present _te manges_ → imperfect _te mangiâs_.
Verbs ending in _-e_ (changes to _-ô_): present _i perdi_ → imperfect _i pordô_.
Verbs ending in _-ëi_ (changes to _-ô_): present _al plej_ → imperfect _al plajô_.
Verbs ending in _-í_ (retains matching vowel _-î_): present _ara dorm_ → imperfect _ara dormî_.
```

# C Domain-Specific Instructions

To guide the translation process according to the specific characteristics and constraints of each domain, we applied targeted domain instructions during generation. In the prompts below, the placeholder `{target_lang}` is dynamically instantiated according to the target language and variety descriptor—specifically, *Ladin, Val Badia, Italy (lld_Latn)* for Ladin or *Ligurian, Italy (lij_Latn)* for Ligurian.

## C.1 News Domain

For journalistic content, the system prompt enforced formal register and preservation of source HTML formatting.

```
You are a professional {target_lang} translator, tasked with providing translations suitable for use in {target_lang}. Your goal is to accurately convey the meaning and nuances of the original text while adhering to {target_lang} grammar and vocabulary and ensuring that the translation is natural. The original text is a news article. Ensure the translation is formal and consistent with journalistic standards. Produce only the {target_lang} translation, without any additional explanations or commentary. Maintain the HTML formatting of the original source text. Please translate the following text into {target_lang}:
```

## C.2 Social Media Domain

For user-generated social media content, the instructions specified an informal, conversational style while handling platform-specific elements such as hashtags, URLs, and expressive punctuation.

```
You are a professional {target_lang} translator, tasked with providing translations suitable for use in {target_lang}. Your goal is to accurately convey the meaning and nuances of the original text while adhering to {target_lang} grammar and vocabulary and ensuring that the translation is natural. The original text is user-generated content from a social media platform. Do not reproduce spelling mistakes. Reproduce marks of expressiveness that communicate meaningful intent (e.g. enthusiasm through capitalisation or elongation) in a way that is natural in {target_lang}. Copy URLs and user handles directly rather than translating them. However, translate hashtags as appropriate for the translation to be natural for social media text. Follow the punctuation of the source text as best as possible. Additional punctuation should be added only if not doing so would seriously alter the comprehension of the text. Translate text in an informal style, like close friends talking, even if it changes the original tone. Produce only the {target_lang} translation, without any additional explanations or commentary. Maintain the HTML formatting of the original source text. Please translate the following text into {target_lang}:
```

## C.3 Spoken Language Domain

For automatically transcribed speech, the instructions prioritized maintaining colloquial flow and handling transcription artifacts like interrupted words and non-linguistic sounds.

```
You are a professional {target_lang} translator, tasked with providing translations suitable for use in {target_lang}. Your goal is to accurately convey the meaning and nuances of the original text while adhering to {target_lang} grammar and vocabulary and ensuring that the translation is natural. The original text is automatically transcribed from spoken language and can contain errors. Maintain the flow and colloquial style of the speaker in the translation. Do not include non-linguistic sounds (e.g. laughter, groans, hesitation sounds, etc.), but do include interjections. If a word is interrupted, either guess the full word if possible or otherwise omit it. Keep foreign words as they are when translating. Produce only the {target_lang} translation, without any additional explanations or commentary. Output the text such that each sentence is on a separate line. Please translate the following text into {target_lang}:
```

### C.4 Software/JSON Domain

For localization of software interface strings, the prompt mandated strict preservation of JSON structure, object keys, placeholders, and escape sequences.

```
Translate the JSON string values into {target_lang}.
Preserve the exact JSON fragment syntax, structure,
object keys, array order, item counts, placeholders,
escape sequences, numbers, booleans, and nulls from the
input. Do not add, remove, or repair braces, brackets,
quotes, commas, or other delimiters. Translate only
natural-language string values; copy keys, placeholders,
product names, code identifiers, URLs, and non-linguistic
tokens unless translation is clearly required inside
user-facing text. Output only the translated JSON text,
with no commentary or Markdown code fences.
```

## D Dictionary Evidence Examples

The following outputs demonstrate the rendered Markdown evidence returned by the dictionary lookup tool, for the lookup requests:

```
{
  "dictionary_lookups": [
    {"lemma": "volere", "tenses": ["IndPres", "Inf"]},
    {"lemma": "mangiare", "tenses": ["Inf"]}
  ]
}
```

### Dictionary evidence for Ligurian (Genoese)

**volere** **v_tr** (avere l'intenzione) _voei_: volevo fargli una sorpresa _voeiva fâghe unna sorpreisa_; mi scusi, non volevo disturbarla _scià me scuse, no voeiva desturbâla_. ◇ (desiderare) _voei_, _(à qcn.) ëse cao_: voglio sapere cosa vi ha detto la vicina _veuggio savei cös'a va dito a vexiña_; non sa nemmeno lui ciò che vuole _o no ô sa manco lê quello ch'o veu_; vuoi che ti accompagni dal medico? _ti veu che t'accompagne da-o mego?_ vorrei diventasse un po' più indipendente _me saieiva cao ch'a vegnisse un pö ciù independente_. ◇ (con valore modale) _voei_: quando gliel'ho detto, non ci voleva credere _quande ghe l'ò dito, o no voeiva creddighe_; voglio proprio vedere come se la caverà questa volta _veuggio pròpio vedde comm'o ne sciortià stavòtta_; vuoi farmi il favore di smetterla? _ti veu fâme o piaxei de ciantâla?_ volete abbassare un po' il volume della musica, che è tardi? _voei ammermâ un pö o volumme da muxica, che l'é tardi?_. ◇ (esigere) _voei_: vogliono essere rispettati _veuan vegnî respettæ_; voglio una spiegazione, e la voglio adesso! _veuggio unna spiegaçion, e â veuggio oua!_. ◇ (concedere) _lasciâ_: non posso uscire stasera, i miei non vogliono _staseia no pòsso sciortî, i mæ no me lascian_; se mia moglie vuole, domani vengo a pescare con voi _se mæ moggê a me lascia, doman vëgno à pescâ con viatri_. **Nota:** Con i verbi modali _dovei_ "dovere", _poei_ "potere" e _voei_ "volere" seguiti da un infinito, in genovese si usa solo l'ausiliare _avei_, mentre in italiano si ricorre ad _avere_ o a _essere_ a seconda dell'ausiliare richiesto dal verbo all'infinito: _ò dovuo corrî_ "sono dovuto correre", _no ò posciuo anâghe_ "non sono potuto andarci", _an vosciuo partî_ "sono voluti partire". Fanno eccezione le forme riflessive intransitive, dove l'uso dell'ausiliare è parallelo a quello dell'italiano: _a se n'é dovua anâ_ "se n'è dovuta andare", _an vosciuo anâsene_ "sono voluti andarsene". ♦ **Multi-word expressions:** `chi troppo vuole nulla stringe`, `non c'è peggior sordo di chi non vuole sentire`, `non volerne sapere più nulla`, `volente o nolente`, `volere bene`, `volere dire` ♦ Conjugations: **ëse**: ind. pres.: son, t'ê, o/a l'é, semmo, sei, en/son / **lasciâ**: ind. pres.: lascio, ti lasci, o/a lascia, lascemmo, lasciæ, lascian / **voei**: ind. pres.: veuggio, ti veu, o/a veu, voemmo/voemo, voei, veuan

**volere** **s_m** (volontà, desiderio) _voentæ_ (fem), _voei_: questo è il volere del popolo _sta chì a l'é a voentæ do pòpolo_; il testamento rispetta il volere della nonna _o testamento o respetta a voentæ da madonnâ_. ♦ Declensions: voei (m. s.), voei (m. p.)

**mangiare** **v_tr** (ingerire del cibo) _mangiâ_, _pittâ_, _ciccâ_: non vedo l'ora di mangiare quella pizza! _no me pâ mai de tardi de mangiâ quella pissa!_ Stefano ha mangiato un panino al volo prima della riunione _o Steva o l'à mangiou un panetto a-a spedia primma da reunion_. ◇ (fare un pasto) _mangiâ_: di solito mangiamo verso le otto di sera _pe-o sòlito mangemmo pe eutt'oe da seia_; vieni a mangiare da noi domenica sera? _ti vëgni à mangiâ da niatri domenega de poidisnâ?_. ◇ (guadagnare illecitamente) _giasciâ_, _mangiâ adòsso (à qcs.)_: hanno mangiato tutti i fondi destinati alla ricostruzione _an giasciou tutti i fondi destinæ a-a reconstruçion_. **Nota:** L'espressione _mette i pê sott'a-a töa_ , letteralmente "mettere i piedi sotto al tavolo", ha il significato di "mangiare serviti". Viene usata, spesso con tono ironico, da chi è abitualmente incaricato di cucinare o servire per sottolineare che, in una data occasione, ha potuto semplicemente sedersi a tavola e mangiare senza dover fare nulla.ă **Nota:** Si segnala anche _mangiâ into papê comme i gatti_ , letteralmente "mangiare nella carta come i gatti", che descrive un modo informale e scomposto di mangiare, senza piatto né posate; e _mangiâ de strangoggion_ "mangiare strangolandosi" o _mangiâ co-o tortaieu_ "mangiare con l'imbuto", che indicano il mangiare in fretta, ingoiando quasi senza aver masticato. ♦ **s_m** (ciò che si mangia) _mangiâ_, _çibbo_, _pitto_ (colloquiale): qui il mangiare è ottimo e abbondante _chì o mangiâ o l'é milia e in abondansa_. ♦ **Multi-word expressions:** `da mangiare`, `la bellezza non si mangia`, `mangiare a quattro palmenti`, `mangiare a secco`, `mangiare fino a scoppiare`, `mangiare il pane a tradimento`, `mangiare la foglia`, `mangiarsi il fegato` ♦ Declensions: çibbo (m. s.), çibbi (f. s.) / pitto (m. s.), pitti (m. p.)

### Dictionary evidence for Ladin (Val Badia)

**volere** **s_m** (varie traduzioni possibili) _dejider_, _orëi_, _orenté_: rispettare il volere di qcn. _respeté la orenté de zacai_. Declensions: d/e/j/i/d/e/r (m. s.), d/e/j/i/d/e/r/s (m. p.) / o/r/ë/i (m. s.) / o/r/e/n/t/é (m. s.)

**volere** **v_tr** (tradotto come 'orëi') _orëi_: «Andiamo al cinema?» «Come vuoi.» _«Junse al chino?» «Sciöche t'os.»_; che cosa vuoi che ti dica? _ci oste pa ch'i te dijes?_ cosa vuoi ancora da me? _ci oste pa ciamó da me?_ Dio ha voluto così _Dí á orü insciö_; il mio mal di denti non vuole passare _mi me de dënz n'ó nia passé_. Declensions: o/r/ü/d/a (m. s.), o/r/ü/d/e/s (m. p.)

**mangiare** **s_m** (varie traduzioni possibili) _mangé_, _mangiaria_, _past_, _patüc da mangé_: il mangiare è pronto _le mangé é arjigné_; il mangiare era buono _le mangé ê bun_; un mangiare leggero _n mangé lisier_; un mangiare pesante _n mangé pesoch_; un mangiare sano _n mangé sann_. Declensions: m/a/n/g/é (m. s.) / m/a/n/g/i/a/r/i/a (m. s.), m/a/n/g/i/a/r/i/e/s (m. p.) / p/a/s/t (m. s.), p/a/s/ć (m. p.)

**mangiare** **v_tr** (varie traduzioni possibili) _ciablé_, _gosté_, _mangé_, _mangé sö_, _se mangé ite_, _cacé jö_: dar da mangiare agli affamati _ti dé da mangé a chi ch'á fan_; dar da mangiare agli affamati _ti dé da mangé ai afamá_; dar da mangiare ai poveri _ti dé da mangé ai püri_; la ruggine mangia il ferro _la rüja mangia sö le fer_; mangia e bevi _mangia y bër_. Declensions: c/i/a/b/l/é (m. s.) / g/o/s/t/é (m. s.) / m/a/n/g/i/a/d/a (m. s.), m/a/n/g/i/a/d/e/s (m. p.)

# HW-TSC's Submission to the WMT 2026 General Machine Translation Track

**Yu He, Xiaoqing Lan, Daimeng Wei, Jiaxin Guo, Yuanchang Luo, Hengchao Shang, Zongyao Li, Jinlong Yang, Zhanglin Wu, Boqi Huang**
Huawei Translation Service Center, Beijing, China

## Abstract

Machine translation based on large language models (LLMs) has achieved remarkable progress in recent years. However, relying on a single translation model and fixed translation instructions often limits translation quality, especially for multilingual and multi-domain scenarios. To address this issue, we propose HW-TSC-Agent, a multi-stage translation agent framework that integrates translation model fine-tuning, dual-model candidate generation, and instruction-aware translation refinement into a unified pipeline. First, we perform Supervised Fine-Tuning (SFT) and Contrastive Preference Optimization (CPO) on openPangu-Embedded-7B using high-quality bilingual data to enhance its multilingual translation capabilities. The fine-tuned openPangu-Embedded-7B and HY-MT2-7B are then used to generate candidate translations. Finally, source-language analysis, candidate translations, and task-specific instructions are incorporated into a dynamic prompt, which guides DeepSeek-V4-Flash to compare, refine, and fuse the candidate translations to produce the final output. Our system is submitted to the WMT2026 General Machine Translation Shared Task, covering 13 translation directions. On the WMT2025 English-to-Chinese development test set, enriching the dynamic prompt generally improves translation quality over an instruction-only DeepSeek-V4-Flash baseline.

## 1 Introduction

In recent years, large language models have demonstrated strong capabilities in contextual understanding, natural language generation, and cross-lingual knowledge transfer, driving substantial advances in machine translation Zhang et al. (2026) Naveed et al. (2025) Raza et al. (2025). Models such as GPT-4 Achiam et al. (2023), Llama 3 Grattafiori et al. (2024), Qwen3 Yang et al. (2025), and DeepSeek-V3 Liu et al. (2024) have consistently achieved state-of-the-art performance across a wide range of multilingual understanding and generation benchmarks, exhibiting remarkable capabilities in semantic reasoning, long-context modeling, and instruction following. These advances have significantly improved translation quality by enabling models to better capture contextual dependencies, preserve semantic consistency, and generate more fluent and natural target-language text. Consequently, large language models have become a promising foundation for modern machine translation systems, particularly in document-level translation and context-aware translation scenarios.

However, relying solely on a single translation model and fixed translation instructions remains insufficient for consistently producing high-quality translations that are accurate, fluent, and well adapted to specific tasks Zhang et al. (2023). Different translation models often exhibit complementary strengths Zeng et al. (2023) Xu et al. (2024), while individual samples may impose varying requirements on semantic fidelity, stylistic consistency, and output format. Therefore, we adopt a multi-source translation knowledge fusion and instruction-aware refinement strategy, integrating candidate translations from multiple models, source-language context, and task-specific instructions to further improve the fluency and accuracy of LLM-based translation.

The Conference on Machine Translation (WMT) serves as an important platform for evaluating advances in machine translation. The WMT2026 General Machine Translation Shared Task aims to assess the overall translation capabilities of systems across multilingual, multi-domain, and multimodal settings, with the test data provided at the document level. This paper presents HW-TSC-Agent, our submission to the shared task, which covers 13 translation directions. Unlike approaches that rely on a single model to generate translations directly, we adopt a multi-stage translation agent framework

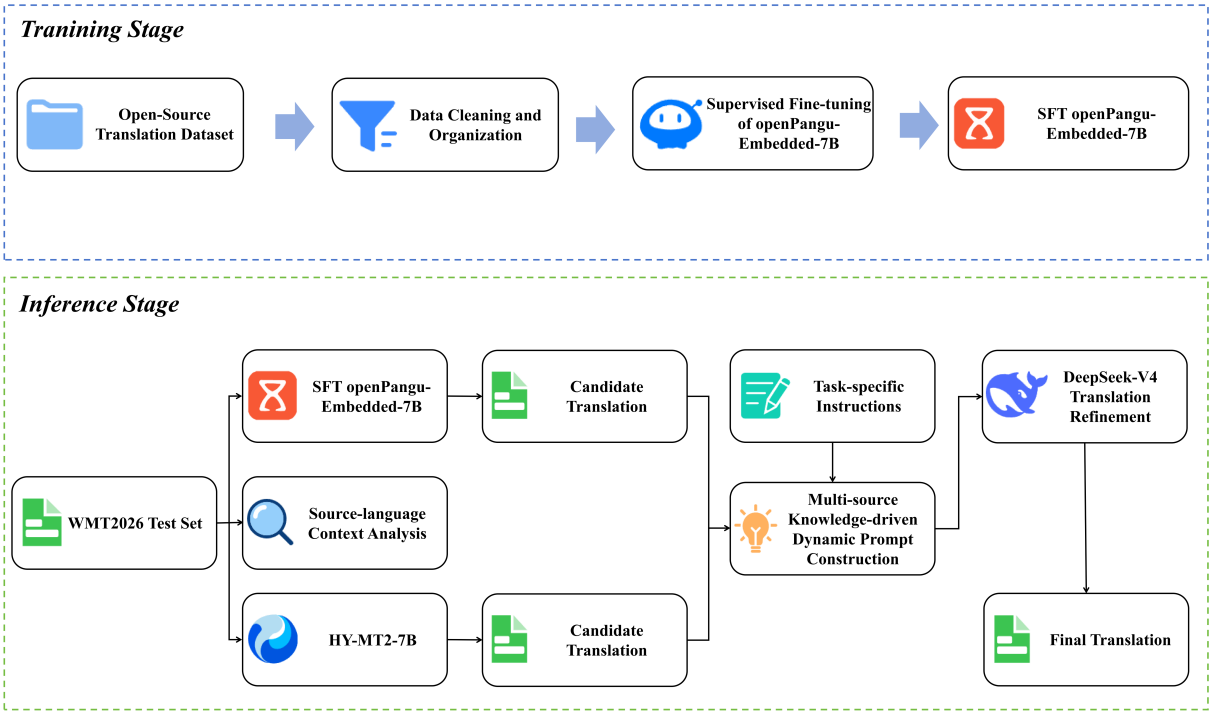

Figure 1: Overview of the HW-TSC-Agent framework, including openPangu-Embedded-7B fine-tuning (SFT and CPO), dual-model candidate generation, dynamic prompt construction, and DeepSeek-V4-Flash translation refinement.

based on large language models. Specifically, multiple models are first used to generate candidate translations, after which source-language analysis, candidate translation knowledge, and task-specific instructions are jointly incorporated into a dynamic prompt and provided to a refinement model.

We propose a multi-stage translation agent framework based on large language models to improve translation quality through three key stages: (1) fine-tuning of openPangu-Embedded-7B Chen et al. (2025) on high-quality bilingual data to enhance its general machine translation capabilities; (2) generating candidate translations using the fine-tuned openPangu-Embedded-7B and HY-MT2-7B Zheng et al. (2026) to obtain complementary translation knowledge; and (3) construction of a dynamic prompt by integrating source-language-aware context, dual-model candidate translations, and task-specific instructions, followed by the use of DeepSeek-V4-Flash to correct, fuse, and refine the candidate translations.

Our main contributions are summarized as follows:

(1) We propose a multi-stage translation agent framework based on large language models, integrating translation model fine-tuning, dual-model candidate generation, and translation refinement into a unified translation pipeline.

(2) We propose a dynamic prompt construction method that incorporates multi-source translation knowledge by jointly leveraging source-language analysis, external model translations, and task-specific instructions to provide multidimensional constraints for final translation generation.

(3) We design an instruction-aware translation refinement mechanism that uses DeepSeek-V4-Flash to compare and revise candidate translations generated by different models. The final translation is then produced according to the document context, linguistic style, formatting requirements, and output specifications of each sample, thereby improving the system's adaptability to complex general machine translation scenarios.

## 2 Methodology

### 2.1 System Overview

Our translation system, HW-TSC-Agent, consists of several stages, including model training, candidate generation, knowledge integration, and translation refinement. The overall pipeline comprises five steps: (1) cleaning, filtering, and organizing high-quality bilingual translation data to construct supervised fine-tuning data; (2) fine-tuning

of openPangu-Embedded-7B to enhance its general machine translation capabilities; (3) generating candidate translations using the fine-tuned openPangu-Embedded-7B and HY-MT2-7B to obtain complementary translation knowledge; (4) constructing a dynamic prompt driven by multi-source translation knowledge through the integration of source-language-aware context, dual-model candidate translations, and task-specific instructions; and (5) using DeepSeek-V4-Flash to correct, fuse, and refine the candidate translations. The overall architecture of the system is illustrated in Fig. 1.

### 2.2 Data Preprocessing

This work preprocesses the multilingual datasets officially released by WMT26. For the 13 submitted language pairs, we design a multi-stage preprocessing pipeline to remove low-quality data from the raw corpus and construct high-quality parallel training data. First, we randomly sample 5 GB of raw data for each language pair and perform an initial filtering step to remove obviously low-quality sentence pairs, such as those with formatting errors or empty content. To address common issues in Chinese corpora, including mixed simplified and traditional Chinese characters and inconsistent character variants, we use OpenCC to normalize the text and eliminate inconsistencies that may interfere with model training.

Second, we perform global and hash-based deduplication to remove identical and highly similar sentence pairs, reducing repeated learning and overfitting. To further improve semantic alignment, we embed each source and target sentence with LaBSE (Language-agnostic BERT Sentence Embedding) and compute the cosine similarity of the resulting bilingual representations. Pairs whose similarity falls below 0.8 are discarded as poorly aligned. The surviving pairs are then ranked by LaBSE similarity in descending order, and the top one million pairs are retained for each language pair as the final fine-tuning set.

### 2.3 openPangu-Embedded-7B Fine-tuning

To fully leverage multilingual data and improve model generalization, this work adopts a two-stage alignment training strategy consisting of Supervised Fine-Tuning (SFT) and Contrastive Preference Optimization (CPO) to enhance the multilingual capabilities of openPangu-Embedded-7B. Both stages are implemented with the ModelScope SWIFT (ms-swift) training framework.

The first stage is Supervised Fine-Tuning (SFT). We combine the training data from all language pairs and perform global shuffling to eliminate language-specific data distribution bias and improve cross-lingual semantic transfer. We then fine-tune openPangu-Embedded-7B on the mixed dataset for one epoch, enabling the model to learn shared translation patterns and semantic alignment across languages.

The second stage is Contrastive Preference Optimization (CPO). To construct high-quality preference pairs, we randomly sample 10,000 held-out examples from each language pair that are not used in SFT. We then use DeepSeek-V4-Flash Xu et al. (2026), Qwen2-72B Yang et al. (2024), and Qwen3-32B Yang et al. (2025) to generate multiple translations for each source sentence, forming multi-translation triplets. Next, we score the candidate translations with COMET20 and select the best translation as the positive sample and the worst as the negative sample. These preference pairs are used for CPO training, which guides the model toward better translation preferences through contrastive learning. This stage corrects issues from SFT, such as translation bias, unnatural phrasing, and semantic omissions, and improves multilingual translation accuracy, fluency, and robustness.

### 2.4 Multi-source Knowledge-aware Dynamic Prompt Construction

To improve the model's understanding of complex translation scenarios and the quality of translation generation, we design a source-knowledge-aware dynamic prompt construction method. For each input sample, the method integrates nine types of information: a source-text summary, translation scenario identification, translation considerations, source-format preservation requirements, domain identification, style alignment, terminology extraction, external-model candidate translations, and task-specific translation instructions (Table 1). Unlike systems that rely on a fixed language-pair instruction alone, the prompt is assembled from the source content, domain characteristics, text format, and task requirements of the current sample, so that DeepSeek-V4-Flash can jointly exploit global document context, local translation constraints, complementary candidate translations, and official task instructions when producing the final output.

Concretely, the prompt is organized in three blocks. The first block is source-language-aware context obtained by prompting a large language

| Translation Information | Main Function |
|---|---|
| Source-Text Summary | Summarize the main content of long texts to ensure document-level consistency. |
| Translation Scenario Identification | Identify the usage scenario and select an appropriate translation strategy. |
| Translation Considerations | Identify key translation points, ambiguities, and error-prone expressions. |
| Source-Format Preservation | Identify the source layout and preserve the corresponding format in the translation. |
| Domain Identification | Identify the domain and apply domain-specific terminology and translation conventions. |
| Style Alignment | Match the target style, such as formal, conversational, promotional, literary, or academic. |
| Terminology Extraction | Extract terms, named entities, and domain-specific abbreviations to ensure translation consistency. |
| External Model Knowledge | Incorporate translations from external models as complementary references. |
| User Translation Requirements | Inject task-specific translation rules and output requirements. |

Table 1: Nine types of translation information used for source-knowledge-aware dynamic prompt construction.

model to analyze the source document along the first seven dimensions in Table 1. The summary captures the main topics and discourse relations of long documents and supports document-level consistency. Scenario identification determines the practical setting of the text and guides strategy selection. Translation considerations highlight polysemous words, coreference, puns, and other spans that are prone to mistranslation or omission. Format preservation recovers titles, lists, tables, and related layout cues so that the target side can mirror the source structure. Domain identification and style alignment supply domain conventions and the intended register (e.g., formal, conversational, promotional, literary, or academic), optionally with short exemplars. Terminology extraction lists technical terms, named entities, and domain abbreviations to encourage consistent rendering throughout the document.

The second block injects external model knowledge: the candidate translations from the fine-tuned openPangu-Embedded-7B and HY-MT2-7B. Because the two models differ in lexical choice, terminology handling, completeness, and fluency, agreement between them provides a high-confidence reference, whereas disagreement encourages the refiner to re-examine the corresponding source span.

The third block injects user translation requirements from the WMT2026 test set. We focus on spoken dialogue and social media. Spoken sources may contain ASR errors, so the prompt asks the model to recover intended meaning while preserving conversational tone. Social-media sources derived from screenshots may contain spelling noise, so the prompt asks the model to correct surface errors while retaining emotional cues. Together, the three blocks turn the nine information types into a sample-specific instruction rather than a static template shared by an entire language pair.

### 2.5 Translation Refinement

DeepSeek-V4-Flash receives the assembled dynamic prompt and produces the final translation by comparing, revising, and fusing the two candidates under the source-analysis and task constraints. The refiner is instructed to prefer information that is supported by the source, to preserve required formatting, and to follow scenario-specific rules when applicable. The DeepSeek-V4-Flash output is used as the submitted translation.

## 3 Experiments

### 3.1 Experimental Setup

**Submission coverage.** Our WMT2026 submission covers 13 translation directions: en→{ar, cs, id,

ja, kk, ko, th, uk, zh, zh_TW}, cs→{uk, vi}, and zh→ja.

**Development evaluation.** We report automatic scores on the WMT2025 General Machine Translation English-to-Chinese test set as a development benchmark for comparing prompt variants under a fixed DeepSeek-V4-Flash refinement backbone. Translation quality is evaluated with COMETKiwi-XL Rei et al. (2023) and XCOMET-XL Guerreiro et al. (2024).

**Inference setup.** All candidate-generation and refinement models are served through self-hosted deployments.

### 3.2 Main Results

Table 2 presents the evaluation results of the DeepSeek-V4-Flash baseline and four Agent variants on the WMT2025 English-to-Chinese test set. The baseline uses only the official translation instructions as the prompt, achieving COMETKiwi-XL and XCOMET-XL scores of 0.5581 and 0.3674, respectively. After introducing seven types of source-language-aware information, Agent-v1 improves the COMETKiwi-XL score to 0.5669. Agent-v2 and Agent-v3 further incorporate ASR error correction requirements for spoken transcripts and spelling correction requirements for social media texts, respectively, leading to additional performance gains. Among them, Agent-v3 achieves the best COMETKiwi-XL score of 0.5706, while its XCOMET-XL score increases to 0.3699.

| Model | COMETKiwi-XL | XCOMET-XL |
|---|---|---|
| DeepSeek-V4-Flash | 0.5581 | 0.3674 |
| Agent-v1 | 0.5669 | 0.3624 |
| Agent-v2 | 0.5700 | 0.3664 |
| Agent-v3 | **0.5706** | 0.3699 |
| Agent-v4 | 0.5670 | **0.3776** |

Table 2: Development results on the WMT2025 English-to-Chinese test set. The best results are highlighted in bold.

Agent-v4 further incorporates explicit contextual understanding cues, achieving an XCOMET-XL score of 0.3776, which is 0.0102 higher than the baseline. Its COMETKiwi-XL score is 0.5670, which is lower than that of Agent-v3 but still exceeds the baseline. Prompt enrichment generally improves at least one of the two metrics, although the variants exhibit different trade-offs between COMETKiwi-XL and XCOMET-XL. The two metrics respond differently to the added prompt components, suggesting that prompt enrichment does not uniformly improve all dimensions of translation quality.

## 4 Conclusion

This paper presents HW-TSC-Agent, our system developed for the WMT2026 General Machine Translation Shared Task across 13 directions. We propose a multi-stage translation agent framework that combines supervised fine-tuning and preference optimization of openPangu-Embedded-7B, dual-model candidate generation, dynamic prompt construction with multi-source translation knowledge, and DeepSeek-V4-Flash refinement. On the WMT2025 English-to-Chinese development set, enriching the dynamic prompt improves COMETKiwi-XL and XCOMET-XL relative to an instruction-only DeepSeek-V4-Flash baseline for the strongest prompt variants.

## Acknowledgments

We thank the WMT2026 organizers for the task design and data, and colleagues at HW-TSC for discussion and engineering support.

# CUNI-MH and CUNI-EdUKate at the WMT26 General MT Shared Task

**Miroslav Hrabal, Josef Jon, Ondřej Bojar**
Charles University, Faculty of Mathematics and Physics
{hrabal,jon,bojar}@ufal.mff.cuni.cz

## Abstract

We describe our constrained CUNI-MH-v3 (based on Qwen3-14B) and unconstrained CUNI-EdUKate (based on Granite 4.1 8B) submissions for the WMT26 General MT shared task. Both submissions use a three-stage training procedure: QLoRA supervised fine-tuning on synthetic sentence pairs, continued supervised fine-tuning on a smaller mixture of paragraph-level and instruction-oriented examples, and iterative preference optimization with automatically generated and scored preference pairs. We document the data construction, training setup, checkpoint selection, and evaluation. We also share the training data and model checkpoints for our constrained system.

## 1 Introduction

The WMT General MT shared task evaluates translation across diverse language pairs. Our submissions focus on adapting instruction-tuned multilingual large language models with parameter-efficient fine-tuning on just four of them: English–Czech, Czech–Vietnamese, Czech–German and Czech–Ukrainian. We used the same general training recipe across all language pairs and put most of our focus on the new Czech–Vietnamese pair. Table 1 summarizes our submissions and the supported language pairs. Although our adapters train bidirectionally, the shared task evaluates only one direction for each pair. The constrained CUNI-MH-v3 covers the four language pairs and uses Qwen-14B (Team, 2025) as a base model. CUNI-EdUKate covers just Czech–German and Czech–Ukrainian and uses Granite-4.1-8B (IBM Research, 2026) as base model. Since it was trained on additional educational domain EdUKate data that cannot be redistributed, it falls into the unconstrained category.

## 2 Data

Our training data is organized around the three different training stages. This year, we choose to focus on using synthetic parallel data created using back-translation.

### 2.1 Stage 1: Synthetic Sentence Data

We took monolingual documents from HPLTv3 (Oepen et al., 2026), split them into sentences, removed exact duplicates and applied deterministic shuffle. We backtranslated the monolingual sentences with `cyankiwi/gemma-4-31B-it-AWQ-4bit`, an AWQ-quantized (Lin et al., 2026) version of the instruction-tuned Gemma 4 31B model (Team et al., 2026). The same model also assigned an integer 0–100 direct-assessment score to each resulting pair. For this stage, we retained pairs with a score of at least 75. We also used the forward translation by swapping source and target, combined both orientations and shuffled the result.

### 2.2 Stage 2: Data Augmented Mixture

The second supervised stage uses a smaller mixture intended to adapt the model for the types of segments we expected to see in the WMT26 test set. We deterministically shuffle each source, normalize the configured mixture weights, and construct the largest mixture that does not require oversampling any source. The resulting datasets contain between 8 943 and 14 399 examples depending on the language pair.

The components, in Table 2 order, are: (1) all synthetic sentence pairs scoring at least 90; (2) the deterministically selected first shard of scored paragraph pairs, with no additional threshold; (3) different paragraph layouts[1] generated from a separate sample of 500 paragraph pairs scoring at least 95; (4) glossary examples using either the fixed English instruction "Use the following glossary"

[1]By paragraph layouts, we mean that the source and target paragraphs consist of several aligned segments and these segments are separated by different whitespace separators, for example newline, double newline, and space. Different combinations of separators mean different paragraph layouts in this context.

| System | Backbone | cs–de | cs–uk | cs–vi | en–cs |
|---|---|---|---|---|---|
| CUNI-MH-v3 | Qwen3-14B | ✓ | ✓ | ✓ | ✓ |
| CUNI-EDUKATE | Granite-4.1-8B | ✓ | ✓ | – | – |

Table 1: Submitted systems and WMT26 evaluation directions.

| Stage-2 source category | Share |
|---|---|
| Filtered synthetic sentences | 25.81% |
| Scored paragraphs | 12.90% |
| Generated/aligned paragraphs | 12.90% |
| Glossary instructions | 25.81% |
| Inline tags | 12.90% |
| Do-not-translate spans | 6.45% |
| Lowercase inputs | 3.23% |

Table 2: Target composition of the Stage-2 supervised mixture.

or LLM-generated paraphrases; (5) variants containing aligned HTML, placeholder, or randomized XML-like tags; (6) up to five do-not-translate (DNT) variants that copy a source span wrapped in `<ufaldnt>` unchanged into the target; and (7) lowercased sources paired with targets in their original casing.

Components 4–6 start from deterministic samples of 500 synthetic pairs per language pair scoring at least 90. We used `cyankiwi/gemma-4-31B-it-AWQ-4bit` for generation or bilingual alignment where it was required, for example when proposing alternative glossary terms and applying them to the segment in question.

### 2.3 Stage 3: Preference Pairs

Preference pairs are generated online rather than generated in advance. For CUNI-MH-v3, each direction uses a pool containing 75% Stage-2 examples and 25% examples derived from WMT25. We included the WMT25 data in order to expose the models to shared-task-style instructions. We therefore do not use WMT25 as an independent development set.

For CUNI-EDUKATE, we use a 50/25/25 mixture of Stage-2, WMT25, and EdUKate examples. The final EdUKate sampling pools have the same sizes as the corresponding general pools because the available WMT25 portion is the limiting source.

## 3 Methods

All stages use the same chat representation. A system message simply states "You are a helpful assistant."[2] The user message gives the source and target language, an optional context (translation instructions) field, and the source text. The exact format can be found in Appendix A. The reference translation is the assistant response.

We train QLoRA (Dettmers et al., 2023; Hu et al., 2022) adapters while loading the base model in 4-bit NF4 format with double quantization and bfloat16 computation. Qwen adapters use rank 128 and $\alpha$ 256. Granite adapters use rank 256 and $\alpha$ 512. In both cases, LoRA adapter is applied to all linear modules with zero dropout. Table 3 summarizes the main settings.

### 3.1 Supervised fine-tuning

Stage 1 starts from either `Qwen/Qwen3-14B` or `ibm-granite/granite-4.1-8b`. We train for at most 10,000 steps with sequence length 512, batch size 16, a paged 8-bit AdamW optimizer, cosine scheduling, and a learning rate of approximately $6.36 \times 10^{-5}$. The first 512 records are reserved for evaluation loss.

Stage 2 continues the same adapter on the structured mixture described in Section 2. We increase the maximum sequence length to 1,024, enable packing and assistant-only loss, and train for 500 steps with batch size 16 and learning rate $2 \times 10^{-5}$. We again reserve the first 512 records for evaluation. Stage 2 is deliberately short: its purpose is instruction and structure coverage rather than another pass over millions of sentence pairs.

### 3.2 Iterative preference optimization

Unlike our submission from previous year (Hrabal et al., 2025), we chose not to pre-generate the preference pairs but train in several iterations and generating the pairs using the latest such version of the model, similarly to Sun et al. (2025).

Stage 3 consists of multiple iterations. At iteration $i$, we use reservoir sampling for 500 records

[2]We included this system message primarily to unify and override system messages of some models we initially experimented. An extreme case of this is for example granite-3.3-8b-instruct, whose chat template dynamically inserts current date to system prompt, which could potentially have hard to predict effects on reproducibility when not overridden.

| Family/stage | Backbone or parent | LoRA $r$ | Steps/rounds | Max. length | Learning rate |
|---|---|---|---|---|---|
| MH-v3 Stage 1 | Qwen3-14B | 128 | 10,000 steps | 512 | $6.36 \times 10^{-5}$ |
| MH-v3 Stage 2 | Stage-1 adapter | 128 | 500 steps | 1,024 | $2 \times 10^{-5}$ |
| MH-v3 Stage 3 | Stage-2 adapter | 128 | $10 \times 500$ samples | 1,024 | $10^{-5}$ |
| EdUKate Stage 1 | Granite-4.1-8B | 256 | 10,000 steps | 512 | $6.36 \times 10^{-5}$ |
| EdUKate Stage 2 | Stage-1 adapter | 256 | 500 steps | 1,024 | $2 \times 10^{-5}$ |
| EdUKate Stage 3 | Stage-2 adapter | 256 | $10 \times 500$ samples | 1,024 | $10^{-5}$ |

Table 3: Training configuration. Stage-3 values for Steps/rounds denote the number of rounds times sampled inputs. Candidate generation may produce multiple pairs per input, and filtering by score-difference then determines the size of the training-set, so the actual number of training steps of each such round is variable. The selected MH-v3 en–cs run uses learning rate $5 \times 10^{-6}$.

from the corresponding preference pool using seed $4243 + i$. We serve the current adapter with vLLM and translate each sampled source greedily. When a reference is available, it forms an alternative candidate. For the CUNI-MH-v3 Czech–German and Czech–Vietnamese runs and both EdUKate runs, Gemma-4-31B-it was also used for one additional candidate through a simple DSPy translation prompt. The MH-v3 Czech–Ukrainian and English–Czech runs use no extra candidate model.

Unique candidates are assigned scores from 0 to 100 by `cyankiwi/gemma-4-31B-it-AWQ-4bit` through a DSPy direct-assessment prompt. We order candidates by this score and retain chosen/rejected pairs whose score differs by at least two points.

We then continue the current adapter on the retained pairs. The objective combines sigmoid DPO (Rafailov et al., 2024), BCO-pair (Jung et al., 2025), and supervised fine-tuning losses with weights 0.8, 0.2, and 1.0, respectively. Training uses a per-device batch size of 2 and gradient accumulation over 16 steps, giving an effective batch size of 32. The learning rate is $10^{-5}$ for most runs. The selected English–Czech run uses $5 \times 10^{-6}$. Each subsequent iteration starts from the adapter produced by the preceding iteration.

### 3.3 Submitted checkpoints

Table 4 records the selected stage and iteration for each submitted direction.

| System | Direction | Selected model |
|---|---|---|
| EdUKate | cs–de | Stage 3, iteration 1 |
| EdUKate | cs–uk | Stage 3, iteration 1 |
| MH-v3 | cs–de | Stage 3, iteration 1 |
| MH-v3 | cs–uk | Stage 3, iteration 2 |
| MH-v3 | cs–vi | Stage 3, iteration 1 |
| MH-v3 | en–cs | Stage 3, iteration 2 |

Table 4: Checkpoints used for the final submissions.

## 4 Internal Evaluation

We compare submitted checkpoints with their unadapted backbones, intermediate supervised checkpoints, prior CUNI WMT25 systems, and Gemma-4-E2B and E4B system baselines. "Direct" denotes the prompt we use during training together with greedy decoding; Prior systems are re-evaluated here rather than represented by their official WMT25 scores.

We evaluated checkpoints internally on FLORES+ dev for Czech–Vietnamese, Czech–Ukrainian, and English–Czech; on WMT23 for English–Czech; and on an EdUKate development set for Czech–Ukrainian. We report corpus BLEU (Papineni et al., 2002), chrF2 (Popović, 2015), and direct assessment by Gemma-4-31B. WMT25 is excluded because it contributes examples to the Stage-3 pools.

We report corpus BLEU, chrF2, and reference-free direct assessment (DA) by the quantized Gemma-4-31B. The evaluator receives source, hypothesis, language pair, and optional context and produces an integer 0–100 segment score; tables report the mean. FLORES+ dev contains 997 examples per direction, WMT23 contains 2,074, and EdUKate dev contains 3,770.

Tables 5 to 8 group the systems into baselines, submitted checkpoints, and later preference-optimization checkpoints. Czech–German and Czech–Vietnamese runs ended after iteration 6, and the EdUKate runs ended after iteration 1; consequently, iteration 10 exists only for the MH-v3 Czech–Ukrainian and English–Czech runs.

The submitted MH-v3 system performs closest to the strongest listed baseline on Czech–Vietnamese: its BLEU is close to Gemma-4-E4B with DSPy, while its DA score is higher. On the three transla-

| System | FLORES+ dev BLEU | chrF2 | DA |
|---|---|---|---|
| *Baselines* | | | |
| WMT25 CUNI-MH-v2 | **27.92** | **58.37** | **93.78** |
| Gemma-4-E2B, direct | 9.32 | 46.17 | 62.13 |

| CUNI-EdUKate, it. 1 | 26.34 | 56.41 | 90.55 |

Table 5: Czech–German development results. No iteration-10 checkpoint was produced; the MH-v3 run ended at iteration 6 and the EdUKate run at iteration 1.

tion directions shared with WMT25, however, the previous systems remain stronger. The gap is largest for English–Czech and on the EdUKate development set. The iteration-10 checkpoints do not seem to improve over the early submitted checkpoints on Czech–Ukrainian or English–Czech. On Czech–Vietnamese, later iterations seem to trade lower BLEU for a higher Gemma DA score.

Overall, we hypothesize that the underwhelming performance on the English–Czech and Czech–Ukrainian language pairs may be at least partly to our tuning of the training hyperparameters being overly focused on Czech–Vietnamese, particularly with respect to the relatively short stage 1 and stage 2 training. Unfortunately, by the time we identified this issue, there was insufficient time to rerun the experiments before the WMT26 submission deadline. One possible explanation is that differences between the language pairs, including differences in morphological complexity, may affect the amount of training required. We leave verification of this hypothesis to future experiments.

Manual experiments with the final checkpoints before submission suggested that the model is sensitive to changes in the provided instructions and that these instructions could, in some cases, degrade translation quality. We therefore chose to disable the context field for our final submissions by ignoring the instruction field in the WMT26 evaluation set. However, because WMT25 data had been used during training and we did not have another authentic development set containing comparable instructions, we were unable to quantify the effect reliably before submission. Consequently, this decision was based on qualitative observations rather than a systematic evaluation.

## 5 Inference and Tools

We use Transformers (Wolf et al., 2020) for model loading, PEFT (Mangrulkar et al., 2022) for LoRA adapters, TRL (von Werra et al., 2020) for supervised and preference trainers, bitsandbytes for quantized loading and optimization, and vLLM (Kwon et al., 2023) for all model inference. We DSPy (Khattab et al., 2022, 2024) for the direct-assessment tool. Preliminary QLoRA hyperparameter experiments use Optuna (Akiba et al., 2019) with a seeded multivariate TPE sampler.

For submission inference, we serve each selected adapter through vLLM with model thinking disabled and greedy decoding. Source text is divided into chunks of at most 128 Qwen tokenizer tokens. Longer inputs are split hierarchically at paragraph, newline, sentence, and finally whitespace or token boundaries; the recorded separators are restored after translation. The outputs are then reinserted into the shared-task JSONL structure.

## 6 Model Weights and Training Data

We publish the weights of the CUNI-MH-v3 model on HuggingFace as separate LoRA adapters per bidirectional language pair: en-cs[3] cs-vi[4] cs-uk[5] cs-de.[6]

The training data for CUNI-MH-v3 SFT stages will also be published.[7]

## 7 Limitations

The Gemma-based DA results scores be interpreted cautiously because variants of the same model family were also used for synthetic-data generation, filtering, preference-pair construction, and candidate generation.

## 8 Conclusion

We described two CUNI submissions submitted to the WMT26 General MT shared task. Both use a large synthetic sentence-level SFT stage, a smaller SFT stage on mixture of sentence-level, paragraph-level, and augmented data, targeting terminology translation, Followed by iterative preference optimization of QLoRA adapters. CUNI-MH-v3 uses Qwen3-14B for four directions, while CUNI-EdUKate uses Granite-4.1-8B and additional EdUKate data for Czech–German and Czech–Ukrainian. For the selected checkpoints we evaluated internally, preference optimization changed the metric trade-off but did not consistently improve every automatic metric.

## Abstract

We describe the Charles University CUNI-AR submission to the WMT26 General Translation shared task for English into Egyptian Arabic. Our pipeline is built around GEMBA (LLM-as-judge) quality estimator that scores translations independently for *accuracy* and *dialect authenticity*. We use it throughout our pipeline: to filter training data, to construct preference pairs for DPO, to select best checkpoints, and to pick the best hypothesis per segment at inference time. Our primary translation model is Gemma-4-12B-it finetuned via QLoRA, we also finetune Jais-2-8B-Chat and Aya-expanse-8B. Gemma-4-12B-it provides a high-quality Egyptian Arabic translation, so SFT yields only marginal quality gains in automatic metrics; DPO is able to improve the metrics it optimizes for, but the real gain in translation quality is to be assessed by human evaluation. The final submission selects the best-scoring translation per segment from 31 candidate checkpoints, with the unmodified base model contributing 31% of the output.

## 1 Introduction

Translating into Arabic dialectal varieties poses challenges that go beyond those of standard machine translation into high-resource languages. Both spoken language and written norms differ across varieties, and the boundaries between dialects are gradient rather than discrete. Standard quality-estimation models such as COMET-QE treat Arabic as a single language and have no mechanism to assess whether a translation is idiomatic in the desired variety, making it harder to automatically evaluate the quality of the translation. Dialect-differentiated test sets are scarce, so even reference-based metrics do not solve the issue.

Our submission (team **CUNI-AR**) is built around a quality estimation using LLM as a judge (GEMBA), which scores translations independently for *accuracy* (meaning preservation) and *dialect authenticity* (idiomatic correctness for the target variety). We use this signal at every stage of the pipeline: to filter training data, to construct preference pairs for Direct Preference Optimization (DPO), to select checkpoints after finetuning, and to perform segment-level best translation selection at inference time. For the translation models themselves we finetune Gemma-4-12B-it (Team, 2026), Jais-2-8B-Chat (Anwar et al., 2026) and Aya-expanse-8B (Dang et al., 2024) using QLoRA (Dettmers et al., 2023) both for supervised finetuning (SFT) and direct/contrastive preference optimization (DPO/CPO).

The main findings of our work are as follows. First, GEMBA with a Gemma-4-31B-it judge correlates strongly with WMT25 human scores (Pearson $r = 0.916$ overall), validating its use as a quality signal. Second, supervised finetuning on GEMBA-filtered synthetic data (WMT23 English sources machine translated to multiple Arabic dialects) yields only marginal or negative gains on chrF and GEMBA, indicating that Gemma-4-12B-it is already a strong Egyptian Arabic translator out of the box (at least compared to other models used to create the synthetic data). With the exception of the Alexandria dataset, all the other datasets we used for finetuning decreased both GEMBA and ChrF scores on the WMT25 test set. Finally, DPO on preference pairs that include both intra-dialect — choosing the best-scoring translation among multiple options, and cross-dialect signal — pairing the best translation into the target dialect against the best translation into a different dialect — improves GEMBA scores beyond the best SFT checkpoint.

The paper is organized as follows. Section 2 describes the related work. Section 3 describes the experimental setup, including base model selection, the GEMBA estimator, datasets, and finetuning procedures. Section 4 reports results for SFT, DPO, and the final segment-level ensemble.

## 2 Related Work

Arabic MT has evolved through the same broad paradigm shifts as the wider field. Early systems combined rule-based and phrase-based statistical approaches with dedicated morphological analysis to handle Arabic's complex inflectional morphology (Habash, 2010; Habash and Hu, 2009). The rise of Transformer-based NMT (Vaswani et al., 2017) rendered many of these hand-crafted components obsolete, yielding strong results on standard Arabic benchmarks (Almahairi et al., 2016; Durrani et al., 2016). More recently, large language models finetuned for Arabic have pushed quality further (Nagoudi et al., 2022a,b) – a broader comparison of current Arabic-capable LLMs is given in Table 1 and Figure 1. Dialectal Arabic MT poses additional challenges: parallel data are scarce, orthographic conventions are unstable, and dialects diverge substantially from MSA and from each other. Early approaches pivoted through MSA as an intermediate (Sajjad et al., 2013; Salloum and Habash, 2013); later work finetuned models directly on dialect data (Zbib et al., 2012; Nagoudi et al., 2021). The MADAR corpus provided the first broad-coverage dialectal resource (Bouamor et al., 2018), and Egyptian Arabic in particular has attracted attention as the most widely understood spoken variety (Darwish et al., 2021). IWSLT has included dialectal tracks (Tunisian, Levantine) since 2024, where LLMs have proved competitive (Ahmad et al., 2024; Abdulmumin et al., 2025; Ben Kheder et al., 2024; Jon et al., 2025).

The GEMBA framework addresses this by prompting an LLM to score translations on explicit criteria (Kocmi and Federmann, 2023a,b); we extend it with a dialect authenticity dimension and use it as the central quality signal throughout our pipeline. Preference optimization methods—DPO (Rafailov et al., 2023) and related contrastive objectives (CPO; Xu et al. (2024))—have recently been applied to MT to push finetuned models beyond what supervised training alone achieves.

## 3 Experimental setting

This section contains an overview of our experimental setting, including models, datasets and tools.

### 3.1 Base Models

We have run extensive evaluation of LLMs on translating from English into Arabic dialects, extending our previous work from Jon et al. (2026).

| | CHRF | | |
|---|---|---|---|

| gemma-4-12B-it | 44.1 | 47.2 | 43.9 |
| gemma-4-31B-it | 44.2 | 47.5 | 44.5 |

Table 1: CHRF scores on WMT24++ Saudi and Egyptian Arabic (24++ sa and 24++ eg) and on WMT25 Egyptian Arabic test set (25 eg) for multiple LLMs.

We expanded the original list of compared models with newly published Gemma 4 (31B) and Karnak (6B, 40B and 70B) and the list of test sets by the WMT25 and WMT24++ English to Egyptian Arabic and Saudi Arabic test sets (Kocmi et al., 2025; Deutsch et al., 2025), while using the same inference setup and postprocessing. Table 1 and Figure 1 show ChrF scores on the WMT and MADAR datasets, respectively. Table 7 in Appendix A shows the corresponding BLEU scores on the WMT test sets. Note that the references are not secret, so they might have been used in the models' training data, especially in the case of the older MADAR test set.

Based on the results, we selected several models for finetuning:

- **Gemma-4-12B-it** – our primary model throughout the experiments. In automated metrics, it performs only slightly worse than the 31B and the number of parameters fits within the WMT constrained-track limit ($\leq$20B parameters).
- **Gemma-4-31B-it** – used for some of the experiments and GEMBA scoring, but not in the final submission.
- **Jais-2-8B-Chat** – a well-performing Arabic-specialized model.

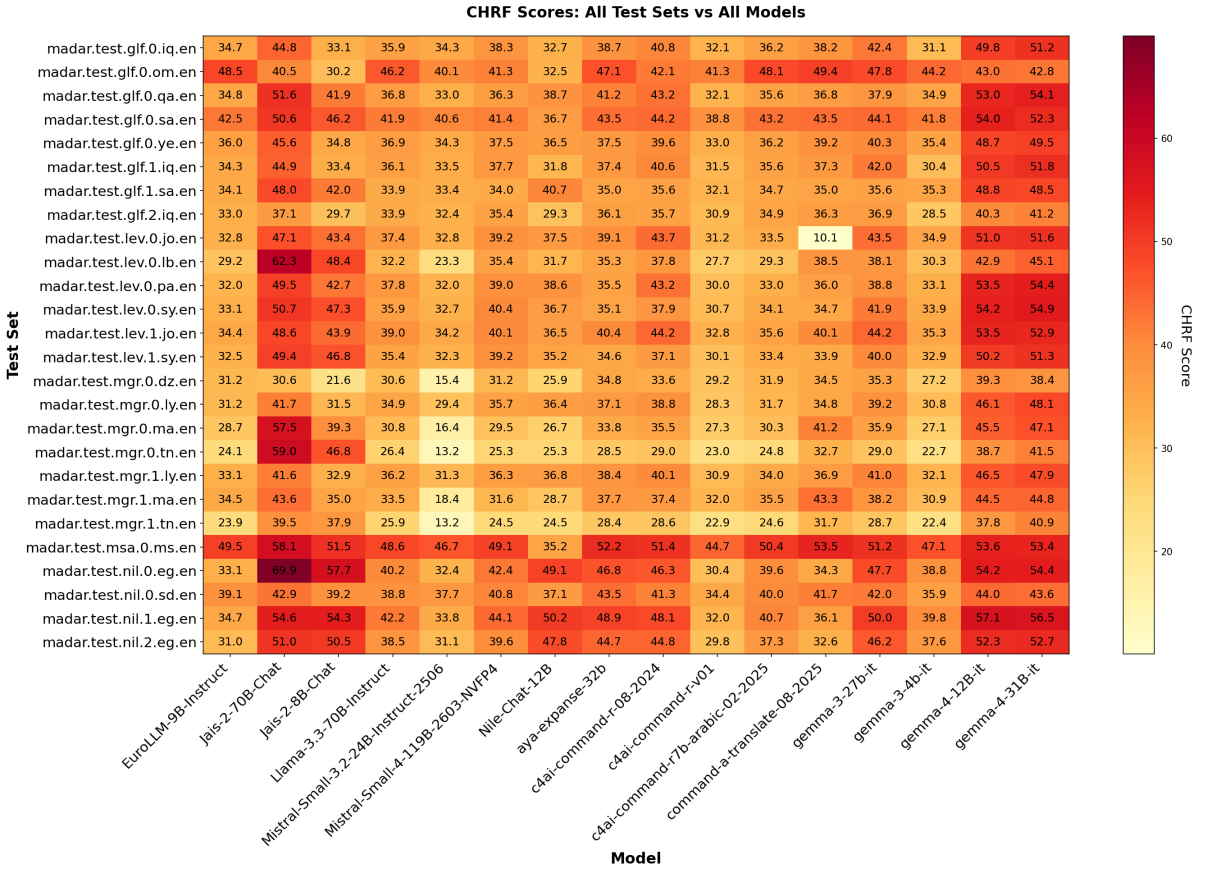

Figure 1: ChrF scores on MADAR test sets.

- **Aya-expanse-8B** – a lower-performing model included to assess how much finetuning can help.

### 3.2 GEMBA evaluation

Standard quality estimation (QE) models, like COMET-QE, are not suitable for dialectal Arabic, since it is not possible to indicate the target language/dialect. Thus, they have no way of taking the dialectalness into account when scoring. In multiple stages of our pipeline, we experimented with prompting multiple LLMs (method also called GEMBA) to score the translations along two dimensions:

- **Accuracy** — whether the translation faithfully conveys the meaning of the source.
- **Dialect authenticity** — whether the target text is in the desired Arabic variety.

We correlated the produced scores with the WMT25 human evaluation on the Egyptian Arabic translation. The results are shown in Table 2. We see that Gemma 4 GEMBA scores correlate quite well with the human scores, even though not for all the systems, suggesting that some types of errors made by these systems might go unnoticed. We chose to use Gemma 4 as the main source of the GEMBA scores in the following experiments, even though we note that our base models are also Gemma 4 and scoring their outputs by themselves is not optimal, for example in the DPO stage.

Table 3 reports GEMBA accuracy, dialect authenticity, and combined scores for a selection of WMT25 competition systems alongside our unmodified base models, evaluated by two judge sizes (Gemma-4-12B-it and Gemma-4-31B-it).

The split into accuracy and dialect immediately clarifies the low human rankings at the bottom of the WMT25 field: AyaExpanse-8B scores 57 on accuracy but only 1–3 on dialect authenticity under both judges, and Algharb shows the same pattern (accuracy 63–68, dialect 0.7–2.2). These systems translate into Modern Standard Arabic rather than Egyptian Arabic, which human raters penalize heavily — and GEMBA captures this correctly. Aya-expanse-8b re-evaluated with our pipeline on the same 199 WMT25 test segments, yields 58.7 / 3.1 / 30.9 (G-12B) and 56.8 / 1.4 / 29.1 (G-31B),

Table 2: Pearson $r$ between GEMBA and WMT25 human scores (English→Egyptian Arabic) by WMT25 system and GEMBA judge model. Acc. = accuracy, Dial. = dialect authenticity, Comb. = combined. Human scores are MQM-style DA on a 0–100 scale; systems sorted by average human score (descending).

compared to 56.8 / 2.5 / 29.7 and 55.4 / 0.9 / 28.2 in the WMT25 scoring. The small discrepancy is expected: mostly due to a different prompt and decoding parameters.

**Overscoring by GEMBA** The first form of overscoring concerns the absolute calibration of GEMBA scores against human direct assessment (DA). Although both GEMBA and human DA nominally use a 0–100 scale, they are not aligned. Even if we focus on the more correlated dialect score, it tends to overestimate the quality compared to human evaluators, especially at the high end (e.g. 77 human vs 94.5 dialect GEMBA for GPT-4.1).

The second form of overscoring, which we hypothesize, is towards the GEMBA evaluator model's own outputs (or outputs of the models from the same family). It is probable that the quality of Gemma-produced translations is overestimated by a Gemma-based GEMBA evaluator. As we do not have human evaluations available for the Gemma models we use, we could not test this hypothesis. However, we still used Gemma 4 models both for translating and quality estimation, keeping this risk in mind, since no other models came close to it in terms of correlation with human judgment.

### 3.3 Tools

**Training** All finetuning was implemented with the HuggingFace `transformers` library (Wolf et al., 2020) and the `TRL` library (von Werra et al., 2020) for SFT and DPO trainers. LoRA adapters were managed via `PEFT` (Mangrulkar et al., 2022). 4-bit QLoRA quantisation used `bitsandbytes` (Dettmers et al., 2023).

**Inference** Translation and GEMBA scoring were performed with `vLLM` (Kwon et al., 2023).

**Evaluation** ChrF (Popović, 2015) and BLEU (Papineni et al., 2002) were computed with `SacreBLEU` (Post, 2018). GEMBA scoring used our own implementation on top of vLLM-served judge models. Prompts are given in Appendix B.

### 3.4 Datasets

We have experimented with multiple datasets, listed in Table 4. We created the WMT23 dataset by translating all of the source segments of WMT23 dev sets using gpt-5.4-nano, Gemma-4-{12,31}B-it and Jais-2-{8,70}B-Chat into 21 Arabic dialects, which we name by the countries in which they are used: Egyptian Arabic (eg), Saudi Arabic (sa), Jordanian Arabic (jo), Palestinian Arabic (ps), Lebanese Arabic (lb), Syrian Arabic (sy), Moroccan Arabic (ma), Mauritanian Arabic (mr), Tunisian Arabic (tn), Algerian Arabic (dz), Libyan Arabic (ly), Iraqi Arabic (iq), Sudanese Arabic (sd), Omani Arabic (om), Yemeni Arabic (ye), Emirati Arabic (ae), Bahraini Arabic (bh), Kuwaiti Arabic (kw), Qatari Arabic (qa), Chadian Arabic (td) and Modern Standard Arabic (msa). We note that this is not a perfect approach to distinguish the dialects, since many dialects are used across multiple countries and multiple dialects can be used in a single country, but we have chosen this approach to align with the MADAR dev/test set we used for evaluation. We then scored all the translations with GEMBA with Gemma-4-31B-it model. These scores were used both for filtering the dataset for SFT and to choose the preferred translations for the preference opti-

Table 3: GEMBA accuracy (Acc.), dialect authenticity (Dial.), and combined score (Comb., 0–100) for selected WMT25 Egyptian Arabic competition systems and our unmodified base models, under two judge sizes. Human scores (Hum.) are MQM-style DA averages from the WMT25 evaluation.

mization methods. We call the filtered SFT dataset wmt23-gemba and the PO dataset wmt23-po.

Our backtranslated HPLT dataset is based on version 3.0 of originally a monolingual dataset compiled by the HPLT project[1]. It contains fine-grained language identification, differentiating between Arabic dialects (Levantine, Tunisian, Egyptian, Moroccan, Najdi and MSA). We backtranslated the texts into English using Gemma-4-31B-it to obtain a synthetic parallel dataset.

**Alexandria conversational dataset (`alexandria`).** The UBC-NLP/Alexandria dataset (EL Mekki et al., 2026) provides multi-turn bilingual conversations (English ↔ 13 Arabic dialectal varieties) covering Egypt, Jordan, Lebanon, Libya, Mauritania, Morocco, Oman, Palestine, Saudi Arabia, Sudan, Syria, Tunisia, and Yemen. We used the full training split.

Other datasets listed in Table 4 are either parallel or monolingual resources found on HuggingFace.

For evaluation, we use WMT25 test set (Kocmi et al., 2025), Alexandria dev split and MADAR (Sajjad et al., 2020) dev and test sets.

### 3.5 Finetuning

**SFT** We have finetuned the pretrained models using QLoRA. We compared Aya-expanse-8B, Gemma-4-12B-it and Jais-2-8B-Chat as the base pretrained models and we finetuned them on different combinations of all datasets. Target dialect sets ranged from Egyptian Arabic only to 21 Arabic varieties. As the sweep narrowed, Gemma-4-12B-it and Jais-2-8B-Chat became the primary base models, with training data converging on GEMBA-filtered WMT23 synth data with and without Alexandria (other datasets did not bring any increases in ChrF scores on the WMT25 test set). Across all models we swept LoRA rank $r \in \{4, 8, 16, 32, 64, 128\}$, LoRA $\alpha = 2r$ and learning rates $\{$1e-5, 2e-5, 4e-5, 5e-5, 6e-5, 6.36e-5$\}$. Training ran for up to 8,000 steps in early broad runs and was capped at 1,000 steps in focused later runs.

**DPO** We generated preference pairs from the same pool of WMT23 hypotheses used for SFT, i.e., for each of the 22,518 WMT23 source sentences, multiple translations were produced across 21 Arabic dialect varieties, each scored by GEMBA (Gemma-4-31B-it judge) along two dimensions: accuracy and dialect authenticity. We used the mean of the two scores as a single combined quality signal.

We constructed two complementary pair types. **Within-dialect pairs** contrast translations of the same source into the same target dialect produced by different translation models: the higher-scoring hypothesis is *chosen* and any lower-scoring hypothesis is *rejected*, provided the chosen score meets a minimum threshold (combined GEMBA $\geq 95$) and the score gap is positive. **Cross-dialect pairs** use the best-scoring translation into dialect $A$ as the chosen side and the best-scoring translation of the same source into a different dialect $B$ as the rejected side, where the prompt requested dialect $A$. This gives the model a direct signal that producing the wrong variety is undesirable, even if that variety would otherwise score well on accuracy. To avoid spurious negative signal, we ex-

Table 4: All training data sources used across SFT and DPO experiments. Segment counts reflect training examples (source–hypothesis pairs) after dialect filtering; sizes vary by dialect subset used in each run.
[a] Derived from WMT23 English–Arabic system outputs translated into 21 Arabic varieties using multiple MT systems (22,518 source segments per dialect).
[b] EG, JO, LB, LY, MA, MR, OM, PS, SA, SD, SY, TN, YE.

cluded cross-dialect pairs where the two dialects belong to the same equivalence group (Gulf cluster: ae/bh/kw/om/qa/sa; Levantine: jo/ps; Maghrebi: dz/ly/ma/mr/td). The resulting dataset contains 535,688 pairs in total: 344,513 within-dialect and 191,175 cross-dialect.

We applied DPO either starting from the base model weights or from an SFT checkpoint in the final experiments. Training used either a CPO loss or a composite loss combining the standard DPO sigmoid objective (weight 0.8), a BCO pair loss (weight 0.2), and an SFT cross-entropy loss on the chosen translations (weight 1.0). We set $\beta = 0.1$, trained for 3 epochs, and used a batch size of 64 (1 example, 64 gradient accumulation steps), maximum sequence length 512 tokens, LoRA $r \in \{8, 64, 128\}$, LoRA $\alpha = 2r$ and learning rates $\in \{3\text{e-}5,\ 6\text{e-}5\}$. Checkpoints were saved and evaluated every 25 steps against the WMT25 Egyptian Arabic held-out set via ChrF.

## 4 Results

This section describes the results obtained in our experiments.

### 4.1 Supervised finetuning

We ran 123 SFT experiments spanning three base models, six LoRA ranks, six learning rates, and multiple data combinations. We present our findings in the following paragraphs. ChrF and GEMBA scores on the WMT25 test set for best or interesting training runs are shown in Table 5, the corresponding WMT26 GEMBA scores are in Table 9 in the Appendix.

**Base model** Gemma-4-12B-it was the winner across all configurations. It achieved average combined GEMBA of 94.23 and ChrF of 42.65 on the WMT25 validation set, compared to 75.88 GEMBA and 36.63 chrF for Jais-2-8B-Chat and 30.88/32.67 Aya-expanse-8B.

**SFT doesn't improve metrics of a good base model** A notable result is that the unmodified Gemma-4-12B-it base model already scores 42.65 ChrF and 94.23 GEMBA on the WMT25 validation set – higher than most finetuned checkpoints. We actually used 4-bit quantized version of the model for the finetuning, so the starting scores were 42.1 and 93.54, but we consider it fairer to compare the results with the full precision baseline.

ChrF and GEMBA scores of finetuned models rarely exceeded the base model (or by a very small margin compared to 4-bit quantized version of the base model), suggesting that Gemma-4-12B-it already produces high-quality Egyptian Arabic and that even our best SFT configs do not help with the translation quality. Also, we are computing the GEMBA scores with the Gemma-4-12B-it model itself, so the scores might be biased towards the base, non-finetuned model. Additionally, the finetuning is done on WMT23-GEMBA dataset, where most of the selected target translations are already pro-

| *Final ensemble — segment-level GEMBA selection across all 31 checkpoints* | | | | | |
| — | — | — | — | 42.62 | **97.41** |

Table 5: WMT25 Egyptian Arabic test-set scores (Gemma-4-12B-it judge; 199 segments) for all 31 checkpoints in the final pool and the segment-level ensemble. GEMBA is $\frac{1}{2}(\text{acc} + \text{dial})$. G = GEMBA-filtered WMT23; A = Alexandria. * pairs of runs with identical hyperparameters, different seeds; † ‡ same for DPO runs.

duced by the Gemma-4-31B-it or Gemma-4-12B-it, leaving too few new translations for the model to learn from. For Jais-2-8B-Chat, the improvements in both metrics after SFT are more clear. Table 9 in Appendix C shows that there are some gains in GEMBA scores after SFT on the WMT26 test set even for the Gemma model.

**Training data** Most datasets led to a decrease in automated metrics. The best-performing dataset was our synthetic WMT23-GEMBA, filtered to only contain examples with GEMBA score $>$ 95. Adding Alexandria conversational data to the GEMBA-filtered WMT23 translations (`G+A`) consistently improved dialect authenticity scores over WMT23-GEMBA-only training (`G`), with the gains most visible on ChrF. Including all 21 Arabic dialect targets in training (`eg-tn-msa` and broader sets) generally matched or exceeded Egyptian-only

| Model / training category | Segments | % |
|---|---|---|
| Gemma-4-12B-it (no finetuning) | 200 | 30.9 |
| SFT — wmt23-gemba, no alx | 152 | 23.5 |
| SFT — wmt23-gemba + alx (Gemma) | 49 | 7.6 |
| SFT — wmt23-gemba + alx (Jais) | 27 | 4.2 |
| DPO — wmt23-pairs | 197 | 30.4 |
| Alexandria SFT → DPO | 23 | 3.5 |
| **Total** | **648** | **100.0** |

Table 6: Segment-level contribution of each model category in the final ensemble submission. For each of the 648 test segments (Egyptian Arabic `arz`/`arz_Arab`, Tunisian `aeb`, MSA `ar_AR`), the hypothesis with the highest combined GEMBA score (Gemma-4-12B-it judge) was selected from 31 candidate checkpoints. Alx means Alexandria dataset.

training, likely because broader dialect coverage acts as a regularizer.

**Hyperparameters** LoRA rank $r = 128$ was the strongest setting for most configurations, though $r = 32$ with a lower learning rate (2e-5) achieved the highest finetuned-checkpoint GEMBA score (94.34). The best-performing learning rate was 6e-5 for $r = 128$ runs. Checkpoints typically peaked early (steps 50–700) and degraded or plateaued thereafter, so the 1,000-step training budget was sufficient.

### 4.2 Preference optimization

Aside from the hyperparameters, we varied the preference pairs dataset for the training. We tried filtering it by GEMBA score thresholds of 80, 90 and 95 for the positive examples. We have also tried using only intra-dialect pairs vs. cross-dialect pairs. We compared the DPO and CPO loss functions.

DPO training on high-quality preference pairs (chosen GEMBA $\geq$ 95, including both within-dialect and cross-dialect pairs) improved the combined GEMBA score by $\approx 0.7$ points over the best SFT checkpoint on the WMT25 test set and by $\approx 0.3$ points on WMT26. The best DPO configuration used lr = 3e-5, $\beta = 0.1$.

### 4.3 Final submission

For the final submission, we selected 20 runs with the best ChrF scores on the dev set (first 150 sentences of the WMT25 test set) across SFT and PO finetuned models. From these 20 runs, we then selected the top 30 checkpoints based on the GEMBA score on the WMT25 test set, with at most 2 checkpoints per each run (model configuration) selected. We translated the WMT26 test set with each selected checkpoint and we also added translations by the original base model to the pool. We computed the GEMBA score on the WMT26 test set using Gemma-4-12B. For each test example, we selected the best-scoring translation. The per-model type breakdown is shown in Table 6. Almost all of the translation models were Gemma-4-12B with small LoRA adapters on top of them, so even though the submission is not considered constrained by the official rules, the total number of different parameters involved is under the 20B limit (same base 12B for translation and scoring and a small number of LoRA adapter parameters on top of them). The only exception is 27 (4.2%) sentences that were translated by a finetuned Jais 8B model. 30.9% of translations were chosen from the base model without any finetuning, however, this exact model was used for the GEMBA scoring for the selection, so preference for its own outputs could be expected. The per-model breakdown for the WMT25 test set ensemble is reported in Table 8 in the Appendix C.

### 4.4 Manual inspection

To complement the automatic evaluation, we manually inspected the first 50 translations and their Gemma-12B-it GEMBA assessments. The inspection suggests that, although the LLM is generally effective at identifying clear differences in translation quality, it can overlook errors that are subtle but noticeable to a native speaker, particularly those affecting fluency, dialect authenticity, lexical choice, and overly literal or word-for-word phrasing. Several translations received very high accuracy or dialect scores despite containing slightly unnatural Egyptian Arabic, MSA-influenced spelling, awkward constructions, minor mistranslations, or typographical errors. A particularly illustrative case is the first inspected example, "You could tell those fuckers where to get off." The explicit insult "fuckers" is not faithfully represented in the translation, yet the GEMBA reasoning effectively treats the Arabic expression as accounting for both the insult and the idiom, leading to a high assessment despite the loss of this source-side detail. We also observed cases of word-by-word translations, where the resulting sentence was unnatural or even difficult to interpret as a whole, as well as overly literal translations that GEMBA scored close to perfectly. Overall, the manual inspection indicates that our Gemma-12B-it GEMBA assessment captures broad semantic adequacy and dialect differences

well, but is less reliable for fine-grained errors in naturalness, register, idiomaticity, and exact meaning preservation that are readily apparent to a native speaker. It is important to note again that the translations were also produced by a finetuned Gemma-12B-it model, so it is expected that when the same model is used as a judge, some translation errors may be ignored. We plan to carry out a more extensive evaluation after the human assessment scores of all the competing systems are published.

## 5 Conclusions

We have compared multiple base models and finetuning methods and datasets with the goal of improving the translation quality on the WMT26 English to Egyptian Arabic task. We saw some increases in various automatic metrics, however, the possible real improvement in translation quality will become clearer after human evaluation. GEMBA with a Gemma-4-31B-it judge correlated strongly with WMT25 human scores ($r = 0.916$), validating its use as a development signal throughout the pipeline. DPO on high-quality cross-dialect preference pairs provided the largest single quality step beyond SFT, while segment-level ensemble selection over 31 checkpoints further boosted scores by exploiting complementary strengths of individual models. The effect on real, human-perceived translation quality remains unknown.

## Limitations

The limitations of our paper are shared across all LLM-based research. The evaluation of our methods is limited by the fact that we use pretrained LLMs, so it is possible that our test data were part of their training data. A more specific concern is that we use the Gemma-4 family both as the primary translation model and as the GEMBA judge. A judge model may favor outputs from models in the same family, which could inflate GEMBA scores for our Gemma-based checkpoints and bias segment selection in the ensemble toward them.

## B Prompts

We have used the following prompt for all translations:

```
<bos><|turn>system You are a professional, very precise translator and a native speaker. Translate inputs based on the instructions and always print out only the text of the best possible translation, no explanations. Keep the same formatting (e.g. markup, lines, spacing) as the original. Do not translate untranslatable parts of the input (URLs, code and similar).<turn|> <|turn>user Translate the following text into {dialect} Arabic, only print out the translation. Do not add any explanations: {text} <turn|>
```

We have used the following prompts for the GEMBA scoring: Accuracy:

```
Score the following translation from {source_lang} to {target_lang} on a continuous scale from 0 to 100 for translation accuracy only (meaning preservation and grammar). You can briefly reason about the errors and describe them, but make sure to output a Score: and a single number as the final score at the end of the output.
{source_lang} source: {source_seg}
{target_lang} translation: {target_seg}
Evaluation:
```

Dialect:

```
Score how authentically the following translation uses {target_lang} (appropriate dialect, register, and locale conventions) on a scale from 0 to 100, where 0 means not authentic / wrong variety and 100 means fully authentic {target_lang}. If a dialect is specified and the translation is entirely in a different dialect, score the translation 0. You can briefly reason about the errors and describe them, but make sure to output a Score: and a single number as the final score at the end of the output.
{source_lang} source: {source_seg}
{target_lang} translation: {target_seg}
Evaluation:
```

## C Additional Results

Table 8 reports the per-model breakdown of segment selection in the WMT25 Egyptian Arabic ensemble (199 segments, same 31-checkpoint pool as the WMT26 submission). Table 9 reports GEMBA scores on the WMT26 test set broken down by dialect for all 31 checkpoints.

| **Model / training category** | **Segments** | **%** |
|---|---|---|
| Gemma-4-12B-it (no finetuning) | 48 | 24.1 |
| SFT — wmt23-gemba | 39 | 19.6 |
| SFT — wmt23-gemba + alx (Gemma) | 23 | 11.6 |
| SFT — wmt23-gemba + alx (Jais) | 7 | 3.5 |

## Abstract

The WMT26 General MT task evaluates systems on 10 language pairs that have no human references (neither translated from scratch nor post-edited from MT output by humans). We describe how we built the pseudo-references for these pairs and six other language pairs (in which some forms of human references are available): seven models translate the 3,277 official documents under up to five prompt conditions, giving a total of 26 system–prompt combinations; then three reference-free quality estimation (QE) models score every candidate; and a per-document selector picks one translation, which GPT-5.5 post-edits where needed. Working without references exposed a failure mode of QE-guided selection: the metrics rank fluent output in the wrong language above correct translations. Adding a confidence-scaled language identification penalty to the score fusion drives the wrong-language count to zero, and the resulting selector still scores better on MetricX than the rank-fusion baseline it replaces. Since no references were available for these pairs while we were building them, we calibrate every selection decision on last year's WMT25 human judgments. The human evaluation, released after construction, shows the cost of getting selection wrong: our references stand with the strongest participating systems when the selector kept a frontier-model candidate, and fall up to 17 ESA points below them when it did not. We release the selection method and the provenance of every reference.[1]

## 1 Introduction

The rise in performance of automatic machine translation (MT) reference-less quality evaluation (commonly referred to as quality estimation, QE) metrics has put the necessity of references in MT evaluation and development in debate. Recent work in the WMT25 unified evaluation and quality estimation task (Lavie et al., 2025) finds that reference-based metrics, including traditional string-based, embedding-based, and LLM-based, achieve top-ranking results in correlation with human judgments on translation quality. Reference-based metrics guide system development and shared-task rankings, and reference quality directly affects the conclusions drawn from evaluation results (Freitag et al., 2020). However, producing human references is costly, time-consuming, and difficult to scale as evaluation expands to more language pairs. A possible solution to the unavailability of human references is using MT output of high quality as reference in evaluation which we called pseudo-references. Pseudo-references offer a practical alternative (Albrecht and Hwa, 2007).

The obvious approach is to generate several candidate translations and keep the one a QE metric scores the highest. That assumes the selection signal is reliable. Neural metrics have systematic weaknesses that optimisation can exploit (Amrhein and Sennrich, 2022), their agreement with humans varies across quality levels, and the systems producing the candidates may have been tuned on the same metric families used to select among them. Any bias in selection is then baked into the references and propagates to every evaluation that uses them. We therefore treat reference construction and metric auditing as one task. Figure 1 shows the pipeline. Seven models generate candidates under several prompt conditions, three reference-free metrics score them, a per-document selector keeps one, and an LLM post-editor repairs it where the selection is weak. Section 3 gives each stage. We entered our selections into the General MT task as a participating team, where the human evaluation scored our primary submission as `PseudoRef` (Section 6.3, Appendix L).

Our main finding is a failure that none of the three metrics detects. A language identifier run over the selector output found 154 of the 3,277

selected documents in the wrong target language, mostly fluent Russian or Ukrainian instead of Kazakh, Belarusian or Armenian, several of them scored best in their pools. Amrhein and Sennrich (2022) induced this behaviour deliberately with minimum Bayes risk (MBR) decoding; it arises on its own once a multilingual candidate pool meets a reference-free metric. A confidence-scaled language-identification penalty in $z$-score fusion removes all 154, improving mean MetricX.

Which metric to optimise is an empirical question, so we answered it on WMT25, re-scoring 25,824 human-judged candidates over the seven pairs that overlap ours. MetricX tracks human system rankings best; CometKiwi and xCOMET collapse among top candidates, which is where selection operates. These results, not the WMT26 QE scores, set our fusion weights and demote error spans to a tiebreak (Section 5). Table 1 shows these 16 pairs. Ten of our language pairs do not have any form of human-involved references; the remaining six language pairs are chosen to support analyses of the effects that reference quality has on automatic evaluation, as conflicting evidence is presented in previous work (Freitag et al., 2020; Mathur et al., 2020; Freitag et al., 2023). The chosen six language pairs cover different source languages, resource levels and target orthographies.

## 2 Task Setting and Data

**The WMT26 GenMT blindset.** The released blindset instances from WMT26 (Kocmi et al., 2026) each contained a source document paired with a target language and an instruction that is part of the graded task. The official core for pseudo-reference construction is 3,277 documents across the 16 pairs listed in Table 1: 198 documents for each of the 14 English-source pairs, 315 for Czech → German, and 190 for Simplified Chinese → Japanese. Six domains are represented: spoken transcripts, social media threads, news, software strings, education, and fact-checking articles. A 2,706-document subset is multimodal: spoken documents are ASR transcripts of videos, social documents come with screenshots, and annotators judge translations against the media rather than the text. Documents are structured, with HTML in social and news and JSON in software, and the official checker requires the reference to preserve markup element counts exactly.

**Language identification.** We label every candidate with py3langid (Lui and Baldwin, 2012): deterministic, offline, 97 languages, and it returns a calibrated confidence that Eq. 2 uses directly. fastText (Bojanowski et al., 2017) and GlotLID (Kargaran et al., 2023) are reasonable alternatives, GlotLID with wider low-resource coverage; we did not benchmark the three against each other, which is a limitation of the gate rather than of the selector. Two of our targets are known confusion cases: Indonesian against Malay, where ours mislabels correct output (Section 4), and Japanese against Chinese in kanji-heavy text.

## 3 The Pseudo-Reference Pipeline

### 3.1 Candidate generation

Seven models generate candidates (Table 2) - five are open-weight: Aya-Expanse-32B (Dang et al., 2024), EuroLLM-22B (Martins et al., 2024), Tower-Plus-9B (Alves et al., 2024; Rei et al., 2025), and two dedicated translation models run under their native templates, TranslateGemma-27B (Finkelstein et al., 2026) and HY-MT1.5-7B (Zheng et al., 2025). Two are closed: GPT-5.5[2] (OpenAI, 2025) and Gemini-3.1-pro (Google DeepMind, 2026).

The instruction-following models run under five prompt (P) conditions. P1 is the verbatim of the document-level translation prompt provided by the WMT26 GenMT organizers; since instruction adherence is graded and shown to annotators, our additions never override it. P2 wraps this instruction in a source analysis stage before translating. P3 adds five-shot examples over P2. P4 adds the multimodal context to P3 as a text caption of the video or screenshot, produced by Qwen3-Omni (Xu et al., 2025) or Gemini-3.5-Flash. P4 runs only on the 2,706-document multimodal subset. Prompts and configurations are present in Appendix I. The caption is an English description of the media generated from the video or screenshot alone, prepended to the source document as background context, the translation model never sees the media itself. We run the two caption sources as separate cells to test whether the gain depends on the captioner rather than on captioning as such. The native-template models take a single pass each. We refer to each (model, prompt condition) pairing as a *cell*: one complete generation run over the document set, contributing one candidate translation per document, totalling 26 scored cells as shown in Table 2.

Not every cell produces a usable translation everywhere. The failures are model capability limits, concentrated on non-Latin targets, and Appendix B gives them per cell. We left failed outputs in the pool, since discarding them is the selector's job.

### 3.2 Reference-free QE

Three QE models score every candidate: MetricX-24 (regression on an error scale, 0 to 25, lower is better), CometKiwi-XL (0 to 1, higher is better), and xCOMET-XL (0 to 1, higher is better, with MQM-style error spans (Lommel et al., 2014) as a by-product, each graded minor, major, or critical). Scoring is unit-level: spoken documents are scored per-utterance (7.8 units per document on average), software per element (17.4), and other domains per paragraph or block, with HTML stripped for scoring only. Document scores are unit means. Each metric scored 80,063 candidate documents, of which 79,971 are scorable; the rest are too broken to segment. Over the full candidate pool the three metrics agree closely with one another (pairwise Pearson 0.79 to 0.87), but that agreement comes from distinguishing usable translations from broken ones rather than from ranking the usable ones.

### 3.3 Baseline selectors and structure gating

The selector picks one candidate per document. We built two baseline selectors. *Rank-fusion* ranks candidates under each metric separately and keeps the best mean rank, a Borda count over MetricX-24 and CometKiwi-XL; xCOMET contributes error spans but no rank. Using ranks rather than raw scores makes it insensitive to the fact that the metrics run on different scales and in different directions. *Cross-reference* re-ranks that selector's top three by cross-system MBR: each is scored by reference-based COMET (Rei et al., 2022a) against the other two as pseudo-references, and the one with the highest mean score is kept.

Both are structure-gated where the official checker requires structured documents to preserve the source HTML paragraph or JSON element count exactly, and the QE metrics ignore markup. On the 1,191 structured documents, the gate admits 62.6% of candidates and leaves every document at least two, so gating fixes alignment without ever having to ship a structurally invalid candidate; on 39 documents none of cross-reference's three was valid and the rank-fusion selection stands. The two selectors agree on only 46% of the documents they ship, and since one chooses within the other's top three, that is a first sign of how unstable selection among near-tied candidates is. Both selectors are superseded by the language-aware selector of Section 4, for reasons the next section sets out.

### 3.4 Automatic post-editing

GPT-5.5 post-edits the rank-fusion selection, given the source, the top three candidates and their QE scores. Two earlier prompts, one showing scores alone (*APE-scores*) and one adding xCOMET spans (*APE-spans*), rewrote 99.5 and 99.9 percent of documents at median similarity of 0.59 and 0.56,

[2]Model version: 2026-04-24; accessed through the National Research Council of Canada's Azure cloud platform

respectively, which defeats the premise that the selection is mostly correct. Both lost content anchors, 0.863 in the input against 0.839 and 0.834 out, a little worse with spans: a flagged number invites the model to correct what was already right. Worse, neither reliably repaired the wrong-language inputs it was given: of the 154 the langid audit finds in the rank-fusion selection, 21 survive APE-scores and 24 survive APE-spans. *APE-tight* therefore pins the target language, names the confusable neighbour for each pair, reframes the QE scores as noisy pointers, and imposes a minimal-edit contract. It is the only run to preserve content anchors better than its own input (0.911). Appendix C compares the three runs.

### 3.5 Verification and the final reference set

Every output file is checked with the alignment script[3] provided by the WMT26 GenMT shared task, and all selections reported check clean: 1,187 structured documents verified, 0 misaligned (the 2,090 plain-text documents are outside the tool's scope). Four Japanese-target documents were generated under both eng → jpn and zho-Hans → jpn. The organisers list each `doc_id` once, so we kept the single Chinese-source copy; these four are the difference between the 1,191 structured documents of Section 3.3 and the 1,187 checked here. We entered seven systems into the General MT task. The language-aware selection of Section 4.1 is the primary, and the only one the human evaluation scored; the rank-fusion and cross-reference selections, the best single open and closed systems, and two pooled variants were contrastive.

## 4 Wrong-Language Identification

We audited the rank-fusion winners with py3langid (Lui and Baldwin, 2012), comparing the predicted language of each selected document with the expected target. Table 3 gives the result: 154 of 3,277 winners are predicted to be in the wrong language, and they concentrate on the low-resource targets, each replaced by a higher-resource language of the same region or script. Of 198 eng → kaz winners 54 are in the wrong language, 51 of them Russian; of 198 eng → bel winners 63 are, 50 of them Ukrainian and 13 Russian; and 14 of 198 eng → hye winners, 13 of them Russian. The substitute need not be a relative: Kazakh is Turkic, and Armenian is not even written in Cyrillic. What these targets share is a neighbouring language with far more training data behind it. By domain, 127 of the 154 are spoken documents. The eng → ind counts are an Indonesian/Malay artefact: the text is Indonesian, so the genuine rank-fusion count is 145. We quote 154 for comparability with the same audit run over the other selectors. The artefact has a cost, since our penalty then demotes correct Indonesian candidates. A language gate is only as good as its identifier.

| Pair | N | RF | XR | APE5 | C6 |
|---|---|---|---|---|---|
| eng → kaz | 198 | 54 | 36 | 0 | 0 |
| eng → bel | 198 | 63 | 29 | 0 | 0 |
| eng → hye | 198 | 14 | 1 | 0 | 0 |
| zho-Hans → jpn | 190 | 4 | 1 | 0 | 0 |
| eng → ekk | 198 | 3 | 2 | 0 | 0 |
| eng → tha | 198 | 3 | 1 | 0 | 0 |
| ces → deu | 315 | 2 | 2 | 0 | 0 |
| eng → zho-Hans, zho-Hant | 396 | 2 | 2 | 1 | 0 |
| eng → ind† | 198 | 9 | 13 | 18 | 0 |
| other 6 pairs | 1,188 | 0 | 0 | 0 | 0 |
| Total | 3,277 | 154 | 87 | 19 | 0 |

Table 3: Wrong-language documents per selector: langid prediction differs from the expected target. RankFusion, Cross-reference, APE5 post-edited (APE-tight), C6 the language-aware selector of Section 4.1. †eng → ind counts are an ind/msa identifier artefact.

Neither of the two straightforward alternatives fully resolves the issue. Cross-reference selection reduces the number of wrong-language outputs from 154 to 87, but does not eliminate them. When multiple candidates are produced in the same incorrect language, consensus-based scoring may treat their agreement as supporting evidence and rank them more highly. Automatic post-editing is more effective: the tightened prompt reduces the number of wrong-language outputs to 19, 18 of which are attributable to the eng → ind language-identification error. However, this approach addresses the problem only after an incorrect candidate has already been selected and rewrites more than 98% of documents to correct an error affecting fewer than 5%. Because the failure arises during candidate selection, we address it directly at the selection stage.

### 4.1 Language-aware selection

The selector we submitted as our primary basis, called C6, works per document. Let $C$ be the structure-valid candidate pool and, for candidate $c$, let $x_m(c)$ be its score under metric $m$, oriented

[3] `genmt_check_alignment.py` from https://github.com/wmt-conference/wmt-collect-translations

so higher is better (MetricX negated). Scores are standardised within the pool, $z_m(c) = \frac{x_m(c)-\mu_m}{\sigma_m}$, and fused:

$$F(c) = \sum_m w_m \, z_m(c), \qquad (1)$$

with weights set from the calibration in Section 5. C6 uses MetricX only ($w = 1, 0, 0$). A soft language penalty is subtracted: If the identifier labels $c$ with language $\ell(c)$ at confidence $p(c)$ and $\ell(c)$ differs from the expected target, then

$$F(c) \leftarrow F(c) - \lambda \, p(c), \qquad \lambda = 3. \qquad (2)$$

Candidates whose fused scores fall within $\varepsilon = 0.10$ of the best score are treated as tied. Ties are resolved in order by: (1) fewest xCOMET critical-error spans; (2) highest cross-reference score, that is, the mean reference-based COMET score of the candidate against every other candidate in the pool, as in Section 3.3; and (3) best balance of content-anchor preservation and fluency (Appendix G). We then apply a conditional repair step in two cases. First, if the selected candidate is in the wrong language, it is replaced with the *APE-tight* output only when the post-edited text is in the target language and satisfies the structural-validity constraints. Second, if the selected candidate falls within the worst 5% of MetricX scores for its language pair, it is replaced only when the post-edited output achieves an equal or better MetricX score. If no structure-valid candidate is available, the procedure falls back to the original rank-fusion selection. In the final run, the repair step replaced 29 low-estimated-quality candidates and no wrong-language candidates, because the language-aware penalty had already excluded wrong-language outputs during selection (Example in Appendix E).

Table 4 compares the weighting schemes. The C-family shares the structure gate, the language penalty, and the repair step of C6, differing only in the fusion weights $w$ of Eq. 1 and in how the language constraint is enforced. C weights MetricX, CometKiwi and xCOMET 0.70/0.15/0.15; C3 uses 0.68/0.10/0.23, set in proportion to how well each metric agrees with human judgement (Section 5); C4 weights the three equally. C2 and C6 use MetricX alone, C6 adding the critical-span tiebreak. C5 keeps C's weights but replaces the soft penalty with a hard gate that drops wrong-language candidates from the pool outright.

C6 reaches a mean MetricX of 4.005, marginally behind the best variant (C2, MetricX only, at 4.004) and well ahead of the unconstrained selector's 4.068. C6 differs from C2 only in breaking near-ties on critical spans, which cuts them from 5,196 to 4,129 at a cost of 0.001 MetricX. C3 and C4 cut spans further but only by upweighting xCOMET and CometKiwi, which Section 5 shows to be unreliable selection objectives.

The ablation shows what each component costs, measured against C6. Setting $\lambda = 0$ in Eq. 2, which disables the language penalty, returns 162 documents with the wrong language for a marginal gain on MetricX (0.05). We accept that trade because the swap costs almost nothing on MetricX: wrong-language winners beat their best correct-language rival by only a small margin, and C6 with the penalty remains 0.063 better than rank fusion. The structure gate is not optional, since misaligned documents are rejected outright.

C6 continues to select outputs from a diverse set of systems. TranslateGemma contributes 809 selected documents, followed by GPT-5.5 with 764, Gemini with 673, HY-MT with 559, Tower-Plus with 189, Aya with 178, and EuroLLM with 76.

| Selector | MX↓ | CK↑ | xC↑ | WL↓ | Crit↓ |
|---|---|---|---|---|---|
| Rank-fusion | 4.068 | **0.670** | 0.697 | 154 | 5,516 |
| APE5 (post-edit all) | 4.515 | 0.644 | 0.678 | 19 | 5,595 |

Table 5: What human-quality translation scores: mean human ESA and our three metrics on the human-best WMT25 candidates (1,409 paragraphs, 7 pairs).

| Metric | $r$ top | $\tau$ sys | Pairwise % | Fitted $w$ |
|---|---|---|---|---|
| MetricX-24 | **0.495** | **0.29** | **58.3** | **0.51** |
| CometKiwi-XL | 0.071 | 0.17 | 56.6 | 0.42 |
| xCOMET-XL | 0.166 | 0.12 | 55.9 | −0.07 |
| 3-metric fusion | – | 0.26 | – | – |

Table 6: Agreement between each QE metric and WMT25 human judgment, computed on WMT25 data. $r$ top: Pearson against ESA on human-best candidates ($n$=1,409); $\tau$ sys: mean per-pair Kendall $\tau$ of system rankings (37 systems, 7 pairs, $n$=25,824); Pairwise: segment-level pairwise accuracy; Fitted $w$: normalised OLS weight.

A further 29 documents use post-edited outputs. Overall, 55% of the selected references come from open models, 44% from closed models, and 1% from post-editing. The selection entropy is 2.54 bits out of a maximum of 3.00 bits, showing that no single system dominates the final reference set.

## 5 External Calibration on WMT25

This section answers one question: which metric should the selector optimise? The answer is MetricX alone, with xCOMET spans used only to break near-ties, because MetricX is the only one of the three that tracks human system rankings. The evidence follows. We calibrate on the WMT25 GenMT human evaluation (Kocmi et al., 2025), which provides human references and human judgments (ESA, 0 to 100, with error spans; Kocmi et al., 2024) for seven pairs that overlap ours: ces → deu, eng → ekk, eng → isl, eng → jpn, eng → rus, eng → ukr, and eng → zho-Hans. Because the two test sets differ, these numbers support relative comparisons only.

**Calibrating the metric scales.** We identified the human-best candidate for each paragraph in the WMT25 evaluation set and scored the resulting 1,409 translations with our metrics (Table 5). Their human ESA scores span 83 to 99, so these are translations human judges rated as good or near-perfect. On our metrics, the same text scores MetricX 4.0 to 8.3 and xCOMET 0.45 to 0.58. Our WMT26 selections, at a mean MetricX of 4.0, and their post-edited counterparts at 4.5, both fall inside the band that human-preferred WMT25 translation occupies, which is also the band in which these metrics discriminate least.

### 5.1 Metric agreement with human judgment

Selection operates among candidates that are already of relatively high quality. We therefore evaluate metric–human agreement in two settings: among the human-best candidate for each paragraph and across the full set of human-scored WMT25 candidates (Table 6; per-pair results are provided in Appendix F). Among the human-best candidates, MetricX correlates with ESA at ($r$=0.495), whereas CometKiwi ($r$=0.071) and xCOMET ($r$=0.166) show substantially weaker agreement. Although restricting the analysis to high-quality candidates reduces the observed correlations for all three metrics, their relative ordering motivates the weighting adopted in our selection procedure.

Across the full set of human-scored WMT25 candidates from 37 systems, all three metrics correlate with human quality at the segment level, with per-pair Pearson correlations ranging from 0.17 to 0.55. However, MetricX is again stronger at the system level, achieving a mean Kendall $\tau$ of 0.29, compared with 0.17 for CometKiwi and 0.12 for xCOMET. The manually defined three-metric fusion reaches 0.26 and therefore does not improve on MetricX alone. ESA scores are not comparable across language pairs, so we fit within each pair and average the resulting coefficients rather than pooling; per-pair ordinary least squares (OLS) gives 0.51 to MetricX, 0.42 to CometKiwi and $-0.07$ to xCOMET, offering no support for weighting xCOMET positively. We test the weightings by leave-one-pair-out cross-validation: weights are fitted on six language pairs and evaluated on the seventh, rotating through all seven. The fitted, hand-set, and equal-weight combinations differ by less than 0.02 Pearson from one another and stay within 0.024 of MetricX alone (Appendix F), so the exact weights matter less than not optimising xCOMET. All three metrics reach only 56–58% segment-level pairwise accuracy against human preference, barely above the 50% of chance. Individual selections are therefore unreliable, and we base our conclusions on differences that accumulate across all 3,277 documents rather than on any single document being correctly chosen.

**Usability of error spans.** The post-editor consumes xCOMET spans and C6 uses them as a tiebreak, so we checked them against the human MQM-style spans (Freitag et al., 2021) on the same WMT25 set. xCOMET flags 6.77 spans per para-

| Selector | Total spans | MQM-wt | Spans/doc | Spans/1k | %crit | %clean | Wrong-lang | MetricX↓ |
|---|---|---|---|---|---|---|---|---|
| Rank fusion | 29,328 | 121,836 | 8.95 | 11.1 | 13 | 14 | 154 | 4.068 |
| Cross-reference | 29,751 | 125,667 | 9.08 | 11.2 | 13 | 14 | 87 | 4.187 |
| Best open system | 27,788 | 113,294 | 8.48 | 10.3 | 14 | 16 | 116 | 4.508 |
| Best closed system | 29,392 | 116,242 | 8.97 | 11.3 | 12 | 17 | 24 | 4.488 |
| Pooled, 3 metrics | 27,725 | 109,619 | 8.46 | 10.4 | 10 | 16 | 131 | 4.067 |
| APE-tight, all documents | 30,414 | 129,457 | 9.28 | 11.4 | 15 | 16 | 19 | 4.515 |
| Per-language APE | 30,261 | 127,653 | 9.23 | 11.4 | 15 | 16 | 20 | 4.519 |
| C6, language-aware | 27,815 | 108,676 | 8.49 | 10.5 | 11 | 16 | **0** | **4.005** |

Table 7: All selections over the 3,277 documents. Rank fusion is Borda over MetricX-24 and CometKiwi-XL; cross-reference is cross-system MBR; the pooled selector rank-fuses over the six prior selections rather than over the 26; per-language APE uses APE-spans on the CJK pairs and APE-tight elsewhere; C6 is the selector of Section 4.1. Span inventory: total; MQM-weighted $1{\cdot}\text{minor}+5{\cdot}\text{major}+10{\cdot}\text{critical}$; per document; per 1k characters; percent of documents with a critical span; percent with no spans.

graph where a single human annotation pass marks 0.72, a ratio of 9.4, and inflates severities: humans mark these errors minor, xCOMET marks them major or critical. Its span counts predict human quality weakly ($r = -0.14$ against ESA, against $-0.69$ for human span counts), and worst on CJK, where over-flagging reaches 39 to 42 times. Across our selectors, total span counts correlate negatively with wrong-language counts ($r = -0.21$): the selectors with fewest spans earned them partly by keeping fluent wrong-language copies that trip no flags. Minimising spans is therefore the wrong objective, and C6 uses them only to arbitrate near-ties and to point the post-editor at suspects.

## 6 Results

Table 7 summarises all selection methods with their span counts and wrong-language counts. Fewer spans does not mean a better reference set: the pooled selector has the fewest spans (27,725) but 131 wrong-language documents, while the post-edited output has the most (30,414) and none outside the known artefact pair. Editing correct-language text appears to attract flags that fluent wrong-language text does not, so span count alone does not measure pseudo-reference quality. The C-family selectors give the best overall balance, with moderate span counts, no wrong-language selections, and the best MetricX. The best-open setting led by TranslateGemma matches the fused selectors on spans, which says something about current dedicated translation models, but it offers no document-level arbitration and no guarantee of the target language.

| Domain | Docs | MX | C6-MX | WL | C6-WL |
|---|---|---|---|---|---|
| spoken | 2,090 | **1.940** | 1.994 | 127 | 0 |

Table 8: Per-domain comparison of rank fusion and C6.

### 6.1 Where the metrics and domains disagree

Across domains, C6 improves the mean MetricX score over rank fusion in every case except spoken (Table 8), where 127 of the 154 wrong-language selections occurred: the 0.05 increase in predicted error is the price of replacing fluent Russian with correct Kazakh. Dedicated translation models supply most selected outputs. Our prompt conditions are nested and P4 ran on a different document set, so the P1-to-P4 difference is not a caption effect: on the multimodal subset, where all four ran, GPT-5.5 scores 4.74, 4.45, 4.45 and 4.45 across P1 to P4, and Gemini 4.47, 4.56, 4.59 and 4.57. The analysis stage in P2 accounts for all of GPT-5.5's gain; five-shot and the caption add nothing, and Gemini is helped by none of the three (Appendix D).

### 6.2 Post-Editing Outcomes

The stricter post-editor cuts wrong-language output from 154 to 19 overall and to 0 on every genuinely confusable pair, with the best structure fidelity (0.996) and content-anchor preservation (0.911) of the three runs and no change in fluency (Table 11, Appendix C). MetricX scores APE-tight 0.45 points worse than the rank-fusion selection it edits, but the calibration of Section 5 places both

inside the range human-quality translation occupies, and part of the decline reflects the removal of fluent wrong-language output that the neural metrics had preferred. Post-editing edits far more than instructed (Section 3.4), so we use it as a targeted repair step rather than a pass over every reference: in C6 it provides 29 documents. On the CJK pairs, where xCOMET over-flags the worst, span counts and a native-speaker author's inspection of a sample both favoured APE-spans; that choice is the per-language row of Table 7, and proper names are kept in their standard target-language forms rather than transliterated.

### 6.3 Reference-based *vs.* Human Ranking

Everything above measures the references themselves. For a shared task the question is whether systems scored against them land in the order a human reference would give. We score each participating system with chrF against our references, rank by that score, and compare with the ranking from human ESA (Kocmi et al., 2026). Over all sixteen pairs, 38 systems agree with the human ranking at Kendall $\tau_b = 0.63$. The informative case is the 1,363 segments that also carry a human from-scratch translation, where 30 of them can be ranked against either reference: our references reach $\tau_b = 0.83$ and the human reference $0.82$. The pipeline does produce a reference set as usable for system ranking as the human reference it stands in for. Two caveats. This is chrF only, and systems are annotated on different subsets, so each is scored on its own segments; the comparison between the two references is unaffected, since both use identical data. One asymmetry is worth recording: GPT-5.5 obtains the highest chrF of any system against our references, 64.0, while placing eighth on human ESA, and GPT-5.5 produced 23% of the reference set. That is the circularity of Section 7.

## 7 Discussion

**Which signals to trust.** The signals available during construction are not equally reliable, and our results order them. Structural checks are exact. Language identification is close, with known confusion pairs to audit by hand. Previous-year human judgments transfer as decisions, not as absolute values. Document-level QE averages are usable as an objective only after the first three have constrained the pool, and error spans belong last, as tiebreaks. The failure we caught sat on the boundary between the second and fourth of these: QE ranked a Russian candidate first, the identifier said it was not Kazakh, and the more reliable signal had to win.

**What the human evaluation shows.** The human evaluation, released after construction, tests that ordering (Appendix L, Table 17). Grouped by the family that produced the selected candidate and compared against participating systems on the same segments, our references split in two. Where a frontier-model candidate was kept they are within two ESA points of the strongest systems, and indistinguishable from them on spoken documents; where a translation-specialised open model was kept they fall 14 to 17 points below, and 24 on spoken documents. The anchors barely move between the groups, 82.8 against 82.5 for Gemini 3.1 Pro, so the loss enters at selection rather than in the documents.

**Circularity and self-preference.** Two cautions attach to reading the WMT26 results. On the three pairs where wrong-language selection is most prevalent (eng $\rightarrow$ kaz, eng $\rightarrow$ bel, eng $\rightarrow$ hye) some pools held no trustworthy candidate at all, and the least bad of 26 machine outputs is still a machine output. And the reference-free metrics that built these references are relatives of the reference-based metrics that will consume them, while our panel plausibly overlaps the GenMT participants and LLM judges prefer their own output over equally good output from others (Panickssery et al., 2024). Three properties limit that exposure without removing it: (1) selection is led by MetricX, a different family from the COMET-family metrics most likely to consume the references; (2) no single system supplies more than 25% of the references; and (3) every reference carries provenance, so downstream analysis can condition on origin or exclude a family outright.

## 8 Conclusion

We built pseudo-references for 16 pairs from WMT26 GenMT by selecting among 80,063 machine-translated candidates with reference-free metrics. The setting exposed a failure those metrics do not detect: they score fluent wrong-language output above correct translation, and an unconstrained selector shipped it at scale. A language-identification penalty removes it without cost to the selection objective. Last year's human judgments inform us on which metric to optimise. This

year's tell us whether it worked. Systems ranked against our references land close to the order human judges put them in, $\tau_b = 0.83$ against $0.82$ for a human reference. The references match the strongest systems in the task wherever the selector kept a frontier candidate and fall well short wherever it did not. The pipeline is sound; the selection objective is not.

## Limitations

The largest limitation is what we did not measure. Translation outputs are only spot checked by one human reader for three out of the 16 language pairs, of which only one language pair is briefly checked for translation quality; the other two language pairs are only checked for formatting and output language compliance. Section 6.3 shows our references reproduce the human system ranking about as well as a human reference does, but on one metric and on the six pairs where a human reference exists. Whether that holds under a neural reference-based metric, and on the ten pairs with no human reference, is untested. Every other quality number in Sections 4 to 6 comes from the same reference-free metrics that built the references, which is circular by construction. The objective and the repair prompt were calibrated on seven of the 16 pairs; for the other nine, including every pair where we found wrong language selection, that calibration is an extrapolation. CometKiwi and xCOMET share the COMET lineage, so their agreement is weaker evidence than it appears. The structure gate checks element counts, not content placement within them. Closed-model candidates are not reproducible.

## Environmental Impact Statement

We present an audit of the carbon emission for parts of the experiments in this work. Although the audit only covered the experiments involving GPT-5.5 and not the complete experiments, we think that the partial information is still valuable as a reference for estimating the environmental impact of different machine translation settings using LLMs.

The accumulated token usage and carbon footprint of GPT-5.5 is reported by the service provider[4]. Table 9 showed the total number of input, reasoning, output tokens and an estimation of the carbon footprint of each GPT-5.5 cell.

## A Related Work

**Pseudo-references.** Using machine translations in place of human references goes back to Albrecht and Hwa (2007, 2008), who trained sentence-level evaluation regressors on pseudo-references from off-the-shelf systems. Reference quality is believed to bound evaluation quality, but inconclusive evidence is presented over the years. Freitag et al. (2020) showed that standard human references reward translationese, and that rankings by automatic evaluation metrics shift when paraphrased references are used instead. Subsequently, Freitag et al. (2023) found that low-quality human references can dramatically hurt the performance and reliability of evaluation metrics. WMT findings have repeatedly reported reference translations losing to top systems in human evaluation (Kocmi et al., 2025). On the other hand, Mathur et al. (2020) found that the variations of metrics' correlation with humans are minimal when they score translations against references with different quality.

Pseudo-references, which by nature are MT output, inherit the potential quality problems from whichever systems and metrics build them, which is why we spend half of this paper on what the selection metrics get wrong and our attempts to add quality control measures for generating pseudo-references of better quality.

**Metric-guided selection and its failure modes.** Choosing among candidate translations by a neural utility function is the basis of minimum Bayes risk (MBR) decoding (Eikema and Aziz, 2020; Freitag et al., 2022), which scores each candidate against the others and keeps the one with the highest expected utility, and of reranking under quality-aware decoding (Fernandes et al., 2022). Our cross-reference selector is cross-system MBR with a COMET utility (Rei et al., 2020), and we claim no novelty in the selection arithmetic. The relevant precedent for our findings is Amrhein and Sennrich (2022), who used MBR as a probe to surface COMET's blind spots. Given a large enough candidate pool, the metric selects untranslated copies of the source and translations with corrupted numbers. We encounter the same failure without setting out to find it. With 26 heterogeneous candidate systems, reference-free metrics promote fluent wrong-language output, and the selector needs an explicit language constraint the metrics do not provide. Kocmi et al. (2021) showed that metric decisions disagree with humans on close system pairs, and our WMT25 calibration extends this to the selection regime, where all candidates are near the top of the quality range.

Similarly, Yan et al. (2023) discovered another failure mode by guiding MBR using BLEURT (Sellam et al., 2020). BLEURT would give high scores to some translation outputs, which they called universal translations, that have nothing to do with the source or the reference translation. Since we did not use BLEURT as our selector and did not observe such universal translations phenomenon in the spot checks of the MT output, we did not add further measures to mitigate this metric-guided selection failure mode.

**Language confusion.** Translating into the wrong language is a documented failure of multilingual systems, both as off-target translation in massively multilingual NMT (Zhang et al., 2020) and as language confusion in instruction-tuned LLMs (Marchisio et al., 2024). Our claim is not that off-target output exists but that reference-free selection actively prefers it. Liu et al. (2026) show the same vulnerability on the training side, where multilingual RL reward models can be hacked by off-target output. Our claim concerns inference: reference-free selection does not merely tolerate off-target output, it prefers it. Presented with a pool that contains a fluent off-target candidate, the metrics

that are supposed to identify the best translation promote it above correct ones. Any pipeline that optimises a reference-free score without an explicit language constraint will therefore concentrate off-target text in the lower-resource pairs, where the reference is the only available anchor and a corrupted one is most damaging.

**Reference-free QE and LLM evaluators.** We score with MetricX-24 (Juraska et al., 2024), CometKiwi (Rei et al., 2022b, 2023), and xCOMET (Guerreiro et al., 2024), three systems from the top of recent WMT metrics and QE tasks (Freitag et al., 2024). LLMs also judge translation quality directly (Kocmi and Federmann, 2023; Zheng et al., 2023), and judge-model self-preference is documented (Panickssery et al., 2024). Self-preference matters here because our candidate systems plausibly overlap with GenMT participants: a reference selected by metrics that favour a model family inflates that family's evaluation. We discuss this circularity in Section 7. For repair we use LLM-based automatic post-editing, following evidence that GPT-4-class models post-edit conservatively when instructed (Raunak et al., 2023).

## B Panel Validation

Table 10 reports the per-cell validation of the candidate panel before scoring. A document is usable if a real target-language translation is present. Misses split into wrong-script output, malformed output (placeholders, truncation), source copies, and, for the analysis-style prompts, leaked reasoning blocks. For each cell we report the dominant failure mode with its count and aggregate the remaining misses under *other*.

HY-MT cannot produce Armenian or Kazakh script and emits mixed-script output on those pairs (404 unusable documents, 375 of them wrong-script). EuroLLM loses 487 to 523 documents per analysis-prompt cell on non-Latin targets, predominantly to wrong-script output (442 to 453 per cell). Aya emits its English analysis block instead of the translation on hard pairs under P2–P4 (109 to 136 documents per cell, of 127 to 152 unusable in total) while its P1 cell is complete.

| Model | Cell | Total | Usable | Dominant failure | Other |
|---|---|---|---|---|---|
| GPT-5.5 | p1 | 3,277 | 3,277 | none | 0 |
| | p2 | 3,277 | 3,277 | none | 0 |
| | p3 | 3,277 | 3,277 | none | 0 |
| | p4-qwen | 2,706 | 2,706 | none | 0 |
| | p4-gemini | 2,706 | 2,702 | malformed - 4 | 0 |
| Gemini-3.1 | p1 | 3,277 | 3,276 | malformed - 1 | 0 |
| | p2 | 3,277 | 3,277 | none | 0 |
| | p3 | 3,277 | 3,277 | none | 0 |
| | p4-gemini | 2,706 | 2,706 | none | 0 |
| | p4-qwen | 2,706 | 2,705 | malformed - 1 | 0 |
| TranslateGemma | native | 3,277 | 3,277 | none | 0 |
| HY-MT1.5 | native | 3,277 | 2,873 | wrong script - 375 | 29 |
| Aya-32B | p1 | 3,277 | 3,277 | none | 0 |
| | p2 | 3,277 | 3,141 | analysis leak - 119 | 17 |
| | p3 | 3,277 | 3,150 | analysis leak - 109 | 18 |
| | p4-qwen | 2,706 | 2,569 | analysis leak - 118 | 19 |
| | p4-gemini | 2,706 | 2,554 | analysis leak - 136 | 16 |
| Tower-Plus | p1 | 3,277 | 3,242 | wrong script - 34 | 1 |
| | p2 | 3,277 | 3,232 | wrong script - 26 | 19 |
| | p3 | 3,277 | 3,234 | wrong script - 27 | 16 |
| | p4-qwen | 2,706 | 2,668 | wrong script - 29 | 9 |
| | p4-gemini | 2,706 | 2,676 | wrong script - 24 | 6 |
| EuroLLM-22B | p1 | 3,277 | 3,209 | wrong script - 50 | 18 |
| | p2 | 3,277 | 2,754 | wrong script - 453 | 70 |
| | p3 | 3,277 | 2,761 | wrong script - 446 | 70 |
| | p4-qwen | 2,706 | 2,219 | wrong script - 442 | 45 |

Table 10: Panel usability per cell. HY-MT's wrong-script output concentrates on en–hy (188) and en–kk (187), scripts it cannot produce. Aya's analysis prompts copy the English reasoning block on hard pairs. EuroLLM fails non-Latin targets.

## C Editing Behaviour of the APE Prompts

APE-tight wins on every signal we trust (language, structure, anchors, restraint) and loses only on neural QE, which Section 5 discounts at this score range. The per-document rate at which APE-tight beats the unedited input is 21.9% on MetricX, 24.0% on CometKiwi, and 31.6% on xCOMET, with the rest ties or losses: on text that is already at the top of the range, post-editing is as likely to move a score down as up, which is the expected behaviour of noisy metrics near their ceiling rather than evidence of harm.

## D Per-Pair Results

Table 12 gives the candidate-level MetricX means per pair for a representative subset of cells, and the best cell per pair under each metric. Two regularities hold across the full 26-cell matrix (available with the released artefacts). The dedicated translation models are the panel backbone: TranslateGemma has the best or near-best mean on most pairs. Restricted to the multimodal subset, where the comparison is valid, the caption cells are indistinguishable from their five-shot counterparts: GPT-5.5 P4 differs from P3 by 0.002 MetricX and Gemini P4 from P3 by 0.022. TranslateGemma remains the best cell on 11 of the 16 pairs.

Rank-fusion selection counts mirror the means: TranslateGemma and HY-MT are the two most-selected systems on 13 of 16 pairs under the unconstrained selector, with GPT-5.5 and Gemini prompt cells taking most of the remainder, concentrated

| | Input (#1) | APE-scores | APE-spans | APE-tight |
|---|---|---|---|---|
| Language (langid, wrong docs) | 154 | 21 | 24 | 19 |
| Structure fidelity | 0.987 | 0.995 | 0.995 | **0.996** |
| Content anchors | 0.863 | 0.839 | 0.834 | **0.911** |
| Fluency | 0.971 | 0.971 | 0.971 | 0.971 |
| Median similarity to input | – | 0.590 | 0.562 | 0.571 |
| Documents byte-identical to input | – | 15 | 3 | **47** |
| MetricX mean ↓ | **4.068** | 4.535 | 4.585 | 4.515 |

Table 11: The three post-editing runs over all 3,277 documents. APE-scores sees QE scores, APE-spans adds xCOMET spans, APE-tight is the tightened prompt. Structure fidelity, content-anchor preservation, and fluency are the heuristic measures of Appendix G. The language row for the runs uses the same langid audit as Table 3 computed on the APE outputs directly (run counts include the en–id artefact).

in news, education, and software. Under C6 the balance shifts toward the closed models on the penalised pairs, since their candidates are language-correct more often on Kazakh, Belarusian, and Armenian.

## E Worked Example: eng → kaz Document 24409

The source is a spoken-domain transcript (Figure 2). The organisers' per-row instruction names the target language explicitly, opening "You are a professional Kazakh translator" and closing "Please translate the following text into Kazakh (kaz_Cyrl)", so the wrong-language candidate does not arise from an ambiguous request.

```
Hello?
Yes, Lois.
I'll hold the wire, please.
Lois, phone.
Take the message, will you, please?
Dad.
She's busy right now.
I'll take the message.
Uh, what was that?
Ralph is calling for instead of Henry.
What?
But he can't meet her in front of the gymnasium.
Can she?
Go where?
Uh, well, wait a minute.
```

Figure 2: The source document for `24409-kaz_Cyrl`: an ASR transcript of mid-century film dialogue, one utterance per line, which the translation must preserve.

Table 13 gives the two candidates that decide the selection: the pool's best-scoring candidate and the one C6 chooses.

Under C6 the Russian candidate's MetricX of 1.65 standardises to $F = 0.82$, the top fused score in the pool ($\mu = -8.42$, $\sigma = 8.21$ on oriented MetricX). The identifier labels it Russian at confidence 1.0, so the penalty subtracts $\lambda p = 3.0$ and takes it to $-2.18$, below every correct-language candidate. The Kazakh candidate that scored 2.58 wins at $F = 0.71$.

The document is also multimodal: the source is a video (`media_00130.mp4`), and the P4 cells receive a caption of it rather than the media itself. Both captioners identify the speakers and the named entities *Lois*, *Ralph* and *Henry*, and the winning candidate comes from a P4 cell.

## F WMT25 Meta-Evaluation Detail

**How well do xCOMET spans locate human-annotated errors?** The comparison uses the 542 human-best documents carrying at least one human span. Matching by character offset, xCOMET recovers 45.8% of human spans (859 of 1,874) and 19.8% of its own flags land on one (878 of 4,433). The two counts differ because several xCOMET flags can fall inside a single human span.

**How much does xCOMET over-flag, by language?** On the 542 documents with at least one human span, xCOMET produces 41.7 spans per human span on en–zh and 39.2 on en–ja, an order of magnitude above the Latin-script pairs (cs–de 14.0, en–ru 10.0, en–is 4.2, en–et 3.7), with en–uk intermediate at 31.2. These ratios are computed on a different base from the 9.4× figure in Section 5, which averages over all 1,409 paragraphs.

**Do span counts track human error counts?** Not usefully. xCOMET's minor-span counts correlate *negatively* with human span counts in all seven pairs: where humans mark more errors, xCOMET marks fewer minor ones. Total-span counts are inconsistent rather than merely weak, ranging from $-0.08$ (en–zh) to 0.43 (en–ru).

**Do the fusion weights matter?** Leave-one-pair-out fitting gives held-out Pearson correlations of 0.370 for per-fold OLS, 0.362 for the hand set weights, 0.358 for equal weights, and 0.346 for MetricX alone. The spread of 0.024 across all four is small, which is why Section 5 concludes that the exact weights matter less than which metric leads.

## G Statistical Methods and Heuristic Measures

Significance for paired selector comparisons uses document-level differences ($n = 3{,}277$): percentile bootstrap over documents (2,000 resamples)

| Pair | TransGemma | HY-MT | GPT5 p1 | GPT5 p4q | Gemini p1 | Gemini p4q | Aya p1 | Tower p1 | EuroLLM p1 |
|---|---|---|---|---|---|---|---|---|---|
| ces → deu | 4.07 | 4.42 | 4.44 | **2.69** | 4.52 | 2.73 | 4.47 | 4.61 | 8.69 |
| eng → bel | **5.32** | 5.51 | 6.29 | 5.60 | 6.05 | 5.81 | 12.12 | 8.50 | 12.59 |
| eng → deu | **2.54** | 3.00 | 3.31 | 2.62 | 3.21 | 2.89 | 3.10 | 3.15 | 3.35 |
| eng → ekk | **6.14** | 6.47 | 6.97 | 6.41 | 7.06 | 6.76 | 15.31 | 14.49 | 7.53 |
| eng → hye | 5.28 | 6.36 | 5.33 | **4.41** | 4.90 | 4.65 | 19.01 | 17.78 | 18.76 |
| eng → ind | **3.27** | 3.57 | 4.41 | 3.68 | 4.08 | 3.77 | 4.36 | 6.13 | 8.50 |
| eng → isl | 6.13 | 6.10 | 6.16 | **5.69** | 6.35 | 6.11 | 14.85 | 6.13 | 16.90 |
| eng → jpn | **4.38** | 4.52 | 5.09 | 4.39 | 4.67 | 4.52 | 5.09 | 4.85 | 5.21 |
| eng → kaz | 5.55 | 11.21 | 6.10 | **5.37** | 5.63 | 5.41 | 15.74 | 11.00 | 15.62 |
| eng → kor | **4.28** | 4.42 | 5.04 | 4.57 | 4.75 | 4.45 | 4.96 | 5.05 | 5.34 |
| eng → rus | **3.72** | 4.11 | 5.15 | 4.18 | 4.99 | 4.62 | 5.03 | 4.83 | 5.12 |
| eng → tha | **3.75** | 4.01 | 4.55 | 3.95 | 4.33 | 3.90 | 9.26 | 7.39 | 15.84 |
| eng → ukr | **4.46** | 4.67 | 5.60 | 5.03 | 5.60 | 5.32 | 5.69 | 5.41 | 5.95 |
| eng → zho-Hans | 3.19 | 3.19 | 3.84 | **3.11** | 3.55 | 3.16 | 3.91 | 3.61 | 3.65 |
| eng → zho-Hant | **3.25** | 3.44 | 3.91 | 3.32 | 3.67 | 3.28 | 3.88 | 3.70 | 3.88 |
| zho-Hans → jpn | 5.54 | 6.28 | 6.77 | 5.64 | 6.24 | **5.42** | 6.27 | 6.22 | 6.61 |
| all pairs | **4.42** | 5.05 | 5.16 | 4.45 | 4.96 | 4.58 | 8.18 | 6.97 | 8.97 |

Table 12: Candidate-level MetricX means (lower is better) per pair for nine of the 26 cells: the two native cells, the P1 and P4-qwen cells of the two closed models, and the P1 cells of Aya, Tower-Plus and EuroLLM, their best condition. Bold: best of the shown cells, except that the P4-qwen columns are computed on that model's 2,706-document multimodal subset and are not comparable with the rest.

| Candidate | MX↓ | CK | xC | langid ($p$) | $F$ | $F - \lambda p$ |
|---|---|---|---|---|---|---|
| eurollm-p3 | **1.65** | 0.772 | 0.945 | ru (1.00) | **0.82** | −2.18 |
| gemini-p4q | 2.58 | 0.720 | 0.890 | kk (1.00) | 0.71 | **0.71** |

Table 13: The EuroLLM candidate is fluent Russian and best on all three metrics, so no reweighting would have rejected it; the language penalty demotes it below every correct-Kazakh candidate.

for confidence intervals, two-sided sign-flip permutation (2,000 permutations) for $p$-values, and Cohen's $d$ as mean over standard deviation of the differences. The penalty saturates at $\lambda = 3$: wrong-language documents fall from 162 at $\lambda = 0$ to 18 at 0.5, 12 at 1, 5 at 2, and 0 at $\lambda \geq 3$. Correlations are Pearson, with Spearman as Pearson on ranks. MetricX is sign-flipped so positive means agreement. The MQM span weighting is $1 \cdot \text{minor} + 5 \cdot \text{major} + 10 \cdot \text{critical}$.

The heuristic measures used for post-edit evaluation are: *structure fidelity (SF)*, agreement of paragraph, line, and markup-element counts between source and output; *content-anchor preservation (CP)*, the fraction of source URLs, handles, hashtags, and numbers present in the output; and *fluency (FL)*, a distinct-4-gram ratio computed over words for spaced scripts and characters otherwise. A fourth measure, *script-ratio language correctness (LC)*, over-counted wrong language on kanji-only Japanese and on untranslated proper names; its findings were retracted and replaced by the langid audit of Section 4, and it is not used in this paper's claims.

## H Reproducibility

Every run in the pipeline is a configuration file. Every stage reads and writes JSONL, and every selected reference carries a provenance record: producing system and prompt cell, the candidate pool with scores, gate outcomes, selector arithmetic, language identification labels, and the post-editing outcome where applied. The selection variants, span inventories, meta-evaluation scripts, and the langid audit are single scripts over these artefacts. Every number in the results tables was recomputed from the raw artifacts during writing: wrong-language counts by re-running the language audit on the submission files; selector score means, span inventories, composition, and significance tests by matching every selected document back to its producing cell and its stored scores; the WMT25 correlations, rankings, fitted weights, and cross-validation by independent reimplementation over the score and judgment archives. The verification scripts and their output accompany the paper sources.

## I Generation Prompt Templates (P1–P4)

All four generation conditions share one instruction spine and differ only in which optional blocks are switched on. Table 2 gives which models run which conditions.

**P1 (template `T0`).** P1 adds no template of our own: the organiser's per-row instruction is passed as the system message and the source document as the user message, so that P1-vs-P2 differences are attributable to our additions and never to plumbing.

```
[system] <<INSTRUCTION>>
  # the WMT26 per-row organiser instruction,
  # released with the blindset, byte-for-byte
[user]   <<SOURCE_DOC>>
  # the source document, whole
```

**P2–P4 (analysis spine, `T2`).** P2, P3 and P4 all render the template below, wrapping the same «INSTRUCTION» used in P1. Slots are filled by token replacement, never `str.format`, so JSON and brace content in the source is safe, and empty slots are dropped before the call. «SCRIPT_NOTE» and «LP_NOTE» are per-pair one-line guides (e.g. "Write the translation in Cyrillic script.", or a regional-variety note). «FEW_SHOT» is empty for P2 and holds the five-shot block for P3 and P4. The caption block is appended for P4 only.

```
You are an expert <<TGT_NAME>> translator and
translation analyst.

Follow this instruction exactly. It is graded and
will be shown to the human evaluators; not following
it counts as a translation error. If it conflicts
with the guidance below, THE INSTRUCTION WINS:

<<INSTRUCTION>>

Work in two stages.

STAGE 1 - Interpret the source (write this analysis
in English, inside <analysis> tags, concise bullet
points):
1. INSTRUCTION: restate the specific constraints
   this instruction imposes (formality/voice,
   glossary or terminology, output format,
   morphology, style) and how each will be
   satisfied.
2. MEANING RISKS: idioms, irony/sarcasm, ambiguous
   words, culture-specific items, ellipsis needing
   context - state the intended meaning of each.
3. FORM RISKS in <<TGT_NAME>>: formality (T-V),
   grammatical gender agreement, honorifics,
   plurals, word order around markup/placeholders -
   decide each.
4. INVARIANTS: what must survive exactly - names,
   numbers, tags, URLs, @handles, placeholders,
   line/paragraph structure.

STAGE 2 - Translate, applying every decision from
Stage 1. Preserve all source structure and markup;
translate only human-readable text; the result must
read as natural <<TGT_NAME>>, and the analysis must
NOT appear in it.
<<SCRIPT_NOTE>>
<<LP_NOTE>>
<<DOMAIN_NOTE>>
<<FEW_SHOT>>
Output format, exactly:
<analysis>...</analysis>
<t>...the translated document...</t>
```

**Domain modules («`DOMAIN_NOTE`»).** One module is selected per document by domain and substituted into the spine. The two conversational domains are given first.

```
--- spoken -----------------------------------------
This is an automatic speech-recognition transcript,
one utterance per line, and may contain recognition
errors. Translate it as natural spoken <<TGT_NAME>>:
- Keep the same number of lines and the same line
  order; do not merge or split lines.
- Render it as speech, not polished prose: keep
  interjections; drop non-linguistic sounds
  (laughter, hesitation noises); if a word is cut
  off, infer the full word or omit it; keep foreign
  words as they are.
- The original video is the human-evaluation
  reference, so favour what the speaker most
  plausibly meant.

--- social -----------------------------------------
This is a social-media post given as HTML. Translate
only the human-visible text:
- Keep every HTML tag and attribute, @mentions, URLs
  and emoji exactly as they appear; never translate
  or reorder them.
- Preserve the blank-line separation between blocks
  exactly (the same number of blank-line-separated
  blocks in and out).
- Match an informal, conversational register; render
  expressive style (capitalisation, character
  elongation, expressive punctuation) naturally in
  <<TGT_NAME>> rather than flattening it.
- Decode HTML entities the way the source uses them;
  do not introduce new tags.
```

The remaining modules cover the text-heavy and structured domains, with a fallback for anything unmatched.

```
--- news / factchecking ----------------------------
This is a news or fact-checking article (plain text,
or HTML):
- Keep the paragraph and blank-line structure
  exactly (the same number of blank-line-separated
  paragraphs), and preserve any HTML tags and
  non-breaking spaces unchanged.
- Translate the headline (first line) using
  <<TGT_NAME>> headline conventions.
- Names, titles, figures, dates, amounts and
  citations stay exact; translate direct quotations
  faithfully using <<TGT_NAME>> quotation
  punctuation.
- Use the register of quality <<TGT_NAME>>
  journalism; report claims neutrally.

--- software ---------------------------------------
This is software / UI localisation content, and may
be a JSON object or array (sometimes inside a code
fence):
- If the source is JSON, return valid JSON of the
  same shape and length: translate the values only,
  never the keys.
- Copy templating placeholders (double-curly tokens
  such as the count placeholder) and any markup
  byte-identical, arranging <<TGT_NAME>> word order
  naturally around them.
- Keep UI strings short enough for buttons and
  labels; keep marketing strings punchy.

--- general (fallback) -----------------------------
Translate faithfully and idiomatically into
<<TGT_NAME>>. Preserve any markup, and keep all
numbers, names, URLs and placeholders exact.
```

**Five-shot block («`FEW_SHOT`», P3 and P4).** The slot is filled with up to five post-edited examples for the canonicalised language pair.

```
Examples:
Example 1
Source: <<SRC_EXAMPLE_1>>
Translation: <<TGT_EXAMPLE_1>>
Example 2
Source: <<SRC_EXAMPLE_2>>
Translation: <<TGT_EXAMPLE_2>>
... (up to 5)
```

**Caption block (P4 only).** P4 runs on the 2,706-document multimodal subset, with captions produced by either Qwen3-Omni or Gemini-3.5-Flash

(the two P4 cells). The model receives the caption text only, never the media itself.

```
Visual context (from the <source video | source
social-media image(s)>, to complement the text;
translate the content, not this note):
<<CAPTION>>
```

**Native templates.** The two dedicated translation models run a single pass under their own native templates, with no analysis stage, five-shot block, or caption.

```
--- TranslateGemma-27B ---
Translate from {src_bcp47} to {tgt_bcp47}:
{src_text}

--- HY-MT1.5-7B ---
Translate the following segment into {tgt_name},
without additional explanation.

```

## J The APE-scores and APE-spans Prompts

These two post-editing prompts share the template below and differ only in whether xCOMET error spans are shown: APE-scores gives the MetricX, CometKiwi and xCOMET document scores, and APE-spans additionally lists each candidate's error spans. Lines marked `[spans only]` appear in APE-spans but not in APE-scores. Both were run at reasoning_effort=medium and post-edit the rank-fusion selection over the top three candidates, which always include the cross-reference winner.

```
You are an expert {TGT} translator and post-editor.
Produce the single best reference translation (a
"pseudo-reference") of the SOURCE for a
machine-translation evaluation: maximally faithful
to the source, fluent and idiomatic, and internally
coherent as a whole document.
Source language:{SRC}.
Target language: {TGT}.
Domain: {DOMAIN}.
SOURCE: {SOURCE_DOC}
You are given the best candidate translations,
pre-ranked by two independent quality-estimation
systems:
- MetricX-24: error score 0-25, LOWER is better.
- CometKiwi-XL: quality 0-1, HIGHER is better.
- xCOMET-XL: quality 0-1, HIGHER is better.
  [spans only: "...HIGHER is better (with flagged
   error spans below each candidate)."] Selector
   opinions: rank-fusion (combining both metrics)
   prefers [{RF_WINNER}]; cross-reference consensus
   prefers [{XR_WINNER}] (they AGREE. | they
   DISAGREE - judge carefully.)
CANDIDATES (ranked best->worst):
[{rank}] {system} | MetricX {mx} |
         CometKiwi {ck} | xCOMET {xc}
{candidate_translation}
  [spans only] xCOMET flagged errors (minor={a},
   major={b}, critical={c}):
  [severity] 'span text' ; [severity] 'span text' ;
... (repeated for the top-3 candidates)

INSTRUCTIONS. Reason carefully (internally): judge
each candidate against the SOURCE for ADEQUACY
(every meaning preserved; nothing added, dropped, or
hallucinated) and for FLUENCY, weighing the QE
scores and BOTH selector opinions[spans only: ", and
the flagged xCOMET error spans"]. Decide whether to
keep the strongest candidate as-is, post-edit it, or
merge the best parts of several; if you merge, keep
the result COHERENT - one consistent terminology,
register and style throughout, with no
contradictions or visible seams. Then output ONLY
the single best {TGT} translation of the WHOLE
source: faithful, natural, and coherent end-to-end,
preserving the source's structure and any markup
EXACTLY (same segment/line/paragraph count; keep
HTML/JSON tags intact). Wrap it in <t></t> and put
NO reasoning or commentary in the output.
```

## K The Tightened Post-Editing Prompt

The APE-tight prompt has five blocks: role and task; a hard language rule with a pair-specific trap line; the source document; the evidence packet with instructions on how to read it; and a procedure with an output contract. Slots in braces are filled at run time. The `{PAIR_TRAP}` slot names the confusable neighbour to avoid for each target: Kazakh not Russian, Belarusian not Russian, Ukrainian not Russian, Armenian script not Cyrillic, Japanese with kana not a Chinese-character-only copy, and Korean Hangul. The prompt was run at `reasoning_effort=high` with a 128k output-token ceiling.

```
You are an expert {TGT} translator and post-editor.
Produce ONE final reference translation (a
"pseudo-reference") of the SOURCE document for
machine-translation evaluation. It must be written
entirely in {TGT} using {SCRIPT}, be maximally
faithful to the source, fluent and idiomatic, and
coherent as a whole document.

Source language: {SRC}.
Target language: {TGT}
({SCRIPT}).
Domain: {DOMAIN}.

HARD LANGUAGE RULE. Every segment of your output
must be in {TGT} ({SCRIPT}). Do not leave, copy, or
emit text in any other language, except for numbers,
dates, units, currency, URLs, emails, @handles, and
code, even if a candidate below is in another
language and reads fluently. {PAIR_TRAP}. A
candidate can score well on the quality metrics
while being in the WRONG language: the metrics are
fooled by fluent non-translations. If any candidate
is wholly or partly not in {TGT}, discard that
candidate (or that part) whatever its scores, and
translate from the SOURCE.

SOURCE:
{SOURCE_DOC}

You are given the strongest candidate translations,
each with quality-estimation signals and, where
flagged, xCOMET error spans:
- MetricX-24: error 0-25, LOWER better.
- CometKiwi-XL: 0-1, HIGHER better.
- xCOMET-XL: 0-1, HIGHER better, with flagged spans.

HOW TO READ THESE. Each score is computed per unit
(segment/paragraph) and does NOT see the whole
document. The scores and spans are noisy and can be
wrong in either direction. Use them ONLY as pointers
to where a problem may be. Do not trust any single
score. For each candidate, combine all three scores
and the spans to judge one thing: how erroneous is
this candidate as a WHOLE document, after you have
checked the flagged places against the SOURCE
yourself.

Selector signals (these are only signals, not ground
truth): rank-fusion prefers [X]; cross-reference
prefers [Y]; (they agree|they disagree). Weigh them,
but do not let them override the language rule or
your own check against the SOURCE.

CANDIDATES (ranked best->worst):
```

```
{CANDIDATES_WITH_SCORES_AND_SPANS}

PROCEDURE (reason internally; your reasoning must be
cogent; output none of this):
1. Apply the language rule: discard any candidate
   not fully in {TGT}/{SCRIPT}, whatever its scores.
2. Among the rest, pick the single least-erroneous
   candidate at document level as your BASE.
3. Verify each flagged span and each score-implied
   problem against the SOURCE. Keep a segment
   EXACTLY as in the base when it is already
   correct; change only the specific spans you have
   confirmed wrong. Do not paraphrase, re-order,
   restyle, or swap synonyms in segments that are
   already correct. Prefer minimal edits to one base
   over merging; borrow a phrase from another
   candidate only when it is clearly and verifiably
   better, keeping terminology, register and style
   consistent with no visible seams.
4. Preserve exactly, never translate or alter:
   numbers, dates, units, currency, URLs, emails,
   @handles, and code that belong in source form.
5. Preserve the source structure and markup EXACTLY:
   same segment/line/paragraph count; keep every
   HTML/JSON tag intact.

OUTPUT. Return ONLY the one final {TGT} translation
of the WHOLE source, entirely in {TGT} ({SCRIPT}),
faithful, natural, coherent end-to-end, structure
and markup preserved exactly. Wrap it in <t></t>.
Put no reasoning, notes, labels, candidate names,
alternatives, or commentary anywhere in the output.
```

## L Post-hoc Validation on the WMT26 Human Evaluation

The WMT26 GenMT human evaluation (Kocmi et al., 2026) scores our reference set as a participating system under the name `PseudoRef`. All figures below are recomputed from that release. Annotation items are joined to our documents through the organisers' identifier crosswalk on (domain, true_doc_id, src_lang, tgt_lang), which is one-to-one over our 3,277 documents and resolves every in-scope item. The identification of our system rests on exact reconstruction: the annotated segments, concatenated in index order, reproduce our C6 submission character for character on 2,292 of 2,292 documents, where the next closest of the fourteen selection files we built reaches 94.8%. Every number in this appendix was produced twice, by two independently written pipelines over the raw release.

**What the release contains.** Twenty-three campaigns, 102,060 annotation items outside the tutorial and attention-check pools, and 561,481 error spans over 48 systems, of which 44 appear in our sixteen pairs. Scoring is Error Span Annotation (Kocmi et al., 2024): annotators mark character spans and grade each minor or major, and the release carries no error typology, the category field being empty on all 561,481 spans. Severities split 49.1% major to 50.9% minor. Where a segment and system pair carries more than one annotation pass, which happens for 19.2% of cells, we average the passes before any other aggregation.

**Coverage.** The release annotates 2,828 of our 3,277 documents for at least one system, and our own references on 2,292 of those, giving 7,666 scored segments. All sixteen pairs are covered. Coverage is complete at 198 documents for eng → hye, eng → jpn, eng → ukr, eng → tha and eng → ind, and thin for eng → zho-Hans and eng → zho-Hant at 25 and 28 documents. Three hundred and eighty-three annotators contribute; the largest supplies 3.8% of annotations.

**The unit of aggregation changes the answer.** The release does not state how the official score aggregates, and the choice is not innocuous for us. Averaging over segments gives our references 75.8 ESA and thirteenth place of 44 systems; averaging within documents first gives 67.4 and twentieth. Table 14 shows why. Every spoken document is presented to annotators as a single item, whereas a software document contributes up to 37. The spoken domain is therefore 19.8% of segments but 66.1% of documents, and it is the domain where our references are weakest. The shift is the largest of any system in the task: human post-editing moves the other way, from eighth to second. We report both conventions throughout and draw no conclusion that depends on the choice.

| Domain | Docs | Segs | Seg/doc | seg ESA | doc ESA |
|---|---|---|---|---|---|
| software | 72 | 1,825 | 25.4 | 86.8 | 86.3 |
| news | 179 | 2,130 | 11.9 | 82.6 | 82.2 |
| factchecking | 6 | 32 | 5.3 | 85.2 | 85.5 |
| social | 509 | 2,130 | 4.2 | 68.5 | 71.9 |
| edu | 10 | 33 | 3.3 | 81.8 | 77.9 |
| speech | 1,516 | 1,516 | 1.0 | 63.2 | 63.2 |
| all | 2,292 | 7,666 | 3.3 | 75.8 | 67.4 |

Table 14: How many annotation items each document contributes, by domain, and the mean human ESA of our references under the two aggregation conventions. The spoken domain is one item per document and drives the difference between the two final rows.

**Position in the evaluation.** Segment-averaged, our references place thirteenth of 44 at 75.8 [75.2, 76.4]; a bootstrap over segments puts the rank between eleventh and fifteenth in 95% of resamples, so the position is a band rather than a point. Document-averaged they place twentieth at 67.4 [66.4, 68.5]. Human translation from scratch leads on both conventions. Human post-editing places eighth segment-averaged, below six partic-

ipating systems, and second document-averaged, which is itself evidence that a single human reference is not a fixed ceiling.

**Distance from human translation.** Table 15 compares our references against the two human systems on identical segments and identical documents. Outside the spoken domain the segment-averaged gap to human post-editing is 2.2 ESA and the interval excludes zero; document-averaged the same contrast is 1.0 ESA and the interval does not. Two domain cells are indistinguishable from a human translator on paired segments: software against translation from scratch at +0.3 [−2.6, +3.0] over 295 segments, and news against post-editing at +0.3 [−2.0, +2.6] over 437 segments. Elsewhere the difference is in the failure tail, with 15.0% of our segments below 50 against 10.8% for human post-editing. Human systems appear in six of our sixteen pairs.

| Unit | Comparison | n | ours | human | gap (95% CI) |
|---|---|---|---|---|---|
| *vs. Human (from scratch)* | | | | | |
| seg | all | 1,363 | 78.0 | 83.7 | −5.7 [−7.0, −4.5] |
| seg | excl. speech | 1,096 | 80.2 | 83.8 | −3.6 [−5.0, −2.3] |
| seg | speech only | 267 | 69.2 | 83.4 | −14.3 [−17.5, −11.0] |
| doc | all | 414 | 71.9 | 83.2 | −11.3 [−13.8, −9.0] |
| doc | excl. speech | 147 | 77.0 | 82.8 | −5.9 [−8.6, −3.2] |
| *vs. Human (post-editing)* | | | | | |
| seg | all | 1,470 | 74.7 | 80.5 | −5.8 [−7.2, −4.4] |
| seg | excl. speech | 1,161 | 77.5 | 79.7 | −2.2 [−3.7, −0.7] |
| seg | speech only | 309 | 63.9 | 83.4 | −19.5 [−22.9, −16.1] |
| doc | all | 487 | 69.1 | 81.8 | −12.7 [−15.4, −10.1] |
| doc | excl. speech | 178 | 78.1 | 79.1 | −1.0 [−4.1, +1.9] |

Table 15: Our references against the human systems, paired on identical segments (seg) or identical documents (doc), mean ESA. Intervals are percentile bootstrap, 2,000 resamples. The speech-only rows are identical across units because every spoken document is one segment. Human systems appear in ces → deu, eng → deu, eng → ekk, eng → isl, eng → jpn and zho-Hans → jpn.

**Domain profile.** Table 16 gives the profile of our own references. Documents carrying video or screenshots score 65.0 against 82.5 for text-only documents at document level, 65.4 against 84.3 at segment level. That gap is not ours alone: Gemini 3.1 Pro scores 74.7 on media documents against 88.6 on text-only ones, so multimodal documents are harder for every system. Our additional deficit on them is 9.3 ESA against 4.3 on text-only documents, and the next paragraph shows where it comes from.

| Domain | Segs | ESA | Median | % <50 |
|---|---|---|---|---|
| software | 1,825 | 86.8 | 95 | 5.5 |
| factchecking | 32 | 85.2 | 92 | 6.2 |
| news | 2,130 | 82.6 | 90 | 7.7 |
| edu | 33 | 81.8 | 90 | 6.1 |
| social | 2,130 | 68.5 | 80 | 20.2 |
| speech | 1,516 | 63.2 | 70 | 29.7 |
| all | 7,666 | 75.8 | 85 | 15.0 |

Table 16: Human ESA of our references by domain, segment-averaged. The document-averaged column is given in Table 14.

**What the selection step cost.** Grouping our references by the model family that produced the selected candidate splits them into two populations, and comparing each against the participating systems on the same segments shows that the split is not a property of the documents. Table 17 gives the paired gaps. On the 4,912 segments where the selector kept a GPT-5.5 or Gemini candidate our reference is within 2.1 ESA of the six strongest systems and ahead of two of them. On the 2,541 segments where it kept a candidate from TranslateGemma, HY-MT, Tower-Plus, Aya or EuroLLM it is 14.4 to 17.3 points behind all six. The anchors themselves barely move between the two groups, 82.8 against 82.5 for Gemini 3.1 Pro, so the open-selected documents were no harder to translate. On spoken documents the contrast is sharper: where a frontier candidate was kept our reference is statistically indistinguishable from five of the six systems and ahead of the sixth, and where an open candidate was kept it is 23.5 to 25.5 points behind all of them. Taking our offset against Gemini 3.1 Pro on the frontier-selected segments and applying it to the anchor level on the open-selected ones estimates 81.1 ESA had a frontier candidate been kept throughout, giving 81.3 overall against the 75.9 obtained on the same 7,453 segments. That estimate assumes the offset transfers, and is quoted as an order of magnitude rather than a prediction. Producer attribution is by exact text match against the generation outputs and is unambiguous at family level for all but one document; 21 of the 2,292 documents match no cell and are excluded from this analysis.

**Which language pairs were hardest.** Ranking pairs by raw ESA is misleading, because the pairs differ in domain mix and in how much of each was annotated. eng → deu has our lowest raw score at 59.7 but is only mid-table once the comparison is controlled, while eng → hye has both the highest

| | | gap against participating system | | | | | |
|---|---|---|---|---|---|---|---|
| Group | Ours | Gem. | TRIVE | Wayf. | Lumen | GPT | UvA |
| *all domains* | | | | | | | |
| frontier, 4,912 | 81.4 | −1.4 | −1.7 | −1.9 | −2.1 | +0.9 | +0.1 |
| open MT, 2,541 | 65.2 | −17.3 | −16.5 | −16.1 | −15.2 | −14.4 | −14.4 |
| *spoken documents* | | | | | | | |
| frontier, 584 | 80.1 | +0.4 | +0.5 | +0.9 | +3.5 | +1.7 | +1.1 |
| open MT, 931 | 52.5 | −25.5 | −24.1 | −24.0 | −23.7 | −23.7 | −23.5 |

Table 17: Mean human ESA of our references by the family of the selected candidate, and the paired gap against each participating system on identical segments. In the frontier rows every gap except Lumen on spoken documents has a 95% interval containing zero or close to it; in the open rows every interval excludes zero by a wide margin. Widths are given in the released verification output.

raw score and the smallest deficit. The measure that answers the question is the paired gap against the six strongest participating systems on identical segments, given in Table 18. Our references are furthest behind on eng → zho-Hans (−11.3), eng → kor (−11.1), eng → jpn (−9.5), eng → deu (−9.3), eng → rus (−9.2) and eng → bel (−9.0), and closest on eng → hye (−1.2, whose interval includes zero, as does the much wider one for eng → zho-Hant), zho-Hans → jpn (−2.7), eng → kaz (−3.1), eng → ekk (−3.2) and eng → isl (−3.4). The five thinnest pairs, eng → zho-Hans and eng → zho-Hant at 25 and 28 documents and eng → kor, eng → deu and ces → deu at 51, 68 and 70, carry intervals two to four times wider than the rest and should not be read as point estimates.

The ordering tracks the share of segments on which the selector kept an open-weight translation model rather than a frontier one: Pearson −0.56 and Spearman −0.65 across the sixteen pairs. It is a tendency and not a rule. eng → bel is the informative exception, at only 17% open-MT selection yet −9.0 overall, because both slices are weak there: its 75 open-MT segments score 41.5 against an anchor level of 65.5, and even its 357 frontier segments sit 5.9 below the anchors, against 1.4 globally. Belarusian is hard for us whatever we select.

The three pairs that motivated the language penalty behave in a way the penalty explains. On eng → hye and eng → kaz the penalty pushed selection almost entirely onto frontier models, 3% and 16% open-MT respectively, and those are two of our three strongest pairs; on eng → hye our references sit 0.4 below the anchors on the frontier-selected segments, which is indistinguishable from the best systems in the task. Removing wrong-language output and improving quality turn out to be the same intervention here, which was not something the construction-time evidence could have shown.

Document averaging changes the magnitudes substantially, eng → kor moving from −11.1 to −26.5, but preserves most of the ordering, with Spearman +0.81 between the two columns.

| Pair | Docs | Segs | ESA | % open | gap (95% CI) | doc gap |
|---|---|---|---|---|---|---|
| eng → zho-Hans | 25 | 70 | 66.0 | 66 | −11.3 [−16.7, −5.9] | −12.8 |
| eng → kor | 51 | 167 | 69.9 | 27 | −11.1 [−15.3, −7.0] | −26.5 |
| eng → jpn | 198 | 691 | 79.0 | 55 | −9.5 [−11.3, −8.0] | −14.2 |
| eng → deu | 68 | 173 | 59.7 | 61 | −9.3 [−12.6, −6.0] | −13.5 |
| eng → rus | 189 | 664 | 72.4 | 48 | −9.2 [−11.2, −7.5] | −17.5 |
| eng → bel | 136 | 435 | 67.5 | 17 | −9.0 [−11.4, −6.8] | −13.5 |
| eng → ind | 198 | 691 | 74.8 | 54 | −7.8 [−9.4, −6.1] | −13.9 |
| eng → tha | 198 | 691 | 77.0 | 26 | −7.3 [−8.8, −5.7] | −17.5 |
| ces → deu | 70 | 192 | 78.4 | 53 | −6.2 [−9.5, −3.0] | −7.5 |
| eng → ukr | 198 | 691 | 78.9 | 44 | −5.7 [−7.4, −4.2] | −13.4 |
| eng → zho-Hant | 28 | 88 | 65.3 | 49 | −3.9 [−9.7, +1.8] | −8.6 |
| eng → isl | 192 | 647 | 79.1 | 24 | −3.4 [−4.9, −1.9] | −7.2 |
| eng → ekk | 172 | 591 | 77.1 | 24 | −3.2 [−4.6, −1.7] | −8.3 |
| eng → kaz | 181 | 643 | 78.4 | 16 | −3.1 [−4.6, −1.7] | −4.3 |
| zho-Hans → jpn | 190 | 541 | 72.9 | 36 | −2.7 [−4.4, −1.2] | −4.0 |
| eng → hye | 198 | 691 | 81.0 | 3 | −1.2 [−2.6, +0.3] | −3.0 |
| all | 2,292 | 7,666 | 75.8 | 34 | −5.9 [−6.4, −5.4] | −11.4 |

Table 18: Per-pair difficulty, ordered by the segment-level gap. ESA is our own segment-averaged score; % open is the share of annotated segments on which the selector kept a translation-specialised open model; gap is our ESA minus the mean of Gemini 3.1 Pro, TRIVE, Wayfinder, Lumen, GPT-5.5 and UvA-MT on identical segments, with a percentile bootstrap interval over 2,000 resamples; doc gap is the same quantity computed on document means. Segments are counted where at least four of the six anchors were annotated, which is 7,644 of our 7,666.

**The same result without conditioning on our selector.** Grouping by what we selected invites the objection that the grouping is itself a consequence of the metric. A test that avoids it: for each annotated document, compare the best frontier candidate with the best open candidate under MetricX and group by which the metric preferred. MetricX preferred an open candidate on 1,579 of the 2,292 documents. On those 4,170 segments, our references score 69.8 [68.9, 70.6] while Gemini 3.1 Pro scores 80.8, TRIVE 80.2, Wayfinder 80.0 and GPT-5.5 78.2. On the 713 documents where MetricX preferred a frontier candidate, our references score 83.1 [82.4, 83.8] against 84.3, 85.0, 85.5 and 82.9. Where the metric preferred an open candidate, we ended around ten points below the achievable level; where it preferred a frontier candidate, we were within two. Note that C6 is not a MetricX argmax, so on the first group we still shipped a frontier

candidate for 1,651 of 4,032 segments.

**Which cells the metric misranks.** The effect is not a general preference for open-weight models. Computed over all candidates on the same documents rather than only the selected ones (Table 19), MetricX penalises Tower-Plus, Aya and EuroLLM heavily and correctly. What it does is rate TranslateGemma best of all seven families, ahead of both frontier models, and HY-MT close behind them. Those two cells produced 941 of our annotated documents at 54.1 and 52.8 human ESA against 80.9 and 79.0 for the frontier families. Across the seven families, the rank correlation between human ESA and MetricX is $+0.07$, that is, absent rather than inverted; the strongly negative value obtained when the metric is averaged only over the documents where each family won selection is an artefact of that conditioning, since a family wins precisely when its score is unusually good.

| Family | Docs | ESA | MX all | MX sel. |
|---|---|---|---|---|
| TranslateGemma | 564 | 54.1 | 4.63 | 3.29 |
| GPT-5.5 | 578 | 79.0 | 5.06 | 5.12 |
| Gemini-3.1-Pro | 506 | 80.9 | 5.11 | 4.98 |
| HY-MT1.5 | 377 | 52.8 | 5.40 | 2.60 |
| Tower-Plus | 122 | 63.9 | 9.51 | 3.26 |
| Aya-Expanse | 89 | 67.1 | 12.53 | 4.56 |
| EuroLLM | 35 | 62.6 | 13.03 | 3.53 |

Table 19: Human ESA of our references by producing family, document-averaged, against mean MetricX (lower is better) computed two ways: over every candidate that family produced for these documents (MX all), and over only the documents where that family won selection (MX sel.). The second column must not be used to rank families.

**Our selection metrics did not predict the human scores.** Scoring our own selected references, the document-level correlation between our QE metrics and human ESA is near zero once multimodality is controlled: MetricX reaches $+0.07$ on text-only documents and CometKiwi $+0.19$, CometKiwi reaches $+0.19$ within news, and MetricX $+0.27$ within the social domain. The uncontrolled correlation is slightly negative, $-0.12$ for MetricX over 2,272 documents. This agrees with Section 5: among top candidates these metrics carry little information about which one a human will prefer.

**Error spans.** Averaging annotation passes within a cell, our references carry 1.58 spans per segment and 0.55 major spans, against 1.22 and 0.30 for human translation from scratch and 0.81 and 0.36 for human post-editing. Span rate on our references tracks the domain profile: 3.16 per segment on spoken documents, 1.85 on social, 1.05 on news and 0.57 on software. Span lengths are not directly comparable across systems, because 12.7% of all spans are zero-width insertion markers and the rate varies from 7.9% for human translation from scratch to 19.7% for human post-editing.

**Checks on the comparison.** Systems are annotated on overlapping but different subsets, so every comparison above is restricted to segments or documents where both were scored, and the leaderboard position is descriptive only. Annotator identity is not a confound: where the same annotator scored both our reference and the human one, the gap is close to the gap across annotators ($-6.4$ against $-5.3$ for translation from scratch, $-5.1$ against $-6.2$ for post-editing). The human systems are distinct text, sharing no document rendering with our references on any of the 414 and 487 documents where both are annotated. The successive releases of 12 August, 19 August and 2 September are cumulative at the level of annotator, item and system coverage, so the analysis was regenerated rather than merged; we have not verified that scores attached to retained items are unchanged between releases.

## Abstract

We present *North Small Translate*, an open-weight, LLM-based machine translation (MT) model with instruction-following capabilities built on the same foundation as Cohere's *Command A+*, a mixture-of-experts architecture with 25 billion active parameters out of 218 billion total parameters. *North Small Translate* is trained using difficulty sampling to obtain challenging documents and a five-step training protocol combining supervised fine-tuning, direct preference optimization, and online reinforcement learning. We prioritized throughput through a non-reasoning base model and supplemented it with optional agentic capabilities to unlock translation quality gains. *North Small Translate* is trained to perform MT-related tasks, including post-editing and quality estimation, as well as related tasks such as general instruction following. The model achieves top MT performance across 50 languages in the class of models under 1T parameters, with no need to run expensive reasoning at inference time.

## 1 Introduction

In recent years, machine translation (MT) has almost fully transitioned to large language models (LLMs), which treat cross-lingual generation as a complex instruction-following task. This shift lets models leverage broad context, translate robustly, and adapt to various requests.

We introduce *North Small Translate* (submitted to the WMT General MT shared task as *Cohere CAT+*), our best-performing MT system built upon the same foundation as Cohere's *Command A+* (Cohere Team, 2026). It is a sparse mixture-of-experts (MoE) transformer with 25 billion active parameters out of a total of 218 billion parameters.

*North Small Translate* is built for efficiency. While most LLMs rely on test-time reasoning to achieve state-of-the-art performance, long reasoning traces introduce prohibitive latency and computational overhead for production-level translation. Model throughput is a primary target for practical MT deployment, so we explicitly trained *North Small Translate* as a non-reasoning model. For latency-insensitive applications, our optional *Agentic Translation* framework bridges the potential quality gap caused by the absence of intermediate reasoning steps.

*North Small Translate* achieves top-tier translation quality through five distinct training steps: (i) Coarse SFT to establish general non-MT instruction-following capabilities and extend the base model's language coverage; (ii) Fine-grained SFT using highly curated synthetic datasets to improve core MT quality and adjacent tasks like error detection and post-editing, followed by three steps focusing primarily on human-aligned translation quality: (iii) DPO; (iv) Online RL using an LLM-as-a-judge reward; and (v) a minimal final DPO with a reduced learning rate to resolve edge-case regressions introduced in RL.

We participate in the WMT 2026 General MT (Kocmi et al., 2026), Terminology (Charkiewicz et al., 2026), and Automated MT Evaluation shared tasks with our model, *Cohere CAT+*. Our submission uses no specialized search heuristics, inference tricks such as Minimum Bayes Risk decoding (Freitag et al., 2022), or Agentic Translation.[1] One

domain for General MT contains videos as sources; we used *Cohere Transcribe*[2] to obtain textual transcripts for English videos, while relying on the officially provided transcripts for Chinese and Czech source data.

## 2 Training Details

### 2.1 Model Architecture

Our model is built on top of Command A+ (Cohere Team, 2026), a decoder-only sparse Mixture-of-Experts transformer (Vaswani et al., 2017) with 218B total parameters and 25B active.[3]

The list of pre-training languages is:

Arabic, Bengali, Czech, Danish, Dutch, English, Filipino, Finnish, French, German, Greek, Hebrew, Hindi, Indonesian, Italian, Japanese, Korean, Malay, Norwegian, Persian, Polish, Portuguese, Punjabi, Romanian, Russian, Simplified Chinese, Spanish, Swedish, Tamil, Telugu, Thai, Traditional Chinese, Turkish, Ukrainian, Urdu, Vietnamese.

The list of languages extended in post-training:

Albanian, Bulgarian, Catalan, Croatian, Estonian, Hungarian, Icelandic, Irish, Latvian, Lithuanian, Maltese, Serbian, Slovak, Slovenian.

### 2.2 Training Approach

We build on top of findings from our previous models and also our previous Command-A-Translate (Kocmi et al., 2025a), which showcased the impact of the Direct Preference Optimization (DPO) (Rafailov et al., 2023) training step on MT quality.

We use five distinct training steps, each focused on a different aspect:

1. Initial coarse SFT: to cover general instruction-following capabilities and extend language coverage from the 35 pre-training languages to 50 languages. We fine-tune four different models and merge them (Cohere et al., 2025).

2. Fine-grained SFT: focusing on improving the MT quality using primarily synthetic datasets and also improving MT-related tasks such as error detection, terminology or post-editing.

3. DPO: primarily focused on improving quality.

4. Online RL: online RL with GSPO (Zheng et al., 2025) and LLM-as-a-Judge as the reward signal to polish performance and increase adequacy.

5. Light targeted DPO with a reduced learning rate: for fixing remaining problems, especially a few introduced by the RL step.

Table 2 shows the MT improvement from each training step. Each step yielded significant gains except RL, which improved some scores, especially adequacy, but degraded performance for a few low-resource languages because the LLM judge is weak in these languages.

of the WMT General MT shared task.

[2] https://cohere.com/blog/transcribe

[3] https://huggingface.co/CohereLabs/command-a-plus-05-2026-bf16

To fix the aforementioned regression, we introduced a final DPO step with a reduced learning rate and only 5 warm-up steps. For this step, we focused only on a few problematic languages and capabilities.

| Step | MT Quality |
|---|---|
| Coarse SFT | 71.3% |
| Fine-grained SFT | 76.2% |
| DPO | 80.1% |
| Online RL | 80.0% |
| Light DPO | 81.8% |

Table 2: Training progression on the WMT25 evaluation with GEMBA-ESA averaged over 14 languages.

### 2.3 Data Preparation

While the main goal is to build a strong MT model, we additionally focused on building a strong instruction-following model that also excels in MT-related tasks, such as post-editing, terminology following, quality estimation, or structured translation.

We processed every translation pair with automated verifiers to remove noisy or malformed text. We enforced structural consistency by requiring source and target segments to have the same number of lines and paragraphs. Additionally, we applied language identification and filtered out instances of unwanted code-switching. Our filtering pipeline also removed segments containing broken Unicode characters and relied on various other internal classifiers to detect and discard anomalies.

#### 2.3.1 Quality of Machine Translation

A primary challenge in curating training corpora for top-performing MT systems is the sparsity of genuinely difficult source material, as we highlighted in Kocmi et al. (2025a). After our initial coarse SFT stage, the model translates without major errors for more than 90% of our training documents. Consequently, randomly sampling source texts would yield a weak learning signal and fail to push the model's quality boundaries.

We use difficulty sampling to focus our synthetic generation exclusively on problematic instances from which the model can learn. Building upon our previous work (Kocmi et al., 2025a), we extend difficulty sampling by using the initial base model with minimal post-training itself as the baseline model and keep only documents where the model produces major errors, or its translation quality is lower than the human reference for parallel data. For each source document, we randomly select a high-resource target language and translate the document with an early-stage model. A judge then evaluates the translation for errors. For monolingual data, we classify a source segment as "easy" and remove it if its translation is largely error-free. For parallel data, we deem it "easy" if the translation outperforms the human reference. Filtering easily translated segments concentrates the corpus on difficult texts, directing downstream synthetic-data generation to documents where the model needs the most improvement.

To achieve top MT performance across all supported languages, we construct our training corpora using two distinct data synthesis and refinement strategies, which we call *Best-per-Language Forward Translation* and *Post-Edit Driven Preference Distillation*. Both approaches are designed to maximize the quality and diversity of the training signal without relying on human-annotated parallel data, which we use solely in the first stage of training.

Best-per-Language Forward Translation combines standard forward translation with Best-of-N selection. For each language, we select the top-performing language-specific expert to translate the source documents. To ensure broad multilingual coverage and improve cross-lingual transfer, we randomly assign the target language during generation. While the majority of the source texts are in English, a significant part consists of non-English sources, yielding a substantial volume of direct non-English to non-English translation pairs. A judge retains only candidates scoring above 70 GEMBA-ESA. Scoring details are in Section 2.4, as we use this approach throughout.

Our second strategy, *Post-Edit Driven Preference Distillation*, is the data preparation pipeline's most critical component and the primary driver of DPO. It aims to generate near-on-policy data offline, creating effective preference pairs that target the model's weaknesses. The orchestration pipeline operates as follows:

1. Generate a draft translation using the current candidate model.

2. A separate judge model identifies and annotates error spans in the generated draft. If no error is present, the sample is deemed "easy" and dropped from the training data.

3. A third model acts as an automated post-editor, taking the draft and fixing the errors.

4. We iterate steps 2 and 3 until no major error is discovered, or we pass 10 iterations.

This multi-model orchestration yields an aligned preference pair: the candidate model's original, flawed output is the worse completion and the corrected version the preferred completion. *Because the flawed translation comes directly from the candidate model, the dataset closely approximates on-policy MT data. Offline DPO can thus function with the precision of online reinforcement learning by penalizing the model's actual failure modes.* This orchestration approach was instrumental in fixing persistent, model-specific errors and driving the most significant quality improvements observed during our DPO stage.

#### 2.3.2 Instruction Following

To give our MT model acceptable general instruction-following abilities and strengthen translation-related tasks and adherence to specific MT instructions, we included non-MT instruction data in the first SFT stage. We used some English-only single-turn datasets used to train Command A+ and multilingual datasets with general-purpose multilingual prompts. We removed reasoning traces from all reused datasets. We reused these data in the second SFT stage with significant downsampling.

#### 2.3.3 Structured Translation

"Structured translation" is the process of translating natural language embedded in data formats such as JSON or HTML without breaking their underlying syntax. It is a critical feature especially for translating webpages, documents or training data.

While the general instruction-following datasets described above contain various formats, in structured translation, we focus solely on JSON and HTML formats. We prepare data from naturally occurring structures or by placing paragraphs or sentences from high-quality MT datasets into diverse structures. The former uses JSON from internal datasets and HTML from web datasets; the latter uses top segments from high-quality sentence corpora. An internal model translates the resulting sources into 35 languages, both field by field and as complete structures. Prompts controlled translation scope, from the entire structure to only a few JSON keys. Lastly, the translations were filtered for structure retention and for translation quality. On top of SFT, we also created a DPO dataset targeting only specific structured errors that our fine-tuned models exhibit. These included over-copying or parsing issues, with the preferred completions remaining as pristine as possible.

#### 2.3.4 Terminology Translation

Terminology translation is the task of producing a translation that adheres to a glossary of source-target term pairs supplied in the prompt. When a customer has an established vocabulary, such as product names, brand names or domain-specific jargon, it is critical that a translation solution render these consistently and have the ability to use translation memories. We focus on building a preference dataset for this capability.

For each document, an LLM identifies source named entities and their reference renderings, proposes an equally valid alternative target-language rendering for each, and rewrites the reference to use the alternatives while leaving other text unchanged. The rewrite is the preferred completion, the original reference is dispreferred, and the proposed term pairs are given to the model as the glossary. Because the completions differ only in term renderings, the preference signal isolates terminology adherence from general translation quality.

A model that blindly copies every glossary entry would score well on such data. To counter this, half the documents receive negative glossary entries: topically related source-language words and phrases that do *not* occur in the document. These are proposed by an LLM, filtered with a substring check against the source and both completions, and verified by a second LLM pass that also rejects inflected forms, compounds and transliterations. A document never receives more negative entries than genuine ones. The dataset contains preference pairs from English into ten languages: Arabic, German, Spanish, French, Hindi, Italian, Japanese, Korean, Portuguese and Russian. Following Section 2.3.8, each glossary uses a random format: a JSON object, a JSON list of pairs, or one term pair per line with a varying separator; it is attached to a random instruction. When negative entries are present, the instruction comes from a separate set warning that some entries may be irrelevant to the source.

#### 2.3.5 Tone and Idiomatic Translation

Human evaluation in early stages revealed that our model struggled with adhering to an expected tone, formality levels and usage of idioms.

To improve the model's adherence to formality instructions, we collected social-domain data in eight languages with explicit formality distinctions: Dutch, Italian, Polish, Greek, Japanese, Spanish, Korean, and Portuguese. Each sample was automatically assigned one of three labels using an LLM: *formal*, *informal*, or *ambivalent*. Both grammatical markers and stylistic cues were considered when determining the appropriate formality label.

We then back-translated each target-language sample into English using our internal MT model, producing supervised training triplets of a back-translated English source segment, a target-language segment with an authentic formality level, and an associated formality label. During training, each label was mapped to its corresponding natural-language instruction in the model prompt highlighting the expected formality level.

In order to tackle the idiom translation, we created multilingual synthetic datasets from existing English monolingual idiom datasets. The collected training set contained 50k idiomatic sentences paired with annotated idioms or literal paraphrases.

We translated literal paraphrases from English into 35 languages with our internal MT model. We then scored each translation using GEMBA-ESA (Kocmi and Federmann, 2023) with a strong LLM judge, retaining only examples scoring at least 70. For idioms without literal paraphrases, we used `best-of-N`: several models generated translations and the LLM judge selected the best. We otherwise followed the same process. Finally, we retained the top 10k candidates per language pair, yielding 512k sentences.

#### 2.3.6 Error Detection and Quality Estimation

Error detection is the task of identifying erroneous spans in a given machine-translated text, while quality estimation assesses the quality of the translated text. Both are evaluated annually by the WMT Automatic Evaluation task (Lavie et al., 2025).

In our preliminary experiments, training on fully human labels alone was only marginally better than the baseline, lagging far behind state-of-the-art models, which may be caused by inconsistency in the human annotations. We therefore focus on synthetic annotations of actual MT errors only, using a strong judge to assess error spans and scores.

Inspired by Treviso et al. (2024), we used an XML tag scheme to annotate the text. We designed a unified XML tag scheme that can represent both ESA-style tags (Kocmi et al., 2024b) encoding only severity (`<error severity="minor or major">`) and MQM-style tags (Lommel et al., 2014) that additionally carry an error category and subcategory (`<error severity="..." category="accuracy/mistranslation">`).

#### 2.3.7 Post-editing

Post-editing is the process of improving an existing translation to capture inaccuracies in fluency and adequacy. Typically, one provides a tuple containing the source and raw translation, and expects an improved translation from an oracle. The oracle can be a human or an automated translation system or model. In our setup, we use another capable judge LLM to be an oracle.

WMT APE came up with the formulation for Automatic Post-editing, where people were given human post-edits of some unknown MT system and were allowed to train ML models that can perform similar fixes when trained on supervised datasets comprising the original translation, source text and the corrected output (Bojar et al., 2015; Chatterjee et al., 2018). Because human post-edits are scarce and hard to scale, researchers have relied on synthetic LLM edits (Bang et al., 2023; Ki and Carpuat, 2024; Singh et al., 2025). LLMs can also be fine-tuned for more faithful post-editing. We adopt this approach and consider inference-time post-editing useful for translation models.

We use post-editing both to refine training targets and teach our model to repair drafts at inference time. For post-training data, a base internal MT system produces a draft that a stronger LLM post-edits. We score the draft and revision with reference-free GEMBA-ESA (Kocmi and Federmann, 2023) and keep the pair only when the post-edit improves the draft, restricting supervision to major quality gaps. Each retained example has two instruction formats: (a) *Blind* post-editing, which provides the source and raw translation, and (b) *Span-assisted* post-editing, which marks erroneous spans in the original translation with XML severity tags (major or minor) and provides the annotated translation with the source (Lommel et al., 2014; Kocmi et al., 2024b).

| Metric | Acc (ties) |
|---|---|
| GEMBA-ESA Fluency+Adequacy | 51.0 |
| GEMBA-ESA | 50.6 |
| xCOMETxl | 44.9 |
| spBLEU | 43.7 |

Table 3: Metric meta-evaluation comparing LLM-as-a-judge (with GPT 5.4) versus traditional metrics on internal human-labeled translations.

#### 2.3.8 Instruction Diversity

Instruction-tuned MT often relies on static prompts (e.g., "Translate this to [Language]"). Although functional, fixed phrasing causes overfitting. We therefore diversify prompt instructions during training to improve robustness.

We introduce variance across three distinct tiers. First, we seed instructions with curated, manually prepared paraphrases to capture human-written translation requests. Second, we automatically prepare thousands of paraphrased instruction variants for broad lexical and syntactic coverage. Finally, we translate each variant into all supported languages. When preparing the training dataset, we randomly select a prompt, alternating the instruction language between English, the source language, and the target language. Furthermore, we added various augmentations such as merging consecutive sentences into a single line, replacing newlines with random paragraph separators, enclosing the source and/or target text in XML tags or Markdown.

To strengthen instruction adherence, we included a small preference dataset in the final DPO step. It targets terminology, formality, custom formatting or style, and combinations of these constraints. We synthesize it by having an LLM add creative translation guidelines to existing prompts, generating translations with best-of-N, and using a judge focused on guideline adherence to select the best; the worst is the negative example.

### 2.4 Reliable Evaluation Metric

Reliable evaluation metrics were crucial to model development. We meta-evaluated metrics using internal human annotations for 24k translated segments across 10 languages and the segment-level pairwise accuracy method from Deutsch et al. (2023). As Table 3 shows, confirming Lavie et al. (2025), LLM-as-a-Judge methods significantly outperform traditional string-based metrics such as xComet and spBLEU. Consequently, we focused on LLM-as-a-judge throughout our work. We also designed an updated GEMBA-ESA (Kocmi and Federmann, 2023) prompt that evaluates fluency and adequacy separately before averaging them. This yields a slightly higher correlation with human judgments while enabling independent diagnosis of translation accuracy and fluency and providing individual error annotations. The full prompt that we used throughout this work with various judges is in Section A.

### 2.5 Agentic Translation

To maximize inference throughput, we train a non-reasoning model, trading potential quality gains from intermediate reasoning for significantly faster generation. For quality-critical applications, we bridge this gap with *Agentic Translation*. It uses the same underlying model in three roles: a translation agent generates a draft, an evaluation agent identifies and annotates errors, and a post-editing agent corrects the draft using those error spans. By decomposing the translation process into iterative, targeted steps, the agentic approach recovers the performance benefits typically associated with reasoning models.

## 3 Evaluation and Results

We analyze the performance of our model over MT capabilities and related tasks. We compare it with our previous models, top-performing MT open-weight systems, and leading providers such as Google Translate and DeepL Pro (the full list is in Section 3.1). We evaluate all systems in an identical setup, in a clean zero-shot approach without any inference techniques.

### 3.1 Benchmark Models

Next to our new model, we evaluate Cohere's two previous models: Command A Translate (Kocmi et al., 2025a) and general-purpose Command A+ (Cohere Team, 2026). We compare them with a broad selection of top-performing open-weight models below 1T total parameters: Google's Gemma 4 31B (Gemma Team, 2026); Mistral Large 3 (Mistral AI Team, 2026) and Mistral Medium 3.5 (Mistral AI, 2026); Alibaba's Qwen3.5 397B (Qwen Team, 2026a) and Qwen3.6 27B (Qwen Team, 2026b); Z.ai's GLM-5.2 (GLM-5-Team et al., 2026); OpenAI's GPT-OSS 120B (OpenAI et al., 2025); NVIDIA's Nemotron 3 Ultra (NVIDIA Research, 2026); Thinking Machines Lab's Inkling-Small (Thinking

Machines Lab, 2026); and Meta's Muse Glimmer 30B (Cuenca et al., 2026). In addition, we compare against two leading commercial translation services: Google Translate and DeepL's NextGen.

We keep the reasoning on for every model that supports reasoning capabilities: specifically, Command A+, Gemma 4 31B, Qwen3.5-397B, Qwen3.6-27B, GLM-5.2, GPT-OSS 120B, and Muse Glimmer 30B.

### 3.2 Machine Translation Capabilities

Our core focus is MT quality across all supported languages. To honestly evaluate capabilities, we evaluate them on a test set released after we finished building the model: the WMT 2026 General MT test set (Kocmi et al., 2026). This dataset contains four distinct domains and translation modes.

Lavie et al. (2025) showed that traditional metrics such as xComet (Guerreiro et al., 2024) and MetricX (Juraska et al., 2024) no longer correlate well with human evaluation, and instead, strong frontier models excel at evaluation. Our internal evaluation in Section 2.4 agrees. Thus, we use GPT-5.6 Sol as a reference-free judge, asking it to score adequacy and fluency separately and averaging the scores.

WMT26 is a document-level test set, where the number of documents differs for each domain. Building on the recommendation of the original test set, we weight each score by the number of segments in the document. This way, each domain is roughly equally represented with about 180 segments.

The speech domain tests multimodal capabilities, but all reported models are evaluated text to text. We use the provided automatic transcript as source text and give the human-cleaned transcript to the LLM judge to reduce ASR noise.

Table 4 shows that North Small Translate ranks first overall, particularly in European and Latin-script languages. It ranks second for Middle Eastern and Asian languages. Per-language results are in Table 6.

We supplement results with a well-known evaluation in the MT community: WMT24++ (Deutsch et al., 2025). WMT24++ contains English to 55 human-translated languages and dialects. The original source text is from Kocmi et al. (2024a) and covers multiple domains. Each language pair contains 171 documents split into 998 mostly paragraph-level segments. We use the prompt instruction from Deutsch et al. (2025) and we evaluate with xComet-XL (Guerreiro et al., 2024), a metric widely used for system rankings. The metric is a 3.5B-parameter model fine-tuned on human judgment data.

Table 1 shows that North Small Translate reaches near-top performance. That said, caution is needed; as discussed in Section 3.6, WMT24++ is significantly easier than WMT26 and mostly "solved" with top-performing systems.

### 3.3 Long-Context Translation

We evaluate long-context translation using a subset of the WMT25 General MT test set (Kocmi et al., 2025b). The English long-context source comprises two documents with approximately 9,900 words divided into two sections. We concatenate them into a single source document, yielding one long-form evaluation instance. As part of the evaluation, we translate it into Egyptian Arabic, Czech, Estonian, Icelandic, Japanese, Korean, Russian, Simplified Chinese, and Ukrainian. The complete document is provided to the model in a single request.

Translations are evaluated against the WMT25 references using the reference-based xCOMET-XL metric (Guerreiro et al., 2024). Since the metric is not able to evaluate a full document, we divide the translations at segment boundaries. xCOMET-XL independently scores each aligned source–hypothesis–reference triple and returns the arithmetic mean over the 85 segments.

Table 1 shows that our model reaches second-best MT quality, outperformed only by DeepL.[4]

### 3.4 Terminology Translation

We evaluate glossary-conditioned translation using the WMT25 Terminology Translation Task (Semenov et al., 2025). We refer readers to that work for the dataset construction, domains, and official shared-task protocol. Our evaluation covers five translation directions: English to German, Spanish, Russian, and Traditional Chinese, and Traditional Chinese to English.

For the scoring, we use only the proper-terminology condition setup. Each model receives the source text together with a source–target glossary and is instructed to apply the supplied terminology while returning only the translation.

[4]DeepL is a closed-source system accessed by API, so we cannot confirm implementation: for instance, whether it might pre-parse the source text.

Table 4: Machine translation capabilities aggregated over different groups of languages over the WMT26 test set.

We measure the corpus-level terminology success rate: a dictionary pair is successful when its source term occurs in the input and its prescribed target form occurs in the translation. As a final score in Table 1, we micro-average language-pair scores from both WMT25 Terminology Tracks.

### 3.5 Evaluation of Structured Translation

Because this task is the first of its kind, we built dedicated test suites and metrics. Our test suites were developed using internal datasets from the same distribution as the training data and also naturally occurring sentences that were combined to create diverse JSON structures. They test instruction following through two tasks: translating all fields and translating only user-specified fields. We dropped a Markdown suite because our base models already saturated it.

For structured translation, we tracked translation quality and, primarily, structural consistency, which we report here. The metrics target errors observed during model development. Table 1 reports their average.

- Overall structure: *Parsing accuracy* checks whether the delimiters permit structured-output extraction. *Decoding accuracy* checks whether the extracted output decodes into a valid object (e.g., JSON or YAML). *Schema accuracy* checks whether the decoded output matches the source schema (e.g., the same JSON keys). Failures cascade to subsequent structured metrics.

- Untranslation issues: The intermediate models exhibited different levels of copying in their outputs, from leaving intermediate fields untranslated to retaining entire translations in the source language. In addition, the instruction-following test suite involved only translating a limited number of fields, requiring the remaining fields to be retained in their source language. Thus, the evaluation measured (i) the percentage of samples where all non-translatable content was copied correctly and (ii) the average per-sample percentage of translatable fields that were incorrectly copied. Lastly, a separate metric evaluated the proportion of examples that were left completely untranslated.

- Line count consistency: Per field, this checks whether the generated and source translations have the same line count.

### 3.6 Quantifying Test Set Saturation

To measure headroom on popular WMT test sets, we ran a human evaluation of the same system with the ESA protocol (Kocmi et al., 2024b). Table 5 shows that for high-resource languages, WMT24 is much easier than WMT26—and nearly solved. This is especially problematic with xComet: as actual errors grow rare, the metric's word preferences

| Language | WMT24 | WMT26 |
|---|---|---|
| Arabic (MSA) | 19.7% | 34.9% |
| German | 22.9% | 37.1% |
| Spanish (Mexico) | 14.2% | 34.9% |
| French | 7.6% | 13.9% |
| Italian | 11.9% | 11.5% |
| Japanese | 14.6% | 28.9% |
| Korean | 29.9% | 19.3% |
| Portuguese (Brazil) | 6.6% | 17.5% |
| Chinese (Simplified) | 14.4% | 18.1% |
| **Overall difficulty** | **15.8%** | **24.0%** |

Table 5: Percentage of segments containing at least one major error, highlighting the saturation of the test sets.

affect score differences more than the errors. We also found that in WMT26, the software domain is easiest, while other domains remain considerably harder.

These results require some caution. Although both evaluations used the Pearmut framework (Zouhar and Kocmi, 2026), some details differ, most notably those affecting the slider anchors. We argue that these changes minimally affected the major-error annotations, which remained comparable. The test sets were also evaluated in different months, alongside different systems, and by slightly different annotator pools. While the pools could not be strictly controlled, we selected one system that was identical across both evaluations. The table shows this model's error percentages in both setups. This strong system outperforms Command A+ but underperforms North Small Translate.

## 4 Conclusion

We introduce *North Small Translate*, Cohere's state-of-the-art machine translation system. A sparse mixture-of-experts non-reasoning transformer-based LLM with 25 billion active and 218 billion total parameters, it achieves top-tier performance across 50 languages.

We build *North Small Translate* via a five-step training protocol spanning SFT, DPO, and online RL. By using difficulty sampling and an orchestrated preference distillation pipeline, we focused our synthetic data generation and training signal strictly on the most challenging documents. Consequently, the model excels in standard machine translation as well as complex related tasks, including structured translation, terminology adherence, and error detection.

For latency-insensitive applications requiring maximum quality, we incorporated an Agentic Translation framework, enabling the model to iteratively evaluate and post-edit its own drafts. We submitted our model to the WMT 2026 General MT shared task as *Cohere CAT+*, demonstrating the model's strong out-of-the-box capabilities.

## Limitations

MT evaluation is limited by noise and the limited discriminative power of automated benchmarks and even human evaluators. Translation quality can be subjective, and high quality in one domain does not guarantee it in another, even for the same language. Preferred system recommendations can thus vary by use case.

Table 6: Machine translation quality of every supported language of the WMT26 test set.

# A GEMBA-ESA Fluency+Adequacy Template

## A.1 System prompt

```
You are an impartial judge whose task is to analyze machine translation outputs and evaluate their quality.

Based on the provided source text, target language, translation guidelines, and translation output, identify translation errors and assess their severity. Then evaluate the quality of the translation according to the provided rubric criteria. For each criterion, provide a brief rationale in English and a score within the allowed range.

Errors have "quote", "severity", and "category" attributes. The "quote" value should quote the part of the translation that contains the error. Use minor severity for imperfections or stylistic issues that do not impact the core message (e.g., awkward phrasing). Use major severity for errors that obscure the meaning, misrepresent the source, or change the message (e.g., incorrect information or confusing wording). The category must be one of: "accuracy", "fluency", "terminology", "style", "locale", "design", "mistranslation", "omission", "addition", "untranslated", "grammar", "spelling", "punctuation", "register", "unidiomatic", "inconsistency", or "other". If the error span is longer than a few words, use an ellipsis (...) to shorten it. If the error concerns the entire translation, such as a translation in the wrong language, set "quote" to "FULL_TRANSLATION". For omissions (missing source content), set "quote" to the adjacent translation words with "OMISSION" between them. If there are no errors, set "errors" to an empty array.

Return your error analysis and quality evaluation as a single, strictly valid JSON object matching the provided output format.
```

## A.2 User prompt

```
## Evaluation rubric
- Fluency score [key: fluency]: Measures how natural and grammatically correct the translation reads in the target language. (score: 0 to 100)
- Adequacy score [key: adequacy]: Measures how completely the meaning of the source is conveyed by the translation. (score: 0 to 100)

## Additional judging rules
### Important rules
- Hallucinations are major adequacy errors and should be penalized severely.
- Outputs in the wrong language, dialect, or script are major fluency errors and should be penalized severely. Borrowed words are allowed if valid in the target language.
- Check translation consistency (e.g., technical terms) across the entire text.
- Over-translation and extraneous text (e.g., introductory statements like "Here is your translation" or unprompted explanations) are major adequacy errors.
- Count guideline adherence issues toward the adequacy score; for these errors, set "quote" to the corresponding guideline.

### Adequacy scale
- 81-100 (Very Good): Complete meaning transfer; no information is lost, added, or distorted.
- 61-80 (Good): Near-complete transfer; minor inaccuracies or omissions that do not affect the core message.
- 41-60 (Acceptable): Main ideas conveyed, but noticeable inaccuracies, omissions, or additions.
- 21-40 (Borderline): Partial transfer; frequent misinterpretation or omission confusing the core message.
- 0-20 (Not acceptable): Complete violation of meaning; large portions mistranslated, hallucinated, or missing.

### Fluency scale
- 81-100 (Very Good): Perfectly natural and grammatical; reads like a native text; requires no or minimal proofreading.
- 61-80 (Good): Mostly natural; minor awkwardness or slight grammatical imperfections; needs light proofreading.
- 41-60 (Acceptable): Uneven naturalness; noticeable awkward phrasing or structural issues; usable only after substantial revision.
- 21-40 (Borderline): Often unnatural; frequent grammatical errors that impede reading flow; requires major rewrite.
- 0-20 (Not acceptable): Incoherent, structurally broken, incomprehensible, or in the wrong language, dialect, or script; unusable without complete retranslation.

## Source text
```
{{SOURCE_TEXT}}
```

## Translation language or dialect
{{TARGET_LANGUAGE_OR_DIALECT}}

## Translation guidelines
{{TRANSLATION_GUIDELINES}}

## Translation output
```
{{TRANSLATION_OUTPUT}}
```

## Expected output format
Return a single, strictly valid JSON object with the following schema:
```json
{
  "errors": [
    {
      "quote": "<string>",
      "severity": "minor|major",
      "category": "<string>"
    }
  ],
  "fluency": {
    "rationale": "<string>",
    "score": "<number>"
  },
  "adequacy": {
    "rationale": "<string>",
    "score": "<number>"
  }
}
```

Every string value must be valid JSON: escape each backslash as \\ and each double quote as \". Do not emit raw control characters or trailing commas.
```

# AdaptiveMT at WMT26: A Controller–Executor–Reducer Agent Harness for Document-Level Translation

**Soyoung Lee**
Independent Researcher
sycj427@gmail.com

## Abstract

We describe AdaptiveMT, our submission to the English–Korean condition of the WMT26 General Machine Translation task (Kocmi et al., 2026) in the unconstrained track. AdaptiveMT is a language-general adaptive translation harness with target-language-specific profiles; this run uses the Korean profile. The system uses a controller–executor–reducer agent harness. For each document, the harness analyzes the source, generates independent candidate translations from two heterogeneous models, compares them with token-level and semantic diffs, and synthesizes a final translation with a judge model. Mandatory QA hooks and deterministic Korean-specific guards run before finalization; failures trigger bounded local repair. Multimodal documents use structured visual context extracted from images or sampled video frames before translation. We processed all 2,078 distributed blindset records under two Korean target tags; the subsequently released General MT evaluation set contains 198 English-to-Korean documents tagged `kor_Hang`. On this official subset, the harness made 1,441 successful LLM calls at an estimated list-price inference cost of $12.03, and all 198 documents finished with passing hooks. In blindset-wide diagnostics, synthesis eliminated observed candidate-level mechanical errors, and a GPT-5 judge preferred the final output over a bare GPT-4.1 baseline on 600 sampled documents (44.5% vs. 30.0%, 25.5% ties).

## 1 Introduction

Recent WMT General MT evaluations (Kocmi et al., 2024) show that strong LLMs translate well when prompted directly, yet single-pass prompting still leaves document-level failure modes: dropped or merged lines, untranslated source fragments, broken placeholders and markup, register mismatches in dialogue, and instruction violations on samples with explicit constraints. These errors are individually rare but recur across a large blindset, and many are easier to expose when an independent model is asked to compare or verify the output.

Our WMT26 submission, **AdaptiveMT**,[1] therefore treats translation as a bounded agent harness rather than a single call. The design borrows three ideas from recent agent harnesses for software engineering: (i) a typed state object that all steps read and write, (ii) a fixed action vocabulary whose preconditions are enforced by a normalizer rather than trusted to the model, and (iii) forced verification hooks that stand between the agent and the FINISH action. Within this frame, translation quality comes from *post-decoding soft fusion*: two heterogeneous candidate models translate independently, their outputs are compared by token-level and semantic diffs, and a judge model synthesizes the final translation from diff-localized evidence, with the option to reject both candidates and translate directly from the source where both are awkward.

We participated in the English→Korean condition only. At submission time, we processed all 2,078 records carrying either of the two Korean target tags in the distributed blindset. The subsequently released General MT evaluation subset contains 198 `kor_Hang` documents, including 174 with image or video context. Section 2 positions the design against prior work, Section 3 describes the harness, Section 4 the Korean target-language profile, Section 5 the submission run, and Section 6 what we learned.

## 2 Related Work

**LLMs for (document-level) MT.** General-purpose LLMs are now competitive with or better than dedicated MT systems for many high-resource pairs (Hendy et al., 2023; Vilar et al., 2023), and recent WMT General MT findings confirm that LLM-based systems dominate the top ranks while document-level and instruction-

[1] Code: https://github.com/8pril/adaptivemt

*Proceedings of the Eleventh Conference on Machine Translation*, pages 1318–1326
October 28-29, 2026 ©2026 Association for Computational Linguistics

following errors persist (Kocmi et al., 2023, 2024). Wang et al. (2023) show that prompting LLMs with full documents improves discourse phenomena over sentence-level translation; our harness also translates whole documents, but adds structural analysis and hook-based verification.

**LLM-as-a-judge and quality estimation.** LLMs are strong reference-free evaluators of translation quality (Kocmi and Federmann, 2023) and are widely used as pairwise or scalar judges (Zheng et al., 2023). We use a judge model not to score candidates but to *synthesize* from them, conditioned on explicit token-level and semantic diff evidence; our QA hooks are a second, targeted use of LLM judging with a deterministic guard layer that can overrule the judge.

**Self-refinement and agentic inference.** Iterative self-correction (Madaan et al., 2023; Shinn et al., 2023) and tool-using agent loops (Yao et al., 2023) improve LLM output quality at inference time, and structured agent–computer interfaces are central to software-engineering agents such as SWE-agent (Yang et al., 2024). Translation-specific multi-step strategies include MAPS (He et al., 2024), which elicits translation-relevant knowledge before translating, and multi-agent pipelines for literary translation (Wu et al., 2024). Our harness differs in that the loop is *bounded and normalized*: the action vocabulary is fixed, action preconditions are enforced in code, revision is budgeted, and finalization is guarded by forced hooks rather than left to the agent's judgment.

**System combination.** Combining multiple MT systems predates LLMs, from confusion-network combination (Rosti et al., 2007) to MBR and quality-aware decoding with neural metrics (Freitag et al., 2022; Fernandes et al., 2022). Our post-decoding soft fusion is a text-level analogue: instead of ensembling token probabilities or selecting a whole candidate, a judge model composes the final translation from diff-localized evidence over two heterogeneous candidates and may retranslate parts where both fail.

## 3 System Architecture

### 3.1 Harness loop

Each document sample is wrapped in an `AgentState` containing the source document, the sample-level instruction, sample-supplied format constraints, deterministically extracted format-safety constraints, and accumulating artifacts (multimodal context, structured source analysis, candidates, diffs, the final translation, repair patches, hook results, a full event log, and LLM-call logs). The harness then loops:

```
while not finished and budget remains:
action = select(state)
obs = execute(action, state)
state = reduce(state, action, obs)
force_hooks_if_needed(state)
```

Figure 1 shows the per-document execution flow of the submitted configuration. Its core action sequence uses EXTRACTMULTIMODALCONTEXT, ANALYZESOURCE, GENERATECANDIDATE, DIFFCANDIDATES, SYNTHESIZEFINAL, CHECKALL (a combined run of four QA hooks), REVISEFINAL, and FINISH. The fixed action vocabulary also contains optional research, terminology, and fact-checking actions. When enabled, these actions retrieve external evidence, construct an evidence-backed terminology table, and extract factual constraints before candidate generation; their artifacts are stored in `AgentState` and made available to downstream translation steps. All were disabled for the submission and are omitted from the figure. A *normalizer* validates every proposed action against the state: FINISH is rejected until a final translation exists and all required hooks have run, SYNTHESIZEFINAL is rejected before at least two candidates and a diff exist, and disabled or repeated actions fall back to a deterministic next step.

The action selector supports three modes. `always` implements a *bounded agent*: the LLM controller selects every next action from the fixed vocabulary, subject to the normalizer and mandatory finalization hooks. `minimal` is partially agentic, consulting the controller only for ambiguous repair decisions after a hook failure. `never` implements a deterministic agentic workflow in which the state-based `fallback_action()` policy selects every action. All three modes share the same executor, reducer, normalizer, and forced hooks. The submission used `never` for repeatability and cost control, and is therefore a *deterministic agentic workflow* rather than an autonomous agent.

### 3.2 Source analysis

ANALYZESOURCE asks an analysis model to convert the sample into structured JSON: explicit constraints (hard rules, format, style, preserve/omit

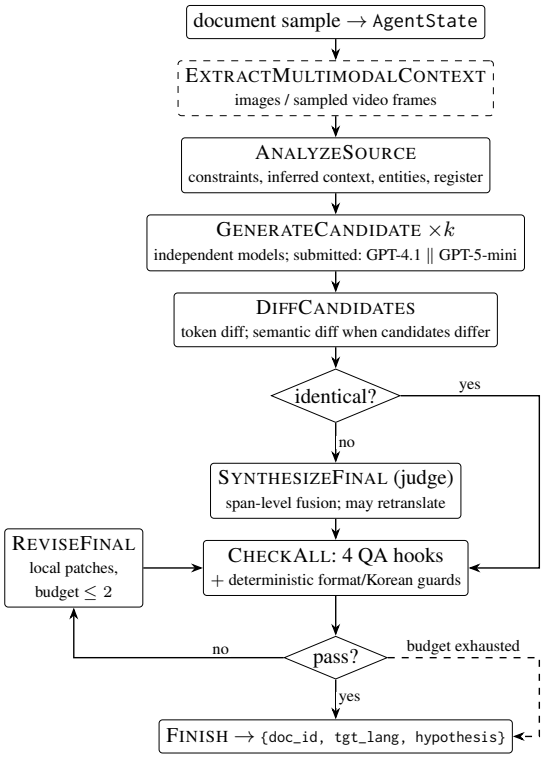

Figure 1: The submission-time AdaptiveMT flow for one document. Solid boxes are actions of the deterministic policy used for the submission; the dashed box runs only for documents with multimodal input. When the two cleaned candidates are byte-identical, judge synthesis is skipped and the shared translation goes directly to validation. Failed hooks trigger at most two local-repair passes; when the repair budget is exhausted, the document finishes best-effort (dashed edge).

lists) derived from the sample instruction and format constraints; an *inferred context* with likely domain and genre, a confidence level, and supporting evidence; a discourse summary and outline; an entity map; coreference notes; and tone/register. Explicit sample instructions always take precedence over inferred context. This avoids relying on handwritten genre heuristics, which would not generalize across the blindset's mix of literary prose, social-media posts, subtitles, and technical strings.

### 3.3 Candidate generation and diff-based synthesis

Two candidate models translate the full document independently, conditioned on the source analysis, format-safety constraints, derived style requirements, and any multimodal context. When the cleaned candidates differ, DiffCandidates produces two artifacts:

- a **localized token-level diff**, obtained by deterministically aligning the cleaned outputs with a custom tokenizer over markup tags, printf placeholders, Hangul spans, Latin tokens, whitespace, and symbols, then grouping adjacent token insertions, deletions, and replacements with surrounding context; and
- a **structured semantic diff** produced by the judge from the source, instructions, contextual artifacts, both candidates, and the token diff. It records meaning and coverage divergences, terminology, fact, style, and format risks, together with a preferred rendering and rationale for each disputed span.

SynthesizeFinal gives the judge model both candidates and both diffs and asks for a single final translation. The judge may take diff-localized portions from either candidate or ignore both and translate a part directly from the source when both candidates are wrong. This is post-decoding, text-level soft fusion: no token probabilities are ensembled at decoding time. When the two cleaned candidates are byte-identical, the harness uses the shared translation as its initial final output and skips the semantic diff and the synthesis call. Across the full 2,078-record processing run, this shortcut fired on 234 documents (11.3%), concentrated in short dialogue lines. Four of these translations were subsequently changed by the hook-and-repair stage. None of the 198 documents in the official evaluation subset had identical candidates.

Figure 2 illustrates the span-level fusion process with an example from the full processing run.

### 3.4 Validation hooks and bounded repair

Before the harness may finish, four hooks must run: *instruction following*, *glossary compliance*, *format preservation*, and *completeness* (no dropped, merged, or hallucinated lines). The default CheckAll action evaluates all four in one checker-model call. Hook results are then post-processed by deterministic guards (Section 4) that can flip a hook to failed regardless of the LLM's verdict.

On failure, ReviseFinal proposes *local repair patches*, which are span replacements targeted at the reported issues. Each proposed span replacement is applied once; patches that cannot be matched exactly are delegated to a constrained patch-applier model. The revised translation is then checked again. Repair is budgeted (up to two revisions per document in the submission run); when

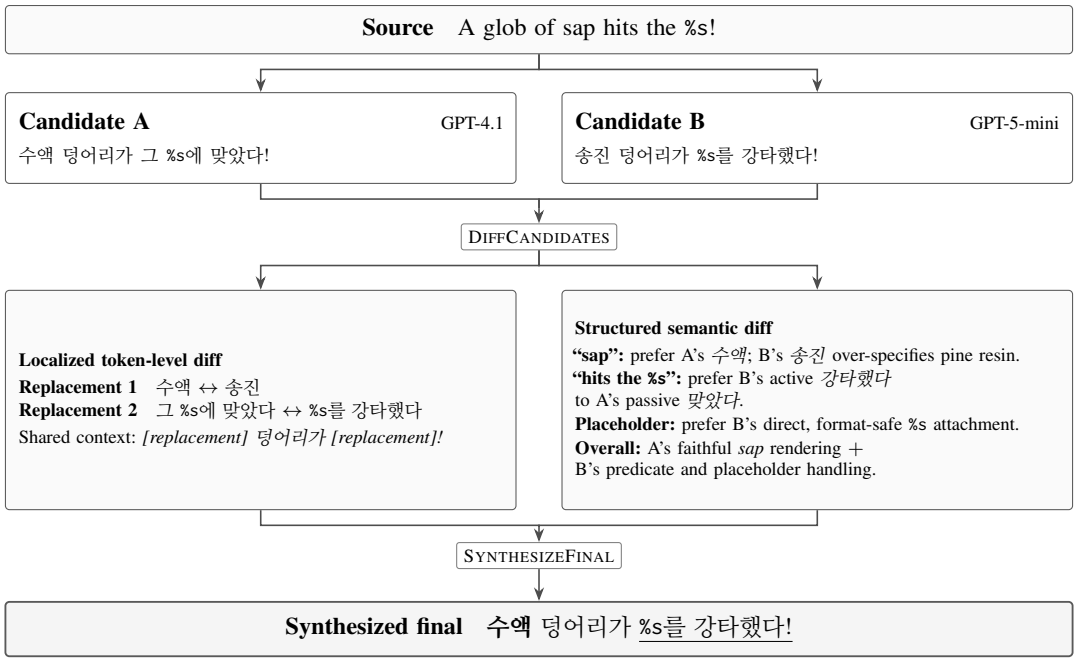

Figure 2: Span-level synthesis, abridged and reformatted from a recorded trace. The diffs favor A's faithful rendering of *sap* and B's predicate and placeholder handling. The resulting translation matches neither candidate and was accepted without repair (bold = from A; underlined = from B).

the budget is exhausted the harness finishes best-effort rather than looping. Across the full processing run, 45 documents (2.2%) went through repair: 42 with one revision and 3 with two. Within the official 198-document subset, three documents received one revision each and all converged to passing hooks. The sole best-effort finish with a failing hook occurred outside that subset.

### 3.5 Multimodal context extraction

The official 198-document evaluation subset includes 174 documents carrying an image (social-media screenshots) or a video file (dialogue clips). For these, EXTRACTMULTIMODALCONTEXT runs before any translation step: images are sent directly to a vision model; videos are sampled into at most six frames with `ffmpeg`, with the frame count scaled to clip duration. The extractor returns a *visual-only* structured context, including scene, participants, on-screen text, and register cues, which is injected into candidate, synthesis, hook, and repair prompts. The extractor is explicitly forbidden from inventing translation rules; it only reports what is visible, and the translation prompts use it to resolve deixis, speaker relationships, tone, and ambiguous referents. Media context also drives derived style requirements: video-sourced samples are treated as spoken dialogue and steered toward natural colloquial Korean endings (-야/-어/-지/-네) rather than literary register (-다/-습니다), unless the speaker's register indicates otherwise. In the submitted implementation, translation prompts carry the sample's main instruction verbatim; the separate multimodal-instruction field is used only by the keyword heuristic that derives style requirements. This was sufficient for the WMT26 blindset: across all 174 multimodal documents, the two instruction fields are near-duplicates, and the only unique content in the multimodal instruction is the video-speech cue that the heuristic converts into register requirements. For future multilingual and multimodal settings, we would pass both fields verbatim.

## 4 Target-Language Profile: Korean

The harness loop, action set, hooks, and synthesis logic of Section 3 are language-agnostic; everything specific to a target language, including deterministic guards, register steering, and script checks, is isolated in a *target-language profile*. Supporting a new language pair means writing a new profile, not a new harness. This mirrors the separation that software-engineering agent harnesses draw between a generic agent loop and pluggable, domain-specific extensions. The submitted system instantiates the Korean profile.

LLM-based hooks occasionally miss mechanical failures, so the profile layers cheap deterministic

checks on top:

**Format safety.** Printf placeholders (`%s`, `%d`, ...) are extracted from the source before translation and must be preserved exactly, in count and order. Notation and separator symbols between word characters (`^`, `|`, `->`, ...) are likewise protected unless the sample instruction says to rewrite them.

**Hangul-ratio guard.** For Korean targets, a translation of a non-trivial source that contains almost no Hangul, or vastly more Latin than Hangul text, is flagged as untranslated. A near-identity check (normalized similarity $> 0.82$ against the source) catches copy-through failures.

**Untranslated-Latin-token guard.** Latin source tokens that survive verbatim into the Korean output are flagged unless they are format-safe (URLs, handles, hashtags, markup, acronyms, code-like tokens) or the sample instruction explicitly licenses preservation. In the submitted system this exemption applied at the sample level: any sample licensing foreign-word preservation was skipped wholesale (later refined; see Section 6). Such an instruction occurs in 133 official-set documents. Flagged tokens are appended to the instruction-following hook as failures, forcing a repair pass that must translate, transliterate, or justify each token.

These guards convert the most common silent LLM failure modes, including copy-through, partial translation, and placeholder corruption, into visible hook failures with a targeted repair path.

## 5 Submission

**Evaluation scope.** The mixed General MT/test-suite blindset contained 1,880 `ko_KR` and 198 `kor_Hang` records.[2] Because the official English–Korean tag was unspecified, we processed both; the subsequent release identifies `kor_Hang` as the 198-document evaluation subset. We report it separately from the 2,078-record full run.

**Configuration.** We submitted to the unconstrained English→Korean condition. The run used deterministic control (`never` mode), two candidates (GPT-4.1 and GPT-5-mini), GPT-4.1 for semantic diffing, synthesis, and repair patching, Upstage Solar-Pro3 for source analysis and combined QA, and GPT-4.1 vision for multimodal extraction, with at most 12 loop steps and up to two revisions per document.

For reproducibility, GPT-4.1 calls left `temperature` and `top_p` unset, using the Responses API defaults of 1.0 for both. During batched candidate generation, GPT-5-mini's reasoning effort was explicitly set to `low` after early batches had used the provider default (medium at the time).[3] The OpenAI API calls used the aliases `gpt-4.1` and `gpt-5-mini`. For reference, OpenAI lists the dated versions `gpt-4.1-2025-04-14` and `gpt-5-mini-2025-08-07`, respectively.[4] Upstage reports Solar-Pro3 as a mixture-of-experts model with 102B total parameters and 12B active parameters per token.[5] OpenAI does not disclose parameter counts for GPT-4.1 or GPT-5-mini.

**Run statistics.** Table 1 separates the official evaluation subset from the broader processing run. Every processed record received exactly one output row with a non-empty hypothesis. The harness logs a full per-document trace (every action event, LLM call, and intermediate artifact); statistics retain the last trace record per document after resumed runs, which is the source of every statistic in this section and supports the error analysis in Section 6.

**Results.** WMT26 did not release preliminary automatic scores. At camera-ready preparation time, finalized official human rankings were unavailable, so we report no official shared-task results. The task and its human evaluation are described in the shared-task findings paper (Kocmi et al., 2026).

**Blindset-wide stage audit.** The released Korean documents contain no reference translations, so a reference-based quality ablation is not possible. To isolate the contributions of synthesis and repair, we instead reconstructed intermediate outputs from the trace and applied three deterministic checks with unambiguous pass/fail semantics: printf-placeholder preservation, structure alignment under the official checker criterion, and non-empty output. Table 2 compares the bare baseline, both independent candidates, the first post-synthesis translation before repair, and the final full-

| harness/baseline | 19.7× | 40.1× |
| Identical shortcuts | 0 | 234 (11.3%) |
| Documents repaired | 3 (1.5%) | 45 (2.2%) |
| Failing-hook finishes | 0 | 1 |

Table 1: Run statistics. API-attempt counts including retries were 1,616 (official) and 13,003 (full). Costs use September 2026 list prices; harness usage was recorded and baseline content-token counts were reconstructed (Section 6). Latency sums sequential action durations. The sole failing hook was a guard false positive outside the official subset.

| Stage | Placeh. | Struct. | Empty | Hook fail. |
|---|---|---|---|---|
| Bare GPT-4.1 | 5 | 0 | 0 | – |
| GPT-4.1 candidate | 6 | 0 | 1 | – |
| GPT-5-mini candidate | 2 | 4 | 1 | – |
| Post-synthesis | **0** | **0** | **0** | 45 |
| Final output | **0** | **0** | **0** | 1 |

Table 2: Stage-wise diagnostic over all 2,078 processed records. The first three numeric columns count mechanical output errors; counts may overlap. Structure mismatch follows the official alignment-checker criterion (top-level element counts for JSON documents and <p> counts for HTML documents; other document types are not covered). Hook failures are defined only after synthesis and repair.

run output. It also reports the number of records with at least one failing mandatory hook at the two stages where hooks are defined. The audit covers all 2,078 records in the broader processing run rather than only the 198 official documents.

All candidate-level mechanical errors disappear immediately after synthesis. The two models did not break the same placeholder in the same record, so the judge selected compliant renderings from the diff evidence. Synthesis also recovered from one empty candidate from each model and prevented GPT-5-mini's four JSON/HTML mismatches, one of which overlaps with its empty candidate, from propagating. Repair reduced records with failing hooks from 45 to one (and from three to zero on the official subset). Thus the audit attributes the observed mechanical gains to synthesis, while repair's measured contribution is the resolution of hook failures in 44 records. Because the hooks are part of the system rather than independent quality judgments, neither result by itself establishes overall translation quality.

**What synthesis does.** Because two-candidate provenance is undefined when either candidate is empty, the two records described above are excluded from this analysis. Comparing the remaining 2,076 records against the stored candidates shows the judge does not simply default to one model: the final translation equals both stored candidates in 230 cases (11.1%), only the GPT-4.1 candidate in 516 (24.9%), only the GPT-5-mini candidate in 979 (47.2%), is a span-level mix or light edit of the closer candidate in 339 (16.3%; SequenceMatcher ratio $\geq 0.6$, median 0.93 among these records), and is substantially rewritten in the remaining 12 (0.6%). The first count is four lower than the 234 identical-candidate shortcuts in Table 1 because four shared translations were changed during subsequent hook-driven repair.

**Blindset-wide pairwise quality comparison.** To add a quality signal on top of the mechanical audit, we ran a pairwise LLM-judge comparison between the bare GPT-4.1 baseline and the full-run output on a random sample of 600 of the 1,871 records where the two systems produced different strings (sampled with a fixed-seed script). The judge used the `gpt-5` API alias with low reasoning effort; OpenAI lists its corresponding snapshot as `gpt-5-2025-08-07`.[6] GPT-5 was not used anywhere in the submitted pipeline (the submission judge was GPT-4.1). It saw the sample's full instruction (including the multimodal instruction where present), the source, and both translations. Position bias is controlled by judging each document twice with the order swapped; a system wins only if it wins both orders, otherwise the document is a tie. The full-run output was preferred on 267 documents (44.5%), the bare baseline on 180 (30.0%), with 153 ties (25.5%); a two-sided sign test over the 447 decisive pairs gives $p < 10^{-4}$. As with the mechanical audit, this comparison covers the broader processed blindset rather than only the subsequently identified official subset. Inspecting the baseline's wins shows they are dominated by fine-grained stylistic preferences on short game

[6] https://developers.openai.com/api/docs/models/gpt-5

strings rather than systematic defects in the full-run output. Latin retention does not explain the losses in aggregate: guard-flag rates are essentially equal in the two win groups, and documents with retained proper nouns concentrate in ties. However, Latin retention is the salient difference in 10 of the 180 losses, where the full-run output kept source-language names or phrases that the baseline transliterated or translated; this is consistent with the sample-level exemption in effect at submission time, later replaced by the token-level guard (Section 6).

## 6 Discussion

**Strengths.** The diff-based synthesis step is most valuable when the two candidates disagree meaningfully: disagreement localizes exactly the spans where at least one model is wrong, and the judge adjudicates with both renderings visible. Conversely, in the full processing run, 234 records (11.3%) had byte-identical candidates and needed no judge, although four were subsequently modified by hook-driven repair and the shortcut did not occur in the official 198-document subset. Heterogeneous-model agreement is a cheap confidence signal that we exploit to skip work.

**Failure modes.** In the broader processing run, one `ko_KR` record outside the official subset finished with a failing hook that turned out to be a guard false positive: the source described a military launcher whose model designation *M202A1* was correctly preserved in the Korean output, but the untranslated-Latin-token guard's format-safe patterns did not cover alphanumeric designations with alternating letters and digits, and the repair model correctly kept the designation unchanged. The output was fine; the guard was wrong. More generally, under a bounded revision budget, a disagreement between a deterministic guard and the repair model cannot be resolved within the loop and surfaces as a best-effort finish.

**Post-submission guard changes.** Error analysis after submission led to two guard changes. First, the format-safe pattern was widened to cover alphanumeric model designations such as *M202A1*, removing the false positive above. Second, we found the guard too permissive on samples whose instructions allow foreign words to be kept unchanged: the exemption applied at the sample level, so transcript interjections and sound-effect-like tokens (e.g., *MM*, *Oh*) could also remain untranslated. The guard is now token-level: exact preservation of proper names and foreign words is honored only where the sample instruction licenses it, while interjection-like Latin tokens are still checked by the guard. The preservation check also reads the multimodal instruction in addition to the main instruction. These changes postdate the submission: the outputs and every number reported in this paper reflect the pre-change run.

**Cost.** We estimated inference cost from the uncached-input, cached-input, and output-token usage recorded for every successful LLM call in the trace. At the providers' published per-million-token list prices, the official 198-document subset cost $12.03 ($0.061 per document) and the full 2,078-record processing run cost $46.78 ($0.023 per record).[7] The estimate uses token usage from successful responses; failed retry attempts reported no usage. It excludes the post-hoc bare baseline and pairwise evaluation, taxes, account credits, and volume or batch discounts. For comparison, we reconstructed the post-hoc bare GPT-4.1 baseline's cost from its exact prompts and saved outputs because its runner did not retain API usage. Applying the uncached GPT-4.1 rates gives approximately $0.61 ($0.0031 per document) on the official subset and $1.17 ($0.00056 per record) on the full run. These estimates assume one successful call per record and exclude message-framing tokens and any unrecorded retries. The harness therefore cost approximately $19.7\times$ the bare baseline on the official subset and $40.1\times$ over the full run. The larger full-run ratio reflects the 1,880 additional, predominantly short non-multimodal records, for which a single-call baseline is especially inexpensive.

**Latency.** We measured end-to-end per-document latency as the sum of the sequential action-event durations retained in the trace. Median and P90 latency were 68.2 and 145.5 seconds on the official subset, and 26.4 and 53.4 seconds over the full processing run.[8] The bare baseline runner did not

[7] Per-model costs (official/full run): $10.94/$41.95 for GPT-4.1, $0.85/$3.56 for GPT-5-mini, and $0.24/$1.26 for Solar-Pro3. Uncached-input/cached-input/output rates: $2.00/$0.50/$8.00 for GPT-4.1, $0.25/$0.025/$2.00 for GPT-5-mini, and $0.15/$0.015/$0.60 for Solar-Pro3. Published pricing, accessed September 2026. GPT-4.1: https://openai.com/index/gpt-4-1/. GPT-5-mini: https://developers.openai.com/api/docs/models/gpt-5-mini. Solar-Pro3: https://www.upstage.ai/pricing/api.

[8] We compute P90 by the nearest-rank method: after sorting $n$ observations, select the observation at rank $\lceil 0.9n \rceil$.

retain timing data, so we cannot report a directly observed baseline increase. As a same-run single-call proxy, the GPT-4.1 candidate-generation call had median latency of 7.80 seconds on the official subset and 2.76 seconds over the full run. The median per-document ratio of harness latency to this proxy was $8.54\times$ and $8.93\times$, respectively. These are deployment-level observations that include network latency, provider load, retries, and local multimodal preprocessing; they do not isolate model inference time and should not be interpreted as hardware-independent speed measurements. The submitted harness executed actions sequentially, so parallel candidate generation could reduce latency without changing the pipeline logic.

## 7 Conclusion

We described AdaptiveMT, a stateful controller–executor–reducer harness for the WMT26 General MT English–Korean condition. The system combines document-level candidate generation, diff-based synthesis over heterogeneous models, normalized action selection, forced QA hooks, and Korean-specific deterministic guards. On the official 198-document evaluation subset, the system made 1,441 successful LLM calls, repaired three documents, and finished every document with passing hooks. In our broader blindset-wide diagnostic, synthesis eliminated the mechanical output errors present in the single-model outputs, and repair resolved the hook failures in 44 of 45 affected records (Table 2). Finally, swappable target-language profiles separate Korean-specific behavior from the core harness.

## Limitations

While the harness itself is language-agnostic and language-specific behavior is isolated in a target-language profile (Section 4), only the Korean profile has been implemented and tuned; the portability claim is a design property that has not yet been demonstrated empirically on another language pair. All component models are closed commercial LLMs accessed through APIs; stochastic decoding means that reruns may not reproduce identical outputs. We report no reference-based quality ablation because the released Korean documents contained no reference translations. The blindset-wide stage audit (Section 5) isolates synthesis and repair only through mechanical failure proxies and internal hook outcomes. That audit and the pairwise comparison cover the broader 2,078-record processing run rather than a separately resampled official subset; the latter also relies on an LLM judge that shares a provider family with the candidate models and cannot see the multimodal inputs. Without finalized official human results at camera-ready time, the reported comparisons should be read as post-hoc diagnostics rather than official shared-task results or a complete evaluation of translation quality.

## Abstract

We present the BSC submission to the WMT26 General Machine Translation shared task: a 7B decoder-only model covering 23 directions, adapted from the SALAMANDRA (Gonzalez-Agirre et al., 2025) family through vocabulary replacement, two rounds of continued pre-training (monolingual, followed by instruction-formatted parallel data), supervised fine-tuning on a translation-only instruction mixture, and preference optimisation applied selectively to six weak directions via CPO-SimPO (Xu et al., 2024; Meng et al., 2024) with LoRA adapters (Hu et al., 2021). Submissions are decoded with Minimum Bayes Risk selection over a candidate pool filtered for truncation, degeneracy and off-target script. As official human evaluation was unavailable at the time of writing, we report a stage-wise internal evaluation on FLORES+ and WMT24++, together with automatic scores for the submitted system on the 12 test-set directions for which references have been released. Instruction tuning accounts for almost all measurable gain, but its size differs by an order of magnitude between the two evaluation sets; preference optimisation moves automatic metrics by less than the drift among untreated directions. The model is released under a Research-Only Licence and is available on request.[1]

## 1 Introduction

We describe the Barcelona Supercomputing Center submission to the WMT 2026 General Machine Translation shared task: a 7B-parameter decoder-only translation model covering 23 directions, adapted from the SALAMANDRA family.

Not all shared-task languages are represented in SALAMANDRA's original vocabulary, and the vocabulary replacement required to cover them is incompatible with the released SALAMANDRA**TA** (Garcia Gilabert et al., 2025) checkpoints. Our pipeline therefore restarts from the SALAMANDRA-7B base model and proceeds in four stages: vocabulary adaptation with monolingual continued pre-training (CPT1); continued pre-training on instruction-formatted parallel data (CPT2); supervised fine-tuning on a translation-only instruction mixture (SFT); and preference optimisation applied selectively to six weak directions (PO). CPT2 was planned as two shards but was stopped at the end of the first, at which point it had seen half of the planned data, when our compute allocation was exhausted. We report what was consumed rather than what was planned.

Because the 2026 task is assessed by human evaluation alone, and those results are unavailable at submission time, we report a stage-by-stage internal comparison of the pipeline. We evaluate three checkpoints (post-CPT2, post-SFT, post-PO) on FLORES+ `devtest` (22 directions) and WMT24++ (16 directions) with BLEU, chrF and COMET. English–Northern Sámi is excluded throughout due to the lack of evaluation data. We also score the submitted system against the human references released for 12 of the 23 directions (§5.2).

Our contributions are: (i) a stage-wise internal evaluation isolating the contribution of each adaptation stage across 23 directions (§5); (ii) a null result on selective preference optimisation, with the conditions under which it is uninformative rather than negative (§6); and (iii) an inference pipeline for the task's structured and instruction-conditioned inputs, in which an ordered eligibility filter removes truncated, degenerate and off-script candidates before Minimum Bayes Risk decoding (Eikema and Aziz, 2020), addressing the two dominant selection failures we observed (§4).

[1]Earlier MT models in the family are public: SALAMANDRA**TA**7B-v1, SALAMANDRA**TA**2B-v1, SALAMANDRA**TA**7B-v2.

## 2 Data

Training proceeds in two rounds of continued pretraining on top of the vocabulary-adapted SALAMANDRA-7B base model. All token counts are measured with our extended tokeniser.

### 2.1 CPT1: monolingual

For CPT1 we assembled a monolingual corpus covering all languages already supported by SALAMANDRA**TA** together with those newly introduced by WMT 2026 (the full split of existing versus new languages is in Appendix A). Each language was sampled up to a 1B-token cap, and languages with less available data contributed everything we had (Table 1). In total, 52 language datasets amounting to 44.91B tokens were globally shuffled into a single shard, with 0.05% held out for validation and 0.05% for testing.

Most data came from FineWeb (Penedo et al., 2024) for English and FineWeb-2 (Penedo et al., 2025) for the remaining languages. Where FineWeb-2 could not fill the budget we drew on CC-100 (Wenzek et al., 2020) (Kazakh, Traditional Chinese, and partially Belarusian and Armenian), Leipzig Corpora (Eckart and Quasthoff, 2013) and the Northern Sámi side of OPUS (Tiedemann, 2012), and regional corpora for Aranese (PILAR, DOGC, WMT24 low-resource Occitan), Valencian (Les Corts Valencianes) and Asturian. Simplified Chinese was obtained by script conversion of the FineWeb-2 Chinese sample. Data was used as released, without additional filtering.

Four coverage gaps should be noted. Thai was unintentionally omitted, as its sample was not ready when the shard was assembled; we compensate in CPT2. Ligurian and Ladin were excluded because no usable monolingual data was available. Northern Sámi was included with only ∼30M tokens, as it was all we could source. Lastly, Turkish (1B tokens) was included despite not being a WMT 2026 language, to provide transfer support for Kazakh.

### 2.2 CPT2: parallel and monolingual

CPT2 uses instruction-formatted parallel data (∼72% of the mix by source–target tokens) and monolingual data (∼28%), restricted to the WMT 2026 languages plus Italian and Turkish. The mix contains 85.1B tokens including template overhead, globally shuffled, with the same 0.05%/0.05% held-out split, trained for a single epoch.

| Languages | Tokens |
|---|---|
| ar, be, bg, ca, cs, da, de, el, en, es, et, eu, fi, fr, gl, hi, hr, hu, hy, id, is, it, ja, kk, ko, lt, lv, nb, nl, pl, pt, ro, ru, sk, sl, sr, sv, tr, uk, vi, zh, zh_TW | ∼1B each |
| nn | 768.0M |
| cy | 723.9M |
| ga | 591.1M |
| mt | 425.5M |
| ast | 202.7M |
| oc | 88.8M |
| val (Valencian) | 39.3M |
| se | 30.0M |
| oc-aranes (Aranese) | 28.0M |
| arg (Aragonese) | 16.9M |
| **Total** | **44.91B** |

Table 1: Monolingual data used in CPT1. Languages above the line were capped at 1B tokens; for those below, all available data was used.

**Parallel data.** We downloaded all corpora permitted for the constrained task with `mtdata` (Gowda et al., 2021) using the official WMT 2026 recipe, and audited licences, discarding corpora that do not permit derived work even for research. The data was cleaned with ParaCLEAN (Mash et al., 2026), which scores every pair with LaBSE (Feng et al., 2022) alignment and GlotLID (Kargaran et al., 2023) language identification, filters pairs below 0.75 alignment or 0.5 language-identification probability on either side, and deduplicates and normalises the remaining data. GlotLID was selected after comparing four identifiers (Lingua-py, fastText, Idiomata Cognitor, GlotLID), achieving the highest accuracy on FLORES+ (91.07%) and on the noisier WMT24++ (87.92%) (Mash et al., 2026). The result was merged with the existing SALAMANDRA**TA** parallel data for the same pairs and cross-deduplicated.

Each direction was converted to plain-text records by embedding sentence pairs in natural-language translation instructions, sampling uniformly from a pool of 35 templates, with and without an explicit source-language name; the pool is listed in Appendix B. Each direction was capped at 5B source-plus-target tokens, giving 52.4B tokens over 937M sentence pairs across 21 directions (Appendix C, Table 6).

**Monolingual data.** We added 1B tokens for each of the 19 CPT2 languages (fresh samples from the CPT1 sources, non-overlapping with the CPT1 shard), for 20B tokens in total. Thai received a double share to compensate for its omission from

CPT1. English monolingual data was not included, as English is abundantly represented on the source side of the parallel data.

**Coverage.** Italian (1B monolingual, 5B en–it parallel) was added to support the closely related Ligurian and Ladin, and Turkish (1B monolingual) to support Kazakh. The shared task's Arabic direction is into Egyptian Arabic, but no variety filtering was applied at either continued pre-training stage: the 5B en–ar tokens in the CPT2 mix are generic Arabic, predominantly Modern Standard, and serve as the base on which the Egyptian variety is acquired at the SFT stage. Ligurian, Ladin and Northern Sámi could not be meaningfully represented: after cleaning, only 1.7M, 9K and 118K tokens respectively remained for en–lij, en–lld and en–se. These were left out of CPT2 and first appear in the SFT mixture.

### 2.3 Supervised fine-tuning

The SFT mixture contains 111,106 examples across eight translation-related tasks: sentence-, paragraph- and document-level MT, HTML tag transfer, terminology-constrained MT, formality-conditioned translation, multi-reference MT, and formality register transfer. Source datasets and language coverage are given in Table 9, and the task distribution in Figure 3. All instructions use the `ChatML` template (OpenAI, 2023).

The composition is motivated on two fronts. First, we previously found that instruction tuning on MT-related tasks either improves translation quality or leaves it unchanged, whereas unrelated chat and code instructions consistently hurt it (Garcia Gilabert et al., 2025); we therefore restrict the mixture to translation-centric tasks. Second, the auxiliary tasks target the instruction-following phenomena introduced this year: formality control, glossary adherence and structured translation. Small datasets were used in full, and larger ones uniformly subsampled to 250–2,000 examples per language pair with a fixed seed. For the lowest-resource pairs we upsampled existing data (en–arz) or reused parallel sentences from the CPT stage (en–be, en–lld, en–lij, en–se). Egyptian Arabic is introduced for the first time at this stage, the continued pre-training data having been generic (mostly Modern Standard) Arabic. The Egyptian variant was used for most tasks in the mixture, with one exception: HTML tag transfer, for which no Egyptian Arabic data was available, so generic Arabic was used instead.

### 2.4 Preference optimisation

We built preference pairs from a subset of the sentence-level SFT data for the six directions with the weakest post-SFT output: English into Egyptian Arabic, Thai, Belarusian, Northern Sámi, Ladin and Ligurian. For five of these we used the SFT reference as the chosen example and the post-SFT model output as the rejected one. For Ligurian we instead used Diverse Beam Search (Vijayakumar et al., 2018) to generate 32 candidates (32 beams, 8 groups) per source, re-ranked by MBR with ChrF++ (Popović, 2017) as utility, and formed two pairs per source with the best candidate as chosen and the 16th and 32nd as rejected, following the BMW strategy (Yang et al., 2024). MBR was limited to Ligurian because MBR-derived pairs are drawn from the model's own output, and applying this to lower-quality directions risks amplifying existing errors. The set totals 20,090 sentences; the breakdown is in Table 11.

## 3 Model and Training

### 3.1 Tokeniser adaptation

The SALAMANDRA models have a 256K-token vocabulary. Rather than appending new tokens for the WMT26 languages, we retrain the tokeniser on a corpus spanning both the original languages and the newly added ones, allowing the merge budget to reallocate jointly across all of them. This changes a substantial fraction of the vocabulary, making the new tokeniser incompatible with released SALAMANDRA**TA** checkpoints; subsequent training therefore resumes from the original SALAMANDRA-7B base model.

We trained two candidate tokenisers, each on a corpus covering both the original SALAMANDRA languages and the new ones, using the SentencePiece (Kudo and Richardson, 2018) implementation of BPE (Sennrich et al., 2016). They differ only in language distribution: one uniform, one down-weighting Traditional Chinese to mitigate Chinese script bias. Fertility across all measurable FLORES+ languages showed no significant bias under the uniform distribution, so we adopted it. Figure 4 compares fertility against multilingual baselines; both candidates achieve consistently lower tokens-per-word and tokens-per-byte. Tokens shared with the original vocabulary retained their embeddings; the remainder were initialised

from a Gaussian derived from the mean of existing embeddings. Replacing the vocabulary at constant size leaves the embedding and unembedding matrices unchanged in shape, so no architectural modification was required.

### 3.2 Continued pre-training

We continually pre-trained the vocabulary-adapted 7B model with NVIDIA NeMo and Megatron-Core, retaining the original decoder architecture: 32 layers, hidden size 4096, SwiGLU intermediate size 11008, 32 attention heads with eight query groups, RMSNorm, rotary position embeddings, an 8192-token context window, and untied input and output embeddings. All parameters were updated in both CPT stages; no layers were frozen.

CPT1 ran for 10,708 updates on 44.91B tokens of multilingual monolingual text. CPT2 combines fresh monolingual data with sentence-aligned parallel data over 21 directions, rendered as translation instructions in both directions, split into two shards of 42.54B tokens each. We trained 10,143 updates, one full pass over the first shard. The second shard was configured for a further 10,145 updates but our compute allocation was exhausted before it began, so the checkpoint carried into SFT has seen half of the planned CPT2 data.

All stages use 8192-token sequences, a micro-batch of one and a global batch of 512 sequences (4,194,304 tokens per update). We optimise the causal LM objective in bfloat16 with distributed fused Adam ($\beta_1$=0.9, $\beta_2$=0.95), weight decay 0.1 and gradient clipping 1.0. CPT1 uses 1,024 warm-up updates and a cosine schedule from $3 \times 10^{-4}$ to $3 \times 10^{-5}$. CPT2 resets the optimiser at $3 \times 10^{-5}$, with 200 warm-up updates. Training uses tensor parallelism of four, sequence parallelism, selective activation recomputation and bfloat16 Transformer Engine kernels without FP8.

CPT1 trained on 32 GPUs to a late validation loss of 2.24; the CPT2 shard trained on 128 GPUs to a final validation loss of 1.64. In total CPT comprised 20,851 updates over approximately 87.46B tokens. Robustness to queue limits and pre-emption came from periodic distributed checkpointing and resumption across Slurm jobs.

### 3.3 Instruction tuning and preference optimisation

The final CPT checkpoint was fully fine-tuned with `FastChat` (Zheng et al., 2023) and DeepSpeed ZeRO-3 on MareNostrum 5, for one epoch over the full mixture with a cosine schedule decaying over the corresponding number of steps; the final checkpoint was carried forward. Preference optimisation used TRL (von Werra et al., 2020) with a combination of CPO (Xu et al., 2024) and SimPO (Meng et al., 2024), which adds length normalisation and a target reward margin, applied through LoRA (Hu et al., 2021) adapters merged into the final model. Hyperparameters for both stages are in Tables 10 and 12.

## 4 Inference Pipeline

The submission is produced by a single checkpoint wrapped in a deterministic, resumable pipeline that converts each blindset document into translation units, decodes and selects a hypothesis per unit, and rebuilds document-level outputs from a manifest of reconstruction metadata.

**Prompt construction.** Each blindset row carries a domain-specific instruction, which we classify from lexical cues into one of eleven prompt types covering plain translation, legal terminology, inclusive gender, ASR transcripts, social media with and without screenshot context, Korean ellipsis, news and educational HTML, game dialogue, and software-localisation JSON. Documents are segmented by type: plain and transcript inputs on non-empty lines, HTML on top-level <p> paragraphs, JSON on top-level string values. Structured genres receive a template instructing the model to preserve markup, structural tokens and placeholders verbatim while translating only readable text; the legal template injects the required-terminology list, and the game-dialogue template supplies the speaker's in-game role for register control. For multi-unit documents the preceding source segment is prepended as context. Templates are given in Appendix E.

**Decoding.** We use Minimum Bayes Risk decoding (Eikema and Aziz, 2020), drawing $N$=8 candidates per unit by nucleus sampling (temperature 0.6, top-$p$ 0.95, top-$k$ 50, up to 2048 tokens). Before scoring, candidates pass an ordered eligibility filter that removes, whenever a compliant alternative exists, candidates that reached the generation cap, are degenerate (repeated 4-gram fraction $\geq 0.35$), or are incompatible with the target script; it then retains those with the fewest structural violations against the required HTML tags, JSON placeholders and ellipses. MBR runs over

the surviving pool with a COMET utility metric (Rei et al., 2022a) (`wmt22-comet-da`). The filter targets the two dominant selection failures we observed: preferring a truncated candidate over a complete one, and preferring an off-target-language candidate when an on-target one was available.

**Reconstruction and validation.** Hypotheses are cleaned of code fences and boilerplate labels, then reassembled using stored prefixes and separators so that whitespace-sensitive structure is reproduced verbatim, with a small set of deterministic content-preserving repairs. Reference-free checks then flag, without altering, the submission: per-segment language identification (Kargaran et al., 2023), numeric-entity preservation, HTML and JSON structural integrity, placeholder and ellipsis retention, inclusive-gender completeness, and the official structural alignment check. Every selected hypothesis is additionally scored with COMET-Kiwi (Rei et al., 2022b) (`wmt22-cometkiwi-da`). Appendix E gives JSON parsing and reconstruction details.

## 5 Results

**Metrics.** We report BLEU and chrF (sacreBLEU 2.4.0 (Post, 2018)), and additionally the neural metric COMET-22 (`Unbabel/wmt22-comet-da`) (Rei et al., 2022a).[2] §5.1 compares training checkpoints using BLEU/chrF/COMET, while §5.2 evaluates the submitted system against the released human references using BLEU and chrF.

### 5.1 Effect of the training stages

**Setup.** We evaluate the post-CPT2, post-SFT and post-PO (Final) checkpoints with MT-Lens (García Gilabert et al., 2025). Decoding is identical across checkpoints (beam search, five beams, batch size five), so differences are attributable to the intervening training stage and not to generation settings. We report BLEU, chrF and COMET on FLORES+ `devtest` (22 directions) and WMT24++ (16).

This configuration is deliberately simpler than the submission-time pipeline of §4: it measures the checkpoints under fixed decoding, with no contribution from MBR or eligibility filtering. Since no degeneracy filtering is applied, repetition loops and prompt echoing are visible in these scores where they occur. The numbers in this subsection therefore characterise the training recipe, not the submitted system.

[2]The BLEU signature is `nrefs:1|case:mixed|eff:no|tok:13a|smooth:exp|version:2.4.0`, except that the tokeniser is selected by target language (`tok:zh` for Chinese, `ja-mecab` and `ko-mecab` for Japanese and Korean), so BLEU for those targets is not comparable with the rest of any table. The chrF signature is `nrefs:1|case:mixed|eff:yes|nc:6|nw:0|space:no|version:2.4.0`.

| | BLEU | chrF | COMET |
|---|---|---|---|

| Final | 23.80 | 58.75 | 0.898 |

Table 2: Pipeline-stage results. Panel (a) gives means over all directions per stage and evaluation set; panel (b) gives the six directions WMT24++ does not cover, so every claim about them rests on FLORES+ alone. Ligurian and Ladin had no parallel data in CPT2, and Egyptian Arabic none of its own variety. Best stage per metric in bold. Full per-direction tables: Appendix D. English–Northern Sámi is excluded throughout.

**Findings.** Mean BLEU rises from 26.40 to 28.79 across the SFT stage on FLORES+ and from 22.98 to 33.65 on WMT24++. The PO stage changes mean BLEU by $+0.04$ on FLORES+ and $-0.01$ on WMT24++. Ligurian is the largest single movement, rising from 4.42 to 27.53 BLEU at SFT;

| System | BLEU | chrF |
|---|---|---|
| Lumen | **41.94** | **60.38** |
| Qingqiu-MT-9B | 39.27 | 56.94 |
| **SalamandraTA (ours)** | 33.01 | 52.00 |
| Gemma 4-4B | 29.73 | 48.33 |
| GPT-OSS-20B | 25.01 | 44.54 |
| Qwen 3.5-9B | 24.32 | 44.82 |
| Tower 9B | 23.46 | 44.64 |
| GLM 4-9B | 23.15 | 42.75 |
| Ministral 3-14B | 18.15 | 42.82 |

Table 3: Constrained-track systems covering all reference directions, ranked by BLEU. Scores are averaged over the 12 WMT26 directions with human references (cs–de, cs–vi, en–cs, en–de, en–et, en–is, en–arz, en–ja, zh–ja, en–lij, en–lld, en–se).

Ladin is the only English-source direction that declines at every stage.

### 5.2 Released test set and human references

We report automatic scores on the WMT26 General Translation Shared Task test set against the organisers' human references,[3] which cover 12 of the 23 directions. We use the post-edited reference (`refPE`) where available and the from-scratch human reference (`refA`) otherwise. We report only surface metrics: many test documents exceed the input length of the neural metrics, which would require re-segmenting to score reliably. For Czech–German and Czech–Vietnamese, which provide both, we also report scores against `refA` in Appendix G. These are our own automatic-metric scores against references released after the evaluation period; official human evaluation and system rankings were not available at the time of writing, and will be reported in the findings paper (Kocmi et al., 2026).

We compare against the nine constrained-track systems that cover all 12 reference directions, out of 19 constrained submissions, using the system outputs published in the task repository.[4] The comparison uses BLEU and chrF, averaged over the 12 directions; per-direction scores are in Appendix G.

Our 7B submission ranks third of the nine on both chrF (52.0) and BLEU (33.0), behind only the larger Qwen-based Lumen (a 14B model with a 4B post-editor) and Qingqiu-MT-9B, making it the smallest of the top three. As `refPE` references are post-edits of machine output, surface metrics may favour systems closer to that output; the ranking should be read with this in mind and is superseded by the official human evaluation.

[3] https://github.com/wmt-conference/wmt26-general-mt

[4] The constrained track admits open-weight models of at most 20B parameters; unconstrained systems, such as proprietary API models, are omitted as not directly comparable. The remaining ten constrained systems are language-specific, covering one to four directions each.

## 6 Analysis

**The evaluation set determines the size of the instruction-tuning effect.** Averaged over directions, SFT gains 2.39 BLEU on FLORES+ against 10.66 on WMT24++, and 0.018 against 0.076 COMET. This is not driven by a few directions: of the sixteen both sets cover, every one shows a larger gain on WMT24++, and four (cs–de, cs–uk, cs–vi, zh–ja) move from flat or slightly negative on FLORES+ to gains of 0.4–6.3 BLEU. On FLORES+ alone these four would suggest that non-English-source directions regress under instruction tuning; the second set does not support that reading. Nor does the gain track CPT2 data volume: Spearman $\rho$ between the FLORES+ SFT gain and per-direction token counts is $-0.08$, and en–zh_TW, with the smallest allocation at 0.23B, gains 5.1 BLEU while the capped directions gain 1.0–2.2. We suggest, as a hypothesis rather than a result, that the sets place different demands on the model: FLORES+ is uniform and sentence-level, and a continued-pre-trained checkpoint prompted with a translation instruction already handles it, whereas WMT24++ is naturalistic post-edited text where instruction compliance, avoiding over-generation and staying on-target matter more. The practical observation does not depend on the explanation: FLORES+ alone would have valued the SFT stage at roughly a fifth of what the second set reports.

**Preference optimisation did not change automatic metrics.** The five treated directions with evaluation data move between $-0.21$ and $+0.98$ BLEU on FLORES+, against $-0.49$ to $+0.31$ among the seventeen untreated directions; on WMT24++ every direction moves by less than 0.75 BLEU. In Tables 7 and 8 the final checkpoint holds the best score in roughly half of all cells, the distribution expected from an intervention with no systematic effect. Preference-set size does not predict the outcome either: Ligurian received the largest set at 7,252 pairs and moved $+0.61$ BLEU, en–th received 4,000 and moved $+0.98$, and en–arz received 5,000 and moved $+0.21$. Only Ladin, at 93 pairs, is small enough that no effect would be expected. Two readings remain open and our

evidence does not separate them: the stage may have had little effect, or reference-based metrics may be insensitive to the failures it was built to remove, namely repetition loops and prompt echoing. These failures would be present in the outputs being scored if they remained, since no degeneracy filtering is applied during evaluation; the question is whether the metrics register them. A repetition-rate measure or targeted human evaluation would distinguish the two. We ran neither, nor the matched-cost uniform-application ablation that would establish whether concentrating a small preference set on six directions was preferable to distributing it.

**Low-resource outcomes track data volume.** Ligurian and Ladin passed through the same stages: no data in either CPT round, Italian as a high-resource relative, first representation at SFT, and preference optimisation on top. Their outcomes diverge. Ligurian rises from 4.42 to 27.53 BLEU at SFT and ends at 28.14, within range of our mid-resource directions. Ladin declines at every stage, 2.90 to 2.79 to 2.58, with chrF falling from 29.93 to 27.52; it is the only English-source direction that ends below its starting score. The difference follows the data: after cleaning, en–lij retained 1.7M parallel tokens against 9K for en–lld, and the Ladin corpus was additionally judged of poor quality on inspection. The same gap holds at the preference stage (7,252 pairs against 93). The Ligurian result is the more informative: a direction with 1.7M cleaned tokens, none seen during continued pre-training, reached mid-resource quality through SFT alone ($+23.12$ BLEU, against $+0.61$ for PO). A qualitative example in our logs suggested that preference optimisation had resolved Ligurian's repetition problem; the stage-wise results do not support attributing the recovery to that stage. We cannot separate data quantity from the other factors that differ between the two directions, since they also differ in typological distance from Italian and in how their preference sets were built. What the pair suggests is a working threshold on this pipeline: roughly 1.7M cleaned parallel tokens introduced at SFT sufficed for a direction absent from continued pre-training, and 9K did not. Both directions fall outside WMT24++ coverage, so this rests on FLORES+ alone. On the WMT26 test set, however, en–lld reaches 17.03 BLEU (Table 3); the FLORES+ result may therefore reflect the evaluation set as much as the model.

## 7 Conclusion

We submitted a 7B decoder-only model covering 23 directions, adapted from SALAMANDRA-7B through vocabulary replacement, two rounds of continued pre-training, instruction tuning on a translation-only mixture, and preference optimisation on six weak directions, decoded through a structure-aware inference pipeline with candidate filtering ahead of MBR selection.

We draw two conclusions. Stage-wise internal evaluation is inexpensive once the checkpoints exist and locates where the measurable value of a pipeline sits. And a single automatic evaluation set is not sufficient evidence for a claim about a training stage: our two sets differed by an order of magnitude on the largest effect we measured, agreed on the null result, and one covers none of our six lowest-resource directions. For directions at the low end, our two Italian-supported cases suggest the binding constraint is the quantity and quality of usable parallel text rather than the choice of adaptation strategy, and we would direct future effort at data collection before pipeline design.

## Limitations

We hold no internal evaluation data for English–Northern Sámi, a shared-task direction and one of the six targeted with preference optimisation; its only automatic assessment is the released test-set reference (Table 3). CPT2 stopped at the end of its first shard, half of its planned data, when our compute allocation was exhausted, so the CPT2 column throughout is an under-trained checkpoint and the gains attributed to later stages are measured against it. The negative result for preference optimisation is a null result on automatic metrics rather than on translation quality; we did not run the degeneracy-specific or human evaluation that would test the failure modes the stage was built to remove. Ligurian and Ladin were not treated identically at the preference stage: Ligurian was the one direction for which we used MBR-derived rather than reference-based pairs. The model is released under a Research-Only Licence by the Language Technologies Unit, Barcelona Supercomputing Center, and may not be used commercially.

## A Language coverage

Table 4 lists the languages introduced for WMT 2026 and Table 5 those carried over from SALAMANDRA**TA**. Counts are the CPT1 monolingual totals measured with the extended tokeniser; † marks a language appearing in at least one shared-task direction, and ∗ a transfer anchor included for cross-lingual support rather than because it is a task language. Three of the ten new languages contributed no CPT1 data at all: Thai was not ready when the shard was assembled, and no usable monolingual Ligurian or Ladin could be sourced. All three are addressed at later stages (§2.2, §2.3).

Egyptian Arabic is a shared-task target but has no row of its own: CPT1 applied no variety filtering, so the Arabic data is generic and appears as `ar` (§2.2).

| **Language** | **Code** | **CPT1 tokens** |
|---|---|---|
| Armenian† | hy | 1.00B |
| Belarusian† | be | 1.00B |
| Chinese (Traditional)† | zh_TW | 1.00B |
| Icelandic† | is | 1.00B |
| Indonesian† | id | 1.00B |
| Kazakh† | kk | 1.00B |
| Northern Sámi† | se | 30.0M |
| Thai† | th | — |
| Ligurian† | lij | — |
| Ladin† | lld | — |
| **Total** | | **6.03B** |

Table 4: Languages newly introduced for WMT 2026, none of which were supported by SALAMANDRA**TA**. All ten are shared-task languages. Dashes mark languages that contributed no CPT1 data.

| **Lang.** | **Code** | **Tokens** | **Lang.** | **Code** | **Tokens** |
|---|---|---|---|---|---|
| Arabic† | ar | 1.00B | Italian∗ | it | 1.00B |
| Aragonese | arg | 16.9M | Japanese† | ja | 1.00B |
| Aranese | oc-aranes | 28.0M | Korean† | ko | 1.00B |
| Asturian | ast | 202.7M | Latvian | lv | 1.00B |
| Basque | eu | 1.00B | Lithuanian | lt | 1.00B |
| Bulgarian | bg | 1.00B | Maltese | mt | 425.5M |
| Catalan∗ | ca | 1.00B | Norw. Bokmål | nb | 1.00B |
| Croatian | hr | 1.00B | Norw. Nynorsk | nn | 768.0M |
| Czech† | cs | 1.00B | Occitan | oc | 88.8M |
| Danish | da | 1.00B | Polish | pl | 1.00B |
| Dutch | nl | 1.00B | Portuguese | pt | 1.00B |
| English† | en | 1.00B | Romanian | ro | 1.00B |
| Estonian† | et | 1.00B | Russian† | ru | 1.00B |
| Finnish | fi | 1.00B | Serbian | sr | 1.00B |
| French | fr | 1.00B | Slovak | sk | 1.00B |
| Galician | gl | 1.00B | Slovenian | sl | 1.00B |
| German† | de | 1.00B | Spanish∗ | es | 1.00B |
| Greek | el | 1.00B | Swedish | sv | 1.00B |
| Hindi | hi | 1.00B | Turkish∗ | tr | 1.00B |
| Hungarian | hu | 1.00B | Ukrainian† | uk | 1.00B |
| Irish | ga | 591.1M | Valencian | val | 39.3M |
| Chinese (Simp.)† | zh | 1.00B | Vietnamese† | vi | 1.00B |
| Welsh | cy | 723.9M | | | |
| | | | | **Total** | **38.88B** |

Table 5: Languages carried over from SALAMANDRA**TA**. † appears in a shared-task direction; ∗ included as a transfer anchor (Italian for Ligurian and Ladin, Turkish for Kazakh, Catalan and Spanish as SALAMANDRA anchors). Counts capped at 1B are exact to three significant figures.

## B Instruction templates

Figure 1 gives the pool from which CPT2 training records were built. The pairing of templates with and without a source-language name is systematic except for `{src_lang} -> {tgt_lang} translation request`, which has no source-language-free counterpart. Placeholders are filled with the language names and the cleaned, normalised sentence pair, the target text following the rendered prompt.

```
Direct
  Translate the following {src_lang} text to {tgt_lang}. Source text: {src_text}
  Translate the following text to {tgt_lang}. Source text: {src_text}
  Please translate this text from {src_lang} into {tgt_lang}: {src_text}
  Please translate this text into {tgt_lang}: {src_text}
  Translate from {src_lang} to {tgt_lang}: {src_text}
  Translate to {tgt_lang}: {src_text}
  Convert this {src_lang} text into {tgt_lang}: {src_text}
  Convert this text into {tgt_lang}: {src_text}
  I need the following {src_lang} text translated into {tgt_lang}: {src_text}
  I need the following  text translated into {tgt_lang}: {src_text}

Role-based
  Provide a high-quality translation from {src_lang} to {tgt_lang} for: {src_text}
  Provide a high-quality translation to {tgt_lang} for: {src_text}
  As a translator, rewrite this {src_lang} passage in {tgt_lang}: {src_text}
  As a translator, rewrite this passage in {tgt_lang}: {src_text}
  Perform a fluent translation of this {src_lang} text into {tgt_lang}: {src_text}
  Perform a fluent translation of this text into {tgt_lang}: {src_text}

Structured
  Task: Translate {src_lang} to {tgt_lang}. \nInput: {src_text}
  Task: Translate to {tgt_lang}. \nInput: {src_text}
  Source Language: {src_lang}\nTarget Language: {tgt_lang}\nText: {src_text}
  Target Language: {tgt_lang}\nText: {src_text}
  {src_lang} -> {tgt_lang} translation request:\n{src_text}
  Input ({src_lang}): {src_text}\nOutput ({tgt_lang}):
  Input {src_text}\nOutput ({tgt_lang}):
  Translate the text below.\nFrom: {src_lang}\nTo: {tgt_lang}\nContent: {src_text}
  Translate the text below.\nTo: {tgt_lang}\nContent: {src_text}

Action-oriented
  Transform the following sentences from {src_lang} to {tgt_lang}: {src_text}
  Transform the following sentences to {tgt_lang}: {src_text}
  Express the meaning of this {src_lang} text in {tgt_lang}: {src_text}
  Express the meaning of this text in {tgt_lang}: {src_text}
  Generate a {tgt_lang} version of this {src_lang} text: {src_text}
  Generate a {tgt_lang} version of this text: {src_text}
  Rewrite the following {src_lang} text using {tgt_lang}: {src_text}
  Rewrite the following text using {tgt_lang}: {src_text}
  Give me the {tgt_lang} translation for the following {src_lang} string: {src_text}
  Give me the {tgt_lang} translation for the following string: {src_text}
```

Figure 1: The CPT2 instruction-template pool, reordered so that each template sits next to its source-language-free counterpart.

## C Data volume by direction

Table 6 collects the parallel data available to each shared-task direction in CPT2 together with the size of its preference set. The instruction mixture (Table 9) is organised by task and source rather than by direction, and several sources cover many directions without a per-direction breakdown, so SFT volume cannot be decomposed per direction and is not given here.

Three directions entered SFT with no parallel data from either CPT round; a fourth, en–arz, entered with generic rather than Egyptian Arabic. For Ligurian, Ladin and Northern Sámi this was a coverage decision: after cleaning, 1.7M, 9K and 118K tokens respectively remained, below the threshold at which inclusion in the CPT2 mix would have contributed usefully. Ladin's figures are the smallest in the table at

| | CPT2 parallel | | PO |
|---|---|---|---|
| **Direction** | **Pairs** | **Tokens** | **Pairs** |
| en–cs | 104.1M | 5.00B† | |
| en–de | 85.3M | 5.00B† | |
| en–id | 88.6M | 5.00B† | |
| en–ru | 73.0M | 5.00B† | |
| en–zh | 85.6M | 4.34B | |
| cs–de | 62.9M | 3.08B | |
| en–uk | 28.3M | 2.76B | |
| en–ja | 53.4M | 2.59B | |
| en–ko | 43.3M | 2.12B | |
| en–et | 30.2M | 1.70B | |
| en–th | 25.4M | 1.28B | 4,000 |
| zh–ja | 15.5M | 0.79B | |
| en–is | 15.7M | 0.77B | |
| cs–uk | 14.7M | 0.70B | |
| en–be | 16.4M | 0.67B | 2,997 |
| cs–vi | 15.0M | 0.52B | |
| en–kk | 11.9M | 0.50B | |
| en–hy | 5.6M | 0.31B | |
| en–zh_TW | 9.4M | 0.23B | |
| *Unfiltered for variety; base for en–arz* | | | |
| en–ar | 73.7M | 5.00B† | 5,000‡ |
| *Transfer support, not a shared-task direction* | | | |
| en–it | 79.5M | 5.00B† | |
| *Excluded from CPT2: insufficient data after cleaning* | | | |
| en–lij | | 1.7M | 7,252 |
| en–se | | 118K | 748 |
| en–lld | | 9K | 93 |

Table 6: Parallel data by direction. CPT2 token counts are source-plus-target, excluding instruction-template overhead; † marks directions truncated at the 5B cap. The three excluded directions were reserved for SFT. ‡ The shared-task direction is en–arz. No variety filtering was applied in either CPT round, so the 5.00B en–ar tokens are generic Arabic; the Egyptian variety is introduced only at SFT, and the 5,000 preference pairs are en–arz. Preference pairs are final counts from Table 11; blank entries received no preference optimisation.

every stage, and it also received the smallest realistic share of the 2,841 resampled examples distributed across four directions in the instruction mixture.

## D Full per-direction results

Tables 7 and 8 give per-direction scores for all three checkpoints. English–Northern Sámi is absent from both: no internal evaluation exists for that direction. English–Arabic and English–Polish were evaluated in error and are not shared-task directions; they are excluded throughout. Note that en–ar here is the generic-Arabic evaluation run in place of en–arz, distinct from the en–ar training data discussed in §2.2.

## E Inference pipeline details

**Prompt templates.** The eleven prompt types of §4 are realised by four template families, listed in Figure 2. Four of the types (plain translation, inclusive gender, ASR transcripts and Korean ellipsis) share the generic template, differing only in the segmentation applied upstream; the five structured genres (news HTML, educational HTML, social media with and without screenshot context, and software-localisation JSON) share the markup-preserving template; legal terminology and game dialogue have one each. Each of the generic and structured families has a context-carrying variant, applied to every unit after the first when a document splits into more than one unit, giving six concrete strings. Line breaks marked `\n` are literal; wrapping in the figure is ours.

**JSON parsing.** Software-localisation inputs are parsed tolerantly. After stripping Markdown code fences we fall back to a string-aware scanner that removes trailing commas before `]` and `}`, leaving

Table 8: Pipeline-stage results on WMT24++, for the 16 directions it covers. Best stage per direction and metric in bold. Instruction-tuning gains are an order of magnitude larger here than on FLORES+ for the same checkpoints and directions; see §6.

commas inside quoted strings untouched, so that these documents split into short value-level units rather than being translated as a single oversized block. Only string values are extracted; keys, non-string values and placeholders are preserved as reconstruction metadata.

**Reconstruction.** JSON documents are rebuilt by substituting only the translated string values and re-emitted as valid JSON with the original code fence restored. HTML paragraphs are normalised to exactly one <p> wrapper per unit, preserving inner markup, which keeps document-level paragraph structure aligned with the source. The content-preserving repairs applied are inclusive masculine and feminine slash forms for Czech, Croatian and Russian, and removal of copied legal candidate labels.

```
(1) Generic
  Translate from {src_lang} to {tgt_lang}: {source}

(2) Generic, with context
  Context: {previous_context}\n
  Translate only this current {src_lang} text to {tgt_lang}; use the context
  only for disambiguation: {source}

(3) Structured (news/educational HTML, social media, software-localisation JSON)
  Source Language: {src_lang}\n
  Target Language: {tgt_lang}\n
  Instructions: Keep all markup, structural tokens, and formatting verbatim
  and in place. Translate only the readable text, leaving the layout
  identical.\n
  Text: {source}

(4) Structured, with context
  Context: {previous_context}\n
  Translate only the current text below. Use the context only for
  disambiguation.\n
  Source Language: {src_lang}\n
  Target Language: {tgt_lang}\n
  Instructions: Keep all markup, structural tokens, and formatting verbatim
  and in place. Translate only the readable text, leaving the layout
  identical.\n
  Text: {source}

(5) Legal terminology
  Translate from Italian to {tgt_lang}. Pay close attention to the required
  terms.\n\n
  Legal context: standard German for {jurisdiction}.\n\n
  Required Terminology:\n\n
  - {source_term} -> choose exactly one listed candidate\n\n
  Candidates:\n\n
  - {candidate_1}
  - {candidate_2}
  ...\n\n
  Source Text:\n\n{source}

(6) Game dialogue
  Context: {speaker_role}\n
  Translate this {src_lang} sentence to {tgt_lang}: {source}
```

Figure 2: Inference prompt templates. The jurisdiction field defaults to "the target legal system" when absent from the instruction. When no source term is extracted, the bullet under `Required Terminology` is empty but the heading is still emitted. The speaker role in template (6) is the speaker's in-game role, parsed from the blindset instruction.

## F Instruction mixture and hyperparameters

This appendix reports the full training configuration for the checkpoints in §5.1. Table 9 and Figure 3 give the SFT instruction mixture and its task distribution; Figure 4 compares the adapted tokeniser's fertility against open baselines; Table 10 lists the SFT hyperparameters; and Tables 11 and 12 give the preference-optimisation data and hyperparameters.

## G Full test-set results

This appendix expands Table 3: per-direction chrF for all nine full-coverage constrained systems (Table 13), and the `refA` comparison for the two directions with two references (Table 14).

| Task | Source | Languages | Count |

## Abstract

We participated in the constrained (open-weight) track of the WMT 2026 General MT Task for the English-to-Japanese and Simplified Chinese-to-Japanese directions. Our system builds on Marco-MT-Algharb, a strong open-weight translation model from the previous WMT General MT task. We further fine-tuned this model to generate more natural Japanese translations. To this end, we constructed a **C**ontext-**A**ware **JA**panese **L**inguistic **A**cceptability dataset (CAJALA). During annotation, human annotators were shown multiple paraphrased variants of a segment within its document-level context and asked to select the most natural one. We then back-translated the CAJALA dataset to create parallel data for Direct Preference Optimization (DPO). We also trained the model to perform fill-in-the-middle (FIM) translation, in which the model reconstructs target-side segments from their surrounding document. At inference, we use Minimum Bayes Risk (MBR) decoding, followed by selective FIM post-editing of low-quality segments.

## 1 Introduction

This paper describes RFMT's submission to the WMT 2026 General MT Shared Task (Kocmi et al., 2026). We participated in the constrained (open-weight) track for the En→Ja and Zh→Ja directions. Our system features two key components: (1) we constructed CAJALA, a dataset that provides context-aware human preferences for specific segments within Japanese documents, and further trained our model on it; and (2) we explored fill-in-the-middle (FIM) translation for post-editing.

In document-level translation, a translation that appears natural at the single-segment level may still fail to maintain the document's anaphora, style, terminology, or discourse flow (Maruf et al., 2021; Lyu et al., 2021). Colloquial and non-standard expressions also affect naturalness, especially in domains such as news, social media, and literature (Michel and Neubig, 2018; Fujii et al., 2020; Le et al., 2021; Karpinska and Iyyer, 2023). Furthermore, translating technical terms and proper nouns requires not only contextual naturalness but also consistency (Hasler et al., 2018; Dinu et al., 2019).

To improve the naturalness of Japanese translations, we collected human preferences for Japanese expressions within their document-level context and used them to train the model. Furthermore, we investigated the effectiveness of FIM translation for correcting local errors generated during standard left-to-right decoding.[1]

## 2 System Overview

Figure 1 provides an overview of our system. Our system builds on Marco-MT-Algharb (Wang et al., 2025b,a). We fine-tuned this base model to specialize in Japanese translation and to support FIM translation. Furthermore, we trained it to accept auxiliary information via prompting, such as the source domain, target styles (e.g., polite or plain forms), and glossary entries.

Our inference pipeline consists of four stages:

**Stage 1: Preprocessing.** We identify the domain, segment the text, and parse inputs in JSON or HTML formats.

**Stage 2: Translation.** We translate the document segment by segment using MBR decoding.

**Stage 3: FIM Post-editing.** We detect and re-translate low-quality segments using FIM.

**Stage 4: Post-processing.** We reconstruct the document and restore its original format.

## 3 CAJALA Dataset

CAJALA is a dataset that annotates the acceptability of segments within Japanese documents.

[1]Our model is publicly available at https://huggingface.co/tohoku-nlp/RFMT.

*Proceedings of the Eleventh Conference on Machine Translation*, pages 1344–1371
October 28-29, 2026 ©2026 Association for Computational Linguistics

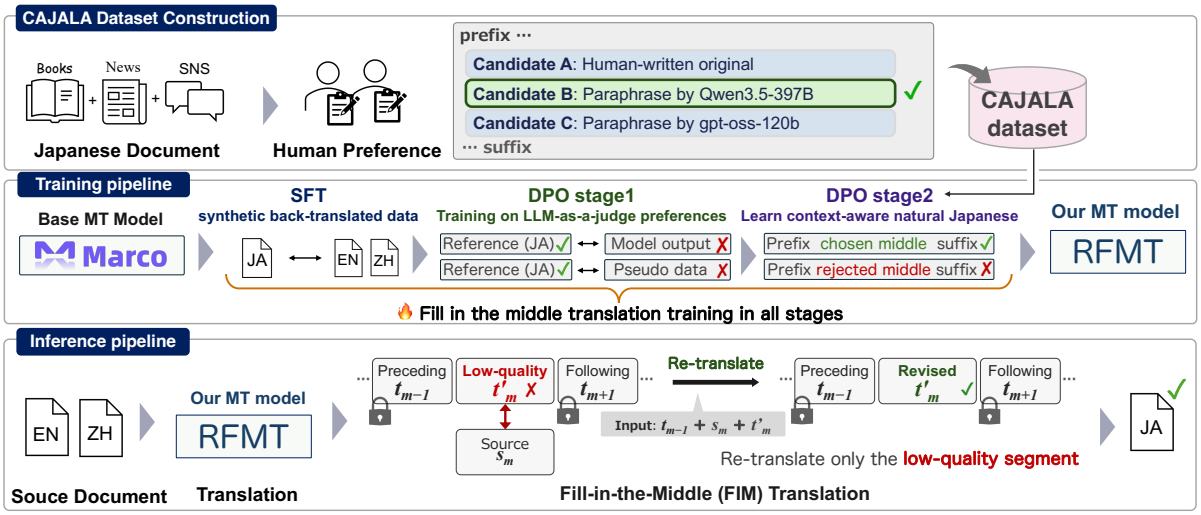

Figure 1: Overview of CAJALA dataset construction, RFMT training with SFT and DPO, and inference with FIM post-editing of low-quality segments.

Specifically, we collect human preferences based on the naturalness and consistency of Japanese expressions within document-level contexts. Each sample consists of a Japanese document and three variants of one segment: the original segment from an existing corpus and two paraphrases generated by LLMs. To construct the dataset, we used crowdsourcing. We showed human annotators three segment variations (the two paraphrases and the original text) alongside their surrounding context. We then asked the annotators to select the variation that best fits the overall flow of the document.

We obtained the original Japanese documents from a subset of the ja_fineweb-2 split in the llm-jp-corpus-v4 (LLM-jp, 2025). We used an LLM to classify these documents by domain and retained samples identified as News, SNS, or Literature, as described in Appendix B.1. We used an LLM-as-a-judge to identify segments that allowed meaningful alternative expressions and retained them for crowdsourcing, as described in Appendix A.3.

### 3.1 Paraphrase Generation and Human Annotation

We generated candidate segments by instructing LLMs to paraphrase the original Japanese expressions into more natural alternatives. We used `Qwen3.5-397B-A17B-FP8` (Qwen Team, 2026) and `gpt-oss-120b` (OpenAI, 2025) for this task. These two generated paraphrases and the original segment formed the three candidates. See Appendix A.2 for more details.

During human annotation, we presented these three segment variations with the same surrounding context and asked annotators to select the most acceptable segment. We instructed them to consider the acceptability of each candidate and its consistency in style and terminology with the surrounding context. Appendix A.4 outlines our quality control measures for the annotation process.

| Number of Valid Annotators per Sample | | |
|---|---|---|
| Item | Count | Proportion |
| 1 annotator | 125 | 1.70% |
| 2 annotators | 1,537 | 20.93% |
| 3 annotators | 5,683 | 77.37% |
| **Candidate Selections** | | |
| Candidate | Selection Count | Selection Rate |
| `human` | 6,741 | 33.29% |
| `Qwen` | 7,111 | 35.12% |
| `gpt-oss` | 6,396 | 31.59% |

Table 1: CAJALA dataset statistics on the number of samples by valid annotator count and the selection counts and rates for each candidate.

### 3.2 Dataset Statistics

We collected 7,345 unique samples, each evaluated by up to three annotators. Table 1 shows the statistics of the selected candidates and the number of annotators. We calculated these selection rates based on a total of 20,248 valid responses in the public release. Appendix A.5 details the sample counts per domain.

## 4 Synthetic Dataset

We constructed synthetic parallel data to adapt the model for translation into Japanese.

### 4.1 Back-Translation Dataset

Except for the WMT 2025 test set (Kocmi et al., 2025), we constructed all parallel training data by back-translating (Sennrich et al., 2016) Japanese monolingual corpora. For these monolingual corpora, we used the llm-jp-corpus-v4 (LLM-jp, 2025), alongside transcriptions from the Japanese subsets of CC Audio (Asai et al., 2025) and YODAS2 (Li et al., 2023). Specifically, we constructed the parallel dataset as follows:

**Domain Identification.** An LLM predicted the domain of each document in the llm-jp-corpus-v4. We retained samples classified as News, Literature, or SNS, following the domains focused on in the previous year's General MT Track.

**Noise Removal.** An LLM identified and corrected speech recognition errors in the video transcriptions (CC Audio, YODAS2).

**Back-translation.** An LLM back-translated these preprocessed corpora into English or Chinese.

**Cleaning.** We applied rule-based filtering using source-target n-gram overlap, language identification, and document length. We evaluated translation quality and validity using an LLM-as-a-judge.

**Terminology Extraction.** We extracted bilingual terminology pairs from the translated sentences. We used these pairs later for glossary prompting and dictionary creation.

**Style Identification.** We classified the target Japanese text into the polite style (*desu/masu*) or the plain style (*da/dearu*). We used this classification later to train the model for style prompting.

For the FIM training samples, we performed two additional processing steps:

**Target-side Segmentation.** We conservatively divided the target documents into roughly sentence-level segments, merging overly short segments with adjacent ones to prevent unnatural splits.

**Source-side Segment Alignment.** An LLM identified the source-side segment that corresponded to the randomly selected target-side segment.

See Appendix B for details on the specific prompts and LLMs we used, along with the token counts of the final dataset.

### 4.2 Glossary Construction

We constructed a dictionary of terms specifically for glossary prompting. It consists of a large number of word-level parallel pairs, primarily targeting low-frequency and domain-specific terms. To build this glossary, we applied multi-stage rule-based and LLM-based filtering to the parallel pairs extracted during the dataset construction process. See appendix E for more details.

## 5 Model Adaptation

As our base model, we used Marco-MT-Algharb (Wang et al., 2025a,b), which ranked first in the En→Ja constrained track of the WMT 2025 General MT Task (Kocmi et al., 2025). Starting from this model, we first conducted supervised fine-tuning (SFT) on synthetic translation data to specialize it for Japanese translation and train it to follow prompting strategies. We then performed direct preference optimization (DPO) (Rafailov et al., 2023) using additional synthetic preference data and CAJALA to improve translation quality. In parallel, we included FIM training, in which the model reconstructs a missing target-side segment from its surrounding context.

### 5.1 Supervised Fine-tuning

Starting from Marco-MT-Algharb, we performed additional training using the back-translation dataset constructed in § 4.1. Appendix D provides the SFT training configuration.

### 5.2 Preference Learning

We applied DPO in two stages.

**Stage 1.** We trained the model on a mixture of three types of preference data. For **LLM-as-a-judge preferences**, we used `gemma-4-31B-it` (GemmaTeam, 2026) to compare the output of a model under development with the reference provided in the dataset. We defined the translation judged as higher quality by the LLM as the chosen response, and the other as the rejected response. For **synthetic repetition**, we artificially added repetition to the reference and used the modified version as the rejected response and the original reference as the chosen response. This data was intended to reduce repetitive outputs. For **synthetic untranslated content**, we replaced part of the reference suffix with the corresponding suffix from the source text. The modified version was used as the rejected response, and the original reference

was used as the chosen response. This data was intended to reduce untranslated source content in the model output. See Appendix D for more details.

**Stage 2.** We trained the model on the back-translated CAJALA dataset. We constructed preference pairs from samples with a majority candidate and excluded samples without a majority. To construct the training pairs, we back-translated the chosen responses into English and Chinese as the source sentences. See Appendix D.1 for details.

### 5.3 FIM Translation Training

Inspired by FIM training (Bavarian et al., 2022), we use FIM to enable localized post-editing while preserving document context. During training, we omit a target-side segment and train the model to reconstruct it from the corresponding source-side segment and both preceding and following target-side context. Unlike standard left-to-right decoding, which only conditions on preceding target context (Ding et al., 2021), FIM translation allows the model to revise a specific segment using context on both sides without regenerating the surrounding translation. Figure 2 shows the input-output format used for FIM translation training. For each training sample, we randomly selected one segment from the source document and enclosed it with the special tokens `<|fim_start|>` and `<|fim_end|>`. We then provided the target document in which the target-side segment corresponding to the selected source-side segment was replaced with `<|fim_skip|>` as the first **Assistant:** response. The omitted target-side segment was provided as the second **Assistant:** response. At inference time, we replace the target-side segment to be retranslated with `<|fim_skip|>` and provide the resulting incomplete target document together with the source document. We then prompt the model to generate the missing target-side segment. This format trains the model to reconstruct a missing target-side segment from its surrounding target-side context.

## 6 Inference

### 6.1 Preprocessing

For each source document, we perform three preprocessing steps: segment splitting (parsing structured input), domain identification, and style identification. These steps enable segment-level translation and allow us to incorporate auxiliary information into prompts. See Appendix C for details.

**Input-Output format example**

```
Human: Please translate the following text into
japanese.If a domain, glossary or style is
specified, please take it into account when
translating.Also, please skip translating the parts
enclosed by <|fim_start|> and <|fim_end|>.

<|im_end|>
Human: Please translate the skipped parts.
Assistant:
<|fim_bos|>この制度は建設費の半額を補助する。<|im_end|>
```

Figure 2: Input-output format for the trained model.

### 6.2 Translation

We translate each source document at the segment level. During translation, we use the following prompting and decoding strategies.

**Context-Aware Incremental Translation.** To maintain consistency within each document, we use context-aware incremental translation (Kudo et al., 2024). We translate the document segment by segment, starting from the first segment. When translating the second and subsequent segments, we provide the preceding source-side segments together with the current source-side segment as input. On the target side, we forcefully decode the hypothesis segments generated up to that point and ask the model to generate the continuation. We repeat this process until all segments have been translated. When the input exceeds the model's context length, we remove the oldest context first.

**Prompting with Auxiliary Information.** We provide three types of auxiliary information in the prompt. **Domain prompting:** We provide the domain information assigned during preprocessing in the prompt. **Style prompting:** We provide the style information assigned during preprocessing in the prompt. **Glossary prompting:** If the source document contains a term included in the glossary, we add the corresponding translation pair to the prompt. To match source-side glossary terms against the source document, we use longest non-overlapping substring matching.

| | Model Adaptation | | Inference | | Score ↑ | | | | |
|---|---|---|---|---|---|---|---|---|---|
| | SFT | DPO | MBR | FIM | JSON | News | Social | Speech | Overall |

Table 2: Translation llm-as-a-judge scores for each system configuration by domain. The upper and lower panels show results for En→Ja and Zh→Ja, respectively. Values are reported as the mean ± 95% CI.

**MBR Decoding.** We generated 32 candidates with a temperature of 0.8 and applied MBR decoding (Kumar and Byrne, 2004; Freitag et al., 2022). We used xCOMET-Lite (Larionov et al., 2024) as the utility function for MBR.

### 6.3 FIM Post-editing

After completing the main translation process, we detect clearly low-quality segments (e.g., untranslated). We then post-edit the detected segments using FIM translation. The post-editing procedure consists of the following steps.

**Error Detection.** We use rule-based criteria to detect clearly low-quality segments. Specifically, we calculate the $n$-gram overlap between each hypothesis and its source-side segment to detect untranslated content, and check whether the hypothesis contains excessive repetition. Segments that meet either criterion are selected for post-editing. Preliminary experiments motivated this conservative selection strategy, as detailed in Appendix G.

**FIM Translation.** We retranslated the detected segments using the FIM format. We used MBR decoding as the decoding algorithm. We generated 32 candidates with a temperature of 1.2, `top_p` of 0.95, and `top_k` of 32, and applied MBR decoding. For the MBR utility function, we used a combined score from xCOMET-Lite (Larionov et al., 2024) and MetricX-24 XL (Juraska et al., 2024).

### 6.4 Post-processing

We reconstructed the translated results into full documents. We performed two steps: (1) we reverted samples parsed from JSON or HTML back to their original input formats, and (2) we concatenated the segments to form the final documents.

## 7 Experiments

### 7.1 Evaluation Metrics

We evaluated the systems on the WMT 2026 blind test set. We evaluated translation quality using an LLM-as-a-judge (Kocmi and Federmann, 2023). Specifically, we employed Gemini 3.1 Pro Preview (DeepMind, 2026), the latest model in the Gemini family. We selected this model because its predecessor, Gemini 2.5 Pro (Comanici et al., 2025), achieved the best performance in the automatic evaluation of the WMT 2025 Metrics Shared Task (Lavie et al., 2025). We provided the source text and the hypothesis as input and asked the model to assign an integer score from 0 to 100. We then averaged the scores over all samples to obtain the mean score for each language pair and system. See Appendix F for more details.

### 7.2 Results and Analysis

Table 2 reports the LLM-as-a-judge evaluation results for `Base`, `SFT`, `DPO-1`, `DPO-2`, `DPO-2+MBR`, and our final `RFMT` system. These configurations are cumulative, with each configuration adding a training or inference component to the preceding one. Specifically, `SFT` adds supervised fine-tuning to `Base`; `DPO-1` and `DPO-2` successively add DPO stages 1 and 2; `DPO-2+MBR` applies MBR decoding to `DPO-2`; and `RFMT` further applies selective FIM post-editing to `DPO-2+MBR`. For `RFMT`, we re-evaluated the four En→Ja outputs changed by FIM post-editing and recomputed the overall

score while retaining the original scores for all other samples. Table 3 provides representative examples for each successive system configuration. Appendix H presents additional examples for the other language direction. In the following, we discuss the impact of each stage.

**SFT.** Compared with `Base`, `SFT` decreased the En→Ja score from 62.9 to 55.2, while increasing the Zh→Ja score from 38.4 to 48.9. We attribute the Zh→Ja improvement to the fact that `Base` had not been trained for Zh→Ja translation, whereas `SFT` introduced training data for this direction. As shown by example (a) 24382-jpn_Jpan in Table 3, `Base` left most of the Chinese source untranslated while `SFT` produced a Japanese translation, increasing the score from 0 to 66.

**DPO Stage 1.** Compared with `SFT`, `DPO-1` increased the scores by 17.0 points for En→Ja and 12.6 points for Zh→Ja. `DPO-1` included preference pairs in which target-language outputs were used as chosen responses and source-language outputs as rejected responses. As shown by the En→Ja example in Table 3, this training reduced untranslated source content in the output.

**DPO Stage 2.** From `DPO-1` to `DPO-2`, the scores changed little for both En→Ja and Zh→Ja. However, the qualitative example in Table 3 shows a substantial improvement in style consistency. In example 24182-jpn_Jpan, a translation containing an informal Kansai dialect and a mixture of plain and polite forms was revised into a consistent polite style, increasing the score from 45 to 85.

**MBR Decoding.** Applying MBR decoding to `DPO-2` resulted in little change in the average scores. However, the qualitative example in Table 3 shows a substantial local improvement. In example 24296-jpn_Jpan, "Need this to work" was revised from "これに期待" (*kore ni kitai*; "counting on this") to "稼働させないと" (*kadō sasenai to*; "need to get this working"), making the intended sense of necessity clearer and increasing the score from 50 to 95.

**FIM Post-editing.** FIM post-editing was eventually applied to only four En→Ja samples; the score increased for three samples and remained unchanged for one. No FIM post-editing was applied to Zh→Ja samples. The qualitative example in Table 3 shows that FIM post-editing made local corrections, including the translation of previously untranslated content.

## 8 Conclusion

We described the RFMT's submission to the WMT 2026 General Machine Translation Task for En→Ja and Zh→Ja translation. We adapted Marco-MT-Algharb through SFT, DPO, and FIM training using the human-annotated CAJALA dataset. Our results show that SFT, DPO, MBR decoding, and selective FIM post-editing somehow improve document-level Japanese translation.

## Acknowledgments

We would like to thank the members of the Tohoku NLP Group for their cooperation and feedback throughout the course of this research. This work was supported by Moonshot R&D Grant Number JPMJMS2011-35 (fundamental research) and by JSPS KAKENHI Grant Number JP25KJ0615 and JP26H02511. A part of the computation was carried out using the computer resource offered under the category of General Projects by Research Institute for Information Technology, Kyushu University

## Contributions

**Ryosuke Matsuda** led the project and conducted crowdsourcing for the construction of the CAJALA dataset, cleaned the synthetic dataset, performed additional training of the language models, and conducted post-evaluation.
**Keito Kudo** constructed the synthetic dataset, performed additional training of the language models, and developed the inference pipeline.
**Ryo Fujii**, **Takumi Ito**, and **Makoto Morishita** provided advice on the crowdsourcing process and guidance on the overall development direction.
**Jun Suzuki** supervised and coordinated the entire project.

# A CAJALA Construction Details

## A.1 Annotation Platform and Crowd Workers

**Platform.** We collected all human annotations through Yahoo! Crowdsourcing, a commercial crowdsourcing platform operated by Yahoo Japan Corporation. Figure 3 shows an example of the annotation interface.

**Crowd Workers.** A total of 2,048 unique workers participated in the annotation project. We recruited general users registered on the platform and did not require any specific professional qualifications. Workers were progressively filtered based on quality criteria across annotation rounds, as described in Appendix A.4.

**Compensation.** For each task, defined as selecting the most appropriate candidate from three options, we set the reward based on the expected time required to complete the task. The unit price was set so that the effective hourly wage exceeded the average minimum wage in Japan. Across the entire annotation project, we paid workers a total of 219,376 JPY, equivalent to approximately 1,371 USD at the time of the experiments.

## A.2 Paraphrase Candidate Generation

We used `Qwen3.5-397B-A17B-FP8` (Qwen Team, 2026) and `gpt-oss-120b` (OpenAI, 2025) to generate paraphrased candidates. Figure 4 shows the prompt used for this task.

## A.3 Candidate Filtering

We evaluated the validity of each MIDDLE segment using an LLM-as-a-judge with the prompt shown in Figure 5. We retained only samples that satisfied all of the following prompt-specified conditions: `decision=keep`, `issue_types=[]`, a score of 5 for all quality criteria, and `risk=1`.

## A.4 Annotation Quality Control

To ensure annotation quality, we progressively selected workers over multiple rounds. In Round 0, we prepared six gold questions with clear correct answers. Each worker was presented with five questions: two randomly selected gold questions and three regular questions. We ranked workers by their accuracy on the gold questions and selected the top 911 workers to participate in Round 1.

Figure 3: Example of the annotation interface showing document-level context and multiple candidates.

**Worker Selection after Round 1.** We used accuracy on the gold questions to select workers from Round 0 to Round 1. From Round 1 onward, we selected workers for the next round based on a worker quality score computed from their responses and annotation behavior. The quality score consisted of four measures: reading time, agreement with other annotators, viewing rates for the candidates and document text, and candidate dwell time.

**Reading Time.** For each question, we denote the reading time in seconds by $s$ and define the reading-time score $r$ as

$$r = \begin{cases} 0, & s < 20, \\ s/40, & 20 \le s < 40, \\ 1, & 40 \le s. \end{cases} \tag{1}$$

Thus, responses completed in less than 20 seconds receive a score of 0, those taking at least 40 seconds receive a score of 1, and scores between these thresholds increase linearly with reading time. The worker-level score is the average over all questions answered by that worker.

**Agreement with Other Annotators.** For each question, we define the agreement rate as the proportion of other workers who selected the same candidate. When no other worker was available for comparison, we set the agreement rate to 0.5. For each round, we first averaged the agreement rates over all non-gold questions answered by each worker and then averaged these worker-level scores

across participating workers. Table 4 reports the resulting agreement rates.

**Candidate and Document Viewing.** For each question, let $v$ denote the candidate-viewing rate and $b$ the document-viewing rate. We define the viewing score $q$ as

$$q = \frac{v + b}{2}. \tag{2}$$

The worker-level viewing score is the average of $q$ over all questions answered by that worker.

**Candidate Dwell Time.** Let $d$ denote the dwell time for a candidate in milliseconds and $m$ the reference dwell time. We define the dwell-time score $h$ as

$$h = \min\left(\frac{d}{m}, 1\right). \tag{3}$$

We used $m = 400$ ms as the reference dwell time. The worker-level dwell-time score is the average of $h$ over all candidates viewed by that worker.

**Overall Quality Score.** Because the four measures have different scales, we ranked workers separately for each measure and converted the rankings to scores ranging from 0 to 100, with 100 assigned to the highest-ranked group and 0 to the lowest-ranked group. Workers with the same value for a measure received the same rank score.

Let $P_{iR}$, $P_{iA}$, $P_{iQ}$, and $P_{iH}$ denote the rank scores of worker $i$ for reading time, agreement, viewing, and dwell time, respectively. We define the final worker quality score as

$$\text{PoliteScore}_i = \frac{P_{iR} + P_{iA} + P_{iQ} + P_{iH}}{4}. \tag{4}$$

At the end of each round, we ranked workers in descending order of $\text{PoliteScore}_i$ and selected the highest-ranked workers according to the number required for the next round. Workers who were not selected did not participate in subsequent rounds.

### A.5 Domain Composition of Data Sources

Table 5 shows the domain composition of the 7,345 samples in the final CAJALA dataset after excluding samples with no valid annotations.

## B Synthetic Dataset Details

### B.1 Construction Process

This section details the construction process of our synthetic dataset.

| Round | Workers | Agreement |
|---|---|---|
| 0 | 2,048 | 80.22% |
| 1 | 911 | 82.02% |
| 2 | 437 | 82.06% |
| 3 | 230 | 84.53% |
| 4 | 109 | 84.56% |
| 5 | 59 | 85.31% |
| 6 | 32 | 85.94% |

Table 4: Statistics for each round of human annotation. Agreement is computed only over non-gold samples with exactly three valid responses.

| Domain | Samples |
|---|---|
| News | 2,212 |
| SNS | 3,645 |
| Literature | 1,492 |

Table 5: Domain composition of the final CAJALA dataset.

**Domain Classification.** We used gemma-4-26B-A4B-it (GemmaTeam, 2026) to classify the domains of the llm-jp-corpus-v4 samples across 19 categories. Figure 6 shows the prompt used for this task.

**Noise Removal.** We used Qwen3-Swallow-30B-A3B-RL-v0.2[2] to identify and correct speech recognition errors in the video transcriptions (CC Audio, YODAS2). Figure 7 shows the prompt used for this task.

**Back-translation.** We back-translated the Japanese documents into English and Chinese using several LLMs: gemma-4-26B-A4B-it, gemma-4-31B-it, Qwen3.6-35B-A3B, and Qwen3.5-122B-A10B-FP8. Figure 8 and 9 show the prompts used for this task.

**Cleaning.** For rule-based filtering, we applied the rules detailed in Table 6. For the LLM-as-a-judge, we used gemma-4-26B-A4B-it and gemma-4-31B-it (GemmaTeam, 2026). The models first evaluated the translations for predefined error types, such as omissions, incorrect target language, and named entity errors. They then made a final binary judgment on the overall translation quality. Figure 10 shows the prompt used for this evaluation.

**Terminology Extraction.** We extracted bilingual terminology pairs from the parallel corpus

[2] https://huggingface.co/tokyotech-llm/Qwen3-Swallow-30B-A3B-RL-v0.2

| Filter | Rejection criterion |
|---|---|
| Language mismatch | Discard samples whose source or target is not identified as the expected language of the pair. |
| Boilerplate text | Remove samples whose source or target contains a boilerplate phrase from a curated list of web-scraping artifacts (citation notices, paywall notices, copyright and RSS footers, site navigation, browser names), with a fixed probability. |
| Target length | Discard samples whose target exceeds the allowed character limit. |
| Newline ratio | Remove samples whose proportion of line breaks exceeds the allowed threshold. |
| Punctuation gap | Discard samples whose Japanese text contains a punctuation-free span longer than the allowed length. |
| Target number ratio | Remove samples whose proportion of numeric characters exceeds the allowed threshold. |
| Number consistency | Discard samples in which a number written in Arabic digits on one side does not appear on the other side. |
| $n$-gram overlap | Remove samples whose source and target share more character $n$-grams than allowed. |
| Repetition | Discard samples whose character $n$-gram repetition rate exceeds the allowed threshold within a local window. |

Table 6: Rule-based filters and their rejection criteria applied to the synthetic parallel data. A sample is discarded if it meets any of the criteria above.

for use in glossary prompting and dictionary construction. For this extraction, we used gemma-4-26B-A4B-it and gemma-4-31B-it (GemmaTeam, 2026). Figure 11 and 12 show the prompts used for this task.

**Style Identification.** We split each document into sentences based on line breaks and Japanese punctuation marks (e.g., “。”, “！”, “？”). We then classified the ending of each sentence using string matching. Specifically, we defined ending patterns for the polite style (e.g., “です”, “ます”, “ました”, “ません”, “ください”) and the plain style (e.g., “だ”, “である”, “だった”, “だろう”, “ない”). We counted a sentence as polite if it matched a polite pattern, and as plain if it matched only a plain pattern. We then assigned the overall document the style of its majority sentence type. To ensure reliability, we only assigned a style if the majority style appeared in at least two sentences, and the minority style appeared in at most one sentence. We left documents unclassified if they failed to meet this condition.

| | **Tokens** |
|---|---|
| SFT | 758,507,883 |
| DPO Stage1 (Synthetic) | 1,230,093 |
| DPO Stage1 (LLM judge) | 70,135,828 |
| DPO Stage2 (CAJALA) | 8,631,489 |

Table 7: Number of training tokens used in each stage.

**Source-side Segment Alignment.** We randomly selected one segment generated during the Target-side Segmentation phase and identified its corresponding source-side segment. For this alignment, we used gemma-4-26B-A4B-it and Qwen3.6-35B-A3B. Figure 13 and 14 show the prompts used for this task.

### B.2 Dataset Size

Table 7 shows the number of tokens in the final dataset.

## C Preprocessing Details

As preprocessing steps, we performed segment splitting, domain classification, and style selection.

**Segment splitting.** We first determine whether the document can be parsed as JSON or HTML, that is, whether it contains structured text. For structured documents, we parse the document using the corresponding parser and treat each extracted text span as a single segment. For documents not identified as structured text, we first split the input document into sentences using spaCy (Honnibal et al., 2020). We then merge adjacent sentences to form segments of at least 130 characters for En→Ja and 50 characters for Zh→Ja, avoiding unnaturally short segments.

**Domain classification.** For each sample in the blind test set, instructions on the translation style and format are provided together with multimodal resources. We use these instructions and resources to assign a domain according to the following four rules. **Video:** If the multimodal resources include a video, assign the “Streaming/Video/Audio” domain. **News:** If the instructions contain the word `news`, ignoring case, assign the “News” domain. **SNS:** If the instructions contain keywords related to social media, assign the “SNS” domain. **Other:** Otherwise, leave the domain unspecified.

**Style selection.** For samples classified as News, we instructed the model through the prompt to use

| Maximum Sequence Length | 16,384 tokens |
| Learning Rate Schedule | Linear warmup followed by constant LR |
| Warmup Steps | 20 |
| Warmup Initial LR | $1 \times 10^{-11}$ |
| Learning Rate | $5 \times 10^{-7}$ |
| Optimizer | Adam (Kingma and Ba, 2015) $\beta_1 = 0.9$, $\beta_2 = 0.999$, $\epsilon = 1 \times 10^{-8}$, |
| Gradient Clip | 1.0 |
| DPO Coefficient $\beta$ | 0.1 |
| Log-probability Reduction | Sum over response tokens |
| Implementation | `NeMo RL` (Megatron backend) (NVIDIA, 2025b) |
| **DPO Stage 2** | |
| Train Steps | 574 |
| Batch Size | 16 preference pairs (32 sequences) |
| Maximum Sequence Length | 16,384 tokens |
| Learning Rate Schedule | Linear warmup followed by cosine decay |
| Warmup Steps | 20 |
| Warmup Initial LR | $1 \times 10^{-11}$ |
| Maximum Learning Rate | $5 \times 10^{-7}$ |
| Minimum Learning Rate | 0 |
| Optimizer | Adam (Kingma and Ba, 2015) $\beta_1 = 0.9$, $\beta_2 = 0.999$, $\epsilon = 1 \times 10^{-8}$, weight_decay $= 0.01$ |
| Gradient Clip | 1.0 |
| DPO Coefficient $\beta$ | 0.1 |
| Log-probability Reduction | Sum over response tokens |
| Implementation | `NeMo RL` (Megatron backend) (NVIDIA, 2025b) |

Table 8: Hyperparameters used during model training.

the plain declarative style. For all other samples, no style was specified.

# D Training Configuration

Table 8 lists the training hyperparameters.

## D.1 DPO Dataset Construction

**LLM-as-a-Judge Preferences.** To generate LLM-as-a-judge preferences, we used `gemma-4-31B-it` (GemmaTeam, 2026) to assign preferences between the output of an in-development model and the reference in the synthetic dataset. Figure 15 shows the prompt used for this evaluation.

**CAJALA Preference Pairs.** For each CAJALA sample, if one candidate received at least two votes, we treated it as the chosen candidate and each of the other two candidates as a rejected candidate, yielding two preference pairs. Samples without a majority candidate, such as those with a 1:1:1 vote split, were excluded from DPO training. For each pair, the document containing the chosen segment was back-translated into English and Chinese and used as the source for both the chosen and rejected responses.

# E Glossary Extraction Details

As described in § 4.2, we built the glossary by applying multi-stage filtering to the bilingual terminology pairs extracted during the dataset construction process. First, we used gemma-4-26B-A4B-it (GemmaTeam, 2026) as an LLM-as-a-judge to evaluate the validity of the extracted pairs. Figure 16 shows the prompt used for this evaluation. Next, using the wordfreq (Speer, 2022) library, we retained low-frequency words with a Zipf frequency of 4.0 or lower for English, and 4.5 or lower for Chinese. We then applied rule-based filters to remove identical source-target pairs, ambiguous cases where a single source word mapped to multiple targets, and terms containing boundary punctuation. Furthermore, we matched the extracted terms against the source sentences at the token level for English and the character level for Chinese. When matches overlapped, we applied the leftmost-longest rule to retain the longest possible matching terms in the glossary. The final En↔Ja and Zh→Ja glossaries contained 215,000 and 90,633 pairs, respectively.

# F LLM-as-a-Judge Evaluation

During the LLM-as-a-judge evaluation, we provided the model with the source language, target language, source-side segment, and target-side segment, and instructed it to score the translation quality on an integer scale from 0 to 100. Figure 17

shows the full prompt used for this evaluation. We excluded two samples for which the Gemini API returned a `PROHIBITED CONTENT` error.

## G FIM Post-editing Strategy

During system development, we also explored strategies for applying FIM post-editing to a broader set of segments, rather than only to the segments detected by the rules described in § 6.3. Specifically, we performed quality estimation for each segment using MetricX (Juraska et al., 2024) and experimented with post-editing the segment with the lowest score in each document. However, we found that the improvements in translation quality achieved by FIM post-editing were limited. We therefore adopted a conservative strategy of correcting only translations that were clearly of low quality, aiming to ensure that post-editing reliably improved translation quality. As a result, only four translation outputs were modified by FIM post-editing. Table 9 shows examples in which translation quality degraded when post-editing was applied more aggressively based on MetricX scores.

## H Additional Qualitative Examples

Table 10 provides qualitative examples for the language direction omitted from each comparison in Table 3. For `Base` → `SFT`, we show an En→Ja example, whereas the remaining comparisons show Zh→Ja examples. Table 11 shows three examples in which FIM post-editing changed the hypotheses of `DPO-2+MBR`.

## I Total System Parameters

Table 12 lists the parameter counts for each model used in our system. Our total parameter count of 18.7B falls below the 20B threshold, satisfying the constraints of the Open weight (constrained) track.

| | Source text | Before FIM post-editing | After FIM post-editing |
|---|---|---|---|
| **(a)** **En→Ja** 24296-jpn_Jpan | So this is my carry on. And then this bad boy, are. You gonna check it? I don't know. I can't decide. It's pretty heavy. But it's so smooth. | だからこれ、私のキャリーオン。それでこのやつは、アレ。預けるかい？ わかんないなー。決められないなー。結構重たいしなー。でもめちゃくちゃ滑るよ。 | これ、俺のキャリーオン。そしてこの野郎、アレだ。チェック入れる？ わかんないな。決められないな。結構重いよな。でもめっちゃ滑る。 |
| **(b)** **En→Ja** 24247-jpn_Jpan | Look, they gave us a little beach bag, a hat. Um. Everything I never want to forget. And some things I do. Oh my God, so cute. So cute. | ほら、小さなビーチバッグと帽子をもらった。えっと。忘れたくないこと全部。そして、忘れたいこともある。やだー、かわいい。かわいい。 | ほら、ビーチバッグと帽子の小さいのをもらった。えっと。私が絶対に忘れたくないもの全部。それから、忘れたくないものも。あらやだ、かわいい。かわいい。 |

Table 9: Examples of samples whose translation quality degraded due to FIM post-editing. Blue marks the parts that were correctly translated in the original translations, while red marks obvious errors introduced by FIM post-editing.

**Paraphrase Prompt**

```
# 文章の一部分を文脈に合わせて自然な表現に書き換える

与えられた文章全体の文脈を踏まえ、指定された「対象部分」を、前後の流れに調和したより自然な日本語表現へと書き換えてください。

## 入力

以下の 3 つが与えられます。

- **文章全体**：対象部分を含む文章の全体。文脈・文体・語調を判断するための材料です。
- **対象部分**：文章全体の中に含まれる、書き換える対象となる箇所。
- **対象部分の翻訳**：書き換える対象部分を翻訳したもの。意味を保持しつつ、自然な日本語表現にするための参考情報です。

## 書き換えの方針

### 1. 意味を保持する
- 対象部分が伝えている内容・主張・ニュアンスを変えない。
- 情報を勝手に追加したり削除したりしない。
- 参考情報として与えられた翻訳結果を尊重し、意味が変わらない範囲で自然な表現にする。

### 2. 前後の文脈と調和させる
- **文体**：文章全体に合わせて、敬体（です・ます調）か常体（だ・である調）かを統一する。
- **語彙・トーン**：硬さ／柔らかさ、専門性のレベル、フォーマルさを周囲と揃える。
- **つながり**：直前の文からの流れ、直後の文への流れが滑らかになるようにする。
- **用語の一貫性**：文章全体で使われている表記・専門用語・固有名詞の言い回しに合わせる。

### 3. 自然さを高める
- 翻訳調・直訳調や、不自然な言い回しを、こなれた日本語に直す。
- 冗長な表現や回りくどい言い方を簡潔にする。
- 助詞の誤りや、係り受けの不明瞭さを正す。
- 同じ語句の不要な繰り返しを避ける。
- 読点の位置や語順を整え、読みやすくする。

### 4. 範囲を守る
- 書き換えるのは **対象部分のみ**。前後の文には手を加えない。
- 対象部分の長さや位置づけを大きく逸脱しない（必要以上に増減させない）。
- すでに十分自然で文脈にも合っている場合は、無理に変えず元の表現をそのまま出力してよい。

## 出力形式

- 書き換え後の **対象部分のテキストのみ** を、次のように ```txt``` のコードブロックで囲んで出力する。
- コードブロックの外側には、前置き・説明・理由などを一切付けない。
- 文章全体を再掲しない。

```txt
（ここに書き換え後の対象部分）
```

---

### タスク
上記の方針に従って、与えられた文章全体と対象部分をもとに、対象部分を自然な表現に書き換えてください。

```
【文章全体】
<<<|FULL_TEXT|>>>

【書き換え対象部分】
<<<|MIDDLE_TEXT|>>>

```
```

Figure 4: Prompt used for paraphrasing

**MIDDLE Suitability Judgment Prompt**

```
# MIDDLE 妥当性判定タスク

text infilling 翻訳の preference アノテーション用データを作成します。
日本語文書から選ばれた MIDDLE が、**パラフレーズ候補を作って人間が「前後文脈に最も自然に入るもの」を選ぶタスク**に向いているか
判定してください。

このタスクでは、パラフレーズ候補は生成しません。
MIDDLE 自体を `keep` / `human_review` / `drop` のどれにするかだけを判定してください。

## 判定で見ること

次の観点を総合して判定してください。

1. MIDDLE が自然な日本語か。
2. PREFIX / SUFFIX と話題・文体・接続が自然につながるか。
3. 意味を保ったまま、自然な言い換え候補を 2 個以上作れそうか。
4. 候補間で「どれが文脈に最も自然か」の差が出そうか。
5. SOURCE と明らかに矛盾していないか。

SOURCE は補助情報です。
日本語側の自然さと前後文脈との整合性を最優先してください。
SOURCE が空、または対応判断が難しい場合、明らかな矛盾がなければ `source_consistency` は 3 にしてください。

## keep したい例

- 日本語として自然で、ノイズや UI 文言が混ざっていない。
- PREFIX / SUFFIX と自然につながる。
- 文体、語順、接続、助詞、文末、語彙などに言い換え余地がある。
- 意味・数量・固有名詞を保ったまま、2〜4 個程度の自然な候補を作れそう。

## drop したい例

- MIDDLE が空、null、または欠損している。
- URL、数字、商品名、コード、メンション、ハッシュタグ、絵文字、記号が中心。
- ログイン案内、引用 UI、エラーメッセージ、HTML、メタ情報などのノイズが中心。
- 定型文すぎて、自然な言い換え候補を複数作れない。
- PREFIX / SUFFIX とつながらない、または文体が合わない。
- 前後文脈を見ても意味や指示対象が曖昧すぎる。
- SOURCE と MIDDLE の対応が明らかに怪しい。
- 言い換えると意味ズレしやすい。

## スコア

各スコアは 1〜5 の整数で付けてください。
`risk` だけは、値が高いほど悪いスコアです。

- `fluency`: MIDDLE 単体の日本語としての自然さ。
  - 1: 不自然・破綻・ノイズ中心
  - 3: 読めるが少し不安
  - 5: 自然な日本語
- `context_fit`: PREFIX / SUFFIX との自然なつながり。
  - 1: つながらない
  - 3: おおむねつながるが不安
  - 5: 自然につながる
- `source_consistency`: SOURCE との整合性。
  - 1: 明らかに怪しい
  - 3: 判断に迷う
  - 5: 問題なさそう
- `paraphrase_potential`: 自然な言い換え候補を複数作れそうか。
  - 1: ほぼ作れない
  - 3: 1〜2 個なら作れそう
  - 5: 複数作りやすい
- `annotation_value`: 人間が preference を付けるデータとして価値があるか。
  - 1: 価値が低い
  - 3: 人手確認が必要
  - 5: 価値が高い
- `risk`: ノイズ、曖昧さ、意味ズレ、固有名詞・数字中心などのリスク。
  - 1: リスクが低い
  - 3: 少し不安
  - 5: リスクが高い
```

Figure 5: Prompt used to assess whether a middle segment was suitable for constructing CAJALA datasets (Part 1 of 2).

**MIDDLE Suitability Judgment Prompt (continued)**

```
## 判定ラベル

- `keep`: そのまま採用してよい。
  - 目安: `fluency >= 4`, `context_fit >= 4`, `paraphrase_potential >= 4`, `annotation_value >= 4`, `risk <= 2`
- `human_review`: 判断に迷うため、人手確認に回す。
  - 日本語や文脈は悪くないが、SOURCE 対応・曖昧さ・意味ズレ・ノイズに不安がある。
- `drop`: 除外する。
  - 空、ノイズ中心、定型的すぎる、文脈に合わない、言い換え価値が低い、SOURCE 対応が怪しい。

## issue_types

問題がある場合だけ、以下から少数選んでください。
問題がない場合は `[]` にしてください。

- `missing_middle`: 空、null、欠損
- `noise_or_non_text`: URL、UI 文言、コード、HTML、メタ情報などのノイズ
- `entity_or_symbol_heavy`: 数字、固有名詞、商品名、メンション、絵文字、記号が中心
- `context_or_style_mismatch`: PREFIX / SUFFIX と文脈・文体が合わない
- `source_mismatch`: SOURCE との対応が怪しい
- `low_paraphrase_value`: 言い換え余地や preference の価値が低い
- `ambiguous_or_drift_risk`: 曖昧すぎる、または意味ズレしやすい
- `other`: その他

## 出力形式

必ず以下の JSON オブジェクトのみを出力してください。
Markdown のコードブロックや説明文は出力しないでください。
`decision` は `"keep"`, `"human_review"`, `"drop"` のいずれか 1 つです。
MIDDLE が空、null、欠損、またはプレースホルダ未置換に見える場合は、`has_middle` を `false` にし、`decision` は `"drop"` にしてください。

{
  "has_middle": true,
  "scores": {
    "fluency": 1,
    "context_fit": 1,
    "source_consistency": 1,
    "paraphrase_potential": 1,
    "annotation_value": 1,
    "risk": 1
  },
  "decision": "keep",
  "issue_types": [],
  "reason": "判定理由を日本語で簡潔に記載"
}

**Domain Classification Prompt**

```
# 文書ドメイン分類タスク

あなたは、与えられた日本語テキストの文書ドメインを分類するアシスタントです。

## タスク

テキストを読み、当てはまるカテゴリを 1 つだけ選んでください。

1. **SNS への投稿**: X(Twitter)、Facebook、Instagram、TikTok などのソーシャルメディアへの投稿。
2. **掲示板**: 5ちゃんねる、なんJ、ふたばちゃんねる、Redditなどの掲示板への書き込み。匿名性が高く、スレッド形式のレスのやり取りや独特のスラング・アスキーアートを含むことが多い。
3. **Q&A**: Yahoo!知恵袋、教えて!goo、OKWAVE、Stack Overflowなどの質問・回答サイトのコンテンツ。質問文と回答文がセットになっているか、明確に質問・回答のいずれかと判別できる形式。
4. **対話**: 会話・チャットログ・インタビュー・座談会・対談・脚本など、複数話者のやり取りで構成されたテキスト。発言者の交代や話者ラベルが明確な形式。
5. **ニュース**: 新聞社・通信社・テレビ局などの報道機関による事実報道記事。「いつ・どこで・誰が・何を」を客観的に記述する報道スタイル。
6. **プレスリリース**: 企業・団体が公式に発表する報道発表資料。新製品発表、業績発表、人事発表、提携発表など、発信元が明示された公式アナウンス。
7. **ブログ・コラム**: 個人・ライターによるブログ記事、コラム、オピニオン記事、エッセイ、note記事など。書き手の主観・経験・意見が中心となる読み物。
8. **文学・web小説**: 小説、詩、戯曲、随筆、web小説、ライトノベル、二次創作など、創作的・物語的なテキスト。地の文と会話文を含む叙述形式。
9. **百科事典・解説**: Wikipedia、コトバンク、ニコニコ大百科などの百科事典記事、用語解説、概念の中立的な説明文。事実を網羅的・体系的に整理した記述。
10. **教育・学術**: 教科書、講義資料、学術論文、研究レポート、学習教材、問題集、参考書など、教育・学術目的で書かれたテキスト。
11. **技術関連・マニュアル・ソースコード**: 技術文書、APIリファレンス、製品マニュアル、取扱説明書、技術ブログ、ソースコード、設定ファイル、プログラミングのコード例・解説など。
12. **商品・EC**: Amazon、楽天市場などのECサイトの商品ページ、商品説明、スペック表、カタログなど、商品の紹介・販売を目的とするテキスト。
13. **レビュー・口コミ**: 商品、サービス、店舗、作品、施設などに対するユーザーによるレビュー、口コミ、評価コメント、感想投稿。
14. **企業・団体・行政**: 企業・団体・行政機関の公式サイトのコーポレートページ、会社概要、IR情報、行政からの告知・通達・広報など、組織の公式情報。
15. **求人・不動産・旅行などの情報サービス**: 求人情報、不動産物件情報、旅行・宿泊・観光情報、グルメ情報、イベント情報など、情報サービスサイトに掲載される定型的な情報。
16. **医療・法律・金融など専門情報**: 医療、法律、税務、金融、保険など、専門分野の情報提供記事・解説・Q&A・コラム。専門家による執筆または監修を伴うことが多い。
17. **広告・SEO・スパム**: 広告コピー、アフィリエイト目的の記事、SEO狙いの薄いコンテンツ、まとめサイトのコピペ記事、スパム的な宣伝文章など。
18. **アダルトサイト**: 成人向けコンテンツを扱うサイトのテキスト。アダルト動画・画像サイトの紹介文や作品説明、出会い系・風俗関連サイト、官能小説、性的内容を含む広告・口コミなど。
19. **その他**: 上記のいずれにも該当しない文書、または複数カテゴリの判別が困難な文書。

## 出力形式

- 出力は `番号. カテゴリ名 ` の形式で 1 行のみ出力してください。
- それ以外の内容は出力しないでください。

# 日本語文字起こしテキストの校正

## 役割

あなたは日本語の文字起こし（音声認識）テキストを校正する編集者です。話し言葉ならではの言い回しや雰囲気はそのまま残しつつ、フィラーや言い淀みを取り除き、認識ミスを直し、文章として自然に読めるように手直しを行います。

## タスク

入力された文字起こしテキストに対して、以下のルールに従って校正してください。話し言葉を書き言葉に変換するのではなく、あくまで話し言葉のまま読みやすく整えることが目的です。

## 修正ルール

1. フィラーや言い淀み（「えー」「あのー」「まあ」「えっと」「なんか」「そのー」など）を削除する。
2. 言い直しや無意味な繰り返し（同じ語句のダブり、言いかけて止めた断片など）を整理し、自然につながるようにする。
3. 音声認識による誤変換（同音異義語の取り違え、語の聞き取り間違いなど）を、文脈から判断して正しい表記に修正する。
4. 句読点を適切に補い、読点・句点を整える。また、不自然な句読点の付け方を修正する。余計な空白やスペースを削除する。
5. 文の区切りや改行を整え、内容のまとまりごとに段落を分ける。
6. 明らかな脱字・衍字（よけいな文字）や、意味の通らない崩れた箇所を最小限に整える。

## 維持すること（書き換えない）

- 話し言葉特有の言い回し・口調・語尾（「〜だよね」「〜なんですよ」「〜じゃん」など）はそのまま残す。
- 口語的な省略や倒置など、意味の伝わる表現はそのままにする。
- 方言・くだけた表現を標準的な書き言葉に直さない。

## 厳守事項

- 発言の意味内容を変えない。要約・追加・独自解釈の挿入をしない。
- 話者の意図や主張、話し方の個性を勝手に補完・脚色・標準化しない。
- 元のテキストに存在しない情報を付け加えない。
- 判断に迷う箇所は、無理に修正せず元の表現をそのまま残す。

## 出力形式

修正後のテキストのみを、以下のように ```txt``` コードブロックで囲んで出力してください。コードブロックの前後に説明・注釈・前置きを一切加えないこと。

```txt
（修正後のテキスト）
```

ただし、入力内容が日本語でない・空欄等の問題があった場合には、

```txt
N/A
```
とだけ出力してください。

## 入力テキスト

以下のテキストを校正してください。

```txt
<<<|TEXT|>>>
```
```

**Translation-pair Quality Judgment Prompt**

```
# 翻訳ペア品質判定
あなたは翻訳データセットをクリーニングするための厳格な品質判定者です。
次の原文と翻訳文を比較し、翻訳ペアをデータセットに採用してよいか判定してください。

## 判定基準
- `OK`: 原文の主要な意味が翻訳文に十分反映されている。
- `NG`: データセットから除外すべき重大な問題がある。

【NG となる重大な問題とエラータイプ（error_types）の対応】
- `omission`: 原文の重要情報が抜けている
- `mistranslation`: 原文と完全に異なる意味に訳している
- `entity_number_error`: 数字、固有名詞、日付などを誤っている
- `addition`: 原文にない重要情報を追加している
- `wrong_language`: 翻訳文が指定された対象言語ではない
- `truncated`: 文章が途中で切れている
- `translation_failure`: 翻訳に失敗している
- `other`: 上記以外の重大な欠陥がある

## 出力形式
必ず JSON オブジェクトのみを出力してください。

**Terminology Extraction Prompt for En→Ja**

```
# Technical Terminology Translation Pair Extraction Task

## Role
You are an expert in extracting technical terminology translation pairs from parallel Japanese and English texts.

## Task
The **Japanese** text and **English** text presented below are in a parallel translation relationship. Carefully
read both texts and extract the **technical terminology translation pairs** contained within them.

## Extraction Rules

### 1. Faithfulness
- Extract the expressions appearing in the texts **exactly as they are written**.
- Do **not perform any processing** such as normalization of notation, completion of okurigana, conversion of
character types, adjustment of word endings, or restoration to base forms.
- Preserve the exact surface form as actually used in the texts.

### 2. Basis of Correspondence
- Extract only terms that **actually exist in both the Japanese and English texts** and correspond to each other as
translations.
- Do not supplement or fabricate translation pairs based on general knowledge or speculation.
- Terms that appear in only one of the languages are excluded from extraction.

### 3. Extraction Targets
- Target technical terms (technical vocabulary, academic terms, industry-specific concept words) and proper nouns.
- Exclude general everyday words, function words, grammatical elements, numerical values, and general-purpose verbs
and adjectives.
- Extract up to five pairs of technical terms and proper nouns.

### 4. Duplicate Handling
- If the same translation pair appears in multiple locations, output it only once.

## Output Format

**The response must be exactly one valid JSON object conforming to the following format.**

- Do not include any text other than the JSON (no preamble, explanation, annotation, conclusion, blank lines,
comments, etc.).
- If the extraction result is zero, output `{"term_pairs": []}`.

```json
{
  "term_pairs": [
    {"ja": "機械学習", "en": "machine learning"},
    {"ja": "教師あり学習", "en": "supervised learning"},
    {"ja": "ラベル付きデータ", "en": "labeled data"}
  ]
}

# Technical Terminology Translation Pair Extraction Task

## Role
You are an expert in extracting technical terminology translation pairs from parallel Chinese (Simplified) and
Japanese texts.

## Task
The **Chinese (Simplified)** text and **Japanese** text presented below are in a parallel translation relationship.
Carefully read both texts and extract the **technical terminology translation pairs** contained within them.

## Extraction Rules

### 1. Faithfulness
- Extract the expressions appearing in the texts **exactly as they are written**.
- Do **not perform any processing** such as normalization of notation, completion of okurigana, conversion of
character types, adjustment of word endings, or restoration to base forms.
- Preserve the exact surface form as actually used in the texts.

### 2. Basis of Correspondence
- Extract only terms that **actually exist in both the Chinese and Japanese texts** and correspond to each other as
translations.
- Do not supplement or fabricate translation pairs based on general knowledge or speculation.
- Terms that appear in only one of the languages are excluded from extraction.

### 3. Extraction Targets
- Target technical terms (technical vocabulary, academic terms, industry-specific concept words) and proper nouns.
- Exclude general everyday words, function words, grammatical elements, numerical values, and general-purpose verbs
and adjectives.
- Extract up to five pairs of technical terms and proper nouns.

### 4. Duplicate Handling
- If the same translation pair appears in multiple locations, output it only once.

## Output Format

**The response must be exactly one valid JSON object conforming to the following format.**

- Do not include any text other than the JSON (no preamble, explanation, annotation, conclusion, blank lines,
comments, etc.).
- If the extraction result is zero, output `{"term_pairs": []}`.

```json
{
  "term_pairs": [
    {"zh": "机器学习", "ja": "機械学習"},
    {"zh": "监督式学习", "ja": "教師あり学習"},
    {"zh": "标注资料", "ja": "ラベル付きデータ"}
  ]
}
```

# Parallel-Text Extraction Task

## Role
You are an **extractor** that, given a **Japanese–English parallel translation pair**, precisely pulls out the
English text corresponding to a specified passage. Your job is **not translation**, but the **identification and
extraction of English text that already exists**.

## Task Overview
1. As input, you are given the **Japanese version** of a document and its corresponding **English version** (a
parallel translation pair).
2. In addition, you are given **one segment** (a few consecutive sentences) taken from the Japanese version.
3. You must identify **which part of the English version** this Japanese segment corresponds to, and extract the
sentence(s) written in the English version **exactly as they appear**.

## Rules You Must Strictly Follow
- **Do not translate on your own.** Translating the Japanese segment into English is prohibited. You must instead
locate the text that already exists in the provided English version and output it by copying it verbatim.
- The English text you extract must be output **without altering the original wording, punctuation, capitalization,
or any other aspect of the source text** in the English version. You must not summarize, paraphrase, or edit it.
- Select a range of English text that covers the content of the Japanese segment **completely and without excess**.
If the corresponding English spans multiple sentences, extract the **entire consecutive range**.
- The sentence boundaries and ordering may differ between Japanese and English. Even if the word order or number of
sentences does not correspond one-to-one, extract the **consecutive range on the English side that corresponds in
meaning**.
- If the corresponding English text **does not exist** in the English version, output only `N/A`. Do not fabricate
English text by guessing.
- Output **only** the extracted English text (or `N/A`), enclosed in a code block beginning with ````` ```txt `````.
Do not add any explanation, preamble, or supplementary remarks whatsoever.

## Input (Example)
### Japanese (full text)
```txt
私たちの会社は2010年に設立されました。設立当初は社員がわずか3名でした。現在では従業員数が500名を超えています。私たちは持続可能
な社会の実現を目指しています。
```
### English (full text)
```txt
Our company was founded in 2010. At the beginning, we had only three employees. Today, our workforce exceeds 500
people. We aim to realize a sustainable society.
```
### Japanese Segment to Extract
```txt
設立当初は社員がわずか 3 名でした。現在では従業員数が 500 名を超えています。
```
### Output (Example)
```txt
At the beginning, we had only three employees. Today, our workforce exceeds 500 people.
```

---

## Input (Actual)
Now, perform the task on the following input.

### Japanese (full text)
```txt
<<<|TARGET_DOCUMENT|>>>
```
### English (full text)
```txt
<<<|SOURCE_DOCUMENT|>>>
```
### Japanese Segment to Extract
```txt
<<<|TARGET_SEGMENT|>>>

# 中日双语对照文本抽取任务

## 角色
你是一个**抽取器**。当给定一对**日文与中文的对照译文**时，你需要精确地抽取出与指定段落相对应的中文文本。你的任务**不是翻译**，
而是**识别并抽取出已经存在的中文文本**。

## 任务概述
1. 作为输入，你会得到某篇文档的**日文版本**，以及与之相对应的**中文版本**（两者互为对照译文）。
2. 此外，你还会得到从日文版本中截取出来的**一个片段**（连续的若干句子）。
3. 你需要判断该日文片段**对应于中文版本中的哪一部分**，并将中文版本中所写的句子**原封不动地**抽取出来。

## 必须严格遵守的规则
- **不得自行翻译。** 禁止将日文片段翻译成中文。你必须在所提供的中文版本中找到已经存在的文本，并将其逐字逐句、原样复制后输出。
- 抽取出的中文文本必须保持中文版本原文的样貌，**不得改动其字词、标点、书写形式等任何方面**。不得进行概括、改写或编辑。
- 所选取的中文文本范围应当**不多不少地**覆盖该日文片段的内容。如果对应的中文跨越多个句子，请抽取出**整个连续的范围**。
- 日文与中文的句子边界及顺序可能并不相同。即使语序或句子数量并非一一对应，也要抽取出**在语义上相对应的、位于中文一侧的连续范围
**。
- 如果中文版本中**不存在**与之相对应的中文文本，则只输出 `N/A`。不得凭猜测捏造中文文本。
- 输出**仅限于**抽取出的中文文本（或 `N/A`），并用以 ```txt 开头的代码块加以包裹。不得添加任何说明、前言或补充性的文字。

## 输入（示例）
### 日文（全文）
```txt
私たちの会社は2010年に設立されました。設立当初は社員がわずか3名でした。現在では従業員数が500名を超えています。私たちは持続可能
な社会の実現を目指しています。
```
### 中文（全文）
```txt
我们公司成立于 2010 年。成立之初只有三名员工。如今员工人数已超过 500 人。我们致力于实现可持续发展的社会。
```
### 待抽取的日文片段
```txt
設立当初は社員がわずか 3 名でした。現在では従業員数が 500 名を超えています。
```
### 输出（示例）
```txt
成立之初只有三名员工。如今员工人数已超过 500 人。
```

---

## 输入（实际数据）
现在，请针对以下输入执行该任务。

### 日文（全文）
```txt
<<<|TARGET_DOCUMENT|>>>
```
### 中文（全文）
```txt
<<<|SOURCE_DOCUMENT|>>>

# Translation Quality Pairwise Evaluation

## Role
You are an expert evaluator of Japanese translation quality.

## Task
You are given a **source text** and **two Japanese translations** (Translation A and Translation B) of that source
text. Carefully compare the two translations and judge **which one is the better translation** of the source text.

## Evaluation Criteria
Assess each translation comprehensively from the following perspectives:

### 1. Adequacy
- How accurately and completely the meaning of the source text is conveyed.
- Penalize mistranslations, omissions, additions of information not present in the source, and unsupported
speculation.

### 2. Fluency

- Whether the Japanese reads naturally and grammatically.
- Penalize unnatural phrasing, grammatical errors, unnatural word order, awkward word choices, and
machine-translation-like expressions such as repeatedly including the subject where it would normally be omitted in
natural Japanese.

### 3. Terminology and Proper Nouns
- Whether technical terms and proper nouns are translated correctly and consistently.

### 4. Style and Register
- Whether the tone, formality, and register are appropriate for the source text.

## Judgment Rules
- Base your judgment **only on the source text and the two translations presented**. Do not rely on outside
information or speculation.
- Compare the two translations relatively and rate their relative quality on the **5-point scale** defined below.
- If both translations are of equal quality and there is no meaningful difference, judge it as a **tie**.

## Output Format

**The response must be exactly one valid JSON object conforming to the following format.**

- Do not include any text other than the JSON (no preamble, explanation, annotation, conclusion, blank lines,
comments, etc.).
- `verdict` must be one of the following five strings:
  - `"A_much_better"`: Translation A is clearly better.
  - `"A_slightly_better"`: Translation A is slightly better.
  - `"tie"`: The two translations are of equal quality.
  - `"B_slightly_better"`: Translation B is slightly better.
  - `"B_much_better"`: Translation B is clearly better.

```json
{
  "verdict": "A_much_better"
}
```

# MakotoAI at WMT26: Per-Pair Model Selection with Deterministic Output Normalization for the General Machine Translation Task

**Chris Nishihama**
Independent Researcher
chris248ma@gmail.com

## Abstract

We describe MakotoAI, an unconstrained submission to the WMT26 General Machine Translation shared task covering all 23 language pairs (4,897 documents). The system performs no training or fine-tuning: it is a lightweight orchestration layer over six off-the-shelf commercial LLMs, in which each language pair is routed to the single model that won a blinded pre-competition shootout for that pair. Translation is document-level with the full task instruction provided in-prompt. Structured output (JSON and HTML domains) is repaired by a small deterministic normalization pass rather than by model-based retry: an ablation on real test data found that a post-hoc validate-and-retry instruction layer was inert on clean documents and net-negative on JSON documents, while deterministic fence and preamble stripping achieved the intended effect at zero inference cost. Quality assurance combined an exhaustive deterministic instruction-adherence scan, a two-judge LLM evaluation whose self-grading bias we measured to be directional by model family, and the organizers' official alignment checker, against which the final submission scores 1,914 of 1,914 structurally checkable documents aligned. Four defective documents (three truncations, one repetition-loop degeneration) were detected and regenerated, one requiring escalation to a different model; all four are disclosed. The entire system runs on commodity hardware; total API cost to produce and verify the submission was just under $25. We argue that for API-orchestrated MT, verification discipline and deterministic post-processing are higher-leverage than added inference-time machinery.

## 1 Introduction

Modern LLMs translate well individually, but no single model is best across all language pairs, and API-based systems introduce failure modes—output-format drift, degenerate generation, structural misalignment—that sit outside the model's translation quality per se. MakotoAI's WMT26 submission takes a deliberately minimal position: select the best available model per pair empirically, interfere with generation as little as possible, and concentrate effort on verification and deterministic repair of the output.

This is also a study in what a single independent participant can field. The submission was produced by one person on commodity hardware with no local inference and no training, competing in the unconstrained track against systems built on the same frontier models by their own vendors. The methodological question the paper documents is therefore not "how to train a better model" but "how to select, drive, verify, and repair existing models so that the delivered artifact is free of mechanical defects." By *defect* we mean a discrete, machine-detectable failure of the deliverable—truncation, degenerate generation, format breakage, structural misalignment, instruction violation—as distinct from translation errors (a continuous quality attribute) and hallucinations (unsourced content), which verification can bound and sample but cannot certify absent. We claim that the submitted system contains none of the former; for the latter we claim only measured estimates.

Our contributions: (1) a per-pair model-selection protocol based on blinded two-judge shootouts; (2) evidence, from an ablation on real WMT26 test data, that a validate-and-retry instruction-enforcement layer is dominated by deterministic output normalization; (3) a measured, directional characterization of LLM self-grading bias relevant to anyone using production models as judges; and (4) a verification pipeline (deterministic scans plus the official alignment checker) that took the submission from four latent content defects and seven structural misalignments to a fully aligned state with zero remaining mechanical defects before the deadline.

## 2 System

### 2.1 Per-pair model selection

The routing table maps each of the 23 pairs to one production model. Candidates were drawn from six commercial LLMs—Claude Opus 4.6 (Anthropic), GPT-5.4 and GPT-5.5 (OpenAI), Gemini 2.5 Flash and Gemma-4-31B-it (Google), and Qwen3.7-Max (Alibaba)—all accessed through a single API aggregator (OpenRouter), which is also the metering source for the cost figures in §7. Selection was empirical: for each pair, candidate models translated a common evaluation set and were compared in blinded pairwise A/B judgments by two independent judges, with the winner locked into the routing table.

The resulting assignment maps the 23 directions across the six models, with one model carrying the largest share (nine directions) and the remainder distributed among the other five. We do not disclose the per-pair assignment or per-pair development scores. The mapping is the distilled output of the selection methodology and constitutes the system's commercial know-how; publishing it would allow exact replication of the submission at negligible cost, while the official per-pair results appear in the findings paper regardless (Kocmi et al., 2026). We instead characterize the selection statistically, which we consider more informative than the mapping itself.

First, selection margins are mostly within noise. Of the 20 directions with head-to-head shootout data, only two winners were separated at the confidence-interval level ($+9.34$ and $+5.78$ chrF; Popović, 2015, computed with sacreBLEU, Post, 2018); the remaining margins overlap. Per-pair selection is therefore a pragmatic tie-break among strong candidates, not a claim that one frontier model dominates another. One direction fields its shootout runner-up ($-2.52$ chrF) because the nominal winner was unavailable through our API provider at production time; two directions were selected from provisional $N{=}50$ shootouts whose planned re-confirmation on the released test data was not recorded before the production run.

Second, development data can lie. During selection we found the English–Northern Sámi development set contaminated: roughly half of it was biblical text present in the models' training data, so the measured 52.22 chrF partly reflected memorization rather than translation. A same-day re-evaluation on real-domain government text ($N{=}80$) scored the same winning model at 32.58—about twenty points lower—without changing the routing decision. We report both numbers as a caution against trusting development figures in low-resource pairs.

Selection was locked on 14 June 2026. No consensus, ensembling, or reranking was applied at inference time: one pair, one model, one generation. The broader MakotoAI platform includes terminology-enforcement components, but the WMT26 task supplies no glossaries, so no terminology machinery was active in this run, and no proprietary or client data of any kind entered the pipeline.

### 2.2 Translation pipeline

Translation is document-level (the blind set default). For every domain, the full task instruction is prepended verbatim to the prompt, and the model output is taken as the hypothesis. There is no fine-tuning, no adapters, no retrieval, and no translation memory in this run; models are used exactly as served by their APIs. Every specialist call uses temperature 0.3 and a 32,000-token output ceiling; all other sampling parameters are left at the provider default, with no streaming and no reasoning modes. A 953k-pair translation-memory cache present in the codebase recorded zero hits during production (verified from the run logs), so every document was generated by its routed model.

### 2.3 Deterministic output normalization

Two systematic output-format artifacts appeared in the raw generations: (a) 112 documents in the JSON (software) domain arrived wrapped in Markdown code fences, and (b) 2 documents echoed a leading "Translate into X:" instruction line. Both are format drift, not translation errors. A small deterministic `normalize_output()` pass strips a single wrapping code fence and a leading instruction-echo line. After normalization, the submission contains zero fenced hypotheses, and the organizers' checker parses every JSON document (the 11 documents whose JSON carries a trailing comma mirror a trailing comma present in the source, i.e., they are faithful).

### 2.4 Structural alignment

WMT26 aligns HTML documents by paragraph (`<p>`) count and JSON documents by key–value count; 1,914 of our 4,897 documents carry such structure and are therefore checkable, the remaining 2,983 being plain-text doc-

uments for which the checker reports no structural verdict. Running the organizers' corrected `genmt_check_alignment.py` against our normalized submission initially reported 1,907 of 1,914 aligned; all 7 failures were HTML paragraph-count drift caused by models reshaping `<br>`/`<p>` boundaries. Six of the seven carried complete, correct text and were repaired deterministically by re-flowing the existing translation into the source's paragraph structure, under the invariant that the tag-stripped text be byte-identical before and after repair—no translated character changed. The seventh is the English–Thai document discussed in §3.3, which required regeneration rather than re-flow. The final submission scores 1,914 checked / 1,914 aligned / 0 misaligned under the official script.

## 3 Quality assurance

### 3.1 Deterministic instruction-adherence scan

Every document (4,897) was checked mechanically against the task instructions: translation-only output (no commentary or preamble), preservation of `{{placeholders}}`, JSON keys, URLs and @-handles, and HTML tag fidelity. Adherence was effectively perfect: 100% translation-only, ∼100% placeholder/key preservation, with only cosmetic emphasis-tag drift in a handful of documents. Notably, this adherence was achieved with the instruction supplied purely in-prompt (see §4).

### 3.2 Two-judge quality evaluation and self-grading bias

Twelve documents per pair were scored for accuracy and fluency by (a) the pair's own production model and (b) an independent Claude cross-read of the identical documents. Because judge (a) grades its own output, we compared the two columns and found the self-grading bias to be real and directional by family: GPT-5.4 graded its own output harshly relative to the independent judge, while Gemma/Gemini graded leniently. Reading both judges together brackets the truth; we suggest practitioners using production models as judges measure this direction rather than assume a uniform inflation. Most pairs scored in the 4.3–4.9 band; a weak tier (English into Ladin, Northern Sámi, and Ligurian) at 3.2–3.9 exhibited language-purity intrusions from dominant neighbours (Italian, Finnish), which we declared honestly in the model card (§5).

### 3.3 Defect detection and targeted regeneration

Exhaustive scanning surfaced four content defects in 4,897 documents (0.08%), all of which we disclose:

1. **English–Japanese, one document** (`24368-jpn_Jpan`): near-total truncation—the hypothesis was 8 characters against a source of roughly 900. Regenerated with the pair's own routed model.

2. **English–Belarusian, one document** (`00706-bel_Cyrl`): near-total truncation—a 2-character hypothesis. Regenerated with the pair's own routed model.

3. **English–Belarusian, one document** (`00770-bel_Cyrl`): truncated to roughly 20% of the source. Regenerated with the pair's own routed model; the repair was verified for paragraph count, length ratio, and entity preservation.

4. **English–Thai, one document** (`45038-tha_Thai`): degenerate repetition-loop output that also dropped a source paragraph, and the seventh alignment failure of §2.4. Regeneration with the pair's production model reproduced the loop (worse), so this single document was regenerated with a different model (Claude Opus 4.6), verified paragraph-by-paragraph against the source. This is the only document in the submission not produced by its pair's routed model, and it is disclosed in our model card.

The first two defects were caught in the first verification pass over the assembled submission; the third and fourth in later passes, together with the alignment repairs of §2.4. Taken end to end, exactly 10 of the 4,897 documents differ between the raw production output and the submitted file—the four regenerations above and the six deterministic paragraph re-flows of §2.4—and the remaining 4,887 are byte-identical. A re-run of every deterministic check after the final repair reported zero broken outputs.

We note that a defect count is only as trustworthy as the baseline it is measured from. Our first internal statement of this figure was taken against an

intermediate snapshot rather than the raw production output, and consequently undercounted; the numbers above are measured against the generated output itself.

## 4 Ablation: validate-and-retry versus deterministic normalization

The system includes an optional instruction-enforcement layer: post-generation validation of checkable constraints (translation-only, JSON validity, HTML tag balance) with up to three critique-guided retries on failure. A standing design question was whether to enable it for the submission. We ran the gate on real WMT26 test data: 24 documents spanning clean prose, HTML domains, and the JSON domain, generated with the layer on, then compared pairwise-blinded against the layer-off (normalized) outputs by the same two-judge method.

The result was decisive in both directions of interest. On the 14 clean documents the layer was inert—one attempt, zero spurious retries, no degradation. On all 10 JSON documents the layer's retry loop fired, failed all three attempts (the model faithfully re-emits a code fence that mirrors the source formatting, which strict validation rejects), tripled the inference cost, and still delivered fenced output—strictly worse than the deterministic normalization already in place, which repairs the same defect at zero cost. The independent judge preferred the layer-off version on 9 of 10 JSON documents. We therefore shipped with the layer off. The general lesson we draw: when an output defect is deterministic in form (fences, echoes, tag drift), repair it deterministically; reserve model-based retry for defects that are actually semantic.

## 5 Language coverage

We submitted all 23 pairs but focused engineering effort (model shootouts, alignment repair, QA depth) on 17 target languages, declared as primary. Three micro-languages—Ladin, Ligurian, and Northern Sámi—were submitted essentially zero-shot for coverage and declared contrastive (not focused on) in the model card, consistent with their weaker measured quality (§3.2).

## 6 Results

Internal evaluation (two-judge, §3.2) and the official alignment check (1,914/1,914) are reported above. Official human-evaluation results were not available at the time of writing and will appear in the WMT26 findings paper (Kocmi et al., 2026). Per-pair development figures remain withheld (§2.1).

| Direction | Docs | chrF |
|---|---|---|
| Czech–German† | 315 | 79.95 |
| English–Egyptian Arabic | 198 | 75.27 |
| Czech–Vietnamese† | 315 | 72.48 |
| English–German | 198 | 66.33 |
| English–Estonian | 198 | 66.12 |
| English–Icelandic | 198 | 65.42 |
| English–Czech | 198 | 62.93 |
| English–Northern Sámi‡ | 198 | 58.04 |
| English–Ligurian‡ | 198 | 53.20 |
| English–Ladin‡ | 198 | 52.19 |
| English–Japanese | 198 | 52.01 |
| Chinese–Japanese | 190 | 42.36 |
| Macro-average | 2,602 | 62.19 |

Table 1: Post-hoc chrF of the submitted output against the references released by the organizers, for the 12 of 23 directions that have them. †two references, scored multi-reference. ‡contrastive micro-language (§5). Not a ranking; the official measure for this task is human evaluation.

After the shared task released reference translations for part of the test set, we scored our submitted output against them with chrF (Popović, 2015), computed with sacreBLEU (Post, 2018); Table 1 reports the result. These are *post-hoc* measurements: the references were published after the submission deadline and played no part in model selection, generation, or any repair described above. References exist for 12 of the 23 directions (2,602 of 4,897 documents); the remaining 11 have none. Czech–German and Czech–Vietnamese carry two references each and are scored multi-reference.

We report these for transparency, not as a ranking, and make no comparison against other participants' systems. One observation is worth recording. The three contrastive micro-languages (§5) score 52–58 chrF, overlapping the band of several focused directions, yet our two-judge evaluation placed them in a distinctly weaker tier (3.2–3.9 of 5, §3.2). We read this as chrF rewarding character overlap with a dominant related language: output drifting from Ligurian or Ladin toward Italian retains substantial character n-gram agreement with the reference while reading poorly to a speaker. Where the failure mode is language-purity drift toward a close neighbour, character-level metrics are a weak quality signal, and the divergence between the two measurements is itself the finding.

Relatedly, English–Northern Sámi scores 58.04 here against 52.22 on the contaminated development set and 32.58 on real-domain government text (§2.1); three measurements of one direction spanning twenty-six chrF points is a further caution against trusting any single development figure in low-resource pairs.

## 7 Cost and reproducibility

The submission was produced by a single participant on commodity hardware with no local inference. The full 23-pair production run took 49 minutes of wall-clock time and cost $22.12, measured as the provider balance delta across the run ($81.82 to $59.70). The run executed as two invocations five minutes apart: the first completed two pairs ($2.62) before being stopped and restarted with the spend cap raised from $35 to $50; the second completed the remaining 21 pairs ($19.50) in 44 minutes, skipping the two already-finished pairs. We report the whole-run figure rather than the second invocation's self-measured $19.50, which excludes the first two pairs.

Generation is one API call per document (4,897 calls), with no batching; the only additional generation was the four targeted regenerations of §3.3 and the deterministic re-flows of §2.4, which required no inference. The quality-assurance passes added approximately $2.58 (two-judge evaluation $1.68; instruction-layer ablation $0.80; targeted regenerations $0.10), for an end-to-end total just under $25. Same-day calibration and selection batches run before the production window cost roughly $25 more and are excluded from these figures as development rather than production spend. We note the total not as a benchmark but as an existence proof: frontier-model orchestration with serious verification is within reach of independent researchers.

## 8 Conclusion

MakotoAI's WMT26 submission is an argument for minimalism plus discipline: empirically routed single models, untouched generation, deterministic repair, and verification run to exhaustion. The two findings we believe travel beyond this submission are the ablation of §4—deterministic normalization dominated a validate-and-retry layer on real data—and the directional self-grading bias of §3.2. Both are cheap to measure and directly actionable for any API-orchestrated MT system.

## Limitations

The system's quality ceiling is that of the underlying commercial models, which we neither control nor can fully characterize (parameter counts undisclosed). All six models were reached through a single API aggregator, so provider-side routing or version drift is a source of variance we cannot observe. Per-pair selection was performed once before the test period; model updates after selection could shift the optimum. The two-judge evaluation uses LLMs as judges and, despite the cross-read, remains weakest exactly where the translations are weakest (low-resource pairs). One document was produced by a non-routed model (§3.3), disclosed. Results on the three contrastive micro-languages should not be read as focused attempts. Throughout, "defect-free" refers strictly to the mechanical class defined in §1: the submission certainly contains translation errors of the ordinary kind, and we make no claim of hallucination-freedom— semantic fidelity was sampled and judged, not certified.

## Acknowledgments

We thank the WMT26 organizers for the shared task, for the corrected alignment tooling released during the evaluation period, and for their responsiveness on the task mailing list. System development made extensive use of AI-assisted engineering: large language models served as coding, analysis, and drafting assistants throughout the build and in the preparation of this paper, under the verification discipline the paper describes. All design decisions, all disclosures, and the final submission are the author's, who reviewed and takes responsibility for every claim.

## Abstract

This paper presents a Belarusian-specific data-cleaning pipeline and fine-tuning for English-Belarusian machine translation. Our cleaning pipeline distinguishes itself from others by employing a correction tool that addresses the issue of the two orthographies of the Belarusian language, noise in the training data, interference from other languages and other misspelling issues common in Belarusian on the internet. A matched ablation on unfiltered training data shows substantial benefits from filtering for all fine-tuned models, with the LLM-based models gaining roughly twice as much from filtering as the dedicated encoder-decoder MT system, supporting the view that for Belarusian MT one of the primary bottlenecks is data quality.

## 1 Introduction

The uneven distribution of languages across the web and the wide variation in available linguistic resources have left many languages, including Belarusian, under-prioritised in the training and evaluation of machine translation systems. We present a Belarusian-specific data-cleaning pipeline and use the resulting corpus to fine-tune translation models from two neural MT paradigms: NLLB (NLLB Team et al., 2022) as an encoder-decoder system, Gemma-4 (Gemma Team et al., 2026) and TranslateGemma (Finkelstein et al., 2026) as decoder-only LLMs. We release our primary model, the fine-tuned TranslateGemma-12B-IT, under the Gemma Terms of Use.[1]

### 1.1 Belarusian variation

Contemporary written Belarusian displays genuine orthographic variation, having two active graphical codified systems: cyrillic (mostly) and latin (rarely), and featuring two competitive normative systems: the official standard orthography (often informally called *Narkamaŭka*) and the alternative orthography, *Taraškievica*, characterized by lesser codification and the lack of common standardizing authority. Although these names originally referred to different orthographic systems, they subsequently came to denote broader normative systems, thus their differences extend beyond spelling – concerning phonetics, morphology, word formation, vocabulary and syntax. The opposition is not entirely categorical, however, because many grammatical forms, allegedly distinctive for *Taraškievica*, are also admitted, stylistically marked, or used as variants within the official standard (Ramza, 2018). Aparovich et al. (2025, p. 513) found that most digital examples in their sentiment dataset followed the official standard, fewer than 10% used *Taraškievica*, and a small minority used the Latin alphabet *lacinka*. This work focuses exclusively on standard Belarusian orthography. Extending the model to other Belarusian varieties will require dedicated evaluation and training data to ensure adequate, variety-specific performance.

**Language interference.** The existence of several orthographic traditions in Belarusian complicates the formation of coherent training data. As a result, a model may learn from heterogeneous linguistic material, creating noise in its outputs. As Nazaranka (2025, pp. 18–19, 24–27) notes, this may manifest itself, for example, in the coexistence of elements from two orthographies within a single text, the use of erroneous constructions at different levels of language, or unstable switching between different norms. An additional problem is interference from other closely related languages, particularly Russian and, according to our observations, Ukrainian and Polish. These languages may fill gaps resulting from the limited amount of

*The name combines the prefix *re-* with Belarusian мова ('language').

October 28-29, 2026 ©2026 Association for Computational Linguistics

Belarusian-language training data. Such interference may occur not only at the lexical level but also at the phonetic, morphological, syntactic, and stylistic levels.

It is worth noting that a significant portion of the modern Belarusophone community consists of "new speakers" raised in Russian-speaking families (Woolhiser, 2013, pp. 63–65). In Woolhiser's pilot sample, performed in 2013, most of these speakers reported shifting to Belarusian in peer-group communication during adolescence or early adulthood, between the ages of 13 and 22 (Woolhiser, 2013, pp. 86–87). Their usage coexists with the two above-mentioned normative systems and displays variation associated with speakers' differing preferences for forms perceived as more or less divergent from Russian (Woolhiser, 2013, pp. 107–111). Considering current trends in Belarusian language, we suspect that the proportion of "new speakers", that learned Belarusian as the second language, has only grown since the date of Woolhiser's work.

**Misspellings.** Orthographic diversity and language interference should be distinguished from misspellings, pseudo-Belarusian forms, and unreviewed machine translation.

Koshchanka and Martysiuk (2025) identify the low level of proficiency for literary Belarusian, together with the desire to produce texts with minimal effort and an insufficient understanding of automatic translation, as factors contributing to the growing presence of machine-translated language in texts of different genres. According to their analysis, artificial and unnatural forms generated by the early Russian-to-Belarusian translation system *Belazar* entered media texts and, through repetition, gradually began to be perceived as correct. The subsequent use of *Google Translate* and *Yandex Translate* intensified this process, with traces of automatic translation reportedly increasing rapidly across genres. The effects described are not limited to isolated spelling errors. Corpus research reports that machine-translated texts introduce artificially formed lexical items and grammatical constructions into ordinary usage and may produce semantic shifts. This calls into question the value of some Belarusian-language textual data and the extent to which such language can be considered representative for research purposes (Koshchanka and Martysiuk, 2025, p. 146–147) and, by extension, for creating a proper Belarusian dataset.

Liasovich (2024, p. 56) offers a different view, arguing that media texts published online reflect the current state of the Belarusian language's lexical resources and their ongoing transformation, thereby revealing the condition of contemporary living Belarusian.

### 1.2 Importance of data cleaning

Looking at the available parallel data, we also noticed the high degree of variability of modern Belarusian language, which emphasizes the need of a proper data cleaning process that distinguishes normative systems, and cleans obvious errors and language interference issues. We propose a balanced approach that does not step into the internal processes of the language change – not imposing subjective views on how the language should change in the future. In our work we try to stabilise the lexical, orthographical and typographical features of the text, according to the standard Belarusian orthography, while accepting new word-forms, without interfering at the syntactical level of the written texts, although we want to mark that syntax should be the matter of future works in this field.

## 2 Methodology

In this study, we use a custom filtering pipeline, which we refer to as ReMova,[2] that combines current tooling and quality metrics to extract reliable parallel segments. The pipeline is organised into stages, each of which writes its output to a file and records summary statistics. Some stages apply to both sides of the parallel data, such as ftfy,[3] NFKC normalisation,[4] and GlotLID-based language identification,[5] while others address the aforementioned issues specific to the Belarusian side (Wikificator[6] and LanguageTool[7]). A schematic representation of the pipeline is shown in Figure 1.

### 2.1 Belarusian-specific normalisation

A central element of our approach is the strict handling of misspellings and *Taraškievica* forms. We

[5] GlotLID: https://github.com/cisnlp/GlotLID.

[6] Wikificator: https://be.wikipedia.org/wiki/Вікіпедыя:Вікіфікатар.

[7] LanguageTool: https://languagetool.org/.

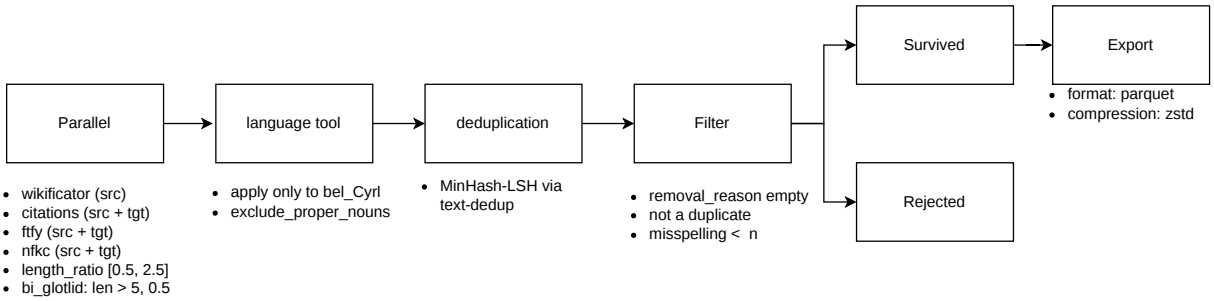

Figure 1: The multiple stages of the ReMova cleaning pipeline employed to ensure the quality of the English-Belarusian parallel dataset.

rely on Wikificator (Belarusian Wikipedia contributors, 2026), a set of regular expressions maintained by the Belarusian Wikipedia community to detect and correct the most common orthographic errors and *Taraškievica* variants found in Belarusian text. We complement this with LanguageTool (LanguageTool, 2026), an open-source proofreading platform whose Belarusian module provides a spellchecker based on the grammatical base of the National Corpus of the Belarusian Language (Koshchanka, 2018). The National Corpus of the Belarusian Language, which is compiled by the Institute of Belarusian Language, currently recommends LanguageTool as the main spellchecker solution for the Belarusian language and contributes to the project (National Corpus of the Belarusian Language, 2026). We therefore considered it the most advanced and reliable solution for our spell-checking workflow. While Wikificator targets a fixed set of high-frequency patterns, LanguageTool offers broader dictionary-based coverage, catching misspellings and grammatical inconsistencies that fall outside the regex rules.

The different stages of the pipeline have distinct roles. Most either normalise text in place (ftfy, NFKC, Wikificator) or annotate each segment with metrics that downstream stages consume: GlotLID adds language-identification confidence, LanguageTool tags the Belarusian side with match counts and match density (matches per non-proper-noun word), and deduplication marks near-duplicates. Removal is concentrated at two places. A dedicated filter stage applies thresholds on the accumulated metrics. Before running the pipeline, we discard trivially short pairs (two words or fewer).

Table 1 shows the effects of the different stages on one of the utilised corpora, Tatoeba. It can be seen that the filter stage dominates the rest:

| Stage | In | Out | Notable effect |
|---|---|---|---|
| prep | 8,980 | 7,899 | 1,081 pairs with $\leq 2$ words dropped |
| parallel | 7,899 | 7,899 | 271 typography, 201 mojibake, 101 NFKC |
| languagetool | 7,899 | 7,899 | 1,051 rows with LT matches (13.3%) |
| dedup | 7,899 | 7,899 | near-duplicates marked (signal-only) |
| filter | 7,899 | 6,953 | 88% survived; 692 LT errors, 231 dup, 23 lang/len |
| BLASER | 6,953 | 6,749 | 204 low-quality pairs dropped (2.9%) |
| export | 6,749 | 6,749 | ∼285 KB parquet (ZSTD) |

Table 1: Tatoeba (Belarusian–English) pipeline execution. 8,980 raw pairs → 6,749 training pairs (75% overall yield).

about 12% of the pairs are dropped there, mostly because they exceed the manually selected LanguageTool density threshold (692 pairs, a proxy for *Taraškievica* influence and chronic misspelling) or were flagged as duplicates (231 pairs). Because the density metric is sensitive to LanguageTool's coverage of Belarusian, we iteratively curated its dictionary: the most frequent matches were either added with their correct spelling or marked as ignorable where the match was a false positive.

## 2.2 Training data

We selected the training dataset through both human review and pipeline-based evaluation. Rather than relying on a single corpus, we combined five sources with per-corpus BLASER (Communication et al., 2023) cutoffs calibrated to their register:

- HPLT web-crawled bitext (Burchell et al., 2025),
- OpenSubtitles-derived paragraph alignments (upsampled 2× to enrich the spoken register; Lison and Tiedemann, 2016),

- Tatoeba crowdsourced pairs (upsampled 2×; Tiedemann, 2020),
- Wikimedia aligned paragraphs (Schwenk et al., 2021a), and
- back-translated segments from a curated subset of HPLT's monolingual Belarusian, itself derived from Common Crawl and the Internet Archive (upsampled 2×).

Table 2 summarises the composition. Per-corpus thresholds were necessary because BLASER's written-text calibration systematically underscores subtitle-style compression even for faithful translations; a uniform cutoff would have discarded most of the spoken-register signal. Other OPUS subcorpora such as WikiMatrix were excluded, as many of their text segments are misaligned.

To strengthen the coverage of informal Belarusian, we augmented the training set with back-translated pairs from selected Common Crawl web resources. To improve the ability of our models to work with spoken registers we created a whitelist-curated subset of the HPLT monolingual Belarusian collection (2,300 segments after cleaning) in two particular registers: ID (Interactive Discussion) and SP (Spoken). The resulting segments were back-translated into English twice with a large language model DeepSeek-V4-Flash (DeepSeek-AI et al., 2026), yielding 4,600 BE-EN pairs whose two targets are textually distinct in 84% of cases and thus function as paraphrastic augmentation.

| Corpus | BLASER ≥ | Rows | × | Share |
|---|---|---|---|---|
| HPLT (web) | 3.5 | 83,770 | 1 | 49.4% |
| OpenSubtitles | 3.0 | 29,849 | 2 | 35.2% |
| Tatoeba | 3.5 | 6,749 | 2 | 8.0% |
| Wikimedia | 3.7 | 7,923 | 1 | 4.7% |
| ID/SP (HPLT) | – | 2,300 | 2 | 2.7% |
| Total | | | | **169,489** |

Table 2: Composition of the fine-tuning corpus. Per-corpus BLASER thresholds are calibrated to each source's register; the × column reports the upsampling factor and *Share* is the resulting share of the combined training set. ID/SP (HPLT) denotes back-translated in-domain parallel text pairs generated from a whitelist-curated subset of HPLT monolingual Belarusian segments.

## 3 Experiments

### 3.1 Identifying strongest baseline

To get a fuller picture, we fine-tune models from both paradigms: an encoder-decoder system and a decoder-only LLM. We target the constrained track which requires releasing a model under 20B parameters under a licence permitting unrestricted non-commercial use (WMT26 General Machine Translation Task Organizers, 2026). We compare a subset of the suggested base models (Gemma-3 (Gemma Team et al., 2025), Aya (Üstün et al., 2024), Qwen-2.5 (Yang et al., 2025)) along with Llama-3.2 (Grattafiori et al., 2024) before fine-tuning to identify the strongest baseline for Belarusian translation. As the encoder-decoder counterparts, we use both NLLB and MADLAD-400 (Kudugunta et al., 2023), a comparably positioned Google model covering 400 languages.

An initial experiment compared base models under 4B parameters, a cap chosen to allow rapid iteration within the available compute budget. Note that no fine-tuning was applied at this stage; the goal was to identify the strongest base model under the parameter budget before committing compute to adapter training.

### 3.2 Fine-tuning

The strongest models were chosen for fine-tuning and further evaluation on the same metrics and dataset: full fine-tuning for the encoder-decoder (NLLB) via `Seq2SeqTrainer`, and LoRA-based supervised fine-tuning of the LLMs (Gemma-4-12B-IT and TranslateGemma-12B-IT) via TRL's `SFTTrainer`. Both regimes use AdamW with warmup ratio 0.05; weight decay is 0.01 for NLLB and 0.0 for the LLMs. LoRA is applied to `all-linear` modules for Gemma-4; TranslateGemma restricts the target set to `q,k,v,o,gate,up,down` projections to avoid adapting the vision encoder. The parameters used for fine-tuning selected models are listed in Table 3. Our training corpus mixes sentence pairs (Tatoeba) with paragraph-level and multi-sentence alignments (Wikimedia, OpenSubtitles, HPLT); the chosen `max_length` budgets (128 per side for NLLB, 256 for Gemma-4 and TranslateGemma) cover the vast majority of pairs, and BOUQuET is evaluated at its native sentence granularity.

### 3.3 Filtering ablation

To quantify the contribution of the ReMova filtering pipeline, we run an ablation in which the selected models are re-fine-tuned on unfiltered data

| | NLLB FT | LLM LoRA SFT† |
|---|---|---|
| Base model | `nllb-200-3.3B` | `gemma-4-12b-it` |
| Epochs | 3 | 2 |
| Eff. batch size | 32 | 16 |
| Learning rate | $3 \times 10^{-5}$ | $1 \times 10^{-4}$ |
| Max seq length | 128 | 256 |
| LoRA ($r$ / $\alpha$ / drop) | — | 16 / 32 / 0.05 |

Table 3: Hyperparameters for fine-tuning. †Both Gemma-4-12B-IT and TranslateGemma-12B-IT share this LoRA recipe.

drawn from the same source corpora. The ablation run matches the cleaned run in both total volume and per-source proportions, so that any difference in downstream translation quality can be attributed to filtering rather than to changes in training data quantity or composition. All hyperparameters (Table 3) and the evaluation protocol are kept identical to the main run.

### 3.4 Evaluation

We use the recent BOUQuET evaluation dataset (Andrews et al., 2025) for its cross-domain sentence coverage and human-verified translations, which lets us track per-domain performance improvements from fine-tuning. The test split contains 854 unique sentences (198 paragraphs), written in the standard Belarusian orthography, across eight domains: comments, conversation, how-to/instructions, narration, other miscellaneous, reflection, social posts, and web miscellaneous, matching the row labels in Table 5. The dev split was used for best-checkpoint selection; all reported metrics come from the held-out test set.

To capture multiple dimensions of translation quality, we report BLEU (Papineni et al., 2002) and chrF++ (Popović, 2017) as surface-level metrics. ChrF++ is more informative for morphologically rich languages, but reporting both is preferable in low-resource settings, as the two metrics expose different translation artefacts (Kumar et al., 2026). We additionally report COMET (Rei et al., 2020), a neural metric that correlates more closely with human judgements. Base LLMs were evaluated with a fixed 3-shot prompt of simple, short demonstration pairs, identical across all base-LLM evaluations.

| Model | Size | BLEU | chrF++ | COMET |
|---|---|---|---|---|
| *Dedicated MT models* | | | | |
| NLLB-200 | 3B | **27.2** | **51.4** | **86.7** |
| MADLAD-400 | 3B | 21.8 | 41.6 | 81.2 |
| *Base LLMs* | | | | |
| Gemma-4† | 12B | **25.2** | 49.1 | 84.8 |
| TranslateGemma†‡ | 12B | 25.0 | **51.7** | **89.6** |
| Gemma-3 | 4B | 22.9 | 46.4 | 84.5 |
| Llama-3.2 | 3B | 10.4 | 30.7 | 69.6 |
| Aya | 3B | 4.6 | 19.8 | 50.5 |
| Qwen-2.5 | 3B | 3.6 | 18.5 | 48.0 |

Table 4: English→Belarusian on BOUQuET test; best per family in bold. Base LLMs use a fixed 3-shot prompt. †Above the 4B screening cap. ‡Native chat template (not 3-shot).

## 4 Results and discussion

### 4.1 Base models

Base model results are summarised in Table 4. Within the dedicated MT family, NLLB-200 outperforms MADLAD-400 by a wide margin at comparable scale (27.2 vs. 21.8 BLEU), consistent with NLLB's targeted Belarusian coverage. Among base LLMs, the Gemma family stands apart: Gemma-3 reaches 22.9 BLEU at 4B. The remaining LLMs trail far behind: Llama-3.2 (10.4 BLEU) recovers only lexical fragments, while Aya and Qwen-2.5 (3.6–4.6 BLEU) are essentially non-functional despite Aya and Qwen-2.5 being positioned as multilingual models, suggesting scale alone does not compensate for limited Belarusian pretraining exposure. Only NLLB-200 and the Gemma family clear the bar for productive fine-tuning; we advance NLLB-200 to full fine-tuning and Gemma-4-12B-IT together with TranslateGemma-12B-IT to the LoRA track.

### 4.2 Fine-tuned models

Fine-tuning results for NLLB, Gemma-4, and TranslateGemma are presented in Table 5, alongside a matched ablation in which the same models are re-fine-tuned on unfiltered data from the same source corpora (§3.3, Table 3).

All three fine-tuned models cluster within a narrow band on aggregate metrics, with TranslateGemma leading both BLEU (32.63) and chrF++ (55.36), Gemma-4 close behind on BLEU (31.40), and NLLB slightly ahead of Gemma-4 on chrF++ (Table 5). The close finish is itself notable: a general-purpose LLM (Gemma-4-12B)

| | | BLEU | | | chrF++ | | | COMET | | |
|---|---|---|---|---|---|---|---|---|---|---|
| Domain | $n$ | base | unfilt. | +FT | base | unfilt. | +FT | base | unfilt. | +FT |

Table 5: Per-domain English→Belarusian test scores. Columns: *base* (pre-fine-tune baseline), *unfilt.* (fine-tuned on unfiltered data from the same sources), *+FT* (fine-tuned on the ReMova-cleaned corpus). Best per row in bold.

with LoRA fine-tuning on cleaned data reaches parity with a fully fine-tuned dedicated MT model (NLLB-3.3B) without any translation-specific pretraining objective.

For TranslateGemma specifically, fine-tuning yields a large lexical improvement (+7.65 BLEU, +3.63 chrF++). Per-domain scores, presented in Table 5, show that fine-tuning improves BLEU in every domain, but by markedly uneven margins: gains range from +9.55 BLEU on Narration and +9.12 on Conversation down to +3.61 on Other misc., the only domain where chrF++ does not improve (−0.17).

Per-domain BLEU gains from fine-tuning vary across models, though Narration improves substantially for all three (+5.2 for NLLB, +9.1 for Gemma-4, +9.6 for TranslateGemma). This is plausibly driven by OpenSubtitles, which contributes 35% of the training data and was upsampled 2× to enrich the spoken register (§2). The distribution of smaller gains differs by model: NLLB benefits least on Reflection and How-to; Gemma-4 on Comments and Conversation and TranslateGemma on Other miscellaneous. Diversifying the stylistic range of training data is a natural direction for future work.

### 4.3 Filtering ablation

To measure the contribution of the ReMova cleaning pipeline in isolation, we compare each model's cleaned fine-tune against a matched fine-tune on unfiltered data from the same source corpora (Table 5, "unfilt." column). Cleaning delivers +1.99 BLEU / +1.10 chrF++ for NLLB, +3.62 / +1.53 for Gemma-4, and +4.38 / +2.63 for TranslateGemma (COMET deltas follow the same ordering). The pattern appears to split along the encoder-decoder-MT versus decoder-only-LLM divide rather than along model size or degree of translation specialisation: NLLB, whose pretraining objective is already close to supervised parallel translation, gains roughly two times less from cleaning than either decoder-only LLM. Notably, TranslateGemma's translation-specialisation does

not close this gap; despite reaching the highest overall quality after fine-tuning, it shows the largest cleaning gain of the three.

At the per-domain level, some cases sharpen this story. For Gemma-4 Conversation, unfiltered fine-tuning actually drops BLEU below the 3-shot base (31.61 vs. 32.54), while cleaned fine-tuning delivers a clear gain (34.74): fine-tuning on noisy data can be net-negative for that domain. On BLEU, cleaning wins every domain for every model except TranslateGemma@Other miscellaneous (−0.09); on chrF++, cleaning wins every domain except three isolated cells (NLLB@Narration, Gemma-4@Comments, and TranslateGemma@Other miscellaneous), consistent with a slightly wider surface-form vocabulary in the unfiltered pool, helping character n-gram matching on domains dominated by rare terms.

As shown in our pipeline results (Table 1), even datasets considered "cleaned" upstream retain substantial noise and require further downstream filtering; we leave deeper investigation to future work. Taken together, the ablation supports the paper's data-quality thesis: for the English–Belarusian pair, systematic filtering of parallel data is a first-order lever on translation quality rather than a secondary tweak.

## 5 Related Work

**Multilingual translation.** While high-resource languages benefit from large parallel corpora suitable for training and evaluating translation models, many low-resource languages long lacked sufficient support. Yet, openly released encoder-decoder systems have been progressively expanding the language coverage: OPUS-MT provided per-pair models trained on the OPUS collection (Tiedemann, 2012; Tiedemann and Thottingal, 2020); M2M-100 introduced many-to-many translation across 100 languages (Fan et al., 2021); NLLB scaled this recipe to more than 200 languages (NLLB Team et al., 2022); MADLAD-400 extended coverage past 400 (Kudugunta et al., 2023); and the recently-announced Omnilingual MT targets 1 600 languages (Alastruey et al., 2026).

**LLM-based translation.** In parallel with the development of dedicated encoder-decoder systems, the scaling of LLMs has opened an alternative path to translation. Off-the-shelf language models were found to already translate well between high-resource languages using few-shot learning (Garcia et al., 2023), but fall behind dedicated systems when translating low-resource languages (Robinson et al., 2023). However, fine-tuning the LLMs can close this gap – with approaches like the Advanced Language Model-based translator (ALMA; Xu et al., 2024). Finetuned from Llama 2 (Touvron et al., 2023), ALMA outperformed the 54B-parameter NLLB model despite its much smaller size of 7B parameters. Its training follows a two-stage recipe: continued pretraining on monolingual data in the target languages, followed by fine-tuning on a modest amount of high-quality bilingual corpus. The authors argue that excessive training on parallel data washes out the LLM's pre-existing knowledge, although a subsequent study (Iyer et al., 2024) shows that this finding does not hold for low-resource languages with limited pretraining coverage. Subsequent work has further refined this recipe: Tower mixes translation with related tasks during fine-tuning, further improving translation quality (Alves et al., 2024; Rei et al., 2024). Its successor, Tower+, scales data quality, quantity, and model size and additionally employs reinforcement learning to refine the generated outputs (Rei et al., 2026). TranslateGemma applies a similar recipe to the open Gemma 3 models, providing one of our fine-tuning bases (Finkelstein et al., 2026).

**WMT General MT Task.** WMT has been focusing on machine translation of low-resource languages for many years: in 2022, the shared task included Livonian and Yakut languages (Kocmi et al., 2022), and the range of low-resource languages has further expanded in the following iterations. In 2023, translation systems based on LLMs started to be competitive in WMT (Kocmi et al., 2023), and then in 2024, finetuned LLM systems started outperforming the standard encoder-decoder approaches (Kocmi et al., 2024). This trend aligns with our findings that the best performance on English-Belarusian translation is achieved with a finetuned LLM.

**Data quality and filtering.** Much of the parallel data behind multilingual MT is web-mined with cross-lingual sentence embeddings: LASER-based mining (Artetxe and Schwenk, 2019) produced corpora such as CCAligned, CCMatrix or WikiMatrix (El-Kishky et al., 2020; Schwenk et al., 2021b,a), and NLLB mined its low-resource bitext with distilled LASER 3 encoders (NLLB Team

et al., 2022). We are using a later improvement of LASER called BLASER in this study (Communication et al., 2023). These heuristically-aligned corpora are known for systematic quality issues, especially for low-resource languages (Kreutzer et al., 2022). Proper filtering of these corpora has thus become an essential step in training NMT systems, supported by tools such as Zipporah (Xu and Koehn, 2017), Bicleaner and Bifixer, its neural successor (Ramírez-Sánchez et al., 2020; Zaragoza-Bernabeu et al., 2022), as well as the modular OpusFilter and OpusCleaner toolkits (Aulamo et al., 2020; Bogoychev et al., 2023). These pipelines combine many approaches but remain largely language-agnostic; our work follows the same overall design while adding Belarusian-specific orthographic normalisation and spellchecking that generic tools cannot provide.

## 6 Conclusion

In this work, we presented ReMova, a Belarusian-specific data-cleaning pipeline, and fine-tuned translation models for the English–Belarusian language pair across both the encoder-decoder and decoder-only paradigms. The pipeline combines language identification, Unicode normalisation, spelling correction with Wikificator and LanguageTool, detection of misaligned parallel segments, and filtering or replacement of *Taraškievica* and obvious non-Belarusian forms; applying it exposed substantial noise even in datasets we initially considered higher-quality. On the cleaned corpus, full fine-tuning of NLLB-200-3.3B, LoRA fine-tuning of Gemma-4-12B-IT, and LoRA fine-tuning of TranslateGemma-12B-IT produced comparable performance on the BOUQuET test set, with TranslateGemma leading on every reported metric (32.63 BLEU, 55.36 chrF++, 90.03 COMET) and Gemma-4 reaching parity with the fully fine-tuned dedicated MT baseline without any translation-specific pretraining objective. A matched ablation in which each model was re-fine-tuned on unfiltered data from the same sources showed substantial BLEU gains from filtering for all three models, with the decoder-only LLMs (Gemma-4 $+3.62$, TranslateGemma $+4.38$) gaining roughly two times more than the dedicated encoder-decoder MT system NLLB ($+1.99$); chrF++ and COMET follow the same architectural split. Taken together, these results support the hypothesis that for the English–Belarusian pair, data quality is a first-order lever on translation quality.

Several directions remain for future work. Scaling back-translation beyond the current 2,300 curated HPLT segments (using a larger monolingual pool, additional back-translation models, and pivoting through related higher-resource pairs such as Belarusian–Russian) could broaden training coverage beyond OPUS-derived sources. Diversifying the stylistic range of training data would likely close the per-domain gap on formal and reflective content. Finally, human evaluation and statistical-significance testing would give the model rankings and ablation deltas reported here a firmer footing than metric-based comparison alone.

## Limitations

We did not conduct a thorough human evaluation, which would provide the strongest signal of translation quality and help analyse mistakes. Metrics such as BLEU underestimate quality for morphologically rich languages like Belarusian and may correlate weakly with human judgements. COMET was trained on human judgements dominated by high-resource language pairs and has not been meta-evaluated on Belarusian; absolute COMET values reported here should be treated as internally consistent within this paper rather than directly comparable to published COMET numbers on other language pairs. We did not test the statistical significance of our results, which would be especially valuable for the smaller ablation gaps and the tight ordering between models.

Some larger or potentially more capable models for Belarusian translation were not evaluated. We did not benchmark against commercial systems such as Yandex Translate or Google Translate, which cover Belarusian; comparison with a strong commercial baseline would help calibrate our absolute scores against production-quality MT and is left for future work. The few-shot examples used for base-LLM evaluation may have affected performance and should be varied in future evaluations to test prompt sensitivity.

Compute constraints motivated the LoRA-only setup for the LLM fine-tuning and the 4B parameter cap on the initial base-LLM screen; both choices may have affected the absolute scores and the cross-model comparisons. The hyperparameter search was limited, and we cannot guarantee the chosen settings were optimal.

## Use of AI assistants

During the preparation of this work, the authors used Claude (Anthropic, `claude-opus-4-7`, `claude-opus-4-8`, `claude-opus-5-0`) and GPT (OpenAI, `gpt-5.6-sol`) to assist with writing the paper, specifically for refining wording and proofreading. All AI-assisted output was reviewed and edited by the authors, who take full responsibility for the correctness, design decisions, and content of the submitted work. No sensitive or personal data was entered into the tools, and all data handling complied with the University of Oslo's data regulations.

## A Belarusian tokenisation across tokenisers

To get insights on Belarusian cyrillic text tokenisation, we constructed the evaluation sample of 1 013 384 characters from the Belarusian Wikipedia articles listed by *Special:LongPages*, processing them in descending page-length order, and made a benchmarking on several tokenisers. Articles were retrieved as plain text through the MediaWiki API. We retained only paragraphs classified as Belarusian whose alphabetic characters belonged exclusively to the Belarusian alphabet, and concatenated complete article extracts until the sample exceeded one million characters. The resulting text was passed unchanged to each tokeniser.

For the Benchmark we used several tokenisers, available at The Tokeniser Playground (Xenova) and the tokeniser from CLARIN project, specifically made for Belarusian language (Hetsevich et al., 2022).

| **Tokeniser** | **Token count** | **Token/ character** |
|---|---|---|
| `Xenova/gpt-4` | 663445 | 0,655 |
| `Xenova/claude-tokeniser` | 684587 | 0,676 |
| `Xenova/gemma-tokeniser` | 448819 | 0,443 |
| `Xenova/llama-tokeniser` | 519320 | 0,512 |
| CLARIN Tokeniser | **326903** | **0,323** |

Table 6: Token counts for the same Belarusian text sample of 1 013 384 characters and 263 707 words from Belarusian wikipedia *Special:LongPages* at the moment of 2 August 2026.

# Apertium-sme-eng for WMT2026 shared task—creating new pair by crossing dictionaries and translating rules

**Flammie A Pirinen**
UiT Norgga Árktalaš universitehta

Tromsø, Norway
first.last@uit.no

## Abstract

In this article I describe an experiment on creation of a new rule-based machine translation model build on two existing models. I built Apertium system between North Sámi and English based on existing translation models between North Sámi and Finnish, and Finnish and English. There were two expert-driven processes involved in building of the system: firstly crossing and validating the bilingual dictionaries and secondly translating and modifying the grammatical and structural rules. I briefly explain why there are no pre-existing systems for this language pair and what limitations and ethical issues are related to it. I will also evaluate some of the training and development corpora provided in the shared task to elaborate on the problem that automatic low quality machine translation can cause to vulnerable minority languages.

## 1 Introduction

North Sámi (ISO-639: se, sme)[1] is an Indigenous low resource language from Uralic language family. There is a long tradition of rule-based natural language processing within Uralic languages and also specifically with North Sámi. This includes several rule-based machine translation systems between North Sámi and languages that are closely related, e.g. other Sámi languages, related and relevant majority languages, e.g. Finnish (ISO-639: fi, fin) in North Sámi speaking areas of Finland, or just related majority languages like the Norwegian Bokmål (ISO-639: nb, nob) language in North Sámi areas of Norway. There was no pre-existing rule-based machine translation that we know of between North Sámi and English (ISO-639: en, eng). Apertium is a rule-based machine translation system that is most popularly used for low-resourced languages including North Sámi and medium-resourced languages like Finnish. This article describes an experiment for building a new Apertium language pair from existing language pairs. Two practical approaches or workflows were used to build the necessary resources for a baseline translator: the North Sámi—English dictionary was created by semi-automatically combining North Sámi—Finnish and Finnish—English dictionaries, and the grammatical and structural transfer rules were created by translating and adapting the rules from the Finnish—English pair.

The shared tasks in WMT[2] are nowadays mainly directed towards data-driven methods like AI, rather than knowledge-driven methods like rule-based machine translation. However, high quality gold data is also crucial for rule-based machine translation. Instead of learning rules from data, the gold translations are used as tests when creating dictionaries and rules. I will describe the process of using corpus data for development phase of rule-based machine translation to draw a parallel towards data-driven approaches. In this article I also briefly go through some problems I faced when using the WMT 2026 data during the testing and development face of my system.

Finally I discuss about the ethical issues in creating machine translations, especially into a low resourced language that is more vulnerable to disruption.

## 2 Background

North Sámi is an Indigenous language in Uralic language family. It is spoken by approx. 25,000 people according to Wikipedia citing Ethnologue, most of the speakers are bilingual with most common majority language being Norwegian or Finnish. Like all Uralic languages, North Sámi is more morphologically complex than Indo-European lan-

[1] we use the ISO-639 codes as shorthand throughout the article in tables etc.

[2] https://www2.statmt.org/wmt26/index.html

*Proceedings of the Eleventh Conference on Machine Translation*, pages 1391–1396
October 28-29, 2026 ©2026 Association for Computational Linguistics

guages. North Sámi is low resource language; the available corpora are in range of few millions of tokens (SIKOR, 2018) and with the number of speakers it is not feasible to expect large corpora of human-written high quality texts in next few years (Steingrímsson et al., 2024). English is an Indo-European language with high resources and number of speakers. It is morphologically simpler than Uralic languages and has different syntactical features. The linguistic distance between languages makes it more tricky for automatic machine translation, especially linguistic rule-based system.

Apertium is a rule-based machine translation system, that is especially popular within low resource languages and also various minority language contexts. (Khanna et al., 2021) Apertium is based on modular system, where the translation is build on pipelines that support different technologies and implementations. For the North Sámi—English experiment, I use standard modern Apertium pipeline with finite-state morphological analysis and generation, lexical transfer, and recursive descent transfer, I did not implement anything extra for the other components (such as anaphora resolution, gapped multiword detection etc.) of the system within the context of the shared task. The resulting system I have built, works for both English-to-North Sámi and North Sámi-to-English directions, but for this paper, I concentrate on the shared task direction English-to-North Sámi. The background for this is elaborated in the discussion section.

The concrete technical implementation of the pipeline at the time of writing was as follows:

1. Finite-State morphology analysis, using HFST (Lindén et al., 2011)
2. Morphological disambiguation, using VISL CG 3 (Bick and Didriksen, 2015)
3. Dependency syntactic disambiguation, using VISL CG 3
4. Apertium pre-transfer
5. Lexical translation using Apertium lttoolbox
6. Lexical selection using Apertium lextools
7. Recursive descent syntactic transfer using Apertium recursive
8. Finite-State morphological generation using Apertium lttoolbox
9. Post-processing using Apertium lttoolbox

For morphological generation (and analysis) of North Sámi I have used the North Sámi language model from GiellaLT repository (Pirinen et al., 2023) called *giella-sme*[3]. This is a mature morphological analyser and disambiguation also used in other apertium-based North Sámi language pairs. For morphological analysis (and generation) of English I have used Apertium's standard *apertium-eng*[4] model.

There are several existing North Sámi translation models in apertium repository:

- apertium-sme-nob[5]: Norwegian—North Sámi (Trosterud and Unhammer, 2012),
- apertium-sme-fin[6]: Finnish—North Sámi (Johnson et al., 2017), and
- apertium-sme-sma[7]: South Sámi—North Sámi (Antonsen et al., 2016),

but there is no existing English—North Sámi pair. I have made use of related high-resource language Finnish and Finnish—English (Pirinen, 2019) resources to help start the development of North Sámi—English.

## 3 Data

There are two types of existing data I utilised in this experiment: dictionaries and rules from pre-existing apertium models and corpora for testing and development.

The language models I used are summarised in the Table 1, as well as our resulting language model that I built during this experiment.

For this experiment, I used the corpora available from the shared task. (Goldhahn et al., 2012; Tiedemann, 2012) There were some problems[8] with the scripts for downloading the corpora that resulted in different machines I used during the testing having slightly different datasets, I have therefore summarised the one that seems most complete in the Table 2.

[3] https://github.com/giellalt/lang-sme
[4] https://github.com/apertium/apertium-eng
[5] https://github.com/apertium/apertium-sme-nob
[6] https://github.com/apertium/apertium-sme-fin
[7] https://github.com/apertium/apertium-sme-sma
[8] e.g. downloads.wortschatz-leipzig.de timed out on 2 of 3 machines I used to run the tests

| Language(s) | Word(pair)s |
|---|---|
| *Giella-sme* | 141,000 |
| *Apertium-eng* | 60,000 |
| *Apertium-sme-fin* | 20,000 |
| *Apertium-fin-eng* | 164,000 |
| **Apertium-sme-eng** | 66,000 |

Table 1: North Sámi and English language data used for building apertium-sme-eng

| Corpus collection | size in MiB |
|---|---|
| OPUS | 2.4 |
| Leipzig | 3.2 |

Table 2: North Sámi corpora in WMT 2026 shared task

While testing the system I have built, I discovered some problems with the dataset, for example, the dataset `OPUS-opensubtitles-v2024-eng-sme.sme` does not appear to have a single word North Sámi, but is fully written in South Sámi (ISO-639: sma) instead.[9] Some other datasets like `OPUS-wikimedia-v20230407-eng-sme.sme` contain some North Sámi parts but also large parts in English, Norwegian and other languages; this is not totally unexpected of Wikipedia to contain large snippets of other languages, but it can become unwieldy and unsuitable if this kind of texts dominate the "training corpus". While tests in North Sámi as input language are not crucial for the use case of building rule-based machine translation from English to North Sámi, they will be for the other translation direction should we continue with that and also for other approaches.

## 4 Methods

In this experiment, I set out to test the process and workflow of building a new language pair for apertium based on existing pairs. The two main components of this experiment are the building of the bilingual dictionary by combining lexical data from other related pairs, or *crossing* dictionaries, and building the structural translation rules by translating and adapting rules from the related pairs. The related pairs we used for this experiment are North Sámi—Finnish and Finnish—English, which are both high coverage dictionaries and have relatively mature structural transfer rules. One of the design goals for this methodology is that it needs to be expert-driven, and semi-automatic, while it would be possible to fully automate this process, in my view, the main value of bilingual dictionaries and grammars in apertium project is that they are human-verified.

Creating new bilingual dictionaries by crossing has been used in context of apertium before. There is an outdated Java programme for this in apertium wiki[10], however, it was faster for me to roll out new interactive dictionary crossing tool in python, given the design requirements, than modify the existing tools in Java. The dictionary crossing logic is relatively straightforward, when crossing sme-fin and fin-eng, we go through words in all dictionaries, and if there is a lemma match in target side of sme-fin and source side of fin-eng, we suggest it as bilingual translation sme-eng. The linguist gets to accept, discard or give penalty weight for each word pair. The penalty weights in apertium's lexical translation work so, that if there is ambiguity, the word-translation with lowest weight gets selected. Throughout the process of ranking translation pairs, few heuristics arose to help the semi-automated ranking:

- if parts-of-speech don't match, default to reject
- if multi-word-entry (i.e. the lemma contains whitespace), add weight
- if either word-pair has existing weight or extra restrictions, add weight

An example of resulting translation set presented to linguist might look like Figure 1. The linguist needs to approve the heuristics or modify the results by accepting, discarding or ranking the word pairs, which generally takes no more than few seconds per word for a person knowing the three languages. For the first ranking run it is recommended to leave hard problems unsolved rather than delving into etymologies and background materials.

The structural rules were created by translating and adapting existing rules, in this case we used English to Finnish rules to create English to North Sámi rules. While languages are closely related, the rules need both translating and adapting, for example the possession in Finnish and North Sámi is expressed by a copula verb and possessor in specific

[9] Despite being related language, the overlap in surface words and mutual intelligibility is limited and therefore the dataset is useless for automated testing or training.

```

Figure 1: Tidied up example of a semi-automatic dictionary crossing session by a linguist

case, but the copula verb needed to be translated and the case is also different, adessive in Finnish but locative in North Sámi. As another example, the verb paradigms of North Sámi include dual forms while Finnish only has singulars and plurals, on the other hand North Sámi does not usually pro-drop despite having full verb paradigms whereas Finnish generally does pro-drop.

For testing and development of the resulting system, we used the corpus data available as part of the shared task. The corpus-based development in context of apertium means running the whole corpora through the translator and reading through the automatically translated texts to find which things are translated wrong, and then fixing them. For this experiment, I only reviewed words that didn't get translated due to them being missing from the dictionaries, I mainly focussed on words missing in bilingual dictionary, and went through both high frequency ones and ones that appeared in the several texts I read more thoroughly. For structural transfer errors, I fixed the most obvious ones that appeared in reading the texts.

The overall workflow that I propose can be summarised in a kind of a cascade of two-step processes, where one first generates candidates of linguistic data based on either corpora, curated test cases or programmatic manipulation of existing data, then a linguist goes through each and every output (e.g. translation, grammar rule, …), either validating them or modifying them.

1. programmatically generate candidate translations by crossing dictionaries and
2. a linguist accepts, discards and ranks them, then
3. programmatically generate candidate rules by copying and replacing and
4. a linguist translates and adapts them, eventually with larger edits if there are divergences between grammars of languages, then
5. programmatically generate OOV lists from training corpora and
6. a linguist translates them (starting in frequency order when there is no time to finish it all) then
7. $^\star$ e.g. generate lexical selection rules from corpora (Tyers et al., 2012) and
8. a linguist goes through and accepts or discards them ($^\star$ we did not reach this phase in the experiment of this paper but it would be one of the likely next steps)
9. …

The effort needed to semi-automatically validate the bilingual dictionary was roughly a week's work, and the testing and development maybe one more work-day, where the work was carried among other non-related tasks. To compare, usual development time of new language pair is approximately 3 months (e.g. student project, Google Summer of Code) before it starts to be usable for any purpose.

## 5 Discussion

Both within the Apertium project and within our project for building resources for Sámi languages, we generally only work on systems and applications that are useful to the language user community. The reason why there is no high demand for English to North Sámi machine translations is that practically all speakers are bilingual, with either Finnish or Norwegian as another language. Most will also be fluent in English. Therefore, many of the common use cases of automatic machine translation from majority to minority languages can actually pose threat to the language and the language community:

- instead of hiring professional translators to do translations, companies and governments send out machine translated documents
- amount of machine translated documents in our corpora overtake the amount of human written documents

To exacerbate the problems, even the existing corpora, that have been used to train these machine translators, do not contain similar quantities of grammatically correct texts with current orthography as one is used to from a established long-term majority language point-of-view; this means

that data-driven models are likely to generate more spelling and grammar errors. As such we generally only build machine translators for the direction of from minority language to majority language, this has several use cases that empower the minority langauge community to use their language while allowing the majority language community to understand, for example in social media. However, for experimentation, such as this article's subject matter, a language pair that is not highly sought after, is perfectly suitable.

## 6 Conclusion

With this experiment we found out that crossing dictionaries and translating rules can be a good starting point for a new language pair, where there is available existing resources in related pairs. The work needed to start a new pair in this way is relatively low. The results from the initial work are not yet good enough for actual use in any normal use cases. However, the pair selected for the competition doesn't have an expected use case so using it for experimentation was a good fit.

## Limitations

The experimental translation model that was built in this article does not represent a mature translation system, while care was taken to manually verify the quality of dictionaries and rules. The system provides insight into possibilities and limitations of semi-automatically created rule-based machine translation pairs and will require further work to be used in end-user systems or even further research.

## Ethical Considerations

Linguistic work was performed by a fully paid computational linguist, no crowd work was used. Compiling and running a rule-based machine translation uses negligible amount of electricity on a local, low-end laptop and wastes no drinkable water.

Automatic machine translation from English to North Sámi has mainly ethically problematic use cases and may contribute to deterioration in quality of North Sámi corpora. The experiment was performed and system will be published to gain insight in semi-automated system building in the super high resource to low resource setting, it is important that the published open source system won't be used for corpus creation or automatic translation without professional translator.

## Acknowledgments

Some of the computations were performed on resources provided by Sigma2 - the National Infrastructure for High-Performance Computing and Data Storage in Norway.

## Abstract

We describe YANDEX and YANDEX-8B, our unconstrained and constrained submissions to the WMT26 General Machine Translation task. Our previous WMT25 submission, a 7B translation specialist, shows strong Fluency but comparatively weaker Accuracy. To combine its translation behavior with the capacity of a much larger model without replaying the full 7B training pipeline at 235B scale, we add two forms of supervision to the instruction-tuning data of an in-house 235B pretrained model: direct translation targets generated by the 7B specialist and in-house translation-related tasks. The resulting YANDEX model improves both Accuracy and Fluency and reduces the LLM-based error score relative to the same 235B model tuned only on general instructions. Relative to the 7B specialist, it improves Accuracy and reduces the error score, while their Fluency point estimates remain similar. YANDEX then provides hard targets for YANDEX-8B, which is trained for English-to-Russian, English-to-Belarusian, English-to-Kazakh, and English-to-Armenian using direct and instruction-conditioned translation data. Across four directions, YANDEX-8B obtains the highest paragraph-level ChrF++ and the highest Accuracy and Fluency under our LLM-based evaluation among five public baselines.

## 1 Introduction

We present the Yandex submissions to the WMT26 General MT shared task (Kocmi et al., 2026). General-purpose large language models (LLMs) are capable translation systems, but competitive machine translation (MT) systems still benefit from task-specific post-training. Existing recipes (Xu et al., 2024a; Karpachev et al., 2025; Wang et al., 2025; Kocmi et al., 2025a) combine monolingual adaptation, supervised fine-tuning (SFT) on parallel data, preference optimization, teacher-generated data, and quality-aware decoding. Our WMT24 (Elshin et al., 2024) and WMT25 (Karpachev et al., 2025) submissions combine different subsets of supervised fine-tuning, preference optimization, structure-preserving supervision, MT post-pretraining, and local-context decoding. Other WMT25 systems (Zheng et al., 2025; Wang et al., 2025; Kocmi et al., 2025a) additionally use multi-teacher distillation, reinforcement learning, post-editing, and Minimum Bayes Risk decoding. Repeating a complete multi-stage recipe becomes expensive for a model with hundreds of billions of parameters. We ask whether an existing translation specialist can instead transfer useful translation behavior through the instruction-tuning pipeline of a much larger model.

Our starting point is the team's 7B English–Russian WMT25 submission, published as Yandex+WMT and referred to here as YANDEX-7B-WMT25 (Karpachev et al., 2025). In our current ORBIT-SC evaluation (Section 3.3), it shows high Fluency but substantially weaker Accuracy than the evaluated frontier LLMs. The system also used local decoding blocks because translation quality declined for inputs of several hundred tokens. We use it as a source of fluent translation targets and ask whether a larger model can improve accuracy and context-sensitive translation choices.

For the unconstrained submission, we use an in-house 235B pretrained model. It was initialized from Qwen3-235B weights (Yang et al., 2025) and then trained using an in-house pretraining pipeline. We tune two models from this checkpoint. GENERAL-235B uses general Russian- and English-language instruction data. YANDEX uses the same general data augmented with direct translation targets from YANDEX-7B-WMT25 and in-house translation-related tasks. This keeps YANDEX in the instruction setup anticipated for WMT26.

YANDEX then provides hard targets for our constrained 8B model. YANDEX-8B is trained for English-to-Russian, English-to-Belarusian,

*Proceedings of the Eleventh Conference on Machine Translation*, pages 1397–1404
October 28-29, 2026 ©2026 Association for Computational Linguistics

English-to-Kazakh, and English-to-Armenian. Its data combines direct translation examples, matched instruction-conditioned examples, and dedicated JSON and HTML subsets.

Our contributions are:

- We adapt an in-house 235B model using targets from our 7B WMT25 specialist and translation-related instruction data. The resulting YANDEX model improves Accuracy and Fluency over the same 235B model tuned only on general instructions. Relative to the 7B model, it improves Accuracy while their Fluency point estimates remain similar.

- We use YANDEX as the teacher to train an 8B model for the constrained track on direct and instruction-conditioned examples in four translation directions. YANDEX-8B obtains the highest paragraph ChrF++ and the highest LLM-based Accuracy and Fluency among five evaluated public baselines in every direction.

## 2 Related Work

### 2.1 Multi-stage MT adaptation

Decoder-only LLMs can be adapted to MT through task-specific training. ALMA (Xu et al., 2024a) combines monolingual language adaptation with fine-tuning on a small, high-quality parallel corpus. Our previous English–Russian system (Karpachev et al., 2025) uses MT post-pretraining, parallel-data SFT, and two alignment stages. Synthetic supervision includes decoded teacher sequences, established in sequence-level knowledge distillation (Kim and Rush, 2016), and LLM outputs used as SFT targets by recent WMT systems.

Learning from human preferences is a common post-training paradigm for LLMs. DPO (Rafailov et al., 2023) directly optimizes a model on preferred and dispreferred responses without fitting a separate reward model. For MT, CPO (Xu et al., 2024b) uses a contrastive objective over preferred and dispreferred translations, although improvements under an alignment metric need not remain stable across neural and lexical metrics (Gisserot-Boukhlef et al., 2024). Command-A-Translate (Kocmi et al., 2025a) combines preference optimization with post-editing and limited Minimum Bayes Risk decoding. Shy-hunyuan-MT (Zheng et al., 2025) distills candidates from multiple LLMs and subsequently applies Group Relative Policy Optimization with a composite reward. Marco-MT (Wang et al., 2025) similarly assembles a multi-stage pipeline comprising two-stage SFT with data distillation, two-stage reinforcement learning, and hybrid alignment-aware and Minimum Bayes Risk decoding. Together, these systems combine multiple data, training, alignment, and decoding stages whose repetition at hundreds of billions of parameters is computationally costly.

### 2.2 Instruction-conditioned MT

Instruction-conditioned MT extends language-direction prompts with requirements concerning style, terminology, domain, or output form. ParroT (Jiao et al., 2023) represents such requirements through translation hints in an instruction-tuned LLM. The Tower model family (Alves et al., 2024) builds TOWERBASE through multilingual continued pretraining and TOWERINSTRUCT through subsequent instruction tuning on tasks from the translation workflow. Raunak et al. (2024) distill instruction-following behavior into a substantially smaller NMT model. Their setup combines formality control, domain adaptation, and multimodal translation, and supports multiple instructions at once. Together, these methods encode translation requirements beyond the source and target languages.

### 2.3 MT evaluation protocols and metrics

Human MT evaluation ranges from fine-grained expert error analysis under MQM (Freitag et al., 2021) to ESA (Kocmi et al., 2024), which combines error-span marking with a continuous quality score. Automatic evaluation includes learned scalar metrics such as MetricX-24 (Juraska et al., 2024) and error-aware metrics such as xCOMET (Guerreiro et al., 2024), which also localizes and categorizes translation errors. LLM-based evaluators can instead elicit MQM-style annotations directly, as in GEMBA-MQM (Kocmi and Federmann, 2023). Scalar metrics support aggregate comparison, while span-based outputs localize predicted errors.

Translation quality is multidimensional. RATE (Popov et al., 2025) separates Accuracy and Fluency and uses a finer error-severity scale than conventional MT evaluation protocols. Its expert English–Russian evaluation found that strong MT outputs could exceed human translations in Accuracy while remaining below them in Fluency.

Table 1: Judge-normalized paragraph-level English-to-Russian results on WMT25. Systems are sorted separately in each panel. Green, gray, and red indicate significantly better, not distinguished, and significantly worse results than YANDEX under the paired bootstrap.

Because this trade-off is central to our analysis, we report Accuracy and Fluency separately.

## 3 Yandex: Unconstrained System

### 3.1 Starting Points and Motivation

We use three names for the large-system experiments. YANDEX-7B-WMT25 is our previously published 7B translation specialist. GENERAL-235B and YANDEX are tuned from the same in-house 235B pretrained model, which was initialized from Qwen3-235B weights (Yang et al., 2025) and then trained using an in-house pretraining pipeline. GENERAL-235B is tuned on an in-house general instruction dataset composed primarily of Russian- and English-language instructions. YANDEX uses the same general data augmented with the translation and translation-related data described below. It is our WMT26 unconstrained submission.

The human RATE evaluation reported in our WMT25 system paper (Karpachev et al., 2025) shows a fluency-oriented quality profile for YANDEX-7B-WMT25: it receives higher Fluency and Style but lower Accuracy than the evaluated GPT-4.1 and Claude 4 outputs. Replaying its complete post-training pipeline at 235B scale would be costly. Instead, we use its translations as targets within the instruction tuning of the larger model and test whether this setup can combine the 7B model's Fluency with the higher Accuracy and better context-sensitive translation choices of the general-purpose 235B model.

### 3.2 Translation-Augmented Instruction Tuning

Most of the added supervision consists of direct English-to-Russian translation. We pair diverse English source texts with prompts that request only the translated text. YANDEX-7B-WMT25 generates the targets.

The mixture also includes in-house translation-related tasks, for example, explaining a word in context, changing the style of a translation, applying a glossary, editing a translation, or assessing translation quality. We retain general instruction data so that YANDEX remains an instruction-following model. This design reflects our expectation that WMT26 inputs would express diverse translation requirements through instructions.

### 3.3 Paragraph-Level Translation Quality

We evaluate English-to-Russian translation on 332 paragraphs from the WMT25 General MT test set (Kocmi et al., 2025b) spanning 87 documents and four domains. We use two ORBIT-SC (Popov et al., 2026) runs backed by GPT-5.4 and Claude-4.6-Opus. ORBIT-SC is our single-call LLM implementation of the RATE protocol (Popov et al., 2025). It assigns separate Accuracy and Fluency

scores and predicts error spans. For each translation, we compute the corresponding MQM score as $5N_{\text{major}} + N_{\text{minor}}$.

For each judge, we first compute A/F as the arithmetic mean of Accuracy and Fluency. We then macro-average the four domains and standardize Accuracy, Fluency, A/F, and MQM separately over the systems shared by both evaluation runs. Finally, we average the corresponding judge-wise $z$-scores. Unlike the four-direction 8B evaluation in Section 4, which uses GPT-5.4 alone, this comparison gives equal weight to two judges with different score scales.

Table 1 shows that the translation-augmented mixture performs significantly better than GENERAL-235B on all four measurements under the paired bootstrap.

Compared with YANDEX-7B-WMT25, YANDEX has higher $z_{\text{Acc}}$ and $z_{\text{A/F}}$ and lower $z_{\text{MQM}}$. Their $z_{\text{FL}}$ point estimates are close. This profile shows improved Accuracy with a similar Fluency point estimate to the 7B specialist. Since all translation-related components are added together, the result cannot be attributed to the 7B targets alone.

The external systems illustrate the same accuracy–fluency trade-off. GPT-5.5 has higher $z_{\text{Acc}}$ than YANDEX, whereas YANDEX has higher $z_{\text{FL}}$. Their $z_{\text{A/F}}$ and $z_{\text{MQM}}$ point estimates are close. YANDEX outperforms GPT-4.1 and Claude 4 on $z_{\text{A/F}}$ and $z_{\text{MQM}}$. Claude-4.6-Opus has higher $z_{\text{Acc}}$ and lower $z_{\text{MQM}}$ than YANDEX, while their $z_{\text{A/F}}$ and $z_{\text{FL}}$ point estimates are close. The two Gemini systems obtain the strongest aggregate scores under this evaluation.

### 3.4 Terminology and Named Entities

We additionally evaluate the three systems on an in-house 820-example terminology and named-entity benchmark. The set targets translation choices that require domain context or model knowledge. For example, *opening* has a specialized translation in Russian chess terminology that differs from its translation outside the chess context.

Errors are categorized as Critical, Major, or Minor. For $N$ examples, we compute

$$\text{Penalty} = \frac{6N_{\text{critical}} + 3N_{\text{major}} + N_{\text{minor}}}{N}, \quad (1)$$

where lower is better.

GENERAL-235B reduces the penalty from 0.765 for the 7B specialist to 0.378 on this context- and knowledge-sensitive evaluation. The translation-augmented YANDEX model further reduces it to 0.340, with fewer Major and Minor errors than GENERAL-235B. Together with Table 1, these results show the intended complementary profile: the 235B models obtain lower terminology penalties than the 7B specialist, while YANDEX retains a similar $z_{\text{FL}}$ point estimate.

| System | Penalty ↓ | Critical | Major | Minor |
|---|---|---|---|---|
| **Yandex** | 0.340 | 2 | 27 | 186 |
| General-235B | 0.378 | 1 | 35 | 199 |
| Yandex-7B-WMT25 | 0.765 | 18 | 87 | 258 |

Table 2: Results on the in-house terminology and named-entity benchmark ($N = 820$ for every system).

## 4 Yandex-8B: Constrained System

### 4.1 Task Setting and Starting Model

Our constrained submission, YANDEX-8B, is trained for English-to-Russian, English-to-Belarusian, English-to-Kazakh, and English-to-Armenian translation. We initialize it from the approximately 8B-parameter YandexGPT-5-Lite-8B pretrained checkpoint (Yandex, 2025). We release the submitted weights on Hugging Face.[1]

During development, the WMT26 General MT task description emphasized instruction-conditioned translation and ESA-based evaluation (WMT26 General MT Organizers, 2026). We expected prompts to specify domain, style, terminology, or structure while requiring only the translation as the response. The final test input contained four prompt templates, but we trained on a broader range of translation requirements.

### 4.2 Instruction and Translation Data

We collect English source texts from news, social, spoken-dialogue, and literary domains, together with JSON and HTML inputs. Translation instructions, usually written in Russian, are selected from an in-house instruction collection. We retain requests whose response should contain only a translation. For each source text, the 235B model selects ten candidate instructions. A second model rates their compatibility with the text on a 1–10 scale. We retain pairs scoring above 8. The instructions are independent of the target language. We specify the translation direction separately, allowing the

Table 4: ORBIT-SC results on WMT25 General MT source paragraphs. Best scores at the displayed precision are in bold, except for the marked MADLAD value discussed in the text.

same matched instruction–source pair to be reused across all four directions.

The resulting mixture contains matched instruction-conditioned examples and direct translation examples. It also contains dedicated JSON and HTML examples with format-preservation instructions. All targets are hard labels generated by the 235B YANDEX teacher. The combined dataset contains approximately one million examples across the four directions. We tune the 8B starting checkpoint on this mixture. YANDEX-8B denotes this supervised checkpoint and is the model submitted to WMT26.

We also tested a two-stage route to adapt the model more explicitly to Belarusian, Kazakh, and Armenian. The first stage used only URL-mined parallel data, with at least 50 million examples per direction, and the second used the instruction mixture above. We identify multilingual versions of web pages through language-specific URL variants and align the corresponding pages at the paragraph or sentence level. This route did not improve our development results. The hard-label mixture may already provide sufficient coverage, while URL-aligned web pages can contain machine-translated or otherwise low-quality parallel text and may require stronger filtering.

### 4.3 Contrastive Preference Optimization

Starting from the supervised checkpoint, we test an additional Contrastive Preference Optimization (CPO) (Xu et al., 2024b) stage. We generate candidate translations with Gemma-4-31B-IT (Gemma Team, 2026), DeepSeek-V4-Pro (DeepSeek-AI, 2026), GLM-5.2 (Z.ai, 2026), Qwen-3.7 (Qwen Team, 2026b), and YANDEX. DeepSeek-V4-Pro compares sampled candidate pairs side by side to produce preferred and dispreferred translations. We report one representative development checkpoint as YANDEX-8B-CPO. It was not submitted.

### 4.4 Evaluation

For reference-based evaluation, we use paragraph-level BOUQuET (Andrews et al., 2025), which provides references for all four directions. Table 3 reports ChrF++ (Popović, 2017) with its default configuration and MetricX-24-XXL (Juraska et al., 2024). To reflect the constrained track's 20B-parameter limit, all five public baselines have at most 20B parameters: TranslateGemma-12B (Finkelstein et al., 2026), Qwen-3.5-9B (Qwen Team, 2026a), MADLAD-400-10B (Kudugunta et al., 2023), NLLB-200-3.3B (NLLB Team, 2024), and GPT-OSS-20B (OpenAI, 2025).

For reference-free evaluation, we evaluate translations of official English source paragraphs from WMT25 General MT (Kocmi et al., 2025b) with ORBIT-SC, using GPT-5.4 as a single fixed judge.

We report Accuracy, Fluency, and the MQM score defined in Section 3.3, and macro-average each score within domain and then equally across domains.

### 4.5 Results and Analysis

As shown in Table 3, the submitted YANDEX-8B obtains the highest paragraph ChrF++ among the five public baselines in all four directions. Its MetricX score is best among those baselines for English-to-Kazakh and English-to-Armenian, while TranslateGemma-12B is slightly better on English-to-Russian and English-to-Belarusian. Table 4 shows that YANDEX-8B also obtains the highest ORBIT-SC Accuracy and Fluency scores among the public baselines in every direction.

The CPO checkpoint produces mixed changes. ChrF++ improves on three directions and decreases slightly on English-to-Kazakh. MetricX improves on three directions but also worsens on English-to-Kazakh. ORBIT-SC Accuracy moves in both directions, and Fluency is lower on all four directions. MQM improves on all four directions, but Accuracy and Fluency do not show a consistent benefit. We therefore selected the supervised checkpoint for the submission.

The marked MADLAD-400-10B English-to-Armenian score illustrates a limitation of span-count aggregation. It has a low MQM score despite low Accuracy and Fluency. A diagnostic proxy flags 99 of 332 outputs as likely non-translations, including 91 with Accuracy zero. These outputs receive a lower mean MQM score than the remaining outputs (22.97 versus 35.64) because their critical spans are fewer but much longer on average (129 versus 37 characters). We therefore interpret MQM together with Accuracy and Fluency. The proxy is not a human label and is used only to diagnose the aggregation behavior.

## 5 Conclusion

We described two WMT26 systems connected through hard-label training. Our 7B WMT25 translation specialist generates English-to-Russian targets for the instruction tuning of an in-house 235B model. The resulting YANDEX system improves both Accuracy and Fluency over the same 235B model tuned only on general instructions. YANDEX then becomes the teacher for YANDEX-8B, our constrained model for four translation directions.

On BOUQuET, YANDEX-8B obtains the highest paragraph ChrF++ among five evaluated public baselines in every direction. On WMT25 General MT source paragraphs, it obtains the highest ORBIT-SC Accuracy and Fluency among the same baselines in every direction. An additional CPO stage produces small and inconsistent changes, so the submitted system is the supervised checkpoint. Overall, the results show how a compact MT specialist, a large instruction model, and a constrained multilingual student can be connected without repeating the complete multi-stage MT pipeline at the largest scale.

## Abstract

This paper presents Wayfinder, our submission system for the WMT26 General Machine Translation (GenMT) shared task. GenMT evaluates document-level translation under natural-language instructions, where structural preservation, formatting constraints, and output cleanliness are part of translation quality. Rather than training a new translation model, Wayfinder treats four API-based system outputs as a document-level candidate pool and produces one final hypothesis through a four-stage agentic pipeline. It aggregates source, instruction, metadata, candidates, and a DeepSeek-V4-Pro ranking-then-scoring signal; applies an anonymized pick-or-rewrite agent; and runs a conservative postcheck for severe objective defects. During development, a judge-guided loop compares outputs with a GPT-5.5 baseline, analyzes loss cases, updates prompts and repair constraints, and selectively reprocesses difficult documents. In automatic pairwise evaluation against GPT-5.5, Wayfinder obtains a pooled document-level weighted win rate of 0.6537 and remains above parity in every evaluated direction. The results suggest that candidate-pool translation, constrained agentic selection, conservative repair, and selective judge-guided iteration are practical components for instruction-conditioned shared-task MT.

## 1 Introduction

Large language models have substantially changed the design space of machine translation (Achiam et al., 2023; Bai et al., 2023; Alves et al., 2024). Beyond improving general translation quality, they make it possible to condition translation on rich, task-specific instructions, moving MT closer to settings where the desired output is defined by both linguistic meaning and downstream use constraints. This shift is reflected in the WMT26 GenMT shared task[1], which evaluates document-level translation under natural-language instructions and extends prior work on document-level MT toward instruction-conditioned evaluation. In such an instruction-conditioned setting, a system is expected to preserve the meaning of the source document while also satisfying explicit requirements on structure, formatting, register, and output cleanliness, such as retaining markup, placeholders, JSON keys, URLs, and line breaks. These requirements are related to constrained generation, where output validity depends not only on content quality but also on satisfying explicit lexical or structural constraints (Hokamp and Liu, 2017; Rei et al., 2025; Sun et al., 2026). As a result, adequacy and fluency alone are insufficient: a translation that reads naturally may still fail the task if it breaks a required format, drops a protected token, or adds content disallowed by the instruction.

Motivated by this instruction-conditioned setting, our submission, Wayfinder, is built on the observation that current LLM translation systems are strong but complementary. Across language directions, document types, and constraint patterns, the best hypothesis may come from different systems, and even a generally strong model may occasionally violate a required structure or protected token. Rather than training a new translation model, Wayfinder treats several system outputs as a document-level candidate pool and uses an agentic selection-and-rewriting stage to produce one final hypothesis per document. This design echoes earlier MT system-combination, reranking, and minimum Bayes-risk selection work (Kumar and Byrne, 2004; Freitag et al., 2021b), while adapting the idea to LLM-based translation, where performance remains sensitive to language, domain, and prompting setup (Jiao et al., 2023; Cui et al., 2025; Wang et al., 2026).

Wayfinder operationalizes this idea as a four-stage agentic pipeline. First, it constructs a per-document evidence record by aligning the source

*Proceedings of the Eleventh Conference on Machine Translation*, pages 1405–1413
October 28-29, 2026 ©2026 Association for Computational Linguistics

document, natural-language instruction, target-language metadata, four candidate translations, and a ranking-then-scoring judge signal. Second, it anonymizes candidate identities and asks a pick-or-rewrite agent to either select the strongest existing hypothesis or synthesize a corrected translation from the candidate pool under an explicit rubric. Third, a conservative postcheck detects severe objective defects, such as broken structure, truncation, repetition, wrong-language residue, or malformed JSON, and applies either deterministic repair or targeted regeneration. Finally, during development, a judge-guided iteration loop treats GPT-5.5 as an anchored baseline and performs multi-round tuning: it compares system outputs against the baseline, identifies judge-underperforming documents, updates prompts and postcheck configurations from the observed failure modes, and reprocesses those documents with the goal of improving beyond the baseline.

As a shared-task system paper, our goal is to make these design choices transparent rather than to claim a new training method. We describe how Wayfinder builds document-level evidence, constrains the agent's decision space, hides candidate provenance during selection, checks only severe objective failures, and uses judge feedback to tune the system across rounds. We also report internal diagnostics, including a small anonymization ablation, to explain why the submitted configuration was chosen; these analyses are intended to characterize the system before official evaluation rather than to establish general claims about automatic judging or anonymization.

The rest of the paper is organized as follows. Section 2 describes the Wayfinder pipeline. Section 3 presents the data, candidate systems, agent models, and judging setup. Section 4 reports automatic development results and diagnostics. Section 6 summarizes limitations.

## 2 System Description

### 2.1 Pipeline Overview

Wayfinder produces exactly one translation for each source document. Let $d$ denote a document, $\iota_d$ its instruction, and $\mathcal{C}_d = \{h_1, \ldots, h_K\}$ the candidate translations from $K = 4$ base systems. The pipeline has four stages:

1. **Evidence aggregation**: join the source document, instruction, target-language metadata, four candidate translations, and a unified ranking-then-scoring judge signal by `doc_id`.

2. **Anonymized pick-or-rewrite**: call an LLM agent on anonymized candidates and judge signals; the agent either picks one candidate or rewrites a fused output.

3. **Conservative postcheck**: detect severe objective defects, then either apply a deterministic repair or ask a repair agent to regenerate with the detected problems as constraints.

4. **Judge-guided iteration**: during development, use GPT-5.5 as an anchored baseline selected from the base-system ranking results; compare each round against it, diagnose judge-underperforming documents, update prompts and postcheck configurations, and selectively re-run those documents to improve the system beyond the baseline.

Figure 1 summarizes the four stages and the development-time feedback loop.

### 2.2 Evidence Aggregation

The first stage converts heterogeneous inputs into a single per-document evidence record. For each `doc_id`, this record contains the source document, natural-language instruction, target-language metadata, four candidate translations, and a unified preference signal from a ranking-then-scoring judge. The goal is to provide the downstream agent with a document-local view of the candidate pool rather than a set of disconnected model outputs.

In our experiments, this judge is instantiated with DeepSeek-V4-Pro (DeepSeek-AI et al., 2026). It evaluates all four candidates in one call, conditioned on the same source document and instruction. It first produces a global ranking, allowing ties when candidates are indistinguishable under the task requirements, and then assigns scalar scores consistent with that ranking. Compared with independent pairwise judgments, this formulation keeps the ranking and score evidence calibrated within the same four-way comparison. The resulting signal summarizes both the judge's preferred hypothesis and the confidence structure of the candidate pool, including cases where candidates are close or complementary.

All inputs are aligned by `doc_id`. Judge outputs that are missing or malformed are preserved as missing fields, not converted into negative evidence. In such cases, the pick-or-rewrite agent

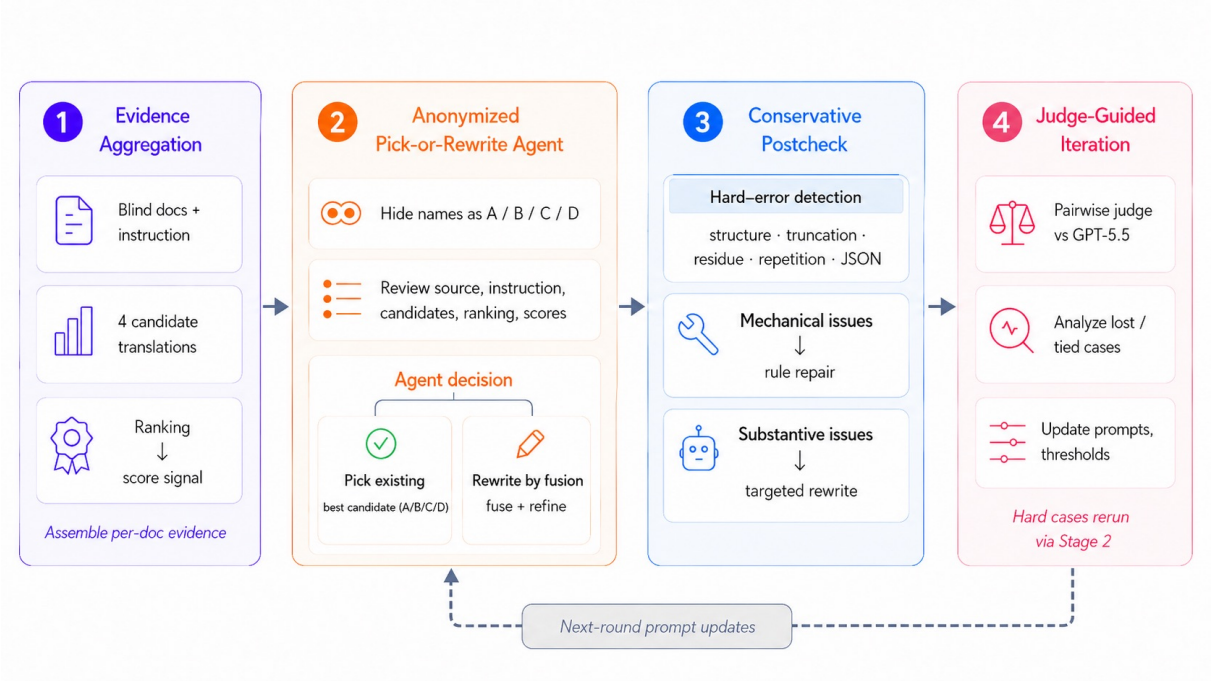

Figure 1: Overview of Wayfinder, our WMT26 GenMT submission system. The pipeline aggregates per-document evidence from four candidate translations, uses an anonymized pick-or-rewrite agent and a conservative postcheck, and applies judge-guided multi-round tuning during development.

still receives the source, instruction, metadata, and candidate translations; the absent judge signal simply removes one source of preference evidence. We also preserve row-level target-language metadata instead of deriving it only from file names, since some WMT26 directions contain fine-grained target-language codes or share target scripts across different source languages.

### 2.3 Anonymized Pick-or-Rewrite Agent

The second stage converts the aggregated evidence record into a single translation hypothesis. For each document, the agent receives the source, instruction, four anonymized candidate translations, and the ranking-then-scoring signal described above. Its output is constrained to a small decision schema:

```
{
  "chosen_base": "A|B|C|D",
  "action": "pick|rewrite",
  "final_translation": "...",
  "issues": ["..."],
  "reason": "..."
}
```

The action field separates two kinds of decisions. When the agent selects `pick`, the final translation is required to be identical to the chosen candidate, preserving a high-quality hypothesis without unnecessary modification. When it selects `rewrite`, the chosen candidate is treated as the primary draft, but the agent may incorporate corrections from the other candidates. Thus, rewriting is used only when fusion or targeted correction is expected to improve the final output, for example by combining the structural fidelity of one candidate with the terminology, completeness, or fluency of another.

**Candidate anonymization.** Before the agent call, Wayfinder masks the provenance of the four candidate systems. For each document, the real system names are mapped to neutral labels A/B/C/D by a stable document-specific permutation. The same anonymized labels are used consistently in the candidate block, ranking, score fields, and textual references to candidate identity. The real mapping is retained outside the prompt for analysis, but it is not exposed to the decision agent.

This design is intended to make the agent compare candidates using document-local evidence rather than model identity. Because the label assignment changes across documents while remaining reproducible for a given document, any residual preference for a particular letter is not consistently tied to a particular base system.

**Evaluation rubric.** The agent prompt uses an ordered rubric to make the decision criteria explicit. The criteria are loosely aligned with error-based

MT evaluation, Direct Assessment, and MQM-style analysis, while being simplified for a system prompt rather than a human annotation protocol (Graham et al., 2013; Lommel et al., 2014; Freitag et al., 2021a). The first two are hard constraints:

1. Instruction adherence: satisfy register, formatting, placeholder, URL, hashtag, markup, JSON-key, and output-only requirements in the task instruction.

2. Structural full match: preserve JSON shape, HTML tag tree, line count, placeholders, punctuation, whitespace, and newlines.

3. Fidelity: avoid omissions, additions, and hallucinations.

4. Terminology, named entities, numbers, dates, and units.

5. Grammar: pronouns, gender, number, tense, and agreement.

6. Register and formality.

7. Target-language fluency.

8. Output cleanliness: no source-language residue, meta-commentary, or stray code fences.

The ranking and score signals are presented as advisory evidence, not as binding decisions. The agent is instructed to override them when direct inspection of the source, instruction, and candidate translations reveals a structural or adequacy problem. The prompt also includes a pass-through exception for garbled or non-linguistic inputs: a candidate identical to the source is not treated as erroneous by itself when translation is not well-defined.

**Robustness to malformed decisions.** Although the agent is prompted to return a schema-constrained decision, malformed outputs can occur. If the chosen candidate label is invalid, the controller attempts to recover it by matching the final translation against the candidate strings. If the decision cannot be parsed or recovered, the system falls back to the top candidate from the ranking-then-scoring judge when available, and otherwise to GPT-5.5. This ensures that every document receives a final hypothesis.

| Postcheck signal | Repair policy |
|---|---|
| Length ratio | Flag likely truncation or over-generation; regenerate when the mismatch reflects content loss or expansion. |
| Repeated chunk | Flag repeated spans not licensed by the source; regenerate when the pattern indicates looping. |
| Line-count mismatch | Flag broken line structure; regenerate unless the difference is limited to blank lines. |
| Latin residue | Flag unexpected Latin text in non-Latin targets; regenerate when it reflects wrong-language residue. |
| JSON validity | Flag malformed structured output; repair mechanically when safe, otherwise regenerate. |
| Empty output | Flag empty or extremely short hypotheses; regenerate. |

Table 1: Postcheck signals and repair policies.

### 2.4 Conservative Postcheck

The third stage is a conservative safeguard for severe objective failures in the current hypothesis. It is not intended to be a general post-editor: open-ended stylistic improvement is avoided because unnecessary rewriting can introduce regressions. Instead, the postcheck asks two narrow questions. First, does the hypothesis exhibit a hard failure that would make the output unusable under the instruction? Second, if such a failure is present, what is the least invasive repair that can address it? This focus on severe failures is motivated by known hallucination, omission, and instability phenomena in neural and LLM-based MT systems (Raunak et al., 2021; Guerreiro et al., 2023).

The detector combines lightweight rules with a repair controller. The rules flag hypotheses that are likely to contain structural or content-level defects, such as truncation, repetition, wrong-language residue, broken JSON, or line-count mismatch. Table 1 summarizes the rule triggers and their typical repair actions.

For each flagged hypothesis, the repair controller chooses among three outcomes. When the issue is purely mechanical and the correction is unambiguous, the system applies a deterministic rule-based repair; for example, it can restore missing code-fence boundaries or repair a recoverable delimiter mismatch in an otherwise intact structured output. When the issue reflects a substantive translation failure, such as hallucination, large omission, wrong-language output, repeated generation,

or a structure mismatch that loses content, the system calls a repair agent. The repair agent receives the source, instruction, current hypothesis, original candidates, and detected issue labels, and regenerates a corrected translation under those constraints. When the flag appears to be a false positive, the hypothesis is kept unchanged.

The repair prompt is deliberately restrictive. It permits edits only for severe failures, including large truncation or omission, hallucination, broken JSON/HTML/line structure, repeated generation, wrong-language output, empty or extremely short output, or incorrect key entities, numbers, and dates. It explicitly forbids tone polishing, synonym substitution, and minor register adjustments. If a repair decision cannot be parsed, the system keeps the original hypothesis rather than risking an uncontrolled change.

Postcheck is applied iteratively by re-scanning the current output after each repair round. In development, this iterative rescanning converged within a small number of repair rounds.

### 2.5 Judge-Guided Iteration

The final stage uses automatic judgments as a development signal for multi-round system tuning. Section 4.1 shows that Qwen3.7-Max and GPT-5.5 form a near-tied top group among the four base systems. We use GPT-5.5 as the anchored baseline because it provides a stable strong single-system reference point: Qwen3.7-Max has a slightly higher Top-1 share, while GPT-5.5 has the higher strict-first rate. Since Qwen3.7-Max also serves as the inference model for the agentic decision and repair components, using GPT-5.5 as the baseline keeps the evaluation anchor distinct from the model that constructs Wayfinder outputs. The baseline is therefore not treated as a gold reference or as the uniquely best base system; it is a fixed anchor for measuring whether prompt and postcheck changes improve the pipeline.

At the end of each development round, the current Wayfinder output is compared against the GPT-5.5 baseline at the document level with randomized A/B presentation. Documents with poor judge outcomes, including losses and selected low-confidence ties, are selected for error analysis. For these documents, the analysis agent examines the source, instruction, system output, baseline output, agent issue codes, postcheck flags, and ranking-then-scoring evidence. The analysis is used to identify recurring failure modes, such as over-aggressive rewriting, failure to preserve structure, weak handling of a particular genre, or over-reliance on a high-scoring candidate.

The next round then updates the system configuration rather than the underlying translation models. Possible updates include revising the pick-or-rewrite prompt, sharpening decision instructions, adding or tightening postcheck rules, or changing repair-agent constraints. Only the selected underperforming documents are reprocessed with the updated configuration, while documents with satisfactory judge outcomes are carried forward. This selective procedure keeps the loop practical while still using judge feedback to push the assembled system beyond the anchored baseline.

During development, we keep the output of each round. For each `doc_id`, the final development set can then use the strongest hypothesis observed so far according to the development judge. We report gains from this procedure only as development diagnostics, since this selection is part of system construction rather than a separately controlled experiment.

## 3 Experimental Setup

### 3.1 Task and Data

We participate in 28 language directions selected from the WMT26 GenMT blind test set. For the selected directions, we parse the raw JSONL blind-test records and group them by source and target language. The resulting submission and automatic evaluation cover 19,880 documents.

### 3.2 Base Candidate Systems

The candidate pool contains four API-based translation systems: Gemini 3.1 Pro,[2] Gemini 3.5 Flash,[3] GPT-5.5,[4] and Qwen3.7-Max.[5] GPT-5.5 is also used as the anchored baseline in our automatic pairwise evaluation, following the ranking-then-scoring results reported in Section 4.1. This gives a fixed near-best comparison point across language directions while still allowing Wayfinder to select or rewrite from any of the four candidates.

[3] https://deepmind.google/models/model-cards/gemini-3-5-flash/

[4] https://developers.openai.com/api/docs/models/gpt-5.5

[5] https://qwen.ai/blog?id=qwen3.7

### 3.3 Agent and Judge Models

Qwen3.7-Max serves as the inference model for the agentic components, namely the pick-or-rewrite agent, the postcheck repair agent, and the round-analysis agent; it is also included in the base candidate pool. To keep automatic evaluation independent of this agentic decision model, the ranking-then-scoring judge and the automatic pairwise evaluation judge are instantiated with DeepSeek-V4-Pro (DeepSeek-AI et al., 2026). Structured stages are constrained to produce JSON outputs matching the schemas described in Section 2.

### 3.4 Automatic Judging Protocol

Automatic development evaluation uses DeepSeek-V4-Pro to compare the system output (SYS) against the GPT-5.5 baseline (REF), aligned by `doc_id`. The protocol is intended as an internal diagnostic rather than a replacement for human evaluation, echoing prior concerns about MT evaluation reliability and judge bias (Zheng et al., 2023; Kim, 2025). The judge sees randomized A/B presentation order and returns one of

$$\text{SYS} \gg \text{REF}, \quad \text{SYS} > \text{REF}, \quad \text{TIE},$$
$$\text{REF} > \text{SYS}, \quad \text{REF} \gg \text{SYS}.$$

We report a weighted win rate. The metric gives 3 points to a strong SYS win, 1 point to a slight SYS win, 0.5 points to a tie, and 0 points to losses, normalized by the maximum possible score. This metric gives more weight to decisive improvements and strong failures.

These automatic scores were used for development and analysis as internal measurements of the system configuration. We use pairwise LLM judging as a development diagnostic rather than standard reference-based metrics such as BLEU, METEOR, TER, chrF, BERTScore, BLEURT, or COMET, since the current task also stresses instruction adherence and hard format constraints (Papineni et al., 2002; Banerjee and Lavie, 2005; Snover et al., 2006; Popovic, 2015; Zhang et al., 2020; Sellam et al., 2020; Rei et al., 2020).

## 4 Results

### 4.1 Base-System Ranking Results

We first summarize the ranking-then-scoring results for the four base systems, using DeepSeek-V4-Pro as the automatic judge. This analysis motivates the document-level selection design and determines the anchored baseline used in the final pairwise evaluation. Table 2 reports aggregate rank-based metrics over the 28 submitted directions. Because raw score values are not directly comparable across all scoring procedures, we aggregate Top-1 share and strict-first rate rather than average scores.

| System | Top-1 | Strict first |
|---|---|---|
| Qwen3.7-Max | 27.3 | 17.7 |
| GPT-5.5 | 27.1 | 19.6 |
| Gemini 3.5 Flash | 26.6 | 16.6 |
| Gemini 3.1 Pro | 19.0 | 10.7 |

Table 2: Aggregate ranking-then-scoring results for the four base systems over the submitted directions. Values are percentages; tied Top-1 positions are fractionally allocated.

The results show that no single base system dominates the candidate pool. Qwen3.7-Max and GPT-5.5 form a near-tied top group: Qwen3.7-Max has the highest Top-1 share by a very small margin, while GPT-5.5 has the highest strict-first rate. Given this mixed evidence, we do not treat the ranking table as identifying a unique best base system. For the pairwise evaluation below, we use GPT-5.5 as REF as a fixed, strong single-system anchor for measuring whether Wayfinder improves over a near-best candidate. At the same time, it keeps the reference system distinct from Qwen3.7-Max, which serves as the inference model for Wayfinder's agentic decision and repair stages. The baseline selection does not constrain the pipeline itself, which may still select or rewrite from any of the four candidates on a document-by-document basis.

### 4.2 Final Pairwise Results against GPT-5.5

Table 3 reports automatic pairwise judging of Wayfinder against GPT-5.5 over the 28 submitted directions. Under this protocol, every judged direction remains above parity under weighted win rate. The per-direction scores range from 0.5283 to 0.8668, and pooling all document-level judgments gives an overall weighted win rate of 0.6537.

The highest scores occur in directions with many decisive SYS wins, such as `en-ind_Latn` and `cs-vie_Latn`. Directions with high tie rates, such as `tr-en` and `en-es_ES`, remain close to the GPT-5.5 baseline. Strong-loss rates are higher in a small number of directions, especially `en-lij_Latn`, `zh-jpn_Jpan`, and `en-sme_Latn`, indicating that the aggregate gains are not uniform across directions.

| Direction | $n$ | SYS≫REF | SYS>REF | TIE | REF>SYS | REF≫SYS | Wtd. |
|---|---|---|---|---|---|---|---|
| en-ind_Latn | 198 | 53.0 | 26.8 | 3.0 | 12.1 | 5.1 | **0.8668** |
| cs-vie_Latn | 315 | 39.4 | 34.0 | 3.5 | 16.5 | 6.7 | **0.8008** |
| cs-deu_Latn | 315 | 30.5 | 42.2 | 6.3 | 14.9 | 6.0 | **0.7908** |

| en-kaz_Cyrl | 0.6096 | 0.6788 | +6.9 pts |
| en-zh_CN | 0.7241 | 0.7335 | +0.9 pts |
| en-ukr_Cyrl | 0.6680 | 0.6566 | -1.1 pts |

Table 4: Effect of candidate-identity anonymization on weighted win rate in three development directions.

### 4.3 Development Diagnostics

We use the following diagnostics to explain several design choices in the submitted system. They are not intended as standalone controlled experiments; rather, they summarize observations that guided the final configuration of Wayfinder. Table 4 compares two candidate-identity settings on three development directions: a name-exposed configuration, where the agent saw the real system names, and the submitted anonymized configuration, where candidates were presented only as A/B/C/D.

The anonymized setting is not uniformly better in aggregate score, but it reduces the chance that the decision agent relies on model provenance rather than document-local evidence. We therefore treat anonymization as a conservative design choice, especially for preventing severe selection errors, rather than as an independent source of consistent score gains.

The postcheck diagnostics support a similarly conservative interpretation. For example, on en-zh_CN, it changed 31 of 945 outputs (3.3%), including deterministic restoration of dropped code fences and targeted repairs for hard structural defects. Across development runs, the postcheck was mainly activated by mechanically verifiable defects, such as missing code fences, broken structured output, line-count mismatch, repetition, or empty hypotheses. This behavior is consistent with its intended role: it is a safeguard against invalid or clearly defective translations, not a general rewriting stage.

Finally, judge-guided iteration was used to tune the system configuration rather than the underlying translation models. Documents with satisfactory pairwise outcomes were carried forward, while documents with losses or low-confidence ties were reprocessed after prompt or postcheck updates. In early development runs, this selective procedure reduced the number of documents sent to later

rounds by roughly 60%, and cross-round selection improved the weighted score by about 2–5 points over the best individual round. We report these numbers as development diagnostics because the iteration loop is part of the system-building process rather than an isolated algorithmic result.

## 5 Conclusion

We presented Wayfinder, our submission to the WMT26 GenMT shared task. Wayfinder is organized as a four-stage pipeline: it aggregates document-level evidence from four candidate translation systems and a ranking-then-scoring judge, applies an anonymized pick-or-rewrite agent, performs conservative postcheck for severe objective errors, and uses judge-guided iteration during development to refine prompts and repair behavior. This design targets instruction-conditioned document translation, where preserving structure, formatting, and task-specific constraints is part of translation quality rather than a separate post-processing concern.

In internal automatic pairwise evaluation against GPT-5.5, Wayfinder remains above parity in all 28 submitted directions, with an overall pooled weighted win rate of 0.6537. These results support the utility of document-level candidate selection, constrained rewriting, severe-error postchecking, and selective judge-guided iteration for instruction-conditioned shared-task MT when strong base systems are complementary rather than uniformly ordered.

## 6 Limitations

Wayfinder has three main limitations. First, the pipeline is relatively expensive: each document starts from four API-based candidate translations and may additionally require ranking, agentic selection or rewriting, postcheck, and selective reprocessing. This design is suitable for an offline shared-task submission, but it is not optimized for low-latency or cost-constrained deployment. Second, Qwen3.7-Max is used both as one candidate translation system and as the inference model for the pick-or-rewrite, repair, and round-analysis agents. Although candidate anonymization and the use of a separate DeepSeek-V4-Pro judge reduce direct provenance effects, this concentration may still introduce model-family-specific preferences into the final system behavior. Third, Wayfinder depends on the diversity and quality of the four-system candidate pool; errors shared by all candidates are difficult for a selection-and-rewriting pipeline to correct reliably. Future work should explore more efficient candidate filtering and judging, broader candidate pools, and stronger safeguards against model-specific decision bias.

## Abstract

We describe the AMI team's submission to the WMT 2026 General Translation shared task, participating in the English→Icelandic translation direction. Building on our 2025 submission, which relied on a 3B-parameter model and substantial rule-based post-processing, this year we aim to reduce that dependency and rely more on the translation model itself. We continually pre-train a Qwen3-4B checkpoint on a mixture of Icelandic, English, code, math, and structured data, then fine-tune it with LoRA on a retrieval-augmented, domain-conditioned instruction-tuning dataset covering five domains. At both training and inference time, source sentences are enriched with dictionary entries and back-translated example translations similar to the sentence being translated, retrieved by a dedicated RAG server, and served through a self-healing inference client that retries and validates generations. We report COMET and chrF++ scores comparing this system against last year's submission, a larger Llama-3.1-8B model adapted with the same recipe, and an instruction-tuned Qwen3-4B baseline, alongside ablations that isolate the contribution of each part of the retrieval-augmented prompt.

## 1 Introduction

Machine translation into Icelandic, a morphologically rich language with roughly 350,000 native speakers, remains a low-resource setting even as general-purpose large language models (LLMs) have become competitive translators for high-resource pairs. The AMI team's 2025 WMT submission (Jasonarson and Steingrimsson, 2025) addressed this with a 3B-parameter fine-tuned model paired with substantial rule-based post-processing to correct systematic model errors after generation. For this year's version (Kocmi et al., 2026), we continue experimenting with smaller models and investigate how far a smaller model can be pushed by moving correction earlier in the pipeline: rather than post-editing a finished translation, we augment the model's input with retrieved dictionary entries and similar example translations at both fine-tuning and inference time, and replace heavy post-hoc correction with a lightweight, on-the-fly validate-and-retry loop during decoding (Section 5). We refer to this combination—retrieving bilingual dictionary entries for terms appearing in the source and retrieving similar sentence pairs from a reference corpus, and injecting both into the translation prompt—as *dictionary retrieval-augmented generation* (DRAG), following the terminology of Zheng et al. (2024).

Concretely, we continually pre-train a Qwen3-4B (Qwen Team, 2025) checkpoint on a mixture of Icelandic, English, code, math, and structured-data text (Section 3.1), then fine-tune it with LoRA (Hu et al., 2022) on a retrieval-augmented, domain-conditioned instruction dataset spanning five domains (Section 3.2). We use LoRA rather than full fine-tuning as we are aiming for an approach that demands the least compute.

At both training and inference time, source sentences are enriched with entries from three bilingual dictionaries and with similar sentence pairs retrieved from a large back-translated reference corpus. The resulting adapter is served behind an OpenAI-compatible endpoint and queried through a client that validates each generation against a small set of rules and resamples on failure (Section 5).

We evaluate this system against our 2025 submission, an 8B-parameter Llama model adapted with the same recipe, and an instruction-tuned Qwen3-4B baseline that received no Icelandic-specific adaptation, alongside a set of ablations isolating the contribution of each component of the retrieval-augmented prompt (Section 6). We release the

fine-tuning dataset[1], retrieval pipeline[2], and model weights[3] publicly.

## 2 Related Work

Adapting a multilingual base model to a target language via continued pre-training (CPT), rather than training from scratch, is now a common recipe for extending LLM coverage to lower-resource languages, see e.g. Joshi et al. (2025). When prompted with few-shot in-context examples, LLMs have been shown to be competitive translators (Garcia et al., 2023) without any translation-specific fine-tuning at all. Our system instead combines lightweight fine-tuning with retrieval-augmented prompting, aiming to get the benefit of both.

Low- and medium-resource languages often lack sufficient data to pre-train broadly capable models from scratch and are frequently underrepresented in multilingual pre-training corpora, resulting in weaker performance than for high-resource languages. A promising alternative is to adapt an existing model to the target language through CPT, which has yielded substantial improvements for languages such as Basque (Corral et al., 2025) and Estonian (Dorkin et al., 2026). However, training predominantly on target-language text risks catastrophic forgetting of capabilities inherited from the base model, degrading performance in other languages and domains (Zhao et al., 2024; Elhady et al., 2025). Replaying English data during CPT mitigates this degradation (Elhady et al., 2025), and recent language-adaptation efforts accordingly mix target-language text with English (Fujii et al., 2024; Joshi et al., 2025) and, sometimes, with data such as code and mathematics (Dorkin et al., 2026).

Selecting good in-context examples for few-shot prompting has been shown to materially affect LLM translation quality (Agrawal et al., 2023), and retrieval over a reference corpus of similar translations is one way to construct such examples automatically (Lee et al., 2025). We adopt this idea for both fine-tuning and inference (see Section 3.2.3), retrieving over a corpus built with back-translation.

Dictionary-augmented prompting has already shown some promise when it comes to English–Icelandic translation. Ingólfsdóttir et al. (2025) describe Erlendur, a multi-stage pipeline that uses a preparatory LLM pass to extract key terms from the source text, looks these up in the Ensk.is dictionary (see Section 3.2.2) and in user-supplied glossaries using inflection-aware fuzzy n-gram matching, and injects the results into an LLM translation prompt.

An alternative to injecting retrieved context directly into the prompt is to expose the dictionary and example retrieval as tools the model can call at its own discretion, e.g. via Model Context Protocol (MCP).[4] We considered this approach but decided on using prompt injection for our submitted system: it guarantees that relevant context is present in every prompt regardless of whether the model would have initiated a lookup, at the cost of always paying the retrieval latency and prompt-length overhead even when a given sentence needed no help.

Icelandic has been a target language in the WMT General Translation shared task in recent years (Kocmi et al., 2024, 2025). We compare directly against our own 2025 submission (Jasonarson and Steingrimsson, 2025) in Section 6.

## 3 Data and Augmentation Data

For pre-training and fine-tuning we use a wide array of available datasets. In Sections 3.1 and 3.2 we give an overview of these datasets and how they were used.

### 3.1 Pre-training Data

Our CPT corpus contained approximately 7.39B tokens, comprising Icelandic (63.0%), English text (27.0%), Python code (4.0%), math (3.5%), and structured data (2.5%). The Icelandic subset consisted of 4.65B tokens from a filtered and deduplicated version (Dađason and Steingrímsson, 2026) of the Icelandic Gigaword Corpus (IGC) (Steingrímsson et al., 2018; Barkarson et al., 2022). For English-language text, we sampled 1.79B tokens from a deduplicated version of FineWeb-Edu (Penedo et al., 2024) and 199M tokens from Cosmopedia v2 (Ben Allal et al., 2024). We sampled 295M tokens from the Python subset of the StarCoder dataset (Li et al., 2023), and 259M tokens of mathematical content from FineMath-4plus (Allal et al., 2025). Finally, we extracted 185M tokens from English-language articles in Structured Wikipedia (Wikimedia Enterprise and Wikimedia Foundation, 2026), with articles in plain text with

[4] https://modelcontextprotocol.io/specification

JSON-formatted tables. All token counts were measured using the Qwen3 tokenizer.

### 3.2 Fine-tuning Data

To adapt our continually pre-trained model for the translation task and teach it to effectively utilize injected context, we construct a multifaceted fine-tuning dataset. Because our system uses retrieval-augmented generation (RAG) at inference time, the fine-tuning data must teach the model how to adhere to domain-specific instructions, apply retrieved dictionary constraints, and mimic structural few-shot examples. To achieve this, our dataset relies on three distinct components: a core set of domain-annotated parallel sentences, a comprehensive collection of bilingual dictionary entries, and a large-scale back-translated reference corpus. We detail each of these resources below.

#### 3.2.1 Training examples

Training examples for the *news* domain are drawn from the official WMT 2024 English–Icelandic test set, split into paragraph-level segments; *general*, *software*, and *speech* domains were synthetically generated with Gemini 3.1 Pro from seed prompts (Appendix B); *social* examples are Gemini-generated from seed prompts drawn from WMT 2025 general translation task test data (Kocmi et al., 2025). In total we used 4,996 examples across the five domains (1,000 general, 996 news, 1,000 social, 1,000 software, 1,000 speech), but although the number of examples is almost the same for all domains, note that the length of the examples differs somewhat, as seen in Table 1. The fine-tuning dataset is available on GitHub.[5]

| Domain | # Ex. | Source | Avg. Words |
|---|---|---|---|
| General | 1,000 | Gemini 3.1 Pro | 20.9 |
| News | 996 | WMT24 test set | 32.5 |
| Social | 1,000 | Gemini 3.1 Pro | 23.8 |
| Software | 1,000 | Gemini 3.1 Pro | 49.9 |
| Speech | 1,000 | Gemini 3.1 Pro | 32.5 |
| Total | 4,996 | | – |

Table 1: Fine-tuning data by domain.

#### 3.2.2 Dictionary lookups

We assembled three English–Icelandic dictionary resources: *Ensk.is*, an open-source English–Icelandic dictionary (40,547 headword entries) (Zoëga and Þórðarson, 2026); a general-purpose glossary generated semi-automatically and then manually error-checked (94,061 entries) (Steingrímsson et al., 2022; Steingrímsson et al., 2021), and *Tölvuorðasafnið*, a computing terminology lexicon containing 7,171 entries (Guðmundsdóttir et al., 2026). Together, these give 141,779 dictionary entries available for lookup at both fine-tuning and inference time. The retrieval and scoring mechanism that selects which entries are injected into a given prompt is described in Section 4.2.2.

#### 3.2.3 Back-translated few-shot examples

To provide naturalistic few-shot translation examples beyond what our fine-tuning data covers, we used a 6-bit quantized version of TranslateGemma 27B[6] (Finkelstein et al., 2026) to build a large reference corpus by back-translating (Sennrich et al., 2016) monolingual Icelandic text from the Icelandic Gigaword Corpus (IGC). We generated an English translation for a large sample of sentences, yielding synthetic English–Icelandic pairs in which the Icelandic side is authentic, naturally occurring text and the English side is machine-generated. We filtered candidate pairs on perplexity calculated by a KenLM (Heafield, 2011) model trained on the 2024 version of the IGC (Steingrímsson, 2026) and automatic language identification using a custom langdetect[7] profile for Icelandic[8] to remove poor translations and off-language content, retaining approximately 106.5 million sentence pairs (Steingrímsson and Hafsteinsson, 2026a,b). This corpus is queried at both fine-tuning and inference time to retrieve similar example translations for a given source sentence, via the FTS5 and MinHash/LSH indices described in Section 4.2.1.

## 4 Building the System

Our submitted translation system is a lightweight, retrieval-augmented pipeline centered around a 4B-parameter language model. Building the system involved a two-stage training process coupled with the development of a dedicated context-retrieval engine. First, we adapted the base model to the Icelandic language via efficient, small-batch continued pre-training. Second, we fine-tuned the model using Low-Rank Adaptation (LoRA) to teach it

[5] https://github.com/stofnun-arna-magnussonar/WMT26_AMI

[6] https://huggingface.co/mradermacher/translategemma-27b-it-i1-GGUF:Q6_K

[7] https://pypi.org/project/langdetect/

[8] https://github.com/steinst/langdetect_profiles

how to follow domain-specific instructions and leverage dynamically injected context. To supply this context, we built a standalone Retrieval-Augmented Generation (RAG) server that scores and retrieves relevant bilingual dictionary entries and back-translated few-shot examples on the fly. The following subsections detail the pre-training and fine-tuning procedures, the architecture of the RAG server, and the mechanisms used to filter, score, and assemble the final context-enriched prompts.

### 4.1 Pre-training

We adapted the Qwen3-4B base model[9] (Qwen Team, 2025) to Icelandic through continued pre-training. We followed the small-batch training approach of Marek et al. (2025), who found that, when Adam's second-moment decay is scaled to maintain a fixed token half-life, small-batch training is stable, more robust to hyperparameter choices, and achieves equal or better per-FLOP performance than larger-batch training. We used a sequence length of 8,192 and a batch size of 1, and set AdamW's second-moment decay rate to $\beta_2 = 0.9994323$, corresponding to a token half-life of 10M tokens. We used a WSD learning rate schedule, with a linear warmup over the first 2,000 steps to a peak learning rate of 3e-5, and a linear decay over the final 10% of steps. We trained on a single NVIDIA RTX PRO 6000 Blackwell GPU for 24 hours and for the downstream experiments, we used the checkpoint saved after 75,000 steps, corresponding to 614M training tokens. Training up to this checkpoint took approximately 23 hours.

### 4.2 Fine-tuning

We fine-tuned the continually pre-trained checkpoint described above using low-rank adaptation (LoRA) (Hu et al., 2022) as implemented in Unsloth[10] (Daniel Han and team, 2023). We used LoRA rank $r = 16$, $\alpha = 16$, dropout 0, no bias term, applied to all attention and MLP projection matrices (`q_proj`, `k_proj`, `v_proj`, `o_proj`, `gate_proj`, `up_proj`, `down_proj`). We trained for 3 epochs with a per-device batch size of 2 and 4 gradient accumulation steps (effective batch size 8), a peak learning rate of 2e-4 with a linear schedule and 10 warmup steps, the 8-bit AdamW optimizer, weight decay 0.01, and bf16 mixed precision.

Each training example pairs a domain-specific system prompt (*social*, *speech*, *news*, *software*, or *general*) with a user turn containing retrieved dictionary entries and example translations for the source sentence (retrieval and prompt construction detailed in Section 4.2.3), and an assistant turn containing the reference Icelandic translation. Examples were rendered through Qwen3's native ChatML-style chat template, with loss computed over the assistant turn only (see Appendix A). We trained on the 4,996 examples described in Section 3.2, with dictionary lookups added to the prompt as well as translations of similar sentences.

#### 4.2.1 Back-translation RAG server

Prompt construction is handled by a single persistent FastAPI service (Ramírez, 2026) that keeps three bilingual dictionaries, a sentence-retrieval index, and a cross-encoder reranker resident in memory, run as a standalone Uvicorn (Trylesinski and Christie, 2026) process and queried over HTTP by both the dataset-building and inference clients. It performs one warm-up retrieval query on startup, then exposes a context endpoint returning a ranked, capped dictionary block and example block as separate fields (the caller assembles the final prompt, Section 4.2.3); an alternative single-call endpoint that returns one pre-assembled prompt exists but is unused by either pipeline.

The example block draws on the large back-translated Icelandic reference corpus (see Section 3.2.3) via two indices: an SQLite FTS5 full-text index over (source, target) pairs, queried by n-gram phrase matching; and a MinHash locality-sensitive-hashing (LSH) index (Broder, 1997) for approximate nearest-neighbor retrieval. Each record's English side is shingled into bigrams, hashed into a 64-permutation MinHash signature, split into 16 bands of 4 rows for bucketing, and candidates are rescored by exact Jaccard similarity; matched records are fetched by direct byte-offset seek via a precomputed offset map.

#### 4.2.2 Dictionary lookup mechanism

The three static English–Icelandic resources described in Section 3.2.2 are loaded at startup: a general English–Icelandic dictionary, a semi-automatically generated, manually-checked glossary, and an EN-IS computing terminology lexicon, each a flat mapping from English word/phrase to Icelandic candidate(s). Multi-word entries are indexed by token sequence so the longest matching

[9] https://hf.co/Qwen/Qwen3-4B-Base
[10] https://github.com/unslothai/unsloth

phrase in a source sentence is preferred over its component words. Single tokens are looked up directly, on failure, under WordNet-derived lemma candidates (noun/verb/adjective/adverb) (Miller, 1995) via NLTK (Bird and Loper, 2004), so inflected forms resolve to their dictionary headword; English stopwords are skipped.

#### 4.2.3 Prompt Construction

The source text is first segmented into sentences (HTML markup and JSON-array-of-strings inputs are normalized into plain segments), which drives both dictionary lookup and per-sentence example retrieval.

**Dictionary block.** For long sentences a very long list of dictionary entries can be found, some of them for common words that the LLM should translate correctly without the help of lookups. In order to reduce long lists of entries to something more manageable, we built an algorithm to find words that are more likely to be rare. To do this, hits are scored. Token rarity weight is $\max(0.1,\ 7.0 - \mathrm{zipf}(\mathrm{token}))$ (Speer, 2022). General-dictionary single-token hits are only considered if the token's Zipf frequency is $\leq 4.5$ (the computing lexicon is exempt from this gate). Score is (in-sentence token frequency) $\times$ rarity for single tokens, or (rarest component word's rarity) $+ 1.5$ for phrase matches; computing-lexicon hits add a further $+2.0$. The top 15 scoring entries survive (words and phrases share this cap); the block is omitted if none are found.

**Example block.** Per sentence, up to 15 LSH neighbors are retrieved and filtered to pairs with $\geq 5$ words on both sides, keeping the top 5; up to 5 FTS5 matches are found by querying n-grams from 7-grams down to 4-grams (falling back to single non-stopword tokens), pooled to 50 candidates before random subsampling to 5. All candidates are scored against their sentence with a cross-encoder[11] (Reimers and Gurevych, 2019) and merged into one pool across the whole input, keeping the best score per unique pair. The pool is filtered to score $\geq -11.0$; if fewer than 2 candidates survive, no examples are emitted. Otherwise a top band of 6–24 candidates (size drawn uniformly at random) is formed, and 2–8 examples (likewise randomly drawn, capped by band size) are sampled without replacement and shown best-score-first, so the injected example count varies per prompt. This was done so that when fine-tuning, the model learns to translate regardless of the number of few-shot examples, as in some cases they may be none, while in others very many sentence pairs can be found.

**Assembly.** The dictionary block (if any) and example block (if any) are each wrapped in a fixed instruction and concatenated with a final translation instruction containing the raw source sentence; a missing block is omitted, not left empty. The fine-tuning and translation prompt and chat template are given in Appendix A. The fine-tuning dataset is available in our GitHub repo.

## 5 Inference

At inference time, source sentences are passed through the identical retrieval and prompt-construction pipeline used to build the fine-tuning data, and the fine-tuned adapter is served behind an OpenAI-compatible endpoint.

### 5.1 Rule-based re-translation

Generations are checked against a fixed set of validation rules before being accepted. A translation is rejected if it: leaks the dictionary- or example-block instruction text verbatim; contains an English-prompt hallucination (e.g. an echoed "English:" label); is empty; repeats the same 5-word sequence five or more times; introduces more paragraph breaks than the source; or, on segments of at least 15 words, has a translation-to-source word-count ratio below 0.70 or above 1.50, or copies more than 50% of its content words directly from the source. Length-ratio and source-copy checks are skipped on shorter segments, where they are not statistically meaningful.

A rejected or truncated (max-token-limited) generation is resampled: the first 11 retries linearly increase temperature from 0.25 to 0.75; if that fails to produce a passing output, five further retries hold temperature at 0.27 and instead sweep the sampling parameters ($\mathrm{top}_p$, $\mathrm{top}_k$, $\mathrm{min}_p$) from a tight to a wide cutoff, on the assumption that a low-temperature failure is a distribution-shape problem rather than one that needs more randomness. The 16th and final attempt is accepted unconditionally regardless of validation outcome, so every input is guaranteed an output.

## 6 Results

In order to evaluate our system, we split the test set from the WMT 2025 general translation task

[11] https://hf.co/cross-encoder/ms-marco-MiniLM-L6-v2

| Dictionaries | Few-shot | $n$ | COMET | chrF++ |
|---|---|---|---|---|
| ✓ | ✓ | 332 | $0.7792^a$ | $45.88^a$ |
| ✓ | × | 332 | $0.7772^a$ | $45.90^a$ |
| × | ✓ | 332 | $0.7695^b$ | $45.19^b$ |
| × | × | 332 | $0.7697^b$ | $45.19^b$ |

Table 2: COMET and chrF++ scores by ablation (dictionary/examples present or not; all domains pooled, $n = 332$). Scores sharing a superscript letter for a given metric are not significantly different from each other on that metric (paired bootstrap resampling, $n_{\text{samples}} = 1000$, seed=12345); different letters indicate $p < 0.05$.

| System/model | COMET | chrF++ |
|---|---|---|
| AMI 2025 | 0.7950 | 48.70 |
| Llama8B+CPT+LoRA | 0.7895 | 46.98 |
| AMI 2026 (4B) | 0.7792 | 45.88 |
| Qwen3-4B-Instruct-2507 | 0.4569 | 30.87 |

Table 3: Comparison of COMET and chrF++ scores for our system and others.

(Kocmi et al., 2025) into paragraphs, translated these with our system using different prompting approaches and calculated COMET[12] (Rei et al., 2022) and chrF++[13] scores (Popović, 2017).

We started by doing an ablation study, where we prepared the prompt in four different ways: including the dictionary lookups, including few-shot examples, including both or neither. As shown in Table 2 we get the best results if we include the dictionary lookups, but there is not a statistically significant difference if we add the few-shot examples.

We decide to stick with using both few-shot examples and the dictionaries for translating our WMT 2026 submission. While the automatic scoring shows a clear positive advantage in using the dictionaries, it doesn't indicate a statistically significant difference when using the few-shot examples. We decide to use the few-shots examples anyway, as such examples have been shown to increase LLM translation quality, see e.g. Agrawal et al. (2023), and the manual evaluation might be more sensitive to finer nuances. On the other hand, if a large back-translated corpus does not exist, our results would not justify one being built for this purpose only.

While our submitted model this year is of similar size to the one submitted last year, the translation pipeline is somewhat easier to run. The post-processing part was quite cumbersome last year, making the system complicated to set up and run in practice. But do we lose quality by skipping the post-processing? In Table 3 we compare our system to our previous submission, as well as a few other available models, and we do indeed find that the system submitted by the AMI team this year is inferior to the submission from last year. By cutting out the post-processing we do seem to lose some quality, although other things may affect the results too, such as the short CPT-process for this model, or the fine-tuning process which was much simpler last year when we fine-tuned it simply by showing it very many examples of parallel sentences, and always used the same short prompt. What is gained on the other hand is a greater overall simplicity of the system.

We also compared our model to another model we did CPT on, an 8B-parameter Llama 3 model (Llama Team, 2024), and then trained a LoRA adapter in exactly the same way as we did with our submitted model. The 8B-parameter Llama 3 was trained on Icelandic, English and Polish, 25 billion tokens in total, 40% Icelandic, 40% Polish and 20% English. While the COMET and chrF++ scores are higher for this model than the submitted model, upon manual inspection of the outputs, we found that this model was much more prone to hallucinations and going off track, although the fluency of the Icelandic texts looked better than in our submitted model. As the submitted model seemed to be more likely to follow instructions correctly we decided to go with that.

Finally, we compared our model to Qwen3-4B-Instruct-2507, an instruction-tuned variant of the base model we continued pre-training on. While this comparison does not isolate the impact of continued pre-training and fine-tuning, it represents a realistic alternative when no language-specific training is performed. As expected, our adapted model substantially outperforms this baseline, which produces low-quality Icelandic output and often fails to follow the domain prompts.

## 7 Conclusions and Future Work

We have evaluated DRAG only for a small language model. Whether dictionary retrieval also improves English–Icelandic translation for state-of-the-art LLMs, which already handle the language pair reasonably well, remains to be measured.

[12]COMET signature: COMET|model:Unbabel/wmt22-comet-dalcomet:2.2.7

[13]chrF++ signature: nrefs:1 | bs:1000 | seed:12345 | case:mixed | eff:yes | nc:6 | nw:2 | space:no | version:2.6.0

Our dictionary retrieval draws solely on English-keyed resources. The DRAG pipeline could potentially be complemented by additional data, such as *Íslensk-ensk orðabók*,[14] an Icelandic–English dictionary that could be queried in reverse. Matching for English source words in IS-EN definitions might bring to the surface Icelandic vocabulary and translations that our English-keyed resources do not contain.

The Qwen3 tokenizer is inefficient for Icelandic, with each token representing only 2.22 characters on average in the Icelandic subset of our CPT corpus. This reduces the effective context length in terms of Icelandic text and increases the number of tokens, and consequently the computation, required to process a given amount of text. In future work, we intend to investigate longer CPT runs together with vocabulary extension to improve the model's tokenization efficiency for Icelandic.

And finally, it may very well be so that when fine-tuning an LLM to be effective at machine translation for a low-resource language, the small-sized model we are working with is not big enough to produce reasonable quality, even after CPT, especially when trying to make it follow long and complicated prompts containing a lot of information. We leave these questions for further work.

## A Translation Prompt and Chat Template

Each prompt is assembled from up to three parts, each emitted only if the corresponding retrieval step returned results:

```
The following are reference translations
retrieved for words and phrases that
appear in the text below.  Use them
to guide your word and term choices,
selecting the option that best fits
the context and inflecting it (case,
number, gender, tense) as Icelandic
grammar requires.  They are aids, not
constraints: ignore any that do not fit,
and translate words not listed here as
usual.

{dictionary_block}

The following are example sentence
translations from a corpus that
contains similar phrasing or contextual
themes. Use them as structural few-shot
references:

{examples_block}

Translate the following English text
into Icelandic.  Only return the best
possible Icelandic translation, without
any explanations or notes.

{source_text}
```

The assembled prompt is rendered into the model's chat format as:

```
<|im_start|>system
{domain system prompt}<|im_end|>
<|im_start|>user
{dictionary block (optional)}

{examples block (optional)}

Translate the following English text into
Icelandic. Only return the best possible
Icelandic translation, without any
explanations or notes.

{source_text}<|im_end|>
<|im_start|>assistant
{translation}<|im_end|>
```

# B Synthetic Data Generation Prompts

Training examples for the *general*, *social*, *software*, and *speech* domains were synthetically generated with Gemini 3.1 Pro (*gemini-3.1-pro-preview*), using structured output constrained to a fixed JSON schema (source text, target text, document/paragraph IDs, and domain metadata) and generated in batches of 5–10 examples per API call. The *news* domain was not Gemini-generated; it is drawn from the official WMT24 English–Icelandic test set (Section 3.2). The base prompt for each domain is reproduced below; batch-specific instructions (starting paragraph ID, exact batch size) were appended automatically at generation time.

## B.1 General domain (temperature 0.9)

> Generate a batch of highly diverse, general-purpose text in English and their natural translations into Icelandic. The topics should be completely arbitrary ranging from scientific facts and philosophical musings to mundane tasks, historical trivia, or creative storytelling. CRITICAL CONSTRAINT: Each source text must be between 7 and 40 words long. Ensure the Icelandic translations are natural, fluent, and stylistically appropriate for the content.

## B.2 Social media domain (temperature 1.0)

> Generate a batch of highly diverse social media posts written in English and their natural translations into Icelandic. The posts should cover a wide variety of topics: hobbies, tech, travel frustrations, gym milestones, pet antics, cooking failures, dating, work, or daily observations. Use realistic social media formatting, including emojis, casual phrasing, slang, internet acronyms, and appropriate cultural adaptations in Icelandic (e.g., translating memes/slang accurately rather than literally).

## B.3 Software domain (temperature 0.4)

Unlike the other three domains, the software prompt is constructed per-batch: for each example in the batch, 1–6 English computing terms are sampled at random from the computing-terminology lexicon (Section 3.2.2), and the model is required to use both the English terms in the source text and their dictionary-specified Icelandic translations in the target text, enforcing terminological consistency with the dictionary the same system also uses at inference time. The shared instruction, with one example's term constraint shown:

> You are an expert bilingual technical writer and translator (English to Icelandic). Generate a batch of highly diverse texts focused on software and technology. For each example, you MUST naturally incorporate the specific English terms provided into the source text, and you MUST use the exact mapped Icelandic terms in the translated text.
>
> Example 1: - Context: Write 1-3 short paragraphs (separated by \n or \n\n). It can be a software description, tech news, or a general webpage mentioning tech. - Required English terms to include in src_text: [. . . ] - Required Icelandic terms to include in tgt_text: [. . . ] - Ensure the Icelandic translation strictly uses these exact translated terms.

## B.4 Speech domain (temperature 1.0)

> Generate a batch of transcribed speech examples in English and their natural translations into Icelandic. The English text should read exactly like a raw transcript from a YouTube video, podcast, or interview. It MUST include characteristics of unscripted spoken language: filler words (um, uh, you know), run-on sentences, abrupt topic changes, self-corrections, and conversational phrasing. Topics should range from makeup tutorials, gaming let's plays, academic lectures, random vlogs, to fitness coaching. The Icelandic translation must accurately convey this messy, spoken tone rather than reading like formal text.

| Domain | System prompt |
|---|---|
| General | You are a professional Icelandic translator, tasked with providing translations suitable for use in Icelandic (isl_Latn). Your goal is to accurately convey the meaning and nuances of the original text while adhering to Icelandic grammar and vocabulary and ensuring that the translation is natural. Produce only the Icelandic translation, without any additional explanations or commentary. Maintain the formatting of the original source text. Please translate the following text into Icelandic (isl_Latn): |
| News | . . . The original text is a news article. Ensure the translation is formal and consistent with journalistic standards. Produce only the Icelandic translation, without any additional explanations or commentary. Maintain the HTML formatting of the original source text. Please translate the following text into Icelandic (isl_Latn): |
| Social | . . . The original text is user-generated content from a social media platform and is accompanied by anonymized screenshot images that provide visual context. Use the screenshot context to resolve ambiguity, but translate only the text provided for translation. Do not reproduce spelling mistakes. Reproduce marks of expressiveness that communicate meaningful intent (e.g. enthusiasm through capitalisation or elongation) in a way that is natural in Icelandic. Copy URLs and user handles directly rather than translating them. However, translate hashtags as appropriate for the translation to be natural for social media text. Follow the punctuation of the source text as best as possible. Additional punctuation should be added only if not doing so would seriously alter the comprehension of the text. Translate text in an informal style, like close friends talking, even if it changes the original tone. Produce only the Icelandic translation, without any additional explanations or commentary. Maintain the HTML formatting of the original source text. Please translate the following text into Icelandic (isl_Latn): |
| Speech | . . . The original text is automatically transcribed from spoken language and can contain errors. Maintain the flow and colloquial style of the speaker in the translation. Do not include non-linguistic sounds (e.g. laughter, groans, hesitation sounds, etc.), but do include interjections. If a word is interrupted, either guess the full word if possible or otherwise omit it. Keep foreign words as they are when translating. Produce only the Icelandic translation, without any additional explanations or commentary. Output the text such that each sentence is on a separate line. Please translate the following text into Icelandic (isl_Latn): |
| Software | . . . The original text is from software data. Translate the content of json, without translating keys and placeholders (i.e. copy them rather than translate them). Produce only the Icelandic translation, without any additional explanations or commentary. Produce a valid json output that matches the input format. Please translate the following text into Icelandic (isl_Latn): |

Table 4: Domain-specific system prompts. Each begins with the shared preamble *"You are a professional Icelandic translator. . . ensuring that the translation is natural."*, elided above with . . . for space.

# Krosny at WMT26 General Translation Task: Dictionary Augmentation and Iterative Refinement for English–Belarusian Translation

**Oksana Volchek, Vladislav Poritski**
Independent researchers, Vilnius, Lithuania
{volchekoa,v.poritski}@gmail.com

## Abstract

This paper describes our submission to the WMT26 General Machine Translation shared task for the English → Belarusian direction. In lower-resourced morphologically rich languages like Belarusian, open-weight large language models (LLMs) frequently struggle with orthographic fidelity, hallucinated vocabulary, and negative transfer from related high-resource languages. To address these issues, we implemented Krosny,[1] an iterative, resource-augmented pipeline built on top of TranslateGemma 12B. The system translates each segment in three stages: (1) dictionary-augmented generation, (2) refinement using a reference grammatical database, and (3) rule-based post-processing followed by an LLM-as-a-judge candidate selection. We find a small but consistent improvement over the baseline TranslateGemma 12B. In comparison with other constrained-track systems of WMT26, the performance of Krosny is mid-tier. We release the source code of our implementation.[2]

## 1 Introduction

The advent of large language models has shifted the machine translation paradigm towards prompting pre-trained models (Zhang et al., 2023; He, 2024). However, for a low-resource language like Belarusian, which is susceptible to negative transfer from related languages (Russian and Ukrainian) and LLM hallucinations, relying on the model's parametric memory alone may yield suboptimal translation quality in resource-constrained settings.

Our submission to the WMT26 shared task is limited to English–Belarusian language pair. The WMT26 blind set for this language pair consists of 198 texts across four domains: 133 speech transcripts, 44 social media posts, 14 news articles, and 7 software localization JSONs. To translate these diverse texts, we chose TranslateGemma 12B (Finkelstein et al., 2026), a strong multilingual local model fine-tuned for machine translation, as our base model and aimed to determine whether it is possible to meaningfully improve its outputs by wrapping it into a language-specific scaffold without any additional training or fine-tuning. We designed a pipeline that augments the model's context with relevant entries from English–Belarusian dictionaries and a grammatical database, applies rule-based post-processing and invokes LLM as a judge for candidate selection.

## 2 Linguistic Resources and Pre-processing

Our pipeline relies on several existing Belarusian linguistic resources. Their intended purpose is to complement the model's parametric knowledge. LLMs are known to be bad at memorizing "long-tail" knowledge (Kandpal et al., 2023); in a low-resource language, TranslateGemma could be therefore expected to know rare vocabulary and morphology poorly.

**Dictionary Context and Orthography Normalization.** Dictionary hints have been shown to improve translation quality between English and low-resource languages (Ghazvininejad et al., 2023). We utilize two English–Belarusian dictionaries available in digital form:[3] one edited under the supervision of T. Susha (2013), another authored by V. Pashkevich and edited by S. Shupa (2006).

Belarusian has two competing written standards: the classical orthography *taraškievica*, named after Branislaŭ Taraškievič's 1918 grammar, was the norm until the Soviet spelling reform of 1933, while the reformed, official orthography (informally *narkamaŭka*), later revised in 1957/1959 and by the 2008 orthography law, is what is taught

[1] In Belarusian: *кросны* 'hand loom'.

in schools, used in official and most media texts, and can be reasonably expected in the WMT26 test data translations. Pashkevich's dictionary uses *taraškievica*, so injecting entries from it directly into the prompt context could cause the LLM to output non-compliant orthography. To prevent this, we applied an offline "detarashkevization" script to Pashkevich's dictionary, converting classical spellings into the official modern orthography with a sequence of regular expressions.

**Filtering by Frequency.** To prevent the prompt context window from being overwhelmed by high-frequency vocabulary (which the LLM is already likely to translate accurately), we implemented a frequency-based filter. We lemmatized the entire input set and counted occurrences of all English nouns, proper nouns, verbs, adjectives, and adverbs. Only words belonging to these parts of speech and appearing $\leq$50 times in the inputs were eligible for dictionary lookup. While the filter is derived in our implementation directly from the test set, it could as well be based on a generic corpus of texts from the same distribution. Its purpose is to ensure that the lemmas whose dictionary entries are injected into the context are sufficiently specific or rare.

**GrammarDB and Error-Weighted Levenshtein Distance.** To validate the LLM's outputs, we used GrammarDB,[4] the reference morphological database of Belarusian. Rather than just rejecting non-attested words, we designed an error-correction module. During the development phase, we manually accumulated a list of ≈150 common morphological and spelling errors produced by TranslateGemma and its base model Gemma 3 12B (e.g.: *тэхналогічнаму* instead of *тэхналагічнаму*). By calculating the statistics of edit operations between these generated errors and their manual corrections, we derived a custom set of weights ranging between 0 and 1: frequent edits, such as *o*/*a* replacement in the above example, get proportionally smaller weights. For a generated token that is missing from GrammarDB, Levenshtein distances with these custom weights are calculated against all tokens of similar length from GrammarDB. Lower penalties assigned to frequent edits increase the chances of suggesting valid GrammarDB counterparts for Gemma-specific hallucinated Belarusian wordforms.

## 3 Translation Pipeline

Our inference pipeline executes in three stages. To optimize context length, input texts are split into segments with mixed granularity depending on the domain (e.g., all transcripts are sufficiently short and don't require splitting); typically, segment length is limited to 500 characters. All LLM inferences were performed with an instance of TranslateGemma 12B in 8-bit GGUF quantization[5] via llama.cpp[6] in the default non-deterministic configuration: temp=1.0, top_p=0.95, top_k=64.

### 3.1 Dictionary-Augmented Generation

For each input segment, we use the respective domain-specific system prompt, provided by the organizers, to generate $N = 3$ "naive" baseline translations. Next, we prepend the filtered English–Belarusian dictionary entries for the vocabulary present in this segment to the prompt and generate $N$ "guided" translations, yielding $2N$ initial candidate translations per segment. At this stage, candidate generation is retried if the output is not in Belarusian (as detected by Lingua[7]) or its length is below 0.5x or above 2x of the input length, i.e. the model either truncates the input or falls into a hallucination loop.

### 3.2 GrammarDB-Guided Merging

We pair the naive and guided translations. From each pair, we extract all tokens eligible for GrammarDB lookup: they should contain Cyrillic characters and shouldn't be too short or belong to one of pre-defined classes, such as hashtags, spellings with digits, proper names (as detected by Stanza[8]). Eligible tokens that do not exist in GrammarDB are flagged. For each flagged token, we retrieve suggestions from GrammarDB, ranked by the error-weighted Levenshtein distance – up to 100 suggestions but typically much less, as the similarity threshold increases with token length. The LLM is then prompted as an "expert editor": given the English source, both candidate Belarusian translations, and a glossary that maps the unverified generated words to GrammarDB suggestions, the model synthesizes a single refined translation. This yields $N$ refined candidates.

[6] https://github.com/ai-dock/llama.cpp-cuda

[7] https://github.com/pemistahl/lingua

[8] https://github.com/stanfordnlp/stanza

### 3.3 Post-Processing and Final Selection

To account for the negative transfer from Russian and, to a lesser extent, Ukrainian orthography in the LLM-generated Belarusian texts, we apply a suite of regex corrections to the refined outputs (e.g., converting *и* to *і*/*ы* depending on the context, *щ* to *шч*, enforcing Belarusian verb endings like *ць*). Consistent formatting (valid HTML or JSON, same number of paragraphs in the output as in the respective input) is also enforced at this stage.

Finally, we use the LLM as a judge to evaluate the post-processed candidates. The model is asked to output only the index $(1 \ldots N)$ of the most adequate and correct translation. To mitigate positional bias, this selection prompt is run $K = 20$ times per segment with randomized order of candidates. The final choice is determined by majority vote.

## 4 Computational Footprint

Our iterative approach trades compute for quality. Translating a single segment requires at least $3N$ "heavy" generation calls (with retries) and $K$ "lightweight" calls for the candidate selection phase, where typically only a single token is generated. The English–Belarusian subset of the WMT26 blind set (198 texts split into 729 segments) was processed on Kaggle using 2xT4 GPUs within the 30-hour free weekly quota, with the GrammarDB suggestions computed locally on a CPU.

## 5 Preliminary Evaluation

As manual gold translations weren't available in the English–Belarusian pair at the time of submission, we used the pseudo-reference provided by the organizers (`PseudoRef.jsonl`). Using the default settings of SacreBLEU (Post, 2018), we calculated BLEU and chrF2 scores against this pseudo-reference for the "naive" and "guided" outputs of TranslateGemma, for our final submission, and for the outputs of five other constrained-track systems that support English–Belarusian translation and two strong proprietary LLMs: Gemini 3.1 Pro and GPT-5.5. The results are shown in Table 1.

The injection of dictionary context provided a small but consistent improvement over the naive baseline across all runs. Our final submission, which adds GrammarDB-informed candidate merging, rule-based post-processing and LLM candidate selection, achieved further incremental gain. However, this improvement falls short of matching the quality delivered by the best constrained systems,

| System | Run | BLEU | chrF2 |
|---|---|---|---|
| Tr.G., naive | 1 | 32.18 | 56.06 |
| | 2 | 32.69 | 56.21 |
| | 3 | 32.80 | 56.14 |
| Tr.G., guided | 1 | 33.49 | 56.60 |
| | 2 | 33.73 | 56.82 |
| | 3 | 33.83 | 56.63 |
| Krosny | | **36.36** | **57.98** |
| Lumen | | **52.61** | **68.57** |
| Qingqiu-MT-9B | | 47.04 | 64.74 |
| ReMova | | 33.39 | 50.43 |
| SalamandraTA | | 36.87 | 56.71 |
| Yandex-8B | | 40.99 | 59.29 |
| Gemini 3.1 Pro | | 51.63 | 67.50 |
| GPT 5.5 | | **54.21** | **69.35** |

Table 1: Automated evaluation scores.

such as Lumen or Qingqiu-MT-9B, which perform at or around the level of proprietary LLMs.

Additionally, for all of the systems listed above, plus the pseudo-reference, we re-used our implementation of GrammarDB lookup to calculate the ratios of generated tokens missing from it. While there may be legitimate reasons for a valid word form not to be listed in the reference database (e.g.: it is a recent neologism, a calque, or its spelling follows the older standard), high out-of-vocabulary token ratio is generally correlated with low fluency. The ratios are shown in Table 2, along with the total counts of word tokens produced by each system.

| System | Run | Tokens | N/E | + | − |
|---|---|---|---|---|---|
| Tr.G., naive | 1 | 38158 | 47.56 | 49.75 | 2.69 |
| | 2 | 37926 | 47.24 | 50.11 | 2.64 |
| | 3 | 37871 | 47.46 | 49.98 | 2.56 |
| Tr.G., guided | 1 | 38086 | 46.57 | 51.32 | 2.11 |
| | 2 | 38083 | 46.66 | 51.28 | 2.06 |
| | 3 | 37873 | 46.53 | 51.47 | 2.00 |
| Krosny | | 37197 | 46.74 | 51.35 | **1.91** |
| Lumen | | 35073 | 45.77 | 53.01 | 1.22 |
| Qingqiu-MT-9B | | 35182 | 45.85 | 51.50 | 2.65 |
| ReMova | | 31120 | 46.37 | 52.47 | 1.17 |
| SalamandraTA | | 36001 | 46.24 | 52.96 | **0.81** |
| Yandex-8B | | 35472 | 47.09 | 50.22 | 2.70 |
| Gemini 3.1 Pro | | 35083 | 45.85 | 52.91 | 1.24 |
| GPT 5.5 | | 34279 | 46.16 | 52.75 | **1.10** |
| Pseudo-reference | | 35628 | 45.54 | 53.36 | **1.10** |

Table 2: Word tokens in the outputs and their percentage breakdown with respect to GrammarDB lookup: not eligible (N/E), hit (+), or miss (−).

Dictionary augmentation alone reduced GrammarDB misses by approximately a fifth, from 2.63% to 2.06%. Stage 2 editing and stage 3 post-processing further reduce this ratio only slightly, indicating that TranslateGemma doesn't make use of the GrammarDB suggestions to the full possible extent. In the outputs of proprietary models and the pseudo-reference, out-of-vocabulary token counts

are even lower (1.1–1.2%). Low or high ratio of GrammarDB misses isn't by itself a reliable predictor of translation quality, as can be seen from the scores of e.g. SalamandraTA and Qingqiu-MT-9B. As a tendency, we observe that SalamandraTA is more fluent in Belarusian but frequently distorts the meaning of the input, while Qingqiu-MT-9B is more faithful, despite many hallucinated or coined words and grammatical errors. The example below illustrates this point, with lexical and grammatical errors highlighted.

| | |
|---|---|
| Input | . . . with the broken shoulder he sustained proving untreatable and he was euthanised by the veterinary team on Saturday. |
| SalamandraTA | У выніку ў яго адламалася лапатка, што не паддалася лячэнню. У суботу ветэрынары адвялі яму эўтаназію. 'As a result, his scapula broke off and could not be treated. On Saturday, the veterinarians euthanized him.' |
| Qingqiu-MT-9B | Атрыманая ім ***пераломленне*** пляча аказалася невылечн***ай***, і ў суботу ветэрынарная група ***эўтаназіявала*** яго. 'The shoulder fracture he sustained proved untreatable, and on Saturday the veterinary team euthanized him.' |

## 6 Discussion and Limitations

**Out-of-Domain Use of a Fine-Tune.** TranslateGemma is a specialized, single-task fine-tune with an opinionated prompt template. In our pipeline, we discard this template and force the model into diverse roles: a context-augmented translator, an expert editor, and a zero-shot evaluator. A priori, it wasn't clear how much of the base model's general instruction-following capability would survive the translation fine-tuning. Our findings suggest that at least partially it remains robust: e.g., the model is able to take dictionary context into account.

**Ablation of Post-Processing.** In our current evaluation, the impacts of GrammarDB-guided editing (stage 2) and rule-based post-processing (stage 3) aren't analyzed separately. We currently lack the numeric evidence to estimate exactly how much of the quality gain is attributable to the GrammarDB context injection vs. the regex corrections.

**Regression to the Mean.** Multi-stage refinement using LLMs carries an inherent risk of "regression to the mean": in each subsequent step (merging, evaluating), the model may inadvertently overwrite or "forget" accurate translation choices made in earlier steps, homogenizing the output. Quantifying the extent of this homogenization in our pipeline is left to future analysis.

**Pipeline Portability and Future Architectures.** Stage 2 of our pipeline is calibrated to the specific failure modes of the Gemma model family. While in principle it is possible to swap the base model (e.g., with a more aggressively quantized version of TranslateGemma), choosing a totally different model may require recalibrating the Levenshtein weights. Furthermore, as newer LLMs demonstrate stronger agentic capabilities, a more dynamic pipeline design might fit them better: instead of forcing offline dictionary and GrammarDB context into the prompts, both types of resources could be exposed via MCP, allowing the model to query them at will.

## 7 Conclusion

We presented Krosny, a scaffold for LLM-based English–Belarusian translation, designed to mitigate LLM hallucinations and improve output fluency. By augmenting TranslateGemma-12B with dictionary context and spell-check suggestions from a reference morphological database, we sought to limit the scope of the model's deviations from the modern Belarusian literary standard. Preliminary evaluation shows that our iterative pipeline reduces the ratio of out-of-vocabulary tokens in the output, yields a +3.8 BLEU / +1.8 chrF2 improvement over a zero-shot baseline, but doesn't help achieve translation quality comparable with the best constrained-track systems. Echoing the bitter lesson (Sutton, 2019), this may be an inherent limitation of our approach, i.e. injecting language-specific knowledge into the prompt context without modifying the weights. Still, we observe that leveraging language-specific resources is a viable path to some quick wins when computational resources are not sufficient for large-scale training or fine-tuning runs.

## Abstract

We present Lumen[1], our submission to the WMT 2026 General Machine Translation Shared Task. We focus on instruction-specialized translation, where systems must produce accurate translations while satisfying fine-grained requirements on style, terminology, and structured output. Lumen follows a four-stage pipeline. First, continued pre-training and supervised fine-tuning jointly strengthen multilingual translation competence and the ability to follow translation-specific instructions, such as terminology, style, and format constraints. Second, we extend the originally offline M$^2$PO preference-optimization framework into an online preference-optimization stage: the current policy samples candidate translations, an LLM judge assigns continuous direct-assessment scores, and the resulting multi-pair preferences are used to update the model. Third, on-policy distillation transfers stronger translation-instruction-following behavior from a larger teacher model to the Qwen3-14B student, improving translation-instruction adherence while retaining a 14B primary translation backbone. Finally, structure-aware inference and postprocessing preserve required formats, while selective repair addresses clear structural or decoding failures before submission. We participate in 23 translation directions. Under an absolute 1–5 LLM-judge rubric that evaluates translation-instruction following and translation quality separately, Lumen reaches an overall mean score of 4.60. Despite using a 14B translation backbone, it achieves performance comparable to leading proprietary systems in both translation quality and translation-instruction following.

[1]The open-source model is available at https://huggingface.co/ATH-MaaS/Lumen_wmt26.

## 1 Introduction

The Conference on Machine Translation (WMT) continues to serve as the primary arena for benchmarking progress in machine translation (Kocmi et al., 2024, 2025). For years the field was dominated by the Transformer architecture (Vaswani et al., 2017), whose powerful attention mechanism set a high standard for translation quality. The recent advent of large language models (LLMs), however, has sparked a paradigm shift: pre-trained on vast amounts of text, these models exhibit remarkable abilities in understanding context, generating fluent text, and leveraging world knowledge, making them exceptionally promising foundations for translation systems (Hendy et al., 2023; Alves et al., 2024). This shift is already evident at recent WMT campaigns, where many of the strongest general-translation submissions are now built on LLM foundations (Wang et al., 2025; Zheng et al., 2025; Zhang et al., 2025).

Despite the strong performance of general-purpose LLMs on translation, adapting them into high-fidelity, specialized translation systems remains challenging. Existing LLM-based MT systems largely focus on generic translation quality, whereas in practical applications users often require the model to follow fine-grained instructions during translation: specifying a translation style (e.g., formal, colloquial, or customer-service tone), adhering to domain-specific terminology, resolving ambiguity from context, or preserving the integrity of structured formats such as JSON or rich text. General translation models struggle to satisfy such requirements reliably, which constitutes a key gap for deploying LLM-based MT in real-world scenarios. To bridge this gap, we propose training and optimization methods for *instruction-specialized translation* that systematically improve both translation quality and instruction-following ability.

*Proceedings of the Eleventh Conference on Machine Translation*, pages 1430–1439
October 28-29, 2026 ©2026 Association for Computational Linguistics

This paper describes Lumen, our submission to the WMT2026 General Machine Translation Shared Task, covering 23 translation directions and built on the Qwen3 foundation (Yang et al., 2025). The system consists of a four-stage pipeline, illustrated in Figure 1. Our main contributions are as follows:

- **An instruction-specialized two-phase adaptation strategy.** We first run continued pre-training (CPT) on a corpus deliberately assembled to follow the WMT domains and language directions, mixed with general instruction data, which pulls the backbone towards the evaluation distribution while preserving its general ability. On top of this CPT-strengthened backbone we design an SFT recipe that mixes general translation data with translation-specific instruction data. A high proportion of translation data preserves the base translation ability, while instruction data covering the four WMT26 instruction categories (formal/informal voice, glossaries, structured translation, and style and expressions) enables the model to internalize instruction-following ability during fine-tuning. The instruction data is built cost-effectively through an LLM-assisted synthesis pipeline.

- **An online preference optimization framework based on M$^2$PO.** We extend the originally offline M$^2$PO (Multi-Perspective Multi-Pair Preference Optimization) (Wang et al., 2026) into an online preference-optimization stage, coupling on-policy sampling with an LLM-judge (direct-assessment) reward. Unlike an offline procedure over a fixed preference set, this framework refreshes candidate translations from the current policy and converts their ranked scores into multi-pair supervision. The remaining gap in instruction compliance is addressed by the subsequent OPD stage.

- **An OPD recipe for translation instruction following.** We adapt on-policy distillation to instruction-specialized translation. After CPT+SFT+RL, our 14B model is strong at translation but remains weaker at following fine-grained translation instructions. We therefore use an off-the-shelf, open-source Qwen3-32B-Instruct model as teacher and our 14B model as student, aligning token-level distributions on trajectories sampled by the student. This transfers the teacher's stronger instruction-following behavior to the student while preserving the student's translation specialization and its 14B primary translation backbone (Kim and Rush, 2016; Gu et al., 2024).

- **Structure-aware inference and selective repair.** At inference time, Lumen processes plain text and structured inputs in a format-aware manner, preserving markup and protected content through postprocessing. Rule-based checks identify clear structural or decoding failures, for which the system applies deterministic repair when possible and selectively rewrites the remaining cases.

On the WMT26 test sets, our 14B system attains an overall mean of 4.60 under an absolute 1–5 LLM-judge rubric (translation-instruction following 4.49, translation quality 4.71). Despite using a 14B translation backbone, Lumen achieves performance comparable to leading proprietary systems in both translation quality and translation-instruction following. The remainder of this paper is organized as follows: Section 2 describes the four-stage system; Section 3 presents the experimental setup and results; and Section 4 concludes.

## 2 System Description

### 2.1 System Overview

Lumen comprises four successive stages, as illustrated in Figure 1. The first stage adapts the Qwen3-14B foundation model through continued pre-training and supervised fine-tuning, jointly strengthening multilingual translation and translation-specific instruction following. The second stage extends M$^2$PO to online preference optimization, using on-policy candidates and LLM-based direct-assessment rewards to improve translation fidelity. The third stage applies on-policy distillation to transfer instruction-following behavior from a larger frozen teacher to the translation-specialized 14B model. The final stage performs structure-aware decoding and targeted postchecking to preserve required formats and repair clear decoding failures.

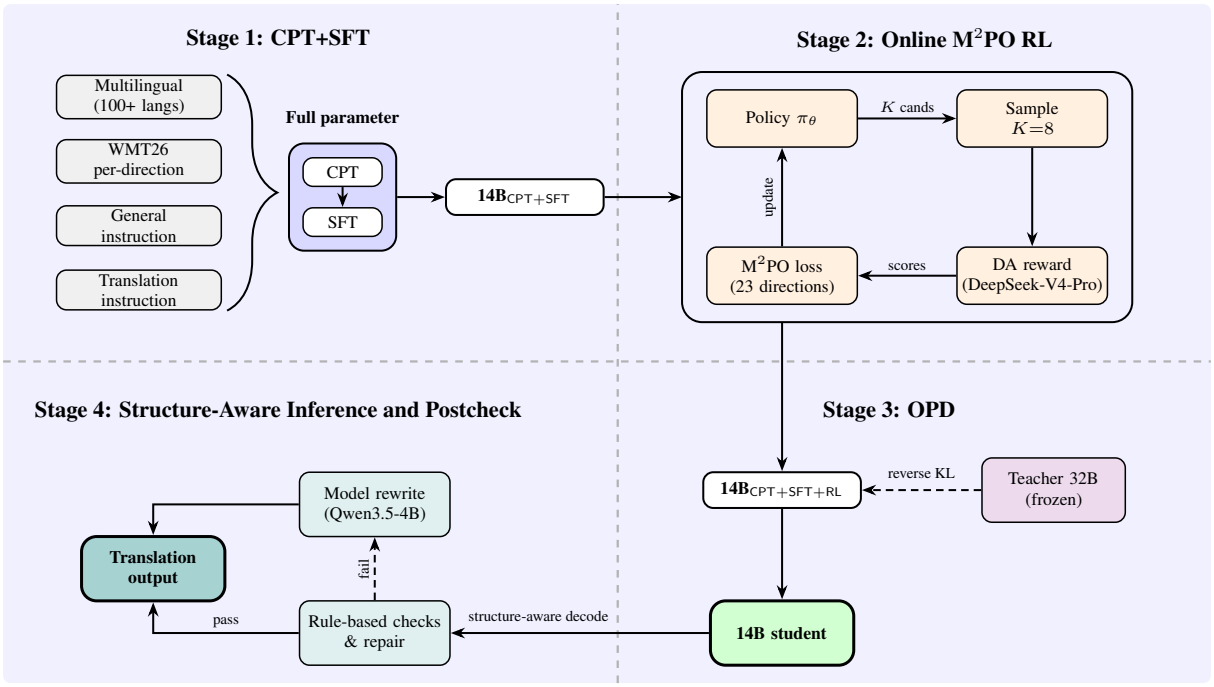

Figure 1: Overall pipeline of Lumen. **Stage 1 (CPT+SFT)** adapts a Qwen3-14B backbone to multilingual translation and translation-specific instruction following. **Stage 2 (online M$^2$PO)** uses direct-assessment rewards from DeepSeek-V4-Pro to optimize the current policy from sampled candidates. **Stage 3 (OPD)** distills instruction-following behavior from a frozen Qwen3-32B-Instruct teacher into the 14B student. **Stage 4** performs structure-aware decoding and conservative postchecking to preserve required formats and repair clear failures before submission.

### 2.2 CPT and SFT Adaptation

In Stage 1, we adapt the Qwen3-14B foundation model in two consecutive full-parameter phases (Figure 1, Stage 1). The first phase is continued pre-training (CPT) on multilingual text covering the task-relevant domains and 23 translation directions, supplemented with general instruction data. This phase strengthens domain and language coverage, particularly for low-resource and regional languages that are underrepresented in general pre-training corpora. The second phase is supervised fine-tuning (SFT) on a mixture of parallel translation and instruction-bearing data. Both phases update all model parameters: CPT strengthens the multilingual translation foundation, while SFT jointly develops translation quality and translation-specific instruction following.

#### 2.2.1 Training Data

**CPT data.** The continued-pre-training corpus combines multilingual text from task-relevant domains and all 23 translation directions with general instruction data. The multilingual component is constructed from monolingual text and the source sides of parallel corpora drawn from internal resources, WMT releases, and public multilingual resources such as FLORES+ (NLLB Team, 2024). We cap and stratify high-resource corpora to prevent them from dominating the mixture, while increasing the representation of low-resource and regional languages.

**SFT data.** The SFT mixture contains four sources: multilingual parallel data, task-specific parallel data for the 23 WMT26 directions, general instruction data, and translation-specific instruction data. Parallel translation remains the majority of the mixture to preserve the model's translation competence, while the two instruction sources provide general and translation-specific instruction-following supervision. When reliable references are unavailable, we supplement the parallel data with model-generated translations retained after quality filtering, with additional synthetic data used to improve the coverage of low-resource directions.

All corpora undergo normalization, deduplication, language and script verification, and length-based filtering. We additionally score parallel pairs with XCOMET-XXL (Guerreiro et al., 2024), from the COMET family of learned MT metrics
