The extended use of LLMs for MT opened a new, training-free perspective. While language modeling was not initially aimed at machine translation, early LLMs developed the emergent ability (Wei et al., 2022) to perform translation for language pairs well represented in their training corpus. However, for languages and domains absent from the training data, quality remains poor. But LLMs can be used via instructions and the prompt can be enriched with contextual information or precise instructions. Many works explored the input flexibility of LLMs to improve MT in low-resource scenarios. These works (2022–2024) focused either on prompting strategies or, mostly, on knowledge injection.

The injected knowledge comes from different sources:

- Use of lexicon / glosses to bridge the lexical gap for low-resource languages or specialized terminologies (Ghazvininejad et al., 2023). The main challenge is to ensure sufficient coverage in the resource used to ensure matching of the terms present in the input, and there is an inherent difficulty in capturing idioms. The matching mechanism often involves other NLP tasks such as lemmatization and Word Sense Disambiguation. Some of this matching process is handled by external code but some rely on the LLM reasoning abilities. This however does not greatly influence fluency and collocational quality: bridging the lexical gap ensures that the right words are made available to the model, but not that they are combined into natural, idiomatic target sentences. The linguistic reference should also follow the language's natural evolution (a dictionary is the partial and fixed image of the state of the language at a given moment in time). It does not include idioms, colloquialism or regional variations. This is particularly relevant for Creoles where there are some differences between the official language (for Haitian, the orthography standardized by the IPN in 1979 Bernard, 1980) versus the Creole spoken or written casually. The Kreyòl of northern Haiti displays some differences from the one spoken in the capital... Traditional linguistic resources mostly fail to capture this diversity.
- **Translation Memory.** The idea is to use relevant parallel sentence examples not at training time but at inference time incorporating them in the model instruction (Mu et al., 2023). This approach boosts fluency and helps produce more idiomatic sentences and correctly use words in context but its efficiency depends on several parameters: the effective closeness between the new sentence to translate and the provided exemplars. Therefore it depends on the size of the aligned corpus and the efficiency is limited in out-of-domain scenarios (same issue as the training based approaches); the quality of the retrieval process, which can be lemma based (precise but risk of a lower recall) or semantic, inspired by the RAG architecture, with the risk of incorporating examples that are further from the input sentence, therefore an important calibration work of the search hyperparameters is mandatory to optimize its benefits on a specific corpus; the number of exemplars provided (hyperparameter) and the ability of the underlying model to actually benefit from these examples.
- **Morphological analyzers**: to help the model identify grammatical features from an inflected form. This is highly relevant for morphologically rich languages such as Sanskrit but less so for Creole, which shows no inflectional morphology and has only a few homonyms from different grammatical categories (e.g. *manje*, both 'to eat' (v.) and 'food' (n.)).

The benefits of these approaches depend naturally not only on the quality and breadth of the LLM used but also on the capabilities of the LLM itself, and more specifically on its natural literacy in the target (and to a lesser extent source) language and its reasoning and metalinguistic abilities. Indeed, if the base model was not trained on sufficient data from the target language it usually fails to produce grammatically correct utterances. Hence another series of work focused on the LLM linguistic abilities and their capacity to learn new languages (either underrepresented or fictitious) from grammar books. Incorporating grammar excerpts and rules in the context of the generative model can steer the production of well-formed utterances but the main challenge faced is identifying which rule(s) to inject in context

with regard to the source sentence. Most of these works were therefore more probing the linguistic and generalization abilities of LLMs rather than applying it directly to MT (Marmonier et al., 2025); see also (Tanzer et al., 2024; Hus and Anastasopoulos, 2024).

All of these techniques have been shown to individually boost a baseline model, but the interaction of these different forms of expert knowledge has rarely been investigated. In a recent paper, Pei et al. (2025) treat the prompt as a modular space and quantify the relative benefit of each type of linguistic knowledge, using Manchu as a test case. The authors leveraged four different resources or techniques (dictionaries, grammar books, parallel examples and CoT prompting) and carried out a methodical ablation study for Manchu. To the best of our knowledge, these approaches have not been attempted on Creole languages and it is already a contribution to measure their efficiency.

### A.3 Agentic approaches to MT

Since 2024, LLMs' inner workings have evolved to let them perform a broader range of tasks: first the shift from train-time to test-time compute, with reasoning models that integrate CoT capabilities and output intermediate reflection traces before outputting a final answer to their instruction. It seems particularly relevant for translation tasks where some arbitrages are necessary to pick the best translation for an expression or where the decision process can be decomposed in multiple steps. A next step was reached with the advent of tool-calling capabilities, where the model can autonomously call provided tools and reason about their output until the task is performed (ReAct; Yao et al., 2023). This tool-calling ability, in what is now called agentic AI, suggests the opportunity to combine the latest LLM reasoning abilities to orchestrate external knowledge injection and thus optimize translation quality.

The main shift is that it introduced a novel paradigm for MT, framing it as a "multi-step, modular and potentially collaborative process" (Briva-Iglesias, 2025). Hence our positioning of this work as a reflection on the shift from train-time to test-time compute adapted for AI translation. What has been explored is multi-agent MT, along several lines:

- *Agents as a translation agency*: role-specialized LLMs (translator, editor, proof-reader) organised like a human translation company, as in TransAgents for ultra-long literary text (Wu et al., 2024).
- *Knowledge- and error-driven pipelines*: a model first mines the knowledge or diagnoses the errors it needs, then translates or refines accordingly: e.g. the human-like strategy mining of MAPS (He et al., 2024), the estimate-then-refine loop of TEaR (Feng et al., 2024), and multi-agent debate (Liang et al., 2024); CRAT (Chen et al., 2024b) adds retrieval to resolve unknown terminology.
- *LLM as a corrector / reviser*: iterative self-refinement (Madaan et al., 2023) applied to MT, but mainly on well-documented languages where the base model was already fluent, with marginal gains, inconsistent across domains, languages and metrics.

The exploration of agentic approaches for MT is, however, rather disappointing. Much work framed as agentic is rarely agentic in the most recent sense (namely tool-calling and reasoning loops). In reality it is mostly a combination of several LLM calls with specialized prompts. It can to a certain extent be called a multi-agent system, but since each individual LLM has no agency and only performs the task assigned to it in a single call, "workflow" describes it better. Kim (2025) is the only work to honestly frame it as "prompt chaining".

These approaches are also costly (Briva-Iglesias and Dogru, 2025): the aforementioned work reports that sequential and iterative agent workflows consume roughly five and fifteen times the tokens of a single-pass system, respectively, while topping no automatic-metric comparison and edging ahead in only a single human-evaluation category. What makes agentic AI specific, the ability to autonomously call tools and leverage their output, was not explored at all, and the picture for low-resource MT remains inconclusive. Are the results more promising for low-resource languages, provided that adequate tooling can be built with quality resources? Our goal is to use the challenge as an opportunity to explore this new paradigm and determine to what extent these new training-free approaches can substitute for or complement fine-tuning.

## B Configuration options

The harness exposes every behaviour as an explicit per-run flag; the default configuration equals the last-known-good baseline (a change ships only after it wins an A/B). Table 4 is the reference key — what each lever means and its value in the eng→hat submission run; shaded cells are the deliberately active (non-baseline) settings that constitute the system.

Table 4: Meaningful harness configuration flags: meaning, dataclass default, and value in the eng→hat *challenge* submission config (`evaluation/submit_challenge.py`). Reasoning is direction-gated and off for eng→hat, so this is the reasoning-off arm (see `enable_reasoning`). Active non-baseline settings shaded green.

| Flag | Meaning | Default | Shipped |
|---|---|---|---|
| **Dictionary / gloss push** | | | |
| `dictionary_variant` | Delivery mode for lexical evidence: `batch`/`single` expose a callable `dict_lookup` tool (ReAct loop); `off` = evidence force-pushed into a direct-translation prompt. | batch | off |
| `gloss_push` | Auto-gloss the source sentence and inject the glosses into the prompt (imposed, not self-served). | False | True |
| `gloss_skip_common` | Push rare words only; `False` = gloss common words too (weak models mistranslate common words as well). | True | False |
| `gloss_common_topn` | Frequency rank below which a source word counts as "common". | 3000 | 3000 |
| `gloss_bridge_lemmatize` | On a look-up miss, resolve an inflected word to its headword with the right POS (called→call) before fuzzy recall. | False | True |
| `gloss_idioms` | Detect Freeman idioms/MWEs in the source and surface them (adds a line only on a hit). | True | True |
| `gloss_pivot` | For a source with no lexicon index (fr), pivot content words FR→EN→hat so the wide-gloss lever fires. | False | False |
| `gloss_clean` | Clean+rank raw gloss blobs into short best-first renderings (strip POS/sense/OCR noise). | False | False |
| **Few-shot demonstrations** | | | |
| `fewshot_k` | Fixed (source⇒target) example pairs prepended to the prompt, selected deterministically from the gold corpus (leakage-safe). 0 = off. | 0 | 5 |
| `fewshot_dynamic` | Retrieve the $k$ demos most similar to the sentence instead of static even-spaced ones. | False | False |
| **Dense retrieval push** | | | |
| `retrieval_push` | Inject dense-retrieved parallel + monolingual-fluency exemplars (a dynamic domain few-shot). Into-hat only. | False | True |
| `retrieval_k` | Exemplars retrieved per channel. | 3 | 3 |
| `retrieval_min_sim` | Cosine floor (bge-m3) below which an exemplar is dropped. | 0.55 | 0.55 |
| `retrieval_mono` | Include the monolingual (fluency) retrieval channel alongside the parallel one. | True | True |
| `retrieval_drop_self_match` | Drop any exemplar whose source is verbatim the query sentence (blind-eval integrity guard). | False | True |
| **Grammar** | | | |
| `grammar_push` | Auto-inject top grammar rule-cards. Helps only where there is no gloss (fr-ht); redundant on en-ht. | False | False |
| `grammar_query_features` | Detect the sentence's marked constructions (TMA, negation, questions) to steer card retrieval. Inert unless `grammar_push` is on, i.e. fr→ht only. | True | True |
| **Prompt rules** | | | |
| `no_codeswitch` | Translate every common word; do not leave/transliterate source words (keep proper names). | False | True |
| `keep_proper_names` | Copy names verbatim, never phonetically respell them. | False | False |
| `idiomatic_hint` | Render the meaning as a native speaker would; treat the glossary as reference, not a script. | False | False |
| **Decoding / robustness** | | | |
| `temperature` | Decoding temperature (greedy). | 0.0 | 0.0 |
| `enable_reasoning` | Emit chain-of-thought before the answer in one decode. Direction-gated: off into Creole, on for ht→fr (**+3.03**); when on, `max_tokens` → 8192 and `final_max_tokens_ratio` → 0, else the per-word cap truncates the CoT. | False | False |
| `final_max_tokens_ratio` | Anti-runaway cap on the final decode: tokens per source word. 0 = disabled. | 6.0 | 6.0 |
| `regenerate_on_collapse` | If the output is degenerate (repetition/length explosion), regenerate that sentence with a frequency penalty; keep the retry only if it scores better. Into-hat only. | False | True |
| `collapse_retry_drop_push` | On a collapse retry, rebuild the prompt without the retrieval block (cures retrieval-induced loops). Into-hat only. | False | True |
| `normalize_repetition` | Deterministic post-edit collapsing degenerate repeated n-grams; safety net, never touches fluent output. | False | True |

**Per-direction adaptation.** Table 4 is the eng→hat configuration; the other three directions run the same stack and differ in four flags only, each following from evidence availability rather than from a per-pair search — French has no direct hat lexicon, the dense index and the collapse guard are Creole-side, and reasoning repairs the hat→fra passthrough collapse (§3.4).

| Direction | Difference from the eng→hat configuration |
|---|---|
| eng→hat | — (the reference configuration, Table 4) |
| fra→hat | + `gloss_pivot`, + `grammar_push` |
| hat→eng | − `retrieval_push`, − `regenerate_on_collapse`, − `collapse_retry_drop_push` |
| hat→fra | as hat→eng, + `enable_reasoning` |

*What was submitted.* The blind-set files enable `enable_reasoning` in all four directions, so our official scores correspond to the + *harness* + *reasoning* row of Table 1, not the *shipped* row.

## C Tool input/output

The three tools the ReAct agent can call: the description and argument schema as shown to the model (from `tools/*.py`, abridged), a *real* call and its real output (tool code run locally).

### C.1 Lexicon — `dict_lookup`

**`dict_lookup(word*, lang, reverse)` — individual word lookup**

**What the model sees.** Look up one source word/lemma in the Freeman dictionaries (one word, not a phrase); forgiving on accent/spelling/clitic variants; returns candidate lemmas with senses (POS + gloss). **Args:** `word*` (str); `lang` (`ht|en|fr`); `reverse` (bool, gloss-side hits too).

```
>>> dict_lookup("shaft", lang="en")
Dictionary candidates for "shaft":
- shaft (n): n. 1 (mach.) chaf 2 (tunnel) tinèl, chemen anba td 3 (handle) manch ...
- shift (n/v) [edit]: n. 1 (change) chanjman, varyasyon 2 (work) (la)relèv, ekip ...
>>> dict_lookup("barb", lang="en")
Dictionary candidates for "barb":
- barb (n): n. 1 (thorn) pikan 2 (insult) pawòl piman bouk, afwon
- barbed (adj) [edit]: adj. bable; ~ wire filfè, fildefè bable [Fr.]
```

### C.2 Translation memory — `tm_search`

**`tm_search(sentence*, k)` — fuzzy bitext retrieval**

**What the model sees.** Fuzzy-match the source against the bitext and return the closest past translations as `source => target` with a chrF++ match %. **Args:** `sentence*` (str); `k` (int, default 3).

```
>>> tm_search("Wash your hands with soap and water.", k=3)
Similar past translations (source => target, % = chrF++ match):
- [87.2%] Wash hands with soap and water.  =>  Lave men ou avèk dlo ak savon.
- [48.7%] Wash your hands frequently with soap and water for at least 20 seconds.
          =>  Lave men ou souvan avèk savon ak dlo pandan 20 segonn.
```

In-domain (health) input hits; on encyclopedic FLORES sentences the same call usually returns nothing.

### C.3 Grammar — `grammar_lookup`

**`grammar_lookup(sentence*, k)` — rule-card retrieval**

**What the model sees.** Retrieve Haitian Creole grammar rule cards for a sentence — preverbal TMA markers (`te`/`pral`/`ap`), postposed determiners, negation `pa`, `se` clefts, possession. **Args:** `sentence*` (str); `k` (int, default 3).

```
>>> grammar_lookup(source, k=2)
Grammar notes (morphosyntax):
- [TMA: past / anterior (te)] Preverbal 'te' marks anterior; subject + te + verb; no verb
  inflection for tense.  e.g. Li te manje. -- He ate / had eaten.
- [Negation: 'pa' placement] 'pa' precedes any TMA marker + verb: pa te, pa ap (pap),
  pa pral.  e.g. Mwen pa konnen. -- I don't know.
```

## D Linguistic resources used

Inventory of the Haitian Creole (`ht`) resources the harness draws on, grouped by **tool destination** (which channel consumes them) and listed alphabetically within each group. The colour code marks whether a resource is loaded by the **final submission config** (final), was queried in an ablation only (exp.), or was considered but **not retained** (decl.), with the reason (copyright or data quality) given in-line. The paper is `ht`-first; the four study languages sit on the Wiktionary/kaikki floor, as discussed in the main body.

final in submission config  exp. ablation only  decl. considered, not retained

| Resource | Size / role | License | Source | Used |
|---|---|---|---|---|
| *Gloss lexicon* (dictionary tool, both directions) | | | | |
| Freeman & Laguerre, *HT–EN Dict.*, 6th ed. (2010) | 78,843 entries (index 80,704, +16k idioms); reference gloss lexicon | CC BY-NC-ND 4.0 | KU ScholarWorks `1808/11816` | final |
| Haiti-Référence online dict. | 13k entries (12k FR glosses); direct HT→FR oracle — *copyright*, dev-aid only | all rights reserved | haiti-reference.info | decl. |
| Freeman & Laguerre, *HT–EN Medical Dict.* (1997) | 1,110 entries; medical domain | CC BY-NC-ND 4.0 | KU ScholarWorks `1808/10892` | final |
| Védrine, *leksik kreyòl* | 25 entries; terminology glossary | free (author-hosted) | Potomitan (Védrine) | final |
| Heurtelou & Vilsaint, *Diksyonè Medikal* (2000) | 2,978 entries; medical domain — *copyright*, cannot use | all rights reserved | Educa Vision (in print) | decl. |
| Targète & Urciolo, *HT–EN Dict.* (1993) | 7,611 entries; secondary bilingual seed — *copyright*, cannot use | all rights reserved | Dunwoody Press (in print) | decl. |
| Valdman et al., *HCEBD* (2007) | ≈30k entries; gold-standard — *copyright*, borrow-only (CDL) | all rights reserved | IU Creole Institute | decl. |
| Vilsaint, *Diksyonè kreyòl–anglè* | 34k terms; commercial — *copyright*, preview-only | all rights reserved | Educa Vision | decl. |
| *Pivot lexica* (fr ↔ ht gloss, via English) | | | | |
| FreeDict *eng–fra* v0.1.6 | 8,799 headwords; EN→FR leg of ht→fr gloss | GPLv2+ / CC BY-SA | FreeDict | final |
| FreeDict *fra–eng* v0.4.1 | 8,505 headwords; FR→EN leg of fr→ht pivot | GPLv2+ / CC BY-SA | FreeDict | final |
| kaikki French (Wiktionary) | 368,109 EN-headed entries; enlarges fr→ht pivot | CC BY-SA 3.0 | `kaikki.org` | final |
| *Parallel corpora* (dense retrieval / TM) | | | | |
| FineTranslations | web-scale; *synthetic* (Gemma3 MT target) — *data quality*, not gold | ODC-BY | HuggingFaceFW | decl. |
| ISI many-eng v2 | ∼52k novel pairs; *data quality* — CCAligned web-junk | per-source | rtg.isi.edu/many-eng | decl. |
| Kreyòl-MT (Robinson et al., 2024) | hat–eng 665k, hat–fra 353k; TM / mBART-baseline probe only | per-source aggregate | Robinson et al. (2024) | exp. |
| NLLB-mined | ht–en / ht–fr 300k/300k; 30k dense retrieval index (into-ht) | ODC-BY | `allenai/nllb` (HF) | final |
| VOA Creole news | ∼23k PD articles; *data quality* — no article-level pairing | mixed (PD + wire) | voanouvel.com | decl. |
| *Monolingual* (target-side fluency channel) | | | | |
| Wikipedia Haitian Creole (2023-11-01) | 30k-sentence sample; bge-m3 fluency channel (into-ht) | CC BY-SA | Wikimedia dump | final |
| *Grammar and orthography* (grammar-RAG / normalization) | | | | |
| DeGraff (2007), *Kreyòl Ayisyen* | descriptive grammar; source of grammar-RAG cards | self-archive; unverif. | MIT (author) | final |
| IPN orthography (1979) | official phonemic spelling standard; normalization target | standard (n/a) | Institut Pédagogique National | final |

Table 5: Haitian Creole resources, grouped by tool destination. Idiom sub-entries fold in via `build --idioms`; the shipping gloss index totals 70,859 entries after OCR / de-columnization repair.

## E Results comparison across systems

Three FLORES+ devtest sentences (en → ht) through five systems: **baseline** (Gemma-4-E2B + Creole-MT LoRA), **qwen** (no harness), **+harness** (forced push, submission config), **+harn+reason**, **frontier** (`gpt-4.1-mini`); the src and gold rows sit in the output column, above the outputs. Output words are matched to the gold *in order* (longest-common-subsequence, tolerating a displacement of up to three words): matched words are green, and a word that differs from its aligned gold word only in accents or case, or by a single character, is yellow; punctuation is ignored. chrF++ is character-level and *case-sensitive*, so yellow words still cost score. chrF++: ≥55 40–54 <40.

| system | chrF++ | output / reference |
|---|---|---|
| **idx 30** | | |
| src | | Because the dinosaur feathers do not have a well-developed shaft, called a rachis, but do have other features of feathers — barbs and barbules — the researchers inferred the rachis was likely a later evolutionary development that these other features. |
| gold | | Kòm plim dinozò yo pa gen yon tij byen devlope, ki rele rachi, men yo gen lòt karakteristik plim — bab ak babil — chèchè yo dedwi ke rachi a te pwobableman yon devlòpman evolitif ki vini apre lòt karakteristik yo. |
| baseline | 36.9 | Pwenn ren asay dinoza yo pa gen yon ti tisi long tankou ras la, men li gen lòt karakteristik nan pwenn tankou rad la ak barbule yo, pou sa rekeyachè yo te konklize ras la te gen tandans yo t ap devlope pita atravè lòt karakteristik sa yo. |
| qwen | 35.2 | Kèk kominote dinazaur yo pa gen yon shaft bien developman, ki apelé yon rachis, men yo gen yon fèt lòt ki sèlman kominote — barb ak barbül — rechèch yo konklize ke rachis yo te pwosedi yon developman evolwayonè lèt ki sa yo. |
| +harness | 53.0 | Paske zwazo dinozò pa gen yon chaf bien devlope, ki apelé yon rachis, men yo gen lòt karakteristik zwazo — pikan ak barbül — chichi yo dedwi ke rachis te pwobabman yon evolisyonnis devlope pita k sa lòt karakteristik yo. |
| +harn+reason | 42.0 | Paske pm il dinozò yo pa gen yon chaf bien devlope, ki te rele rachis, men genyen lòt kalite pm il — pikan ak pikan minil — chichi yo te dedwi ke rachis te genlè yon evolisyonnis developman ki te pita pase sa lòt kalite yo. |
| frontier | 72.1 | Paske plim dinozò yo pa gen yon baton byen devlope, yo rele l yon rachis, men yo gen lòt karakteristik plim — barbs ak barbules — chèchè yo dedwi ke rachis la te pwobableman yon devlopman evolisyonè ki te vini apre lòt karakteristik sa yo. |
| **idx 39** | | |
| src | | During his trip, Iwasaki ran into trouble on many occasions. |
| gold | | Pandan vwayaj li, Iwasaki te gen plizyè pwoblèm. |
| baseline | 60.4 | Pandan vwayaj li a, Iwasaki te rankontre pwoblèm anpil tan. |
| qwen | 30.9 | Pou li te fè yon pèw, Iwasaki te ranpli kounye a nan peryò diferan. |
| +harness | 61.5 | Pandan vwayaj li, Iwasaki te eksplike anpil okazyon. |
| +harn+reason | 67.2 | Pandan vwayaj li, Iwasaki te kounye a pwoblèm anpil okazyon. |
| frontier | 75.0 | Pandan vwayaj li, Iwasaki te jwenn pwoblèm plizyè fwa. |
| **idx 185** | | |
| src | | France is the seventh country in the European Union to suffer this virus; following Austria, Germany, Slovenia, Bulgaria, Greece and Italy. |
| gold | | Lafrans se setyèm peyi nan Inyon ewopeyèn k ap soufri ak viris sa, aprè Otrich, Almay, Esloveni, Bilgari, Grès ak Itali. |
| baseline | 47.4 | Frans se sètèm peyi nan Inyon Ewopeyen an pou soufize a maladi sa a; sa a te swiv Otrich, Almay, Sloveni, Bulgarie, Gris ak Itali. |
| qwen | 23.9 | Frans la se septèm pwovans yo nan Unyon Europeen ki te fèt vire yo; aprè Austri, Alman, Slovene, Bulgar, Gres e Italyen. |
| +harness | 76.2 | Frans se setyèm peyi nan Inyon Ewòpeyen ki soufri viris sa; aprè Otrich, Almay, Esloveni, Bilgari, Grès ak Itali. |
| +harn+reason | 67.2 | Lafrans se setyèm peyi nan Inyon Ewdpeyen ki soufri sa viris sa; apre Otrich, Lalmay, Esloveni, Bilgari, Lagrès ak Itali. |
| frontier | 63.6 | Lafrans se setyèm peyi nan Inyon Ewopeyen an ki soufri viris sa a; apre Otrich, Almay, Sloveni, Bulgari, Lagrès ak Itali. |

*Proper names are not exempt.* The released FLORES+ Haitian reference for idx 39 reads `lwasaki` where both source columns read `Iwasaki`, an l/I confusion in the gold itself; the scores above use our patched local copy.

## F Official shared-task results

Official scores on the task's blind test set for our four directions. Our three submitted systems were the bare model (`contrastive2`), the harness (`contrastive1`) and the harness with reasoning (`primary`). $\Delta$ is against the primary baseline (Gemma-4-E2B + Creole-MT LoRA); rank is among all entries scored in that direction, baselines included. **Bold** = best in the direction; green = our best submission.

| System | chrF++ | $\Delta$ | Rank |
|---|---|---|---|
| **en→ht** | | | |
| Kreyòl-MT (secondary baseline) | **37.44** | +4.41 | 1/6 |
| best other participant (gmu) | 34.62 | +1.59 | 2/6 |
| Gemma + LoRA (primary baseline) | 33.03 | — | 3/6 |
| ours: qwen3-8b + harness + reasoning | 30.16 | −2.87 | 4/6 |
| ours: qwen3-8b + harness | 30.10 | −2.93 | 5/6 |
| ours: qwen3-8b, no augmentation | 21.87 | −11.16 | 6/6 |
| **fr→ht** no other team entered | | | |
| Gemma + LoRA (primary baseline) | **31.31** | — | 1/5 |
| Kreyòl-MT (secondary baseline) | 31.11 | −0.20 | 2/5 |
| ours: qwen3-8b + harness | 24.79 | −6.52 | 3/5 |
| ours: qwen3-8b + harness + reasoning | 24.68 | −6.63 | 4/5 |
| ours: qwen3-8b, no augmentation | 19.42 | −11.89 | 5/5 |
| **ht→en** | | | |
| best other participant (pik) | **50.70** | +11.63 | 1/10 |
| Kreyòl-MT (secondary baseline) | 40.97 | +1.90 | 5/10 |
| Gemma + LoRA (primary baseline) | 39.07 | — | 7/10 |
| ours: qwen3-8b + harness | 35.65 | −3.42 | 8/10 |
| ours: qwen3-8b + harness + reasoning | 35.57 | −3.50 | 9/10 |
| ours: qwen3-8b, no augmentation | 33.95 | −5.12 | 10/10 |
| **ht→fr** | | | |
| best other participant (uqam) | **42.43** | +8.48 | 1/8 |
| Gemma + LoRA (primary baseline) | 33.95 | — | 3/8 |
| Kreyòl-MT (secondary baseline) | 33.70 | −0.25 | 4/8 |
| ours: qwen3-8b + harness + reasoning | 31.06 | −2.89 | 5/8 |
| ours: qwen3-8b + harness | 28.69 | −5.26 | 6/8 |
| ours: qwen3-8b, no augmentation | 28.23 | −5.72 | 7/8 |

Three readings. We finish below both baselines in every direction, and behind every other team that entered the same one. The harness itself still works on unseen data: it adds +8.23 (en→ht) and +5.37 (fr→ht) over the bare model against +1.70 and +0.46 out of Creole, and reasoning is worth +2.37 in ht→fr and nothing elsewhere, both as on our dev set. Every system scores far lower here than on FLORES+ devtest (ours −11.7 to −22.5 chrF++, Gemma −7.4 to −17.1, Kreyòl-MT −9.9 to −18.6), so our dev-set margin over the primary baseline does not survive the domain change.

## G Anatomy of a run

One en → ht sentence (FLORES+ devtest, idx 30) shown as a **complete run in both delivery modes**; verbose evidence blocks are abridged for space. The base model (`qwen3-8b`) and the tools are identical across modes; only the delivery differs. The forced-push prompt is a nest of blocks, one shell holding a **SYSTEM** and a **USER** prompt, each assembled in a fixed order.

base template  filled variable  few-shot  lexical gloss  retrieval

### G.1 Forced push

**Forced-push prompt** — single LLM call • blocks in shipping-assembly order

**1 • SYSTEM** — per-direction • prompt-cache-friendly

a base template

```
You are an expert English->Haitian Creole translator specialised in Haitian Creole.
Translate the user's English sentence into accurate, natural Haitian Creole, using
Haitian Creole's IPN-1979 orthography. Output ONLY the translation -- every ordinary word
in Haitian Creole; never leave or transliterate a foreign word (e.g. "speeds" -> "vitès").
```

b static few-shot exemplars (5 total; 2 shown)

```
English:        In all cases, you must book by phone directly with the airline.
Haitian Creole: Nan tout ka yo, ou dwe rezève nan telefòn dirèkteman bò kote konpayi ...
English:        Dump trucks were used to block tube entrances ...
Haitian Creole: Kamyon baskil yo te itilize pou bloke antre tib ...
```

**2 • USER** — per-sentence • assembled top-to-bottom in order

a task + source sentence

```
Translate this English sentence into Haitian Creole:
Because the dinosaur feathers do not have a well-developed shaft, called a rachis, but do
have other features of feathers -- barbs and barbules -- the researchers inferred ...
```

b lexical gloss 18 glosses + 5 idioms (candidate senses, verbatim; 10 shown)

```
Optional lexical hints for less-common words (candidate senses -- use only if helpful;
prefer natural, idiomatic phrasing and do NOT translate word-for-word):
Glossary (source word -> candidates):
- because (conj): conj. paske, pase, diske, piske, akoz (de), dapre, poutet ~ of ...
- feather (n): n. pm il (zwazo) ~ neither God nor man san fwa in fine ~ frekou kola ...
- do (v): v. fe - it! baye!, koupe kloure! don t ~ that! fok ou pa fe sa! ...
- have (m/v): v. genyen, gen I don t ~ anything M pa genyen anyen to ~ (beard) ...
- develop (v): v. 1 (to evolve) devlope, evolye, tounen, dewoule 2 (fix up) amenaje ...
- shaft (n): n. 1 (mach.) chaf 2 (tunnel) tinel, chemen anba td 3 (handle) manch ...
- but (conj): conj. 1 (however; yet; still) men, sepandan, tanselman 2 (only) selman ...
- feature (n/v): n. kalite, karakteristik [Fr], kalbas, kannannan, mak fabrik ...
- barb (n): n. 1 (thorn) pikan 2 (insult) pawol piman bouk, afwon
- later (adv/n): adv. pita, yon lot ... ~ on pi devan; see you ~ n a we pita
  ... + 8 more (18 glosses total)
Idioms / multiword expressions (prefer these over word-by-word):
- pa pile si li te konnen -- to be careful so as not to have later regrets
- woule nan/sou lwil -- to be rolling in clover, have it made, be well-off
  ... + 3 more (5 idioms total)
```

c retrieval few-shot -- into-Creole, k=3 dynamic domain exemplars

```
Similar sentences (source => reference target), nearest first:
<k=3 nearest bitext pairs, injected for into-Creole directions -- abridged>
```

**MODEL — Final Answer (1 call)** — chrF++ 55.7

```
Paske plim dinozò yo pa gen yon chaf bien devlope, ki apelé yon rachis, men yo gen
lòt karakteristik plim -- pikan ak pikan minil -- chichi yo te infere ke rachis yo
genlè pwobab li te yon evolwiyonnis devlope pita ki sa lòt karakteristik yo.
```

The output adopts the pushed glosses almost verbatim: **dinozò, plim, chaf, karakteristik, pikan, evolisyonnis, chichi, genlè, pita**.

## G.2 Agentic (ReAct)

The same instruction, but the tools are now *callable* and native `qwen3` reasoning is on: the model runs a Thought → Action → Observation loop until it answers (two LLM calls).

**Agentic prompt — SYSTEM** base template + callable tools

**a base template**

```
You are an expert English->Haitian Creole translator specialised in Haitian Creole.
Your job: translate the user's English sentence into accurate, natural Haitian Creole,
using Haitian Creole's IPN-1979 orthography.
```

**b callable tool interface (abridged)**

```
You may consult tools before answering:
- dict_lookup(word, lang): one source word -> candidate lemmas with senses (POS + gloss).
- tm_search(sentence, k): closest past translations, 'source => target' with a match %.
- grammar_lookup(sentence, k): Haitian Creole grammar rules (TMA markers, determiners, ...).
Format -- Thought: <reasoning>  Action: <tool>  Action Input: <JSON> ; when ready,
Thought: <final>  Final Answer: <the Haitian Creole translation only>.
```

**THOUGHT 1** (plan)

```
First I'll identify the technical terms -- "rachis", "barbs", "barbules" -- and check whether
Haitian Creole has established translations or keeps them as is.
```

**→ ACTION dict_lookup**

```
Action Input: {"word": "rachis", "lang": "ht"}
```

**← OBSERVATION 1 candidate (edit-distance match)**

```
Dictionary candidates for "rachis":
- rach (n) [edit]: n. ax, hatchet; Ax (for felling trees). Cf. Hatchet.
```

**REASONING** native qwen3 chain-of-thought (condensed)

```
The lookup returned "rach" (an ax) -- unrelated; a rachis is a feather shaft. I'll keep the
technical terms as is and translate the rest.
[It then fabricates "barbs"/"barbules" lookups it never issues, and drafts from its own knowledge.]
```

**MODEL — Final Answer** 2 calls, reasoning on **chrF++ 31.7**

```
Kèk kounye a, poulè dinosaù yo pa gen yon shaft bien développè, ki apelé rachis, ma yo gen
lòt fèt yo--barb ak barbule--èske konesans yo te pran kounye a ke rachis te yon developman
evolwayon ki te pase sa lòt fèt yo.
```

The agent's one lookup fuzzy-matches `rachis` → `rach` ("ax") and rightly discards it, then leaves `shaft`, `barb` and `barbule` untranslated and hallucinates the rest; reasoning recovers none of it. Forced push (above) had handed it `plim`, `chaf`, `pikan` and `dinozò` up front and scored chrF++ 55.7 against 31.7. Same model, same tools; only the delivery changed.

## G.3 Reference and overlap

**Gold reference — FLORES+ ht (idx 30)**

```
Kòm plim dinozò yo pa gen yon tij byen devlope, ki rele rachi, men yo gen lòt karakteristik
plim -- bab ak babil -- chèchè yo dedwi ke rachi a te pwobableman yon devlòpman evolitif ki
vini apre lòt karakteristik yo.
```

Forced push adopts the top *pushed gloss* — which only sometimes equals the gold word: = gold exact match, syn a valid Creole synonym, OCR? a likely Freeman OCR artifact; the agent instead leaves English / wrong sense.

| source | gold ref. | forced push (= pushed gloss) | agentic |
|---|---|---|---|
| dinosaur | dinozò | dinozò | dinosaù |
| feather | plim | plim | poulè |
| shaft | tij | chaf | shaft |
| barb | bab | pikan | barb |
| researcher | chèchè | chichi | konesans |
| later | apre | pita | — |

The win is not that the gloss equals the gold, only `dinozò` and `plim` do. It is that forced push reliably yields *Creole* (a gold word, a synonym, or even a noisy gloss), which chrF++ rewards, whereas the agent leaves English (`shaft`, `barb`). `chichi` for "researcher" is copied faithfully even though it looks like an OCR corruption of `chèchè`.

## H Score distribution across systems

Does the harness lift qwen3-8b's whole per-sentence score distribution onto the primary baseline's, or only its mean, and is the floor (the worst sentences) equalized or still poor? Figure 6 compares five systems on one en→ht FLORES+ devtest index set ($n$=1010).

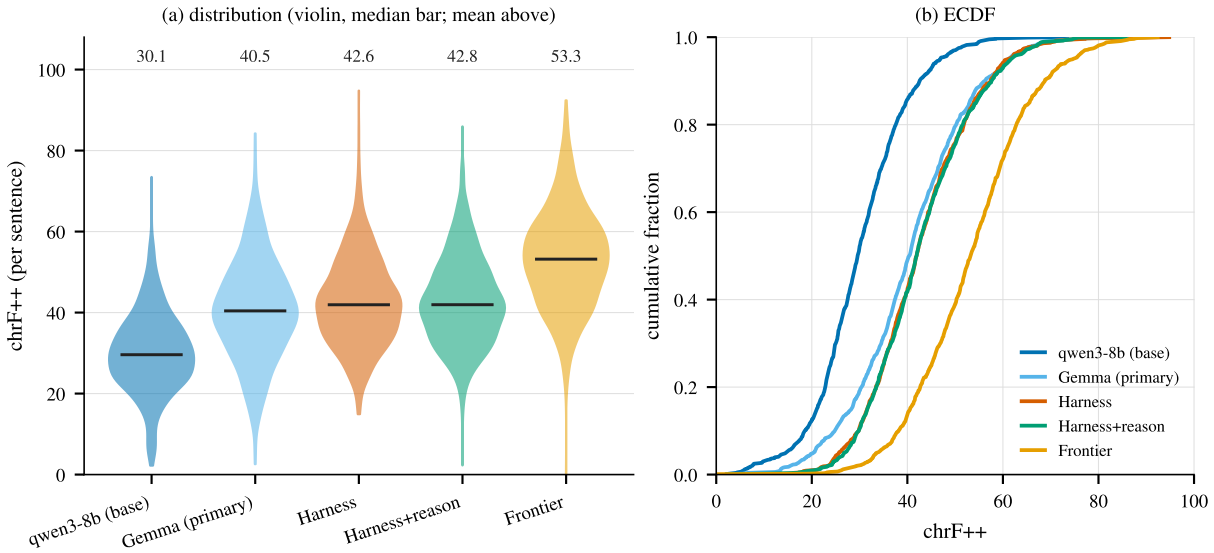

Figure 6: Per-sentence chrF++ distributions across five systems, en→ht (common index, $n$=1010): (a) violins, median bar and mean above; (b) ECDFs.

The harness shifts the bare SLM's distribution right onto the Gemma baseline's (means 42.6 vs. 40.5), with mild compression rather than a reshape (standard deviation of 10.9, between base 9.8 and Gemma 12.3). The gain concentrates at the floor: sentences below chrF++ 20 fall from 12.3% (base) to 0.9% (under Gemma's 4.8%) and the base's worst-decile mean rises 13.0 → 36.3 (Gemma 35.1). So the equalizer raises the worst sentences to baseline level rather than translating the curve uniformly; reasoning adds nothing, and the residual gap to the frontier is entirely at the top (median 53).

# I Ablation by tool

This appendix works through the harness one lever at a time. For each variant we give the chrF++ delta against the stated baseline ( green = a confirmed gain). Each row also names the direction it was measured in (**Dir.**) and the eval set it was measured on (**Set**): `full-1010` is the whole devtest, while `first-200` and `isolated` are the smaller slices we use for cheaper estimates. Because the two kinds of run are mixed here, compare deltas within a lever rather than across sets. All numbers are chrF++ (sacrebleu). These are the runs behind Table 3 in the body.

## I.1 Dictionary / gloss push

The core lever: content-word glosses (Freeman HT↔EN, plus mined idioms) injected into the prompt.

| Variant | Dir. | Set | Δ chrF++ |
|---|---|---|---|
| `gloss_skip_common`=False (wide) | en→ht | isolated | +3.83 |
| `gloss_idioms`=True (default on) | en→ht | – | (kept; no isolated A/B) |
| `gloss_collocations`=True | en→ht | full-1010 | −0.06 (n.s.) |
| `sense_select` (vocab sub-agent) | en→ht | full-1010 | −0.83 |

Using glosses: narrow 35.58 → wide 39.42, isolated. Collocations are too rare on FLORES; the same-model vocab sub-agent hurts (re-thinking underperforms injecting). Vocabulary delivery mode matters too: agentically, a batch lookup gives qwen3-8b +4.29 (sig., $p$=.004) vs. +0.83 (n.s.) for one-word-per-turn, at ∼6× lower cost (en→ht, $n$=60).

## I.2 Source lemmatizer / gloss bridge

A POS-aware source lemmatiser (NLTK + WordNet) resolves inflected source words to the headword with the correct sense (*called*→call, *found*→find→jwenn); the from-ht analogue adds coverage but no score.

| Variant | Dir. | Set | Δ chrF++ |
|---|---|---|---|
| `gloss_bridge_lemmatize` | en→ht | full-1010 | +1.30 ($p$<.001) |
| `gloss_bridge_lemmatize` | fr→ht | full-1010 | +0.54 ($p$<.001) |
| `gloss_bridge_variants` | ht→en | – | +0.02 (n.s.) |
| `gloss_bridge_variants` | ht→fr | – | −0.05 (n.s.) |

Into-ht deltas are combined with the +2,762-entry Freeman lexicon recovery. From-ht is neutral (the target en/fr is high-resource, not source-coverage-limited).

## I.3 FR→EN→HT pivot gloss

French has no on-disk lexicon, so we pivot `fra→eng` (FreeDict) then `eng→hat` (Freeman) to give fr→ht the wide-gloss lever it lacked. `gloss_pivot` (FR→EN→HT), fr→ht, first-200: +4.56 (34.52 → 39.08, CI [3.20, 5.77], $p$≈0) — the largest single fr→ht lever.

## I.4 Dense retrieval push (into-ht)

For each source sentence we retrieve the three most similar sentence pairs from the NLLB-web parallel data (bge-m3 cosine, floor 0.55), plus a few Creole-only sentences, and put them in the prompt as worked examples. What the model gets is a fresh set of examples of how the target language is actually written, chosen per sentence instead of fixed in advance.

| Variant | Dir. | Set | Δ chrF++ |
|---|---|---|---|
| `retrieval_push` $k$=1 | en→ht | full-1010 | +0.94 |
| `retrieval_push` $k$=3 | en→ht | full-1010 | +1.14 ($p$<.001) |
| `retrieval_push` $k$=3 | fr→ht | full-1010 | +1.43 ($p$<.001) |

en→ht: 41.52 (OFF) → 42.46 ($k$=1) → 42.65 ($k$=3); fr→ht: 41.27 → 42.70. $k$ plateaus at 3, min sim=0.55; into-ht only. It *beats* reasoning (42.65 > 41.93) at lower cost (1.1× vs 1.7× tokens) but is substitutive with it (+0.01 stacked).

### I.5 Grammar-card push (direction-gated)

Targeted morphosyntactic cards (TMA markers, postposed determiners, negation) pushed into the prompt were valuable only where there is no gloss to lean on.

| Variant | Dir. | Set | Δ chrF++ |
|---|---|---|---|
| `grammar_push` (ON) | fr→ht | first-200 | $+0.77$ |
| `grammar_push` (ON) | en→ht | – | $-0.30$ (redundant) |
| `grammar_push`, reason ON | en→ht | full ($n$=1005) | $-0.03$ (n.s.) |
| two-pass select (draft×2) | en→ht | full-1012 | $+0.48$ (rejected, $\sim 2.2\times$ cost) |

Direction-gated: ON for fr→ht (only evidence), OFF for en→ht (gloss present ⇒ redundant; reasoning-on A/B confirms it). Two-pass output selection (base $40.43$ | push $40.30$ | two-pass $40.77$, CI $[+0.32, +0.65]$) is real but costs $\sim 2.2\times$; default-OFF.

### I.6 Reasoning (`enable_reasoning`)

Enabling the model's reasoning mode. Its decisive win is repairing a deterministic Creole-passthrough collapse in ht→fr.

| Variant | Dir. | Set | Δ chrF++ |
|---|---|---|---|
| `enable_reasoning` | ht→fr | full-1012 | $+3.02$ |
| `enable_reasoning` (into-ht) | en→ht | full-1012 | $+1.47$ |
| `enable_reasoning` (into-ht) | fr→ht | full-1012 | $+0.73$ |

ht→fr: $50.51 \rightarrow 53.54$, the recommended ht→fr configuration. Into-ht deltas are over the reasoning-on baseline (additive) and are partly superseded by the retrieval push (which beats reasoning into-ht at lower cost). Reasoning stays the lever out of Creole.

### I.7 Prompt levers (few-shot, anti-code-switch)

Held constant, reported separately from the harness (a confound). Static FLORES-dev demonstrations ($k$=5) plus the anti-code-switch rule ("translate every word; do not transliterate the source") are worth $\sim +1.2$ combined on the wide-gloss stack (en→ht). Dynamic few-shot is the retrieval push above.

### I.8 Second-pass / revision

Same-model self-revision after a first draft. `revise`/post-edit (2nd pass), en→ht, full: $-0.40$. A second pass over-edits already-correct text and was kept default-OFF. The one second pass that does help is two-pass grammar selection (not self-edit), covered under the grammar-card push section above and likewise rejected on cost.

### I.9 Collapse guardrail

A safety net for the degenerate repetition/length-explosion outputs the weak base occasionally produces into Creole. Deterministic `normalize_repetition` is worth $+0.5$–$1.5$ on collapse cases with $0$ harm to clean outputs; `regenerate_on_collapse` (with retrieval, into-ht) fires only on the $\sim$0.3% degenerate outputs and keeps the retry only if it scores better.

## J Harness error typology

We group the harness's errors into seven types, each with a full example. The useful question is not whether an error is fixable in principle but where it originates, which we tag on three axes:

R **resource**: the lexicon or corpus is itself wrong or noisy.

U **use of evidence**: the evidence was there and correct, but the model picked the wrong sense or over-trusted a bad push.

M **base model**: its own limits, in target fluency, world knowledge or decoding stability.

In each box the offending span in our output is marked, and the gold form shown where useful.

**src** source **gold** gold reference **ours** our output **pushed gloss** what the tool injected

### J.1 Hallucination

The output invents content absent from the source such as a fabricated entity, mid-sentence (hallucination).

**en→ht • challenge set**

| | |
|---|---|
| **src** | Indeed, John the Baptizer called Jesus "the Lamb of God that takes away the sin of the world." |
| **gold** | Vrèmanvre, Jan Batis la te rele Jezi "Mouton Bondye a ki rache peche tout moun". *(frontier & Gemma; challenge set has no blind gold)* |
| **ours** | Vrèmanvre, Madan Viktò te rele Jezi "ti mouton dyè sa ki pran peche mondi". |

M **Origin.** The verse is rendered faithfully (*Vrèmanvre … te rele Jezi … ti mouton*) except that the subject "John the Baptizer" is replaced by an invented person, "Madan Viktò" (Madam Victor); frontier and Gemma both give the correct "Jan Batis la". A base confabulation, not a gloss item.

### J.2 Repetition / decay

The decoder collapses into a fixed n-gram loop or runaway length.

**en→ht • base (no harness) • chrF++ 5.0 → 40.8 fixed**

| | |
|---|---|
| **src** | In fact, it is not easy to find at all even if one knew it existed. Once inside the cave, it is a total isolation. |
| **gold** | An fèt, li pa fasil ditou pou jwenn menm si ou ta konnen egzistans li. Depi li anndan gwòt la, se izolman nèt. |
| **ours** | Faktè, pa fasil *pou w pote yon chans* … (that four-word phrase repeats 96×) |

M **Origin.** A decoding collapse of the weak 8B base into a single repeated phrase; the shipping collapse guardrail (Appendix B) regenerates the sentence and recovers it to chrF++ 40.8.

### J.3 Word-sense disambiguation

The correct sense is in the pushed gloss, but the model picks a different offered sense.

**en→ht • chrF++ 37.9**

| | |
|---|---|
| **src** | Plants make oxygen which humans breathe, and they take in carbon-dioxide which humans exhale (that is, breathe out). |
| **gold** | Plant yo pwodwi oksijèn imen yo respire, epi absòbe di oksid kabòn imen yo lage (sa vle di degaje). |
| **ours** | Planti yo fè oksijèn ki moun yo soufle, epi yo pran gaz kabonik ki moun yo lage (sa vle di ki yo soufle deyò). |
| **pushed gloss** | breathe (v): soufle, respire |

U R **Origin.** The pushed gloss lists two senses: "breathe/inhale" ( respire ) and "blow" ( soufle ); for "humans breathe oxygen" the model picks the first one, *soufle* (blow), and ignores the better sense. Freeman lists the two senses flat and unranked.

### J.4 Push-induced error

The push injects a wrong item and the model faithfully adopts it.

**ht→en • challenge set (from-Creole)**

| | |
|---|---|
| **src** | Jezikri konprann enjistis epi Li gen pouvwa pou pote remèd pou sa. |
| **gold** | Jesus Christ understands injustice and He has the power to bring a remedy for it. *(unambiguous; frontier and Gemma agree)* |
| **ours** | The sandal understands injustice and has the power to carry a remedy for that. |
| **pushed gloss** | jezikri (n): sandal (usu. leather, without heel strap) (the only sense pushed for a common noun). |

**R** **U** **Origin.** A Freeman entry-bleed defect makes "sandal" the head (and only pushed) sense of the proper noun *Jezikri*; the push injects it and the model adopts it over the obvious name. The model copies the retrieved gloss without a critical analysis.

## J.5 Calque

A source word or structure is transferred literally, not idiomatically.

**en→ht • chrF++ 44.5**

| | |
|---|---|
| **src** | However, the percentage of XDR-TB in the entire group of people with tuberculosis still seems to be low; 6,000 of the total 330,000 people infected at any particular moment in South Africa. |
| **gold** | Sepandan , pousantaj XDR-TB a nan ansanm gwoup moun ki gen tibèkiloz yo sanble fèb; 6,000 moun sou yon total 330,000 moun te enfekte nan yon moman presi an Afrik di Sid. |
| **ours** | Men tou , pousantaj XDR-TB nan tout moun ki gen tebe akòz toujou parèt ba; 6,000 nan total 330,000 moun enfekte nan kounye a nan Sid Afrik. |

**M** **Origin.** The connector "However" is transferred form-by-form as "Men tou" ("but also") instead of the idiomatic discourse marker Sepandan . We could also interpret that one as a synonym choice.

## J.6 Fluency

Lexically mostly right but non-native: word order, TMA markers, or determiners are off.

**en→ht • chrF++ 49.0**

| | |
|---|---|
| **src** | With Kundalini Yoga the Kundalini energy (enlightenment energy) is awakened through yoga postures, breathing exercises, mantras and visualizations. |
| **gold** | Avèk Kundalini Yoga a, enèji Kundalini an (enèji iliminasyon) reveye pa pozisyon yoga yo , egzèsis respirasyon yo , mantra yo ak vizyalizasyon yo . |
| **ours** | Ak Yoga Kundalini, enèji Kundalini (enèji eklerasyon) te leve atravè pozisyon yoga, egzèsis soufle, mantra ak vizualizasyon. |

**M** **Origin.** Vocabulary is essentially right, but every postposed plural determiner yo is dropped and a spurious past marker te is inserted where gold is bare-stative. This if a grammatical, not a lexical gap and echoes the base-competence of the model in ht.

## J.7 Lexicon-retrieval error (pivot / wrong POS)

The retrieval itself returns wrong data: a pivot false-friend sense, or the wrong POS.

**fr→ht • chrF++ 51.6**

| | |
|---|---|
| **src** | Cette découverte permet également de mieux comprendre l'évolution des plumes chez les oiseaux. |
| **gold** | Dekouvèt sa pèmèt tou pou pi byen konprann evolisyon plim yo lakay zwazo yo. |
| **ours** | Dekouvèt sa pèmèt tou pou konprann pito evolwasyon pikan nan zwazo. |
| **pushed gloss** | plumes: pivot fr→en {feather, quill, nib}; feather → "pm il" (OCR-mangled plim ), quill → pikan (thorn): model takes the clean pikan . |

**R** **Origin.** The pivot expands "plumes" to three English words and merges their Freeman glosses; the right "feather" gloss is OCR-corrupted to "pm il" while the false friend "quill"→"pikan" (thorn) comes through clean, so the model takes it . This is an error propagated from the processing of the lexical ressources.

# GMU WMT 2026 CreoleMT System Description

antonis@gmu.edu

## Abstract

We present our submissions to the machine translation track of the WMT26 Creole Language Translation Shared Task (Robinson et al., 2026). Our systems cover all English-Creole language pairs supported by the KREYÒL-MT dataset (Robinson et al., 2024), comprising 80 translation directions. We mainly explore the use of large language models (LLMs). In particular, we fine-tune LLMs and, given the limited amount of parallel data available for many language pairs, also evaluate few-shot prompting as an alternative to supervised fine-tuning. We also explore data cleaning, temperature-based multilingual data sampling, and extracting additional parallel data from archival grammar books. Our experiments show that LLM-based systems outperform NLLB-based systems in most cases. For the lowest-resource language pairs, few-shot prompting proves substantially more effective than supervised fine-tuning.[1]

## 1 Introduction

Recent advances in machine translation (MT) have been driven by large language models (LLMs) trained on massive multilingual corpora (Xu et al., 2024; Alves et al., 2024; Xu et al., 2025; Zheng et al., 2025; Finkelstein et al., 2026). These models have demonstrated superior performance over traditional encoder-decoder MT models such as NLLB (NLLB Team et al., 2022).

The Creole-MT shared task provides the publicly available KREYÒL-MT dataset (Robinson et al., 2024), which supports many-to-many translation across 40 Creole languages. In this work, we focus on English↔Creole language translation. Among the 40 Creole languages, only Haitian (`hat`) has substantial training data, with more than 600K parallel sentence pairs, whereas most of the remaining languages contain fewer than 1,000 parallel sentence pairs. This extreme data imbalance presents two key challenges: (1) effectively leveraging LLMs for extremely low-resource languages; and (2) acquiring additional parallel data.

To address the first challenge, we investigate both supervised fine-tuning and few-shot prompting with LLMs. Our experiments show that few-shot prompting substantially outperforms supervised fine-tuning for the lowest-resource language pairs. To address the second challenge, we use a vision language model (VLM) to extract incidental parallel data from archival grammar books (Virk et al., 2020). Although the extracted bitext is noisy, incorporating it into training often improves translation quality.

## 2 Data

We mainly rely on the parallel data between English and 40 Creole languages from the official KREYÒL-MT dataset (Robinson et al., 2024). As shown in Figure 1, the dataset is extremely imbalanced. `hat` contains more than 600k sentence pairs, whereas most languages contain fewer than 1,000. We first apply sentence cleaning and filtering to the training data (Section 2.1). We then augment the training data with additional parallel sentences extracted from archival grammar books (Section 2.2).

### 2.1 Data Cleaning and Filtering

We first preprocess sentences by removing parentheses and text inside them, as such content is often noisy and rarely contributes to the sentence meaning (e.g., `"[...]"`).

Motivated by Koehn et al. (2018, 2019), we further filter out noisy sentence pairs that satisfy any of the following conditions:

1. Fewer than 50% of the characters are alphabetic;
2. Either sentence contains fewer than 3 words or more than 60 words;

[1]We release the additional parallel sentences at https://github.com/mct10/CreoleMT-2026 to ensure the reproducibility of our work.

*Proceedings of the Eleventh Conference on Machine Translation*, pages 2448–2454
October 28-29, 2026 ©2026 Association for Computational Linguistics

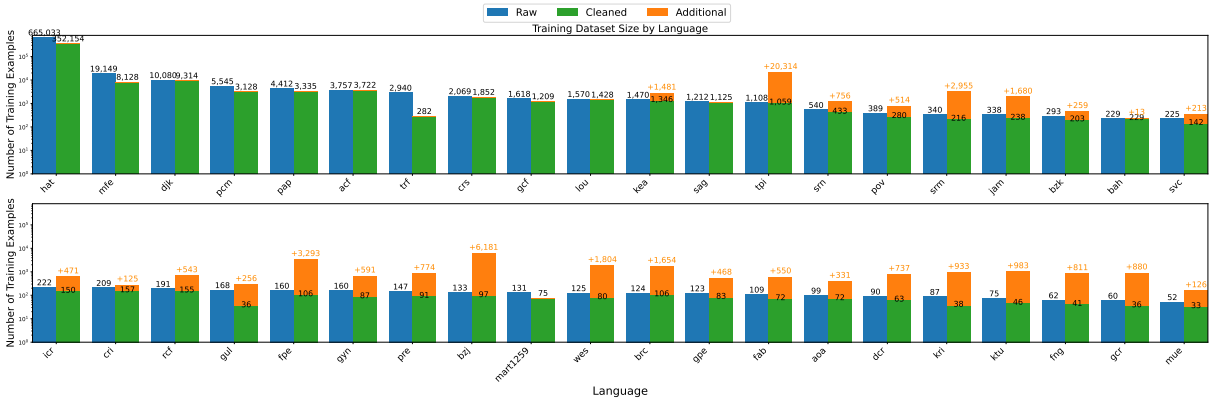

Figure 1: Number of sentence pairs of the raw training data, the cleaned training data, and the additional data we extracted from Virk et al. (2020). The y-axis is in log-scale.

3. The source-to-target or target-to-source character length ratio exceeds 2.2;
4. The Levenshtein ratio exceeds 0.8;
5. Either side is identified as the wrong language by the language identification model released with NLLB (NLLB Team et al., 2022). Specifically, the English sentence must be identified as English, while the Creole sentence must not be identified as English.

### 2.2 Additional Bitext from Archival Data

Because most languages contain fewer than 1,000 parallel sentence pairs, we extract additional bitext to help with model training. We use the DReaM corpus (Virk et al., 2020) as our source, as it contains linguistic resources, including grammar books and dictionaries, for more than 4,000 languages.

Since the documents are available only in PDF format, we first perform optical character recognition (OCR) using `dots.ocr` (Li et al., 2025), which provides strong multilingual OCR performance.

Next, we use the VLM `Qwen/Qwen3.5-27B-FP8`[2] (Qwen Team, 2026a) to extract incidental bitext from each page independently. Our key observation is that parallel text often exhibits distinctive visual layouts, such as interlinear glosses or adjacent bilingual columns, making it well suited for VLM-based extraction.

To reduce computational cost, we apply this pipeline only to the 28 lowest-resource languages. As shown in Figure 1, the extracted bitext substantially increases the amount of training data for these languages.

We acknowledge that the extracted bitext is noisy. Some sentence pairs may use non-standard orthographies, while others may suffer from OCR or VLM errors. Nevertheless, we consider this level of noise acceptable, as large-scale sentence mining methods such as global mining (Schwenk et al., 2021; NLLB Team et al., 2022) also produce imperfect alignments.

We removed sentence pairs for which either side has a Levenshtein similarity ratio greater than 0.9 with a sentence in the dev sets. However, since the test sets are released during the evaluation period, after the systems have been developed, we have not applied the same filtering to remove potential duplicates with the test sets.

## 3 Experiments

We investigate two approaches based on large language models (LLMs): supervised fine-tuning and few-shot prompting. We also fine-tune a NLLB model (NLLB Team et al., 2022) as baseline.

### 3.1 Model Fine-tuning

Since `hat` contains substantially more training data than other languages, we train one model exclusively for `hat` and a separate multilingual model for the remaining languages.

For multilingual training, we employ temperature-based sampling to upsample

**System:** You are a professional translator. Do not say you do not speak the language. Do not say you do not have enough information. You must provide a translation. Do not include explanations, comments, or extra text. The entire response must be a single line containing only the translation. When provided with example translations, use them as reference to help ensure correct translation.

**User:** Translate the following sentence from SRC_LANG to TGT_LANG: SRC_SENTENCE
Below are some example translations that might be useful:
SRC_LANG_1: SRC_SENTENCE_1
TGT_LANG_1: TGT_SENTENCE_1
SRC_LANG_2: SRC_SENTENCE_2
TGT_LANG_2: TGT_SENTENCE_2
...
Now, please provide the translation.
SRC_LANG: SRC_SENTENCE
TGT_LANG:

Figure 3: Instruction template used for few-shot prompting.

low-resource languages:

$$p_i = \frac{|D_i|^{1/T}}{\sum_j |D_j|^{1/T}}$$

where $D_i$ denotes the number of training sentence pairs for language $i$, $T$ is the temperature, and $p_i$ is the probability of sampling a sentence pair from language $i$ at each training step. We mainly consider $T = 5$, following the setting used by the baseline model.[3]

We fine-tune the pre-trained Gemma-3 model, `gemma-3-4b-pt` (Gemma Team et al., 2025) (hereafter `gemma-3`), using LoRA adapters (Hu et al., 2022), due to its strong multilingual capabilities. The prompt template is shown in Figure 2. We compute the training loss only over the target translation.

As a baseline, we also fine-tune `nllb-200-distilled-1.3B` (NLLB Team et al., 2022) (hereafter `nllb`) using LoRA adapters. For Creole languages not supported by NLLB, we introduce new language code tokens.

We choose relatively small models (4B for Gemma-3 and 1.3B for NLLB) mainly due to computational constraints and small training sets.

### 3.2 Few-shot Prompting

Even after augmenting the training data with incidental bitext, a few thousand sentence pairs are often insufficient for effective fine-tuning. We therefore investigate few-shot prompting as an alternative. We use `Qwen/Qwen3.6-27B`[4] (Qwen Team, 2026b) as the backbone model. We choose a much bigger model than those used for fine-tuning because few-shot prompting requires much less computation than fine-tuning. To enable inference on a single 40GB GPU, we apply 4-bit quantization.

The prompt template is in Figure 3. For each input sentence, we retrieve similar examples from the training set of the corresponding language using the chrF2++ score (Popović, 2017). The 512 highest-scored sentence pairs are then included as in-context examples. If the training set contains fewer than 512 sentence pairs, we use all available pairs.

### 3.3 Evaluation Metrics

We evaluate our systems on the KREYÒL-MT dev set. We leave the dev set untouched and do not apply any cleaning or filtering strategies.

We report spBLEU[5] with the flores200 tokenizer (NLLB Team et al., 2022) and chrF2++[6] scores, computed by SacreBLEU (Post, 2018).

## 4 Results and Analysis

We report the results of fine-tuning `nllb-200-distilled-1.3B` and `gemma-3-4b-pt` in Section 4.1. Results for few-shot experiments are presented in Section 4.2.

### 4.1 Model Fine-tuning

Results for the `eng-hat` system and the multilingual systems are presented in Table 1 and Table 2. Given the large number of language directions, we report the average performance of the multilingual systems.

For both `nllb` and `gemma-3`, we progressively introduce modifications to improve performance. The baseline models are fine-tuned on the raw KREYÒL-MT dataset.

Applying data cleaning yields significant gains for `eng`→`hat` with `gemma-3`. In contrast, it degrades the performance of the multilingual systems. We hypothesize that data cleaning reduces the training data to a level that is insufficient for these low-resource language pairs.

Temperature-based data sampling does not improve the performance of multilingual `nllb`. In

contrast, it substantially improves multilingual gemma-3 for translation into Creole languages, increasing the average BLEU score from 17.97 to 23.54.

Finally, incorporating additional training data consistently improves both base models. For translation into Creole languages, the additional data improves multilingual nllb by more than 2 BLEU and multilingual gemma-3 by nearly 1 BLEU. For translation into English, the gains are even larger. There is nearly 10 BLEU improvement for multilingual nllb and almost 3 BLEU improvement for multilingual gemma-3. These results suggest that incorporating additional training data is beneficial, even when the data may contain some noise.

### 4.2 Few-shot Prompting

Due to time and computational constraints, we conduct few-shot experiments on only 20 languages (40 translation directions). The results are presented in Table 3.

We are interested in comparing few-shot prompting and fine-tuning for LLMs under these extremely low-resource settings. We use our best multilingual fine-tuned gemma-3-4b-pt model as the baseline, incorporating all methods described in the previous section. For few-shot prompting, we evaluate two settings: with and without the additional training data.

Among the 40 translation directions, the fine-tuned model achieves the best performance on only 7 directions, 5 of which are translation into English. This result suggests that, under such limited-data conditions, few-shot prompting is generally more effective than fine-tuning, especially for into-low-resource-language translation.

Consistent with our observations from the fine-tuning experiments, incorporating the additional training data generally improves few-shot performance. Few-shot prompting *with* the additional data achieves the best results on 22 translation directions, compared with 11 directions for few-shot prompting *without* the additional data.

### 4.3 Submissions

Our primary submission is the best performing gemma-3-4b-pt model, fine-tuned with data cleaning, temperature-based sampling, and additional training data. Since no additional data were extracted for eng↔hat, this language pair is excluded. The primary system covers 78 translation directions.

Our contrastive 1 system is the gemma-3-4b-pt model fine-tuned on the cleaned data with temperature-based sampling. For eng↔hat, where data sampling is unnecessary, we use the gemma-3-4b-pt model fine-tuned on the cleaned eng↔hat data. These two systems cover all 80 translation directions.

Our contrastive 2 system uses the 512-shot prompting setup with additional training data and the Qwen3.6-27B backbone model. This system covers 20 selected languages (40 translation directions).

## 5 Conclusion

In this paper, we describe GMU systems for the WMT 2026 CreoleMT shared task. We explore both fine-tuning and few-shot prompting for low-resource translation. Our experiments show that incorporating additional parallel data automatically extracted from archival resources often improves translation performance, even when the data contains noise. Moreover, few-shot prompting generally outperforms fine-tuning when only a very limited amount of parallel data is available, especially for translation into low-resource languages.

## Limitations

We did not perform a thorough audit of the parallel sentences automatically extracted from archival resources. As a result, the extracted data likely suf-

fers from issues such as orthography inconsistencies and language mismatch. More careful cleaning and normalization could further improve the quality of the extracted corpus and, consequently, downstream translation performance.

While we removed sentence pairs that overlap with sentences in the dev sets from the extracted additional data, some overlap with the test data may still remain.

## Acknowledgments

We are grateful to the anonymous reviewers and area chairs for WMT whose feedback improved the paper. This work was financially supported by the National Science Foundation under CAREER award 2439202. # The University of Melbourne WMT 2026 CreoleMT Submission: A Domain-Balanced Approach to Low-Resource Pacific Creole Machine Translation

**Raphaël Merx** **Nick Thieberger** **Ekaterina Vylomova**
The University of Melbourne

## Abstract

For our submission to the WMT26 Creole Language Translation Shared Task, we focus on machine translation (MT) models for Pacific creoles: Tok Pisin, Bislama, and Solomon Pijin, with particular attention to broad domain performance. After pre-training on a large collection of domain-imbalanced data, we continue fine-tuning on a diverse mix of domain-balanced data. We rely on a number of data collection and preparation techniques, including LLM-assisted respelling and alignment, back-translation, and distillation from Gemini for domains originally not present in training data. Evaluated on Bouquet and a novel test set made of spoken language transcripts, our models beat open model baselines by 3+ chrF++ points in all directions with human-original references. Looking ahead, we plan to develop human-translated test sets for Solomon Pijin and Bislama, and to distil our best models into much smaller ones that retain broad domain coverage.

## 1 Introduction

For this second WMT shared task on Creole machine translation (Robinson et al., 2026), we focus on the three main Pacific creoles: Tok Pisin (tpi, Papua New Guinea), Bislama (bis, Vanuatu), and Solomon Pijin (pis, the Solomon Islands). They share common characteristics: they are a lingua franca in their respective countries, with widespread use for daily communication (Eberhard et al., 2025); they are all English-based contact languages from the Melanesian pidgin family (Tryon and Charpentier, 2004); and for Tok Pisin and Bislama, are official languages of their country (Smith and Siegel, 2013; Meyerhoff, 2013).

Together, they are spoken by over 10 million people (Eberhard et al., 2025). However, they have relatively little MT coverage: Google Translate and NLLB only cover Tok Pisin (NLLB Team et al., 2022), with no consumer-facing model deployment for Bislama or Solomon Pijin. Availability of test sets that cover a wide range of domains (e.g. beyond religion and news) is also limited, with the exception of the recent addition of Tok Pisin to Bouquet (Andrews et al., 2025).

As part of this shared task, we focus on training a single model that supports all three languages, with broad domain coverage. To this end, we collate a training set that includes a mix of parallel data from religious sites, but also synthetic data in the educational and informal domains. We rely on Bouquet tpi as our main test set, with the addition of in-house test sets that cover spoken transcripts for all three languages, provided by the Pacific Creole Project (Passmore et al., 2025).

We provide the following contributions:

- A single joint model per translation direction covering all three languages which we pre-trained on the broad but religion-heavy union of the data that we collected and then continued training on a smaller domain-balanced mix. On Bouquet and the held-out spoken transcripts, it beats every open model baseline by at least 3 chrF++ in all directions with human-original references.
- A demonstration that distilling a strong closed model is a cheap way to better cover some domains that scraped data lacks, and that the gain saturates early: the first 1.5k English→Tok Pisin pairs bring +1.54 chrF++, and the remaining 14.5k add +1.20.
- Evaluation using novel held-out spoken transcripts for all three languages, showing that performance in this domain is poorly represented by other test sets, and that adding just a few thousand rows of this domain to the training mix provides a substantial lift in it, while not moving performance in other test sets.
- Three findings that we believe generalise be-

*Proceedings of the Eleventh Conference on Machine Translation*, pages 2455–2462
October 28-29, 2026 ©2026 Association for Computational Linguistics

yond this task: spelling normalisation brings large chrF++ gains, which may not matter as much to end-users as the numbers suggest; domain coverage added in one creole can carry to its neighbours; and joint training helps the two lowest-resource languages while leaving the highest-resource one unchanged.

## 2 Related Work

**Creole MT.** Creole languages have long been under-served by NLP, despite communities' needs that often differ from those assumed by work that simply translates existing English resources (Lent et al., 2022b). Recent efforts have started to close this gap: CreoleVal assembles multitask benchmarks spanning 28 creoles (Lent et al., 2024), and Kreyòl-MT gathers the largest parallel corpus to date across 41 creoles, finding that a genre-diverse model can outperform a genre-specific one (Robinson et al., 2024). The first WMT shared task on creole MT (Robinson et al., 2025) brought these threads into a shared evaluation, of which the present task is the second edition. Past findings include: transfer from English is weaker than the surface similarity between the languages suggests (Lent et al., 2022a); and the available data is dominated by religious text, which transfers poorly to everyday language, while even a few hundred in-domain sentences noticeably lift translation quality (Rowe et al., 2025). This applies to the Pacific creoles we target, with Tok Pisin the only one to have a broad-domain test set.

**Cross-domain low-resource MT.** Neural MT quality degrades sharply outside its training domain, at times producing fluent but inadequate output (Koehn and Knowles, 2017). The problem is acute for low-resource languages, where the little parallel data that exists is concentrated in a few domains such as religion and news, spurring efforts to build corpora in other domains (Merx et al., 2025). Domain adaptation for NMT (Chu and Wang, 2018) addresses this with data-centric methods, such as selecting or synthesising in-domain data, and model-centric methods, such as continued fine-tuning. A common recipe first trains on all available, largely out-of-domain data and then fine-tunes on in-domain and back-translated data (Imankulova et al., 2019). Back-translating target-side monolingual text (Sennrich et al., 2016) and transfer from massively multilingual models (NLLB Team et al., 2022) are the standard levers for widening coverage. We combine these: we start from a massively multilingual model, train it on all collected data, and then continue fine-tuning on a domain-rebalanced mix that adds back-translated news and synthetic educational and informal text to counter the religious skew.

## 3 Data

### 3.1 Collection

#### 3.1.1 Test sets

We evaluate on three held-out sets, chosen to reach beyond the religious and news domains that dominate the available creole corpora.

**Bouquet** (854 sentences per language) (Andrews et al., 2025) is a broad-domain benchmark spanning everyday speech, how-to, narration, social-media posts and more. It covers Tok Pisin, but not the other two languages we target, so we build silver references for them using an LLM (Section 3.2).

**FLORES-200** (2,009 sentences, Tok Pisin only) (NLLB Team et al., 2022) is the standard multilingual benchmark: general encyclopaedic and news prose with gold human translations, used as a second independent Tok Pisin reference point.

**Spoken transcripts** (300 sentences per language) (Passmore et al., 2025) are transcribed and translated speech from the Pacific Creole Project, a spoken register not found in other sets and originally produced creole-to-English. We hold out 300 rows per language for testing and fold the rest into training (Tok Pisin 10.0k, Bislama 4.5k, Solomon Pijin 1.6k).

**Decontamination.** Some of the CreoleMT shared task evaluation set overlaps public text that was in our training data. Before filtering, most English eval sentences already appeared in our data (75% for Tok Pisin, 95% for Bislama, 99% for Solomon Pijin) as did 66% of the Tok Pisin creole side (the Solomon Pijin and Bislama creole sides far less, 3% and 8%). We drop from every training corpus any pair that shares a sentence with an eval source, on either side, after aggressive normalisation; afterwards no eval sentence remains in our training files.

#### 3.1.2 Training data

Table 1 gives the per-source counts. The data falls into three kinds.

**Scraped parallel.** English↔creole pairs, consolidated, sentence-aligned and deduplicated per language, then decontaminated; this forms the training corpus: 472.7k pairs for Tok Pisin, 42.5k for Solomon Pijin and 80.8k for Bislama. It is heavily religious in domain, with JW300 and the Bible, with, for Bislama, 35.1k back-translated Vanuatu news. Verse-level scripture is joined on the canonical verse id, so those pairs are exact and need no alignment.

**Monolingual, back-translated.** Creole-only text machine-translated back into English (Gemma-4-31B or Gemini) to add colloquial and news register: Tok Pisin news (34.0k sentences) and web text (FineWeb-2, 18.9k); Vanuatu news and government pages (FineWeb-2, 2.5k documents, 35.2k pairs) for Bislama; and news for Solomon Pijin (33 documents). Most of the FineWeb-2 data however is not used for our best model training mix, after finding it was detrimental to translation quality (favouring English passthrough).

**Synthetic (distilled).** 6.0k English-to-Tok-Pisin pairs generated by a strong closed model (Gemini 3.5 Flash), sampled evenly from three everyday domains (narration, how-to, social posts) to supply the colloquial registers the scraped data lacks. Figure 1 measures how far this scales.

**Usage.** We train one joint Tok Pisin + Solomon Pijin + Bislama model per direction. Each first pretrains on the broad decontaminated union of the data above (596k pairs: 472.7k Tok Pisin, 42.5k Solomon Pijin, 80.8k Bislama), then continues on a smaller on-domain mix: scripture and synthetic data for both directions, plus the Tok Pisin high-quality mix (forward) or held-out spoken transcripts (reverse). Tables 2 and 3 give the full recipe and per-stage scores.

### 3.2 Data preparation

Three cleaning steps, each applied where a language needed it and each measured as a single-factor ablation (Table 4).

**Loanword respelling (Solomon Pijin).** The scraped Pijin data, almost all from jw.org, spells English loanwords the English way ("first", "change"), whereas everyday and test Pijin use local spellings ("fas", "senis"). We use Gemma-4-31B, guided by a Pijin dictionary, to respell the training targets into the local convention: spelling only, same words and meaning. This was the largest single lever we found (+7.7 chrF++).

| Source | tpi | pis | bis |

Table 1: Training data mix, in number of sentences. Under eng→creole, the jw.org, *Watchtower*, back-translated news and example-sentence rows form the Tok Pisin high-quality mix.

**Alignment.** Extract parallel sentences from parallel documents with an LLM aligner (Gemini). Separately, we pass the Tok Pisin corpus through a Gemma-4-31B judge (using vLLM) that scores each pair and drops the clearly-misaligned ones (490.8k judged, 463.8k kept). Verse-level Bible and Book of Mormon text is joined using verse id.

**Silver test sets (Solomon Pijin, Bislama).** Neither language has a Bouquet set, so we generate silver references with Gemini from the English source, the Tok Pisin reference, bilingual dictionary entries (SIL Webonary, 3.0k for Pijin; 4.3k for Bislama) and 20 curated example sentences per language. Because the reverse-direction source is then model-generated, we mark those cells in our results tables and do not read them as gold.

## 4 Models

**Baselines.** We compare against open multilingual systems that already cover at least one of our three languages: NLLB-200-3.3B (tpi only, NLLB

| | English → Tok Pisin | | | Tok Pisin → English | | |

Table 2: Tok Pisin results, chrF++ on Bouquet (854 human-translated rows), FLORES-200 (2,009 rows) and held-out spoken transcripts (300 rows). **Bold** marks the best score in each column and every score within 1 chrF++ of it (our noise floor); the * row is the system we submit. Pre-training on all data barely moves the forward direction, but continued fine-tuning and Gemini distillation bring us level with Gemini 3.5 Flash, the strongest baseline, everywhere but FLORES. Table 3 reports the same systems and stages for Solomon Pijin and Bislama.

Team et al., 2022), MADLAD-400-3B (bis/pis only, Kudugunta et al., 2023), Kreyòl-MT (tpi only, Robinson et al., 2024) and CreoleM2M (all 3, Lent et al., 2024). We also report Gemma-4-31B zero-shot and, as a closed frontier model, Gemini 3.5 Flash. Among the systems small enough to fine-tune on a single GPU, NLLB-3.3B is the strongest base on Tok Pisin, beating others on Bouquet and on the spoken transcripts in both directions (except Tok Pisin→English transcripts, where it sits 1 chrF++ below Kreyòl-MT); Gemma-4-31B is competitive zero-shot but too large to fine-tune on one GPU. We therefore select NLLB-3.3B for fine-tuning.

**Joint multilingual fine-tuning.** We add Solomon Pijin and Bislama target tokens to NLLB (initialised from the Tok Pisin token) and fine-tune one joint model per direction on all three languages, using the clean data from Section 3.2. We also add new tokens for punctuation missing in the NLLB tokenizer (e.g. curly quotes, en/em-dashes). Training the related languages together beats per-language fine-tunes on the two minority languages (Table 4).

**Continued fine-tuning on diverse mix.** Following the joint pre-training above, we continue with fine-tuning on a smaller but more domain-diverse mix. Tables 2 and 3 report the per-stage staircase.

**Limited Gemini distillation.** Because Gemini 3.5 Flash performs well on tpi zero-shot, and because we find very limited domain diversity in scraped data, we distill Gemini 3.5 Flash on a couple thousand sentences for each of social media text (TweetEval, Barbieri et al., 2020), how-to articles (WikiLingua, Ladhak et al., 2020) and literature (ROCStories, Mostafazadeh et al., 2016). For each, we split into sentences, and run Gemini forward from English to Tok Pisin. We report on the benefit of this distillation in Figure 1.

**Ablations.** Table 4 isolates each part of our recipe, varying one factor and holding the rest fixed. Gains are measured on Bouquet chrF++ for the en-xx direction. We also ran a number of data ablations, and ended up using only a limited subset of the data available to us, guided by evaluation on Bouquet chrF++. Data ablations however are mostly not reported in this table.

## 5 Results

**Pretrain.** NLLB-3.3B (base) sits 5.2 chrF++ behind Gemini 3.5 Flash on Tok Pisin Bouquet (46.7 vs 51.9). The first stage (broad pre-train on all data) adds almost nothing on Tok Pisin in the forward direction (46.7 to 46.9), but does in the reverse (+6.2, 39.2 to 45.4). For the other two languages, the pre-train is enough to beat every baseline we compare against: 52.8 on Pijin Bouquet, 13.6 above CreoleM2M, and 52.9 on Bislama, 8.4 above it. These Bouquet references are silver (Section 3.2) and should be read with care, but the spoken transcripts are human-original, and they show gains of the

Table 3: Solomon Pijin and Bislama results, chrF++; same systems as Table 2. Note Bouquet references are Gemini-generated from the Tok Pisin reference (+ lexicon and example sentences, Section 3.2). Spoken transcripts (300 rows/lang) are human-original in both directions. Unlike Tok Pisin, these two languages gain most from the broad pre-train, which already beats every baseline.

same size over CreoleM2M (+7.1 for Pijin, +8.6 for Bislama), so we read the improvement as real.

**Continued fine-tuning.** The three continued fine-tuning stages (domain-balanced data, spoken transcripts, and Gemini distillation) close the gap with Gemini-3.5-Flash (the best model we measured for Tok Pisin): our shipped model scores 51.5 against Gemini's 51.9 on Bouquet, and pulls ahead on the spoken domain, 47.7 against 41.0 on transcripts. FLORES is the exception, where we stay 2.6 points behind (47.6 against 50.2), but FLORES' age and widespread use may mean contamination in recent models (Tan et al., 2026). In the reverse direction the shipped model is 0.9 below Gemini on Bouquet (49.2 against 50.1) and 3.9 above it on transcripts (53.9 against 50.0).

| Ablation | Lang | w/o → w/ | Δ |
|---|---|---|---|
| Loanword respelling | pis | 45.8 → 53.4 | +7.7 |
| Continued FT | tpi | 46.9 → 50.0 | +3.1 |
| Gemini distil. (6k pairs) | tpi | 48.5 → 50.9 | +2.4 |
| Joint training | bis | 50.7 → 52.5 | +1.8 |
| | pis | 44.4 → 45.8 | +1.4 |
| | tpi | 45.6 → 46.3 | +0.7 |
| Alignment filtering | tpi | 46.0 → 46.3 | +0.3 |

Table 4: Ablations, sorted by effect size; each varies one factor and holds the rest fixed. Scores are Bouquet en-xx chrF++. Respelling and alignment filtering use Gemma-4-31B for cleaning. Continued FT is the two-stage pre-train→continued-FT recipe from Table 2. Gemini distillation adds 6k synthetic eng→tpi pairs (the 0 and 6k points of Figure 1). The joint-training rows compare each language's single-language NLLB (w/o) against the joint model (w/) on raw-spelling data, so a positive Δ means joint training helps that language.

**Fine-tuning LLMs: promising but expensive.** We also try LoRA fine-tuning of Gemma-4 using the same two-stage recipe, at two sizes (E4B and 26B). Both land below the NLLB fine-tunes: 47.7 and 47.4 on Tok Pisin Bouquet against 51.5 for our shipped model, with the same ordering on Pijin (46.3 and 46.1 against 53.1) and Bislama (53.0 and 52.5 against 57.8). Going from E4B to 26B does not improve the scores, which suggests the limit is the LoRA recipe, not model capacity. Gemma-4-31B, on the other hand, is competitive with no fine-tuning at all: zero-shot it reaches 45.4 on Tok Pisin, just below base NLLB, 51.0 on Bislama, above every open baseline we test. Fine-tuning a model of that size therefore looks like a promising direction, but it does not fit our single-GPU budget, so we leave it to future work.

**Domain diversity.** Breaking Tok Pisin Bouquet down by domain shows where the base model falls short and where fine-tuning helps most. Out of the box, NLLB trails Gemini most on the informal, conversational registers that our scraped corpora (religion and news) barely contain: it is 7.4 chrF++ behind on conversation (48.4 against 55.9), 6.5 on user comments, 5.3 on narration and 5.0 on social posts, against only 2.5 on reflective prose. Our fine-tune recovers most of this gap: it now beats Gemini on how-to (52.9, 2.4 above) and draws level on conversation (56.3 against 55.9) and social posts (51.5 against 52.2). The registers where we still trail are the ones our training data covers least, and only by 1 to 3 points: comments (47.0 against 49.8) and narration (52.1 against 53.6). The remaining

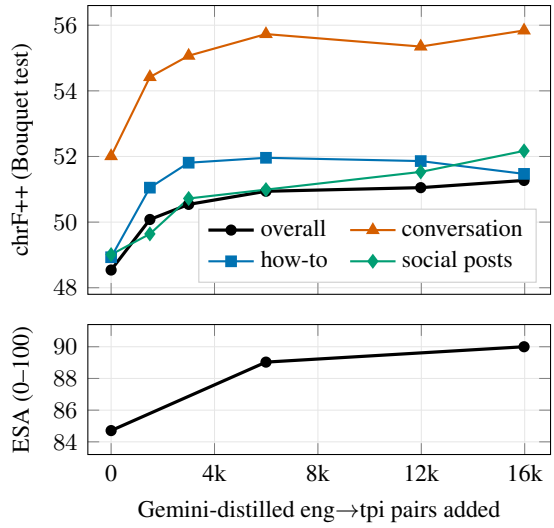

Figure 1: Translation quality gains from adding Gemini distillation in ChrF++ points (top) / ESA through LLM-judge (bottom). Gains are measurable with only 6k sentences (2k each of TweetEval / WikiLingua / ROC-Stories), then plateau.

half-point deficit to Gemini on Bouquet is thus concentrated in a few under-covered registers rather than spread evenly.

### 5.1 Discussion

**Distillation is cheap and beneficial.** Figure 1 scales the Gemini distillation set from 0 to 16k pairs, holding the 122.4k human tpi mix and the recipe fixed. The curve rises steeply and then flattens: the first 1.5k pairs are worth +1.54 chrF++, more than half of the +2.73 that 16k pairs buy in total, and the remaining 14.5k pairs add only +1.20 between them. No single increment past the first is individually resolvable (1.5k→3k, 3k→6k, 6k→12k and 12k→16k all have 95% intervals spanning zero), yet the accumulated 1.5k→16k gap is significant, so the plateau slopes gently upward rather than being flat. The takeaway is that distillation from a strong closed model is cheap to exploit and quick to exhaust: a few thousand well-chosen source sentences capture most of the available gain, and buying an order of magnitude more yields roughly one further chrF++ point. Beside ChrF++, we also score with a reference-based LLM judge (GPT-5.6-luna, ESA-style 0–100 with error spans). The LLM-judge also measures translation quality gains: +4.3 ESA from 0 to 6k with a 95% interval clear of zero, and a further +1.0 to 16k that is not resolvable.

**Adding transcripts reduces over-translation of spoken text.** On the (in-domain) spoken transcript test set, the reverse model trained without transcripts tends to render terse spoken text as more formal, idiomatic English, whereas the transcript-augmented model mirrors the literal register of the references. For example, for *stap klostu wantaim mi olgeta taim* (ref. "stay close to me at all times"), the no-transcript model outputs the idiomatic "always by my side", while the +transcripts model gives the literal "stay close to me all the time".

**The outsize weight of orthography.** Spelling consistency between training data and reference drives chrF++ to an extent that may not reflect end-user priorities. Respelling pis to the reference convention gained +**7.7** (45.8 to 53.4), while the two languages left unrespelled in the same run barely moved (bis −0.2, tpi +0.3). Adding more religious-register data then helped bis, whose orthography matches (+2.1), but hurt pis (−3.6), whose text uses a different yet valid convention (`bilong` rather than `blong`): a 5.7 chrF change from spelling alone, against +2.0 for our best modelling change. As `bilong` is perfectly comprehensible Pijin, and the dominant spelling in the Pijin religious publications we scrape, we question whether chrF++ measures quality or mere conformity to the reference's spelling, and whether optimising for it trades away subtler gains in terminology or register.

**Domain coverage added in one creole may carry to its neighbours.** The final stage adds a tpi-only Gemini distillation set. Beyond the +1.6 it adds on Tok Pisin Bouquet (49.9 to 51.5), it also improves the silver **bis** Bouquet set by +**1.8** (56.0 to 57.8) and nudges **pis** up +0.6 (52.5 to 53.1), although neither receives new training data at that stage. A plausible explanation is that broadening domain coverage in one language generalises to the other two sharing the joint model. Two caveats here: the added tpi pairs also enlarge the joint mix, so every language sees marginally more optimisation steps, and the silver bis references are also Gemini-generated, as is the distillation data, so some of the gain may be convergence toward the reference author's style rather than improved translation.

**Joint training mainly helps the two lowest-resource languages.** Fine-tuning the three creoles together rather than separately (holding data and recipe fixed) gains +**1.8** for bis (50.7 to 52.5) and +**1.4** for pis (44.4 to 45.8), but only +**0.7** for

tpi (45.6 to 46.3), inside our 1 chrF++ noise floor (Table 4). We hold far more tpi data, and across more domains, than pis or bis (463.8k cleaned pairs against 83k for bis and 44.7k for pis), so joint training lets the two data-poor languages draw on the larger and more varied tpi corpus through the shared model, while tpi is already well covered on its own and has little left to gain. This is the cross-creole transfer of the previous finding seen from the data side, and it is why we train one joint model rather than three: the low-resource languages benefit and the high-resource one is not harmed.

## 6 Conclusion

In this work, we develop a first model that focuses on Pacific creoles (Tok Pisin, Solomon Pijin, Bislama), targeting good performance across domains. We show that pre-training on an unbalanced mix of data, then fine-tuning on a more balanced and diverse mix can bring substantial translation quality gains across domains, and that these cross-domain gains can transfer across languages (e.g. tpi diverse bringing quality gains to pis/bis). We also show the value of forward-distillation from a strong LLM, on domains that are otherwise unrepresented in available training data.

In future work, we plan to develop more reliable test sets for Solomon Pijin and Bislama, as we feel like Gemini-generated test sets, even though they are guided by Tok Pisin ground truth and a lexicon, are unsatisfactory. We also plan to develop a very small (< 50M) model that can translate across 6 directions, and that has good performance across domains.

## Abstract

This paper presents the KYX submission to the WMT 2026 CreoleMT shared task for Réunion Creole to English (`rcf-eng`). It is mostly about how such a system should be evaluated. The pair is an extreme case: 191 training pairs, a 34-sentence development set, and no standard orthography. On a benchmark this small, a single chrF++ score is easy to over-read, so we pair our system with a contamination- and orthography-aware evaluation. The system continue-trains the official baseline adapter with QLoRA and raises the raw dev score by $+13.3$ chrF++. But a near-duplicate audit finds that six of the 34 dev sources are paraphrases of training sentences, which the exact-match check WMT26 mandates reports as 0% overlap. After decontamination the gain is $+10.0$. Our official test score then comes in $0.8$ chrF++ below the decontaminated estimate and $5.1$ below the raw one, but our margin over the baseline falls to $+3.9$, so even the adjusted gain was optimistic. A data-scaling ablation traces the gain to the provided real pairs, not to synthetic data. A source-spelling stress test then shows the advantage shrinks when the input is re-spelled into equally valid variants, though at this sample size the effect is not stable. We conclude that exact-match contamination checks are not enough on tiny benchmarks, and that scores like ours should be read with care. The same caution applies to any low-resource pair with only a few dozen dev sentences. We release the system, the audit, and all data.

## 1 Introduction

Extremely low-resource machine translation increasingly rests on very small benchmarks. For many endangered, indigenous, and creole languages, a development set of 30 to 50 sentences is close to all that exists, and at this scale evaluation is as much of a problem as modelling. Two artifacts can dominate a single automatic score. First, small train/dev overlaps that an exact-match check does not catch can raise it, because even a few memorized paraphrases move the mean of a 34-sentence set. Second, when a language has no standard orthography, a character metric such as chrF++ partly rewards a system for reproducing the development set's spelling rather than for translating well. Neither problem is visible in the number itself.

We study these effects on an extreme case, Réunion Creole to English (`rcf-eng`) in the WMT 2026 CreoleMT shared task (Robinson et al., 2026), which has 191 training pairs, a 34-sentence development set, and no standard orthography (the same word is written `manzé`, `mangé`, or `manjé`). We build a system for the pair, but our main point is about how to measure it: a single dev score does not, on its own, reflect the translation quality it appears to.

To that end we add three components to standard corpus chrF++ (§3): a near-duplicate audit for leakage that exact matching misses, decontaminated scoring for the inflation those near-duplicates cause, and a source-spelling stress test for orthography-driven overestimation. On `rcf` the audit flags six of the 34 dev sources as paraphrases of training sentences, which the exact-match statistic WMT26 mandates reports as 0% overlap, and re-scoring on the clean subset moves our system's raw $+13.3$ chrF++ to $+10.0$. The official test scores, which arrived after these experiments, confirm that correction and then go past it: our test score comes in $0.8$ chrF++ below the decontaminated estimate and $5.1$ below the raw one, while our margin over the baseline is $+3.9$ rather than $+10.0$ (§4.4).

The system is a QLoRA continuation of the official baseline adapter, and we use it as a case study rather than as the main result. Its adjusted $+10.0$ chrF++ is stable across three seeds, but a data-scaling ablation shows the gain comes from the provided real pairs and not from synthetic data, and the spelling stress test suggests part of it is tied to the source's surface form. That last effect is not stable across rulesets, so we report it as exploratory.

**Contributions.**

1. A contamination- and orthography-aware evaluation for extremely low-resource MT: three components, each tied to a concrete way a single chrF++ score misleads (§3).
2. Evidence that the exact-match contamination statistic WMT26 mandates is not enough on tiny benchmarks: it reports 0% overlap for `rcf` while six dev sources are paraphrase-level duplicates that move the score (§4).
3. A case-study system whose raw +13.3 chrF++ becomes an adjusted +10.0, with an ablation and a spelling stress test showing how little of the number reflects the language pair itself (§4, §5).
4. A held-out check on the protocol: on the official test set the decontaminated dev estimate predicts our own score to 0.8 chrF++ where the raw one is 5.1 optimistic, while the margin over the baseline falls from +10.0 to +3.9 (§4.4).

We release the system, the audit, and all perturbation data.

## 2 Task, Data, and System

**Task.** WMT 2026 CreoleMT, Subtask 1A, single unconstrained track (Robinson et al., 2026). We focus on a single direction, **`rcf-eng`**, evaluated with chrF++ (Popović, 2017).

**Data.** Réunion Creole is among the smallest pairs in the task (Table 1), which is drawn from the kreyòl-mt collection (Robinson et al., 2024). We train on 1,528 rows: all 191 provided pairs together with 1,337 synthetic `rcf`–eng pairs. A separate 150-sentence synthetic set is used only as an overfitting monitor, never to judge quality.

**Synthetic data.** The synthetic pairs are LLM back-translations of English sentences taken from OPUS-100 en–fr (Zhang et al., 2020). We stream that corpus, keep sentences of 3 to 14 words, and rank them by character-trigram Jaccard similarity against the English side of the 191 provided pairs, retaining the closest. Sampling English at random would have produced material from outside the narrow domain of the provided data; ranking against those pairs keeps the generated Creole in that domain. Claude Sonnet (Anthropic, 2026) then wrote a Réunion-Creole rendering of each sentence, prompted with the five nearest provided pairs as exemplars and with the French side of the OPUS sentence, `rcf` being French-lexified. Claude Opus rated the 1,495 resulting pairs 4.63 out of 5.

| pair | train | dev | lexifier |
|---|---|---|---|
| hat–eng | 665,033 | 646 | French |
| mfe–eng | 19,149 | 472 | French |
| pcm–eng | 5,545 | 311 | English |
| **`rcf`–eng** | **191** | **34** | **French** |

Table 1: Selected per-pair sizes (kreyòl-mt). `rcf` is an extreme case: a 34-sentence dev.

That rating is the only quality signal available to us. Automatic quality estimation is not applicable here, since QE encoders have not been trained on `rcf`, so the adequacy of the synthetic data cannot be verified independently (§7). We then removed the synthetic pairs that the audit of §3 flags as near-duplicates of a dev item, which dropped 10, mostly variants of "What are you doing?". Of the 1,485 that remain, 1,337 go into the training set and the other 148 make up all but two of the 150-sentence overfitting monitor. The ablation in §4 shows that the synthetic data contributes little to the decontaminated score in any case.

**System.** The baseline is `google/gemma-4-E2B` plus the official `gemma4-creole-mt-2026-baseline-adapter` (CreoleMT Shared Task, 2026), a generalist LoRA the organizers trained on public data across about 50 creoles. We *continue-train* this adapter with QLoRA, and select the winning epoch by chrF++ on the human dev, never by the synthetic eval-loss (which is anti-correlated with chrF++ here). Because we continue-train the provided adapter, the system and the baseline stay directly comparable, so any score difference between them comes from our training and not from a change of model.

**Training details.** We load the base model in 4-bit NF4 with double quantization and attach the official adapter with `is_trainable=True`, so training continues the organizers' weights rather than initialising a new LoRA. The LoRA configuration is therefore inherited: $r$=64, $\alpha$=128, dropout 0.05, no bias, applied to all linear projections. We train for 8 epochs at learning rate $2 \times 10^{-4}$ with `paged_adamw_8bit`, a linear schedule with no warmup and no weight decay, per-device batch 8 with gradient accumulation 2 (effective batch 16), and maximum sequence length 256. A checkpoint is saved every epoch and all 8 are scored; §4 reports the mean over seeds 42, 43, 44. Training

uses about 9.5 GB of VRAM. Decoding is greedy (`do_sample=False`) everywhere.

**Metric.** All scores are sacrebleu 2.6.0; chrF++ is `CHRF(word_order=2)`. The signatures are

```
nrefs:1|case:mixed|eff:yes|
nc:6|nw:2|space:no|version:2.6.0
  nrefs:1|case:mixed|eff:yes|
nc:6|nw:0|space:no|version:2.6.0
  nrefs:1|case:mixed|eff:no|tok:13a|
smooth:exp|version:2.6.0
```

for chrF++, chrF and BLEU respectively. Evaluation ran under Python 3.12 with transformers 5.14.1, peft 0.19.1 and torch 2.13.0.

## 3 The Evaluation Protocol

Standard practice reports one corpus chrF++. On a 34-sentence benchmark that number can be dominated by leakage or by orthographic variation, so our protocol adds one component for each failure mode:

| problem with one chrF++ score | component |
|---|---|
| exact-match overlap misses paraphrases | (a) near-duplicate audit |
| near-duplicates bias the score | (b) clean-subset scoring |
| non-standard spelling inflates apparent quality | (c) spelling stress test |

We never alter the official benchmark or the provided real data; we decontaminate only our own synthetic training data.

**(a) Near-duplicate contamination audit.** *Problem.* WMT26 asks teams to report train/dev overlap by *exact* string match on the *pair*, which flags only verbatim duplicates of a whole example, so paraphrase-level leakage passes straight through. *Solution.* We normalise both sides (NFKC, lowercase, strip punctuation, collapse whitespace) and score the two sides *separately*. For every dev item we find its most similar training source and, independently, its most similar training target, by a character-level `difflib` ratio. We flag the item if *either* side matches: source ratio $\geq 0.70$ **or** target ratio $\geq 0.90$, and report this *near-duplicate* overlap alongside the exact-match statistic. Neither side is redundant: on `rcf` the source rule alone flags five items, the target rule alone flags two, and only one item (#24) is caught by both. Target-side leakage matters in its own right because chrF++ scores the English output, so a training example whose English matches a dev reference leaks the answer even when the two Creole sources are unrelated sentences (#12 in Table 2). The higher target threshold reflects the fact that short English sentences collide by chance far more readily than Creole ones do. The ratio is deliberately conservative, since a semantic or embedding similarity would flag at least as many items, so our count is a lower bound, and the conclusion that exact matching misses paraphrases holds for any threshold below 1.0.

**(b) Decontaminated (clean-subset) scoring.** *Problem.* Near-duplicates bias the mean, and on 34 sentences a handful of memorized items can dominate it. *Solution.* We report chrF++ on the full dev ($n$=34) and on the decontaminated subset ($n$=28) that drops the flagged items. The gap between the two is a direct read-out of near-duplicate-driven inflation, and the clean number is the one we treat as the contamination-adjusted estimate.

**(c) Source-spelling stress test.** *Problem.* With no standard orthography, a high chrF++ may reflect a model reproducing the dev's particular spelling rather than translating well, and a character metric cannot tell the two apart. *Solution.* We re-spell each dev source into attested variants using the French-to-Creole correspondence rules described for `rcf` by Bollée (2013), and realised differently by the three competing orthographies in use on the island (Lékritir 77, KWZ, and Tangol). We then re-translate and measure how much of the system's advantage over the baseline survives, against a random-noise control given the same number of edits (§5). Because both systems see the same perturbed input, we track the *change in advantage*, which within one ruleset does not depend on how harsh that ruleset is; comparing *across* rulesets does depend on it, and §5 shows this matters. This last component is exploratory: at $n$=28 its own conclusion is unstable, which is itself evidence that scores at this scale are fragile.

## 4 Applying the Protocol

### 4.1 Contamination audit and adjusted score

The statistic WMT26 mandates reports 0% overlap, and that is correct on its own terms: no training *pair* is a verbatim copy of a dev *pair*. Our audit reports six of 34 (indices 12, 21, 24, 27, 28, 32). The two statistics disagree because they measure different things. The mandated one compares raw strings and requires both sides of an example to match at once; ours normalises the text and scores each side on its own. Items #21 and #27 are character-identical to a training source after normalisation,

| dev | flagged by | ratio | dev segment | nearest training segment |
|---|---|---|---|---|
| 12 | target (eng) | 1.000 | The sun has risen. | The sun has risen. |
| 21 | source (`rcf`) | 1.000 | La fam i ariv, pran lalé, kas son banann. | La fam i ariv, pran lalé, kas son banann. |
| 24 | both | 0.765 / 1.000 | komansman le mwá | ó kómansman du mwá |
| 27 | source (`rcf`) | 1.000 | Mwen lé fayfay. | Mwen lé fayfay. |
| 28 | source (`rcf`) | 0.800 | Moin la fine ariv la kaz. | Bann la i ariv la kaz. |
| 32 | source (`rcf`) | 0.812 | [. . . ] li manz enn, li donn son syin sakin enn. | Li donn son syin sakin enn. |

Table 2: The six flagged dev items, shown on the side that flagged them: `rcf` for source-side matches, English for target-side ones. #21 and #27 are byte-identical to a training source but their English differs (*I am tired.* against *I am a bit tired.*), so the pair is not a duplicate and the mandated check reports 0%.

but their English references differ from that training example's English, so the pair is not a duplicate and the exact-match check passes them. In #27 the Creole source *Mwen lé fayfay.* appears in both, but the dev reference reads *I am tired.* where the training target reads *I am a bit tired.* Item #12 is the mirror image: its English is identical to a training target while the two Creole sources are entirely different sentences. Only #24 is close on both sides at once, and even there the Creole is a paraphrase rather than a copy. Table 2 lists all six.

Every one of the six traces to the real provided pairs rather than to our synthetic data. We therefore cannot drop them from training without making the baseline comparison unfair, since the baseline adapter was trained on the same public data; instead we drop them from scoring. On the full dev the system beats the baseline by +13.3 chrF++, and on the clean subset the advantage is +10.0 (Table 3). The 3.3-point gap between the two is the near-duplicate inflation the audit predicts, and it is visible in all three metrics we report (Table 3, bottom).

The six flagged items are also where the two systems differ most. Our system scores 72.8 chrF++ on them against 40.1 for the baseline, a gap of +32.7, while on the remaining 28 items the gap is +10.0. Six items scored three times better than the rest pull the 34-sentence mean up by 3.3 points on their own. Whether the underlying behaviour is memorisation or paraphrase generalisation cannot be settled at this sample size, and the two would be scored identically here; what the full-dev number cannot do either way is estimate quality on input the model has not seen. We therefore report both subsets.

### 4.2 Where the gain comes from

Because the data here is small enough to make the experiment cheap, we add training data in stages and score the best epoch by decontaminated chrF++ at each stage (Table 4). Almost the entire decontaminated gain comes from the real pairs (+6.8 clean). Adding the synthetic pairs on top raises the clean score by only a further +1.1, which is not significant. So the clean-dev gain reflects the real pairs; the rest of the raw number is the contamination gap, not the extra data. The full-dev column stays between 47 and 48 once training starts while the clean column separates the two stages: on the raw benchmark the two trained systems look interchangeable, and only decontaminated scoring shows which addition did the work.

| System | full ($n$=34) | clean ($n$=28) |
|---|---|---|
| Baseline (adapter) | 36.26 | 35.49 |
| **Ours** | **49.60 ±1.37** | **45.51 ±2.01** |
| Δ vs baseline | +13.3 | +10.0 |
| Merge (3-seed soup) | 48.26 | — |

| | full ($n$=34) | | clean ($n$=28) | |
|---|---|---|---|---|
| metric | base | ours | base | ours |
| chrF++ | 35.98 | 49.47 | 35.24 | 45.20 |
| chrF | 35.68 | 49.36 | 35.01 | 44.98 |
| BLEU | 25.62 | 40.57 | 24.88 | 36.61 |

Table 3: `rcf-eng`. Top: chrF++, 3-seed mean±std over the best epoch per seed. Bottom: the submitted system under three metrics; the advantage shrinks by 3.5 chrF++, 3.7 chrF and 3.2 BLEU on the clean subset, so the gap is not an artifact of the character metric. Each comparison is scored within one decoding environment.

### 4.3 Statistical reporting

At $n$=28 a paired significance test has little power, so we treat intervals and effect sizes as more informative than $p$-values. The main effect size is the adjusted $\Delta = +10.0$ chrF++ (full-dev $\Delta = +13.3$). Across the three seeds the clean score is $45.5 \pm 2.0$ (mean±std) against a baseline of 35.5, so every seed clears the baseline by a wide margin. A paired approximate-randomization test on the submitted system gives $p \approx 0.013$, but we do not rely on it,

| training data | rows | full | clean | Δ prev |
|---|---|---|---|---|
| baseline (no training) | 0 | 36.72 | 36.08 | — |
| + real pairs | 188 | 47.82 | 42.84 | +6.8 |
| + synthetic | 1,528 | 47.53 | 43.97 | +1.1 |

Table 4: Data-scaling ladder (single seed), chrF++ on the full and decontaminated dev; Δ prev compares clean scores against the row above. Neither step is individually significant on the clean subset ($p = 0.054$ and $p = 0.76$). Scored in a different environment from Table 3.

because with 28 items such a test is easily moved; the bootstrap intervals in §5 are the better guide.

### 4.4 Official test set

After the experiments above were complete, the organizers released scores on the held-out test set for `rcf-eng`, which contains 28 sentences (Table 5). Our system scores 44.38 chrF++ there.

Our own score transfers from the dev set, and it is the decontaminated estimate that transfers. That estimate sits 0.8 chrF++ above the test result where the raw dev score sits 5.1 above it, and chrF and BLEU behave the same way, with errors of 0.2 against 4.6 and 0.5 against 4.5. For the question of what our system scores on unseen input, dropping the six leaked items did most of the correcting that §3 claims for it.

The margin over the baseline does not transfer. The official Gemma baseline scores 40.49 chrF++ on this pair, so our advantage on the test set is +3.9 against the +10.0 we measure on the decontaminated dev subset. The difference comes from the baseline rather than from us. Our score moves by −0.8 between the two sets, while the baseline scores about five points higher on the test set than it does on our dev set. Dropping leaked items corrects the inflation that our own training introduced; it does nothing about two evaluation sets being differently hard for a system that has seen neither. We therefore read the +10.0 of §4 as an upper bound rather than an estimate, which is the more cautious of the two readings our protocol supports and the one the test set favours.

Some caution is due on the comparison itself. The organizers report chrF++ and BLEU but not chrF for their baselines, and their scores were produced in a different environment from our dev scores, where the baseline moves about 0.7 chrF++ (Table 3). The task's second baseline, kreyòl-mt-pubtrain, scores 47.72 on the test set and is therefore ahead of ours.

| | chrF++ | chrF | BLEU |
|---|---|---|---|
| *our system, by evaluation set* | | | |
| raw dev ($n$=34) | 49.47 | 49.36 | 40.57 |
| decontaminated dev ($n$=28) | 45.20 | 44.98 | 36.61 |
| **official test** ($n$=28) | **44.38** | **44.73** | **36.07** |
| error of the raw estimate | +5.1 | +4.6 | +4.5 |
| error of the clean estimate | +0.8 | +0.2 | +0.5 |
| *official test set, task baselines* | | | |
| Gemma | 40.49 | — | 30.89 |
| kreyòl-mt-pubtrain | 47.72 | — | 40.88 |

Table 5: The submitted system on the official test set. The decontaminated dev estimate predicts our own test score to within 0.8 chrF++ while the raw one is about 5 points optimistic, but our margin over the Gemma baseline is +3.9 rather than the +10.0 measured on the decontaminated dev. chrF is not reported for the baselines.

## 5 Exploratory Stress Test: Spelling Robustness

This test is exploratory rather than a main result. It asks whether the remaining +10.0 reflects translation quality or partly the dev set's particular spelling, and what it shows most clearly is how unstable such a check is at this sample size.

The results are mixed. One of the three spelling rulesets we tried erases almost all of our advantage and the other two do not, and part of that disagreement comes from the rulesets perturbing the source by different amounts. The probe therefore shows that surface form matters here, without settling how much of the gain depends on it.

We re-spell each dev source into equally valid variants using the `rcf` spelling correspondences of Bollée (2013), re-translate, and measure how much of our advantage over the baseline survives. We compare three versions of the source: the original, the re-spelled one, and a control with the same number of random character edits, which changes the surface as much but follows no spelling rule. A gain that is real translation should survive all three. We repeat this with three rulesets (Table 6): v1, our main one; v2, a milder set; and v3, an accent-stripping set.

Under v1 the advantage almost vanishes under re-spelling, falling from +10.0 to +0.2 chrF++, while it stays at +8.9 under the random control. On its own this looks like the model leaning on the dev's spelling rather than translating, and it is the only one of the three drops whose bootstrap

| | edits | | advantage | |
|---|---|---|---|---|
| ruleset | re-sp. | ctrl | re-sp. | ctrl |
| v1 (main) | 9.9% | 13.7% | +0.2 | +8.9 |
| v2 (mild) | 4.9% | 4.9% | +7.2 | +3.1 |
| v3 (accents) | 7.4% | 7.2% | +5.9 | +3.0 |

Table 6: Spelling stress test on the decontaminated dev ($n$=28), where the unperturbed advantage is +10.0 chrF++. "edits" is the share of source characters changed. Drop in advantage under re-spelling, 95% bootstrap CI: v1 +9.8 $[+1.3, +19.1]$, v2 +2.8 $[-6.3, +12.1]$, v3 +4.0 $[-4.9, +13.4]$.

interval excludes zero ($[+1.3, +19.1]$). But it does not replicate: under v2 and v3 re-spelling only lowers the advantage to +7.2 and +5.9, and it now hurts *less* than the random control rather than more.

Part of that disagreement is magnitude, not linguistics. v1 rewrites 9.9% of the source characters against v2's 4.9% and v3's 7.4%, and touches 30 of 34 sentences against 23 and 25, so it is simply a harsher perturbation and the ordering of the three drops follows the ordering of their edit rates. The within-ruleset control is the part that is properly matched (51 versus 51 edits for v2, 77 versus 75 for v3), and under v1 the control is if anything *harsher* than the re-spelling, at 142 edits against 102. v1's result is therefore not an artefact of its spelling perturbation being the larger of the two.

The two systems respond differently to the same perturbation. Under v1 the baseline loses 1.1 chrF++ to re-spelling while our system loses 10.9; under the random control they lose 12.1 and 13.2. The baseline is thus insensitive to re-spelling specifically, not to surface change in general, whereas our system is not. Continued training on 191 sentences written in one orthography is the obvious candidate explanation, but we cannot separate it from the other differences between the two systems here.

The probe therefore suggests that part of the gain is tied to surface form, but cannot say how much. At 28 sentences even a purpose-built check is unstable, and comparing across rulesets confounds the severity of a perturbation with its content. We report it as supporting, exploratory evidence that a single score here should not be read at face value.

## 6 Related Work

**Contamination in evaluation.** Benchmark leakage is a recognized confound, systematized by the CONDA shared task (Sainz et al., 2024); for MT, Kocyigit et al. (2025) show that source–target contamination inflates scores, motivating the overlap reporting WMT26 mandates. Near-duplicate leakage of the kind we target is the problem addressed by MinHash deduplication (Lee et al., 2022). The WMT25 Creole task made a related point empirically (Robinson et al., 2025): contamination was serious enough to require the organizers' own decontaminated re-evaluation, and EdinHelsOW reported gains that held only on the decontaminated test set (Rowe et al., 2025). That precedent is the closest existing answer to whether other creole MT tasks would benefit from filtering of this kind: on those pairs decontamination already changed which systems looked better, but it was applied after the fact and only for exact overlap. Our result indicates that the same correction is needed before scores are reported, and at a looser matching threshold than exact. How much leakage a paraphrase-level audit would find on those larger pairs remains open.

**Orthographic variation and robustness.** chrF++ (Popović, 2015, 2017) is character-based, so it is sensitive to spelling: Aepli et al. (2023) show that non-standard spelling degrades metric reliability on dialects without a standard orthography. Robustness of NMT to input noise is well studied (Belinkov and Bisk, 2018), but for creoles no prior work probes the model's own spelling robustness as part of evaluation. Our stress test does, and finds it unstable at $n$=28.

## 7 Limitations

The evidence base is 34 sentences (28 decontaminated), so all point estimates carry wide intervals and every selection step is noisy: the best epoch varies across seeds, and chrF++ swings up to about 5 points across epochs within a seed (42.96 to 49.47 on the full dev). Reporting over three seeds reduces but cannot remove this fragility, and the stress test (§5) inherits it; cross-validation would give a fuller picture of the variance and we leave it to future work.

The audit thresholds (0.70 and 0.90) are heuristic, though our claim is threshold-independent for any cutoff below 1.0; a looser rule flags eight items instead of six, and the direction of every conclusion is unchanged. We evaluate a single direction (`rcf-eng`) and do not report into-Creole results, where chrF++ is unreliable for the same orthographic reasons. The single-direction scope is the main limitation of this work: we show that the mandated exact-match statistic misses paraphrase-level

leakage on rcf, but not that this holds for the task as a whole.

Moving the spelling component to a second pair is harder than moving the audit, because most of the collection does not have the property that component tests. Haitian, Mauritian and Seychellois Creole have had codified orthographies since 1979, 2011 and 1981 respectively, and Guianese Creole is written in the semi-official GEREC system; rcf is written in at least three competing ones and has no agreed standard. Louisiana Creole is the closest parallel in the collection, with several orthographies in concurrent use and a 92-sentence development set, and it is where we would take the spelling test next. That requires a documented correspondence set for Louisiana Creole rather than a reuse of ours, so we do not report it here. COMET-style metrics are omitted as primary because their encoders have not seen rcf, and for the same reason we could not apply quality estimation to the synthetic training data, whose adequacy therefore rests on an LLM judgement alone.

We also do not test whether a long-context model prompted with the entire 191-pair training corpus, rather than fine-tuned on it, would score differently. Such a system retrieves from a visible corpus instead of memorising into weights, so it might show a different gap between the raw and the decontaminated score, and the comparison would isolate what fine-tuning contributes over in-context access to the same data. We leave that to future work. Official test-set scores are reported in §4.4. They show that the decontaminated dev figure, which is the estimate this paper argues for, still overstated the margin over the baseline by roughly a factor of three, so the protocol narrows the error on a benchmark this small without removing it.

## 8 Conclusion

Benchmarks of a few dozen sentences are now the norm in extremely low-resource MT, and at that scale a single chrF++ score should be read with care rather than at face value. We proposed a contamination- and orthography-aware evaluation, a near-duplicate audit, decontaminated scoring, and a source-spelling stress test, and applied it to WMT 2026 Réunion Creole to English. The audit exposes paraphrase-level dev/train leakage that the exact-match statistic WMT26 mandates reports as 0%, which moves our system's raw +13.3 chrF++ to an adjusted +10.0, and the ablation and stress test show how little of even that number reflects the language pair rather than the data and its spelling. The gap between the two numbers is a property of the benchmark, not of the system: it is produced by six items that any exact-match check passes, and it survives a change of metric. The official test scores arrived after the analysis was complete. They put our system 0.8 chrF++ below the decontaminated estimate and 5.1 below the raw one, and they put our margin over the baseline at +3.9 rather than +10.0, so the adjusted dev figure was the closer of the two and still too high. We release the system, the audit, and all data.

## Abstract

This paper describes ongoing efforts to build an n-gram text classifier for several major French-lexifier creoles. Our model is based on a simple text processing pipeline, limited training data, and a deliberately lightweight architecture. Despite this, it achieves substantially stronger performance than existing baselines on our target languages. These results suggest that long-established machine learning approaches remain effective for new language identification needs.

## 1 Introduction

Language identification (LID) is a classic text processing task that involves automatically determining the language used in a written string. Compared to machine translation or speech synthesis, categorizing a text into a limited set of candidate languages is relatively straightforward. However, the reliability of LID systems can be critical to the proper execution of these more sophisticated downstream tasks. For example, automatic translation tools fail when the language of a source text is incorrectly identified. Meanwhile, multilingual and code-switching text-to-speech (TTS) systems require modeling how text maps to speech in each language, and correctly applying these models to the relevant segments. In linguistically diverse regions, LID can streamline the task of categorizing and preprocessing multilingual texts on websites and social media. Existing LID tools achieve excellent performance on the 100 or so best-resourced languages, but support is limited for the marginal majority without large text corpora.

Among these languages, creoles are broadly underserved by language classifiers when considered as a category.[1] As comparatively recent products of the early modern spice and slave trades, creoles lack the long written traditions of their mostly European lexifiers, and have historically been overlooked as nonstandard varieties *of them* rather than as distinct languages in and of themselves. Like many other low-resource languages, they often lack an official administrative status,[2] while their speakers mainly reside in historically agricultural economies with delayed access to digital resources.

In spite of these challenges, or perhaps because of them, creoles present a genuinely interesting use case for LID tools. Many creoles today coexist with their lexifiers in a complex state of diglossia, with intermediate syntactic constructions sometimes blurring the line between creole and lexifier grammars.[3] Formal and informal spelling conventions can also complicate matters. Some creoles, like West African Pidgin English, spell words as they are written in their language of origin. Others have adopted orthographies distinct enough to obscure otherwise straightforward etymologies, as in the English-based Tok Pisin, or 'Talk Pidgin'. Some have no codified orthography whatsoever, leading to multiple competing standards in practice.[4]

The preference for creoles in informal contexts complicates matters further. While French's digraphs and silent letters easily distinguish it from the phonemic spellings of its creole offshoots, this distinctiveness evaporates among the abbreviated stylizations of informal writing. A simple *qu'est-ce que tu fais* 'what are you doing' can be rendered as a superficially far more creole-like *kesk tu fai* in

[1] Whether creoles represent a coherent typological class or a loose sociohistoric construct grouping disparate colonial varieties is a matter of debate. See McWhorter (2018) and Mufwene (2015) for two contrasting visions of creoleness.

[2] Haitian Creole and Papua New Guinea's Tok Pisin being two major exceptions.

[3] See the concept of creole continuum popularized by Bickerton (1973).

[4] In some cases, competing norms can reflect both linguistic and identitarian concerns. See the tension between a pragmatic English-style orthography and a distinctly 'nativized' phonemic system proposed for Naijá, or Nigerian Pidgin (Ofulue, 2017; Ekundayo and Enwerem, 2021).

*Proceedings of the Eleventh Conference on Machine Translation*, pages 2471–2475
October 28-29, 2026 ©2026 Association for Computational Linguistics

the very informal contexts where a creole is most likely to be used.

In this paper, we present early steps towards addressing these issues with Gwo-K, a lightweight n-gram classifier for differentiating French-lexifier creoles. This model was produced as part of the 2026 WMT Shared Task on Creole Machine Translation. Indirect comparison with the current state-of-the-art suggests that our model outperforms existing LID tools for creoles, demonstrating the effectiveness of long-established machine learning approaches when applied to task-specific datasets supported by targeted augmentation strategies.

## 2 Model design

As specified in the Shared Task challenge, our language classifier was designed to categorize texts into twelve distinct language categories, nine of which are French-lexifier creoles spoken in the Caribbean and the Indian Ocean. The remaining categories are reserved for English and French texts, and a catch-all 'Other' category for any other language.

### 2.1 Data selection

As training data, we primarily used the `train` subset of the Kreyòl-MT dataset, which includes text-translation pairs in numerous creoles and several European lexifiers (Robinson et al., 2024). We extracted all texts in the Creole-English and Creole-French subsets of the corpus. All creole language tags not included in our list of target languages were mapped to `oth` (other), while examples of English and French were sourced from the translated texts. Any duplicate creole texts were excluded without exception. Texts underwent minimal preprocessing: case distinctions were eliminated, and common punctuation marks were discarded. The same set of treatments were applied to the `validation` set. While exploring the training data, we noticed that a large portion of Haitian texts were composed of product numbers, HTML tags, and other linguistically uninformative strings. To eliminate such texts, we discarded all entries where common HTML tags were present, or where numerals, punctuation marks, and upper-case letters comprised more than 30% of characters.

The full list of categories and dataset sizes is outlined in Table 1. Note that Guianese Creole (`gcf`) and Reunion Creole (`rcf`) were especially underrepresented in the Kreyòl-MT dataset. To overcome this shortcoming, we augmented our training set with external texts manually gathered online. Reunion Creole was supplemented with 2163 sentences provided by Cellier (1985) and McLellan (2024), while the Guyanese data was reinforced with 1000 sentences from geography-focused Wikipedia entries. The majority of the supplemental texts were far longer and more formal than the brief and syntactically simple examples used in the Kreyòl-MT dataset.

As a self-imposed limitation, we restricted our supplemental data to sources explicitly published under a permissive license. Potentially useful texts published by religious and cultural organizations were excluded because of unclear reuse conditions. However, we did secure access to an additional 2823 examples of prose and poetry by collaborating with the Reunion Creole advocacy organization *Lofis*.[5] These were included in the augmented training set.

| Code | Language | Samples | |
|---|---|---|---|
| | | Train | Test |
| `acf` | Saint Lucian | 3757 | 222 |
| `crs` | Seychellois | 1963 | 104 |
| `gcf` | Guadeloupean | 4400 | 204 |
| `gcr` | French Guianese | 346 **(+1k)** | 78 |
| `hat` | Haitian | 814k | 1544 |
| `lou` | Louisianan | 1532 | 92 |
| `mart` | Martinican | 4346 | 281 |
| `mfe` | Mauritian | 26.1k | 619 |
| `rcf` | Reunionese | 189 **(+5k)** | 34 |
| `eng` | English | 576k | 3800 |
| `fra` | French | 319k | 1970 |
| `oth` | Other | 38.4k | 2592 |

Table 1: Language categories and dataset sizes. Figures in parentheses represent text samples gathered from external sources.

### 2.2 Model training and variants

After preprocessing our train and test sets, we trained a classifier based on character-level TF-IDF representations combined with a linear support vector machine (SVM). Our system extracts character sequences of length three to five from each text, allowing it to capture orthographic patterns, grammatical monosyllables, and frequent subword structures unique to each language class. The resulting feature vectors are weighted using

[5] https://lofislalangkreollarenyon.re/kisa-ni-le/

term frequency-inverse document frequency (TF-IDF) and passed to a LinearSVC classifier with balanced class weighting to mitigate the effects of uneven training data distribution.

For this paper, we evaluated two model variants on our test set. `Gwo-K_1` was trained using only the texts available in the Kreyòl-MT corpus, while `Gwo-K_2` included the additional data gathered for the data-poor Reunion and Guyanese creoles.

## 3 Results and analysis

### 3.1 Global performance

Both `Gwo-K_1` and the data-augmented `Gwo-K_2` models achieve accuracy around 97%, though this figure is skewed by the overrepresentation of Haitian, English, French, and Other classes. Average and language-specific precision, recall, and F1 scores for both models are presented in Table 2.

Table 2: Classification performance comparison between `Gwo-K_1` and `Gwo-K_2`. Bold values indicate better performance between models; * indicates a notable absolute difference (≥0.03).

| | Gwo-K_1 | | | Gwo-K_2 | | |
|---|---|---|---|---|---|---|
| **Class** | **P** | **R** | **F1** | **P** | **R** | **F1** |
| acf | 0.93 | 0.91 | 0.92 | **0.94** | 0.91 | 0.92 |
| crs | 0.97 | **0.96** | **0.97** | 0.97 | 0.94 | 0.96 |
| gcf | 0.80 | 0.92 | 0.86 | **0.83*** | 0.92 | **0.87** |
| gcr | **0.95** | 0.47 | 0.63 | 0.94 | **0.58*** | **0.71*** |
| hat | 0.94 | 0.99 | 0.97 | **0.95** | 0.99 | 0.97 |
| lou | 0.98 | **0.89** | 0.93 | 0.98 | 0.88 | 0.93 |
| mart | 0.93 | 0.82 | 0.87 | **0.94** | **0.84** | **0.89** |
| mfe | 0.97 | 0.98 | 0.97 | 0.97 | 0.98 | **0.98** |
| rcf | **0.92*** | 0.35 | 0.51 | 0.82 | **0.79*** | **0.81*** |

| fra | 0.99 | 0.99 | 0.99 | 0.99 | 0.99 | 0.99 |
| oth | 0.99 | 0.96 | 0.98 | 0.99 | 0.96 | 0.98 |
| **Accuracy** | | 0.9699 | | | **0.9720** | |
| **Macro Avg.** | **0.95** | 0.85 | 0.88 | 0.94 | **0.89*** | **0.91*** |
| **Weighted Avg.** | 0.97 | 0.97 | 0.97 | 0.97 | 0.97 | 0.97 |

`Gwo-K_1` performs poorly on both French Guianese Creole (`gcr`) and Reunion Creole (`rcf`), with recall scores below 0.5 and F1 scores in the low 50s and 60s. This likely reflects the shortage of training data mentioned earlier. Languages with lower amounts of training data are broadly associated with lower F1 scores, though the relationship is not fully predictive. For example, Louisiana Creole (`lou`) is identified far more effectively than its Guadeloupean (`gcf`) and Martinican (`mart`) counterparts despite having less than one third as much training data. This is somewhat unsurprising given the language's geographic and historic isolation from the Caribbean creoles, and suggests that more linguistically distinct classes require fewer examples to build effective LID tools.

`Gwo-K_2`, which was trained on expanded Guianese and Reunion Creole datasets, far outperformed `Gwo-K_1` on those languages. These respectively exhibit 11- and 44-point improvements in recall, and 8- and 30-point improvements in F1 measure. The difference in gains is roughly proportionate to the amount of supplemental data included in each language's training set. Despite marked improvements over `Gwo-K_1`, performance on these languages lags behind the other classes. It is especially interesting that gains made on Reunion Creole were partially offset by a lower overall precision. We attribute this performance gap to the fact that we chose not to expand the evaluation sets for these languages. It is therefore likely that differences in genre between the training and test sets contributed to higher error rates. This is especially true for Reunion Creole, whose supplemental data contained an orthographic standard not used in the Kreyòl-MT corpus. Still, the high overall improvement does suggest that the additional data is largely generalizable beyond its original sources.

Overall, the augmented model enjoys a 3-point macro average improvement thanks to the superior performance on these two creoles, with significantly higher recall and slightly lower precision.

### 3.2 Error analysis

To better understand sources of errors, we produced confusion matrices for each model.

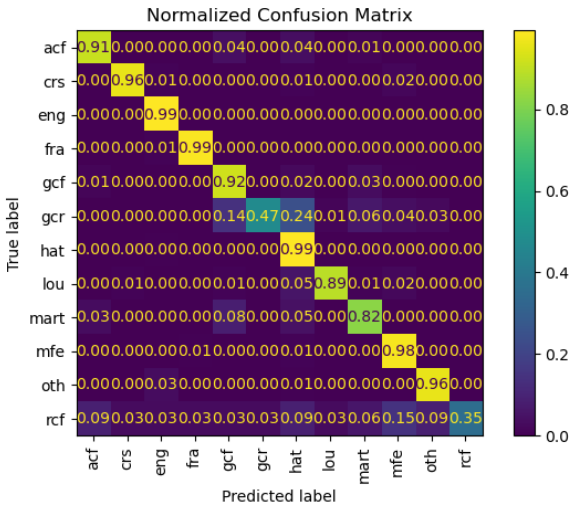

Figure 1: Confusion matrix for the `Gwo-K_1` classifier on the test set. Values are normalized by true class.

The matrix produced from `Gwo_K-1` in Figure 1

shows that French Guianese Creole (gcr) is almost exclusively confused with Guadeloupean, Martinican, and Haitian creoles, all of which are spoken in the Caribbean. Meanwhile, Reunion Creole is most likely to be confused with Mauritian Creole (mfe), also spoken in the Indian Ocean. To some extent, geographic and linguistic proximity appears to reflect the types of errors this model produces.

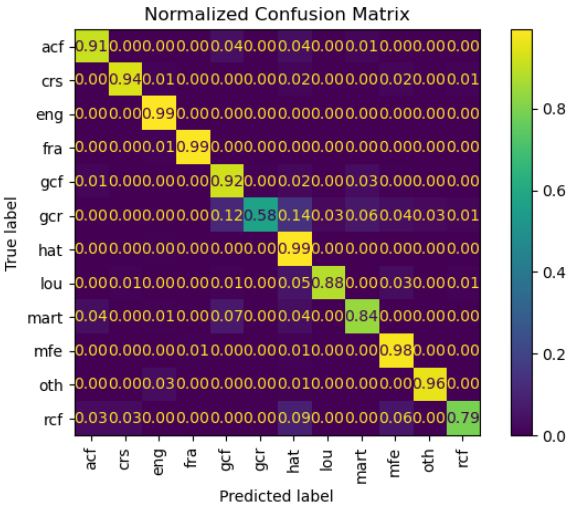

Figure 2: Confusion matrix for the Gwo-K_2 classifier on the test set. Values are normalized by true class.

The confusion matrix produced from the Gwo-K_2 model in Figure 2 reveals similar trends. Even with the marked improvements made from our data augmentation strategy, errors continue to cluster around the same groups of languages. Interestingly, the French-based creoles are almost never confused with their French lexifier, suggesting that the creoles pattern much closer to each other than they do to French. Nor are creoles often confused with 'Other' languages. Despite occasionally high error rates *between* creoles, both systems are exceptionally good at differentiating French-based creoles from other categories of language. This could make our system especially useful in contexts where the geographic origins of texts are already known. In such cases, creole classification tasks could be simplified into a matter of differentiating between a generic 'French creole' label and a limited set of other likely candidates.

### 3.3 Comparison with existing baselines

While our models yield excellent results for most creoles and promising results for the rest, it is important to compare our scores to existing baselines. However, this is difficult when it comes to creole languages. FastText, a popular language classifier, only offers coverage to Haitian Creole (Joulin et al., 2017).

However, GlotLID offers coverage of all languages discussed in this paper, with the exception of Martinican Creole which it does not distinguish from Guadeloupean (Kargaran et al., 2023). This model was tested by Shared Task organizers on a separate evaluation set similar in content and structure to our own. This model yielded a macro F1 score of 0.68, a weighted F1 score of 0.74, and an overall accuracy of 74.87%. While our scores far outperform those of GlotLID, we must also acknowledge that their results are artificially deflated by the lack of a dedicated mart label.

## 4 Perspectives and conclusion

The model presented in this paper is a work in progress, and is likely to undergo substantial revisions in the coming months. The primary contributions of this work are to highlight the usefulness of basic n-gram language classification strategies in data-rich scenarios, and simple data-augmentation approaches for more marginal languages.

Our most significant gains were made from including additional data provided by a language advocacy organization. While exploring other potential sources of data, we identified many texts which we believe could further improve the performance of our system, but these were excluded due to ethical and legal concerns. Going forward, we believe that the most substantial improvements will be made not from architectural modifications or preprocessing strategies, but from our ability to forge similar partnerships with organizations and rights holders willing to contribute their data to open-source language tools.

This and future iterations of our tool will be available on a public GitHub repository[6] where external partners will be recognized for their data contributions. In the longer-term, we would also like to test our tool against major large language models, both with one-shot prompting and supervised finetuning using our dataset. Regardless, we believe that the simple approach provided in this paper will be more than sufficient for most practical applications. It will carry the additional benefit of low training time, fast inference, and minimal package dependencies and hardware requirements.

## Abstract

We present a human-translated, native-script Chakma (ccp_Cakm) extension to FLORES+. The corpus comprises the 997-sentence dev and 1,012-sentence devtest English splits, for 2,009 records in total. We recruited three native Chakma speakers through a screening task, conducted six virtual training sessions, and required direct translation without machine-translation or language-model output. A native reviewer checked meaning, grammar, script, terminology, named entities, numbers, and punctuation, returning problematic items for revision. We describe the Bangladeshi Chakma variety used and our orthographic and Unicode decisions. We then report a completed release audit: FLORES+ identifiers were recovered from the canonical English order and renumbered to the 1-based scheme, all 2,009 records were verified one-to-one against the English source, text was normalised to Unicode NFC, a character inventory was produced, and all twenty-seven residual non-Chakma characters were located and resolved. The package passes every check with no open defects, is fixed by SHA-256 checksums, and has been submitted to FLORES+ through the Open Language Data Initiative under CC BY-SA 4.0. The work provides a native-script evaluation resource for a language whose existing computational resources frequently rely on Bengali-script transliteration.

## 1 Introduction

Machine-translation evaluation remains difficult for languages that lack trusted, independently produced test data. FLORES-101 established a professionally translated, many-to-many benchmark for 101 languages (Goyal et al., 2022), and the No Language Left Behind work expanded this framework to 200 languages (NLLB Team, 2022). FLORES+ continues that effort through the Open Language Data Initiative (OLDI), which supports community contributions for languages and varieties not yet adequately represented (Burchell et al., 2024; Dale et al., 2025).

Chakma is a clear case for this kind of extension. It has its own Unicode-encoded writing system, but most computational work involving Chakma text has used Bengali-script transliteration or has focused on tasks other than native-script machine-translation evaluation. A benchmark written in the Chakma script is therefore necessary to distinguish translation ability from transliteration ability.

We contribute a human translation of the English FLORES+ dev and devtest material into the Chakma script, together with a documented workflow for translator selection, translation, adjudication, and release validation. This work was prepared for the OLDI open-data shared task at WMT 2026, and the dataset contribution has been submitted to the FLORES+ repository.[1] We make three contributions. First, we contribute native-script Chakma translations for the 2,009-sentence target corpus, aligned to the canonical FLORES+ identifiers and fixed by SHA-256 checksums. Second, we document a community-based workflow that excludes machine-generated translation output. Third, we describe the orthographic and quality-control decisions, and report the concrete defects that a systematic release audit uncovered, that must accompany a benchmark for a language with limited digital infrastructure.

This paper focuses on the resource and its preparation. We do not present a new MT model, and we do not use automatic model scores as a substitute for human review. Instead, we report the available evidence and state the limitations directly.

## 2 Chakma and Existing Resources

### 2.1 Language and writing system

Chakma is identified by ISO 639-3 code `ccp` and Glottocode `chak1266` (Glottolog, 2026). Bangladesh's 2022 census reports 483,299 Chakma people in the country (Bangladesh Bureau of Statistics, 2022). Chakma communities are concentrated in the Chittagong Hill Tracts and also reside in parts of India and Myanmar. Sociolinguistic work documents sustained pressure from nationally dominant languages and limited institutional space for Indigenous languages in Bangladesh (Sultana, 2023).

The Chakma script is Brahmi-derived and occupies Unicode block U+11100–U+1114F (Unicode Consortium, 2025). We use ISO 15924 code `Cakm` and the OLDI dataset label `ccp_Cakm_chak1266`. The dedicated script matters methodologically: a system that produces Bengali-script Chakma or romanized Chakma has not demonstrated native-script generation, even if a reader can recover part of the intended content.

Our translations represent the Bangladeshi variety used by contributors from the Chittagong Hill Tracts. We do not claim that every spelling choice generalizes to Indian or Myanmar Chakma varieties. Where variants occurred, translators discussed them in a shared glossary and selected forms that were familiar in Bangladeshi Chakma writing. The release should therefore be interpreted as one documented variety rather than as a universal orthographic standard.

### 2.2 Related computational work

ChakmaNMT introduces Chakma–Bangla parallel and monolingual data and a Chakma–Bangla–English benchmark, using transliteration to exploit Bangla resources (Chakma et al., 2024). MELD provides sentence-level Chakma, Garo, and Marma material in Bengali script with Standard Bangla and English translations (Mahi et al., 2025). ChakmaBridge expands MELD into an 807-sentence, five-way corpus spanning English, Standard Bangla, Bengali-script Chakma, Romanized Bangla, and Romanized Chakma (Rahman et al., 2025). Khisa et al. (2025) use native-speaker-validated, Bangla-transliterated Chakma literature for masked-language-model adaptation. These resources demonstrate the utility of transliteration, but do not replace native-script evaluation.

Other work contributes complementary infrastructure. DChakma develops part-of-speech tagging resources (Apu et al., 2025), and Self-ChakmaNet addresses handwritten-character recognition with a 47-class dataset (Podder et al., 2023). Recent language-identification studies recognize Chakma among several Bangladeshi languages from text or speech (Ahmod et al., 2025; Khan et al., 2025; Anik et al., 2026; Nirob et al., 2026). These tasks differ from translation evaluation: recognizing a language or its characters does not show that an MT system preserves sentence meaning in the native script. Ahmed et al. (2024) show how an OLDI language contribution can pair careful human data creation with transparent validation. Our work follows that resource-building tradition while focusing on native-script Chakma evaluation data.

Table 1: Dataset and workflow summary.

## 3 Dataset Construction

### 3.1 Source data and scope

We translate from the English FLORES+ material rather than from Bengali or another intermediary language. The English source files contain 997 `dev` sentences and 1,012 `devtest` sentences, for a target total of 2,009. Direct English-to-Chakma translation avoids adding an uncontrolled pivot stage and retains compatibility with multilingual FLORES evaluation. Reviews of low-resource Indic parallel corpora likewise identify alignment quality, script variation, and domain representativeness as central data concerns (Raja and Vats, 2025). Table 1 summarises the resource.

### 3.2 Translator recruitment

We required native Chakma proficiency, literacy in the Chakma script, strong English proficiency, and prior translation or language-work experience. Four candidates completed a 20-sentence screening task. We assessed source fidelity, grammaticality, spelling consistency, and control of the script. We selected three contributors: two undergraduate

translators with approximately two years of experience and one senior Chakma language researcher with more than fifteen years of experience.

We conducted six virtual sessions. The first sessions introduced the purpose of evaluation data and the FLORES and OLDI requirements. Later sessions reviewed examples, named-entity handling, punctuation, numerals, and recurring spelling decisions. All three translators gave informed consent and were compensated for their translation work.

### 3.3 Translation protocol

We required direct human translation. Translators did not use, consult, or post-edit machine-translation or large-language-model output. This rule follows OLDI guidance for evaluation data, where model-generated text would contaminate the reference and compromise later evaluation (Open Language Data Initiative, 2026). The restriction applies to the dataset translations; our use of generative tools for manuscript editing is disclosed in the Acknowledgments.

Translators were instructed to preserve meaning, tone, register, units, and discourse function. Personal names were transliterated into Chakma script. Organizations were translated when a familiar Chakma form existed and transliterated otherwise. Translators could consult dictionaries and the shared glossary, but not machine-generated candidate translations. We used the Chakma Keyman keyboard for text entry.

Working documents used sequential labels written in Chakma digits to support discussion. These display labels are not release metadata. For the archival package, we discarded them and recovered alignment from the canonical English sequence, as described in Section 4.2.

### 3.4 Orthography and text representation

We use native Chakma Unicode characters and Bangladeshi spelling preferences established through contributor discussion. We retain conventional punctuation and permit non-Chakma characters where the source requires an acronym, symbol, scientific expression, or other conventional form. Consequently, script validation flags characters for review rather than deleting every character outside the Chakma block. This distinction proved to be productive: the audit in Section 4.2 separated 79 records whose Latin characters were justified acronyms from 19 records whose non-Chakma characters were genuine defects.

| **Check** | `dev` | `devtest` |
|---|---|---|
| Records | 997 | 1,012 |
| Aligned 1:1 to English | ✓ | ✓ |
| Identifiers 1-based, contiguous | ✓ | ✓ |
| Non-empty | ✓ | ✓ |
| Unicode NFC | ✓ | ✓ |
| No control characters | ✓ | ✓ |
| No duplicate targets | ✓ | ✓ |
| Metadata constant | ✓ | ✓ |
| Chakma-script characters | 98.6% | 98.5% |
| Characters mechanically repaired | 10 | 11 |
| Records revised by native reviewer | 1 | 0 |
| Records with open defects | 0 | 0 |

Table 2: Release audit of the 2,009-record package. Script percentages are computed over non-space characters.

## 4 Quality Assurance and Validation

### 4.1 Native-speaker review

The second author, Dinalo Chakma, a PhD student in English who is proficient in both Chakma and English, reviewed the dataset against its English source. The review covered meaning preservation, omission and addition, grammar, spelling, punctuation, terminology, named entities, numerals, units, and register. Items that failed a criterion were returned to the original translator with an edit request and reviewed again after revision.

We performed this review over the full target corpus rather than relying only on spot checks. However, one reviewer conducted the adjudication, and we did not compute a FLORES-style sampled quality score or inter-annotator agreement. We therefore treat the evidence as procedural and human-reviewed, not as a quantified estimate of error rate.

### 4.2 Release audit

We ran a record-level audit over the complete package; Table 2 reports the outcome. The audit was scripted and re-runnable.

Three findings are worth reporting. First, the working export numbered records from zero, whereas FLORES+ identifiers are 1-based. Because the working files preserved the canonical English order, we recovered the correct identifiers by renumbering positionally against the English source and re-verified the result record by record; the sample in Section 5 carries its recovered identifier.

Second, the character inventory located 27 non-Chakma Indic characters in 19 records. Of these, 21 were mechanical defects with unambiguous repairs: a Devanagari DANDA (U+0964) used as a sentence terminator in place of the Chakma DANDA (U+11141), a Bengali letter RA WITH MIDDLE DIAGONAL (U+09F0) substituted for Chakma LETTER RAA (U+11122), and a spurious Bengali NUKTA (U+09BC) attached to Chakma vowel signs. All three are keyboard artefacts rather than translation choices, and we corrected them. The remaining six characters formed a single untranslated Bengali word in one `dev` record. We referred it back to the native reviewer rather than substituting a form on our own authority; he supplied a Chakma rendering, which the released package carries. No record in the corpus now holds an unresolved defect.

Third, the Latin characters that script validation flagged were overwhelmingly justified: they occur in retained acronyms such as *AOL*, *RSPCA*, *COVID*, *ISIL*, and *pH*, consistent with the policy in Section 3.4. This is the concrete reason a script validator should flag rather than strip characters outside the target block.

The audit also confirmed that the independent plain-text and JSONL copies of the corpus are byte-identical after normalisation, which closes out the divergence that had accumulated across collaborative editing. We computed SHA-256 checksums for the final files so that any later divergence is detectable.

### 4.3 Experimental validation

We do not report an MT-system baseline. Existing Chakma systems are centred on transliteration or Bengali-script resources, and a score from such a pipeline would not by itself validate native-script references. We also avoid presenting informal outputs from commercial systems as a reproducible experiment. The first post-release experiment should evaluate a documented baseline in both directions with chrF and spBLEU, alongside a script-validity diagnostic and native-speaker error analysis.

## 5 Data Sample

Table 3 shows record 6 of the `dev` split with its recovered FLORES+ identifier. Each released record is a JSON object carrying the twelve FLORES+ fields: `id`, `iso_639_3`, `iso_15924`, `glottocode`, `variant`, `text`, `url`, `domain`, `topic`, `has_image`, `has_hyperlink`, and `last_updated`.

| | |
|---|---|
| `id` | 6 |
| **English** | 28-year-old Vidal had joined Barça three seasons ago, from Sevilla. |
| **Chakma** | ২৮ ৺ঁ৺ঃ ৺ঁ৺ঌ৲ঔ ঈ৹ঽ৲ ৬ ৺ঁ৺ঃ ৹৸৲ ঽঈ৲ঁ৺ঁ৲ঞ ৺ঃ৲ঽ৲৻ঞ৺ঃ ঈ৹ঌ৲ঁ৻ |
| `domain` | `wikinews` |
| `topic` | `sports` |

Table 3: A released `ccp_Cakm` record, shown with its recovered FLORES+ identifier.

## 6 Discussion

A native-script benchmark changes what can be measured. It allows researchers to test whether a model produces Chakma characters, handles Chakma orthography, and preserves content without relying on a Bengali-script intermediary. It also makes errors more interpretable to literate community members who should participate in future evaluation and correction.

Our audit experience suggests a more general point for script-first contributions. The defects that survived careful human review were not translation errors; they were encoding artefacts introduced by input tooling, and they were invisible to a reader because the substituted characters are visually close to their Chakma counterparts. A character-level inventory over the whole corpus, rather than a sampled proofread, is what surfaced them. We would encourage other OLDI contributors working in less-supported scripts to treat that inventory as a required release step.

The resource should not be interpreted as training data or as a complete representation of Chakma variation. FLORES+ is an evaluation benchmark with a limited number of topic-diverse sentences. Its value lies in consistent multilingual alignment and careful reference translation. Future work should add independently reviewed Seed data, document Indian and Myanmar varieties, and compare native-script evaluation with transliteration-mediated pipelines.

## 7 Conclusion

We have described the preparation of a human-translated, native-script Chakma extension to FLORES+. Three native speakers translated the English `dev` and `devtest` material under a workflow that prohibited machine-generated translation out-

put, and a native reviewer adjudicated the translations. We document the language variety, writing system, orthographic decisions, and quality checks, and we report a completed release audit in which the canonical 2,009-record package was aligned to the FLORES+ identifiers, normalised, corrected, and fixed by SHA-256 checksums. The data provide a reproducible basis for evaluating machine translation into and out of native-script Chakma.

## Limitations

Our quality evidence is based on one native reviewer and does not include inter-annotator agreement or a sampled numerical quality score. We have not evaluated a native-script MT baseline, so the paper does not establish the current performance of available systems. The contributors represent Bangladeshi Chakma, and the data should not be assumed to cover Indian or Myanmar orthographic preferences.

Our release audit is also mechanical in scope. It verifies alignment, encoding, identifiers, and script validity, and it caught defects that careful human proofreading had missed; it cannot establish that a sentence is semantically faithful or idiomatic. That judgement rests entirely on the native review described in Section 4.1, and therefore inherits the single-reviewer caveat above.

## Ethics Statement

The translators and reviewer are members of the language community represented by the resource. The three translators received information about the dataset's purpose, intended public release, and use for MT evaluation; they gave informed consent and were compensated for their work. We do not release private translator information with the sentences. The source material contains publicly available content and named entities inherited from FLORES+. The dataset contribution has been submitted to FLORES+ through OLDI under CC BY-SA 4.0. Because language technology can reproduce unequal access and representation, future work should retain community participation in decisions about spelling, correction, attribution, and downstream use.

## Acknowledgments

We thank the Chakma translators who contributed their linguistic knowledge and time, and the OLDI organizers for maintaining an open contribution pathway. Generative AI assistants were used for manuscript drafting, restructuring, citation checking, language editing, formatting, and for scripting the release audit described in Section 4.2. They were not used at any stage of the translation itself. We reviewed the final text and remain responsible for its claims, citations, translations, and release artifacts.

# Measuring the Cost of Variety Conflation in Multilingual MT Evaluation: Adding Mozambican Xichangana, Nyanja and Sena to FLORES+

**Felermino D. M. A. Ali[1], Delfina Lázaro Mateus[2], Manuel Valente Mangue[2]**

## Abstract

In this paper, we extend FLORES+ with Portuguese-source evaluation sets for three Mozambican Bantu varieties: Xichangana, Mozambican Nyanja, and Sena. We compare Xichangana with the existing Tsonga reference and Mozambican Nyanja with Chichewa, and evaluate NLLB-200, Google Translate, GPT, and a variant-aware NLLB model. Holding system output fixed reveals substantial reference sensitivity. On *devtest*, changing only the reference from Tsonga to Xichangana reduces spBLEU by 13.10 points for NLLB-200 and 15.30 for Google. On matched Nyanja subsets, replacing Chichewa with Mozambican Nyanja produces smaller but consistent reductions of 3.03 and 6.10 spBLEU, respectively. Variant-aware fine-tuning reverses this pattern on the intended targets: relative to NLLB-200, it improves Xichangana by 7.04 spBLEU and Mozambican Nyanja by 5.33 on *devtest*, while losing performance on the sibling references. GPT is competitive on Tsonga and Chichewa but substantially weaker on the Mozambican varieties. For Sena, the finetuned model reaches 12.64 spBLEU and 36.21 chrF++ on *devtest*. These findings motivate variety-aware language identifiers, references, and reporting for cross-border languages or language dialects/variants. The data is publicly available on Hugging Face at https://huggingface.co/datasets/MOZNLP/FLORES_MOZ.

## 1 Introduction

Bantu languages are spoken across wide, contiguous regions of Africa, and colonial-era borders rarely coincide with linguistic ones. A single language is frequently spoken in several countries, developing varieties that differ in lexicon, orthography and, above all, in the languages they borrow from. These differences determine whether a speaker can actually use a translation system, and whether an evaluation score is a meaningful estimate of that usability.

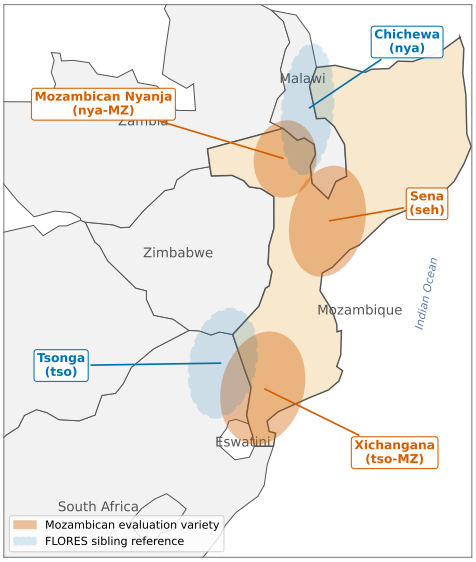

Figure 1: Locations of the evaluated Mozambican varieties and their FLORES sibling references.

Lexical borrowing is the clearest illustration. Malawian Chichewa and the Nyanja of Tete and Niassa in Mozambique share the code nya, but the former borrows overwhelmingly from English and the latter borrow from both Portuguese and English. A speaker in Tete reading *matilikula*, *munisipiyo* or *dhowutori* encounters forms that are at best unfamiliar, where *regisita*, *tawoni chipi* and *dokota* would be expected. The same asymmetry holds between South African Tsonga and Mozambican Xichangana, both tagged tso. Because FLORES+ contains only the South African and Malawian varieties, systems evaluated on those sets are credited for output a Mozambican user would not accept — the argument recently made for Sudanese Arabic by Samil and Adelani (2026).

We contribute (i) FLORES+ dev and devtest sets for **Xichangana** and **Mozambican Nyanja**, translated from Portuguese by native speakers of those varieties; (ii) the first FLORES+ set for **Sena** (seh_Latn), a two-million-speaker language of the

*Proceedings of the Eleventh Conference on Machine Translation*, pages 2482–2492
October 28-29, 2026 ©2026 Association for Computational Linguistics

Zambezi valley almost absent from public corpora; (iii) a controlled comparison showing the existing `tso_Latn` and `nya_Latn` sets are not valid proxies for the Mozambican varieties; and (iv) a fine-tuning experiment showing the gap is a variety effect and is cheaply addressable. With Emakhuwa (Ali et al., 2024), these sets bring Mozambican coverage in FLORES+ from one language to four.

## 2 Related Work

FLORES progressed from two low-resource language pairs (Guzmán et al., 2019) to 101 languages (Goyal et al., 2022) and subsequently 200 languages (NLLB Team, 2022), while establishing a multi-stage translation–review–adjudication protocol. FLORES+ is now maintained through community governance under the Open Language Data Initiative (Open Language Data Initiative, 2024).

Recent contributions have expanded coverage, introduced language varieties, and audited existing references. Kalejaiye et al. (2025) add four minority Nigerian languages and demonstrate their poor coverage by current models. Ali et al. (2024) contribute Emakhuwa, previously the only Mozambican language in FLORES+, using Portuguese as the source and documenting orthographic instability. We follow a similar protocol while adding Sena and two Mozambican varieties.

Our variety-focused contribution is closest to the Sudanese Arabic extension of Samil and Adelani (2026). However, because FLORES+ already contains sibling references for Tsonga and Chichewa, we can directly measure how evaluation changes when the reference represents the intended Mozambican variety and whether targeted fine-tuning reduces the mismatch.

## 3 The Three Languages

Portuguese is the official language of Mozambique but the first language of a minority; most of the population speaks one of roughly twenty Bantu languages natively. **Xichangana** (`tso`) is spoken by approximately 1.8M people in Gaza, Maputo and Inhambane, and belongs to the Tswa–Ronga group with South African Xitsonga (see Figure 1), from which it diverges in borrowing source, orthographic convention, and administrative register. **Nyanja** (`nya`) is spoken by approximately 1.2M people in Tete and Niassa, continuous with Chichewa in Malawi and Chinyanja in Zambia. **Sena** (`seh`) is spoken by approximately 2M people along the lower Zambezi; unlike the others it has its own code and no FLORES+ entry at all, and it is the least standardised of the three in writing, with religious translation the dominant written genre.

## 4 Approach

We follow the FLORES+ contribution guidelines (Open Language Data Initiative, 2024) so that the resulting sets are directly comparable to existing entries.

### 4.1 Source data

We translate the *dev* (997 sentences) and *devtest* (1,012 sentences) splits of FLORES+ from Portuguese (*pt*) into each of the three target varieties. Portuguese was chosen as source rather than English for two reasons. Practically, our translators are proficient in Portuguese and their native language but not uniformly in English; Portuguese is the language of schooling and administration in Mozambique and thus the language in which bilingual professional translators for these varieties actually exist. Following Ali et al. (2024), who translated Emakhuwa from Portuguese for the same reason, we treat translator proficiency as a stronger determinant of reference quality than source-language canonicity.

Because FLORES+ is multi-parallel, the Portuguese side is itself a professional translation of the same English source used by every other entry, so our sets remain sentence-aligned with `tso_Latn` and `nya_Latn`. This is what makes the controlled comparison in Section 7 possible: any score difference is attributable to the target variety alone. Pivoting risks propagating Portuguese-side artefacts, which we revisit in Limitations. Translators saw full document context and worked exclusively from the Portuguese side.

### 4.2 Target variety and translators

For each language, we collaborated with two language experts, all of whom were trained linguists by the Bantu Linguistics Department at Eduardo Mondlane University. Translators had to be native speakers of the targeted variety, resident where it is spoken, professionally competent in Portuguese, and experienced in Portuguese-to-target translation. All contributors were paid at or above local professional rates.

### 4.3 Translation platform

We developed a custom web-based computer-assisted translation (CAT)[1] platform to support translation, quality control, and review (see Figure 2). The platform was mobile-friendly and allowed translators to work offline, with completed work and local changes synchronized automatically when an Internet connection became available. This was particularly important for participants working in settings with intermittent connectivity. Translators were assigned individual segments and given access to bilingual Portuguese–target-language dictionaries. For each source segment, the CAT platform automatically identified and highlighted potentially relevant glossary entries, helping translators select appropriate terminology and maintain consistency. The platform also performed automatic quality-assurance checks and displayed warnings for potential misspellings, mismatched punctuation or numbers, possible untranslated text, disproportionate source–target lengths, and inconsistent capitalization. Translators could inspect each warning, revise the translation where necessary, or confirm that the flagged difference was intentional. Completed segments were assigned to reviewers for independent verification. Reviewers could correct an issue directly or return the segment to the translator with feedback. Returned segments remained open until the translator submitted a revision and the reviewer approved it. A segment was considered complete only after this review cycle had been successfully concluded.

## 5 Reference-Variety Analysis

Before evaluating MT systems, we compare each Mozambican reference with the corresponding FLORES sibling variety. The analysis covers all 2,009 aligned segments: 997 from *dev* and 1,012 from *devtest*. Because the references were translated independently, dissimilarity may reflect variety, orthographic convention, lexical choice, paraphrase, or data quality.

### 5.1 Mozambican Nyanja and Chichewa

Mozambican Nyanja and Chichewa are related but far from textually interchangeable. Mean character similarity is 54.39%, median character similarity is 54.98%, mean token-set overlap is 14.33%, and vocabulary Jaccard overlap is 17.37%. No sentence pair is an exact match. The corpora remain broadly balanced in length with a mean sentence-level token-length ratio of 1.05. No Mozambican segment contains fewer than half as many tokens as its Chichewa counterpart. The observed divergence is therefore not explained by systematic truncation.

| Reference pair | Segments | Char. sim. | Token overlap | Length ratio | $< 0.5$ length |
|---|---|---|---|---|---|
| Nyanja MZ / Chichewa | 2,008 | 54.39 | 14.33 | 1.05 | 0 |
| Xichangana / Tsonga | 2,008 | 48.97 | 9.47 | 0.80 | 40 |

Table 1: Reference-pair diagnostics. The Nyanja MZ/Chichewa row uses only trusted assignee-B segments; the Xichangana/Tsonga row uses the complete splits. Similarity and overlap are percentages; length ratio is the sentence-level ratio of Mozambican-reference tokens to sibling-reference tokens. The final column counts Mozambican segments with fewer than half as many tokens as the sibling reference.

The strongest recurring distinction is the treatment of *c* and *ch*. A bare *c* not followed by *h* occurs 1,610 times in the Mozambican reference but 367 times in Chichewa; *ch* occurs 281 and 1,849 times, respectively. The most frequent aligned orthographic correspondences include *ca*/*cha* and *nchito*/*ntchito*, each observed 12 times, followed by *awili*/*awiri* and *nzinda*/*mzinda*. Additional examples include *cifukwa*/*chifukwa*, *caka*/*chaka*, and *mwacitsanzo*/*mwachitsanzo*.

The difference is not reducible to spelling. Recurrent substitutions such as *zimene*/*zomwe*, *amene*/*omwe*, and *monga*/*ngati* indicate differences in lexical and grammatical selection. Names and borrowed forms also vary, as illustrated by *afilika*/*africa*.

### 5.2 Xichangana and Tsonga

Xichangana and Tsonga show a stronger separation. Mean character similarity is 48.94%, median character similarity is 49.47%, mean token-set overlap is 9.47%, and vocabulary Jaccard overlap is 9.87%. Again, no sentence pair is an exact match. The Xichangana reference contains 40,893 tokens, compared with 52,443 in Tsonga, yielding a mean token-length ratio of 0.80.

The most prominent orthographic distinction is nearly complementary: *sv* occurs 3,681 times in Xichangana and only 5 times in Tsonga, whereas *sw* occurs 42 and 4,191 times, respectively. Examples include *sva*/*swa*, *lesvaku*/*leswaku*, *lesvi*/*leswi*, and *nasvona*/*naswona*. Other recurring correspondences include *la*/*ra*, *doropa*/*doroba*, *ndzhaku*/*endzhaku*, *nkama*/*nkarhi*, and *mpimu*/*mpimo*. Function words and agreement

[1] CATfrica: https://mozcat.vercel.app

forms also vary, including alternations among *na*/*ni*, *ka*/*eka*/*ku*, and several noun-class agreement markers.

## 6 Experimental Setup

We evaluate three systems for Portuguese-to-target translation. The **NLLB-200** baseline is `facebook/nllb-200-distilled-600M`. **Google** denotes the Google Cloud Translation general NMT model[2], with Portuguese specified as the source and `ny` or `ts` as the target. Google provides no separate identifiers for the Mozambican varieties, so each Google output is scored against both the sibling and Mozambican reference. No Google Sena output was collected.

**GPT**[3] denotes openAI API endpoints. A zero-shot translation prompt (see Appendix B) specified Portuguese as the source and separately described standard Chichewa, Mozambican Nyanja, standard Xitsonga/Tsonga, Xichangana, and Sena as the five targets. Each response was constrained to structured JSON and validated for complete segment and target coverage. GPT therefore generates a distinct output for every target variety, including Sena, rather than sharing one hypothesis across each sibling–Mozambican pair.

**NLLB+finetuned** starts from the same distilled 600M NLLB checkpoint. We retain the standard `nya_Latn`, `tso_Latn`, and `seh_Latn` tokens for Chichewa, Tsonga, and Sena, and introduce `nya_MZ_Latn` and `tso_MZ_Latn` for Mozambican Nyanja and Xichangana. The two new token embeddings are initialized when the tokenizer vocabulary is extended and learned during fine-tuning. We also prepend an explicit target marker such as `<2nya-MZ>` or `<2tso-MZ>` to each source sentence. The fine-tuned model can therefore generate different hypotheses for the sibling and Mozambican targets.

### 6.1 Fine-tuning data

Table 2 reports the amount of direct Portuguese data and the total number of eligible rows involving each target variety, together with the corpus or domain coverage represented in the training data.

### 6.2 Optimization

Training uses four NVIDIA RTX A6000 GPUs with DistributedDataParallel.

The model is trained for 15,000 optimizer steps with maximum sequence length 200. We use Adafactor with learning rate $1 \times 10^{-4}$, weight decay $1 \times 10^{-3}$, clip threshold 1.0, and a constant schedule after 250 warmup steps. Random seeds are initialized from 222 with a rank-specific offset. Model, tokenizer, optimizer, and scheduler states are saved every 500 steps.

### 6.3 Evaluation

The aligned evaluation data contain 997 *dev* and 1,012 *devtest* sentences per direction. We translate the complete Portuguese source into `nya`, `nya-MZ`, `tso`, `tso-MZ`, and, where supported, `seh`.

For the off-the-shelf NLLB baseline, the sibling and Mozambican labels map to the same standard NLLB tokens, so its hypotheses are identical within each pair and only the reference changes. Google similarly produces one `ny` output and one `ts` output per Portuguese sentence. NLLB+finetuned instead uses the distinct regional tokens described above.

We recompute all scores from the saved hypotheses using SacreBLEU 2.6.0. spBLEU uses the `flores200` tokenizer[4]; chrF++ uses character order 6 and word order 2[5]. Results are reported separately for *dev* and *devtest*.

## 7 Results and Discussion

Table 3 reports spBLEU and chrF++ on the Portuguese-source evaluation data. The Tsonga, Xichangana, Chichewa, and Sena columns use the complete splits: 997 *dev* and 1,012 *devtest* sentences.

On the complete sibling-language sets, Google is the strongest system. On *devtest*, it obtains 22.42 spBLEU / 47.89 chrF++ for Tsonga and 18.16 / 45.65 for Chichewa. GPT is close on Tsonga at 21.39 / 47.68 and reaches 15.14 / 44.75 on Chichewa, while NLLB-200 obtains 18.91 / 44.82 and 14.70 / 42.12, respectively. The ranking changes on the Mozambican targets. NLLB+finetuned is strongest for Xichangana at 12.85 / 38.95 and for Mozambican Nyanja at 17.89 / 44.98. It also provides the baseline Sena result on *devtest*, reaching 12.64 / 36.21.

| Target variety | Corpus/domain coverage | Train (pt↔XX) |
|---|---|---|
| Chichewa (nya) | Jehovah Witness | 56,902 |
| Nyanja (nya-MZ) | Portuguese news: culture, sport, economy | 8,164 |
| Tsonga (tso) | Jehovah Witness | 54,678 |
| Xichangana (tso-MZ) | Jehovah Witness; UDHR; Legal; Portuguese news: culture, sport, economy | 43,662 |
| Sena (seh) | Jehovah Witness; Portuguese news: culture, sport, economy | 64,532 |

Table 2: Data coverage. Counts are directed sentence-pair rows for Portuguese–variety translation directions.

| System | Dev | | | | | Devtest | | | | |
|---|---|---|---|---|---|---|---|---|---|---|
| | pt→tso | pt→tso-MZ | pt→nya | pt→nya-MZ | pt→seh | pt→tso | pt→tso-MZ | pt→nya | pt→nya-MZ | pt→seh |
| NLLB-200 | 20.67 / 46.12 | 5.15 / 30.74 | 15.21 / 42.60 | 10.41 / 39.08 | – | 18.91 / 44.82 | 5.81 / 32.98 | 14.70 / 42.12 | 12.56 / 39.70 | – |
| Google | **23.94 / 48.84** | 5.01 / 31.57 | **18.08 / 45.81** | 10.11 / 39.54 | – | **22.42 / 47.89** | 7.11 / 36.03 | **18.16 / 45.65** | 12.37 / 39.96 | – |
| GPT | 22.17 / 48.30 | 7.05 / 33.77 | 15.07 / 44.84 | 7.12 / 33.21 | 9.26 / 34.46 | 21.39 / 47.68 | 7.46 / 34.55 | 15.14 / 44.75 | 8.71 / 33.52 | 9.92 / 35.30 |
| NLLB+finetuned | 17.42 / 42.30 | **10.34 / 36.45** | 10.76 / 36.81 | **15.87 / 44.13** | 10.56 / 34.07 | 17.50 / 42.05 | **12.85 / 38.95** | 11.06 / 37.35 | **17.89 / 44.98** | **12.64 / 36.21** |

Table 3: Portuguese-to-XX results on dev and devtest. Each cell reports spBLEU / chrF++.

### 7.1 Sibling references substantially overestimate Xichangana quality

Xichangana exhibits a large and consistent mismatch with the existing FLORES Tsonga reference. On *devtest*, the same NLLB-200 hypothesis scores 18.91 / 44.82 against Tsonga but only 5.81 / 32.98 against Xichangana, reductions of 13.10 spBLEU and 11.84 chrF++. Google shows the same pattern, falling from 22.42 / 47.89 to 7.11 / 36.03, with reductions of 15.30 spBLEU and 11.87 chrF++.

The mismatch is larger on *dev*. NLLB-200 falls from 20.67 / 46.12 on Tsonga to 5.15 / 30.74 on Xichangana, while Google falls from 23.94 / 48.84 to 5.01 / 31.57. The corresponding differences are 15.53 and 18.93 spBLEU and 15.38 and 17.27 chrF++, respectively. Because these comparisons change only the reference, the gaps cannot be attributed to decoding, prompting, or model selection. They demonstrate that performance measured on tso_Latn is not a reliable proxy for performance on Mozambican Xichangana.

This finding is consistent with the reference analysis in Section 5. Xichangana and Tsonga exhibit low token overlap, systematic orthographic differences such as *sv* versus *sw*, and substantial lexical and grammatical divergence. A system can consequently receive a strong Tsonga score while failing to produce forms appropriate for Xichangana.

### 7.2 Mozambican Nyanja evaluation

Google obtains 10.11 / 39.54 on *dev* and 12.37 / 39.96 on *devtest*, close to NLLB-200 at 10.41 / 39.08 and 12.56 / 39.70. GPT is weaker, reaching 7.12 / 33.21 and 8.71 / 33.52.

In *devtest*, NLLB-200 decreases from 15.59 / 42.80 in Chichewa to 12.56 / 39.70 in Mozambican Nyanja, resulting in reductions of 3.03 spBLEU and 3.10 chrF++. Google decreases from 18.47 / 45.88 to 12.37 / 39.96, reductions of 6.10 spBLEU and 5.92 chrF++. On *dev*, NLLB-200 decreases from 14.38 / 42.61 to 10.41 / 39.08, while Google decreases from 17.19 / 45.62 to 10.11 / 39.54.

The matched data therefore reveal a systematic Chichewa–Mozambican Nyanja gap, but one smaller than the Xichangana–Tsonga gap.

### 7.3 Variant-aware fine-tuning

Variant-aware fine-tuning produces substantial gains on both Mozambican targets. On the complete Xichangana *devtest* set, NLLB+finetuned improves over NLLB-200 from 5.81 / 32.98 to 12.85 / 38.95, gains of 7.04 spBLEU and 5.97 chrF++. It also exceeds Google at 7.11 / 36.03 and GPT at 7.46 / 34.55. On *dev*, it reaches 10.34 / 36.45, compared with 5.15 / 30.74 for NLLB-200, 5.01 / 31.57 for Google, and 7.05 / 33.77 for GPT.

On the Mozambican Nyanja subsets, NLLB+finetuned improves over NLLB-200 from 12.56 / 39.70 to 17.89 / 44.98 on *devtest*, gains of 5.33 spBLEU and 5.28 chrF++. It exceeds Google by 5.52 spBLEU and 5.02 chrF++, and GPT by 9.18 spBLEU and 11.46 chrF++. On *dev*, it obtains 15.87 / 44.13, compared with 10.41 / 39.08 for NLLB-200, 10.11 / 39.54 for Google, and 7.12 / 33.21 for GPT. The results therefore show a clear fine-tuning advantage on both splits.

The Mozambican gains coincide with lower scores on the complete sibling sets. On *devtest*, fine-tuning changes Tsonga from 18.91 / 44.82 to 17.50 / 42.05 and Chichewa from 14.70 / 42.12 to 11.06 / 37.35. The same trade-off appears on *dev*, where Tsonga falls from 20.67 / 46.12 to 17.42 /

42.30 and Chichewa from 15.21 / 42.60 to 10.76 / 36.81. This pattern is consistent with the model learning variety-specific lexical and orthographic choices rather than receiving a uniform improvement across related targets. Because the adapted system generates separate hypotheses for each target identifier, the result demonstrates controllable specialization rather than a reference substitution effect.

### 7.4 Sena, and broader implications

GPT performs competitively on the established sibling languages but is much weaker on the Mozambican targets. On *devtest*, its Tsonga result (21.39 / 47.68) approaches Google, and its Chichewa result (15.14 / 44.75) exceeds NLLB-200 in chrF++. However, GPT reaches only 7.46 / 34.55 on Xichangana and 8.71 / 33.52 on the Mozambican Nyanja subset. This contrast suggests that specifying a variety in a zero-shot prompt does not provide sufficient control for these underrepresented targets.

For Sena, NLLB+finetuned obtains 10.56 / 34.07 on *dev* and 12.64 / 36.21 on *devtest*, compared with 9.26 / 34.46 and 9.92 / 35.30 for GPT. Finetuning yields higher Sena spBLEU on both splits and higher chrF++ on *devtest*, although GPT is marginally higher in chrF++ on *dev*. Since no NLLB-200 or Google Sena output is available, this comparison covers the two systems with complete Sena predictions but does not establish improvement over the original NLLB baseline.

Overall, the results support following conclusions: (1) sibling references can substantially overestimate translation quality for Mozambican varieties, especially Xichangana. (2) supervised variety-aware fine-tuning is substantially more effective than generic decoding or zero-shot target naming on the Mozambican targets.

We therefore report sibling and Mozambican references separately. Automatic metrics establish reference sensitivity and the value of target-specific adaptation, but they cannot determine whether an output is acceptable to the intended speakers.

## 8 Conclusion

We contribute Portuguese-source FLORES+ evaluation sets for Xichangana, Mozambican Nyanja, and Sena. The results show that an existing reference in a closely related national variety is not necessarily an adequate proxy for the community being evaluated. Under identical hypotheses, replacing the Tsonga reference with Xichangana reduces *devtest* spBLEU by 13.10 points for NLLB-200 and 15.30 for Google. The corresponding Chichewa–Mozambican Nyanja reductions on matched evaluation subsets are smaller but remain systematic, at 3.03 and 6.10 spBLEU. These differences are consistent with the orthographic, lexical, and grammatical patterns observed in the reference analysis and demonstrate that aggregate language codes can conceal meaningful variety-level differences.

Variant-aware NLLB fine-tuning substantially improves performance on the intended Mozambican targets. On *devtest*, it gains 7.04 spBLEU and 5.97 chrF++ over NLLB-200 for Xichangana, and 5.33 spBLEU and 5.28 chrF++ for Mozambican Nyanja. These gains coincide with lower scores on Tsonga and Chichewa, indicating target-specific specialization rather than a uniform model improvement. GPT remains competitive on the established sibling languages but performs markedly worse on the Mozambican varieties, while the adapted model establishes a reproducible Sena result of 12.64 spBLEU / 36.21 chrF++ on *devtest*. We therefore recommend variety-specific references, target identifiers, and disaggregated reporting for cross-border Bantu languages so that benchmark scores correspond to the communities that MT systems are intended to serve.

## 9 Limitations

Our references were produced from Portuguese rather than the original English source. Although the Portuguese side is itself a professional translation and the sets remain sentence-aligned with all other entries, pivoting risks propagating Portuguese-specific phrasing and existing errors into our targets; an English-sourced control subset is left to future work.

## 10 Ethical Considerations

All translators were professionals compensated at or above prevailing local rates, gave informed consent for release.

## Acknowledgements

| Language | Reference sentence |
|---|---|
| **Example 1:** "Photons are even smaller than the stuff that makes up atoms!" | |
| **Portuguese source** | Os fótons são ainda menores do que as partículas que formam os átomos! |
| Mozambican Nyanja | Fotoni tili **tocepa** kwambiri kuposera mbali **zimene** zimapanga matomo! |
| Chichewa | Ma photon ndi **ocheperapo** kuposa zinthu **zomwe** zimapanga ma atom. |
| Xichangana | **Mafotoni** mahali matsongo kutlula **sviphemu lesvi sviwumbaka** ma-atomo! |
| Tsonga | **Tifothoni** i titsongo eka **swilo leswi** endlaka tiathomu! |
| **Example 2:** "It's worth half an hour to stroll about the intriguing village." | |
| **Portuguese source** | Vale a pena caminhar meia hora pela intrigante vila. |
| Mozambican Nyanja | Ndi kosangalatsa kwambiri kuyenda hafu **awala** muvila **yocititsa** kasoyo. |
| Chichewa | Ndikofunikila theka la **ola** kuuyendela mudzi **wopatsa chidwiwo**. |
| Xichangana | **Svayampsa** kufambafamba hafu ya wara hi mugaga **wohlamalisa**. |
| Tsonga | **Swi fanele** awara na hafu ku famba famba eka tiko xikaya **leri ro tsakisa**. |

Table 4: Aligned examples showing the English reference, Portuguese source, Mozambican varieties, and their FLORES sibling references. Boldface highlights selected orthographic and lexical contrasts;

## A Reference-Variety Examples

Table 4 presents two aligned examples from the evaluation data. For each example, it shows the English reference, the Portuguese source used for translation, the Mozambican Nyanja and Chichewa references, and the Xichangana and Tsonga references. Selected forms are highlighted to make recurring orthographic and lexical contrasts easier to identify.

## B GPT translation prompts

The following system and user prompts were used for GPT translation. In the user prompt, <INPUTS_JSON> represents the JSON serialization of a batch of Portuguese source segments, each containing its split, segment identifier, and source text. Long lines below are wrapped for typesetting; the wrapped portions are joined with spaces in the actual prompt.

**System prompt.**

```
You are a professional African-language translator. Translate faithfully
from Portuguese. Preserve meaning, names, numbers, punctuation, and
sentence boundaries. Produce natural target-language text, not
explanations. Keep regional varieties distinct. Return valid JSON only.
```

**User prompt.**

```
Translate every input into all five targets.

Target definitions:
- "nya": standard Chichewa as used in Malawi; use standard Malawian
  Chichewa vocabulary and orthography
- "nya-MZ": Mozambican Nyanja; use vocabulary and orthographic
  conventions appropriate for Nyanja speakers in Mozambique
- "tso": standard Xitsonga/Tsonga as used in South Africa; use standard
  South African Xitsonga vocabulary and orthography
- "tso-MZ": Xichangana as used in Mozambique; use Mozambican vocabulary
  and orthography rather than South African Xitsonga
- "seh": Sena as used in Mozambique; use natural Sena vocabulary and
  orthography

Return exactly this JSON shape:
{"translations":[{"split":"dev","segment_id":1,"nya":"...",
"nya-MZ":"...","tso":"...","tso-MZ":"...","seh":"..."}]}

Return one object per input, in the same order. Do not omit, merge, or add
segments. Do not include Markdown.

Inputs:
<INPUTS_JSON>
```

Each input object in <INPUTS_JSON> has the following form:

```
{"split":"dev","segment_id":1,"portuguese":"..."}
```

## C The CATfrica Translation Tool

CATfrica is a web-based Computer-Assisted Translation (CAT) tool built to support translation work for low-resource languages. It covers the whole cycle of a translation job: project preparation, task distribution, translation, quality control, revision, delivery and payment.

**Roles and workflow.** Five roles are supported: administrator, project manager, translator, revisor and annotator. A project passes through the stages *draft*, *in progress*, *under review*, *approved* and *paid*, and each sentence carries its own status, so different parts of a document can be assigned to different translators and progress can be monitored precisely. Large documents can be split automatically into sub-projects translated in parallel.

**Project preparation.** Managers upload one or more text files and choose sentence- or paragraph-level segmentation. The original layout is preserved, so the translated document can be rebuilt with the same paragraphs, spacing and punctuation. Translators may split or merge segments when the automatic division is inadequate.

**Translation editor.** Source and target are shown side by side. For every sentence the tool automatically offers previous translations of identical or similar sentences from the project's translation memories, terminology suggestions from its glossaries, and machine translation. It further provides search and replace, concordance search, per-sentence comments, version history and automatic saving. If the connection is lost, work continues offline and is uploaded automatically when connectivity returns.

**Quality assistance.** A spell checker flags words absent from the target-language word list and proposes corrections. Automatic checks warn about unusual length differences, unbalanced brackets or quotes, missing or altered numbers, inconsistent final punctuation, double spaces, wrong apostrophes and stray line breaks. Both components were adapted to the orthographic conventions of African languages; word-internal apostrophes, for instance, are not treated as errors.

**Memories, glossaries and annotation.** Translation memories and glossaries can be created in the tool or imported from spreadsheets and attached to any project. Current version support biligual dictionary for Portuges— Nyanja, Xichangana, Emakhuwa and Sena, and English — Swahili, Xhosa. Matching is tolerant: suggestions appear for merely similar sentences, and terms are recognised in inflected forms. Terms may be labelled as ordinary terms, loanwords, code-switching or bilingual expressions. An alignment function additionally lets annotators link a source expression to its counterpart in the translation, so that annotated bilingual lexicons and code-switching resources are produced alongside the translation itself.

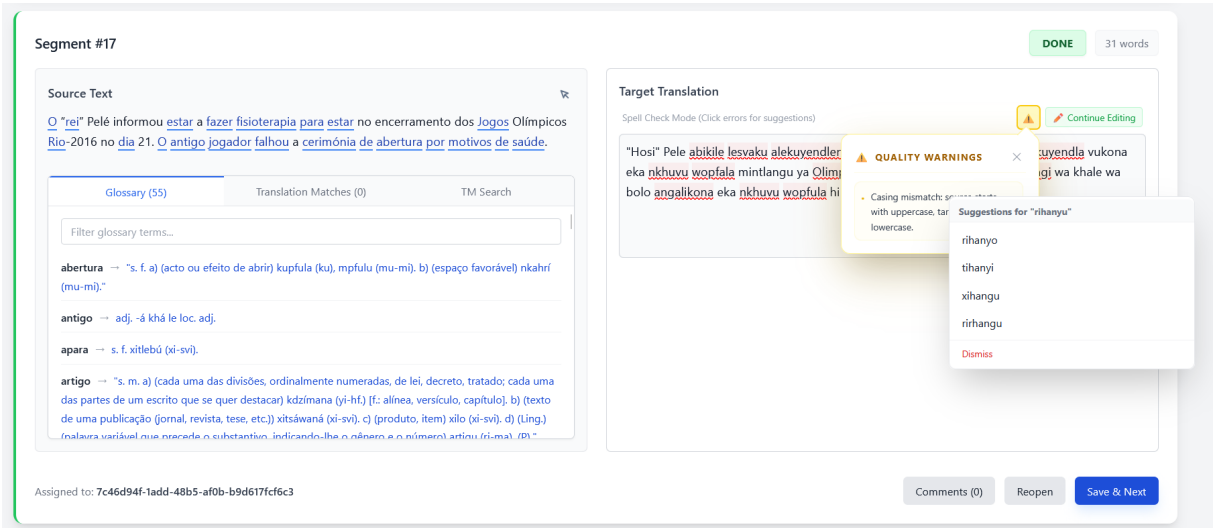

Figure 2: Screenshot of the custom web-based computer-assisted translation (CAT) platform to support translation.

**Machine translation.** Each project can be linked to an engine adapted to its language pair. Suggestions are reused when the same sentence recurs, and models can alternatively be downloaded and run on the translator's own computer, which matters where connectivity is limited.

**Revision and delivery.** Finished translations are reviewed sentence by sentence by a revisor, who cannot be the original translator; rejected sentences return to the translator for correction. Approved projects are exported as formatted text, as an archive with one file per uploaded document, as structured data including the alignments, or in a standard translation-memory format for reuse as a resource or as training data.

**Payment and administration.** Managers set a per-word rate; earnings are computed from completed words and settled through invoices. Users purchase word credits via PayPal or M-Pesa, with all transactions recorded in a transparent statement. An administration area manages accounts and invitations, supported languages, translation engines and backups.

## Abstract

Benchmarks do more than report scores: they provide a shared basis for evaluating methods, comparing systems, and measuring progress. As language technologies are now widely integrated into everyday life, efforts should also be made to include minority languages in the resources that underpin language-technology development. If languages are absent from relevant benchmarks, they remain harder to evaluate, compare, and incorporate into future language technologies. Expanding benchmark coverage is therefore essential for ensuring fair evaluation, increasing visibility, and enabling continued development of language technologies for these communities. To support MT development for Ladin, we contribute a Ladin extension of BOUQuET to the WMT 2026 OLDI shared task, covering the Val Badia and Gherdëina varieties. We present a systematic reference-creation workflow combining human translation, expert revision, cross-variant alignment, and blind ranking to produce high-quality references. The dataset is released[1] under the CC BY-SA 4.0 license.

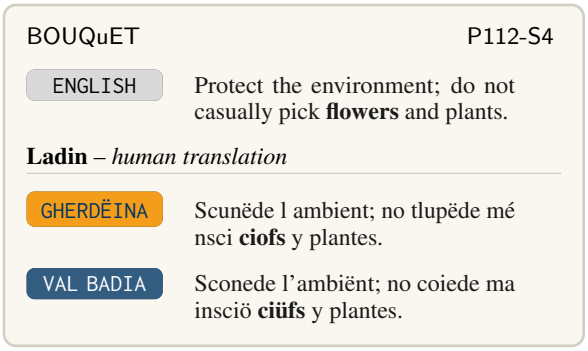

Figure 1: Our main contribution: extending the BOUQuET benchmark to Ladin with reference translations in the two written varieties Val Badia and Gherdëina. The figure shows a sentence-level example from the resulting parallel dataset taken from paragraph P112.

## 1 Introduction

Benchmarks are one of the main coordination mechanisms in NLP. They make progress measurable, allow systems to be compared under shared conditions, and provide a common target around which data collection, modelling, and error analysis can accumulate. This role is especially important in machine translation (MT), where model quality cannot be meaningfully discussed without reference to a particular language pair, domain, granularity, and evaluation protocol.

The title of this paper follows the BOUQuET metaphor quite literally: a useful multilingual benchmark becomes richer when more linguistic varieties are represented in it. This is what we aim to do with our contribution, illustrated in Figure 1.

For MT, the long-term usefulness of a benchmark depends on the interaction of reference quality, difficulty, language and linguistic coverage, and alignment with intended use. BOUQuET was designed around these considerations by combining multi-way translation and paragraph-level structure with texts drawn from a diverse range of domains and registers, including, for example, social media posts, conversational texts, and how-to content (Andrews et al., 2025). For languages with limited digital resources, adding carefully produced references to such a benchmark therefore creates an open reference point for future system development, error analysis, and community discussion.

For Ladin, computational resources exist currently only in limited quantities. Ensuring that such resources exist therefore requires more than model development: it requires community involvement. The Open Language Data Initiative (OLDI)[2] shared task[3] supports this idea by coordi-

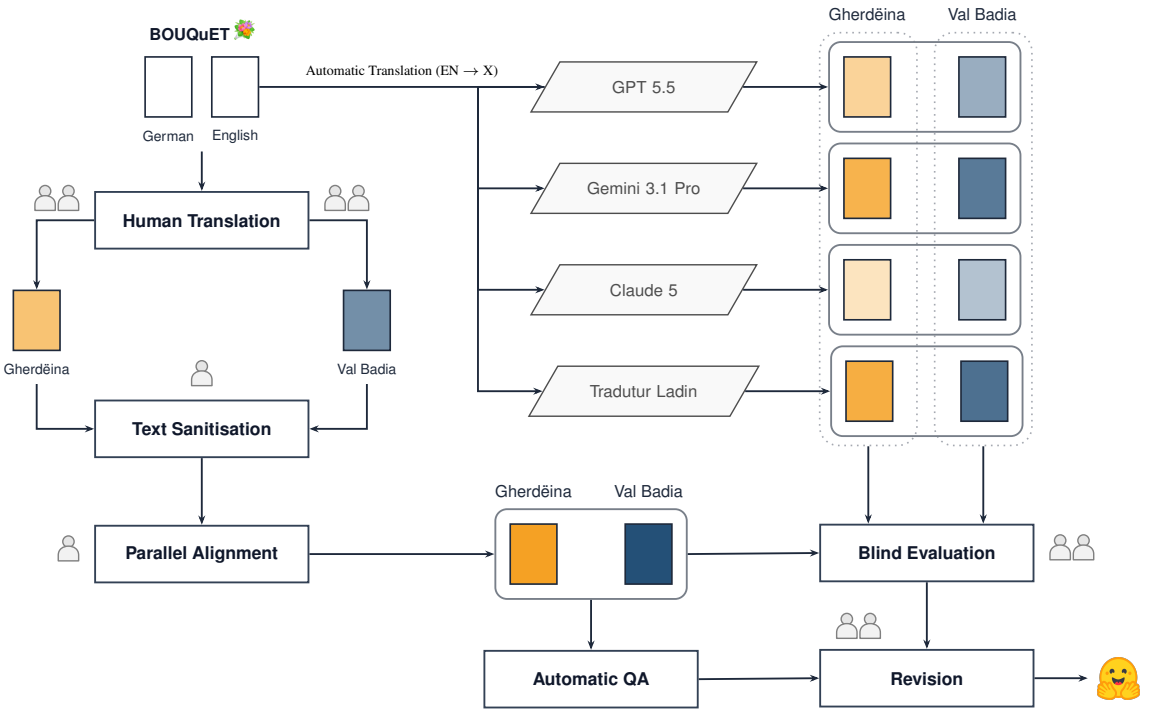

Figure 2: Workflow of the dataset creation process. BOUQuET source texts were manually translated into Val Badia and Gherdëina, sanitized, and parallel-aligned across varieties. The aligned outputs were then blind-evaluated against automatic translations, and the resulting evaluator feedback was used in a final revision step to refine the parallel references before release.

nating open additions to foundational multilingual datasets. BOUQuET was originally introduced with the idea of building a universal translation quality evaluation (Andrews et al., 2025). Its subsequent extension to additional languages and to quality-estimation data was described in the Omnilingual MT work on translation for 1,600 languages (Omnilingual MT Team et al., 2026).

Ladin is still not adequately supported by general-purpose LLMs and MT systems, and the problem is not only low resource availability. The ISO 639-3 code `lld` is necessary for identifying Ladin as a language, but it is not sufficient for representing the written standards that speakers actually use. Outputs that mix spelling, morphology, or terminology of the different varieties are not acceptable benchmark references (even if they may appear plausibly Ladin to a system).

Here, we present a BOUQuET extension for two Ladin varieties: Val Badia and Gherdëina. (IETF BCP 47 language tags `lld_valbadia` and `lld_gherd`, respectively) and provide a documented workflow for translation, revision, quality assurance, and benchmark validation. Using explicit BCP 47-style tags for the standardized written forms is therefore a practical step toward making this distinction visible to data infrastructure and model developers.Table 1 shows the concrete output of this work: BOUQuET text with English and German references and two variant-specific Ladin translations. The structure of BOUQuET makes the resource usable for both sentence-level and paragraph-level evaluation.

Adding two (of the main five written) Ladin varieties[4] to it makes also visible a real sociolinguistic and orthographic distinction that would be lost under a single `lld` label. Finally, inclusion in an established open benchmark lowers the barrier for future system developers, who can evaluate Ladin MT with standard BOUQuET tooling, metrics, and data conventions used for other languages with limited public resources.

The dataset and accompanying metadata will be made available as part of the BOUQuET dataset at `https://huggingface.co/datasets/facebook/bouquet` and are released under the Creative Commons Attribution-ShareAlike 4.0 International (CC BY-SA 4.0) license[5].

[4] A Ladin standard written variety, called "ladin dolomitan", would be available (Schmid, 1998) but has not yet been widely accepted.

## 2 Language Overview

Ladin, also referred to as *Ladin of the Dolomites* (Salvi, 2016; Moroder, 2022), is a Rhaeto-Romance language spoken in several valleys of the Dolomites of Northern Italy. It should not be confused with Judeo-Spanish Ladino (lad); the Ladin considered here has ISO 639-3 code lld and is written in the Latin script (Latn).

**Background** The linguistic unity of the ladin area in the Dolomites was first systematically identified by Ascoli (1873), who described a set of features characterizing the language group; later work discusses this classification and its linguistic basis in more detail (Goebl, 2020; Videsott et al., 2020). These features include, among others, preservation of the plural marker *-s* and of the second-person verbal ending *-s*, as well as palatalization of Latin velars before A, as in *cian* /tʃaŋ/ or /caŋ/ 'dog' from Latin CANE(M).

Unlike territorial languages with a dominant urban center, Ladin historically lacked a single demographic or economic center that could provide a natural koiné. The language therefore developed as a pluricentric cluster of localized idioms. The glottonym Ladin encompasses five major written varieties spoken across Alpine valleys in the provinces of Bolzano/Bozen, Trento, and Belluno: Val Badia, Gherdëina, Fascian, Fodom, and Anpezan Ladin. Recent estimates place the number of speakers at approximately 32,650 (Pan et al., 2016, 63–64). The single ISO 639-3 identifier lld is therefore only a partial representation of the written language situation: it identifies Ladin as a whole, but not the standardized written varieties that are relevant for MT evaluation.[6] Owing to the historical administrative fragmentation of the Ladin valleys, language policies differ across the speech area; in the autonomous region of Trentino–South Tyrol, Ladin enjoys official recognition as a minority language and is used compulsorily in administration and education in Ladin-speaking areas (Videsott, 2023).

**Val Badia and Gherdëina** In this contribution we focus on the two standardized varieties of South Tyrol, Val Badia and Gherdëina Ladin. For Glottolog mapping, Gherdëina corresponds to gard1241; Val Badia is most closely represented by badi1244, although this written standard also covers areas that are not perfectly captured by a single Glottolog entry. The two varieties share most linguistic features but can differ in orthography, morphology, and lexical choice. These differences matter for MT: final *-s* plural marking, palatalized consonants, local vowel marking, and contact-induced vocabulary from German and Italian all affect tokenization and generation. Closely related forms can also create false confidence for automatic systems, which may produce plausible-looking Ladin that follows the wrong variety or mixes standards.

To give an empirical indication of the distance between the two released references, we computed sentence-level character $n$-gram overlap (chrF) and token Jaccard similarity between corresponding Val Badia and Gherdëina translations of the 854 BOUQuET test sentences. Only 6 sentence pairs (0.44%) are identical across the two varieties;the mean sentence chrF is 48.0 and the mean token Jaccard similarity is 0.273. These values are not intended as a linguistic classification of the varieties, but they confirm that the two benchmark targets

[6] This situation is common to many minority languages. It would therefore be important that ISO allows a further subdivision of its ISO 639-3 codes.

differ substantially at the surface level and should not be treated as interchangeable references.

**Linguistic Resources** Existing language resources include printed and online dictionaries (Forni et al., 2014; Moling et al., 2016; Mischí, 2025), orthographic guides (Forni, 2019a; Mischí et al., 2015), grammars (Videsott, 2025; Forni, 2019b), spellcheckers, and a small body of parallel data, including a complete Ladin smartphone user interface (Videsott and Frenademez, 2025). In the present workflow, dictionaries and spellcheckers were actively used during translation and revision. In particular, translators consulted the online Val Badia and Gherdëina dictionaries provided by the Ladin Cultural Institute "Micurá de Rü",[7] [8] [9] the digitized German–Ladin Val Badia dictionary in Wörterbuchnetz,[10] and existing online dictionary portals for both varieties.[11]

## 3 Related Work

**BOUQuET.** BOUQuET (Andrews et al., 2025) was launched in early 2025 with nine pivot languages and has since expanded through vendor commissions, a partnership with Mozilla Common Voice, and the OLDI open initiative. As of the time of this paper, BOUQuET covers 275 languages, 56 distinct language families, and 33 scripts; 18 of these languages were contributed entirely through community efforts (16 via Mozilla Common Voice, 2 through the open initiative), with the remainder commissioned through vendors (Omnilingual MT Team et al., 2026).

The large-scale extension effort in Omnilingual MT Team et al. (2026) is relevant for the present work because it frames benchmark extension as both a linguistic and an operational problem. In addition to adding languages, it reports that pivot language choice affects translation quality and resourcing: French, Indonesian, Swahili, and Spanish facilitated translation more readily than German or Hindi, while exclusive reliance on English as a pivot was associated with lower output quality and higher costs.

**OLDI Shared Task and Ladin Contributions** Similar community-driven contributions to open multilingual datasets have been documented in preceding editions of the OLDI shared task. Burchell et al. (2024) report ten accepted submissions at WMT 2024, covering 16 languages and extending FLORES+ (Team et al., 2022; Goyal et al., 2022) and MT Seed. Dale et al. (2025) report eight accepted submissions at WMT 2025, including further extensions of FLORES+ and a new parallel training dataset. These shared tasks demonstrate the viability of coordinated, open data contributions as a mechanism for expanding multilingual evaluation coverage, and the present work follows in the same tradition.

The present work builds directly on our earlier extension of FLORES+ to Val Badia and Gherdëina Ladin (Frontull et al., 2025), which provided the first sentence-level parallel evaluation data for the two varieties. Compared with that earlier work, the present workflow was designed from the beginning as a parallel two-variant process: both varieties were translated in parallel, revised jointly, and then compared against automatic systems in a blind evaluation. For Ladin, BOUQuET now complements FLORES+ by offering paragraph-level, multi-register evaluation; together, the two benchmarks cover both granularities needed for a comprehensive assessment of Ladin MT systems.

**MT for Ladin.** Prior computational work on machine translation Ladin includes investigations on the impact of backtranslated data generated by paradigmatically different systems (Frontull and Moser, 2024), as well as LLM-based approaches for both Val Badia and Gherdëina using few-shot prompting strategies (Frontull and Ströhle, 2026).

## 4 Data Collection and Annotation

Our contribution consists of human translations of BOUQuET into Val Badia and Gherdëina Ladin. The full resource contains 1,358 sentence-level translations for each variant, with 854 sentences across 198 paragraphs in the test split and 504 sentences across 120 paragraphs in the dev split.

### 4.1 Translation Team

In total, six people were involved in the human translation workflow and two independent experts in the validation process. Four translators produced the initial translations, with two assigned to Val Badia and two Gherdëina. Two served as reviewers and revised the translated outputs. The people involved were native speakers of the correspond-

ing Ladin variety, had high proficiency in German, Italian and English, and were familiar with written Ladin norms. We estimate the total effort at 100 hours per variant for the initial translation pass and a further 100 hours for revision and blind evaluation, amounting to roughly 300 hours of expert work across the full project.

### 4.2 Human Translation

The first translation pass was carried out in the BOUQuET web interface[12] provided by Meta. Figure 3 shows the *Translate* page of the web application used during this step. Translators worked from the BOUQuET source material, using English and German as the reference languages, and could consult available dictionaries as well as the publicly released Italian and Rumantsch dataset translations as supplementary points of reference during the translation process. The web interface was used in Firefox, which allowed to use the existing Ladin spellchecker plugins for Gherdëina[13] and Val Badia[14]. This setup was useful for distributed work because translators could work in a shared interface while receiving immediate orthographic feedback in the relevant variety. It also reduced format handling outside the benchmark platform, kept the required segment identifiers and paragraph units visible during translation, and made it easier to return to uncertain items during later review.

### 4.3 Text Sanitisation

We then carried out automated quality checks on the exported corpus,[15] covering line alignment, length ratios, special symbols, numeric expressions[16], (sentence-final) punctuation, and spellchecker statistics. We also incorporated notes collected during translation to identify uncertain terms, ambiguous source sentences, and cases requiring further discussion between the two Ladin varieties.

### 4.4 Parallel Alignment

The translated corpora for the two Ladin varieties were then reviewed side by side. We used AlignFix (Frontull and Haller-Seeber, 2026) to support alignment and inspection at sentence and word level and to identify inconsistent terminology, accidental omissions, and cases where the two varieties had solved the same translation problem in different but instructive ways. This comparison was mutually useful: a well-formed solution in one variant often helped detect an omission, ambiguity, or inconsistent term in the other. The reviewers did not force the varieties into identical structures; instead, they harmonized terminology where appropriate while preserving legitimate differences in Val Badia and Gherdëina usage. At the same time, cases where differences reflected only translation choices rather than genuine linguistic variation were aligned where possible, such as maintaining consistent sentence structure across varieties.

[14] https://addons.mozilla.org/en-US/firefox/addon/ladin-val-badia/

[15] Jean Maillard kindly provided us with this preliminary version of the corpus exported from the BOUQuET platform.

[16] Numbers written out as words were normalized to numerals to match the English source.

| Metric | Gherdëina | Val Badia |
|---|---|---|
| Sentences | 1,358 | 1,358 |
| Untouched Sent. | 180 (13.25%) | 138 (10.16%) |
| Modified Sent. | 1,178 (86.75%) | 1,220 (89.84%) |
| Total Word Edits | 7,515 | 8,262 |
| · Insertions | 1,803 | 1,719 |
| · Deletions | 790 | 1,230 |
| · Substitutions | 4,922 | 5,313 |
| Translation Edit Rate | 39.76% | 42.28% |

Table 2: Quantification statistics for parallel alignment.

To quantify the effort required for parallel alignment, we measured word-level differences between the initial translations and the final aligned outputs using standard Levenshtein distance metrics. As reported in Table 2, the alignment process affected roughly four-fifths of the sentences in both varieties, with around one-fifth remaining unchanged. Substitutions accounted for the majority of edits, while insertions and deletions were limited. This distribution indicates that the initial translations already provided a strong structural and semantic basis. The alignment mainly involved fine-grained adjustments to improve consistency and linguistic naturalness across the two varieties.

In addition to lexical harmonization, the alignment process addressed grammatical and stylistic differences arising from source-language influence and variety-specific conventions. For instance, German recipe instructions frequently employ the polite form of address, while Ladin instructional texts generally favor the second-person form. Similar adaptations were made for agreement patterns and tense selection, ensuring that the final versions reflected natural Ladin usage.

### 4.5 Blind Human Evaluation

For human validation, we conducted two rounds of evaluation, before and after the parallel alignment, to assess the effectiveness of the parallel alignment process and to obtain additional guidance for the final revision step. Two independent native-speaker evaluators used LITRA[17] to rank five anonymized candidate translations: the final human reference, Tradutur Ladin, Gemini 3.1 Pro, GPT 5.5, and Claude Sonnet 5. Candidates were ranked from best to worst without revealing system identity. We performed the evaluation at sentence level (which may not fully capture document-level coherence).

[17] https://github.com/schtailmuel/litra

### 4.6 Revision

Following the automatic quality analysis and blind human evaluation, we performed a final revision of the aligned corpora. The revision process combined the results of both evaluation stages: automatic quality signals from COMET-based analysis and qualitative feedback from native-speaker judgments. These signals were used to identify segments requiring additional inspection, including cases where automatic analysis indicated potential inconsistencies or where human evaluators preferred one or more MT outputs over the initial reference translation. Native speakers subsequently revised the reference translations where appropriate, improving fluency, naturalness, and fidelity while maintaining consistency across the corpus. The resulting revised translations constitute the final version of the parallel corpora included in our benchmark.

Table 3 reports word and character counts for the final dataset alongside the existing BOUQuET references for English, German, and Italian, together with ratios relative to English. These values provide practical reference points for expected length ratios in downstream checks, for example when flagging unusually short or long translations during automatic QA.

## 5 Experimental Validation

We assessed the quality of the new references and translations through three complementary analyses. First, we evaluated current MT systems on the BOUQuET test split to characterize the performance of existing translation technologies on the new Ladin benchmark. For translation from Ladin into English, this evaluation determines whether current systems can reliably translate Ladin texts into English, supporting the use of English as a pivot for subsequent automatic quality estimation. For translation into Ladin, it provides a reference point for interpreting benchmark difficulty and the results of the subsequent blind human evaluation.

| Language | Words | Chars | Word r. | Char r. |
|---|---|---|---|---|
| English | 17,678 | 98,650 | 1.00 | 1.00 |
| German | 16,973 | 110,009 | 0.96 | 1.12 |
| Italian | 17,094 | 105,490 | 0.97 | 1.07 |
| Gherdëina | 20,078 | 106,223 | 1.14 | 1.08 |
| Val Badia | 19,912 | 107,287 | 1,13 | 1.09 |

Table 3: Word and character counts across languages for the full BOUQuET dataset (test + dev, 1,358 segments).

Second, we applied COMET-based automatic quality estimation by translating the generated Ladin outputs back into English and comparing the resulting translations against the original English references. This analysis provides an additional quality signal and helps identify potential issues, such as omissions or severe translation inconsistencies, that may not have been detected during manual review.

Third, we conducted a blind human ranking study in which independent evaluators compared the final human translations with automatic system outputs. The outcomes of these evaluations informed the final revision process, while also providing an overview of the performance of current zero-shot LLM baselines and dedicated MT systems on the new Ladin benchmark.

### 5.1 Benchmarking Current MT Systems for Ladin

We generated automatic translations of the test subset for all four evaluated directions: English → Val Badia, English → Gherdëina, Val Badia → English, and Gherdëina → English.[18] The systems were GPT 5.5, Gemini 3.1 Pro, Claude Sonnet 5, and Tradutur Ladin, the current Ladin MT system deployed at the University of Innsbruck.[19] The three LLMs were selected as representative general-purpose commercial systems, while Tradutur Ladin provides a dedicated Ladin neural MT baseline.

All LLM calls used temperature 0.0 and batched prompts instructing the model to preserve punctuation, numbers, proper names, and sentence boundaries; the full system prompt is reproduced in Appendix A. Tradutur Ladin was queried through its API with the corresponding source and target settings for each direction and variant. We report BLEU, chrF++, and TER computed with SacreBLEU using default settings.[20]

**English to Ladin** The results indicate that the Tradutur Ladin is the strongest automatic baseline for translation into both Ladin varieties. More importantly for the present paper, the scores show that the benchmark does not saturate: there remains a clear gap between automatic outputs and the human references, and the systems are separated by all three metrics. We also observe lower scores for Gherdëina than for Val Badia across systems, consistent with prior results (Frontull et al., 2025; Frontull and Ströhle, 2026). Because BLEU can be brittle in morphologically rich and low-resource settings, we interpret it together with chrF++, which provides a complementary character-level view of translation similarity.

| System | BLEU ↑ | chrF++ ↑ | TER ↓ |
|---|---|---|---|
| *English → Gherdëina* | | | |
| Claude Sonnet 5 | 9.99 | 32.44 | 81.37 |
| GPT 5.5 | 14.52 | 39.64 | 70.26 |
| Gemini 3.1 Pro | 25.27 | 48.60 | 59.06 |
| Tradutur Ladin | **28.51** | **52.26** | **55.39** |
| *English → Val Badia* | | | |
| Claude Sonnet 5 | 8.90 | 32.44 | 81.37 |
| GPT 5.5 | 16.34 | 41.59 | 68.54 |
| Gemini 3.1 Pro | 27.06 | 49.71 | 57.45 |
| Tradutur Ladin | **33.34** | **55.32** | **51.72** |
| *Gherdëina → English* | | | |
| Claude Sonnet 5 | 35.85 | 58.28 | 53.75 |
| GPT 5.5 | 38.91 | 60.78 | 50.40 |
| Gemini 3.1 Pro | **43.02** | **63.48** | **46.10** |
| Tradutur Ladin | 33.24 | 56.31 | 54.46 |
| *Val Badia → English* | | | |
| Claude Sonnet 5 | 36.94 | 58.75 | 52.84 |
| GPT 5.5 | 39.35 | 61.55 | 49.96 |
| Gemini 3.1 Pro | **42.98** | **63.69** | **45.74** |
| Tradutur Ladin | 34.22 | 57.25 | 53.19 |

Table 4: MT results on the BOUQuET Ladin test sets for all translation directions. LLM rows are zero-shot baselines. Higher is better for BLEU/chrF++; lower is better for TER.

**Ladin to English** The reverse direction (lower half of Table 4) reveals a different pattern. General-purpose LLMs in a zero-shot setting outperform Tradutur Ladin for both varieties, reversing the ranking observed in the English → Ladin direction. This is not presented as a new general property of LLMs; related translation asymmetries have also been reported for Romansh varieties (Vamvas et al., 2026).

**Domain Specific Performance** Figure 4 shows that the aggregate patterns in Table 4 are broadly stable across domains, but not uniform. For English → Ladin, Tradutur Ladin has the largest area in both varieties and performs especially strongly in domains such as comments, reflection, and web miscellaneous; the LLM baselines are closer in some conversational material, particularly for Gherdëina. In the reverse directions, Gemini 3.1

[18] The automatic MT outputs described in Section 5 were generated only after the human references had been produced; they were not used for translation or post-editing.

[19] https://tradutur-informatik.uibk.ac.at/

[20] BLEU tokenizer 13a; chrF++ with character order 6 and word order 2; TER with standard tokenization.

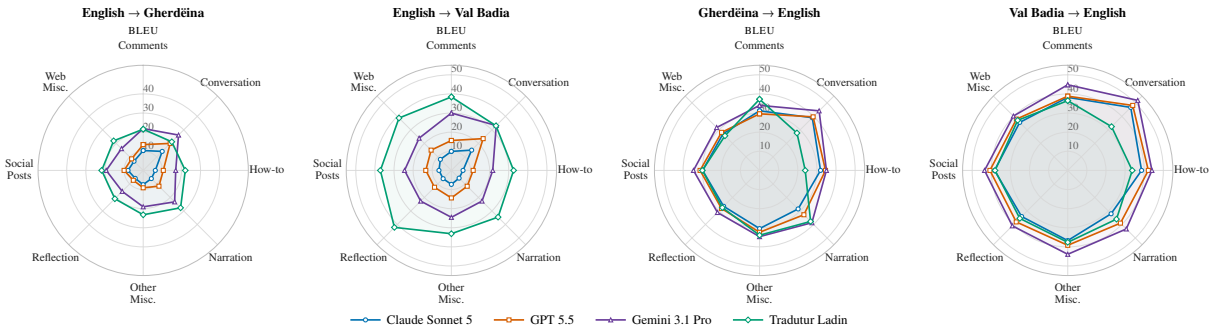

Figure 4: Domain-level translation performance across four translation directions, measured using BLEU. Each radar chart reports performance across eight domains. The legend is shared across all panels. Note that the radial scales differ across translation directions to preserve within-direction variation.

Pro is generally strongest across domains, while differences between the remaining systems vary by domain. The domain plots therefore reinforce the main conclusion without suggesting a single domain-independent ranking: translation direction and text type both affect the observed system gaps.

A notable exception is comparatively weaker performance of the Tradutur Ladin in the conversation domain. This drop is likely driven by a training-data mismatch: the Tradutur Ladin is primarily trained on formal parallel corpora (such as news, historical texts, and institutional documents).

### 5.2 Automatic Quality Estimation

The Ladin → English MT results presented above confirm that English translations of Ladin texts can be used as a reliable pivot for automatic quality checks. We therefore translated all generated Ladin outputs for both variants (lld_valbadia and lld_gherd) into English using the four independent MT systems. Each resulting sentence was then evaluated using the reference-based COMET model `Unbabel/wmt22-comet-da`[21] (Rei et al., 2022). For each sentence, we first averaged the COMET scores obtained from the four English translations, reducing the impact of any single pivot system. We then aggregated these sentence-level averages separately for each Ladin variety by reporting the global mean, minimum, and 99% confidence interval.

For Val Badia, the average sentence-level COMET score was 0.8485 (min.: 0.4417; 99% CI: [0.8424, 0.8546]). For Gherdëina, the corresponding average was 0.8323 (min.: 0.4395; 99% CI: [0.8263, 0.8383]). We used lower-scoring outliers to flag sentences for closer human inspection.

[21] https://huggingface.co/Unbabel/wmt22-comet-da

### 5.3 Human Evaluation Results

Table 5 presents the pairwise win-rate heatmaps for both Ladin varieties before and after parallel alignment. Values are strict win rates, and ties are implicit as the remainder to 100% for each pairwise comparison. The pre- and post-alignment rounds used different evaluation items ($N = 51$ before and $N = 50$ after), while maintaining the same evaluation procedure and evaluator. This design preserved blinding and avoided exposing evaluators to post-edited variants of previously evaluated items. The results show a consistent shift in favor of the human references following parallel alignment. Before alignment, *Tradutur Ladin* was preferred to the human reference in 33.3% of comparisons for Gherdëina and 30.0% for Val Badia. After alignment, these proportions decreased to 22.0% and 20.0%, respectively. Thus, in both Ladin varieties, the revised human translations were more frequently preferred to the automatic translations. The consistent reduction across both varieties provides evidence that the alignment process improved the quality of the human reference translations.[22]

## 6 Conclusion

In this work, we have contributed a Ladin extension of BOUQuET covering two major written varieties, Val Badia and Gherdëina, along with a documented workflow for benchmark creation that combines human translation, revision, parallel alignment, and blind evaluation. The automatic MT results serve as validation baselines that demonstrate the benchmark provides meaningful evaluation signal

[22] Because the evaluation sets were independently sampled and relatively small, however, the magnitude of this improvement should be interpreted with caution as the observed differences may also reflect variation in the evaluated items.

| Model | | A | B | C | D | E |
|---|---|---|---|---|---|---|
| Human | **A** | – | 44.0% | 68.0% | 86.0% | 98.0% |
| Tradutur Ladin | **B** | 30.0% | – | 64.0% | 90.0% | 96.0% |
| Gemini 3.1 Pro | **C** | 8.0% | 14.0% | – | 68.0% | 92.0% |
| GPT 5.5 | **D** | 4.0% | 8.0% | 18.0% | – | 66.0% |

| Gemini 3.1 Pro | **C** | 10.0% | 24.0% | – | 88.0% | 100.0% |
| GPT 5.5 | **D** | 0.0% | 8.0% | 12.0% | – | 76.0% |
| Claude Sonnet 5 | **E** | 0.0% | 0.0% | 0.0% | 24.0% | – |

(d) Gherdëina, After Parallel Alignment ($N = 50$)

Table 5: Pairwise win-rate heatmaps showing head-to-head human preference across all evaluated candidate translations for both Ladin dialects (Val Badia and Gherdëina), before and after human parallel alignment. Each cell in row $R$ and column $C$ reports the percentage of total evaluation items ($N$) where model $R$ was ranked strictly higher than model $C$ by native evaluators.

across current systems. Together with the FLORES+ Ladin extension presented in earlier work, BOUQuET now offers complementary sentence-level and paragraph-level evaluation resources for the assessment of MT systems for Ladin.

**Future Work** The released benchmark should remain held out for evaluation. Beyond this test resource, however, a similar community workflow could be used to create companion training corpora for Ladin. Even small amounts of high-quality parallel text can have a substantial impact on translation quality in low-resource settings (Maillard et al., 2023; Wu et al., 2024; Caswell et al., 2025). Future efforts could therefore also focus on creating additional Ladin training data by translating suitable multilingual resources into the language, such as OLDI Seed (Team et al., 2022) and SMOL (Caswell et al., 2025; Jones et al., 2023). In this context, the released benchmark could serve as a reference point for quality control and evaluation, helping to ensure the consistency and reliability of newly created training material. With respect to the BOUQuET benchmark extension introduced in this work, future directions will incorporate the previously undocumented terms surfaced in this work into existing lexicographic resources and expand coverage to the other Ladin written varieties (Fascian, Fodom, Anpezan and Ladin Dolomitan). For this, the current dataset can serve as a useful source of translation support and cross-checking, but it will not serve as a normative target. In particular, since the translations were finalised by native-speaker reviewers with full authority over variety-specific choices, they represent stable, independently justified reference points rather than compromises made to force cross-variety consistency. Consequently, expanding the benchmark will neither trigger revisions of the current varieties nor obligate new varieties to conform to them.

## Acknowledgments

We thank the Open Language Data Initiative (OLDI) organizers for coordinating this shared task, Irene Prinoth, director of the Istitut Ladin Micurá de Rü, and Paolo Anvidalfarei for their support in this initiativ, and the reviewers for their valuable comments and questions, which helped us improve and refine the presentation. We also gratefully acknowledge the financial support of the Autonomous Province of Bolzano–Bozen.

## A Translation Prompt

The following system prompt was used for all LLM translation calls (GPT 5.5, Gemini 3.1 Pro, Claude Sonnet 5) in all translation directions. The placeholders {source_variant}, {target_variant}, and {batch_size} are substituted at runtime with the source-language name (e.g., *English*), the target-language name (e.g., *Ladin (Val Badia)*), and the number of sentences in the current batch, respectively.

```
You are a professional literary translator.
Translate the given list of {source_variant}
sentences into {target_variant}.

**CRITICAL INSTRUCTIONS**:

- Return ONLY a JSON object containing a key
`translations`.
- The output array MUST contain exactly
{batch_size} translations.
- Preserve punctuation, numbers, proper names,
and sentence boundaries.
- Do not add any extra commentary or text
outside the JSON object.
```

## B Selected Challenging and Previously Undocumented Terms

In this section, we present a selection of terms that proved particularly challenging during the translation process, partly because they were previously undocumented. For each term, we report the translations submitted for Val Badia and Gherdëina, together with the submitted translations.

1. **exercise program** (P006), VB: program d'alenamënt, GH: program d'alenamënt 2. **God willing** (P015), VB: sce Dî ó, GH: sce Die uel 3. **chicken (food)** (P038), VB: galüc, GH: gialuc 4. **marriage website** (P042), VB: portal matrimonial, GH: portal matrimuniel 5. **setting (phone)** (P059), VB: impostaziun, GH: impustazion 6. **brightness (screen)** (P059), VB: lominosité, GH: linëus 7. **game pieces** (P060), VB: toc de jüch, GH: pec de juech 8. **draw (game)** (P060), VB: parité, GH: pèr 9. **health supplements** (P063), VB: integradus alimentars, GH: ntegradëures alimenteres 10. **spring onion** (P065), VB: ciola d'aisciöda, GH: ciola d'ansciuda 11. **consumer feedback** (P084), VB: feedback di cliënc, GH: feedback di tlienc 12. **short stocks** (P086), VB: venüda de aziuns a öt, GH: venduda de azions a uet 13. **macro factors (stock market)** (P086), VB: faturs macroeconomics, GH: fatores macroeconomics 14. **Residence Permit** (P100), VB: lizënza de sojornanza, GH: lizënza de sujurnanza 15. **railway passenger** (P100), VB: passajiers dla ferata, GH: passajieres dla ferata 16. **online classes** (P109), VB: insegnamënt a destanza, GH: nseniamënt a destanza 17. **load-bearing wall** (P114), VB: mür che porta, GH: mur che porta 18. **vaccination criteria** (P113), VB: criters de vazinaziun, GH: criters de dlavea 19. **decorating style** (P120), VB: stil por l'aredamënt, GH: stil per l aredamënt 20. **order number** (P127), VB: numer d'apostaziun, GH: numer de apustazion 21. **sparkling apple cider** (P129), VB: n süch de pom frizant, GH: n such de mëil frizant 22. **spaceship** (P138), VB: barca spaziala, GH: berca spaziela 23. **pink giant donuts** (P142), VB: donuts rosa giganc, GH: donuts rosa giganc 24. **bank clerk** (P144), VB: impiegat bancar, GH: mpiegat de banca 25. **wealth management** (P144), VB: gestiun de patrimoni, GH: gestion de patrimonesc 26. **self-pick-up** (P158), VB: da gní a do instësc, GH: da unì a tò nstësc 27. **caring** (P159), VB: da orëi bun, GH: da ulëi bon 28. **dog treats** (P161), VB: golosaries por cians, GH: gulujaries per cians 29. **Editor-in-Chief** (P165), VB: caporedadëssa, GH: caporedadëura 30. **painter's tape** (P171), VB: vëta adesiva da moler, GH: vëta adesiva da moler 31. **loyalty** (P187), VB: lealté, GH: redlëza 32. **corner of her eye** (P199), VB: piza dl edl, GH: piza dl uedl 33. **dashboard** (P217), VB: dashboard, GH: dashboard 34. **collaborative tools** (P217), VB: stromënc de colaboraziun, GH: strumënc de culaburazion 35. **productivity loss** (P220), VB: pordüda de produtivité, GH: perduda de produtività 36. **endurance** (P224), VB: dorada, GH: artenienza 37. **diametrically opposed** (P224), VB: contrar, GH: cuntrer 38. **support innovation** (P231), VB: sostëgn la inovaziun, GH: sustën la inuvazion 39. **high voltage power line** (P232), VB: linia eletrica a tensciun alta, GH: linia eletrica a tenscion auta 40. **death by electrical shock** (P232), VB: prigo de mort por scassada eletrica, GH: pericul de mort per scasseda eletrica 41. **dearest** (P247), VB: mia cera, GH: mi cëra 42. **regular check up** (P252), VB: vijita regolara de prevenziun, GH: vijita regulera de prevenzion 43. **heartbeat** (P253), VB: bate dl cör, GH: bater dl cuer 44. **superheroine** (P254), VB: supereroina, GH: supereroina 45. **self-promotion** (P260), VB: fá reclam a se instës, GH: fé retlam a sé nstësc 46. **simple look** (P265), VB: aspet scëmpl, GH: aspet scëmpl 47. **swag** (P270), VB: segurëza, GH: segurëza 48. **guardians** (P276), VB: ghiraui, GH: respunsabli per l'educazion 49. **sewer** (P300), VB: canal dles eghes fosces, GH: canal dal'eghes fosces 50. **dude** (P300), VB: vedl, GH: ueidl 51. **media design** (P323), VB: design multimedial, GH: design multimediel 52. **domestic commissions** (P323), VB: inciaries nazionales, GH: ncëries nazioneles 53. **wolf spider** (P325), VB: aragn lu, GH: arani lëuf 54. **courier service** (P328), VB: sorvisc de spediziun, GH: servisc de spedizion 55. **account** (P334), VB: acunt, GH: acont 56. **nut on your guitar** (P350), VB: selina de tüa chitara, GH: capotast de ti chitara 57. **trapezius muscle** (P355), VB: muscul trapez, GH: mustl trapez 58. **blazer** (P363), VB: blazer, GH: blazer 59. **handsome young man** (P363), VB: bel jonn, GH: blòt jëun 60. **everything is hanging (software)** (P366), VB: döt é bloché, GH: dut ie blocà 61. **post (social media)** (P375), VB: post, GH: post 62. **middle-aged** (P378), VB: mesa eté, GH: mesa età 63. **budget** (P381), VB: budget, GH: budget 64. **so cool** (P384), VB: ci bel, GH: ce bel 65. **current law** (P392), VB: lege varënta, GH: lege n droa 66. **business analyst** (P394), VB: analist aziendal, GH: analist aziendel 67. **plastic-free packaging** (P396), VB: produc nia fac ia te plastica, GH: prudoc nia fac ite te plastica 68. **smartphone** (P399), VB: smartphone, GH: smartphone 69. **teenage daughter** (P399), VB: möta adolescënta, GH: muta jëuna 70. **reliability** (P399), VB: segurëza, GH: segurëza 71. **neck of the bottle** (P412), VB: col dla boza, GH: col dla boza 72. **survival mode** (P420), VB: modalité de suravivënza, GH: modus de sëuravivënza 73. **inconvenience** (P422), VB: galia, GH: galia 74. **follow us** (P437), VB: gnidesse do, GH: unidenes do 75. **one's own image** (P452), VB: so bun inom, GH: si bon inuem 76. **freedom of expression** (P452), VB: liberté de minunga, GH: lidëza de minonga 77. **tourist apartments** (P458), VB: abitaziuns da vacanza, GH: cuatieres da vacanza 78. **essential goods** (P461), VB: bëgns essenziai, GH: bëns essenziei. 79. **income tax returns** (P463), VB: detlaraziun dles cutes, GH: detlarazion dla chëutes

## Abstract

We introduce a new fork of the SMOL training dataset along with forks of the BOUQuET and WMT24++ translation benchmarks for the Chechen language. We train a model on SMOL and calculate BLEU and chrF++ scores on the introduced benchmarks to evaluate how training on such a limited amount of data may contribute to the model's Chechen-Russian translation capability. The introduced resources provide a unified evaluation framework for Chechen machine translation and allow measuring the transfer of improvements across different benchmark datasets. Our experiments establish baseline results for future research on Chechen translation and demonstrate the potential of utilizing small-scale parallel corpora for improving low-resource language models.

## 1 Introduction

In recent years, the Chechen language has been rapidly digitized: new translation models supporting Chechen are emerging, Chechen corpora are being published (Jones et al., 2023; Penedo et al., 2025), and the Chechen language is appearing in closed-source products such as Google Translate[1]. Chechen is a Northeast Caucasian (Nakh) language spoken primarily in the Chechen Republic of the Russian Federation and by diaspora communities. Despite having more than one million speakers (Institute of Linguistics, Russian Academy of Sciences, 2024), it remains severely underrepresented in natural language processing resources compared to widely studied languages. Its rich morphology and limited availability of parallel corpora create additional challenges for machine translation.

However, parallel datasets for this language remain few compared to other European languages, and the Chechen language remains "low-resource". Furthermore, no generally accepted benchmark for assessing translation quality has yet been published for this language.

In our work, we contribute to addressing these limitations. We prepare professional translations of the SMOL parallel training dataset (Caswell et al., 2025) along with the BOUQuET (Team et al., 2025) and WMT24++ (Deutsch et al., 2025) translation benchmarks for Chechen. We also fine-tune the MADLAD-400-3B-MT model (Kudugunta et al., 2023) on the SMOL smoldoc split and measure BLEU and chrF++ changes after training to evaluate how a limited amount of parallel data can improve a model's Chechen-Russian translation capabilities.

The resulting Chechen versions of SMOL, BOUQuET, and WMT24++ are publicly released on their corresponding Hugging Face dataset pages. We hope that these resources will facilitate future research on Chechen machine translation and provide a common basis for evaluating progress in this low-resource language.

## 2 Related Work

To our knowledge, there are three widely recognized evaluation benchmark datasets for translation tasks: FLORES+ (Team et al., 2022), WMT24++ (Deutsch et al., 2025), and BOUQuET (Team et al., 2025). Among these benchmarks, we chose WMT24++ and BOUQuET for this work for several reasons: both datasets have Russian versions that could be used by our translators as references, they cover various text domains, and their texts were considered convenient for translation by our translators.

Since the survey provided in our previous paper (Umishov and Grigorian, 2025), new monolingual and parallel datasets for the Chechen language have emerged: (Penedo et al., 2025, 2026). We examined the FineTranslations[2] parallel dataset containing Chechen-English sentence pairs with human eval-

[1] https://blog.google/products/translate/google-translate-new-languages-2024/

October 28-29, 2026 ©2026 Association for Computational Linguistics

uation by Chechen native speakers and concluded that it cannot be used for training due to the poor quality of its parallel pairs. Another relevant resource is the SMOL dataset (Caswell et al., 2025), a professionally translated multilingual parallel training dataset designed for machine translation model development. Its Russian version[3] curated by Ali Kuzhuget and Isaac Caswell made it a suitable source dataset for creating a Chechen translation, as it could provide translators with an additional reference during the translation process.

## 3 Datasets

We present Chechen versions of three multilingual datasets: SMOL, BOUQuET, and WMT24++. The Chechen versions of the datasets were prepared by Marem S. Magomaeva, a philologist specializing in the Chechen language and translation. The Russian versions of the original datasets were used as references during the translation process. A subset of the translated sentences was additionally inspected by one of the authors, Abu-Viskhan A. Umishov, a native speaker of Chechen, as a quality check.

The SMOL dataset (Caswell et al., 2025) was selected as the training corpus due to the availability of a Russian version, which was used as an additional reference during translation. We translated the smoldoc split into Chechen, creating a Chechen-Russian parallel training dataset. The resulting dataset contains 114 document pairs (863 sentence pairs) and was used for fine-tuning experiments.

During the preparation of the Chechen version of SMOL, we used only the Cyrillic Letter Palochka (U+04C0) character. At that time, the conventions for representing this letter in digital text were not fully established: major smartphone keyboard providers included only the uppercase form in their Chechen layouts, despite the grammatical use of both uppercase and lowercase forms. After the publication of the Chechen SMOL version, the convention of following the grammatical distinction between Cyrillic Letter Palochka and Cyrillic Small Letter Palochka (U+04CF) became preferable. The benchmark datasets prepared in this work follow the grammatically correct usage of both forms. The Chechen version of SMOL will be updated in a future release to follow the current orthographic convention.

For evaluation, we translated the BOUQuET benchmark (Team et al., 2025). BOUQuET was selected because it covers diverse text domains and provides a Russian version that could be used by translators as a reference. The resulting Chechen version contains 504 sentence pairs in the dev split and 854 sentence pairs in the test split, which are used as validation and test benchmarks, respectively.

The WMT24++ benchmark (Deutsch et al., 2025) was translated into Chechen to provide an additional evaluation resource for measuring translation quality. Similarly to BOUQuET, WMT24++ was selected due to the availability of a Russian version, which could be used by translators as an additional reference, and its coverage of diverse text domains. The resulting Chechen version contains 998 sentence pairs.

The translation guidelines used for preparing all Chechen datasets, including orthographic and consistency requirements, are provided in Appendix A. After the translation was completed, we post-processed the datasets to normalize the orthographic representation of the Chechen Cyrillic Letter Palochka. During the translation process, the Digit One symbol was temporarily used by translators for convenience due to its visual similarity and easier availability on standard keyboards. Before releasing the datasets, all such occurrences were replaced with the appropriate Cyrillic Letter Palochka character.

For the SMOL dataset, we replaced Digit One with Cyrillic Letter Palochka; the corresponding code is provided in Appendix E. For BOUQuET and WMT24++, we used a two-stage procedure to correctly initialize Palochka characters. First, we replaced Digit One with either Cyrillic Letter Palochka or Cyrillic Small Letter Palochka based on its position in the Chechen sentence. The corresponding code is provided in Appendix F. We then manually checked the sentences for proper names beginning with Cyrillic Small Letter Palochka and replaced it with Cyrillic Letter Palochka where appropriate.

## 4 Experiments

We fine-tuned the MADLAD-400-3B-MT model (Kudugunta et al., 2023) on the Chechen version of the SMOL dataset using Low-Rank Adaptation (LoRA). For translation direction specification, we

[3] https://huggingface.co/datasets/Agisight/google-smol-en-ru

used the special tokens <2ce> and <2ru> for Russian-to-Chechen (RU→CE) and Chechen-to-Russian (CE→RU) translation, respectively. The LoRA configuration and training hyperparameters are summarized in Tables 2 and 3. We used a low LoRA rank ($r = 4$) with dropout regularization and applied adapters to all linear layers.

Due to the limited size of the training data, overfitting was a primary challenge during fine-tuning. To mitigate this issue, we used small microbatches during training. The increased stochasticity of gradient updates reduces the risk of memorizing individual training examples and improves generalization to unseen evaluation datasets. Additionally, we applied early stopping with a patience of four consecutive evaluations and a minimum improvement threshold of 0.001 based on validation loss. The best-performing checkpoint was selected according to the validation loss.

We used the PEFT library (Mangrulkar et al., 2022) for LoRA implementation and the Transformers framework (Wolf et al., 2020) for organizing the training process. The models were trained on one NVIDIA V100 GPU using BF16 mixed precision. We later found that V100 does not provide native BF16 hardware support, although the training completed successfully with BF16 enabled in the Transformers/PyTorch environment. For detailed LoRA and training configurations, see Appendix B and Appendix C.

The Chechen versions of BOUQuET and WMT24++ prepared in this work were used for evaluation. The inference parameters for the model we used are described in Appendix D. We report results for both translation directions using BLEU and chrF++ metrics, computed with SacreBLEU (Post, 2018). BLEU was computed using the default SacreBLEU configuration, while chrF++ was computed with word_order=2. The BOUQuET dev split was used as a validation set during training, while all test splits were reserved for final evaluation. For all splits, we used the dataset versions released in our Hugging Face repository without further preprocessing.

We report the fine-tuned model scores and the absolute improvements over the base MADLAD-400-3B-MT model.

## 5 Results

Table 1 presents the translation performance of the base MADLAD-400-3B-MT model and the model fine-tuned on the Chechen version of SMOL. Values in parentheses show the absolute improvement over the base model. Fine-tuning consistently improves both BLEU and chrF++ scores across all evaluated directions and benchmarks, demonstrating that even a relatively small amount of professionally translated data can substantially improve the model's ability to process Chechen.

| Benchmark | Direction | BLEU | chrF++ |
|---|---|---|---|
| BOUQuET | CE→RU | 0.18 (+0.18) | 13.41 (+13.19) |
| | RU→CE | 0.02 (+0.02) | 4.59 (+4.35) |
| WMT24++ | CE→RU | 0.23 (+0.23) | 9.98 (+9.67) |
| | RU→CE | 0.02 (+0.02) | 5.66 (+5.40) |

Table 1: Translation performance of MADLAD-400 fine-tuned on SMOL. Values in parentheses denote the improvement over the base model.

The largest improvements are observed for the Chechen-to-Russian direction. On the BOUQuET benchmark, fine-tuning increases chrF++ from 0.22 to 13.41 and BLEU from approximately 0 to 0.18, while on WMT24++ chrF++ increases by 9.67 points. The improvements in the reverse Russian-to-Chechen direction are smaller, with chrF++ gains of 4.35 and 5.40 points on BOUQuET and WMT24++, respectively. This asymmetry can be explained by the fact that MADLAD-400 already had stronger generation capabilities for the resource-rich Russian language, while acquiring the ability to process and translate Chechen required additional language-specific adaptation.

## 6 Conclusion

In this work, we introduced Chechen versions of the SMOL training dataset and the BOUQuET and WMT24++ evaluation benchmarks. We evaluated the impact of fine-tuning MADLAD-400-3B-MT on the prepared SMOL dataset and showed that even a limited amount of professionally translated parallel data can substantially improve Chechen translation performance.

The obtained results demonstrate consistent improvements over the base model across both evaluated benchmarks and translation directions, with the largest gains observed for Chechen-to-Russian translation. This indicates that language-specific adaptation can significantly improve the model's ability to handle a low-resource language, while generating Chechen remains more challenging due to the limited prior exposure of the model to this language.

The released datasets provide additional resources for future research on Chechen machine translation and evaluation, helping to improve the coverage of low-resource languages in multilingual translation systems.

## 7 Acknowledgements

We thank Marem S. Magomaeva for preparing the Chechen translations and for her linguistic expertise.

We also thank David Dale for his advice on this article and for his broader efforts to support the Russian-speaking low-resource language community.

## A Translation guidelines (English version)

1. The sentences must be translated accurately and sound natural in Chechen.
2. Consider the context of the other sentences in the paragraph when translating each sentence.
3. If you have difficulty with a sentence, skip it.
4. Use dictionaries if needed, but do not rely on Google Translate or any other machine translation systems.
5. Use 1 (Digit One) for Cyrillic Letter Palochka and Cyrillic Small Letter Palochka.
6. Maintain the capitalization of the original text. Example: "Кот - Цициг", "КОТ - ЦИЦИГ".
7. For Chechen words, use only Cyrillic characters (and 1 for both cases of Palochka). An example of what not to do: "парень - k1ант", here letter k is Latin.
8. Preserve the original untranslatable parts of the text, such as emojis, IDs and words that were not translated in the Russian reference, exactly.

# Closing the Resource Gap for Tigre: A Diaspora-Sourced English–Tigre Parallel Dataset for SMOL

**Beshir Ibrahim**
BeitTigreAI
bbeshir@gmail.com

## Abstract

Tigre, an Afro-Semitic language maintaining strong linguistic continuity with Classical Ge'ez, holds a significant presence in Eritrea as well as across native and intergenerational refugee communities in eastern Sudan. It remains absent from major machine translation benchmarks and resources such as FLORES-200, despite an established orthography and active use in education. As a submission to the WMT26 Open Language Data shared task, we present a community-driven contribution of 11,998 English–Tigre pairs (word-, phrase-, and sentence-level) to the SMOL parallel corpus, written in the standardized Ge'ez-script form of Tigre used in Eritrean education and media. The data were produced through a structured, multi-stage post-editing and cross-validation pipeline involving two diaspora native-speaker translator groups. We document the collection methodology and translator workflow, and validate the data's usefulness by fine-tuning NLLB-200-3.3B on the contributed pairs, observing about a 4.4× improvement in chrF++ over an untrained baseline for English-to-Tigre translation (4.92 to 21.63), with gains in both translation directions. We release the dataset under a Creative Commons Attribution (CC-BY 4.0) license to support future NLP research on this severely under-resourced language.

## 1 Introduction

Tigre, an Afro-Semitic language exhibiting deep archaic continuity with Classical Ge'ez, holds a significant presence in Eritrea as well as across native and intergenerational refugee communities in eastern Sudan. Despite possessing an established orthography, active use in education, and a growing community presence on digital platforms, Tigre remains severely under-served in natural language processing (NLP). Notably, while closely related languages within the Afro-Semitic branch—such as Tigrinya (tir_Ethi)—have been integrated into massively multilingual translation models like Meta's NLLB-200, Tigre (tig_Ethi) itself is entirely absent from major benchmarks such as FLORES-200 and standard commercial translation systems. This absence creates a persistent digital resource gap for Tigre speakers, hindering the automated creation of educational materials, cross-lingual retrieval, and localized technology tools.

To directly address this resource divide, we present a community-driven, parallel translation initiative that constructs and evaluates the English–Tigre dataset within the SMOL parallel corpus (Anaghnostopoulos et al., 2025). Our effort produced 11,998 high-quality English–Tigre pairs through a structured, multi-stage post-editing and cross-validation pipeline involving two distinct native-speaker diaspora organizations. This work documents the dataset's collection methodology, establishes baseline experimental validations, and is submitted to the WMT26 Open Language Data shared task.

The main contributions of this paper are three-fold:

1. **Parallel Dataset Contribution:** We release a human-annotated and multi-stage peer-reviewed English–Tigre parallel dataset under a permissive Creative Commons Attribution (CC-BY 4.0) license.

2. **Quality & Experimental Validation:** We establish benchmark translation experiments in both directions by fine-tuning NLLB-200-3.3B with expanded Tigre vocabulary, demonstrating a signifi-

*Proceedings of the Eleventh Conference on Machine Translation*, pages 2510–2516
October 28-29, 2026 ©2026 Association for Computational Linguistics

cant 4.4× increase in chrF++ (English to Tigre) and substantial BLEU gains over non-fine-tuned baselines.

3. **Documentation of Community Workflow:** We outline a reproducible, standard-conformant post-editing and cross-validation methodology tailored for diaspora-led, low-resource language preservation efforts.

## 2 Language Overview

### 2.1 Speaker Population and Geographic Distribution

Tigre is commonly estimated to be the second most widely spoken language in Eritrea[1]. No census has been conducted in Eritrea since its independence, so speaker numbers are estimates rather than official figures. Speakers are concentrated in the northern, western, and coastal lowlands of Eritrea, as well as adjacent regions of eastern Sudan (Idris, 2015), which also host Eritrean refugee communities settled since the 1960s (Kibreab, 1987). In Eritrea, the language enjoys formal institutional recognition: since the early 1990s, national education policy has allowed children to attend elementary school in their mother tongue, including Tigre, which is taught in the Ge'ez script (Woldemikael, 2003; Asfaha et al., 2009). Implementation has been uneven, with Tigrinya, Arabic, and English dominating many schools (Woldemikael, 2003), but the policy gave Tigre a classroom and literacy tradition in the Ge'ez script, providing a base for digital adoption.[2]

### 2.2 Linguistic Classification and Typology

Tigre belongs to the Afro-Semitic (South Semitic) sub-branch of the Afro-Asiatic language family. It is genetically distinct from, though frequently confused with, its geographical neighbor Tigrinya. While both languages descend from Classical Ge'ez and share common structural affinities, they remain mutually unintelligible separate languages. Like Classical Ge'ez, Tigre exhibits non-concatenative root-and-pattern morphology, synthetic verbal paradigms, and conservative Semitic features such as broken plurals.

Both languages also retain substantial but differing degrees of lexical similarity to their common ancestor, Ge'ez, the liturgical language of the ancient Aksumite Empire. Tigre shows 71% lexical similarity to Ge'ez, reflecting a highly conservative vocabulary, and is considered the closest living language to the extinct Ge'ez (Bender, 1971). Tigrinya shows 68%, having diverged slightly more in its core vocabulary (Bender, 1971).

### 2.3 Script and Orthography

Tigre is written in the Ge'ez abugida. While the writing system is standardized for formal education and broadcasting in Eritrea, minor orthographic variations persist in digital text. Three sources of variation are particularly relevant to this contribution. First, gemination (consonant length) is phonemic in Tigre—e.g. *kəbər* 'pride' vs. *kəbbər* 'proud, bossy'—but the Ge'ez script has no dedicated diacritic for it, so writers rely on context or informal doubling conventions that vary across texts (Idris, 2015). Second, labialized velar consonants ($k^w$, $q^w$, $g^w$), attested mainly in the 'Algaden and Beni-'Āmər dialect areas,[3] use a distinct, less common glyph that some digital keyboard layouts do not support, leading typists to substitute the plain velar form instead (Idris, 2015). Third, the mid-central vowel /ə/ is realized with several allophones depending on dialect and phonetic environment, which can lead to inconsistent vowel-sign choices across writers (Idris, 2015).

### 2.4 Existing Resources and Under-Resourced Status

Historically, digital resources for Tigre have been severely fragmented. Early documentation was limited to descriptive grammars and localized dictionaries. While recent participatory movements have seen Tigre content emerge on platforms like Tatoeba, Wikipedia[4], and Mozilla Common Voice, the language lacks large-scale, standardized NLP corpora,

[1] Readers unfamiliar with Tigre may find useful background and ongoing digitization efforts at https://beittigreai-resources.static.hf.space/.

[2] For the history and implementation of the policy, see Hailemariam et al. (1999) and Woldemikael (2003).

[3] Transliteration follows the Semitistic convention: ' marks alef and ' marks ayn.

[4] https://tig.wikipedia.org/

pre-trained language models, or public evaluation benchmarks.

The Tatoeba platform, a volunteer-contributed collection of mostly short, everyday sentences, hosts a larger parallel Tigre resource than the present dataset: its Tigre portion comprises 51,994 parallel sentence pairs, of which about 59% are paired with Arabic, 20% with English (10,546 pairs), 18% with Swedish, and 3% with German. The Tatoeba sentences are very short, averaging about four words, and typical examples are commands, questions, exclamations, and simple statements. By comparison, the SMOL contribution is English-centered, its sentence-level items average 14–15 English words, and it adds word-level and document-level items (Section 3.3), multi-stage review by two native-speaker groups, and the SMOL format used for massively multilingual training. The two resources are therefore complementary, and because they differ in data type and evaluation setup, we compare them descriptively rather than by translation quality.

### 2.5 Target Variety: Standardized Written Tigre

The dataset is written in a single variety: standardized written Tigre in the Ge'ez script. As part of its 1990s primary mother-tongue education initiative, the Eritrean government standardized a Ge'ez orthography and grammar baseline for Tigre, providing the language with its first formal state textbooks and classroom instruction. This standard is the variety used in primary school education, state journalism, and national media across Eritrea. The dataset does not encode dialect-specific forms: all text is in the standard orthography, and no per-example dialect labels are provided. Dialectal variation in Tigre is documented in detail by Idris (2015). The language is identified by ISO 639-3 code `tig` with script code `Ethi` (`tig_Ethi`); Glottolog code `tigr1270`.

## 3 Data Collection

The creation of the English–Tigre parallel dataset (SMOL) was organized as a collaborative translation and post-editing effort. Initiated by **BeitTigreAI** (huggingface.co/BeitTigreAI)—an open-source portal dedicated to Tigre language data and AI models—the initiative brought together diaspora communities to construct high-quality, human-annotated parallel text for downstream machine translation and language technology development.

### 3.1 Translator Background and Expertise

The translation and quality assurance process involved two distinct diaspora native-speaker groups comprising over 25 contributors in total:

- **Mahber Wlad Hayghet:** A group of more than ten individuals residing in the United States. Its members include many native speakers whose home area is Mansa (also spelled Mensa).
- **Tigre Language Digital Advancement Group (TLDAG):** A team of approximately 15 members based across Europe and the Middle East. Most members received their primary formal education in Eritrea, bringing native fluency in the standardized written Tigre used in official communication and contemporary media.

Both groups worked toward the same written standard (Section 2.5); they differ in location and background, not in target variety.

### 3.2 Machine Translation Disclosure and Workflow

To seed the initial parallel text, a preliminary translation draft was automatically generated using BeitTigreAI/tigre-nllb-200-3.3B, a fine-tuned model hosted on Hugging Face. The base NLLB-200-3.3B model predates SMOL and did not support Tigre until its tokenizer and embeddings were extended for the language, and this seed model was not trained on any SMOL sentences. Native speakers then executed a multi-tier human post-editing and quality assurance pipeline:

1. **MT Post-Editing & Initial Translation:** An individual contributor from one of the two groups post-edited the draft output generated by the seed MT model, correcting syntactic errors and lexical inaccuracies.

2. **In-Group Review:** The draft underwent two independent rounds of peer review by other members within the primary author's group to ensure natural phrasing and accurate semantic alignment.

3. **Cross-Group Quality Assurance (QA):** Once internal consensus was reached, the translated batch was transferred to the secondary group for cross-validation. The receiving team performed a joint review to check conformance to the standard orthography and usage, resolve remaining disagreements, and finalize the entry.

The two groups therefore acted as successive stages of a single pipeline, not as separate translators of parallel versions.

| Stage | Process | Responsible Party |
|---|---|---|
| 1. MT Draft | Automated translation generation | BeitTigreAI/tigre-nllb-200-3.3B |
| 2. Initial Post-Editing | Syntax and lexical correction | Single primary translator |
| 3. In-Group Review | Peer review, semantic alignment | 2 internal reviewers (same group) |
| 4. Cross-Group QA | Conformance to standard orthography and usage; final validation | Secondary group joint review |

Table 1: Translation and QA pipeline stages.

### 3.3 Dataset Composition

The 11,998 pairs come from 7,997 source entries across the three SMOL components (Table 2), of which 7,988 are distinct English strings. GATITOS contains 4,000 word- and phrase-level entries. An entry can have several accepted Tigre renderings (1 to 11; 2,267 of the 4,000 entries have more than one), and each rendering is listed as its own pair, which is why 4,000 entries give 8,001 pairs. SmolSent contributes 863 sentences, and SmolDoc contributes 3,134 sentences from 260 documents. Only the 3,997 SmolSent and SmolDoc pairs (about one third of the total) are sentence-level.

The data is two-way parallel and contains a single written variety. Each source entry went through the pipeline described above once; for GATITOS entries, the pipeline output may list several accepted renderings.

| Component | Entries | Pairs | Words En/Tig |
|---|---|---|---|
| GATITOS | 4,000 | 8,001 | 1.10 / 1.24 |
| SmolSent | 863 | 863 | 14.22 / 14.14 |
| SmolDoc | 3,134 | 3,134 | 15.19 / 13.62 |
| Total | 7,997 | 11,998 | 5.72 / 5.40 |

Table 2: Composition of the contributed data by SMOL component. Word counts are averages of whitespace-delimited tokens per pair; Tigre counts are computed on the normalized text used for training (Section 4.1).

### 3.4 Execution, Data Management, and Licensing

The end-to-end execution of the data collection effort spanned approximately nine months. The parallel data was distributed across three Google Sheets documents with restricted, role-based access control. Cross-group sync meetings and joint QA sessions were conducted weekly over Zoom, allowing the teams to discuss edge cases, standardize orthographic conventions in the Ge'ez script, and reach consensus on non-standard vocabulary.

To support future research and open-source NLP development for under-resourced Afro-Semitic languages, the finalized dataset is released under a **Creative Commons Attribution (CC-BY 4.0)** license, permitting free, unrestricted access, modification, and distribution. The data follows the SMOL file format, with one file per component (GATITOS, SmolSent, SmolDoc), and preserves the original Tigre text, including punctuation.

## 4 Experimental Validation

To validate the quality and usefulness of the contributed data, we fine-tuned the out-of-the-box Meta NLLB-200-3.3B checkpoint with its vocabulary extended to include Tigre (tig_Ethi)—distinct from the already Tigre-adapted BeitTigreAI/tigre-nllb-200-3.3B model used in Section 3.2 to seed the initial translation drafts.

### 4.1 Setup

**Vocabulary and initialization.** A SentencePiece model (13,618 pieces) trained on the Tigre side of the training split is merged into a frequency-trimmed NLLB vocabulary, adding 13,282 new tokens for a total of 57,151 pieces, and the embedding matrix is resized; after trimming, the model has about 2.94B parameters. Existing tokens keep their embeddings; new tokens are initialized as the mean embedding of their pieces under the original tokenizer; the new language code tig_Ethi is initialized from tir_Ethi (Tigrinya). The model has a single Tigre language code and no variety-selection control, since the data contains one variety.

**Data and training.** The pairs are split at random into 10,799 training and 1,199 validation pairs (seed 42) and used in both directions (English↔Tigre; 21,598 training examples). Stage 1 trains only the shared embeddings (117.7M parameters) for one epoch; stage 2 trains all parameters for three epochs. Both stages use AdamW, learning rate $10^{-4}$, batch size 16, 200 warm-up steps, weight decay $10^{-3}$, and maximum length 128 tokens. We use the final checkpoint; the validation split is not used for model selection or early stopping. Results come from a single run.

**Preprocessing.** Tigre text is normalized to Ge'ez letters and whitespace for training and scoring: punctuation, digits, and Latin characters are removed. This changed 4,084 of the 11,998 targets (nearly all SmolSent and SmolDoc sentences). Because deletion inserts no space, in 518 targets (4.3%) punctuation sat directly between letters, so its removal fused neighboring words; Latin letters or digits were also removed from 272 targets. The released files keep the original text (Section 5).

**Evaluation.** We evaluate on the 1,199 held-out pairs in both directions using chrF++ (word order 2) and BLEU, both computed with sacreBLEU 2.6.0 (Papineni et al., 2002; Popović, 2015, 2017), with default metric and decoding settings. We compare against an untrained baseline: the same vocabulary-extended stock model prior to any Tigre fine-tuning, decoded with tig_Ethi as the forced target-language token, isolating the contribution of the training data itself from the tokenizer/embedding initialization.

| Direction | Model | chrF++ | BLEU |
|---|---|---|---|
| En→Tig | No fine-tuning | 4.92 | 0.10 |
| En→Tig | Fine-tuned | 21.63 | 6.74 |
| Tig→En | No fine-tuning | 10.11 | 0.19 |
| Tig→En | Fine-tuned | 29.62 | 12.33 |

Table 3: Translation quality on the 1,199 held-out pairs before (vocabulary-extended NLLB-200-3.3B, no fine-tuning) and after fine-tuning on the contributed data.

### 4.2 Results

Fine-tuning on the contributed data yields about a 4.4× improvement in English-to-Tigre chrF++ (4.92 to 21.63) and a BLEU gain from near-zero, with gains in the reverse direction as well (10.11 to 29.62 chrF++; Table 3), demonstrating that the dataset provides meaningful, learnable signal for English–Tigre translation despite its modest size. The baseline starts from a very low base, since the model has not seen Tigre text and the tig_Ethi embedding is initialized from Tigrinya, so the ratio should be read accordingly.

Table 4 breaks the scores down by SMOL component. Two thirds of the validation set (807 of 1,199 pairs) are single words or short phrases, which score lowest, so the overall figures mostly reflect the mix of word-level and sentence-level items. SmolDoc scores highest (25.50 chrF++ English to Tigre). SmolSent has only 101 validation pairs, so its BLEU is unstable. GATITOS items are scored against a single reference although several renderings may be acceptable, which lowers their scores.

### 4.3 Limitations

We note an important limitation of this validation: the held-out set (1,199 pairs) is drawn from the same distribution and collection process as the training data, rather than from an independent benchmark, since Tigre does not currently appear in FLORES-200/FLORES+ and no established external benchmark exists for this language pair. Evaluating on held-out portions of one's own training data is a comparatively weak signal of true generalization and can often tell one relatively little beyond confirming the data is learnable; we

| Component | Model | Pairs | En→Tig chrF++ / BLEU | Tig→En chrF++ / BLEU |
|---|---|---|---|---|
| GATITOS | No fine-tuning | 807 | 2.44 / 2.38 | 5.53 / 0.03 |
| | Fine-tuned | | 10.45 / 9.17 | 17.48 / 17.88 |
| SmolSent | No fine-tuning | 101 | 5.27 / 0.14 | 11.11 / 0.19 |
| | Fine-tuned | | 17.16 / 1.62 | 21.53 / 1.91 |
| SmolDoc | No fine-tuning | 291 | 5.43 / 0.12 | 10.96 / 0.29 |
| | Fine-tuned | | 25.50 / 8.62 | 35.49 / 16.02 |

Table 4: Scores by SMOL component on the held-out pairs.

present these results accordingly, as a lower-bound demonstration that the dataset carries meaningful signal rather than as a definitive measure of translation quality. The absolute BLEU score is modest, which is expected given the corpus size and limited fine-tuning epochs. The data also spans multiple sources and styles (SMOL combines GATITOS, SmolSent, and SmolDoc) rather than a single genre, which may further affect metric stability.

The split is random at pair level, so training and validation overlap. 605 of the 1,199 validation English sources (50.5%) also occur in training, almost all of them GATITOS words (604 of 807) whose other Tigre renderings are in training; only one validation pair is an exact duplicate of a training pair. All 164 SmolDoc documents in the validation set also contribute sentences to training. On the 594 validation pairs whose English source is not in training, the fine-tuned model scores 23.07 chrF++ and 6.98 BLEU English to Tigre, close to the overall 21.63 and 6.74, but this subset contains proportionally fewer GATITOS words, so the comparison reflects composition as much as overlap. Results are from a single run with one hyperparameter setting, and the normalization described above (punctuation and digits removed) means the reported scores do not measure punctuation or numerals. We see establishing an independent benchmark for Tigre, potentially via a FLORES+ contribution, as important future work enabled by this dataset.

## 5 Data Sample

Table 5 (last page) shows representative GATITOS and SmolSent pairs in their released form, with punctuation. Where a GATITOS entry has several renderings, only one is shown.

## 6 Conclusion

This SMOL contribution is one of several ongoing language-technology initiatives undertaken by the Tigre diaspora community, alongside a separately underway effort to translate the FLORES evaluation set into Tigre, which we expect will provide the independent benchmark this work's evaluation currently lacks.

# A French Version of the SMOLSENT Corpus

**Malik Marmonier** **Rachel Bawden** **Benoît Sagot**
Inria, Paris, France
{firstname.lastname}@inria.fr

## Abstract

We present a French version of the SMOLSENT corpus, a contribution to the WMT 2026 Open Language Data Initiative (OLDI) shared task. Originally curated to maximize unique-word coverage across 863 English sentences, SMOLSENT constitutes a valuable, token-efficient training set for the machine translation of low-resource languages. We describe our translation workflow, which relied on a custom-built interface to select and refine translation hypotheses generated by a traditional encoder-decoder model, alongside two state-of-the-art reasoning-enabled large language models (LLMs). Experimental validation based on the MetricX-24-XXL model for quality estimation, supported by bootstrap resampling significance tests, indicates that human post-editing results in significant quality improvements over all raw model outputs, even as reasoning models like Gemma-4-31B-it achieve a competitive 39.51% zero-edit rate. This French partition is not an end in itself, but a pivot resource meant to facilitate ongoing data collection efforts for under-resourced regional languages of France, such as Savoyard and Gallo.

## 1 Introduction

While machine translation (MT) has advanced tremendously in recent years, its progress remains overwhelmingly concentrated on a small set of high-resource languages (Joshi et al., 2020; Haddow et al., 2022). For most language varieties, the development of state-of-the-art MT systems is hampered by a lack of quality training and test data. The WMT Open Language Data Initiative (OLDI) shared tasks (Burchell et al., 2024; Dale et al., 2025) aim to redress this imbalance by empowering language communities to expand key foundational datasets. We contribute to this effort by compiling a French version of the SMOLSENT dataset (Caswell et al., 2025). Originally curated to maximize unique-word coverage across 863 English sentences, SMOLSENT constitutes a valuable, token-efficient training set for low-resource MT.

Since French is a high-resource language, this new partition is naturally not an end in itself; rather, it is meant to serve as a pivot for the under-resourced languages of France, such as Savoyard, Réunion Creole, or Gallo, languages which typically exist in a diglossic relationship with French and whose translators are predominantly native French speakers likely to benefit from a French source text or to need it as a prerequisite.

In the following sections, in compliance with shared task requirements, we present the French language, our data collection process, which followed a machine-translation-post-editing (MTPE) approach, and the results of validation experiments conducted through quality estimation.

## 2 Linguistic Overview

French is a Romance language.[1] It evolved from Vulgar Latin, which was brought into Northern Gaul by the Roman conquest and gradually replaced the local Celtic languages, taking hold first in urban centers before spreading across the wider territory (Rickard, 2014). This spoken Latin was markedly influenced by the Germanic languages of the fifth-century invaders who toppled the Roman Empire, and particularly by that of the Franks, which caused the loss of final unstressed syllables,[2] initiating a process of phonetic erosion that starkly distinguishes French from its southern Romance counterparts to this day. By the ninth century, this spoken vernacular had diverged so much from Latin that it was recognized as a distinct language, with the Oaths of Strasbourg of 842 considered the earliest French written document. In the following centuries, the dialect of the Île-de-France region

[1] Some parts of this section draw closely on material and language from our previous work (Marmonier et al., 2025).

[2] This point is now debated, however; see (Marchello-Nizia, 1995; Noske, 2009).

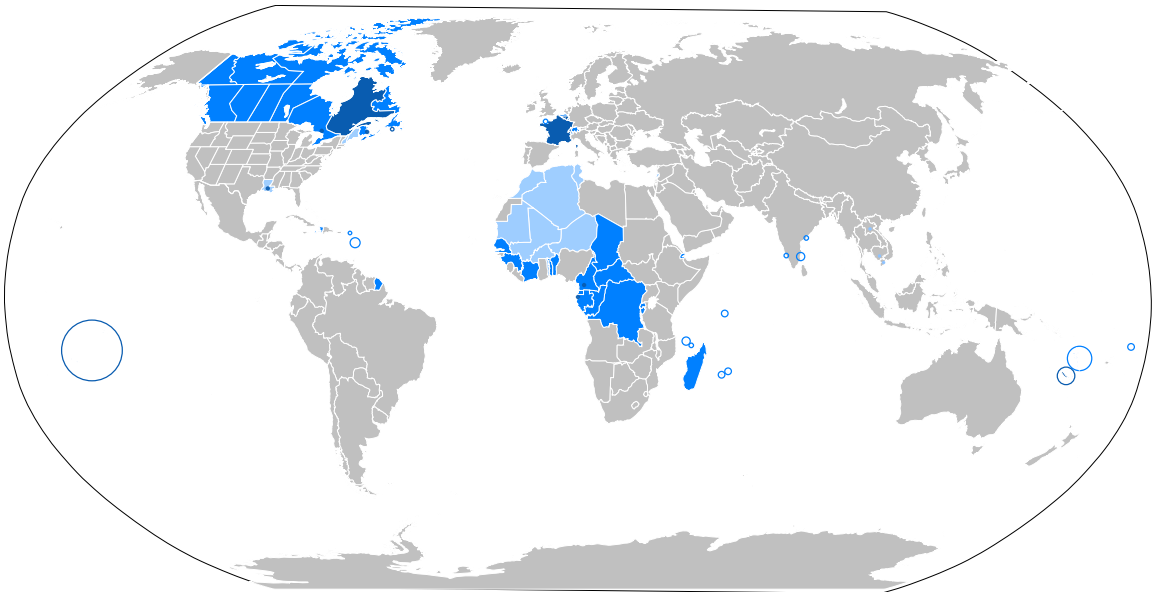

Figure 1: The French language in the world. States where French is the majority native language; states where it is a *de jure* official language; states where it is an administrative language or is culturally important without holding official status. Map by Wikimedia Commons contributors.

(Francien) began to emerge as a standard due to the political and cultural prominence of Paris.

This Old French still maintained a two-case declensional system and was written according to heterogeneous spelling conventions. The Middle French period—spanning the fourteenth to early seventeenth centuries—saw the final collapse of this two-case system and significant phonological changes, such as the muting of final consonants, making French spelling increasingly complex and etymological—a property for which French is faulted to this day by second-language learners and native speakers alike. The 1539 Ordinance of Villers-Cotterêts established French as the exclusive language of legal and judicial proceedings in the Kingdom of France, while scholars and poets like Joachim du Bellay fiercely defended it as a literary medium capable of rivaling both Latin and Greek (Du Bellay 2008 [1549]). During this time, French vocabulary expanded massively through deliberate borrowings from Latin, Greek, and Italian, at times replacing older Germanic loanwords. In the seventeenth century, the French language underwent rigorous codification and standardization, spearheaded by grammarians like de Malherbe (1862, [1606]) and Favre de Vaugelas (2009, [1647]), as well as the newly founded *Académie Française*.

This classical era established a rigid linguistic standard that remained the preserve of a privileged elite until the profound social upheavals of the French Revolution at the end of the eighteenth century. The revolutionary government viewed the linguistic fragmentation of France as a direct threat to national unity and republican ideals (Grégoire, 1794). This ideological stance drove the First French Republic to actively repress and attempt to destroy minority languages and regional dialects, an aggressive nation-building effort systematically enforced through a highly centralized administration, universal military conscription, and later through compulsory state education. Concurrently, the French language was exported globally through France's expanding colonial empire, initially to the Americas and the Caribbean, where colonization and the slave trade gave rise to French-based creoles, and later to territories across Africa, the Far East, and Oceania, and French consequently became a major international language.

Today, the latest report of the *Organisation Internationale de la Francophonie* (OIF) estimates the global Francophone population at 396 million, ranking French as the fourth most spoken language worldwide (Organisation internationale de la Francophonie, 2026). However, this demographic optimism relies heavily on a new counting method that includes millions of young African schoolchildren and masks a contested geopolitical reality. French is experiencing significant pushback in its former colonies, losing ground to both indigenous

languages and English. Following similar constitutional downgrades by Mali and Burkina Faso, Niger officially demoted French to a mere "working language" in early 2025, elevating Hausa to the status of national language. Underscoring this anti-colonial sentiment, all three Sahelian nations formally withdrew from the OIF in March 2025. French also faces fierce competition from English in North African educational systems and a continuous decline in second-language learner enrollments internationally (Lusin et al., 2023; Collen and Duff, 2025). English pressure, moreover, is not confined to France's former colonies: within France itself, English also dominates high-prestige domains like scientific publishing (OST, 2024) and higher education, and increasingly encroaches on the domestic sphere, with some scholars arguing that a dramatic surge of anglicisms across media, everyday speech, and corporate branding is reshaping the French language itself, in effect turning English into a linguistic superstratum within France (Meney, 2024)—a claim other linguists dispute (Les Linguistes atterrées, 2023).

Despite these trends, French still retains substantial international standing, making it a valuable pivot for future data collection efforts targeting the under-resourced languages of France and its former colonies. France French is one of several standardized varieties of French; owing to its extensive documentation, we adopted it as the target variety for our corpus.

## 3 Data Collection

In order to produce the French partition of SMOLSENT, we adopted an MTPE workflow, a *de facto* norm in the translation industry, particularly for the English-French language pair (International Organization for Standardization, 2017; ELIS Research, 2026). We obtained a set of three candidate translations per source segment, using three distinct systems comprising a "traditional" NMT model—NLLB-200 3.3B (NLLB Team, 2024)—and two reasoning LLMs—Gemma-4-31B-it (Google DeepMind, 2026) and DeepSeek V4 Pro (DeepSeek-AI et al., 2026).

For NLLB-200 3.3B, inference was conducted on the Jean Zay HPC cluster in FP16 precision via the `transformers` library (Wolf et al., 2020), using beam search decoding with a beam size of 4.

For the LLMs, we crafted zero-shot prompts—one per source segment—giving the models the persona of an expert English-French translator, asking for an accurate and fluent French translation of the English source segment, targeting the France French locale. The prompts encouraged the models to reflect on the task prior to outputting the final target-language segment between specified `<translation>...</translation>` XML tags. We provide a prompt sample in Appendix A.

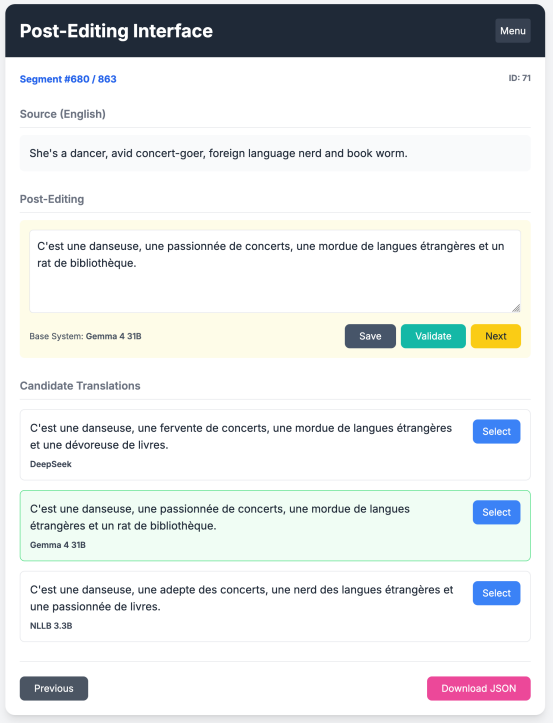

Figure 2: Our custom-built post-editing interface, adapted from Marmonier et al. (2025).

Gemma-4-31B-it's reasoning mode was triggered through the addition of a <|think|> token at the beginning of its system prompt, and inference was conducted on the Jean Zay HPC cluster via the vLLM framework (Kwon et al., 2023), with a sampling temperature of 0.3.

For DeepSeek V4 Pro, candidate translations were obtained via the official DeepSeek API with the model's reasoning effort set to "high", the lowest of the two settings available via the API at the time.[3]

The candidate translations were extracted from LLM output through regular expressions targeting the specified XML tags and loaded into an online post-editing interface we adapted from previous work (Marmonier et al., 2025). The interface presented each source segment with the three previ-

[3]The DeepSeek API silently ignores any temperature parameter passed while reasoning mode is enabled; the value used internally in this mode is not documented.

ously generated candidate translations and allowed the annotator to select the most promising translation hypothesis as a starting point and refine it in an editable text field (see Figure 2). The post-editors were the first and third authors of this work, both native French speakers with C2 command of English and translation experience.[4]

The SMOLSENT corpus was pleasant to translate, with minimal terminological challenges (compared to OLDI Seed, for instance) and no insurmountable complications resulting from disfluencies in the crawled source segments.[5] Out of the 863 segments that make up SMOLSENT, 495 (57.36%) required no alteration in post-editing, which is not unexpected for the language pair at hand.[6] A breakdown of these zero-edit matches reveals a clear advantage for the reasoning LLMs, with Gemma-4-31B-it and DeepSeek V4 Pro producing the final, unaltered translation for 39.51% (341 segments) and 25.26% (218 segments) of the total corpus, respectively. Conversely, the traditional NLLB-200 model lagged significantly behind its larger counterparts, generating a zero-edit candidate for a mere 3.13% (27 segments) of the compiled dataset.

The final version of the dataset was reviewed manually in the Grammalecte interface,[7] and all its quotation marks and apostrophes were normalized to their straight forms (" / " and '), rather than French guillemets (« / ») and curly apostrophes (’), against official stylistic conventions but in keeping with actual contemporary French digital writing practices.[8]

We provide a random sample of the compiled data in Appendix B.

[4]The second author, a native English speaker with C2 command of French, was consulted on occasion to dispel ambiguities in the source segments.

[5]Segment #743 “The entire castle of every Disney movie has featured a logo in the shape of an ‘s’!” was the only one whose meaning was not immediately transparent.

[6]We note that a segment being left unaltered does not reflect the silent post-editing work involved in verifying the correctness of its terminology, for instance.

[7]https://grammalecte.net/

[8]We note that this normalization operation was deliberately performed after the reported zero-edit matches were computed rather than during the post-editing work so as to not artificially distort these figures with trivial alterations. Should users require strict adherence to official typographical norms, restoring standard French guillemets and curly apostrophes from their straight counterparts is a trivial operation using regular expressions.

## 4 Experimental Validation

To assess the quality of the compiled French partition and measure the added value of human post-editing over raw system outputs, we evaluated all candidate translations alongside the final post-edited dataset using MetricX-24-XXL[9] (Juraska et al., 2024) in a reference-free Quality Estimation (QE) configuration. MetricX-24 scores predict translation error on a continuous scale from 0 to 25, where lower values denote higher translation quality.

Table 1 presents the mean MetricX-24-XXL scores across all 863 segments. To determine whether the differences in translation quality between “systems” were statistically significant, we conducted paired bootstrap resampling tests (Koehn, 2004), with $10,000$ resamples across all pairwise system combinations (see Figure 3).

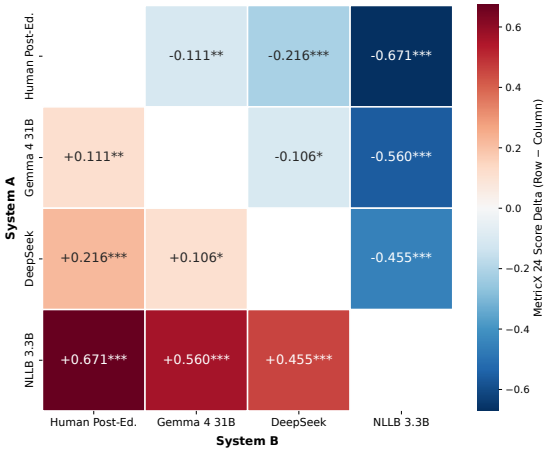

Figure 3: Heatmap of MetricX-24-XXL score differences between raw system outputs and human post-edits. Negative deltas (blue) indicate that the row system outperforms the column system. Statistical significance was computed via paired bootstrap resampling ($10,000$ iterations); asterisks denote significance level ($^{*}: p \leq 0.05$, $^{**}: p < 0.01$, $^{***}: p < 0.001$).

| System | MetricX-24-XXL (↓) |
|---|---|
| NLLB-200 3.3B | 3.1143 |
| DeepSeek V4 Pro | 2.6595 |
| Gemma-4-31B-it | 2.5540 |
| **Human Post-Ed.** | **2.4434** |

Table 1: Mean MetricX-24-XXL Quality Estimation scores across all 863 segments. Lower is better.

The validation results highlight three key empirical observations.

[9]metricx-24-hybrid-xxl-v2p6

**Human post-editing results in statistically superior quality** The final post-edited dataset achieved the best overall score (2.4434), demonstrating significant quality gains over all raw model outputs—including Gemma-4-31B-it ($\Delta = -0.111, p < 0.01$), DeepSeek V4 Pro ($\Delta = -0.216, p < 0.001$), and NLLB-200 3.3B ($\Delta = -0.671, p < 0.001$).[10]

**Reasoning LLMs outperform traditional NMT** Both reasoning-enabled LLMs generated significantly higher quality candidate translations than the traditional NLLB-200 3.3B baseline (3.1143). Among the raw candidate systems, Gemma-4-31B-it achieved the strongest performance (2.5540), followed by DeepSeek V4 Pro (2.6595).

**Strict system hierarchy** Pairwise significance tests reveal a clear ranking among automated systems. Gemma-4-31B-it significantly outperformed DeepSeek V4 Pro ($\Delta = -0.106, p < 0.05$), while both LLMs demonstrated a massive, statistically significant lead over NLLB-200 3.3B ($\Delta = -0.560$ and $\Delta = -0.455$, respectively; $p < 0.001$).

## 5 Related Work

Data-driven approaches to MT have been explored as early as the 1950s (Edmundson and Hays, 1958), but only came into their own in the early 1990s thanks to the pioneering work on statistical MT (SMT) of IBM researchers (Brown et al. 1990; Berger et al. 1994).[11] Anecdotally, the French-English language pair played a central role in these seminal efforts, largely thanks to the Canadian Hansard, a bilingual record of parliamentary proceedings. This role was so central, in fact, that a lasting convention in SMT literature consisted in using the letters $f$ and $e$ as the standard variables denoting source ($f$rench) and target ($e$nglish) language strings in equations, regardless of the actual languages considered.

Caswell et al. (2025) compiled SMOLSENT together with the larger SMOLDOC corpus as the two sentence- and document-level components of SMOL, an initiative that also incorporates the older GATITOS corpus of parallel wordlists (Jones et al., 2023) and is continuously extended through volunteer efforts.[12]

SMOL is one of several open datasets targeted by the OLDI shared task (Burchell et al., 2024; Dale et al., 2025) in order to grow foundational MT resources through community contributions. Among these are also the OLDI Seed corpus (originally the NLLB Seed corpus; NLLB Team et al., 2022; Maillard et al., 2023; Cols, 2024; Ferrante, 2024; Haberland et al., 2024; Ahmed et al., 2024; Marmonier et al., 2025; Oktem et al., 2025), the FLORES+ benchmark (Goyal et al., 2022; NLLB Team, 2024; Gordeev et al., 2024; Kuzhuget et al., 2024; Ali et al., 2024; Abdulmumin et al., 2024; Perez-Ortiz et al., 2024; Mæhlum et al., 2025; Oktem et al., 2025; Frontull et al., 2025; Lou et al., 2025; Samil and Adelani, 2026), and test sets such as NTREX-128 (Federmann et al., 2022), WMT24++ (Deutsch et al., 2025; Vamvas et al., 2025) and BOUQuET (Andrews et al., 2025). The present submission is a small step in this effort—fittingly, on the SMOL side.

## 6 Conclusion

We have presented a French partition of the SMOLSENT corpus, produced through an MTPE workflow in which candidate translations from NLLB-200 3.3B, Gemma-4-31B-it, and DeepSeek V4 Pro were selected and refined by native French speakers in a dedicated interface. Of the 863 source segments, 57.36% had at least one candidate translation that required no alteration on the part of the post-editors, with the reasoning-enabled LLMs accounting for the vast majority of these zero-edit matches. Quality estimation with MetricX-24-XXL nevertheless shows that human post-editing yields statistically significant gains over every raw system output, indicating that strong state-of-the-art LLMs still benefit from human revision, even for a high-resource language pair such as English-French.

This partition is intended primarily as a pivot resource for the regional languages of France, whose translators are typically native speakers of French. It has already served a similar purpose in a companion submission to the present shared task, where its French segments were used as the source side of a synthetic data pipeline for French→Savoyard translation.

[10] We further note that our choice to normalize the quotation marks and apostrophes to their straight forms might slightly penalize the human post-edited translations in the eyes of MetricX-24.

[11] Elements of this section draw closely on language from our previous work (Marmonier et al., 2025).

[12] See https://huggingface.co/datasets/google/smol.

## Limitations

We acknowledge two related primary limitations arising from this work.

First, because the English source segments are isolated sentences drawn from a broader web crawl, their original document-level context was not easily recoverable. To account for the resulting ambiguity, our post-editing strategy favored translations that preserved the widest plausible range of meanings, rather than committing to a single, context-dependent reading. This cautious approach occasionally came at the cost of stylistic fluency and naturalness in the target language.

Second, our reliance on a machine translation post-editing (MTPE) workflow introduces the well-documented risk of translationese (Zhang and Toral, 2019; Graham et al., 2020). Even with careful human revision, target segments generated via MTPE may retain lexical or syntactic traces of their English source material—a phenomenon sometimes called "interference" by translation scholars (Toury, 1995) and generally considered to be a universal property of translated texts, but one that is likely more pronounced in an MTPE setting (Toral, 2019).

## Acknowledgments

This work was funded by the French *Agence Nationale de la Recherche* (ANR) under the project TraLaLaM ("ANR-23-IAS1-0006"), as well as by Inria under the "*Défi*"-type project COLaF. It was also partly funded by Benoît Sagot's chair in the PRAIRIE-PSAI institute, funded by the ANR as part of the "France 2030" strategy under the reference ANR-23-IACL-0008.

This work was also granted access to the HPC resources of IDRIS under allocations 2025-AD011015117R2, 2025-AD011012254R5 and 2025-AD011017228 made by GENCI. The authors acknowledge the use of LLMs as coding assistants during the implementation of this work.

The authors wish to thank Isaac Caswell for providing valuable assistance during the initial phase of this project.

## A Prompt Sample

The following are populated examples of the system and user prompts used to obtain translation hypotheses from Gemma-4-31B-it and DeepSeek V4 Pro.

**System Prompt**

You are an expert translator. Your working languages are English and French.

**User Prompt**

Translate the following English segment into French (for the France locale). Provide a high-quality translation that is both accurate and fluent. You can reflect on the task, prior to producing your final translation. Your final translation must, however, be wrapped inside XML tags thusly: `<translation>your translation here</translation>`

Here is the English segment you must translate:
**Processes outgoing mail, maintains files, orders supplies, and ships packages.**

## B Data Sample

We provide a random sample of the compiled dataset in Table 2.

| ID | English Source | French Translation |
|---|---|---|
| 53 | The injured boy lost consciousness and fell to the pavement and his blood imbued the road dust. | *Le garçon blessé perdit connaissance et tomba sur la chaussée, et son sang imprégna la poussière de la route.* |
| 274 | Drop by and say hello; stay strong and live awesome, my friend. | *Passe dire bonjour ; reste fort et vis ta vie à fond, mon ami.* |
| 613 | Madam, your glasses are fogged up! | *Madame, vos lunettes sont embuées !* |
| 787 | He tells me he originally tried the injection technique and, as he expected, it was too fiddly and gave him zero success. | *Il me dit qu'il a d'abord essayé la technique de l'injection et que, comme il s'y attendait, c'était trop fastidieux et ne donnait aucun résultat.* |
| 417 | What I mean is, you can't buy stuff cheap and sell it dear. | *Ce que je veux dire, c'est qu'on ne peut pas acheter des trucs bon marché et les revendre cher.* |
| 286 | You can arrange in rows, in a circular pattern, whatever takes your fancy. | *Vous pouvez les disposer en rangées, en cercle, ou comme bon vous semble.* |
| 806 | Sets were moved, lighting was adjusted, and actors made costume changes. | *Les décors ont été déplacés, l'éclairage a été ajusté et les acteurs ont changé de costume.* |
| 372 | If you missed the signs of the first stage, you will not have a clue that the cow should have already delivered a calf. | *Si vous avez manqué les signes du premier stade, vous ne vous rendrez pas compte que la vache aurait déjà dû vêler.* |
| 32 | So, considering the ratio of net value added to gross output does not yield a complete picture. | *Ainsi, le rapport entre la valeur ajoutée nette et la production brute ne permet pas d'obtenir une vision complète.* |
| 667 | Use fresh basil, flax oil, or virgin coconut oil and replace the cheese with yeast. | *Utilisez du basilic frais, de l'huile de lin ou de l'huile de coco vierge, et remplacez le fromage par de la levure.* |

Table 2: Random sample of ten sentence pairs from the French partition of the SMOLSENT dataset.

# A Savoyard Version of the FLORES+ Corpus

**Malik Marmonier**[†] **Alain Favre**[‡] **Benoît Sagot**[†] **Rachel Bawden**[†]
[†]Inria, Paris, France [‡]Institut de la langue savoyarde
{firstname.lastname}@inria.fr[†] {firstname.lastname}@langue-savoyarde.com[‡]

## Abstract

We present a Savoyard version of the FLORES+ corpus, a contribution to the Open Language Data Initiative (OLDI) shared task at WMT 2026. Savoyard, an endangered Arpitan dialect of the Gallo-Romance language family, is currently undergoing active revitalization. We give an overview of its linguistic history, describe our data collection process, and report baseline scores for a range of systems on the resulting French↔Savoyard evaluation set as a point of comparison for future work. We hope that this dataset will stimulate further data collection efforts for Savoyard and the broader Arpitan dialect continuum, supporting the development of NLP resources for these endangered languages and contributing to the preservation of humanity's linguistic heritage.

## 1 Introduction

Machine Translation (MT) has advanced considerably over the past four decades (Brown et al., 1990; Koehn et al., 2003; Sutskever et al., 2014; Bahdanau et al., 2015; Vaswani et al., 2017). This progress owes much to the field's departure from evaluation practices based on nebulous, self-reported notions of linguistic coverage in favor of shared, empirical evaluation frameworks (Liberman, 2010). Yet these advances have primarily benefited a handful of dominant languages, leaving lower-resourced varieties largely excluded (Joshi et al., 2020; Haddow et al., 2022). Addressing this disparity requires extending the same empirical evaluation rigor that drove earlier advances to low-resource settings.

It is explicitly to this end that the FLORES+ dataset was initially compiled (Goyal et al., 2022, as Flores-101) and continuously expanded (NLLB Team, 2024; Gordeev et al., 2024; Kuzhuget et al., 2024; Ali et al., 2024; Abdulmumin et al., 2024; Perez-Ortiz et al., 2024; Mæhlum et al., 2025; Oktem et al., 2025; Frontull et al., 2025; Lou et al., 2025; Samil and Adelani, 2026, *inter alia*), establishing a standardized evaluation framework for more than 200 languages and script variants, with a deliberate focus on otherwise underrepresented languages.

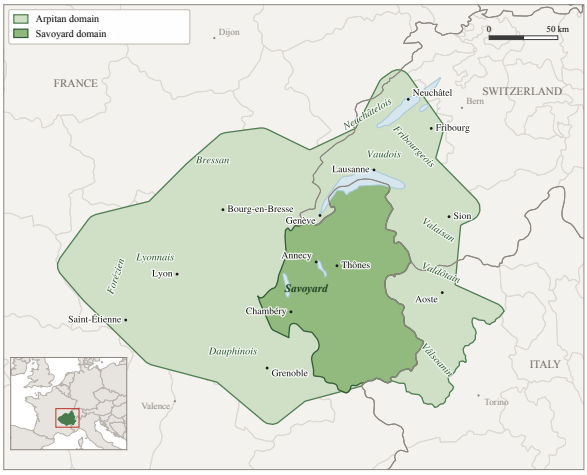

Figure 1: The Arpitan dialect continuum, with the Savoyard domain in a darker green. Outer boundaries are schematic renderings based on (Kristol, 2016) and French Wikipedia maps; political borders and hydrography are drawn from Natural Earth.

As a direct extension of these past efforts, our work presents a version of the FLORES+ corpus in the Savoyard language, an endangered Arpitan dialect of the Gallo-Romance family currently the object of active revitalization efforts. In the following sections, we provide an overview of the linguistic history of Savoyard, present our data collection process, and report various baseline performance scores on the resulting evaluation set.

We hope that this dataset will stimulate further data collection efforts for Savoyard and the broader Arpitan dialect continuum, ultimately supporting the development of NLP resources to aid in the preservation of these endangered languages.

## 2 Language Overview

### 2.1 What's in a name: Arpitan, Franco-Provençal, or Francoprovençal?

Latin, implanted across Gaul in the wake of the Roman conquest, gave rise to a family of Romance vernaculars spanning modern France and Belgium, together with parts of Switzerland and northern Italy. These "Gallo-Romance" languages were long divided into two branches along a north–south axis, named for their medieval reflexes of Latin *hoc* ('yes'): the *langues d'oïl* of the north (Smith, 2016), chief among them French, and the *langues d'oc*, or Occitan, of the south (Oliviéri and Sauzet, 2016)—echoing a classification of the Romance vernaculars famously articulated by Dante in the early 14th century (Alighieri, 1996). A third grouping went unrecognized until Ascoli (1878) demonstrated, on phonetic grounds, that the dialects of east-central France, French-speaking Switzerland, and the Aosta Valley of Italy form a coherent group, neither varieties of an Oc or Oïl language nor a mixture of both, but constituting a distinct linguistic development characterized by its own treatment of the Latin substratum.

Ascoli baptized this new grouping *franco-provenzale* ('Franco-Provençal'), a hyphenated name that—in yoking together the labels of an Oïl and an Oc language—seemed to some to announce precisely the hybrid status his analysis had refuted, and the label has therefore been faulted ever since (Tuaillon, 1983). In an attempt to mitigate this perceived misnomer, later scholars suppressed the hyphen, *Francoprovençal*, recasting the two elements as a unified linguistic sign (Tuaillon, 1983)—a spelling now standard in the scientific literature (Kristol, 2016). Nonetheless, this solution was deemed unsatisfactory by language activists who promoted the neo-endonym "Arpitan" as a replacement (from a local root *arp-* 'mountain pasture').[1] Once contentious for its separatist and ethno-nationalist overtones in the Italian context that birthed it (Bichurina, 2019), the term "Arpitan" has since been largely depoliticized and is seeing growing institutional adoption. It has now supplanted *Franco-Provençal* and *Francoprovençal* as the reference name of the language under SIL.[2] It is also the term preferred by the *Institut de la langue savoyarde*—whose translation services produced the FLORES+ partition this paper presents—to refer to the broader language grouping to which Savoyard belongs.

### 2.2 Savoyard

Savoyard[3] is a subset of the Arpitan dialect continuum. It denotes the Arpitan varieties historically spoken in the County of Savoy—a feudal state of the Holy Roman Empire founded in 1003 and raised to a duchy in 1416, which straddled the modern French–Italian–Swiss alpine borders, with its Arpitan-speaking core comprising the present-day French *départements* of *Savoie* and *Haute-Savoie*, and most of the Swiss Canton of Geneva.[4]

As Latin receded from administrative and literary use in the late European Middle Ages, Romance vernaculars—such as French or the various dialects of the Italian city-states—moved into the registers it vacated. Arpitan did so outside Savoy, to a limited extent.[5] Savoyard, however, was deprived

[1] As is often the case with stigmatized vernaculars in French-speaking diglossic contexts, the actual endonym is the pejorative term "*patois*/*patouè*".

[2] https://iso639-3.sil.org/code/frp; we note that ISO 639-3 code is still `frp`.

[3] Glottocode `savo1253`. We follow Glottolog in using "Savoyard," though we note that the Institut de la langue savoyarde prefers "Savoyan" as the English name of the language.

[4] Excluding the city of Geneva itself.

[5] For instance, in the Lyonnais, in the devotional writings of

of such an opportunity due to the Duchy's early adoption of French as the language of its court and chancery.[6] It was therefore left without the administrative or literary functions through which other vernaculars acquired prestige.

The prestige of Savoyard nonetheless improved markedly in the 19th century, when an abundant literature written in Savoyard began to emerge, prompted by Romantic interest in folklore and popular tradition (Bichurina and Dunoyer, 2021), with poet Amélie Gex (1835–1883) as its most accomplished representative. This development, however, was cut short by the annexation of Savoy to France in 1860. Aggressive French nation-building policies had long identified linguistic diversity with anti-republican feudalism (Grégoire, 1794), and the vernaculars—now uniformly denigrated as *patois*—were driven out of public life across France. In Savoy, this process was particularly virulent, compressed as it was into a shorter time span due to the region's more recent inclusion into the French polity, and the school system was its principal instrument: children were forbidden to speak Savoyard, humiliated and punished when they did, translating political assimilation into practices of *de facto* linguicide (Skutnabb-Kangas, 2000).

Revitalization efforts began in earnest in the second half of the 20th century, as the vocabulary of decolonization was taken up by minority-language communities in the First World itself, and gathered pace around the turn of the millennium, when the framing of language loss in terms borrowed from environmental conservation entered French public debate and inflected public policy (Bichurina, 2019).

A late-1980s estimate placed the number of Savoyard speakers at approximately 30,000 (Tuaillon, 1989), though reliable counts remain difficult to establish (Boutillier, 2022). Indeed, recent sociolinguistic work—the FORA survey (Bert and Costa, 2009) and subsequent fieldwork by Bichurina and Dunoyer (2021)—reveals a complex linguistic landscape characterized by four main categories of speakers. The "native" or traditional speakers, generally aged between 80 and 90 years old, acquired the language in early childhood but their use of Savoyard often remains invisible in the public sphere due to past stigmatization. In contrast, "late" speakers—predominantly educated retirees in their 60s and 70s who had limited exposure to Savoyard in their childhood but re-engaged with the language in adulthood—are highly visible and drive preservation efforts through dedicated associations. Alongside these, a small but growing group of "new" speakers, primarily teenagers and young adults, approach Savoyard as a learned language, driven by broader cultural motives. Finally, the landscape includes a vast pool of "passive speakers" who comprehend the language but struggle to express themselves in it. Because these individuals can rapidly transition into active speakers within supportive environments, their fluctuating proficiency complicates attempts to establish static speaker counts.

While a comprehensive linguistic description of Savoyard falls outside the scope of this paper,[7] its defining characteristic—marked dialectal fragmentation—is highly relevant to corpus building. As an Arpitan variety, Savoyard exhibits significant micro-linguistic diversity, exacerbated over centuries by the geographic isolation of alpine valleys. This diversity extends beyond lexical variations to encompass morphological and phonetic divergences, where the evolution of shared Latin roots often differs from one village to the next. In a computational context, this significant local variance presents a unique modeling challenge, underscoring the necessity of a supra-dialectal orthography capable of unifying these diverse variants.

### 2.3 Revitalization and Written Standards

Savoyard revitalization efforts rest mainly on networks of private non-profit associations: the local *groupes patoisants* and, since 2002, the *Institut de la langue savoyarde*.[8] A persistent barrier to the revitalization of Savoyard—and Arpitan more broadly—through French public education stemmed from the absence of a unified orthography. Despite a softening stance toward regional languages, the French state's ideological framework still equates linguistic legitimacy with a codified written standard (Bichurina and Dunoyer, 2021). This text-centric ideology historically underpinned the *loi Deixonne* (1951)—the foundational law for the teaching of regional languages in

the mystic Marguerite d'Oingt (d. 1310), and in the Dauphiné, where Justinian's *Institutes* were rendered into the dialect of Grenoble (Bichurina and Dunoyer, 2021).

[6] An early adoption that predated even that of the French Kingdom. The neighboring Republic of Geneva replaced Latin with French on a similar timeline, and to the equal detriment of the local Arpitan vernacular.

[7] See (Désormaux, 1981) and (Viret, 2015) for detailed accounts and additional references.

[8] In Savoyard: *Enstitut de la Lengoua Savoyârda*.

France—which systematically excluded uncodified vernaculars.

Defining a written standard for Arpitan thus became a strategic imperative for this linguistic community, albeit a deeply divisive one. For decades, the dominant written form in Savoy was the *Graphie de Conflans* (Tuaillon, 1984). Developed in the 1980s by linguists and native speakers, this highly phonetic system was designed to faithfully transcribe the exact pronunciation of local village dialects. While it preserved the region's immense micro-linguistic diversity, its hyper-local fidelity severely hindered broader intercomprehension and official recognition. To bridge this gap, linguist Dominique Stich introduced the *Orthographe de Référence B* (ORB) in the early 2000s (Stich, 2001). As a supra-dialectal, etymological system, ORB aims to abstract local phonetic and morphological variations into a single graphemic standard for the entire Arpitan domain.

While ORB initially faced fierce resistance from traditional speakers—who found it harder to master and feared it erased their specific local heritage—it was championed by "new" speakers and revitalization activists for its unifying character and political leverage (Bichurina, 2019; Dunoyer, 2019). Ultimately, the strategic necessity of a unified standard appears to have prevailed, and it is in great part thanks to the growing acceptance of the principle of a supra-dialectal written standard that the French Ministry of Education officially authorized the teaching of Arpitan in French public schools in 2021 (Ministère de l'Éducation nationale, de la Jeunesse et des Sports, 2021), with the active collaboration of the *Institut de la langue savoyarde*.

## 3 Data Collection

This section outlines the data collection process for the Savoyard partitions of the FLORES+ dev and devtest sets, which were translated from French by the translation service of the *Institut de la langue savoyarde* (ILS).

### 3.1 Target Linguistic Variant and Orthography

The Savoyard variant selected as the target language for the partition is termed *Savoyard médian* (Median Savoyard) by the ILS. It is the emergent standard that the ILS teaches through MOOCs and online seminars. It is closest to the dialect of Thônes, a town located near the geographic center of Savoy, and therefore broadly understandable by the greatest number of speakers, though its emergence as a written standard is mostly tied to lexicographical efforts by Favre and Stich (2005), recently expanded by Favre (2026). The orthographic norm selected for the partition is the aforementioned supra-dialectal ORB spelling as documented in (Stich, 2003).

### 3.2 Translation Process

The translation workload, initially shared between two translators, was ultimately borne almost entirely by Alain Favre, a proficient late speaker and lexicographer who contributed in the past to the development of a rule-based Apertium system for the French-Arpitan language pair (Forcada and Tyers, 2016; Alòs, 2020).

Translators were instructed to follow the official OLDI guidelines,[9] which were presented to them during an online meeting. They worked within a customized spreadsheet interface (see Figure 3), with one sheet for each of the dev and devtest partitions. A source text column displayed the French segments of FLORES+, originally extracted from English Wikinews, Wikijunior, and Wikivoyage documents and translated into French by the original compilers of the corpus (Goyal et al., 2022). A column displaying the URL of the source documents allowed the translators to refer to them, but since these documents are in English, a column displaying the Italian translation of the segments proved more useful for resolving ambiguities in the French text. While the translators were instructed to translate the devtest partition strictly from scratch, for the dev partition they were provided with translation hypotheses generated by the rule-based French-Arpitan Apertium system (Forcada and Tyers, 2016) for inspiration (column not shown in Figure 3). This design choice was motivated by the desire to collect in-context-learning or finetuning data for the automatic post-editing of Apertium output into Savoyard.[10] Such data would in turn facilitate large-scale data augmentation.

The translators were given three and a half months to complete the assigned task and were compensated at a fair rate. During their work, they faced diverse challenges, both stylistic (the formal "press release" style typical of Wikinews source texts, for instance, does not historically exist in

[9] https://oldi.org/translation-guidelines.pdf

[10] This design choice was discussed with and approved by the OLDI shared task organizers beforehand.

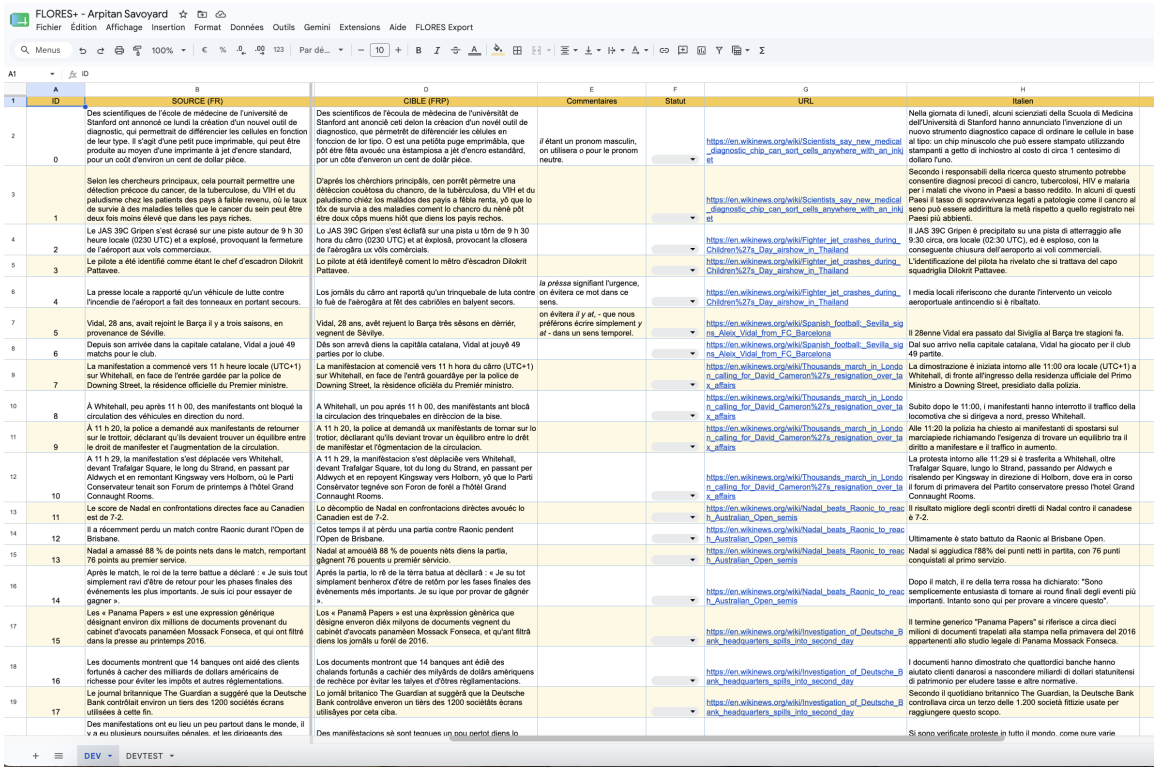

Figure 3: Translation interface.

Savoyard) and terminological. When the translation of FLORES+ surfaced terminological gaps in the existing Savoyard lexicography (Favre and Stich, 2005; Viret, 2019; Favre, 2026), neologisms were coined by prioritizing the intrinsic lexical resources of Arpitan over direct French borrowings.

The second translator—a linguistics student—contributed to the early stages of the project, providing a small batch of translations and reviewing the first several hundred segments before having to unexpectedly withdraw from the project; their involvement nonetheless yielded valuable stylistic and grammatical discussions. Following their departure, the primary translator established a formalized lexical and syntactic review grid, based on various reference texts, to ensure consistency across the entire dataset. All drafted translations were subsequently proofread and standardized against this grid.

Upon receipt of the translations, length-ratio heuristics were used as a first validation step to check for alignment problems. More substantial validation was provided by the baseline process presented in the next section and by the accompanying human annotation campaign; a random sample of the resulting dataset is displayed in Appendix D.

## 4 Baselines

To contextualize the difficulty of the French↔Savoyard translation task, and to provide reference points for future work on this dataset, we report the performance of a range of baseline approaches, spanning naïve copy of the source segment, rule-based systems, vanilla finetuning of neural MT (NMT) systems, sequence-level distillation of rule-based and LLM[11]-post-edited MT output into NMT systems, and LLM-based approaches. All systems are evaluated on the devtest partition of the Savoyard FLORES+ corpus we compiled, in both translation directions (FR→FRP and FRP→FR),[12] using the BLEU (Papineni et al., 2002), chrF++ (Popović, 2015, 2017), and TER (Snover et al., 2006) metrics.[13] Results are given in Table 1.

**Naïve copy** As a lower-bound reference, we report the performance of a trivial copy-source baseline, which simply returns the source seg-

[11]Large Language Model

[12]We rely on the ISO 639-3 *FRP* code for the Arpitan language as a shorthand for Savoyard in this section.

[13]Metrics were computed using sacreBLEU (Post, 2018). `BLEU : nrefs:1|case:mixed|eff:no|tok:13a|smooth:exp|version:2.6.0; chrF++ : nrefs:1|case:mixed|eff:yes|nc:6|nw:2|space:no|version:2.6.0; TER : nrefs:1|case:lc|tok:tercom|norm:no|punct:yes|asian:no|version:2.6.0`

Table 1: Evaluation metrics for both translation directions (FR → FRP and FRP → FR).

ment (French in the FR→FRP, Savoyard in the FRP→FR) unmodified as the translation hypothesis under evaluation. Despite the close phylogenetic relationship and ongoing diglossic contact between French and Savoyard, this baseline performs poorly in both directions (BLEU 10.5, chrF++ 40.2/39.3), indicating that the two languages display only marginal overlap in their surface forms and that the FLORES+ test partition meaningfully discriminates between systems with genuine translation ability and mere copying.

**Rule-based system** We next evaluate the French–Arpitan Apertium rule-based system (Forcada and Tyers, 2016; Alòs, 2020),[14] which performs strongly in both directions, and in fact constitutes the best-performing system for FR→FRP (BLEU 74.7, chrF++ 86.0, TER 15.3). While the Arpitan Apertium system was not used by the translators to translate the devtest partition of FLORES+, one of the translators was instrumental in its development, as previously mentioned, and its output is therefore likely to closely mirror this translator's idiolect. Apertium performance is, however, asymmetric: it is comparatively weaker for FRP→FR (BLEU 68.8, chrF++ 81.4, TER 19.8), a pattern we return to below.

**NMT finetuning** We finetune NLLB-200-600M (NLLB Team, 2024) directly on the dev partition of our Savoyard FLORES+ corpus (with 20% held out for validation), using a learning rate of 2e-5, an effective batch size of 16, weight decay of 0.01, mixed-precision training, and a best-epoch-saving strategy over 10 epochs. Given the limited size of this gold-reference training signal, performance is considerably lower than that of Apertium, and strikingly asymmetric across directions: FRP→FR reaches BLEU 63.2 (chrF++ 78.3), whereas FR→FRP falls to BLEU 35.0 (chrF++ 62.9). This gap suggests that, under a small-data regime, generation into the lower-resourced Savoyard is substantially harder than generation into French, for which NLLB's pretrained capacity can offset the scarcity of in-domain supervision.

**NMT distillation-finetuning** Our second NMT configuration, Distilled (Gold+Silver), augments the gold development data with silver parallel data generated through a two-step translation pipeline. First, we translate the French source text from the OLDI Seed (Maillard et al., 2023; NLLB Team, 2024; Marmonier et al., 2025) and SMOLSENT (Caswell et al., 2025)[15] corpora into Arpitan using Apertium. Second, we use Gemma-4-31B to post-edit this Arpitan draft into Savoyard. To guide the LLM, we prompt it with few-shot triplet demonstrations consisting of the French source segments from the FLORES+ dev set, the Apertium Arpitan draft translations presented to the human translators during the annotation process, and the gold Savoyard reference from the compiled Savoyard dev partition (see Appendix A). We then finetune NLLB-200 on the concatenated gold and silver datasets. This approach substantially closes the gap with Apertium and reverses the direction-wise asymmetry observed for rule-based translation, consistent with the pattern already seen for the NLLB Baseline model above: for FRP→FR, the distilled model (BLEU 72.4, chrF++ 84.2) outperforms Apertium, while for FR→FRP it remains

[14] https://github.com/apertium/apertium-fra-frp

[15] We compiled a French version of SMOLSENT, which we contribute to the same 2026 OLDI Shared Task.

slightly behind (BLEU 69.6 vs. 74.7).

**LLMs** We also evaluate three models from the Gemma-4 family (31B, E4B, and E2B; Google DeepMind 2026) across two binary axes. The first axis, Zero-Shot vs. Few-Shot, varies the level of in-context supervision. Zero-shot models receive only a brief prompt instructing them to translate the segment based on prior knowledge, while few-shot models are supplied with the entire *dev* partition structured as ordered bitexts within their prompt. The second axis, Direct (No-Think) vs. Reasoning, controls the generation modality. Direct models must emit the translation immediately within XML tags, whereas Reasoning models are permitted an explicit internal monologue before producing the tagged output.[16] See Appendix B for prompt examples.

Two patterns in LLM performance emerge from Table 1.

First, few-shot demonstrations provide substantial and consistent gains across all model sizes and translation directions. For instance, under Direct generation, Gemma-4-31B improves from 12.3 to 58.4 BLEU for FR→FRP, and from 71.4 to 77.3 BLEU for FRP→FR; identical trends hold for E4B and E2B. This indicates that the dev partition of FLORES+, despite its modest size, offers a potent in-context-learning signal for a genuinely low-resource variety that is likely absent from pretraining data while closely related to a high-resource language.

Second, while standard model ranking remains constant across modalities (Gemma-4-31B > E4B > E2B), allowing models to reason before translating is universally harmful, with the performance penalty exhibiting a non-monotonic relationship to model size. Performance degrades most sharply at both ends of the model-size spectrum, though through distinct failure mechanisms: the 31B variant falls into infinite self-checking loops that exhaust the token limit (dropping extraction rates to 82.61% for few-shot FR→FRP), whereas the smaller E2B model frequently emits its chain-of-thought directly within the output tags (driving TER scores above 160). The intermediate E4B model incurs a milder penalty, only suffering from reasoning-induced linguistic drift, occasionally yielding Italian-inflected or French-lexified pseudo-translations (e.g., "*L'armonia al luo de travai...*") adequately penalized by the metrics. Ultimately, no model, at any scale, appears to successfully leverage an explicit internal monologue productively for this translation task.[17]

## 5 Human Validation

To validate the automatic metrics and incidentally the quality of the human translations, we conducted a blind pairwise human evaluation campaign. The annotation was performed by Alain Favre, who also served as the primary translator for the evaluation set. To preserve statistical power while remaining mindful of the annotator's time, we restricted the experiment to a subset of the most promising systems: the rule-based Apertium platform, the distilled NLLB-200 (600M) model, and Gemma-4-31B (Few-Shot | Direct). The annotator was presented with 100 round-robin matchups per translation direction and asked to indicate his preference between two anonymized system outputs, with the option of declaring a tie, and with the gold human reference injected as a hidden system. The resulting pairwise judgments were aggregated into a global ranking using the TrueSkill algorithm (Herbrich et al., 2007), with default priors ($\mu = 25.0$, $\sigma = 8.333$) and ties resolved via TrueSkill's native draw mechanism. For each system, we report in Table 2 a conservative score ($\mu - 3\sigma$) and, for adjacent pairs in the ranking, the probability that the higher-ranked system's true skill exceeds the lower-ranked system's, computed in closed form from the difference of their posterior Gaussians.

These results show that human judgments closely mirror the trends observed in the automatic metrics, highlighting a stark asymmetry depending on the translation direction. In the FR → FRP di-

[16] We use a regular expression to extract the string within the `<translation>...</translation>` tags. Extraction failures (reported as *Extr. %* in Table 1) are penalized as empty strings. Inference is powered by vLLM (Kwon et al., 2023) and Hugging Face `transformers` (Wolf et al., 2020). Max output tokens are capped at 1,024 for Direct and 16,384 for Reasoning; vLLM's `max-model-len` is set to 240,000 for the few-shot settings.

[17] To test whether these performance differences are statistically significant, we performed paired bootstrap resampling (Koehn, 2004). The Direct-over-Reasoning advantage is significant ($p < 0.05$) in ten of the twelve model/regime/direction comparisons. Two comparisons deviate: zero-shot Gemma-4-31B in FRP→FR, where the two modalities are statistically indistinguishable (+0.5 chrF++, n.s.), and few-shot Gemma-4-E2B in FRP→FR, where Reasoning significantly outperforms Direct (−2.0 chrF++, $p < 0.05$). Full pairwise significance matrices are given in Appendix C. We note that the significance matrices report *segment-level* mean chrF++ differences, whereas Table 1 reports corpus-level scores; the two diverge for the degenerate E2B Reasoning configurations, whose spurious chain-of-thought output is penalized far more heavily under corpus-level aggregation.

| Direction | System | Cons. Score | $\mu$ | $\sigma$ | Prob. > Next | Significance |
|---|---|---|---|---|---|---|
| **FR → FRP** | Hidden Human Reference | 27.32 | 31.41 | 1.36 | >99.9% | $p < 0.001$ |
| | Apertium (Rule-Based) | 20.53 | 23.94 | 1.14 | 67.3% | n.s. |
| | NLLB-200 Distilled (600M) | 19.79 | 23.22 | 1.14 | 81.3% | n.s. |
| | Gemma-4-31B (Few-Shot) | 18.29 | 21.77 | 1.16 | – | – |
| **FRP → FR** | Hidden Human Reference | 25.26 | 28.92 | 1.22 | 88.1% | n.s. ($p \geq 0.05$) |
| | Gemma-4-31B (Few-Shot) | 23.51 | 26.94 | 1.14 | 97.5% | $p < 0.05$ |
| | NLLB-200 Distilled (600M) | 20.30 | 23.75 | 1.15 | 81.4% | n.s. |
| | Apertium (Rule-Based) | 18.67 | 22.27 | 1.20 | – | – |

Table 2: TrueSkill human evaluation leaderboards for both translation directions. The Conservative Score represents the lower 99% credible bound of the system's estimated true skill ($\mu - 3\sigma$). The "Prob. > Next" column indicates the probability of the system's true skill being strictly greater than that of the system ranked immediately below it, alongside its corresponding statistical significance threshold (n.s. = not significant).

rection, the hidden human reference ($\mu = 31.41$) significantly outperformed all machine systems ($p < 0.001$). Among the automated approaches, the hand-crafted rules of Apertium ($\mu = 23.94$) and the Distilled NLLB model ($\mu = 23.22$) performed comparably, effectively tying for first place. Notably, the Distilled NLLB model outperformed Gemma-4-31B ($\mu = 21.77$). Conversely, in the FRP → FR direction, Gemma-4-31B Few-Shot Direct ($\mu = 26.94$) demonstrated overwhelming superiority over both NLLB and Apertium. Remarkably, the probability of superiority between the hidden human reference and Gemma-4-31B was only 88.14%, indicating that the LLM achieved near-human parity ($p \geq 0.05$) when decoding into standard French.

The automatic and human evaluations therefore converge, validating both the automatic metrics for this language pair and the quality of the reference translation, to an extent that is further discussed in the Limitations section. The resulting picture is asymmetric: translation into French is approaching human parity, while into Savoyard the human reference remains significantly preferred over all systems and the best baseline system is rule-based.

## 6 Related Work

The first MT evaluation dataset bearing the name "FLORES" was released in 2019 and targeted two resource-constrained Indo-Aryan languages: Nepali and Sinhala (Guzmán et al., 2019). Its source segments were extracted from Wikipedia articles, and professionally translated, with stringent iterative rounds of quality assurance. In order to mitigate the effects of translationese on MT evaluation (Zhang and Toral, 2019; Graham et al., 2020), source segments were also sampled from Nepali and Sinhala Wikipedia, rather than English alone.

The subsequent FLORES-101 dataset (Goyal et al., 2022) forms the actual basis of FLORES+. While it retained the core methodology of professional translation and rigorous quality assurance protocols, its 2,009 source segments bear no relation to those of the original FLORES, having been drawn instead from English-language Wikimedia projects (Wikitravel, Wikinews, Wikijunior) and translated into 101 target languages. This English-centric design made possible a fully aligned many-to-many evaluation across 10,100 language pairs, allowing researchers to assess regionally relevant, non-English translation directions.

FLORES-101 was further expanded into FLORES-200 in the context of the NLLB-200 project (NLLB Team, 2024), covering 200 languages as the name implies. The corpus, now curated by the Open Language Data Initiative (Burchell et al., 2024; Dale et al., 2025) under the name FLORES+, is regularly extended into new low-resource languages (Gordeev et al., 2024; Kuzhuget et al., 2024; Ali et al., 2024; Perez-Ortiz et al., 2024; Frontull et al., 2025; Lou et al., 2025; Samil and Adelani, 2026), with important contributions also including corrections to previously released partitions (Abdulmumin et al., 2024; Perez-Ortiz et al., 2024; Mæhlum et al., 2025; Oktem et al., 2025).

Other multi-parallel evaluation corpora include TICO-19 (Anastasopoulos et al., 2020), which targets the medical domain across 38 languages, and NTREX-128 (Federmann et al., 2022), which translates 1,997 WMT19 news segments (Barrault et al., 2019) into 128 languages.[18] Similarly, WMT24++ (Deutsch et al., 2025) extends the WMT24 test set

[18]NTREX-128's exposure to web crawlers on GitHub appears to have contaminated LLM pre-training data, limiting its use as a strict evaluation benchmark but making it a valuable few-shot training resource.

(Kocmi et al., 2024) to 55 languages. Despite potential GDPR constraints regarding its social media data, it uniquely provides both initial translations and final post-edits, making it ideal for studying translation dynamics (cf. Marmonier et al. 2026). Moving away from English-centric models, the BOUQuET dataset (Andrews et al., 2025) uses original texts handcrafted across eight pivot languages. Spanning 275 variants, it covers diverse registers—such as fiction and dialogues—while maintaining low structural complexity to encourage crowd-sourced extensions.

To the best of our knowledge, no machine translation evaluation corpora for Savoyard or the broader Arpitan dialect continuum currently exist, making the present dataset the first of its kind for this language family.

## 7 Conclusion

We have presented a Savoyard partition of the FLORES+ corpus, together with a range of baseline scores intended to give future work a point of comparison. Savoyard is but one variety within a much larger and diverse whole: the Arpitan dialect continuum extends across the French departments of eastern and central France (including varieties such as Bressan, Lyonnais, Forézien, and Dauphinois), French-speaking Switzerland (encompassing dialects like Vaudois, Genevois, Neuchâtelois, Fribourgeois, and Valaisan), and the Aosta Valley of Italy. All of these are low-resource varieties from the point of view of natural language processing, and their revitalization would likely benefit greatly from translation technology. We hope that the present work will stimulate similar efforts for these dialects elsewhere, contributing in turn to the preservation of humanity's linguistic diversity.

## Limitations

The main limitations of this work stem from the very scarcity of speakers that motivates it.

**A single-translator corpus.** The workload, initially to be shared between two translators, was ultimately borne almost entirely by one, the pool of expert translators being extremely small. This does not bear on the quality of the resulting corpus, as it was produced by a lexicographer of Savoyard working under the auspices of the *Institut de la langue savoyarde*, the body whose lexicographical and normative work defines the Median Savoyard standard the partition targets. It does, however, bound what the corpus attests.

**Human evaluation.** The annotation campaign was conducted by the translator himself. The design was blind: outputs were anonymized and the annotator was not informed that the gold references had been injected as a hidden system. Some residual self-preference along stylistic lines cannot be excluded, since the norms against which the systems were judged are those the annotator/translator himself applies. The campaign is best read, accordingly, as establishing agreement with the ILS standard—which is the property our references are meant to have—rather than as an independent measure of acceptability across the entire Savoyard dialect continuum.

**Confounds in the baselines.** The translator contributed in the past to the French–Arpitan Apertium system. Although the devtest was translated from scratch, Apertium's FR→FRP scores are plausibly inflated by this shared provenance.

## Acknowledgments

This work was funded by the French *Agence Nationale de la Recherche* (ANR) under the project TraLaLaM ("ANR-23-IAS1-0006"), as well as by Inria under the "*Défi*"-type project COLaF. It was also partly funded by Benoît Sagot's chair in the PRAIRIE-PSAI institute, funded by the ANR as part of the "France 2030" strategy under the reference ANR-23-IACL-0008.

This work was also granted access to the HPC resources of IDRIS under allocations 2025-AD011015117R2, 2025-AD011012254R5 and 2025-AD011017228 made by GENCI. The authors acknowledge the use of LLMs as coding assistants during the implementation of this work.

We are grateful to François Yvon for his help with the administrative aspects of this project. We also thank Franck Monod, Operations Manager at the *Institut de la langue savoyarde*, and Amandine Pinget, Data Scientist at the *Institut de la langue savoyarde*, for their assistance and support in coordinating this collaboration.

## A Data Distillation prompt

This appendix provides an example of the template used for the *Distilled (Gold+Silver)* dataset generation, where Gemma-4-31B was provided with French–Arpitan–Savoyard few-shot triplet demonstrations to post-edit the rule-based Apertium drafts.

**Gemma-4-31B Distillation Prompt Template**

Savoyard (endonym: *savoyârd*) is a Franco-Provençal dialect of the Gallo-Romance family. It is spoken in some territories of the historical Duchy of Savoy, nowadays a geographic area spanning Savoie and Haute-Savoie, France, and the Canton of Geneva, Switzerland.

You are to translate a French segment of text into Savoyard. To assist you in this task, we will provide you with translation hypotheses produced by Apertium, a rule-based machine translation platform. It will provide a rough candidate translation from French into an Arpitan macrolanguage. Your task is to post-edit and refine this candidate to produce a fluent, orthographically correct, and natural Savoyard translation.

To guide your style and vocabulary, here is a parallel corpus of expert translations demonstrating the task at hand:

`<parallel_corpus>`
**French:** *Des scientifiques de l'école de*

*médecine de l'université de Stanford ont annoncé ce lundi la création d'un nouvel outil de diagnostic, qui permettrait de différencier les cellules en fonction de leur type. Il s'agit d'une petit puce imprimable, qui peut être produite au moyen d'une imprimante à jet d'encre standard, pour un coût d'environ un cent de dollar pièce.*
**Apertium Candidate:** *Des scientificos de l'ècoula de mèdecina de l'univèrsitât de Stanford ant anonciê ceti delon la crèacion d'un novél outil de diagnostico, que pèrmetrêt de difèrenciér les cèlules en fonccion de lor tipo. Il s'agét d'una petit puge imprimable, que pôt étre fête u moyen d'una èstampiosa a jèt d'encro estandârd, por un côte d'enveron un cent de dolâr piéce.*
**Savoyard:** *Des scientificos de l'ècoula de mèdecina de l'univèrsitât de Stanford ant anonciê ceti delon la crèacion d'un novél outil de diagnostico, que pèrmetrêt de difèrenciér les cèlules en fonccion de lor tipo. O est una petiôta puge emprimâbla, que pôt étre fêta avouéc una èstampiosa a jèt d'encro estandârd, por un côte d'enveron un cent de dolâr piéce.*

...

**French:** *Les compagnies aériennes qui les proposent sont notamment Air Canada, Delta Air Lines, Lufthansa pour les vols en provenance des États-Unis ou du Canada, et WestJet.*
**Apertium Candidate:** *Les compagnies d'aviacion que los propôsont sont spècialament Air Canadâ, Dèlta Air Lines, Lufthansa por los vôls en provegnance des Ètats-Unis ou du Canadâ, et WestJet.*
**Savoyard:** *Les compagnies d'aviacion que los propôsont sont spècialament Air Canada, Dèlta Air Lines, Lufthansa por los vôls que vegnont des Ètats-Unis ou du Canadâ, et WestJet.*

**French:** *Dans tous les cas, vous devez réserver par téléphone directement auprès de la compagnie aérienne.*
**Apertium Candidate:** *Dens tôs los câs, vos dête resèrvar per tèlèfono dirèctament uprés de la compagnie d'aviacion.*
**Savoyard:** *Diens tôs los câs, vos dêde resèrvar per tèlèfono dirèctament uprés de la compagnie d'aviacion.*
</parallel_corpus>

You must only output your final translation between the XML tags and absolutely nothing else. Do not include any reasoning, notes, or introductions. The expected XML format is: <translation>your translation here</translation>

Here is the segment you must translate:
**French:** *La première avancée majeure en termes d'abstraction fut l'utilisation de chiffres pour représenter les nombres.*
**Apertium Candidate:** *La premiére avanciê majore en tèrmenos d'abstraccion at étâ l'usâjo de chifros por reprèsentar los nombros.*
**Savoyard:**

## B LLM Translation Prompt Templates

This appendix contains the prompts used for the evaluation of the Gemma-4 models (31B, E4B, and E2B) described in Section 4. We provide examples in the FR→FRP translation direction; the FRP→FR differs minimally, for instance in the order in which dev set bitexts are presented.

### B.1 Zero-Shot Templates

#### B.1.1 Direct (No-Think) Modality

The following template was used for the zero-shot direct generation condition. The model was instructed to output the final translation immediately within XML tags.

**Zero-Shot Direct Translation Prompt**

Savoyard (endonym: *savoyârd*) is a Franco-Provençal dialect of the Gallo-Romance family. It is spoken in some territories of the historical Duchy of Savoy, nowadays a geographic area spanning Savoie and

Haute-Savoie, France and the Canton of Geneva, Switzerland.

You are to translate the following French text segment into Savoyard. **You must only output the translation between the XML tags and absolutely nothing else. Do not include any reasoning, notes, or introductions.** The expected XML format is: `<translation>your translation here</translation>`

Segment to translate:
*Les travailleurs doivent souvent obtenir l'accord de leurs supérieurs pour toute décision qu'ils prennent et sont censés obéir aux instructions de leurs supérieurs sans poser de questions.*

#### B.1.2 Reasoning Modality

The following template was used for the zero-shot reasoning condition, explicitly allowing the model to utilize an internal monologue prior to emitting the translation.

**Zero-Shot Reasoning Translation Prompt**

Savoyard (endonym: *savoyârd*) is a Franco-Provençal dialect of the Gallo-Romance family. It is spoken in some territories of the historical Duchy of Savoy, nowadays a geographic area spanning Savoie and Haute-Savoie, France and the Canton of Geneva, Switzerland.

You are to translate the following French text segment into Savoyard. **You can reflect on the task at hand prior to producing your final translation.** You must output your final translation between XML tags thusly: `<translation>your translation here</translation>`

Segment to translate:
*Les travailleurs doivent souvent obtenir l'accord de leurs supérieurs pour toute décision qu'ils prennent et sont censés obéir aux instructions de leurs supérieurs sans poser de questions.*

### B.2 Few-Shot Templates

#### B.2.1 Direct (No-Think) Modality

For the few-shot direct condition, the prompt was appended with the entire structured *dev* partition bitext as in-context demonstrations, immediately followed by the target source query.

**Few-Shot Direct Translation Prompt**

Savoyard (endonym: *savoyârd*) is a Franco-Provençal dialect of the Gallo-Romance family. It is spoken in some territories of the historical Duchy of Savoy, nowadays a geographic area spanning Savoie and Haute-Savoie, France and the Canton of Geneva, Switzerland.

You will be asked to translate a French text segment into Savoyard. **You must only output the translation between the XML tags and absolutely nothing else. Do not include any reasoning, notes, or introductions.** The expected XML format is: `<translation>your translation here</translation>`

To assist you in this task, here is a small parallel corpus. It should dispel doubts you might have regarding the orthography and grammar of this romance dialect:

`<parallel_corpus>`
**French:** *Des scientifiques de l'école de médecine de l'université de Stanford ont annoncé ce lundi la création d'un nouvel outil de diagnostic, qui permettrait de différencier les cellules en fonction de leur type. Il s'agit d'une petit puce imprimable, qui peut être produite au moyen d'une imprimante à jet d'encre standard, pour un coût d'environ un cent de dollar pièce.*
**Savoyard:** *Des scientificos de l'ècoula de mèdecina de l'univèrsitât de Stanford ant anonciê ceti delon la crèacion d'un novél outil de diagnostico, que pèrmetrêt de difèrenciér les cèlules en fonccion de lor tipo. O est una petiôta puge emprimâbla, que pôt étre fêta avouéc una èstampiosa a jèt d'encro estandârd, por un côte d'enveron un cent de dolâr piéce.*

**French:** *Selon les chercheurs principaux, cela pourrait permettre une détection précoce du cancer, de la tuberculose, du VIH et du paludisme chez les patients des pays à faible revenu, où le taux de survie à des maladies telles que le cancer du sein peut être deux fois moins élevé que dans les pays riches.*
**Savoyard:** *D'aprés los chèrchiors principâls, cen porrêt pèrmetre una dètèccion couètosa du chancro, de la tubèrculosa, du VIH et du paludismo chiéz los malâdos des payis a fêbla renta, yô que lo tôx de survia a des maladies coment lo chancro du nènè pôt étre doux côps muens hiôt que diens los payis rechos.*

...

**French:** *Dans tous les cas, vous devez réserver par téléphone directement auprès de la compagnie aérienne.*
**Savoyard:** *Diens tôs los câs, vos dêde resèrvar per tèlèfono dirèctament uprés de la compagnie d'aviacion.*
</parallel_corpus>

Here is the French segment you must translate into **Savoyard:**
*Les travailleurs doivent souvent obtenir l'accord de leurs supérieurs pour toute décision qu'ils prennent et sont censés obéir aux instructions de leurs supérieurs sans poser de questions.*

**A reminder that you must only output the translation between the XML tags and absolutely nothing else.** Do not include any reasoning, notes, or introductions. Format: `<translation>your translation here</translation>`

#### B.2.2 Reasoning Modality

For the few-shot reasoning condition, the system prompt instructed the model to reason before outputting the final tags, combined with the structural sequence of the *dev* bitext.

**Few-Shot Reasoning Translation Prompt**

Savoyard (endonym: *savoyârd*) is a Franco-Provençal dialect of the Gallo-Romance family. It is spoken in some territories of the historical Duchy of Savoy, nowadays a geographic area spanning Savoie and Haute-Savoie, France and the Canton of Geneva, Switzerland.

## C Statistical Significance Matrices

To assess whether the observed performance margins between systems are statistically meaningful, we conduct paired bootstrap resampling with $1,000$ iterations. Figures 4 and 5 illustrate the mean chrF++ differences between all evaluated configurations for both translation directions.

Cells marked with an asterisk (*) indicate that the performance delta between the row system and column system is statistically significant at $p < 0.05$.

*"En fiùr sul el fà mìa primaéra."*
'A single flower alone does not make spring.'

— Lombard saying

## Abstract

While recent initiatives have expanded machine translation benchmarks to include low-resource and minoritized languages, regional dialect continuums remain severely underrepresented. Current datasets for the Lombard language predominantly feature Western Lombard, with Eastern Lombard varieties almost absent from the digital landscape. In this paper, we introduce, a new benchmark dataset providing an Eastern Lombard translation of the FLORES+ dev and devtest splits. We detail the methodology of translating a largely oral, unstandardized language, including orthographic regularization and the handling of Italian loanwords. Finally, we establish zero-shot baselines by prompting current LLMs and MT models, demonstrating that existing systems struggle with Lombard varieties overall, and exhibit a strong Western Lombard bias, struggling even more to accurately generate Eastern Lombard text.

## Introduction

The advancement of Machine Translation (MT) and Large Language Models (LLMs) relies on standardized benchmark datasets. Resources like FLORES+ have become foundational for evaluating cross-lingual generalization. Recent initiatives such as the WMT Open Data Shared Task actively aim to democratize natural language processing by extending coverage to under-resourced and minoritized languages. Formally integrating an endangered language into a globally recognized benchmark is a crucial milestone for its digital survival; it not only increases visibility but provides the infrastructure necessary to develop and evaluate downstream community-driven NLP tools.

However, bringing language continuums into the digital sphere introduces complex challenges regarding representativeness. While linguistic variation is pervasive (Lutgen et al., 2026), language continuums are frequently flattened into single, monolithic ISO codes.

This also holds true for the language varieties of Italy (Ramponi, 2024) and for Lombard (ISO 639-3: lmo), an endangered Gallo-Romance language continuum spoken in Northern Italy and Southern Switzerland. As illustrated in Figure 1, the continuum is characterized by a high degree of internal variation and is broadly divided into Western and Eastern branches. Current iterations of FLORES+ and major web-scraped corpora predominantly feature Western Lombard (Signoroni and Rychlý, 2026), leaving Eastern Lombard vastly unrepresented. To address this gap, we present our Eastern Lombard translation of the FLORES+ dev and devtest splits.

## 1 Linguistic Background

### 1.1 Lombard

Lombard is a Gallo-Romance language (Brasca, 2026), with a speaker base of roughly 2.5 million.[1] Its geographic footprint covers the Italian regions of Lombardy and Piedmont (specifically the provinces of Novara and Verbano-Cusio-Ossola), alongside the Swiss cantons of Ticino and Graubünden. Functioning as a dialect continuum rather than a strictly standardized system, Lombard exhibits notable lexical, morphological, and phonetic diversity, yet speakers largely retain mutual comprehensibility (Coluzzi et al., 2018; Bonfadini, 2010;

[1] Based on recent demographic assessments (ISTAT, 2026), this figure reflects a drop of around 1 million speakers compared to the older, frequently cited estimate of 3.5 million (Moseley and Nicholas, 2010).

*Proceedings of the Eleventh Conference on Machine Translation*, pages 2547–2560
October 28-29, 2026 ©2026 Association for Computational Linguistics

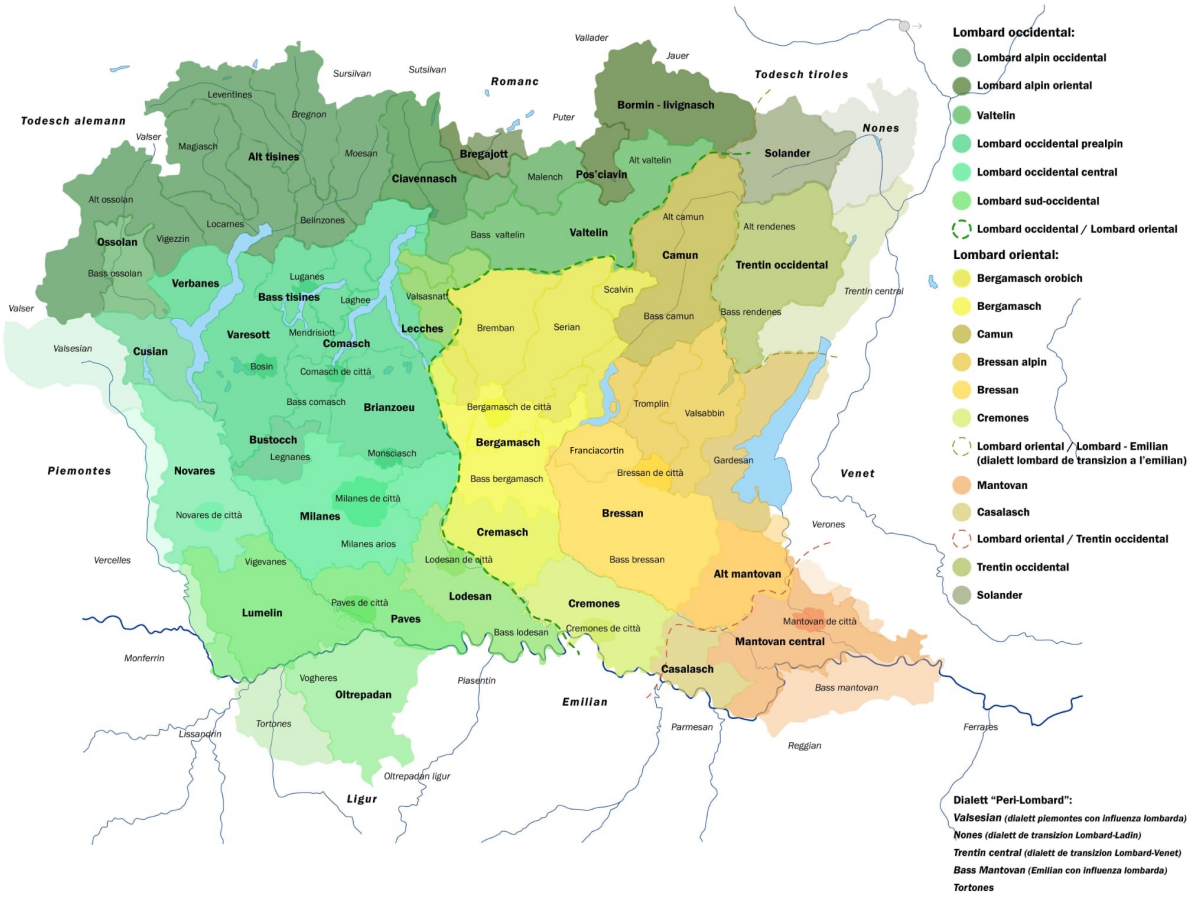

Figure 1: Map of the Lombard variants (names are in Western Lombard). While the internal subdivisions of the Lombard continuum are not always clear even to scholars, this illustrates the high degree of the internal diversity and overlap of varieties, and shows the distinction of the two main agreed-upon branches: Western Lombard (green shades) and Eastern Lombard (orange shades), divided by the dashed line.

Loporcaro, 2009). Scholars traditionally partition this continuum into two to four branches. The two most prominent are Western Lombard (spanning eastern Piedmont, Canton Ticino, and the provinces of Milan, Monza, Varese, Como, Lecco, Sondrio, Lodi, and Pavia) and Eastern Lombard (covering the Bergamo, Brescia, and Cremona provinces).[2] Figure 1 shows a map of the main varieties of Lombard.[3]

The continued survival of the language is severely threatened. UNESCO's "Atlas of the World's Languages in Danger" (Moseley and Nicholas, 2010) categorizes Lombard as "Definitely endangered".[4] Furthermore, under the Extended Graded Intergenerational Disruption Scale (EGIDS) (Lewis and Simons, 2010), its status hovers between "threatened" and "moribund".

The sociolinguistic reality of Lombard differs depending on the national context. In Switzerland, the language is supported by institutional frameworks and enjoys a relatively high degree of social prestige, spearheaded by the Bellinzona-based *Centro di dialettologia e di etnografia* (CDE). In contrast, within Italy, Lombard and comparable regional varieties face significant social stigma. They are often dismissed as mere *dialetti* ('dialects'), a term adopted even by the speakers themselves (Tamburelli et al., 2025). Because "dialect" frequently carries a negative connotation, incorrectly framing these languages as debased offshoots of Standard Italian rather than historically independent Romance languages, contemporary NLP literature prefers the bias-free term "language varieties" (Ramponi, 2024), bypassing the prejudice

[2]Due to historical emigration patterns in the 19th and 20th centuries, a variant of Eastern Lombard (Bergamasque) survives in parts of southern Brazil (Paganessi, 2017).

[3]Adapted from https://www.reddit.com/r/LearnLombardLanguage/comments/1s553nh/mappa_di_dialett_lombard/.

[4]This designation indicates that children are no longer learning the language natively at home, restricting the youngest fluent speakers to the parental generation or older.

still present in some traditional scholarship (Brasca, 2026).

In Italy, institutional recognition is virtually nonexistent outside of symbolic regional legislation. For example, Lombardy's Regional Law 25/2016 formally commits to the promotion and protection of local Lombard varieties as expressions of intangible cultural heritage. However, these declarations have not translated into actionable preservation policies (Brasca et al., 2024). As a result, academics increasingly characterize Lombard and similar Italian linguistic systems as "contested" or "minoritized" languages (Tamburelli et al., 2025; Brasca et al., 2024).

Currently, the interaction between Lombard and Standard Italian takes the form of *dilalìa* (Berruto, 1987; Ramponi, 2024). Standard Italian exclusively occupies high-prestige, official domains, pushing Lombard into purely informal environments where it is constantly blended with the national language—which now serves as the primary language of socialization for children. This "vertical bilingualism" (Tamburelli, 2012; Brasca et al., 2024) actively drives language loss, as the community struggles to find practical reasons to maintain the local variety. Recent statistics highlight this rapid decline: ISTAT data from 2024 (ISTAT, 2026) shows that just 4.2% of Lombardy's population relies primarily on the local variety in domestic settings, with 18.1% alternating it with Italian. This is a noticeable drop from the 2015 data (ISTAT, 2017), which reported 5.6% and 26.1% respectively. Usage rates in public spaces or among friends are even lower, worsening the fracture of the continuum.

Although Lombard has a rich historical literary tradition, it operates almost exclusively as an oral language in the modern era. Various standardized spelling systems have been designed,[5] but none have achieved widespread community acceptance or official codification. As a result, individuals who write in Lombard usually rely on ad-hoc, subjective phonetic spelling rules to represent the sounds of their specific local variety.

### 1.2 Eastern Lombard

Assuming the same numbers we used before, we can roughly estimate the number of Eastern Lombard speakers at 0.6–1.0M (of whom only about 100,000 [4%] use it outside their immediate household or family circle).[6]

Eastern areas began to develop some innovations with respect to the then more uniform Milanese model starting from the Late Middle Ages (Bonfadini, 2015). Historically, the Eastern area never had a "reference" dialect comparable to *Milanès* for the West.[7] *Bergamàsch* and *Bresà* thus exhibit some differences, but also many shared distinguishable features and lexical choices that somewhat distance them from Western varieties (Bonfadini, 2010).

Specifically, vowel length is lost as a distinctive feature,[8] and Latin /s/, /ke, ki/, and /tj/ all merge into [s]. The close vowels /y/ and /i/ lower to [ø] and [e], respectively. Intervocalic /v/ is deleted, and syllable-coda /n/ after a stressed vowel is dropped without nasalization. In nominal and verbal morphology, nouns ending in /-t/ and /-n/ undergo plural palatalization to [-ʧ] and [-ɲ], the masculine singular past participle retains the final dental stop, and plural endings of feminine words in /-a/ shift to [-e].

***Bresà*** has also its own peculiarities, sometimes due to proximity to *Vèneto*. For example BG, MI [nɔʧ] ('night') and [laʧ] ('milk') become BS [nɔ] and [lat] (ven. [ˈn ɔte]), BG [i ˈsøke] ('the pumpkins') becomes BS [le ˈsøke] (ven. [le ˈsuke], and BG [bat]/[baˈti] ('to pound') becomes BS [ˈbater] (ven. [ˈbatar]). Moreover, BG [ɔˈrɛʤa] ('ear') corresponds to BS [ɔˈrɛʧa], and the first person plural of BG [ˈnɔtɛr an ˈkanta] ('we sing') is BS [nɔˈaltɛr kanˈtɔm].

On the western borders, the distinction between *Bresà* and *Bergamàsch* fades, with transitional zones where features from both varieties overlap. Relevant to the present work, both translators are speakers of one of these contact varieties. Thus the translation features some phenomena due to the proximity to *Bergamàsch*, such as the alternative use of BG *i* and BS *le* for the definite feminine plural and of the verb forms (e.g. BG *scrif*/*scrìi* and BS *scrìer* 'to write'). Moreover, the indefinite masculine article *un* becomes *en*.

Some local phonetic features include: [o] and

[5] For example, the orthography used on the Lombard Wikipedia: https://lmo.wikipedia.org/wiki/Wikipedia:GrafCat (in Lombard).

[6] This is a very rough estimate done by using the percentages found in the most recent ISTAT report (ISTAT, 2026) and applying them to the combined populations of the provinces of Bergamo, Brescia, Cremona, and Mantova.

[7] Sanga (1997) seems to suggest that at least for a time *Bergamàsch* had a much more vibrant and prestigious status.

[8] According to Bonfadini (2015), distinctive vowel length existed and still exists (in some varieties) both in *Bergamàsch* and *Bresà*.

[ø] become [u] and [y] before the stress; [s] can (and almost always does) become [h]; unstressed word-final [a] is rendered as [ø].

## 2 Related Work

### 2.1 FLORES+

Since its first iteration (Guzmán et al., 2019), the FLORES+ dataset has evolved through the successive iterations of FLORES-101 (Goyal et al., 2022) and FLORES-202 (Team et al., 2022) to reach the current form of FLORES+, becoming an established benchmark dataset for MT.

The dataset is currently under the curation of the Open Language Data Initiative (OLDI), which hosts and makes available the data for an ever growing number of languages. Since 2024, OLDI has organized a shared task of the same name at WMT (Maillard et al., 2024; Dale et al., 2025) with the stated aim to add an increasing number of under-resourced languages to widely used open benchmark datasets.

The shared task has already yielded contributions for several languages: Uzbek (Mamasaidov et al., 2025), Hausa, Northern Sotho (Sepedi), Xitsonga, and isiZulu (Abdulmumin et al., 2024), Emakhuwa (Ali et al., 2024), Wu (Yu et al., 2024), Karakalpak (Mamasaidov and Shopulatov, 2024), Nko (Doumbouya et al., 2023), Aragonese, Aranese, Asturian, and Valencian (Perez-Ortiz et al., 2024), Tamazight (Oktem et al., 2025), Norwegian Bokmål (Mæhlum et al., 2025), American Sign Language (Tanzer, 2025), Erzya (Gordeev et al., 2024), Ladin (Frontull et al., 2025).

### 2.2 Lombard Datasets

Some recent research released data and tools for Lombard, such as parallel corpora for MT (Signoroni, 2022), multi-variety dataset for orthographical recognition (Signoroni and Rychly, 2026), and for code-mixed LangID (Signoroni et al., 2026).

Some multilingual web-scraped corpora such as NLLB (Team et al., 2022), WikiMatrix (Schwenk et al., 2021), XLEnt (El-Kishky et al., 2021), Glot500 (Imani et al., 2023), CulturaX (Nguyen et al., 2024), and HPLT 3.0 (Oepen et al., 2025), list Lombard among the languages they cover.

However, Kreutzer et al. (2022) have shown that these kind of resources are often unreliable or even unusable especially for under-resourced languages, with the text being only boilerplate, in the wrong language, or just non-linguistic noise altogether. These findings were also replicated for Lombard by Signoroni and Rychlý (2026), on a wide array of available text resources for Lombard.

On top of the low-quality alignments and examples found in the web-scraped corpora, they also show their lack of representativeness in terms of internal linguistic variation. Language varieties and variation (Lutgen et al., 2026) cannot faithfully be represented under a single ISO label (Ramponi, 2024).

## 3 Methodology

### 3.1 Translation

**Translation Source** We opted to translate from the Italian version of the FLORES+ `dev` and `devtest` datasets. Since most of the Lombard speakers are from the older generations, it was considered easier to find Italian-Lombard bilingual speakers, instead of English-Italian-Lombard trilingual individuals.

**Searching for Volunteers and Language Perception** The search for volunteers was conducted locally and in-person. We targeted cultural associations and similar groups, but there was a common perception that writing Lombard is "hard and a thing that people simply do not do". Even if anecdotal, this feedback on the perceived difficulty of the written language informed other parts of the methodology, such as the choice of orthography to adopt for the translation.

**Orthography** As mentioned in Section 1, Lombard does not have a standardized orthography, since nowadays it is mostly a spoken language.

During the preliminary phases, when presented with the alternative orthographies proposed, many (e.g. Pan-Lombard orthographies, devised for all Lombard variants) were considered by the translator as "another language", or even "incomprehensible" at times (due to unfamiliar characters or lexical choices).

Of the ones currently being proposed and used, we chose to adopt the *Ortografia Orientàl Ünificàda* (LORUNIF). This was created for Eastern Lombard on the Lombard Wikipedia starting from the local orthographies for the most spoken varieties of Eastern Lombard, mainly *Bergamàsch* (*Ortografia del Dücat*) and *Bresà* (*Ortografia bresàna modèrna*)[9].

While agreeing in principle that the LORUNIF

[9] See Signoroni and Rychly (2026) for an overview of some of the proposed Lombard orthographies, mostly used on the Lombard Wikipedia

| Split | Language / Variety | Sentences | Total Words | Words/Sent | Total Chars | Chars/Sent |

Table 2: Bidirectional mean CER and WER between language varieties on FLORES+ dev and devtest. The

was closer to their representation of how the language should be written, in the beginning the volunteer proposed their own modifications to the system, out of concern that local phonological variations were not fully represented in the data, e.g. $ for the local pronunciation of [s] as [h] or @ for the grapheme <a> as [ø]. This is due to the perceived value and role of the language for personal sentimental and cultural heritage highlighted by the volunteer. After some discussion on the practicalities and on linguistic matters, it was decided to keep the current formulation of the spelling rules.

Appendix B gives the spelling conventions for the LORUNIF orthography. Accents are used to mark the word stress on the words with more than one syllable, and to distinguish between open (/ɛ/ /ɔ/) and closed (/e/ /o/) vowels.[10] Rounded vowels are always marked with umlauts, even if unstressed.[11]. The sequence /stʃ/ is marked as <s-c> (e.g. *s-cet* 'boy').

**Regularization and Loanwords** Together with the orthography, another recurrent issue is that of unregulated loanwords and idiolects: nowadays several words, even common ones, are increasingly being substituted by Italianized non-integrated loanwords. These cases are even recorded in modern-day dictionaries, such as the Bergamasque one (Francia and Gambarini, 2001). After analyzing the issue and discussing with the translator, we agreed to some modifications in post-editing, with the objective to avoid code-mixing (Muysken, 2000).

Loanwords and Lombard forms were used interchangeably without a clear pattern. In some other cases, the mixing occurred due to the perceived register of the sentence: Italian loanwords were consistently used for "higher" topics and meanings (e.g. Italian *inizio* 'beginning' was translated as *prensépe*, but *principio* 'principle' was used as-is in *princìpio*, whereas there should not have been any distinction, since it. *principio* is a synonym of *inizio*, of which lmo *prensépe* is a cognate).

Words such as *viàgio* ('journey'), *elètrone* ('electron'), *giudìce* ('judge') and others were found across the original draft text. Without a common, widespread reference to use as foundation, we opted to reinstate the Lombard forms where possible in case of unmodified lexical borrowings (e.g. *rìschio* → *rìsech* 'risk'), or integrate the loans coherently with Lombard sound changes (e.g. *càcia* → *càsa*, as the verb *casà*, 'to hunt'). And so, *viàgio* becomes *viàs*, *elètrone* becomes *eletrù*, and *giudìce* becomes *giödes* (as in the idiom *fà giödése* 'to be responsible'). In some cases, such as the latter, a further change could be possible: older Brescian dictionaries (Pellizzari, 1759), for example, spell *giustìsia* ('justice') as *zustìsia*, thus reflecting the *gi-* → *z-* change, still recognizable in more frequent words such as *zöch* ('game, toy'), *zugà* ('to play'), *zontà* ('to join'), *zenér* ('January'), *zèner* ('son-in-law') for which the forms in *gi-* are not used. Table 3 gives an overview of the rules we applied for these integrations.

Another widespread phenomenon in Eastern

[10]These accents can be omitted if there is no danger of confusion between similar words, e.g. sét /set/ 'thirst' sèt /sɛt/ 'seven'.

[11]Some edge cases still remain in the rare cases in which a rounded vowel also carries the word stress (e.g. *cümü* 'township')

| Draft | Change | Example |
|---|---|---|
| gi | s, z | *viagiatùr* → *viazadùr* |
| one | ù | *protóne* → *protù* |
| smo | zem | *buddìsmo* → *buddizèm* |
| rno | ren | *intórno* → *entùren* |
| o | ∅ | *concèrto* → *consèrt* |
| e | ∅ | *variànte* → *variànt* |
| ci | s | *cèrto* → *sert* |
| sc | s | *sciensiàto* → *sensiàt* |
| io | e | *telescòpio* → *telescòpe* |

Table 3: Summary of the changes we adopted to regularize Italian loanwords.

Lombard speech is elision and assimilation. The most represented case is the masculine singular article BS *èl*/BG *ól* ('the'), which almost always becomes *'l*. Thus, the form *l'* is always feminine and *'l* is always masculine. We kept this rule also for the prepositions: e.g. *de 'l* (masculine 'of'), *dela* (feminine 'of'). Other cases of elision due to assimilation are words starting with a vowel: e.g. *andàl'ndà* ('to go'); *importànt*/*'mportànt* ('important'), and so on.

Another point that we tried to address was the deletion of the *v*, e.g. *vìga*/*ìga* ('to have'). We kept the form in *v-* when it was preceded by a vowel (e.g. *gh'o vest* instead of the phonetically closer *gh'o est* 'I have seen'). A few instances of intervocalic *-v-* were removed (e.g. *università* → *uniersità* 'university').

**Resources** To aid in the translation process, we suggested several available resources in addition to the Lombard Wikipedia LORUNIF page: *Vocabolario bresciano e toscano* (so-called "*del seminario*" 'of the seminar') (Pellizzari, 1759), *Vocabolario Italiano-Bresciano* (Melchiori, 1817), *Vocabolario Bergamasco-Italiano per ogni classe di persone e specialmente per la gioventù* (Zappettini, 1859), *Vocabolario dei Dialetti Bergamaschi Antichi e Moderni* (Tiraboschi, 1873), *Vocabolario Italiano-Bergamasco* (Francia and Gambarini, 2001).

**Translators** The work was carried out by two people (one of them being the first author), both native speakers of Eastern Lombard. The translation was done by one volunteer. While holding a Master's Degree, they are not a professional translator. We made sure that they were familiar with the OLDI Translation guidelines, which we translated into Italian, and briefed them on some relevant linguistic concepts (e.g. dialect vs language, phonetic vs phonemic, loanwords, code-switching) to address some of the volunteer's concerns and give them some theoretical framework.

**Translation Workflow** The volunteer was presented with the Italian version of FLORES+ `dev` and `devtest` splits in `.txt` format. After the translation, the first author manually reviewed the translation with the help of a custom web app. The translation work spanned around 90 hours, while the post-editing took around 25 hours. Table 2 reports CER and WER between the Italian, English, and Lombard versions of FLORES+. Table 1 gives some figures regarding the size of the datasets.

## 4 Evaluation

To evaluate the dataset, we conduct some brief translation experiments with off-the-shelf models: NLLB-200-distilled-600M (NLLB Team, 2024), Minerva-7B-Instruct-2407 (Orlando et al., 2024), LLaMAntino-3-ANITA-8B-Inst-DPO-ITA (AI@Meta, 2024; Basile et al., 2023; Polignano et al., 2024), Mistral-Nemo-Instruct-2407 (Mistral AI Team, 2024), EuroLLM-22B-Instruct-2512 (Ramos et al., 2026), and Qwen2.5-32B-Instruct (Qwen Team, 2025). We use ChrF++ (Popović, 2017) since it is currently the least suboptimal automated metric for under-served languages (Mathur et al., 2020; Signoroni et al., 2025). We still compute and report (in Table 5) other metrics, such as BLEU (Papineni et al., 2002) and TER (Snover et al., 2006), to allow for comparison.

To establish a baseline for lexical and orthographical overlap, we first compute the ChrF++ scores for a verbatim copy baseline. The highest overlap occurs between Italian (28.69 for Italian → lmo_east) and the Lombard varieties, reflecting the shared phylogenetic roots. The copy baseline between `lmo_east` and `lmo_west` sits at roughly 25 ChrF++, indicating that their surface-level orthographic and lexical realizations in the translation differ significantly. There is minimal overlap with English (16.36 ChrF++).

As for actual MT, we prompt the models cited above in a zero-shot scenario. Figure 2 presents the zero-shot MT performance of our selected LLMs. While models like EuroLLM 22B and Qwen 32B perform robustly on standard high-resourced, Italian-English pairs, their performance drops when generating Lombard. NLLB-200 achieves the highest scores when translating from English to both Lombard varieties, but a distinct

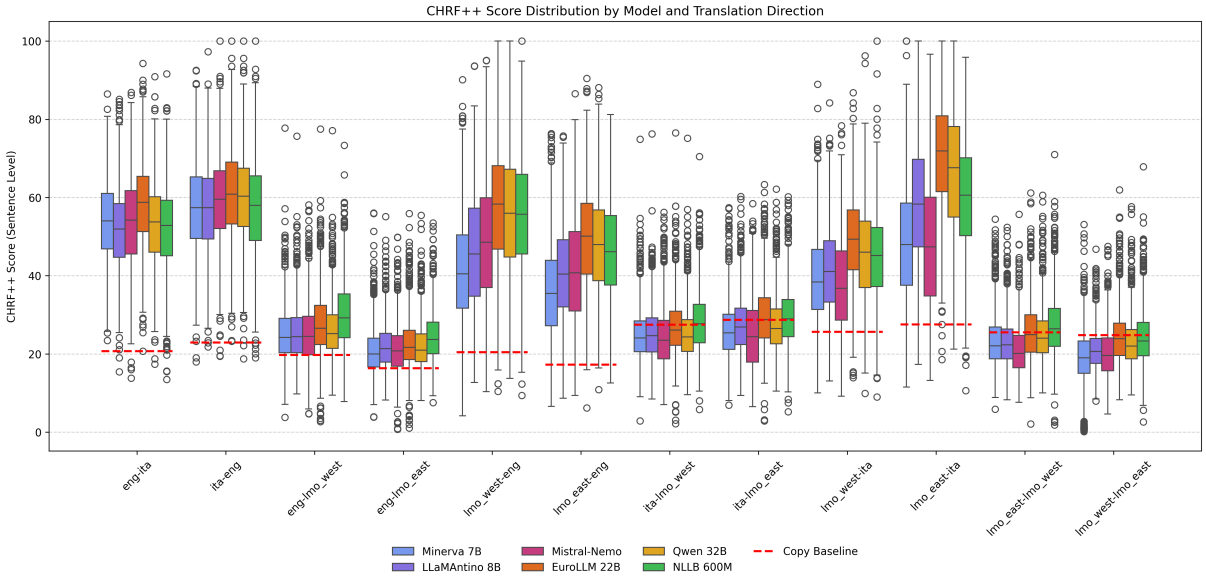

Figure 2: Zero-shot performance on MT (ChrF++) of the models we tested. We include English-Italian as a high-resource reference.

performance gap remains: all score close or below the copying baseline when translating into a Lombard variety, and universally lower when translating into `lmo_east` compared to `lmo_west`. Translating from Italian seems to be easier overall, with *lmo_west* being the harder one instead.

The discrepancy when translating from English, suggests a training data imbalance. Western Lombard is more heavily represented in existing web-scraped corpora (Signoroni and Rychlý, 2026), and models default to Western morphology and lexicon even when prompted for Eastern Lombard. By manually examining some examples, we notice that the models, even when the scores are high, tend to output Western Lombard. To verify this, we evaluate the output of the models when they are asked to translate into Eastern Lombard against the current Western reference. When translating from English, the models are more likely to generate Western Lombard (avg. +3.95 ChrF++), whereas when the source text is in Italian they are more reliant on the surface similarities with the Eastern Lombard text (avg. -2.09 ChrF++). When substituting *lmo_west* for *lmo_east* in inter-variety translation, ChrF++ scores spike (+24.62), signaling that the models are copying the source text. Similarities in the structure of the text can also explain the higher scores for *lmo_east* when translating from Italian.

These scores mirror those found by Signoroni and Rychlý (2026) when evaluating similar LLMs on a broader selection of language varieties from Italy.

## 5 Conclusions

In this paper we introduced a high-quality Eastern Lombard translation of the FLORES+ benchmark designed to address the lack of evaluation datasets for Eastern Lombard varieties. Translating an endangered, predominantly oral language continuum required navigating complex methodological challenges that should be addressed by involving local communities and volunteers. Our zero-shot evaluations confirmed that current LLMs and MT models are virtually blind to Eastern Lombard, consistently defaulting to Western forms due to their prevalence in training data. By providing the critical infrastructure to measure and mitigate this bias, our translation lays the groundwork for future efforts in variant-aware NLP for Lombard.

## Limitations

While this translation represents a significant step forward for Lombard NLP, the dataset has some limitations. First, the translation relies on the effort of a single volunteer and the post-editing of the first author. Consequently, the dataset inevitably reflects their specific idiolects and generational linguistic habits. Second, both contributors speak a contact variety situated on the border between the Bergamasque and Brescian areas. While this could, arguably, be an advantage, the dataset does not capture the full geographic spectrum of East-

ern Lombard, and ideally each variety should be represented by its own data.

Finally, the adoption of a unified orthography, while necessary for computational consistency, forces an orthographic compromise. As noted during the translation process, the volunteer initially expressed a desire to use highly localized phonetic spelling (e.g., marking the local aspiration of /s/ to [h]). By standardizing the spelling to maintain NLP reliability, we actively flattened these localized phonetic features, which restricts the dataset's ability to represent the true phonetic granularity of the spoken language.

## Ethical Considerations

Creating an NLP benchmark for an endangered, predominantly oral language continuum introduces some ethical tensions. By standardizing spelling and regularizing vocabulary in a widely used benchmark dataset, we risk implicitly crowning our specific translation as a "correct" or prestige version of Eastern Lombard. This artificial standardization can inadvertently alienate speakers whose local varieties or personal writing habits differ from our conventions, flattening the highly varied nature of the continuum. We encourage speakers to contribute translations in other varieties and orthographical standards to enable for a more comprehensive representation of Lombard.

Furthermore, we acknowledge a significant domain mismatch. Eastern Lombard varieties are socially perceived and utilized almost exclusively as a colloquial, informal heritage language. The FLORES+ benchmark, however, includes highly technical, scientific, and journalistic domains. Translating these sentences required the extensive adaptation of Italian loanwords and the generation of neologisms that may not organically exist in the everyday spoken language. Consequently, while the dataset is grammatically and lexically accurate, some of the resulting text may feel artificial to native speakers. We sought to strike a balance between respecting the natural linguistic reality of the community and the engineering necessity of creating a benchmark, prioritizing the creation of a functional NLP resource. To mitigate this issue, we provide extensive information in the text regarding which variety we are representing and the linguistic and orthographical choices we made. In this spirit, we store (on a secure server) the original draft translation as given by the translator, to be able to revert the regularization we applied.

## Acknowledgments

We would like first and foremost to acknowledge Luigi Signoroni, the volunteer translator without whose patient collaboration and tireless effort this dataset would not exist.

We also wish to thank Alex Caporali, for the insightful feedback and discussion on Lombard spelling and orthography; David Dale and Samuel Frontull, for the useful suggestions regarding evaluation and validation of the data, and the reviewers for suggesting improvements to the text.

The work described herein has been supported by the Ministry of Education, Youth and Sports of the Czech Republic, Projects No. LM2023062 LINDAT/CLARIAH-CZ.

## A Automated Classification

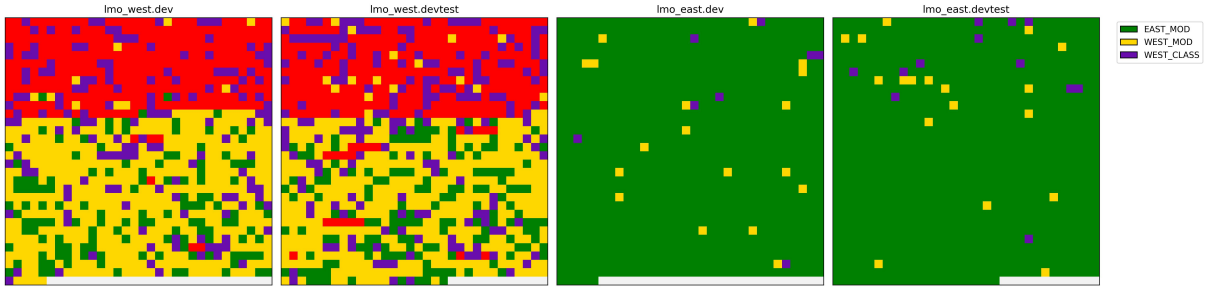

Figure 3: Plots of the orthographical composition of the FLORES+ `dev` and `devtest` according to automated classification (1 square = 1 example). Western Classical in purple; Western Modern in yellow; Eastern Modern (our) in green; *Scriver Lombard* (SL) in red.

As we mentioned in the Introduction, the motivation for this work is the lack of a benchmark dataset for Eastern Lombard. This claim is supported by audits of the data (Signoroni and Rychlý, 2026), and by our own observations, which show that the current `lmo` data in FLORES+ is almost exclusively in Western Lombard. Hence, we will refer to it provisionally as *lmo_west*.

To validate our manual observations on the whole dataset, we run the `LombardoGraphia` classifiers (Signoroni and Rychly, 2026) on both the current `lmo_west` and our `lmo_east` translation.

Following Signoroni and Rychlý (2026), we aggregate the orthographical tags in four macrogroups to smooth out variant under-specification and differing performance of the classifiers on minority classes. The grouping is guided by both linguistic and empirical evidence. The first group is "Western Classical" (WESTCLAS), which comprises the Milanese Classical Orthography (MILCLASS) and the *Noeva Ortografia Lombarda* (NOL), a Pan-Lombard orthography which is heavily influenced by MILCLASS. The second group is Western Modern (WESTMOD), formed by the *Urtugrafia insübrica ünificada* (LOCC) and by the LSI orthography, that are both "modern" (i.e. phonological, using umlauts) systems for Western (and Alpine) Lombard. "Eastern Modern" (EASTMOD) covers all the major Easter Lombard variants (LORUNIF *Ortograféa Orientàl Ünificàda*, BERGDUC *Ortografea del Dücat*, BREMOD *Ortograféa Bressàna Modèrna*, CRES *Urtugrafia Cremàsca*), which are similar to one another. Lastly, *Scriver Lombard* (SL), another Pan-Lombard orthography, constitutes a separate group due to its use of proprietary characters (e.g. *ç*, *x*) and orthographical choices (e.g. *qe* vs *che*) which render it somewhat removed from the other proposed orthographies.

While orthographies cannot be the sole indicator of linguistic variety, they cannot be firmly disentangled, not even in the case of Pan-Lombard systems. However they can still be usable proxies for the provenance of the lexical content of the text (Signoroni and Rychly, 2026). Simply put, we maintain that one can safely assume that a text written in e.g. MILCLASS will be lexically *Milanés*, and not in e.g. *Bergamàsch*; and vice-versa a text orthographically in BERGDUC, will be most assuredly not from a Milanese speaker, but from a Bergamasque one.

Figure 3 visualizes the results for the automatic classification. Even at a first glance, the difference in composition for the two versions is striking: the `lmo_west` version presents an almost clean split between SL and WESTMOD. As is expected, some examples are classified as WESTCLAS and EASTMOD, but most of these are misclassifications due to the models not being perfect or the sentences being ambiguous or under-specified orthographically.

The presence of multiple orthographic systems in a benchmark dataset poses problems for the representativeness and the reliability of the dataset itself, confounding both models and humans about the nature of the Lombard language continuum and the current MT performance for its varieties.

Our `lmo_east` translation is, instead, mostly uniform. EASTMOD dominates the classification plot, with other tags being misclassified examples.

## B Orthographical Conventions

| Phoneme | Grapheme | Examples |
|---|---|---|
| **Vowels** | | |
| /a/ | a | *áqua* (‘water’) |
| /e/ | é | *sét* (‘thirst’) |
| /ɛ/ | è | *sèt* (‘seven’) |
| /i/ | i | *ìga* (‘to have’) |
| /o/ | ó | *póm* (‘apple’) |
| /ɔ/ | ò | *òm* (‘man’) |
| /u/ | u | *ùlem* (‘elm’) |
| /y/ | ü | *giü* (‘one’) |
| /ø/ | ö | *öa* (‘grapes’) |
| **Consonants** | | |
| /p/ | p | *scarpù* (‘boot’), *pà* (‘bread’), *gróp* (‘knot’) |
| /b/ | b | *bò* (‘ox’), *sbòss* (‘sketch’) |
| /t/ | t | *tòch* (‘piece’) |
| /d/ | d | *dit* (‘finger’), *stràda* (‘road’) |
| /ʧ/ | c (before *e, i*)<br>ci (before *a, o, u*)<br>cc (word-final) | *cél* (‘sky’), *cìca* (‘marble, pellet’)<br>*ciar* (‘clear’), *ciós* (‘field’), *paciüch* (‘mud’)<br>*öcc* (‘eyes’), *gacc* (‘cats’) |
| /ʤ/ | g (before *e, i*)<br>gi (before *a, o, u*) | *getà* (‘to throw’)<br>*giàca* (‘jacket’), *giöst* (‘right, correct’), *giupì* (‘clown’) |
| /k/ | c (before *a, o, u*)<br>ch (before *e, i* or word-final)<br>q (before *u* /w/) | *còl* (‘head’), *àca* (‘cow’), *cuacià* (‘to caress’)<br>*chèst* (‘this’), *sorèch* (‘mouse’)<br>*quat* (‘how much’) |
| /g/ | g | *gombèt* (‘elbow’), *sórga* (‘rat’) |
| /f/ | f | *röfa* (‘dandruff’), *féra* (‘fair, market’), *catìf* (‘evil’) |
| /v/ | v | *vagù* (‘wagon’) |
| /s/ | s | *servèl* (‘brain’), *spössà* (‘to smell bad’), *fés* (‘more’) |
| /z/ | z | *zùen* (‘young’) |
| /ʃ/ | sc (before *e, i*)<br>sci (before *a, o, u*) | *scèr* (‘Turkey oak’), *scì* (‘ski’)<br>*sciàl* (‘shawl’), *sciùra* (‘lady’), *sciòr* (‘gentleman, rich man’) |

# Script Matters: Benchmarking Open-Source Machine Translation for Manipuri in Meetei-Mayek and Bengali Script

## Abstract

Manipuri (Meiteilon) officially recognised the Meetei-Mayek script alongside the Bengali script in 2021, with both scripts permitted for concurrent use during a 10-year transition period. However, the FLORES-200 devtest release still encodes Manipuri only as Bengali script, leaving the language's current official script without a standard benchmark. We address this gap by contributing the (mni_Mtei) layer, aligned with the existing Bengali-script (mni_Beng) data, to form a four-way parallel resource comprising English, Hindi, Meetei-Mayek Manipuri, and Bengali-script Manipuri, with 1,012 sentences per language. This resource enables separate evaluation of open-source MT and LLM systems on the two Manipuri scripts, rather than treating them as a single "Manipuri" target. Across three IndicTrans2 checkpoint families, Sarvam-Translate, and five general-purpose LLMs, evaluated using six automatic metrics, we find that legacy Bengali-script output often scores higher than Meetei-Mayek despite the latter being the official script; IndicTrans2's family degrades sharply on Bengali-script Manipuri; Sarvam-Translate cannot produce Bengali script at all; and none of the five general-purpose LLMs we test can reliably read or write Meetei-Mayek. Script identity is therefore a first-class evaluation variable for Manipuri MT: a single "Manipuri" score can mask large, direction-dependent quality gaps. We release our data[1], inference scripts, and evaluation harness.

## 1 Introduction

Manipuri (ISO 639-3: mni), spoken primarily in Manipur, India, is officially written in Meetei-Mayek (Unicode block mni_Mtei), reinstated as the state's official script in 2021 after decades of Bengali-script (mni_Beng) usage following historical script suppression. FLORES-200 (Team et al., 2022), the standard $n$-way parallel benchmark used to evaluate MT systems across low-resource languages, predates this switch: its Manipuri devtest split is encoded only as mni_Beng, so every existing FLORES-based Manipuri leaderboard number describes a script the language officially stopped using in 2021.

We fill this gap directly: we contribute a mni_Mtei devtest split aligned sentence-for-sentence to the original 1012-sentence FLORES-devtest split, alongside a matching Hindi split, so the same underlying content is available in English, Hindi, and *both* Manipuri scripts. This lets us evaluate current MT and LLM systems on Meetei-Mayek under the same FLORES-devtest protocol used for hundreds of other languages, and lets us hold everything except script constant when comparing mni_Mtei against mni_Beng output for the same model.

The stakes are not merely academic: a system deployed for Manipuri government or education services today is expected to produce Meetei-Mayek, since school and college curricula have used it as the medium of instruction since 2021, while a system trained on legacy web-crawled text may default to the wrong script for that use case. Meetei-Mayek is also, unlike Bengali script, used exclusively for Manipuri, which removes a specific source of ambiguity we return to in Section 4: several systems we test, when asked to produce Bengali-script Manipuri, instead default to producing plain Bengali or otherwise misidentify the language, an error that is structurally impossible when the target script is Meetei-Mayek. To our knowledge, no existing benchmark evaluates the same set of MT systems on both scripts side by side to quantify this gap.

We make the following contributions:

- We contribute, to our knowledge, the first publicly documented FLORES-devtest-

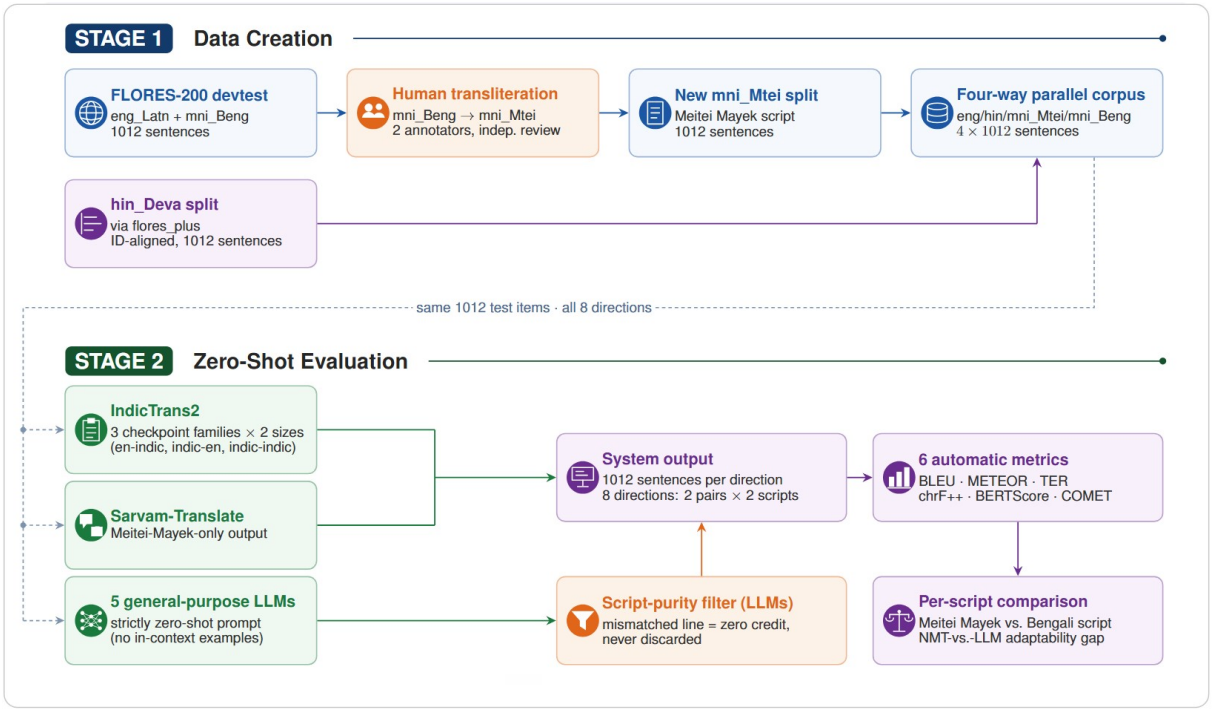

Figure 1: End-to-end pipeline. **Stage 1** extends FLORES-200 with an ID-aligned `hin_Deva` split and a human-transliterated `mni_Mtei` split, yielding a four-way parallel corpus (1012 sentences per language/script). **Stage 2** evaluates IndicTrans2, Sarvam-Translate and five LLMs on all eight directions; script-mismatched LLM lines are zero-credited rather than discarded, so every system is scored on the same 1012 sentences.

aligned Meetei-Mayek (`mni_Mtei`) evaluation split (human transliteration with independent second-annotator review, not independent re-translation), with a matching Hindi (`hin_Deva`) and English (`eng_Latn`) split, forming a four-way parallel resource (1012 sentences each). Wording is held fixed across the two Manipuri scripts by construction, so the resource also supports direct `mni_Beng`↔`mni_Mtei` transliteration evaluation.

- We benchmark IndicTrans2 (three checkpoint families, two sizes each) and Sarvam-Translate across both scripts and both translation directions, using six automatic metrics: BLEU, METEOR, TER, chrF++, BERTScore, and COMET.

- We benchmark five general-purpose instruction-tuned LLMs on the full 1012-sentence split across all eight directions with the same six metrics. None can reliably read or write Meetei-Mayek, and even the best LLM/direction result we score (chrF++ 25.76) falls short of the weakest reliable dedicated-MT result (chrF++ 32.89), establishing this as currently a dedicated-MT-system task, not a general-LLM one.

- We document three qualitatively distinct failure modes that only appear on the Bengali-script side of dedicated MT systems: a checkpoint-specific hallucination artifact, register drift into Sanskritized vocabulary, and beam-search repetition collapse. None occur for the same models on Meetei-Mayek.

- We show that Sarvam-Translate, the strongest system on Meetei-Mayek, cannot be steered to produce Bengali-script Manipuri at all via prompting, and that dedicated MT and general-purpose LLMs favor *opposite* scripts on average – a training-data-curation effect, not an inherent property of either script.

## 2 Related Work

**Multilingual MT benchmarks and Indic-focused MT.** FLORES-200 (Team et al., 2022) provides $n$-way parallel evaluation data for 200 languages, including Manipuri, encoded as `mni_Beng`; its release predates Manipur's 2021 re-instatement of Meetei-Mayek, so systems trained purely on FLORES/NLLB data (NLLB-200,

MADLAD-400 (Kudugunta et al., 2023), SeamlessM4T (Seamless Communication et al., 2023)) inherit Bengali-script-only support. IndicTrans2 (Gala et al., 2023), trained for India's 22 scheduled languages, is to our knowledge the first widely used open MT system to treat Meetei-Mayek as a first-class target script, shipping separate checkpoint families for `en-indic`, `indic-en`, and `indic-indic` translation. Sarvam-Translate (Sarvam AI, 2025), a Gemma3-4B instruction-tuned model from Sarvam AI with AI4Bharat, lists Manipuri among its supported languages but per its model card supports only English↔Indic directly.

**General-purpose LLMs for translation.** Instruction-tuned chat LLMs are increasingly used for translation without dedicated MT training, but published multilingual coverage claims rarely extend to recently-changed-script languages: none of the five LLMs we screen (Section 5) lists Meetei-Mayek as a supported language, so their behavior on `mni_Mtei` is, to our knowledge, previously undocumented.

**Evaluation metrics.** We report metrics with different sensitivities: surface $n$-gram overlap (BLEU; Papineni et al., 2002), edit distance (TER; Snover et al., 2006), synonym-aware overlap (METEOR; Banerjee and Lavie, 2005), character-level $F$-score (chrF++; Popović, 2017), and learned semantic similarity (BERTScore; Zhang et al., 2020, using XLM-R Conneau et al., 2020; COMET; Rei et al., 2020, 2022).

## 3 Data

Figure 1 gives an overview of the full pipeline, from data creation through evaluation.

We extend the FLORES-devtest split (1012 sentences) with four parallel, strictly line-aligned reference files: `eng_Latn` and `mni_Beng` from the original FLORES-200 devtest release; `hin_Deva`, sourced via `openlanguagedata/flores_plus` and aligned by sentence ID; and `mni_Mtei`, likewise ID-aligned. This lets us evaluate any of the twelve ordered pairs among {English, Hindi, Manipuri-Meetei, Manipuri-Bengali} and, critically, isolate script as the only varying factor when comparing `mni_Mtei` against `mni_Beng` translations of the same content.

## 4 Script-Level Evaluation

`mni_Mtei` and `mni_Beng` are script-level counterparts of each other (the same underlying translation, transliterated rather than independently re-translated), unlike a prior 997-sentence Meetei-script overlap produced by independent translators for each script, where word choice can diverge and confound script identity with translator choice. The `mni_Mtei` split was produced by two native-speaker professional translators: one transliterated the FLORES-devtest `mni_Beng` split into Meetei-Mayek, and the second independently reviewed every sentence (Appendix A has the full transliteration guidelines).

## 5 Models and Experimental Setup

We evaluate two dedicated MT systems and five general-purpose LLMs. IndicTrans2 (Gala et al., 2023) ships three checkpoint families (`en-indic`, `indic-en`, `indic-indic`, each a 1B model plus a distilled 200–320M variant), with `mni_Mtei` and `mni_Beng` as distinct tokenizer language tags in every family. Sarvam-Translate (Sarvam AI, 2025) is prompted as a chat model and supports only English↔Indic directly; we pivot through English for Hindi↔Manipuri. The five general-purpose LLMs – Aya Expanse 8B (Cohere For AI, 2024), Qwen3-14B (Qwen Team, 2025), Gemma-3-12B-it (Gemma Team, 2025), Llama-3.1-8B-Instruct (Llama Team, AI @ Meta, 2024), and GLM-4-9B-0414 (Zhipu AI and Tsinghua KEG, 2024) – are evaluated with a role-primed prompt (Appendix D) across all eight directions (both scripts × both language pairs); none was screened out, since our goal is to characterize *how* they fail, not to find one that succeeds. Appendix B gives full checkpoint, decoding, and prompting configuration.

All inference uses greedy or low-temperature decoding, batch sizes of 8–16, and bfloat16 precision on a single GPU. We report six metrics per direction: BLEU and chrF++ (`sacrebleu`), TER (`sacrebleu`), corpus-averaged sentence METEOR (`nltk`), BERTScore $F_1$ (`xlm-roberta-large`), and COMET (`wmt22-comet-da`). The twenty dedicated-MT combinations are each run over the full 1012-sentence split, discarding and re-running any output with blank lines or a line-count mismatch; the five LLMs are run over the same split with a looser criterion, since a script-purity filter can legitimately zero out a failed line rather than

| Direction | Model | chrF++↑ | BLEU↑ | METEOR↑ | TER↓ | BERTScore↑ | COMET↑ |
|---|---|---|---|---|---|---|---|
| eng → mni_Mtei | IndicTrans2-1B | 33.16 | 3.37 | 16.12 | 112.12 | 97.64 | **85.24** |

Table 2: Translation performance on the Bengali-script variant for English–Manipuri and Hindi–Manipuri directions; Sarvam-Translate is excluded due to lack of support, and results are reported for models supporting the Bengali-script variant.

signal an interrupted run – Appendix B details both criteria.

Our central finding is that dedicated MT and general-purpose LLMs favor *opposite* scripts on average. Full per-model, per-direction tables (twelve Meetei-Mayek and twenty Bengali-script/LLM directions) are in Appendix C.

**The legacy script scores higher on English→Manipuri.** Both IndicTrans2 sizes score `eng→mni_Beng` above `eng→mni_Mtei` (BLEU 7.10–7.64 vs. 3.37–3.43), even though Meetei-Mayek is the current official script – we attribute this to training-data recency asymmetry (Appendix C). Notably, BERTScore and COMET *disagree* with this ordering here, which we read as encoder unfamiliarity with both scripts at this quality range rather than a genuine vote for Meetei-Mayek.

**Two Bengali-script-only failure modes in IndicTrans2.** The `indic-en` checkpoint intermittently hallucinates a literal escape-like fragment (e.g., ◌ at Unicode code point `U+09BC`) into English output when the `mni_Beng` source contains a foreign proper noun – confirmed as a decoding-time artifact, not present in the source, and absent on `mni_Mtei` input. The `indic-indic` family (direct Hindi↔Manipuri) shows our largest script-dependent gap: `hin→mni_Beng` collapses to near-zero BLEU (0.30–0.42) via Sanskritized register drift and, for the smaller checkpoint, script-mixing and repetition loops, versus 2.35–2.55 BLEU on `hin→mni_Mtei`. Appendix C gives full examples of both artifacts.

**Sarvam-Translate cannot produce Bengali script at all.** Across all four Bengali-script directions, explicitly instructing the model to translate to or from "Manipuri (Bengali script)"

Table 3: Zero-shot LLM screening on Meetei-Mayek translation directions using the full 1,012-sentence devtest set. As in Table 1, BERTScore/COMET should be read cautiously for `mni_Mtei` rows.

still produces fluent Meetei-Mayek; we treat this as a capability gap and report no Bengali-script Sarvam-Translate numbers.

**General-purpose LLMs cannot read or write Meetei-Mayek.** A script-purity filter (emptying lines where fewer than half the letters match the target script) scores 0.00–0.01 purity on the overwhelming majority of `mni_Mtei`-target lines across all five LLMs – total failure, not marginal. On generation, models mix in characters from unrelated scripts (Odia, Devanagari, Thai, Korean, and others); chrF++ never exceeds 4.53. On comprehension, models instead *confabulate* fluent, grammatical, entirely unrelated English/Hindi text rather than declining – e.g., a source about a diabetic mouse study translated as a fabricated paragraph about a village in Assam. Bengali-script comprehension is comparatively less broken (every model scores higher on `mni_Beng`→`eng/hin` than the `mni_Mtei` equivalent) but still unreliable for translation. Appendix C has the full per-model metric tables.

## 6 Discussion

Two lessons follow. First, *script cannot be assumed constant across a language's benchmark entries*: a "Manipuri" score, reported without qualification, conflates two eras of training data and, as our `indic-indic` results show, potentially two very different quality regimes for the same model. Second, *failure modes are script-specific, not just magnitude differences*: the hallucination, register-drift, and repetition-collapse artifacts we observe on Bengali-script input have no Meetei-Mayek counterpart for the same checkpoints, suggesting data scarcity interacting with architecture rather than uniform degradation.

**Which script is more adaptable depends on the system class.** IndicTrans2 favors Meetei-Mayek in three of four direction buckets (Sarvam-Translate, being Meetei-only, pushes the dedicated-MT picture further that way), while all five LLMs favor Bengali script in all four, with roughly triple the gap on generation versus comprehension. We read this as evidence that script adaptability reflects *training-data curation*, not either script's inherent suitability: AI4Bharat built `mni_Mtei` into IndicTrans2 as a first-class target, while the LLMs' pretraining absorbed whatever legacy Bengali-script Manipuri text was already circulating online. Practitioners should expect a dedicated MT system and a general-purpose LLM to favor opposite scripts by default (full numeric breakdown in Appendix C). We suggest that benchmarks

Table 4: Zero-shot evaluation of five general-purpose instruction-tuned LLMs on Bengali-script Manipuri across four translation directions. Results are reported on the full 1,012-sentence FLORES-devtest set using chrF++, BLEU, METEOR, TER, BERTScore, and COMET, highlighting the models' ability to generate and comprehend Manipuri written in Bengali script.

for languages that have undergone a script transition report script explicitly as an evaluation axis alongside language pair, analogous to domain or genre in MT evaluation. As future work, we plan to extend the same script-paired methodology to the NLLB Seed/OLDI (Open Language Data Initiative) datasets, bringing Meetei-Mayek coverage to these broader low-resource-focused resources as well.

## 7 Conclusion

We contribute the first publicly documented FLORES-devtest-aligned Meetei-Mayek split, produced by human transliteration and independent review, paired with a matching Hindi split for direct, script-controlled evaluation of Manipuri MT. Benchmarking IndicTrans2, Sarvam-Translate, and five general-purpose LLMs across six automatic metrics, we show that script identity substantially changes both quantitative scores and qualitative failure modes for the same models: the legacy Bengali-script convention sometimes outperforms the current official script on surface metrics, the `indic-indic` checkpoint family and every LLM we tested collapse specifically on Bengali-script Manipuri or Meetei-Mayek respectively, and dedicated MT and general-purpose LLMs favor opposite scripts on average. A single "Manipuri" number, as reported by prior benchmarks built on `mni_Beng` alone, would have missed all of this. We release the dataset, inference scripts, and evaluation harness so script can be evaluated as a first-class variable for Manipuri, and, as future work, for other languages that have undergone a similar script transition.

## Limitations

BERTScore and COMET rely on multilingual encoders (XLM-R, and the COMET encoder) with, to our knowledge, minimal-to-no training exposure to Meetei-Mayek script, which was not in wide digital circulation until after these encoders' pretraining corpora were collected. We report these metrics for completeness but recommend treating their absolute values on `mni_Mtei` rows as low-confidence; chrF++ and BLEU are the more trustworthy metrics for Meetei-Mayek here. Bengali-script rows are on firmer footing since Bengali is well represented in both encoders.

Our study covers a fixed set of open-source systems available at the time of writing and a single, general-domain test set (FLORES-devtest); results may not transfer to domain-specific or dialectal Manipuri text.

## Acknowledgments

We thank the NLLB/FLORES-200 team for the original 1012-sentence devtest corpus and its Bengali-script Manipuri translations, on top of which we contribute the Meetei-Mayek layer that is the subject of this paper; the Open Language Data Initiative (OLDI) for accepting our proposal to contribute this resource; the COIL-D project for providing resources used in this work; and the AI4Bharat and Sarvam AI teams for releasing open, gated-but-accessible model weights that made this comparison possible.

# A Transliteration Guidelines

## A.1 Transliteration and Review (`mni_Mtei` Split Creation)

Given to both annotators (Section 4), each a native-speaker professional translator holding a graduate degree and at least five years of translation experience:

1. **Task**: Transliterate each sentence in the FLORES-devtest `mni_Beng` (Bengali-script Manipuri) split into Meetei-Mayek script. This is a script conversion, not a re-translation: preserve the exact wording, word order, and meaning of the `mni_Beng` source sentence. Do not paraphrase, simplify, or "improve" the phrasing.

2. **Numerals and Latin text**: Retain digits, proper nouns in Latin script, and punctuation exactly as they appear in the source unless Meetei-Mayek orthographic convention requires a native numeral or punctuation mark; when in doubt, prefer the form already used in existing Meetei-Mayek educational text (see the reference textbook list provided separately to annotators).

3. **Ambiguous or archaic `mni_Beng` spellings**: Where the Bengali-script source is ambiguous between two Meetei-Mayek renderings, choose the rendering consistent with current Manipur school-curriculum orthography; flag the sentence ID in a shared tracking sheet for second-annotator discussion rather than resolving it unilaterally.

4. **Review pass (second annotator)**: Independently read every transliterated sentence against the `mni_Beng` source (not against the first annotator's output in isolation) and mark each as Accept, Minor Edit (typo, incorrect character, orthography), or Flag for Discussion (meaning-level disagreement). Apply Minor Edits directly; resolve Flagged items jointly with the first annotator before finalizing.

5. **Output**: One Meetei-Mayek sentence per line, line-aligned to the source `mni_Beng` file, with no added commentary, footnotes, or alternate readings in the released file.

# B Model and Screening Details

## B.1 IndicTrans2 checkpoints

IndicTrans2 ships three separate checkpoint families, each independently gated on HuggingFace, because AI4Bharat trains distinct weights per translation direction rather than a single shared encoder-decoder: **en-indic** (English→Indic, 1B and a distilled 200M variant), **indic-en** (Indic→English, 1B and 200M), and **indic-indic** (Indic→Indic, used here for Hindi↔Manipuri, 1B and a distilled 320M variant). We verified directly against the tokenizer vocabulary that both `mni_Mtei` and `mni_Beng` exist as distinct language tags in every family, confirming Bengali-script support is a genuine modeling target rather than an accidental byte-fallback artifact. Inference uses the `IndicTransToolkit` pre/post-processing pipeline (normalization, script-aware digit conversion).

## B.2 Sarvam-Translate prompting

Sarvam-Translate is prompted as a chat model (`"Translate the text below to {language}."`) with greedy-leaning decoding (`temperature=0.01`). For Hindi↔Manipuri we implement the model card's recommended two-hop English pivot: two forward passes per sentence with the same checkpoint.

## B.3 Completeness criteria

Each of the twenty dedicated-MT (model, checkpoint, direction, script) combinations is run over the full 1012-sentence devtest split; we discard and re-run any output containing blank lines or a line-count mismatch against the reference, treating this as an interrupted run rather than a model failure. The five LLMs are run over the same full split across all eight directions each (forty (model, direction) combinations total), scored with the same six metrics; a purity-filtered (emptied) line is scored as zero-credit against the reference rather than discarded, so a model that fails on most sentences still receives a real, near-floor score. Here, only a line-count *mismatch* against the reference – not the presence of blanks – causes us to exclude a combination, since a blank can be a legitimate scored failure rather than an interrupted run. All forty LLM

(model, direction) combinations pass this check and are reported in Appendix C's tables.

## C Extended Results and Failure-Mode Analysis

This appendix expands the summarized findings of Section 4 with full per-model, per-direction metric tables and the detailed evidence behind each failure mode.

### C.1 English→Manipuri: legacy script vs. official script

Both IndicTrans2 sizes score `eng→mni_Beng` noticeably above `eng→mni_Mtei` (BLEU 7.10–7.64 vs. 3.37–3.43; chrF++ 36.75–37.01 vs. 32.89–33.16), even though Meetei-Mayek is the script IndicTrans2 was explicitly built to target and the one with current official status. We attribute this to training-data recency asymmetry: Bengali-script Manipuri text has circulated on the web for decades and is well represented in legacy corpora, while Meetei-Mayek web text is comparatively young (large-scale digital adoption began only after 2021). The reverse direction (Manipuri→English) shows the same ordering but with a smaller gap (BLEU 21.09–23.97 for Bengali script vs. 24.35–27.07 for Meetei-Mayek), suggesting source-side script recognition is more robust than target-side script generation for the less-represented script.

Notably, the learned metrics *disagree* with this ordering on `eng→mni`: both BERTScore and COMET rank Meetei-Mayek output above Bengali-script output (COMET 84.7–85.2 vs. 67.9–68.2), the opposite of BLEU and chrF++. Since absolute quality is low on both sides (chrF++ in the low-to-mid thirties throughout), we read this as evidence that the multilingual encoders behind BERTScore and COMET are not well calibrated to discriminate translation quality in either script at this quality range, rather than a genuine vote for Meetei-Mayek.

Averaging across both IndicTrans2-1B sizes makes the asymmetry precise: on `eng→mni`, Bengali script leads by $+3.73$ BLEU and $+3.85$ chrF++ but trails by $-17.01$ COMET; on `mni→eng`, Meetei-Mayek leads on every metric, but by a much smaller margin ($+3.10$ BLEU, $+1.72$ chrF++, $+0.42$ COMET). The size of the COMET gap on `eng→mni` (16.91 points) dwarfs the corresponding gap on `mni→eng` (0.42 points) even though the lexical-overlap metrics move by comparable amounts in both directions – a further sign that COMET's judgment on `eng→mni` is dominated by encoder unfamiliarity with the target-side script, rather than by anything in the source.

### C.2 A checkpoint-specific hallucination on Bengali-script input

The `indic-en` checkpoint (Manipuri→English, both sizes), when given `mni_Beng` input containing a foreign proper noun (person or company name), intermittently emits a literal escape-like fragment resembling spliced into the English output. We confirmed via direct inspection that ◌ (Bengali sign nukta) does not appear anywhere in the corresponding source sentence, ruling out a source-data artifact; this is a decoding-time hallucination specific to this checkpoint on this script, and the identical model on `mni_Mtei` input never exhibits it. We mitigate it with a post-hoc regular-expression cleanup (stripping the fragment and any stray backslash) in the released inference scripts, which raises usable output rate substantially, though sentence content lost during the original hallucination is not recoverable by this cleanup. Rows marked † in Table 2 reflect this mitigation.

### C.3 indic-indic degrades sharply on Bengali-script Manipuri

The `indic-indic` checkpoint family, used for direct Hindi↔Manipuri translation, shows the largest script-dependent gap we observe. On `hin→mni_Beng`, both sizes collapse to near-zero BLEU (0.30–0.42) and very low chrF++ (4.10–9.85), an order of magnitude below the same models' `hin→mni_Mtei` scores (2.35–2.55 BLEU). Manual inspection shows the 1B checkpoint drifting into a Sanskritized register with Sanskrit function words and verb morphology rather than producing colloquial Manipuri, while the 320M checkpoint additionally mixes Bengali, Meetei-Mayek, and Latin scripts within a single sentence and, on at least one output, degenerates into a repeated-token loop (the same Hindi word repeated over fifty times). The reverse direction (`mni_Beng→hin`) is degraded but not catastrophic (BLEU 8.76–11.51 vs. 14.31–16.04 for `mni_Mtei→hin`), consistent with the source-recognition-is-more-robust-than-target-generation pattern noted above, compounded by numeral corruption reminiscent of the artifact in

Appendix C.2 manifesting in Hindi rather than English.

### C.4 General-purpose LLMs cannot read or write Meetei-Mayek

We probed five general-purpose instruction-tuned chat LLMs (Aya Expanse 8B, Qwen3-14B, Gemma3-12B, Llama-3.1-8B-Instruct, and GLM-4-9B) on the full 1012-sentence FLORES-devtest split across all eight directions each, using an explicit, role-primed system prompt (Appendix D). To separate genuine script failures from formatting noise, we built a script-purity filter that classifies each output character by Unicode block and empties any line where fewer than half of its letters belong to the target script or a recognizable Latin romanization; every model we tested this way scored a purity of 0.00–0.01 on the overwhelming majority of `mni_Mtei`-target lines, confirming the failure is total rather than marginal. A purity-filtered (emptied) line is scored as zero-credit against the reference rather than discarded, so a model that fails on most sentences still receives a real, near-floor corpus score rather than an inflated average over its rare successes.

Two distinct failure modes emerged, one on each side of the pair. On *generation* (English/Hindi→Manipuri), all five models mix characters from several unrelated scripts within a single line: we observed fragments of Odia, Bengali, Devanagari, Gujarati, Punjabi, Lao, Thai, Korean, Ol Chiki, and Thaana in outputs nominally targeting Meetei-Mayek, none of which is the requested script. Table 3 makes this quantitative: chrF++ on `eng/hin→mni_Mtei` never exceeds 4.53, an order of magnitude below the weakest dedicated MT system in Table 1. On *comprehension* (Manipuri→English/Hindi), the failure is more concerning: rather than producing garbled output, models generate fluent, grammatical English or Hindi that is *entirely unrelated to the source sentence*. For example, one model's translation of a source about a diabetic mouse study returned a fabricated paragraph about a village in Assam's Naga hills, and another invented an unrelated news item about a WHO pandemic-preparedness designation. This is confident confabulation, not a failed translation attempt: the models cannot parse Meetei-Mayek as input at all, and default to generating plausible-sounding but unrelated text rather than declining or hedging; the resulting `mni_Mtei→eng/hin` chrF++ scores (6.73–19.95) are not zero, but reflect fluent off-topic text matching stray reference words by chance, not usable translation. Bengali-script Manipuri comprehension is comparatively less broken: several models produce recognizable phonetic transliterations of the source or retain correct proper nouns, and Table 4 shows every model scoring higher on `mni_Beng→eng/hin` than on the `mni_Mtei` equivalent, though absolute quality remains too low for usable translation. We conclude that Meetei-Mayek support in current general-purpose LLMs is not a prompting problem but a training-data coverage gap, consistent with the script's short digital history, and that dedicated MT systems remain necessary for this language pair.

### C.5 Which script is more adaptable: full numeric breakdown

Averaging chrF++ within each direction bucket across all evaluated models reveals a split between dedicated MT systems and general-purpose LLMs. For IndicTrans2, Meetei-Mayek is the better-supported script in three of four buckets: `hin→mni` favors Meetei-Mayek by +23.1 chrF++ (the `indic-indic` collapse from Appendix C.3), `mni→hin` by +4.4, and `mni→eng` by +2.2; only `eng→mni` favors Bengali script, by +3.9. Sarvam-Translate is Meetei-only by construction, pushing the dedicated-MT picture further toward Meetei-Mayek. The five general-purpose LLMs show the opposite and more consistent pattern: Bengali script wins all four buckets, by +7.2 chrF++ on `eng→mni`, +7.6 on `hin→mni`, +2.7 on `mni→eng`, and +2.2 on `mni→hin` – generation shows roughly triple the comprehension-direction gap, the same source-recognition-is-more-robust-than-target-generation asymmetry noted above, just uniformly shifted toward the legacy script.

## D Prompt Templates and Zero-Shot Examples

For the general-purpose LLM screening in Appendix C.4, each of the eight direction-specific prompts follows the same role-primed template, instantiated with the appropriate source/target language names:

> *"Translate the text below to {target language} (target language). Output only the translation, with no explanation or extra text."*

# The Croatian Dataset Seed Submission to the WMT26 Open Language Data Initiative Shared Task

## Abstract

We present a new English–Croatian parallel corpus for the WMT26 Open Language Data Initiative (OLDI) Seed shared task, consisting of 6,193 sentence pairs. To ensure high quality, the resource was produced via machine translation followed by a two-stage verification process (post-editing and independent revision) conducted by professional translators. We validate the corpus by fine-tuning NLLB-200, TranslateGemma, and Gemma-4-31B. The dataset improves every dedicated translation model in both directions and the strongest open LLMs in the Croatian→English direction. Through a training-data ablation, we demonstrate that the benefit of human verification increases with model capacity and is visible only to neural metrics, not to surface-overlap metrics such as chrF++. Finally, we analyze the quality ceiling for the strongest models, identifying a trade-off between naturalness and surface overlap in the English→Croatian direction.

## 1 Introduction

Machine translation has undergone substantial development in recent years. However, these improvements have predominantly benefited high-resource languages, while low- and medium-resourced languages progress at a slower pace. Simultaneously, the number of available parallel datasets also differs across languages, with low- and medium-resourced languages at a disadvantage. Croatian is variously classified as a low- or a medium-resourced language.

The Croatian dataset we submit to the WMT26 Open Language Data Initiative (OLDI) shared task consists of 6,193 sentence pairs covering a broad range of domains of human knowledge. The Croatian translations were generated using machine translation, which was subsequently followed by a two-stage verification process. To ensure terminological consistency, grammatical, semantic and lexical correctness, machine translation post-editing and revision were performed.

The contributions of this paper are threefold: (1) a human-validated, domain-diverse Croatian dataset of 6,193 sentence pairs for the WMT26 OLDI shared task; (2) a documented two-stage quality-assurance workflow combining machine translation post-editing and independent revision; and (3) experimental results showing that the dataset improves every dedicated translation model in both directions and the strongest open LLMs in the Croatian→English direction. This includes an ablation study that specifically quantifies how much the human verification stage contributes to the final model quality, and an analysis of when fine-tuning on such data stops helping.

## 2 Related Work

Modern language technologies do not preserve language diversity and promote multilingualism equally across all languages. Many high-resource languages, such as English, Spanish or German, benefit from extensively developed parallel web corpora. On the other hand, low- and medium-resourced languages suffer from data scarcity on the Internet. Although the situation is improving to some extent, the gap between such languages still exists and needs to be addressed (Joshi et al., 2020). Croatian is one such language. This language has been classified as a mid-resource language (Thakkar et al., 2024) in some works, while others argue that it belongs to the group of low-resourced languages (Bago et al., 2022; Koloski et al., 2022). The Seed corpus itself was introduced by Maillard et al. (2023), who showed that even a few thousand professionally translated sentence pairs measurably improve machine translation for low-resource languages. The Open Language Data Initiative has collected such datasets through a WMT shared task since 2024 (Dale et al.,

*Proceedings of the Eleventh Conference on Machine Translation*, pages 2571–2583
October 28-29, 2026 ©2026 Association for Computational Linguistics

2025).

Croatian is currently spoken by approximately 5 million people and has been an official language of the EU since 2013 (Tadić, 2023). It belongs to the group of South Slavic languages. As such, it is a morphologically rich language that differs substantially from English because of its inflectional system, which includes grammatical case, number, person and verbal aspect. These differences may create a challenge for quality machine translation (Popović et al., 2020).

While parallel English-Croatian corpora, such as ParaCrawl (Bañón et al., 2020), hrenWaC (Ljubešić et al., 2016), MARCELL (Váradi et al., 2020) and MaCoCu (Bañón et al., 2023), do exist, detailed, domain-specific corpora remain scarce and thus require resource-intensive collection efforts. Besides that, the existence of large-scale web-crawled corpora does not guarantee uniformly high-quality data. Such resources often contain ungrammatical output, unnatural phrasing and literal translations (van Noord et al., 2025). Human translation and evaluation play a key role in ensuring high-quality resources for machine translation model training.

Furthermore, correct translation into Croatian requires context beyond the single sentence to keep gender, case, and verb forms consistent across a text, which sentence-level benchmarks cannot fully capture (Oliver and Álvarez-Vidal, 2026). In addition to domain-specific datasets, broad-coverage datasets spanning a wide variety of domains, such as Wikipedia articles, also represent good evaluation benchmarks (Goyal et al., 2022). As machine translation has seen significant improvements, translators and other language experts often engage in machine translation post-editing (Brockmann et al., 2022). Additionally, machine-translated data that undergo human verification and post-editing can also serve as a valuable resource for machine translation research (Popović and Arčan, 2016).

## 3 Data Creation

We compiled the Croatian portion of the OLDI Seed dataset, consisting of 6,193 sentence pairs and covering a wide range of domains, such as history, biology, arts, physics, architecture and many other areas of human knowledge, present on Wikipedia. This process aimed to create a high-quality English-Croatian parallel corpus that can support the training and development of machine translation models. Instead of relying solely on machine translation output, we subjected the translations to two steps of human verification:

1. Machine translation post-editing
2. Revision

This combined the speed of machine translation with human linguistic expertise.

The Croatian translation of the OLDI Seed dataset was curated using Matecat, a free and open-source computer-assisted translation tool (CAT tool) developed as part of a project funded by the European Commission. The tool's integrated machine translation engine, ModernMT Lite, supports over 200 languages, including Croatian (Matecat, 2026).

As mentioned previously, the 6,193 English sentences were translated into Croatian using Matecat's integrated machine translation system. The outputs served as the initial version of the Croatian dataset. However, pure machine translation still contains errors, and human involvement is necessary to bridge the gap between machine-generated content and natural language suitable for real-world use (Marashian et al., 2025). We had each sentence manually post-edited by a native speaker of Croatian with formal education in translation studies. This stage included comparing the target text with the source text to detect potential errors. The error types ranged from mistranslations, inadequate lexical choices in cases of polysemy and literal translations, omissions or additions of elements in the sentences, to grammatical and typographical errors or lexemes from other languages within the same language family (e.g., Serbian) and terminological inconsistencies. Representative examples of problematic machine translation outputs, along with their corrections, are provided in Table 1 and briefly characterized below:

- 57: unnatural use of passive voice in Croatian (*viđena je*), prepositional error (*do*)
- 112: incorrect gender pronoun (masculine instead of feminine; context from previous segments indicated the correct gender)
- 5411: literal translations that were not suitable in the context of philosophy of mathematics (*structures* as *građevine* instead of *strukture*; *concrete* as *betonski* instead of *konkretni*)

Throughout this stage, several additional tools were consulted to ensure natural and appropriate vocabulary choices. These included the bilingual corpus Glosbe, the Dictionary of Medicine (Školska knjiga), the English-Croatian Economic Dictionary (Mate), the Croatian-English and English-Croatian Dictionary of Idioms (Ljevak), the Pravopis.hr website and Struna (an online terminology database for specific fields developed by the Croatian Institute for Language). Particular attention was paid to the correct terminology for each of the domains included in the dataset, grammatical accuracy regarding cases, gender, number, as well as agreement and word order. Another important aspect was the translation of idiomatic expressions, which often display a different form in the respective languages.

Following the machine translation post-editing (MTPE) phase, the entire Croatian dataset was subsequently independently revised by a second editor, also a native speaker of Croatian with an academic background in linguistics and translation studies. The aim of this second phase was to identify any errors that remained after the post-editing stage, thus adding another layer of quality assurance. The reviser compared the source and target segments and made corrections where necessary, thus ensuring consistency, grammatical correctness, terminology appropriateness, semantic adequacy and fluency in Croatian. This second phase of linguistic validation was also important since it contributed to stronger uniformity, especially given the broad scope of domains and topics across the dataset.

Appendix A shows a verbatim excerpt of the released data.

## 4 Experimental Validation

To confirm the practical value of the dataset, we performed a series of fine-tuning and evaluation experiments spanning three model families, along with corpus-level quality estimation and a training-data ablation that isolates the contribution of human verification.

### 4.1 Experimental setup

**Models.** We fine-tuned three model families to assess the transferability of the results among different model types:

- NLLB-200 (NLLB Team et al., 2022), representing the dedicated multilingual MT systems that seed data primarily targets;
- TranslateGemma 4B and 27B (Finkelstein et al., 2026), open translation-specialized LLMs for which Croatian is among the 55 languages evaluated in the accompanying technical report;
- Gemma-4-31B-it (Gemma Team, 2026), a strong general-purpose instruction-tuned LLM, which showed strong Croatian fluency in our internal evaluations.

In addition to the fine-tuned models, we evaluate DeepSeek-V4-Flash (DeepSeek-AI, 2026), a 284B-parameter mixture-of-experts model with 13B active parameters, as an external zero-shot reference point; it is not fine-tuned.

NLLB models are fully fine-tuned, while the LLMs are fine-tuned with LoRA (Hu et al., 2022; r=32, $\alpha$=64) applied to the language-model projections, with prompt tokens masked from the loss. TranslateGemma is trained and evaluated using its native prompt format (Appendix B).

The native prompt formats of NLLB and TranslateGemma accept only the sentence to be translated, not wider context.

Fine-tuning and evaluating Gemma-4-31B, as a general-purpose instruction-tuned model, allows for more freedom in prompt format selection. Thus, Gemma-4-31B is trained and evaluated in a document-context prompt in which the sentence to be translated is stated first, followed by its full same-article source-side context (its best zero-shot configuration, selected in a pilot).

For TranslateGemma, we additionally report a full fine-tune of the 4B model and, for both sizes, a single bidirectional model trained on both directions at once; for Gemma-4-31B, the reported model is bidirectional. Checkpoint selection uses the FLORES+ dev set exclusively (chrF++ for NLLB, development loss for the LLMs, with early stopping); dev data is never used for reporting.

All fine-tuning was performed on RTX 6000 Pro Blackwell 96 GB GPUs, where full fine-tuning of 27B and 31B models was not feasible and only LoRA adaptation was performed. Learning rates were swept for the LLMs (Table 5).

**Evaluation.** We report chrF++ (Popović, 2017) as the primary surface metric and spBLEU as secondary, computed with sacreBLEU (Post, 2018), along with two architecturally independent neural metrics: COMET (wmt22-comet-da; Rei et al., 2022) and MetricX-24-XXL (Juraska et al., 2024).

| Sentence ID | Source text | Machine translation | Target text |
|---|---|---|---|
| **57** | Buster Keaton's wife Eleanor also was seen in the series (notably as Juliet to Buster's Romeo in a little-theater vignette). | U seriji **je viđena** i supruga Bustera Keatona Eleanor (osobito kao **Julija do Busterovog Romea** u maloj kazališnoj vinjeti). | U seriji **se pojavljuje** i supruga Bustera Keatona, Eleanor (posebno kao **Julija Busterovu Romeu** u maloj kazališnoj vinjeti). |
| **112** | Davis died from a heart attack in 1969, two years before Lloyd's death. | Davis je **umro** od srčanog udara 1969. godine, dvije godine prije Lloydove smrti. | Davis je **umrla** od srčanog udara 1969. godine, dvije godine prije Lloydove smrti. |
| **5411** | Structures are held to exist inasmuch as some concrete system exemplifies them. | Smatra se da **građevine** postoje u mjeri u kojoj im neki **betonski** sustav daje primjer. | Smatra se da **strukture** postoje u mjeri u kojoj ih neki **konkretni** sustav utjelovljuje. |

Table 1: Examples of problematic machine translation outputs and their post-edited corrections

Test sets are the FLORES+ devtest (in-domain for seed-style text) and NTREX-128 (Federmann et al., 2022) as an out-of-domain check.

NLLB decodes with beam size 4; the Gemma-family LLMs use a fixed prompt and greedy decoding; while the external DeepSeek-V4-Flash reference uses its model-card sampling parameters (Appendix B). All system comparisons use paired bootstrap resampling (Koehn, 2004) with 2,000 resamples, applied to chrF++/spBLEU and to per-segment COMET scores. Two caveats apply throughout: (1) Croatian was only recently added to metric evaluation sets and the neural metrics are largely untested on it (Deutsch et al., 2025) and it is unclear how well the learned metrics correlate with human judgments (Singh et al., 2024); and (2) reference translations exhibit natural variability (e.g., inconsistent renderings of the same named entity within one article), which adds noise to reference-based metrics and provides further motivation for the multi-metric evaluation. The NLLB English→Croatian training runs are replicated with three random seeds, while the LLMs are single-seed runs. Seed standard deviations ($\leq$0.1 chrF++/COMET) are well below the main effects reported in almost all cases.

### 4.2 Post-editing effort and corpus-level quality estimation

The two-stage human verification described in Section 3 shows that the Editors modified 71.5% of all segments. The corpus-level TER between raw machine translation and the final text is 16.27, i.e., roughly one in six machine-translated words was changed by a human. The mean normalized character edit distance is 0.099 (0.139 over edited segments only) and the median editing time is 32.3 seconds per segment. Matecat records editing time as the interval a segment remains open, so segments left open between sessions accumulate durations that do not correspond to work. We therefore cap per-segment time at 30 minutes, which affects 65 segments (1.05% of the corpus) and gives a tracked editing time of 184.8 hours. The distribution stays heavily skewed after capping: the median segment takes 32.3 seconds, while the slowest 10% of segments account for 62.3% of the total. Most segments needed only quick fixes, and a minority of long sentences required terminology research.

Reference-free quality estimation confirms that this effort improved the text. Scoring the whole corpus with MetricX-24-XXL in QE mode (lower is better), the raw machine translation scores 1.644 and the final human-verified text 1.473. The paired per-segment improvement is +0.171 with a 95% bootstrap confidence interval of [0.146, 0.196].

### 4.3 Does the data help? Fine-tuning results

Table 2 shows the effect of fine-tuning NLLB models on the dataset. Fine-tuning improves every model size, in both directions, on both test sets, on both surface and neural metrics. All gains are significant at $p<0.05$, most at $p=0.0005$. The exception is COMET on FLORES+ (in-domain data, $p=0.15$) for the NLLB 600M model. Gains on English→Croatian direction rise with model capacity, and more importantly, gains persist on out-of-domain data, indicating genuine translation improvement rather than adaptation to the test-set style.

Table 3 reports the LLM results on the FLORES+ devtest, with each fine-tuned row using the best learning rate from that model's sweep (full sweeps in Appendix D). For TranslateGemma, fine-tuning yields significant surface-metric gains in both directions (up to +4.96 chrF++ on NTREX;

| Model | Direction | FLORES+ chrF++ | FLORES+ COMET | NTREX chrF++ | NTREX COMET |
|---|---|---|---|---|---|
| NLLB-600M | en→hr | 51.94→53.08 | 87.43→87.59 | 53.70→54.62 | 85.45→85.87 |
| NLLB-600M | hr→en | 59.56→60.49 | 86.66→86.87 | 61.30→61.38 | 86.04→86.26 |
| NLLB-1.3B | en→hr | 54.41→55.86 | 89.46→90.10 | 56.18→57.42 | 87.54→88.54 |
| NLLB-1.3B | hr→en | 61.67→62.65 | 87.72→87.93 | 63.35→63.91 | 87.12→87.43 |
| NLLB-3.3B | en→hr | 56.02→57.87 | 90.07→90.84 | 57.44→58.90 | 87.93→89.26 |
| NLLB-3.3B | hr→en | 62.38→62.94 | 88.02→88.24 | 64.47→64.58 | 87.49→87.68 |

Table 2: NLLB-200 zero-shot → fine-tuned on the Croatian Seed data (chrF++ / COMET).

Appendix D). We find that a single bidirectional model matches the performance of two direction-specific models (deltas $\leq$0.28 chrF++, n.s.; Appendix D), allowing one model to serve both directions without a loss in quality. For the 4B model, the choice between LoRA and full fine-tuning is less critical than the learning rate: at the gentler rates the two methods differ only marginally and with mixed signs ($\leq$0.6 chrF++, $\leq$0.35 COMET), though full fine-tuning overfits more quickly and trails LoRA at $10^{-5}$. Due to hardware constraints, the larger models were adapted using LoRA only; however, the 4B results suggest that this choice entails little to no quality penalty. All gains in this section were obtained using standard recipes and a limited learning-rate sweep, representing a lower bound on the dataset's value for models below the quality ceiling (Section 4.5). Fine-tuned Gemma-4-31B produces the strongest Croatian→English system in this study (66.10 chrF++), while the best English→Croatian chrF++ score is achieved by an external zero-shot reference: DeepSeek-V4-Flash (Section 4.1), the largest model we can run on our infrastructure. The English→Croatian behavior of these strongest models on the neural metrics is analyzed in Section 4.5.

### 4.4 Isolating the human contribution: raw-MT ablation

The Matecat export preserves the raw machine translations from before post-editing, allowing us to directly test what the human verification contributes. For each NLLB size we fine-tune four models that differ only in their training data: (1) original English → raw MT Croatian; (2) original English → verified Croatian; (3) raw MT Croatian → original English; and (4) verified Croatian → original English. Comparing models (1) and (2) measures the value of the verified text as the translation target. While surface metrics show the raw MT and human-verified text are statistically similar (chrF++ deltas are within $\pm$0.4), both neural metrics systematically prefer the human-verified text. Table 4 shows the COMET results (mean $\pm$ sd over three seeds). The model trained on the verified text scores higher in all six model and test-set comparisons, while the seed variation is an order of magnitude smaller than most of the differences. Paired bootstrap tests confirm the advantage ($p<0.05$) in every comparison except the NLLB 600M on FLORES+. MetricX independently prefers the verified text in five of the six comparisons, with the same single exception. Notably, the advantage of human verification increases with model capacity and is largest on the out-of-domain test (NTREX): from +0.10 COMET (600M, FLORES+) to +0.98 (3.3B, NTREX).

Comparing models (3) and (4) isolates a second contribution. Here, the Croatian side serves as the source text and the target, the original English, is identical in both conditions, so any difference between them measures the value of human verification purely as comprehension input. Results show that the human-verified text as input wins on COMET in all six model $\times$ test-set cells (+0.11 to +0.22, $p \leq 0.023$; seed 42), while the chrF++ differences are again small and inconsistent in sign ($-$0.21 to +0.26).

Three conclusions follow. First, the human post-editing and revision effort is precisely where the dataset's value over freely producible machine translation lies, and its value increases with the capacity of the model being trained. Second, that value is two-sided: as target text, the verified Croatian supplies better style and content, and as source text it trains measurably better comprehension. Third, surface metrics are blind to both effects: an evaluation based on chrF++ alone would have concluded that human verification adds nothing.

### 4.5 Behavior at the quality ceiling

We use the term quality ceiling for the point at which a model's zero-shot output already matches or exceeds the register and quality of the corpus's

| System | en→hr chrF++ | en→hr COMET | hr→en chrF++ | hr→en COMET |
|---|---|---|---|---|
| TranslateGemma-4B zero-shot | 49.96 | 89.47 | 58.96 | 87.55 |
| TranslateGemma-4B LoRA ($10^{-6}$) | 52.66 | 89.03 | 61.71 | 87.94 |
| TranslateGemma-4B full FT ($3{\cdot}10^{-6}$) | 53.02 | 88.92 | 61.79 | 87.82 |
| TranslateGemma-27B zero-shot | 56.19 | **92.15** | 62.16 | 88.62 |
| TranslateGemma-27B LoRA ($10^{-5}$) | 58.88 | 91.59 | 64.50 | 88.79 |
| Gemma-4-31B zero-shot (ctx) | 58.64 | 91.76 | 64.81 | 89.17 |
| Gemma-4-31B zero-shot (ctx, thinking) | 59.13 | 92.02 | 64.77 | 89.18 |
| Gemma-4-31B ctx-LoRA ($10^{-5}$) | 59.65 | 91.81 | **66.10** | **89.26** |
| DeepSeek-V4-Flash zero-shot (ctx; thinking) | **60.08** | 92.05 | 64.58 | 89.02 |

Table 3: LLM results on FLORES+ devtest (chrF++ / COMET per direction). Models show the best adapter/full-FT learning rate in parentheses. All fine-tuned LLM rows are the bidirectionally trained models. Bold marks the column best.

| Model | FLORES+ verified | FLORES+ raw MT | NTREX verified | NTREX raw MT |
|---|---|---|---|---|
| NLLB-600M | $87.65 \pm 0.05$ | $87.55 \pm 0.02$ | $85.85 \pm 0.03$ | $85.39 \pm 0.04$ |
| NLLB-1.3B | $90.14 \pm 0.03$ | $89.65 \pm 0.01$ | $88.53 \pm 0.01$ | $87.78 \pm 0.02$ |
| NLLB-3.3B | $90.78 \pm 0.05$ | $90.23 \pm 0.02$ | $89.24 \pm 0.02$ | $88.26 \pm 0.02$ |

Table 4: Training-data ablation, en→hr, COMET (mean ± sd over 3 seeds).

own Croatian side. By register we mean the characteristic style of the text rather than its correctness; for this corpus, that is the style of post-edited machine translation, which stays close to the source structure and phrasing. The NLLB models sit below this point, while the LLMs in Table 3 sit at or above it. Zero-shot DeepSeek-V4-Flash serves as an external reference point and is not fine-tuned. Notably, the strongest models in this study run on accessible hardware: Gemma-4-31B fits on a single 96 GB workstation GPU, while DeepSeek-V4-Flash was served on two DGX Spark units.

All fine-tuned models in this section are bidirectionally trained and use the learning rate reported in Table 3 (best COMET in each sweep). Appendix D shows that unidirectional vs. bidirectional training results in no practical difference at this model tier. Regardless, the two translation directions still behave differently. In the Croatian→English direction, fine-tuning improves both metric families for all three LLMs, in- and out-of-domain (Gemma-4-31B: +1.29/+3.07 chrF++ and +0.10/+0.28 COMET on FLORES+/NTREX, $p \leq 0.034$; TranslateGemma-27B: +2.34/+4.96 and +0.17/+0.56, $p \leq 0.0055$; TranslateGemma-4B: +2.75/+3.92 and +0.39/+0.79, p=0.0005). The fine-tuned Gemma-4-31B is the strongest Croatian→English system in this study (66.10 chrF++). In the English→Croatian direction, fine-tuning yields comparable surface gains (+1.0 to +4.0 chrF++, p=0.0005), but the effect on COMET depends on the model. For Gemma-4-31B, the difference from zero-shot is statistically zero (+0.05 in-domain, −0.14 out-of-domain, both n.s.), while both TranslateGemma sizes remain significantly below their zero-shot COMET (27B: −0.56 on both test sets, p=0.0005; 4B: −0.44/−0.66, $p \leq 0.007$). MetricX ranks the fine-tuned English→Croatian systems in the same order and mildly prefers zero-shot output in the Croatian→English direction (Appendix D).

This English→Croatian cost is not fixed; it shrinks as the learning rate decreases. On TranslateGemma-4B, a four-point sweep ($10^{-4}$ to $10^{-6}$) reduces the COMET gap to zero-shot from −1.37/−1.98 (FLORES+/NTREX) to −0.44/−0.66. The reduction is monotone; every gentler rate is significantly better than $10^{-4}$ (the usual LoRA learning-rate recommendation), and the gap never reaches zero. TranslateGemma-27B shows the same pattern (−0.98/−1.19 at $10^{-4}$, −0.56 at $10^{-5}$), while on Gemma-4-31B the gap closes entirely (from −0.42 at $10^{-4}$ to the statistical zero above at $10^{-5}$). Since every curve is monotone across its swept range, we report the best swept rates without claiming they are optimal. Notably, on the 4B model the gentler rates also give up some surface overlap (−0.5 chrF++ from $10^{-4}$ to $10^{-6}$), so the learning rate trades one metric family against the other, consistent with the accuracy-naturalness trade-off formalized by Flamich et al. (2025). On the two larger models, the gentlest rate is best on both families.

We see a straightforward explanation for this

asymmetry. The Croatian side of the corpus descends from machine translation, so when used as the training target, it teaches the register of post-edited machine translation. For models whose zero-shot output is less natural than that register (the NLLB family), this is an upgrade on both metric families. For LLMs whose output is already more natural, it trades naturalness for surface overlap. Interestingly, the cost is predicted by the model's output register rather than by its measured quality: TranslateGemma-4B pays the largest penalty despite having the lowest zero-shot COMET of the three LLMs. When the same text is used as the input, with the original English as the target, it helps every model at no measured cost. Manual inspection of the outputs supports this account: fine-tuned models translate more literally and closer to the references (occasionally calquing idioms), while zero-shot outputs are freer and score higher on the neural metrics.

Prompt-level results support this explanation. Injecting the full translation guidelines into the prompt changes nothing measurably (58.76/91.71 vs. 58.64/91.76 chrF++/COMET). Enabling the model's reasoning mode, on the other hand, improves both chrF++ (+0.49, p=0.016) and COMET (+0.27, p=0.005), making it the only prompt-level intervention in this study that improves both metric families at once.

Finally, zero-shot DeepSeek-V4-Flash achieves the best English→Croatian chrF++ in the study (60.08) and matches the best Gemma-4-31B configuration on COMET (92.05 vs. 92.02 for the thinking zero-shot), trailing only zero-shot TranslateGemma-27B (92.15). In the Croatian→English direction, however, it trails the fine-tuned Gemma-4-31B (64.58 vs. 66.10 chrF++; 89.02 vs. 89.26 COMET). The two systems differ in prompt, decoding and reasoning mode, so this is a reference point rather than a controlled comparison.

## 5 Discussion

**What the seed data is worth.** For dedicated translation models, the class that seed data primarily targets, the result is simple: fine-tuning on the corpus improves every NLLB size, in both directions, on both test sets, on both metric families. The ablation shows where this value lies. Since raw machine translation of the English side can be produced for free, the dataset's contribution over such a baseline is the human post-editing and revision. This contribution grows with the capacity of the model being trained, from +0.10 COMET at 600M to +0.98 at 3.3B out of domain. We consider this an encouraging property of seed-style resources: the better the models become, the more the human verification matters.

**Where the value ends.** The quality-ceiling experiments show the limits of the dataset. For models whose zero-shot output already matches or exceeds the register of post-edited machine translation, English→Croatian fine-tuning buys surface overlap at a cost on the neural metrics. The cost shrinks as the learning rate decreases, but for the translation-specialised models it never reaches zero within the swept range: statistically zero for Gemma-4-31B, −0.56 COMET for TranslateGemma-27B and −0.44 for TranslateGemma-4B at the gentlest rates (Section 4.5). The asymmetry between the two directions, observed within a single bidirectional training run, points to the mechanism. A post-edited corpus carries its machine-translation ancestry on the target side of one direction only. Used as the training target, the Croatian side teaches the register of post-edited machine translation, which is an upgrade for models below that register and a downgrade for models above it. Used as the input, with the original English as the target, the same corpus helps models at every scale at no measured cost, including through the verification of the source-side text itself (Section 4.4). This gives simple guidance for using post-editing-derived seed corpora. Below the ceiling, the data can be used freely in both directions. At the ceiling, prefer the direction in which the post-edited text serves as the input; for the opposite direction, the natural complement is back-translation from native target-language text (Sennrich et al., 2016), which places the derived text on the input side by construction. We leave this controlled comparison to future work.

**What this means for evaluation.** The ablation would be invisible to an evaluation based on surface metrics alone: chrF++ cannot separate the raw-MT and human-verified training conditions, while both neural metrics separate them consistently. At the quality ceiling, the two metric families can even move in opposite directions under fine-tuning. Neither family can be dropped. chrF++ measures closeness to the reference, the neural metrics measure quality as judged by a learned model, and the two disagree exactly where the interesting effects are.

This is expected in theory as well, since no single score can reward accuracy and naturalness at the same time (Flamich et al., 2025). The prompt-level results fit the same picture: reasoning mode was the only intervention that improved both families at once, while adding the translation guidelines to the prompt changed nothing. In settings like ours, where the evaluated language is zero-shot for every neural metric and reference sets are small, we recommend reporting both metric families together with paired significance tests.

## 6 Conclusion

We presented the Croatian contribution to the OLDI Seed corpus: 6,193 English–Croatian sentence pairs produced by machine translation and post-edited and verified in two independent stages by professional translators. Beyond describing the resource, we validated it experimentally. Fine-tuning NLLB-200, TranslateGemma, and Gemma-4-31B shows that the corpus improves every model below the quality ceiling in both directions, and the strongest models in the Croatian→English direction. A single bidirectional model matches two direction-specific ones, so one model can serve both directions. Through a training-data ablation, we showed that the human verification itself carries measurable value: it grows with the size of the model being trained, it helps on both the target and the source side of training, and surface metrics cannot detect it. For the strongest models, we traced the limits of the corpus to the fact that its Croatian side originates from machine translation, and we discussed how corpora built this way are best used. The dataset is released to the community through the Open Language Data Initiative. As follow-up work, we plan a further revision pass over the corpus and a controlled comparison against back-translation from native Croatian text.

## 7 Data Availability

Our Croatian Seed contribution will be made publicly available as part of the OLDI Seed dataset (`https://huggingface.co/datasets/openlanguagedata/oldi_seed`) under the CC BY-SA 4.0 license.

## Limitations

All findings concern a single language pair, and the neural metrics are largely untested on Croatian, which makes the neural-metric separations conservative, but less calibrated than for high-resource languages (Deutsch et al., 2025; Singh et al., 2024). The quality-ceiling analysis rests on automatic metrics and manual inspection; a human MQM-style evaluation was not possible with the available annotators. The English→Croatian fine-tuning effects replicate across three random seeds and three model families, while the Croatian→English ablation cells and the individual LLM configurations are single-seed. The learning-rate sweeps cover two points for TranslateGemma-27B and four for TranslateGemma-4B, and the reported rates are the best swept rates, not a located optimum. Finally, the corpus inherits the domain profile of its Wikipedia source; validation of the strongest models on specialized domain material is left for follow-up work.

## A Data sample

The dataset is released as a JSON Lines file with one record per sentence. Each record carries the sentence text, the OLDI language identification (ISO 639-3 code, ISO 15924 script code, Glottocode), and the URL of the source Wikipedia article; records pair with the English side of the Seed corpus through the shared `id`. Figure 1 shows two consecutive records from the released file. The corresponding English records read: "Inside one of the chambers, near the ceiling, is a painted hand print." (5208) and "The location of the cave has been well known in modern times." (5209).

## B Prompts and decoding

All Gemma-4-31B systems use a modular zero-shot prompt assembled from the following templates (verbatim; `{sl}`/`{tl}` are language names, `{slc}`/`{tlc}` ISO codes):

- Role (always present): `You are a professional {sl} ({slc}) to {tl} ({tlc}) translator.`
- Task (no-context conditions): `Produce only the {tl} translation, without`

```

  "iso_639_3": "hrv",
  "iso_15924": "Latn",
  "glottocode": "croa1245",
  "text": "Unutar jedne od komora, blizu stropa, nalazi se oslikani otisak ruke.",
  "url": "https://en.wikipedia.org/wiki/Chichen_Itza",
  "last_updated": "1.0"
}
{
  "id": 5209,
  "iso_639_3": "hrv",
  "iso_15924": "Latn",
  "glottocode": "croa1245",
  "text": "Lokacija špilje u današnje je vrijeme dobro poznata.",
  "url": "https://en.wikipedia.org/wiki/Chichen_Itza",
  "last_updated": "1.0"
}
```

Figure 1: Two consecutive records from the released Croatian Seed file (pretty-printed; the released file stores one record per line).

any additional explanations or commentary. Please translate the following {sl} text into {tl}:\n\n{text}

- Document context (ctx conditions, "sandwich" layout): `You are translating this sentence:\n{text}\n\nHere is the document it comes from, for context:\n{ctx}\n\nProduce only the {tl} translation, without any additional explanations or commentary. Translate the sentence given above.`

- Guideline injection (guide conditions): `Follow these translation guidelines strictly:\n\n{guidelines}`, where `{guidelines}` is the full text of the OLDI translation guidelines.

The context block contains the complete source text from the same article (FLORES+ lines filtered by metadata; for NTREX, see Appendix E) without any markers or target-side texts, so no reference leakage is possible. The sentence-first layout was chosen over a context-first layout in a 200-sentence test. TranslateGemma is prompted exclusively through its native chat template (technical report, Figure 3), with source and target language codes set per direction. DeepSeek-V4-Flash uses the same modular prompt as Gemma with the model-card recommended parameters (temperature 1.0, top-p 1.0, reasoning effort *high*, 16,384-token budget with automatic doubling on truncation).

Decoding is greedy for all Gemma-family systems and beam-4 for NLLB; DeepSeek-V4-Flash used model-card recommendations. Google's recommended sampling for Gemma (temperature 1.0, top-p 0.95, top-k 64) was evaluated on all four prompt conditions and scored 0.2–0.5 chrF++ below greedy in English→Croatian and on par in Croatian→English, validating the greedy choice. "Thinking" rows enable the model's native reasoning mode with the same prompts and a 32k token budget; only the final answer channel is scored.

## C Training hyperparameters

All training uses AdamW, bf16, warmup ratio 0.05, and checkpoint selection on the FLORES+ dev set exclusively (chrF++ for NLLB, loss for the LLMs; early stopping with patience 2). Prompt tokens are masked from the loss in all LLM runs.

Bidirectional runs mix both directions in one training set (the prompt encodes the direction). LoRA adapters are merged before evaluation; all LLM inference uses vLLM.

## D Full sweep and MetricX results

Gemma-4-31B learning-rate sweep, English→Croatian, FLORES+ devtest (chrF++ / COMET / MetricX):

Factorial contrasts isolate learning rate as the driver: at fixed rate, the direction mix changes chrF++ by $\leq$0.14 and COMET by $\leq$0.09 (n.s.), while the $10^{-4}$→$10^{-5}$ rate contrast is significant on both families. The hr→en cells of the non-headline bidirectional 31B configuration (LoRA $10^{-4}$) are 65.93 chrF++ / 89.23 COMET.

Table 6: Gemma-4-31B learning-rate sweep, en→hr, FLORES+ devtest. Bold marks the column best.

TranslateGemma learning-rate sweeps (chrF++ / COMET; bidir. LoRA and full FT, both test sets):

Direction-specific (unidirectional) LoRA at $10^{-4}$, FLORES+ devtest (chrF++ / COMET): TranslateGemma-4B 53.17 / 88.29 (en→hr) and 61.61 / 87.83 (hr→en); TranslateGemma-27B 58.58 / 91.38 and 64.34 / 88.73 — within 0.28 chrF++ of the corresponding bidirectional models (n.s.).

MetricX (FLORES+ devtest, lower is better) for the main LLM configurations, including those summarised only in this appendix:

MetricX agrees with COMET on every learning-rate and recipe ordering except one (TranslateGemma-4B full FT, $3{\cdot}10^{-6}$ vs. $10^{-6}$, 0.04 COMET apart); the remaining disagreements are between systems within 0.03 COMET of each other. Its systematic divergence is a preference for zero-shot output over fine-tuned systems that shrinks monotonically with the rate in English→Croatian and persists mildly in Croatian→English, consistent with the accuracy–naturalness trade-off (Flamich et al., 2025).

## E Document context for NTREX

FLORES+ metadata provides source URLs for each line, which enable grouping and providing the source-side context block directly. NTREX does not have such labels. We reconstruct context by letting the base Gemma-4-31B judge, for each sentence, which of its ±10 neighbours belong to the same document, and use the accepted neighbours as the context block. This model-inferred context was validated against no-context prompting on NTREX: it improves Croatian→English by +0.81 chrF++ / +0.54 COMET (both $p<0.05$) and English→Croatian by +0.30 COMET ($p=0.0005$) with flat chrF++ — the method improves neural-judged quality even where surface metrics are blind to it. All NTREX ctx rows in the paper use this context.

## Abstract

The paper introduces QwenSub-MT, a system that is context-aware and constraint-controlled and has been developed for the WMT 2026 Video Subtitle Translation shared task. It carried out the translation of Simplified Chinese subtitles into 6 different languages. QwenSub-MT used Qwen3.5-Instruct together with a multistage 4-bit QLoRA adaptation and treated adjacent subtitle cues as contextual blocks. In order to enhance consistency and disambiguation, the system incorporated video synopsis information, previous translations, terminology memory and selective visual grounding. A revision stage was carried out to correct semantic, terminology and formatting errors, while duration-aware length control, line-break optimization and deterministic SRT validation were used to make sure that the outputs were readable and structurally valid. 500 subtitle files were submitted in five language directions and obtained a macro-average score of 58.459, placing sixth in the overall ranking. The results show that contextual modelling and structural control are useful, but candidate diversity, independent quality estimation and stronger adaptation to the target language still needs improvement.

## 1 Introduction

The rapid expansion of online video, streaming platforms, digital education and social-media content has increased the demand for high-quality multilingual subtitles. Subtitles support accessibility, international distribution and cross-cultural communication, but video subtitle translation is more demanding than conventional sentence-level machine translation. A successful subtitle must preserve meaning while remaining synchronized with the video, respecting limited display time and maintaining readability. It must also retain dialogue style, emotional tone, speaker intention and should maintain narration continuity. Therefore, even a linguistically correct translation may be unsuitable when it is too long, poorly segmented, inconsistent with surrounding dialogue or disconnected from the visual scene. Subtitle translation is further constrained by temporal and spatial limitations. Subtitle cues are short, time-aligned units that do not always correspond to complete grammatical sentences. A single sentence may span several cues, while individual segments may contain ellipsis, pronouns, discourse markers or short responses whose interpretation depends on contextual information. Consequently, subtitle quality involves not only translation accuracy but also segmentation, timing and readability. This has motivated subtitle-specific evaluation measures such as SubER, which jointly evaluates textual errors, subtitle segmentation and timing rather than considering translated text alone (Wilken et al., 2022).

Context is particularly important in Chinese subtitle translation because subjects and other sentence components are frequently omitted when they can be inferred from discourse. Pronouns, forms of address, character relationships, lexical choices and politeness levels may therefore remain ambiguous when cues are translated independently. Context-insensitive systems can produce translations that appear acceptable in isolation but become inconsistent within the larger dialogue. Voita et al. (2019) identified deixis, ellipsis and lexical cohesion as major sources of contextual errors, while Vincent et al. (2024) showed that extra-textual information such as film metadata can reduce context-related errors during professional subtitle post-editing.

Video subtitle translation is also inherently multimodal. Text alone may not clearly indicate speaker identity, referents, objects, emotions or actions. Visual information can provide evidence

*Proceedings of the Eleventh Conference on Machine Translation*, pages 2584–2591
October 28-29, 2026 ©2026 Association for Computational Linguistics

about characters, locations, objects and scene context, thereby resolving ambiguities. However, irrelevant or temporally misaligned frames may introduce noise. This motivates selective visual grounding, where visual evidence is used primarily for subtitle segments containing contextual or referential ambiguity.

The WMT 2026 Video Subtitle Translation task requires translation of Simplified Chinese subtitles into English, Thai, Indonesian, Malay and Traditional Chinese, while considering contextual ambiguity, timing, readability, terminology consistency and SRT preservation. To address these challenges, we propose QwenSub-MT, a context-aware and multimodal framework based on Qwen3.5-Instruct. The system performs block-level subtitle translation using neighbouring dialogue, synopsis information, previous translations, dynamic terminology memory and selective visual keyframes. Duration and readability constraints are incorporated during generation, followed by revision and SRT validation. Multistage QLoRA fine-tuning enables multilingual, subtitle-domain and metadata-enriched adaptation within a unified framework.

## 2 Literature Review

Machine translation for subtitles has evolved from rule-based and statistical approaches to neural, contextual, multimodal and large-language-model-based systems. Early work by Turcato et al. (2000) showed that subtitle translation requires careful preprocessing because closed captions contain colloquial expressions, incomplete sentences, irregular segmentation and named entities. Volk et al. (2010) demonstrated the practical use of statistical MT for television subtitles and emphasized domain-specific training and professional post-editing. With neural MT, Matusov et al. (2019) integrated domain adaptation, inter-sentence context and subtitle segmentation, showing that translation and presentation constraints should be addressed jointly.

Research has also focused on subtitle-specific corpora and production constraints. Karakanta et al. (2020a) introduced MuST-Cinema, which preserves subtitle boundaries and supports joint modelling of translation, punctuation and segmentation. Karakanta et al. (2020b) further demonstrated that subtitle quality cannot be determined by character limits alone, since timing, pauses and semantic structure influence segmentation. From a professional perspective, Koponen et al. (2020) found that translators evaluate MT subtitles not only for linguistic accuracy but also for timing, segmentation, contextual consistency and editing effort. For evaluation, Karakanta et al. (2022) proposed Sigma for measuring subtitle segmentation, while Wilken et al. (2022) introduced SubER, which jointly considers translation errors, segmentation and timing.

Context-aware translation has gained importance in subtitle translation, as dialogue often relies on pronouns, ellipsis, and discourse-level information whose interpretation depends on surrounding context. Wang et al. (2023) showed that large language models can exploit document-level context to improve translation coherence, although excessive context may introduce irrelevant information. Karpinska and Iyyer (2023) similarly reported that paragraph-level LLM translation improved grammaticality and consistency but could still produce omissions. Cui et al. (2024) demonstrated that selectively retrieving and summarizing relevant context can improve document-level translation, supporting the use of compressed and focused context rather than unrestricted document input.

Multimodal research has investigated whether visual information can resolve textual ambiguity. Caglayan et al. (2019) found that images are particularly useful when textual information is incomplete, whereas Wu et al. (2021) cautioned that improvements under complete-text conditions may sometimes reflect regularization rather than genuine visual grounding. Ji et al. (2022) proposed information-theoretic mechanisms to increase visual awareness. Kang et al. (2023) introduced BigVideo, containing approximately 4.5 million subtitle pairs and 9,981 hours of video, while Li et al. (2023) developed the EVA dataset to evaluate genuinely video-helpful translation cases. More recent approaches employ selective visual processing: Liu et al. (2025) proposed DeDiT, which activates visual reasoning only for ambiguous inputs, and Guan et al. (2025) introduced SHIFT, which selects useful video frames rather than uniformly processing all frames.

Large language models further enable metadata-guided subtitle translation. Pramodya et al. (2025) showed that movie titles, summaries and genre information can improve subtitle translation with

GPT and LLaMA models. The Yang et al. (2025) introduced the multilingual Qwen3 family with thinking and non-thinking modes, providing a suitable foundation for controlled instruction-based translation.

## 3 Methodology

This section describes the proposed QwenSub-MT framework developed for the WMT 2026 Video Subtitle Translation task. It translated Simplified Chinese subtitles into English, Thai, Indonesian, Malay, and Traditional Chinese for Taiwan. Unlike conventional sentence-level MT, the system was designed to preserve meaning while also satisfying subtitle-specific requirements.

The complete workflow consisted of SRT parsing, subtitle-block construction, metadata processing, Qwen3.5-based translation, revision, length control, line-break optimization, SRT reconstruction, and final validation. A single Qwen3.5-Instruct model was used for translation, terminology processing, and revision, thereby reducing system complexity and keeping the overall model size within the shared-task restriction.

| Hyperparameter/Setting | Initial Configuration |
|---|---|
| Quantisation method | NF4, 4-bit |
| Compute datatype | BF16 |
| LoRA rank | 32 |
| LoRA alpha | 64 |
| LoRA dropout | 0.05 |
| Per-device batch size | 1 |
| Gradient accumulation steps | 16 |
| Effective batch size | 16 |
| Learning rate | $1/10^{-4}$ |
| Learning-rate scheduler | Cosine |
| Gradient checkpointing | Enabled |
| Training epochs | 2–3 per training stage |

**Table 1:** Hyperparameters Used

### 3.1 Model Selection and Adaptation

The Qwen model operated in non-thinking instruction mode. Although it supports very long context windows, training sequences were restricted to approximately 2,048–4,096 tokens to make fine-tuning practical on a 24 GB GPU. Thinking mode was disabled to reduce unnecessary generation, avoid reasoning traces in subtitle output, and ensure deterministic structured responses. Qwen3.5-4B was retained as a fallback configuration if the 9B model exceeds available memory during fine-tuning.

The model was adapted through 4-bit QLoRA. The initial configuration used NF4 quantisation. The parameters of the model are shown in table 1. LoRA adapters are applied mainly to the language-model layers. The data for training the model was provided by the organizers of the shared task.

### 3.2 SRT Processing

Each SRT file was parsed into subtitle events containing sequence number, start time, end time, duration, text, and formatting information. Unicode is normalized, punctuation was standardized. Music markers, speaker labels, numbers, dates, and special symbols were preserved.

Instead of translating every cue independently, adjacent subtitle events were grouped into short translation blocks. A new block was started when sentence-final punctuation was detected, a substantial time gap occurred, the speaker changed, the combined source became too long, or the block reached a maximum of four cues. Qwen translated all cues in the block jointly while returning one translation for each original subtitle identifier. This improved handling of sentences that extended across multiple SRT events while preserving the original subtitle structure.

### 3.3 Metadata, Context and Terminology Memory

Before translation, the available video synopsis and metadata were compressed into a compact context record describing the domain, setting, tone, characters, and terminology. A dynamic video-level glossary stored character names, organizations, locations, forms of address, technical expressions, and recurrent phrases. After each translated block, new terminology was added to the memory and later translations were checked for consistency.

For each translation block, the model received a package containing three preceding subtitle events, their accepted target translations, the current block, two following source events, the compressed synopsis, relevant glossary entries, and duration or length constraints. Previous target translations helped maintain consistent spelling, pronoun use, terminology, and dialogue style.

### 3.4 Multistage Finetuning

Fine-tuning was performed in three stages. Stage 1 strengthened multilingual translation using general parallel corpora across all target languages. Stage 2 performed subtitle-domain adaptation using dialogue, slang, short utterances, speaker changes, duration information, and segment-level structured outputs. Stage 3 introduced metadata-enriched and multimodal examples containing synopsis information, character glossaries, previous translations, and subtitle-length constraints.

This progressive training strategy preserved the multilingual knowledge of the pretrained model while specializing it for contextual and constrained subtitle generation.

### 3.5 SRT Reconstruction

After translation, each target segment was mapped back to its original SRT event. Sequence numbers, timestamps, event order, formatting tags, and encoding were preserved. A deterministic validator checked cue counts, timestamp syntax, empty segments, language correctness.

## 4 Evaluation and Discussion

The QwenSub-MT system that has been proposed was tested as part of the WMT 2026 Video Subtitle Translation shared task, this task involving the translation from Simplified Chinese into 5 languages. BVSLP provided translations for all five destination languages, including 100 SRT files for each translation direction. Thus, 500 subtitle files in total were submitted. BVSLP was one of only three teams, along with ReopenAI and laniqo, to take part in all five language directions, which meant that the system could be evaluated in a wide multilingual environment rather than just for one target language.

A human-verified LLM-as-a-Judge evaluation method was used in the shared task. For each combination involving a team, a language, and a video, the source and translated SRT files were analyzed and aligned on the basis of the subtitle numbers. The multi-line subtitle entries were combined together and the resulting source-translation pairs were then evaluated at the level of the entire video. Each video was assessed three times using a Language Quality Assessment prompt that was specific to the language in question, and the median of the valid scores was taken in order to reduce the variability among the automatic judgments. The automatic evaluations were then examined by human assessors, who verified that the errors identified were actually present in both the source and the translation, that the cue numbers were correct, and that the penalties and severity labels were suitable. When needed, the human reviewers made the necessary corrections to the structured assessments and to the final scores.

The assessment was carried out using a rubric based on a 100-point scale divided into four different areas. In the case of Accuracy and Fidelity, 40 points were possible and this area looked at mistranslation, omissions, errors regarding terminology, inconsistencies, and semantic deviation. For Fluency and Readability, 35 points were allocated and took into account grammaticality, structural problems, translationese, spelling, and punctuation. The aspect of Subtitle Text Conventions was worth 5 points and dealt with matters such as excessively long lines and violations of formatting rules. Lastly, Cultural and Stylistic Adaptation accounted for 20 points and examined cultural appropriateness, tone, register, and stylistic distance. Scores between 90 and 100 were considered to be Excellent, those between 75 and 89 were classified as Good, scores between 60 and 74 were regarded as Fair, and anything below 60 was deemed Poor.

### 4.1 BVSLP Performance

The final language-wise results for BVSLP are presented table 2.

| Target Language | Final Score | Rank | Quality Band |
|---|---|---|---|
| English | 60.48 | 6th | Fair |
| Indonesian | 62.42 | 4th | Fair |
| Malay | 62 | 3rd | Fair |
| Thai | 56.025 | 4th | Poor |
| Traditional Chinese (Taiwan) | 51.37 | 3rd | Poor |
| Macro-average | 58.459 | 6th overall | Poor |

**Table 2:** BVSLP Results

The system achieved a total macro-average score of 58.459 and thus came in sixth place out of the eight teams that were assessed. The best score was achieved for Indonesian, with a score of 62.420, then Malay at 62.000 and English at 60.480. These three language versions were in the

Fair quality range of the shared-task rubric. Thai obtained a score of 56.025, and Traditional Chinese for Taiwan had the lowest BVSLP score, which was 51.370, with both of them falling into the Poor band.

Although it should be considered in light of the number of systems that took part, English had the widest participation since all eight teams submitted results, whereas both Indonesian and Thai each had four participating systems and Malay and Traditional Chinese each had only three. It is therefore the case that BVSLP's third-place position for Malay and Traditional Chinese is based on a much narrower competitive field than that of English. The macro-average assigns equal weight to each of the languages submitted and so shows multilingual breadth, but it does not directly reward more extensive language coverage.

### 4.2 Effect of Human Verification

Human verification had a clear impact on the final BVSLP scores, especially in the cases of Indonesian and Malay. For Indonesian, the final score was reduced by 5.330 points as compared to the automatic evaluation, while the Malay score increased by 2.525 points after human verification. English showed only a slight change, Thai stayed the same, and Traditional Chinese was adjusted only slightly downwards. These trends were not specific to BVSLP; the shared-task results also showed a general tendency that the automatic assessments of Indonesian had been relatively lenient and those of Malay had been relatively strict before human correction.

The fact shown here highlights the need for human verification in the evaluation of multilingual text. The automatic judge was not equally calibrated for all the target languages, and the corrections had an effect on the absolute scores even though the general rank order stayed the same. In the case of BVSLP, it therefore follows that the final results should be regarded as human-verified estimates rather than as direct outputs from the automatic judge alone.

### 4.3 Analysis of the QwenSub-MT System

BVSLP was very different from most of the other systems in terms of its architectural design. It employed Qwen3.5-Instruct together with a multistage 4-bit QLoRA adaptation. The training process involved adaptation for multilingual translation, adaptation for the subtitle domain, and adaptation using enriched metadata. At inference time, adjacent subtitle cues were grouped into short translation blocks rather than being treated separately. The framework included several factors viz a dynamic terminology memory, line-break optimization, deterministic SRT reconstruction etc. BVSLP was the only entry that was explicitly documented as making use of selective visual grounding.

The design decisions made, took into account a number of important aspects of subtitle translation, including cross-cue dependencies, the consistency of characters and terminology, the preservation of structure, and readability. However, the results of the shared task indicate that these features on their own were not sufficient to achieve the level of performance attained by the best-ranked systems.

A major outcome of the shared task was the importance of having a varied range of candidate translations and of restricting the number of candidate translations. Of the five systems that performed best, four produced more than one candidate translation and used some form of selection or reranking procedure. ReopenAI developed four candidates and applied an agreement-based selection method. laniqo generated 25 candidates and then carried out Pareto reranking before proceeding to the fusion stage. AuditTranslate employed best-of-three generation together with a critic and targeted retranslation, and rupiah generated the candidates using temperature diversity and selected the outputs by reference-free quality estimation.

On the other hand, QwenSub-MT consisted of producing one translation with Qwen3.5 followed by a revision stage. Although this revision process enabled the identification of semantic, terminology, and formatting problems, the approach still relied on the quality of the initial translation. The results obtained in the shared task therefore suggest that selecting among a number of alternative translations rather than repeatedly editing a single output could provide a more effective way of ensuring quality.

Another important point is concerned with functional specialization. In several instances, more powerful systems have split off the task of translation from that of criticism or selection. Specialized models for translation have been used to generate the outputs, while general-purpose instruction models or quality-estimation tools have been used to carry out the evaluation or selection of

the candidates. This kind of division reduced the likelihood that a single model would make an error when performing the translation and then reinforce that error during self-revision. In the case of BVSLP, employing Qwen3.5 for both translation and revision simplified the architecture, but it also have decreased the independence of the quality-control phase.

Yet the results do show that QwenSub-MT was capable of generating multilingual and structurally valid subtitle outputs in all five WMT26 directions. The incorporation of subtitle blocks, terminology memory, metadata, previous translations, and deterministic SRT validation is in keeping with the general finding of the shared task that context and structural control are essential for the translation of video subtitles.

The scores achieved by BVSLP indicate that semantic fidelity and target-language adaptation remain the main limitations; the worse performance in the cases of Thai and Traditional Chinese also suggests that multilingual fine-tuning alone may not be sufficient to obtain adequate language-specific adaptation, especially when issues such as register, cultural conventions, lexical preferences, or localization decisions are taken into account.

## 5 Conclusion

The paper introduced QwenSub-MT, a framework that is context-aware and constraint-controlled and was developed for the WMT 2026 Video Subtitle Translation shared task. The system carried out the translation of Simplified Chinese subtitles into 6 different languages by using Qwen3.5-Instruct which had been adapted through a multistage 4-bit QLoRA approach. This framework incorporated subtitle-block translation, video metadata, previous translations, terminology memory, revision, line-break optimization, and deterministic SRT reconstruction in order to meet both the linguistic and structural demands of subtitle translation.

A total of 500 SRT files for all five of the target languages and secured a macro-average score of 58.459, placing sixth overall. The best results were achieved in Indonesian, then in Malay and English, whereas Thai and Traditional Chinese proved to be more difficult. Additionally, human verification revealed that the automatic evaluation had not been equally calibrated for all languages, especially for Indonesian and Malay, thus highlighting the need for human review in the assessment of multilingual subtitles.

The results from the shared task also showed that although contextual information and structural control were helpful they were not on their own enough to achieve the best performance. Systems which used multiple candidate generations, reranking, independent criticism, and had a specialization of translator and critic generally performed better. This indicates that future versions of QwenSub-MT should include diverse candidate generation and independent quality estimation methods rather than simply relying on single-output revision. Altogether, the study shows that it is feasible to use a unified Qwen-based approach for multilingual subtitle translation and identifies semantic fidelity, language-specific adaptation, and candidate selection as the key areas needing further improvement.

## Abstract

We describe **SubVision**, our submission to the WMT26 Video Subtitle Translation shared task. The system fine-tunes the 1.8B-parameter multilingual translation model Hy-MT2-1.8B (Zheng et al., 2026) using 4-bit QLoRA (Dettmers et al., 2023) on 60,000 sentence pairs sampled from the TVsub Chinese-to-English subtitle corpus (Wang et al., 2018). The training pipeline uses a single instruction style prompt template, LoRA adapters (rank 16, $\alpha = 32$) on all attention and MLP projections, and early stopping based on dev set sacreBLEU. We fix the decoding with beam search with beam size 4, repetition penalty 1.15, and no-repeat 3-gram constraints. The fine-tuned model on a 200 pair TVsub test split with multiple references achieves sacreBLEU 37.63, chrF 52.76, and TER 53.93, compared with zero-shot NF4 baselines of sacreBLEU 11.60 for Hy-MT2-1.8B and 15.79 for Hy-MT2-7B on the same test pairs, prompt, and decoding configuration. The same configuration is used for official inference, translating subtitle lines independently while preserving SRT timing. We report our full training and inference configuration, describe a data processing detail in parsing the corpus's multi-document, multi-reference SGM files, and compare our final configuration against nine additional trained configurations that differ in training pair count, sequence-length budget, LoRA rank, and decoding generation length. The paired bootstrap analysis over this comparison shows that given the 200 segment test set size, the nominal ranking of the submitted configuration is not statistically distinguishable from several of the alternatives. We report this analysis along with the point estimates rather than presenting the ranking as an established result. We note that evaluation uses an in-domain TVsub split. The code is available at: https://github.com/praaajg/wmt26-hymt2.

## 1 Introduction

The WMT26 Video Subtitle Translation shared task asks participants to translate the spoken dialogue of video subtitles, distributed as SRT files, from Chinese into English (WMT26 Organizers, 2026). Subtitle translation differs from sentence level document translation in that each line is short, colloquial, and time boxed, and the organizers additionally provide per-video metadata (descriptions, character lists, and glossaries) that participants may use to disambiguate character names and recurring terminology across a video.

Our system **SubVision** takes a compute constrained approach built around a single publicly released small model. We adapt Hy-MT2-1.8B (Zheng et al., 2026) which is a 1.8B-parameter multilingual translation model, by fine-tuning it with QLoRA (Dettmers et al., 2023) on the TVsub corpus (Wang et al., 2018) which is a large Chinese-to-English corpus of subtitles drawn from Chinese television dramas. The shared task itself supplies no training or validation data, only the unlabeled demonstration and official test files described in Section 3.5. Therefore, participants must source their own training corpus. All the training and evaluation of automatic metrics uses TVsub. We then apply the resulting fine-tuned model directly to the organizer provided official test files using the same translation prompt and decoding configuration used in training and evaluation, without incorporating the accompanying video metadata for the shared task submission itself.

We underscore this scope explicitly because it shapes how our results should be read. We report BLEU, chrF, and TER numbers that come from an in-domain TVsub test split with references, not from the official test set, for which we have no references and therefore no automatic score. Our contribution is consequently a fully specified, reproducible fine-tuning, decoding, and inference pipeline for a small, resource friendly subtitle translation model, together with an honest account of what our internal evaluation does and does not tell us about performance on the shared task's actual test data. Our contributions are:

- A resource efficient QLoRA fine-tuning pipeline that adapts Hy-MT2-1.8B to

*Proceedings of the Eleventh Conference on Machine Translation*, pages 2592–2607
October 28-29, 2026 ©2026 Association for Computational Linguistics

Chinese–English subtitle translation using 60,000 TVsub sentence pairs and a single 23.7 GB GPU.

- An empirical comparison showing a substantial improvement from task specific adaptation over zero-shot Hy-MT2-1.8B under an identical prompt, evaluation split, and decoding configuration, together with a comparison against nine additional trained configurations.
- A paired bootstrap analysis of the ten fine-tuned configurations, showing that the nominal differences among the strongest systems are not statistically distinguishable at the 200 segment test set size.
- A fully specified SRT inference pipeline for the official WMT26 test files, including preservation of subtitle indices and timestamps, together with the released LoRA adapter and inference resources.
- A documented correction to the multi-document SGM reference parsing procedure used for all reported evaluation, addressing segment-ID collisions across document boundaries.

## 2 Related Work

**Subtitle machine translation.** Subtitle translation introduces constraints on brevity, timing, and register that distinguish it from general document or sentence level machine translation (Matusov et al., 2019). Matusov et al. (2019) show that NMT systems adapted specifically for subtitling outperform general purpose systems by better matching the length and reading speed constraints of on screen text. The recent subtitling systems explicitly optimize for these constraints via length controlled MT that condenses translations to respect characters per line, lines per block and reading speed limits without large quality loss (Petrick et al., 2025). For movie subtitles, prompting LLMs with movie meta information such as title, summary and genre improves translation accuracy, with the movie title giving the most consistent gains (Pramodya et al., 2025). Video context can also improve subtitle translation when the textual input is ambiguous. Li et al. (2023) found that incorporating paired video clips improves translation over text only models, particularly for ambiguous subtitles (Li et al., 2023). The TVsub corpus (Wang et al., 2018), which we use for fine-tuning, provides large scale Chinese-to-English subtitle pairs drawn from television dramas and captures the colloquial, turn taking register typical of subtitle dialogue.

**Document level context in MT.** A natural extension for subtitle and dialogue translation is to condition on surrounding context. Maruf et al. (2019) survey document level neural MT methods, architectures, training and decoding strategies, and evaluation. Cross-sentence history has been shown to improve Chinese-English NMT by up to +2.1 BLEU points (Wang et al., 2017). MTCue shows that unstructured document and metadata context in dialogue improves translation quality (+0.88 BLEU, +1.58 COMET over a non-contextual baseline) and enables zero-shot control of attributes such as formality (Vincent et al., 2023). At the same time, document level evaluation finds that contextual information is pervasive across sentences but does not always change human judgments (Kim, 2025).

**Parameter efficient fine-tuning.** Domain adaptation is important because vanilla NMT performs poorly under domain mismatch when in-domain corpora are scarce (Chu and Wang, 2018). LoRA (Hu et al., 2021) adapts large pretrained models by injecting trainable low rank matrices into frozen weight projections, substantially reducing the memory required for fine-tuning. Adapter modules originate as compact alternatives attaining within 0.4% of full fine-tuning on GLUE while adding only 3.6% parameters per task (Houlsby et al., 2019), and for NMT specifically tiny task specific adapter layers match full fine-tuning for domain adaptation at a fraction of per-task cost (Bapna and Firat, 2019). QLoRA (Dettmers et al., 2023) extends LoRA by additionally quantizing the frozen base model to 4-bit NF4 precision with double quantization which is what makes fine-tuning a 1.8B-parameter model practical on a single GPU with limited memory in our setup. Two stage QLoRA curriculum fine-tuning has been shown to substantially improve low-resource MT, e.g. chrF++ from 22.73 to 41.10 over NLLB-200 on an unseen language (Umar et al., 2026). We use the PagedAdamW8bit optimizer, building on 8-bit block-wise quantized optimizers that maintain 32-bit performance at a fraction of the memory footprint (Dettmers et al., 2021), for the same reason.

**Instruction style translation prompting.** Instruction tuning (Ouyang et al., 2022) is now a standard way of aligning language models to task-specific behavior. Instruction finetuning has also been shown for NMT itself which allows a single small NMT model to follow multiple customization instructions (formality, multi domain, multi modal translation) at GPT-3.5-level quality (Raunak et al., 2024). We follow this convention by framing translation as a single turn chat completion with an explicit instruction, rather than a raw sequence-to-sequence mapping.

## 3 Dataset and Preprocessing

### 3.1 Corpus

The WMT26 Video Subtitle Translation shared task provides no training or validation data of its own: the only organizer released material is the unlabeled demonstration package and official test files (Section 3.5). Therefore, any training corpus is a participant's own choice. We use the TVsub corpus (Wang et al., 2018) as this training proxy, cloned directly from the corpus's public repository. The TVsub dataset provides pre-split, pre-processed Chinese–English subtitle pairs under `data/processed/{train,dev,test}`, with a plain-text source file for each split and a multi-reference SGM file for the dev and test references.

### 3.2 Sampling and Filtering

The training pairs from the processed training file we build as follows. Each source and target line is detokenized (Section 3.3) and discarded if either side is empty after cleaning, if either side exceeds 512 characters (twice our configured maximum subtoken length), or if the character length ratio between target and source falls outside $[0.3, 4.0]$, which removes badly misaligned pairs. The filtered pairs are shuffled with a fixed random seed (42) and truncated to 60,000 training pairs. The same detokenization (but not the ratio/length cutoffs, which apply only to training) is applied when building the 500-pair development split used for early stopping and best-checkpoint selection during training, both of which additionally require overlapping segment IDs between the source file and the parsed multi-reference file.

All test set metrics and qualitative examples reported in this paper (Table 7 onward) come from an evaluation script run against the saved best adapter, using its own default of 200 pairs from the same `data/processed/test/` split (the first 200 segment IDs with both a source line and at least one parsed reference). The same 200 source lines and multi-reference sets are reused without modification for the zero shot baseline evaluations of the un-adapted base models reported in Section 6.5.

### 3.3 Detokenization

TVsub's released text contains subword-joiner artifacts (`@-@`, `@@`) and HTML escaped entities from its original crawl. Our detokenizer removes joiner artifacts, HTML-unescapes the text, collapses repeated whitespace, corrects spacing around punctuation, and applies Unicode NFKC normalization. This detokenization is applied uniformly to training pairs, dev/test sources, and references before scoring so that reported metrics are computed on cleaned text throughout.

### 3.4 Multi-Reference SGM Parsing

The dev and test reference files are provided as SGM markup with segments grouped under `<DOC>` blocks and numbered with `<seg id="...">` tags. Two `<DOC>` blocks (docids `SUB01` and `SUB02`) each restart segment numbering at 1, since each block corresponds to a different source document (television episode) in both files. A parser that reads `<seg id="...">` without also tracking which `<DOC>` block it belongs to will silently conflate segments from the two episodes that share the same local ID. Our parser instead iterates over `<DOC>` blocks in file order, accumulates an offset equal to the maximum local segment ID seen so far, and adds that offset to each segment's local ID to obtain a corpus-level ID that is unique across the whole file. This is applied identically when building the dev and test reference sets. We flag it here because an earlier, pre-fix version of our own pipeline lacked this offsetting. It corrupted the dev-set sacreBLEU that drives early stopping and best-checkpoint selection during training, as well as the final test report, motivating the corrected parser used throughout this paper. The nine locally trained configurations catalogued in Section 6.3 and SubVision, were designed and run only after the fix and never used the flawed offsetting. The same corrected parser is used to build the reference set for the zero shot baseline evaluations in Section 6.5, so the fine-tuned and baseline numbers we compare are scored against an identical, correctly offset reference set.

### 3.5 Official Test Set

The shared task additionally distributes a demonstration package for the official test set, consisting of a per-video `*_zh.srt` subtitle file and a metadata record. Neither the demonstration package nor the full official test set includes reference translations: both are unlabeled source side releases, consistent with a shared task that scores submissions after the fact rather than allowing participants to self score against the official test data. For the example video `b4101o4evls` (episode 2 of the drama 万福金安 *Wànfú Jīn'ān*, lit. "ten-thousandfold blessings, golden peace"), the metadata record provides the video and album titles and an album level synopsis. The source file contains 231 subtitle blocks. Table 9 (Appendix A) shows several consecutive source lines exactly as provided by the organizers, with Pinyin and an English gloss added for readers who do not read Chinese, illustrating the short, dialogue style utterances and period register (forms of address, court vocabulary) typical of this genre.

## 4 Methodology

### 4.1 Base Model and Quantization

We fine-tune `tencent/Hy-MT2-1.8B` (Zheng et al., 2026), quantized to 4-bit NF4 precision with double quantization via `bitsandbytes`, using a bfloat16 compute dtype where supported. The LoRA adapters (Hu et al., 2021) of rank $r = 16$ and scaling factor $\alpha = 32$ with dropout 0.05 are attached to all attention and MLP projection matrices (query, key, value, output, gate, up, and down projections). The quantized base weights remain frozen throughout training and only the adapter weights are trainable. Section 6.5 evaluates this same 4-bit NF4 quantization of the base model, without any adapter attached, as a zero shot reference point.

### 4.2 Model Choice and Task Constraints

We adapt `tencent/Hy-MT2-1.8B` rather than a larger general-purpose LLM for reasons tied directly to the shared task's rules (WMT26 Organizers, 2026). The Video Subtitle Translation task runs a constrained track only: any submitted model, or the sum of an ensemble's weights, must total under 20B parameters, and teams must release the fine-tuned weights under a license permitting at least unrestricted non-commercial use. The organizers explicitly recommend the Hy-MT2 family as a strong base model for fine-tuning within this constraint, and teams that use a Hunyuan-MT-derived base model and achieve competitive results are additionally eligible for the task's monetary prizes. We chose the 1.8B-parameter variant specifically within that family because it lets the entire pipeline, quantization, QLoRA training, early stopping, and inference, run on a single 23.7 GB GPU, which matches our available hardware far more comfortably than the 7B variant would while still leaving substantial parameter budget headroom under the task's 20B cap. It also keeps the artifact we must open-source small: because only the LoRA adapter (rank 16) needs to be redistributed on top of the frozen, publicly available base model. Our released weights are ~74 MB (Open Weights, below) rather than a multi-gigabyte merged checkpoint. This choice is not merely a compute budget default: the reduced budget model configuration sweep in Section 6.4 fine-tuned `Hy-MT2-7B` under the identical QLoRA recipe and found it reached a higher TVsub sacreBLEU than the 1.8B baseline, but at roughly 4.6× the wall clock cost on the same hardware, and the zero shot comparison in Section 6.5 shows that fine-tuning the smaller model closes, and on this in-domain test split reverses, the gap to the larger model's un-adapted translation quality. We did not fine-tune the 7B variant at full scale ourselves, both for this compute-cost reason and because it falls outside the scope stated in Section 7, so we cannot say whether full-scale QLoRA fine-tuning would narrow, preserve, or widen the reduced-budget gap for the larger model.

As per the task description (WMT26 Organizers, 2026), all primary submissions to the Video Subtitle Translation task are judged with both automatic metrics and human evaluation, rather than by an automatic score alone. The exact automatic metric suite and the human evaluation protocol are not published on the task page as of this writing, which is one reason we present our TVsub numbers (Table 7) strictly as internal validation rather than as a prediction of official leaderboard performance. The task also distributes per-video metadata (video description or synopsis, with the task page additionally referencing character lists and glossaries) and explicitly encourages participants to use it to resolve domain specific terminology and character names, since this is one of the properties the shared task is specifically designed to evaluate. Our decision not to condition on this metadata at inference time (Section 5) is examined with reduced-budget evidence in Section 6.4 and plausibly costs us quality on exactly the cases the official evaluation is intended to reward (Section 8).

### 4.3 System Architecture

Figure 1 illustrates the training architecture.

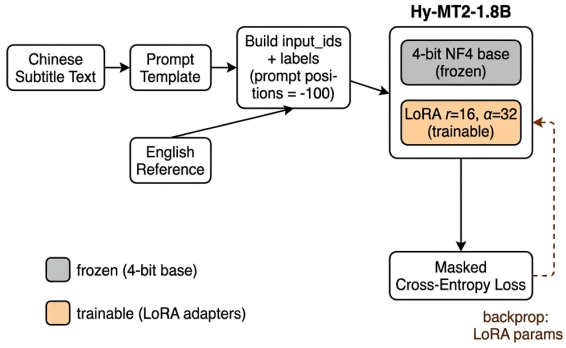

Figure 1: Training architecture of the submitted model.

The source subtitle line is embedded in the fixed instruction prompt (Section 4.4) and tokenized via the model's chat template. The target translation is appended and only its tokens contribute to the loss. The frozen, 4-bit-quantized projection weights are augmented with a trainable low-rank LoRA branch (Section 4.5) inside each transformer block; gradients flow only through the LoRA pa-

rameters and the (dequantized, bf16) activations, never into the frozen 4-bit weights themselves.

### 4.4 Prompt Format

Both training and inference use the same single-turn instruction prompt, applied via the tokenizer's chat template:

```
Translate the following text into
{tgt_lang}. Note that you must ONLY
output the translated result without
any additional explanation:{src}
```

with `tgt_lang` fixed to `English`. The target translation followed by an end-of-sequence token is appended after the prompt, and only target tokens contribute to the loss (prompt tokens are masked with label value $-100$) during training. The target is truncated from the end to fit if a prompt-plus-target sequence would exceed our maximum total length. The identical prompt, applied via each model's own chat template, is used for the zero shot baselines in Section 6.5, so that the only differences between the baseline and fine-tuned conditions are the presence of the trained LoRA adapter and, where noted, the decoding configuration of Section 4.9.

### 4.5 LoRA Reparameterization

For each targeted projection matrix $W_0 \in \mathbb{R}^{d\times k}$ in the quantized base model, LoRA (Hu et al., 2021) adds a low-rank update

$$W = W_0 + \frac{\alpha}{r} BA, \tag{1}$$

where $B \in \mathbb{R}^{d\times r}$, $A \in \mathbb{R}^{r\times k}$, $r = 16$ is the adapter rank, and $\alpha = 32$ is the scaling factor, so that $\alpha/r = 2$. $A$ is initialized from a Gaussian distribution and $B$ is initialized to zero, so that $W = W_0$ at the start of training. For an input activation $x$, the forward pass through an adapted projection is

$$h = W_0 x + \frac{\alpha}{r} B\,(A\,\mathrm{drop}_{0.05}(x)), \tag{2}$$

with dropout applied to the LoRA branch's input only, and $W_0$ frozen (stored 4-bit NF4, dequantized on the fly for the matrix multiply).

### 4.6 Training Objective

For a tokenized prompt-plus-target sequence of length $T$ with target tokens occupying positions $p+1,\dots,T$ (positions $1,\dots,p$ being the masked prompt), the model is trained to minimize the token averaged, masked causal language-modeling loss

$$\mathcal{L}(\theta_{\mathrm{LoRA}}) = -\frac{1}{T-p}\sum_{i=p+1}^{T} \log P_\theta\big(y_i \mid y_{<i}\big), \tag{3}$$

where $\theta_{\mathrm{LoRA}}$ denotes the trainable LoRA parameters $\{A, B\}$ across all targeted projections (the base weights $\theta_{\mathrm{base}}$ are held fixed), and $y_{<i}$ includes both the prompt tokens and any previously generated target tokens. Equivalently, every prompt-position label is set to $-100$ so that the standard cross-entropy loss ignores it, matching the masking in Section 4.4.

### 4.7 Learning Rate Schedule

The learning rate at optimizer step $s$ follows a linear warmup for the first $s_w = \lceil 0.03\,S \rceil$ steps followed by cosine decay over the remaining steps, where $S$ is the total number of optimizer steps:

$$\eta(s) = \begin{cases} \eta_{\max}\dfrac{s}{s_w}, & s < s_w \\ \eta_{\max}\cdot\dfrac{1}{2}\Big(1+\cos\Big(\pi\,\dfrac{s-s_w}{S-s_w}\Big)\Big), & s \geq s_w \end{cases} \tag{4}$$

with $\eta_{\max} = 2\times10^{-4}$. $S = \lceil N_{\mathrm{batches}}/8 \rceil \times 3$ accounts for gradient accumulation over 8 steps and up to 3 epochs (fewer if early stopping triggers first).

### 4.8 Training Configuration

Table 1 summarizes our training configuration. We train for up to 3 epochs with early stopping (patience 2, minimum improvement 0.05 sacreBLEU) evaluated on the 500-pair development split at the end of each epoch, using gradient accumulation over 8 steps of batch size 4 (effective batch size 32). The optimization uses PagedAdamW8bit (Dettmers et al., 2021) with a cosine learning rate schedule and 3% linear warmup, gradient clipping at norm 1.0, and no weight decay. The training ran on a single NVIDIA L4 GPU (23.7GB) on a Lightning AI Studio instance.

| Hyperparameter | Value |
|---|---|
| Base model | `tencent/Hy-MT2-1.8B` |
| Quantization | 4-bit NF4 with double quantization |
| LoRA rank / $\alpha$ | 16 / 32 |
| LoRA dropout | 0.05 |
| Target modules | $q$, $k$, $v$, $o$, gate, up, down |
| Training pairs | 60,000 |
| Development pairs | 500 |
| Trainable / total parameters | 19,398,656 / 1,810,479,104 (1.07%) |
| Maximum sequence length | 640 tokens |
| Maximum epochs | 3 (early stopping) |
| Batch size / Grad. accumulation | 4 / 8 |
| Optimizer | PagedAdamW8bit |
| Learning rate | $2\times10^{-4}$ (cosine) |
| Warmup ratio | 0.03 |

Table 1: Training hyperparameters and optimization settings.

### 4.9 Decoding Strategy

We decode with beam search, no sampling, and a fixed token budget (Table 2) at both dev/test evaluation time and for the official test submission, which we found to be generous relative to typical subtitle line lengths. We apply a repetition penalty of 1.15 and a no-repeat n-gram size of 3 to reduce repetition collapse. This decoding configuration is held identical across every reported condition in this paper: dev/test evaluation of the final adapter, the zero shot baselines in Section 6.5, and official test inference (Section 5); the only exception is the generation length, which we ablate explicitly in Section 6.3 because several of our exploratory local runs used a shorter 40 token generation budget rather than the 160 token budget used for the final reported configuration. We treat decoding as an experimental variable rather than an implementation detail: Section 6.3 reports both the nominal effect of repetition penalty, no-repeat n-gram size, and generation length budget on the scores we obtain, and a paired bootstrap significance analysis of that effect given the size of our test set.

| Generation Parameter | Value |
|---|---|
| Max new tokens | 160 |
| Beam size | 4 |
| Do sample | False |
| Temperature | 1.0 |
| Repetition penalty | 1.15 |
| No repeat n-gram size | 3 |

Table 2: Decoding configuration, identical across dev/test evaluation, the zero shot baselines (Section 6.5), and official test inference. This is the single decoding strategy used for every number reported as "SubVision" in this paper.

## 5 Official Test Inference Pipeline

We run inference directly on the organizer-provided test files for the official shared-task submission. Each source file is a `*_zh.srt` subtitle file; we parse it into blocks of (index, timestamp, text) using a line-based SRT parser that tolerates blocks with or without subtitle text. Each block's text is embedded in the training prompt template (Section 4) with target language fixed to English; blocks with empty source text are still passed through the model (with a placeholder single-space input, to keep batch shapes uniform), but their generated output is discarded and the block's translation is forced back to an empty string, so empty subtitle timings are preserved without asking the model to hallucinate content. The batches of 16 blocks are decoded with the same beam search and generation settings as training time evaluation (Table 2). The first line of the decoded continuation is kept as the translation (guarding against rare cases of trailing spurious continuation), and the result is written back into a new SRT file with the original index and timestamp preserved, so that timing synchronization from the source file is not altered.

Figure 2 below illustrates the pipeline. Critically, this pipeline does *not* incorporate the per-video metadata (title, description, character list, glossary) that the shared task makes available. Each subtitle line is translated in isolation, using only the fixed instruction prompt and the line's own text, with no document level or cross-line context and no metadata conditioning (Sections 4.2, 8).

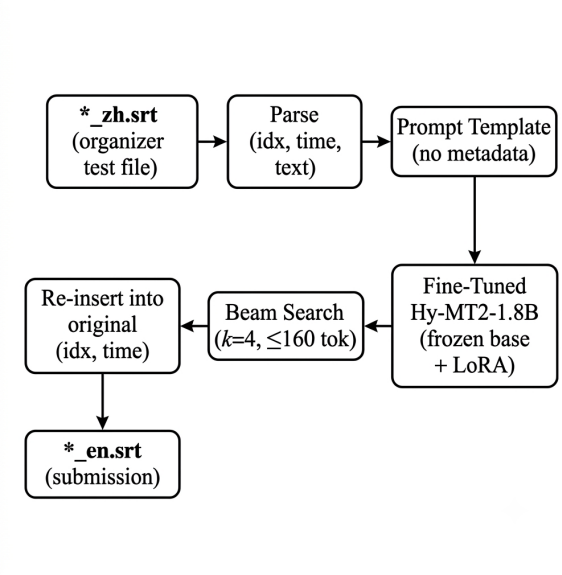

Figure 2: Test inference pipeline

## 6 Experiments

### 6.1 Setup

We evaluate on the TVsub test split (200 pairs with multi-reference SGM annotations, parsed as described in Section 3), reporting corpus-level BLEU (Papineni et al., 2002), sacreBLEU (Post, 2018), chrF (Popović, 2015), and TER (Snover et al., 2006), with generation performed under the fixed decoding configuration of Section 4.9 (Table 2). We report both BLEU and sacreBLEU because they are not directly comparable: BLEU uses our own tokenization, whereas sacreBLEU applies a fixed, standardized tokenizer (13a) specifically to make scores reproducible and comparable across papers. Therefore, we treat sacreBLEU as the primary metric for this reason and include raw BLEU only for continuity with the original TVsub benchmark protocol. All references for a given source segment are used jointly (multi-reference scoring), padding shorter reference lists to a common length as required by the scoring implementation. We additionally report a paired bootstrap significance

analysis given the modest size of this test split alongside the point estimates (Section 6.3.1), following standard practice for small sample MT evaluation.

### 6.2 Hyperparameter Tuning

We explored alternative settings including different LoRA ranks, learning rates, batch sizes, numbers of training pairs, numbers of training epochs, source/target/total sequence-length limits, and generation-length budgets, beyond the final configuration in Table 1. Section 6.3 reports these nine locally trained configurations directly, evaluated under the corrected SGM parser and, where noted, under two different decoding generation-length budgets, so that the nominal effect of decoding choice on the ranking is visible; Section 6.3.1 then tests how much of that ranking survives resampling uncertainty at this test set size.

### 6.3 Comparison Across Locally Trained Configurations

We trained nine further QLoRA configurations locally, varying training-pair count (60k vs. 100k), LoRA rank/$\alpha$ (16/32 vs. 32/64 vs. 32/32), learning rate ($5\times10^{-5}$–$2\times10^{-4}$), maximum sequence length (96 vs. 640 tokens), and batch/accumulation configuration, while holding the QLoRA target modules ($q, k, v, o$, gate, up, down), maximum gradient norm (1.0), checkpoint interval (every 500 steps), early-stopping patience (2), and the 500-pair (60k runs) or 800-pair (100k runs) development split fixed across all ten configurations. These nine configurations were run after, and partly to test, the findings of the reduced-budget ablation sweeps described in Section 6.4, which were conducted earlier in development. Table 11 (Appendix A) summarizes the ten training configurations, and Table 3 summarizes the decoding relevant evaluation settings used for each.

**Sequence Length budget derivation.** Runs R5–R9 use a substantially shorter length configuration (`max_src_len=56`, `max_tgt_len=40`, `max_total_len=96`, `eval_gen_max_new=40`) than the 640-token budget used for the final configuration. These four values were derived empirically, using two independent data sources cross-checked against each other. TVsub was used as a training proxy because no official WMT26 training data exists for this task, so its length distribution alone could not be trusted to reflect the real evaluation target. Therefore, prompt-token lengths were measured directly from the actual WMT26 demo and 100-video test set (41,837 real subtitle segments, tokenized with the model's own tokenizer and wrapped in the exact same instruction template and chat-template scaffolding used at inference), giving a source-prompt length of $p_{99} = 37$ and $p_{999} = 42$ tokens under this task's real conditions. This was then matched against TVsub's own post-template prompt-length distribution (measured the same way, via `build_input_ids` over 10,000 sampled training pairs), which showed a $p_{99}$ of 49 and a maximum of 55 tokens. TVsub's fine-tuning sentences run slightly longer than the actual WMT26 test lines, so the training side cap needed to dominate rather than the target-side estimate. The setting `max_src_len=56` and `max_total_len=96` therefore covers the full observed TVsub source-length range (max= 55) with the target evaluation distribution safely nested well inside it ($p_{999} = 42$), while `max_tgt_len=40` and `eval_gen_max_new=40` are sized from TVsub's target-length $p_{999}$ (23) and maximum (30) with comfortable headroom. The generation side cap only needs to bound how much the model is allowed to produce and is therefore decoupled from prompt length. This approach, grounding the choice in tokenized percentile statistics of both the training proxy and the real evaluation data rather than a round-number default, make sure under 1% of examples are truncated during fine-tuning while avoiding the unnecessary compute and memory cost of an oversized context window. The placeholder values of 256/256/640 used for the final configuration and R1–R4 would have been 4–7× larger than what the data actually requires, a difference we deliberately keep in the comparison (Section 6.3) because it lets us measure what the shorter, empirically justified budget costs in practice against the final configuration's more generous one.

| Run | Max new | Beams | Rep. pen. | No-repeat $n$ |
|---|---|---|---|---|
| R1 | 160 | 4 | 1.15 | 3 |
| R2 | 160 | 4 | 1.15 | 3 |
| R3 | 160 | 4 | 1.15 | 3 |
| R4 | 160 | 4 | 1.15 | 3 |
| R5 | 40 | 4 | 1.15 | 3 |
| R6 | 40 | 4 | 1.15 | 3 |
| R7 | 40 | 4 | 1.15 | 3 |
| R8 | 40 | 4 | 1.15 | 3 |
| R9 | 40 | 4 | 1.15 | 3 |
| **SubVision** | 160 | 4 | 1.15 | 3 |

Table 3: Decoding configurations used to evaluate the ten runs. Repetition penalty, beam width, and no-repeat 3-gram constraints are held fixed throughout; only the maximum number of newly generated tokens varies, with 40 tokens used for five exploratory runs (R5–R9) and 160 tokens used for the remaining five runs (R1–R4 and SubVision).

Table 4 reports test set metrics (200 TVsub pairs, multi-reference, sacreBLEU 13a) for all ten configurations under their respective decoding settings from Table 3. SubVision obtains the highest nominal sacreBLEU among the ten configurations, with R6 and R3 close behind (37.34 and 37.13 re-

spectively). Section 6.3.1 tests whether this ordering is statistically meaningful given the size of the test set; as summarized there, it is not: none of the pairwise comparisons involving SubVision reach significance at the 95% level.

| Run | sBLEU | chrF | TER | BLEU |
|---|---|---|---|---|
| **SubVision** | **37.63** | **52.76** | **53.93** | **38.56** |
| R6 | 37.34 | 52.73 | 54.43 | 38.39 |
| R3 | 37.13 | 52.49 | 54.61 | 37.92 |
| R4 | 36.40 | 52.33 | 56.59 | 37.25 |
| R7 | 36.36 | 52.54 | 56.78 | 37.21 |
| R5 | 36.35 | 51.38 | 56.28 | 37.40 |
| R1 | 35.46 | 51.21 | 57.27 | 36.44 |
| R2 | 35.33 | 51.10 | 58.07 | 36.23 |
| R9 | 34.98 | 50.90 | 57.58 | 35.91 |
| R8 | 34.76 | 50.65 | 56.96 | 35.61 |

Table 4: Test set metrics for all ten configurations, sorted by sacreBLEU descending. Lower is better for TER. All rows use the identical 200-pair TV-sub test split, the corrected multi-reference SGM parser, and the decoding settings of Table 3.

#### 6.3.1 Statistical Significance of the Run Comparison

We assessed how much of the observed ranking survives resampling uncertainty because Table 4 is computed on only 200 segments. For each of the ten configurations we drew 1000 paired bootstrap resamples of the test set (sampling segment indices with replacement, and recomputing corpus-level sacreBLEU on each resample using the same segments for every system in a given resample), giving a 95% confidence interval and a pairwise win rate for every one of the $\binom{10}{2} = 45$ system pairs.

| Run | Boot. mean | 95% CI | Std |
|---|---|---|---|
| **SubVision** | 37.36 | [33.10, 41.76] | 2.17 |
| R6 | 37.09 | [33.09, 41.50] | 2.14 |
| R3 | 36.87 | [32.81, 41.17] | 2.13 |
| R4 | 36.16 | [31.58, 40.60] | 2.35 |
| R5 | 36.09 | [31.96, 40.10] | 2.17 |
| R7 | 36.07 | [32.03, 40.17] | 2.10 |
| R1 | 35.26 | [31.14, 39.47] | 2.17 |
| R2 | 34.94 | [31.12, 38.82] | 2.02 |
| R9 | 34.78 | [30.71, 39.21] | 2.12 |
| R8 | 34.50 | [30.36, 38.71] | 2.14 |

Table 5: Bootstrap mean sacreBLEU and 95% confidence interval (1000 resamples) for each of the ten configurations, sorted by bootstrap mean descending. Only 1 of the 45 pairwise comparisons among these ten configurations has a 95% bootstrap confidence interval for the paired sacreBLEU difference that excludes zero, and it does not involve SubVision.

Table 5 reports the bootstrap mean and 95% CI for each configuration's sacreBLEU. Across the full set of 45 pairwise comparisons, only one has a 95% bootstrap confidence interval for the paired sacreBLEU difference that excludes zero (R6 vs. R8); this pairing does not involve SubVision. SubVision's difference in particular, from the lowest-scoring configuration in the table, R8, is nominally the largest gap observed (2.86 sacreBLEU) but is not significant (95% CI $[-0.52, 6.28]$, bootstrap win rate = 0.949). We therefore report SubVision's ranking in Table 4 as the nominal top score among the ten configurations tested, rather than as a statistically established advantage over the other nine. We also tested the paper's grouped decoding-budget claim directly: pooling the five 160-token-budget configurations (SubVision, R1–R4) against the five 40-token-budget configurations (R5–R9) under the same paired bootstrap procedure gives a mean difference of 0.41 sacreBLEU in favor of the 160-token group (95% CI $[-1.15, 2.10]$, bootstrap win rate = 0.691), which is not significant. The nominal ordering in Table 4, where the five 160-token configurations have a higher mean score than the five 40-token configurations, although R6 (40 tokens) ranks second and exceeds several of the 160-token configurations, is consistent with a real effect of generation budget, but at $n = 200$ we cannot distinguish it from sampling noise with this analysis, and we report it as directional rather than established.

We select SubVision as our reported and submitted configuration on the basis of its nominal top score in Table 4 and because it uses the longer, 160-token generation budget together with the 640-token training sequence length, which is directionally, though not significantly, the stronger combination among those tested; we do not claim this selection is supported by a statistically distinguishable advantage over the nearest alternatives (R6, R3).

### 6.4 Reduced Budget Ablations Justifying Design Choices

Four additional sweeps were run at a deliberately reduced training budget (fewer samples and epochs than a full run, so that a whole grid fits in a single session on 2×T4 GPUs) to decide, before committing full-scale compute, among alternative prompting strategies, hyperparameters and decoding settings, metadata-conditioning methods, and model/quantization configurations. These sweeps were conducted first, ahead of the ten full-budget training configurations reported in Section 6.3; the nine locally trained configurations were designed and run afterward, informed by these sweep results, including deliberately re-testing at full scale a setting the reduced-budget sweep had favored (LoRA rank 32/$\alpha$64, in R1 and R2) to check whether the reduced-budget advantage held once training reached convergence. Like the ten full-budget configurations and the zero shot baselines, all four sweeps were run against the corrected multi-reference SGM parser (Section 3), so every sacreBLEU figure reported in this section and in

Table 10 is post-fix and free of the reference conflation error described there. Each candidate was subject to a promotion gate that blocks a nominal TVsub sacreBLEU winner from being carried into the full-scale run unless it also (i) stays within a noise floor of 0.5 sacreBLEU over the instruction-prompt baseline (29.49 sacreBLEU), (ii) does not exceed a maximum repeated n-gram run under a decoding stress test, and (iii) renders a small set of anchor terms, 王妃 (*wángfēi*, "princess consort"), 仵作 (*wǔzuò*, "coroner"), and 王爷 (*wángyé*, "prince"), consistently across repeated occurrences in a held out episode. We treat these reduced budget results as a cheap screening pass rather than a confirmatory evaluation: candidates were filtered using the noise floor and consistency gate described above, run at a single reduced training scale with no resampling or significance testing, rather than with the bootstrap procedure of Section 6.3.1. A candidate passing this gate indicates it is worth the cost of full scale training, not that its nominal improvement is statistically established. Only the ten full-budget configurations of Section 6.3 receive that stronger evaluation. Table 10 (Appendix A) summarizes every candidate tested and the outcome. The paragraphs below give the reasoning behind each row.

**Prompting strategy.** Five templates were compared under matched fine-tuning and evaluation: the submission's default single-turn instruction (`instruction_v1`), the same instruction moved into a system turn with a bare source string as the user turn (`bare_v1`), a minimal tag format with no natural-language instruction (`tagged_v1`), the default instruction preceded by one static in-context example (`fewshot_v1`), and an instruction-as-system-message variant (`system_role_v1`). `bare_v1` scored highest on test sacreBLEU but was blocked at the promotion gate (Table 10). We retained `instruction_v1` as the submitted prompt (Section 4.4): the nominal metric gain did not survive the consistency check, and instruction-format templates are also the most transparent to reason about and reproduce.

**LoRA rank and decoding parameters.** At the reduced budget, LoRA rank 32 ($\alpha = 64$) outperformed the submission's rank 16 ($\alpha = 32$) and cleared the promotion gate, suggesting the larger adapter converges faster under a short schedule. We do not carry this result forward as-is: the full-budget comparison in Table 4 shows the opposite ordering once training reaches convergence, which we read as the reduced-budget rank advantage being a convergence-speed artifact of the short sweep rather than a capacity advantage that persists at full scale. We note that per Section 6.3.1, this reversal itself involves comparisons (R1/R2 vs. R3) that were also not individually significant under the bootstrap test, so we treat the reduced-budget rank result as suggestive rather than as a confirmed reversal. A decoding-parameter grid over repetition penalty $\{1.0, 1.15, 1.30\}$ and no-repeat n-gram size $\{0, 3\}$ found no measurable repetition collapse at any setting under this specific stress test, but repetition penalty 1.30 began to alter translation content (Table 10). This is why SubVision uses repetition penalty 1.15 (Table 2): the point that still protects against repetition failures observed in production scale generation without the content drift seen at 1.30.

**Metadata conditioning.** Because TVsub carries no document boundaries in its training split and the released splits ship no real per-video titles or synopses, two document-context proxies were tested quantitatively on TVsub itself (Table 10), while genuine WMT26 title/synopsis metadata was tested only qualitatively on the official demo package, since it carries no reference translations to score. Both quantitative proxies were blocked or net-negative, and the one qualitative test possible with real metadata showed no observable effect at all on the small set of probes examined. We treat this qualitative result as a weak signal rather than a settled finding, since it reflects a handful of hand inspected outputs rather than a scored evaluation. A systematic test of metadata conditioning against real WMT26 metadata remains open (Section 8). These results together are why SubVision does not condition on per-video metadata for this submission (Sections 5, 8).

**Model size and quantization.** The fine-tuning of larger `tencent/Hy-MT2-7B` using the same QLoRA setup (still 4-bit NF4, LoRA r16/$\alpha$32) produced a gain over the 1.8B baseline, but at roughly 4.6× the wall clock cost on the same hardware (Table 10). The restriction of LoRA to attention only or MLP only projections underperformed adapting all targeted projections, confirming the choice to target all seven projection types in Table 1. An 8-bit quantization variant scored marginally higher than the 4-bit NF4 default at roughly double the memory footprint, and two "combined-best" configurations assembled from the individually best scoring settings above were both blocked at the promotion gate. This combination of findings is consistent with, and adds a reduced-budget data point to, the model-choice rationale already given in Section 4.2; as with the other reduced-budget results in this section, these deltas were not evaluated with the bootstrap procedure of Section 6.3.1 and should be read as screening evidence rather than confirmed effects. A larger base model or higher precision quantization can nominally raise the TVsub score, but neither survived the consistency gate and the more expensive combined configurations

did not compound into a net improvement.

### 6.5 Baseline Comparison

We evaluate two zero shot baselines: the same 4-bit NF4-quantized `tencent/Hy-MT2-1.8B` used in Section 4, but with no LoRA adapter attached, and the larger `tencent/Hy-MT2-7B` variant from the same model family, also 4-bit NF4-quantized and without any adapter to isolate what QLoRA fine-tuning contributes on top of the base model. The both baselines are decoded directly from the publicly released checkpoints, with no exposure to TVsub during training. We evaluate both on the identical 200 pair TVsub test split and multi-reference set used in Section 6, with the identical instruction prompt (Section 4.4) and the identical decoding configuration (Table 2), so that the fine-tuned adapter is the only variable that differs between these numbers and Table 7. Table 6 reports the results.

| System | BLEU | sBLEU | chrF | TER |
|---|---|---|---|---|
| Hy-MT2-1.8B | 11.80 | 11.60 | 38.32 | 72.96 |
| Hy-MT2-7B | 16.08 | 15.79 | 42.81 | 68.20 |
| **Hy-MT2-1.8B + QLoRA** | **38.56** | **37.63** | **52.76** | **53.93** |

Table 6: Zero shot NF4 baselines versus QLoRA fine-tuned Hy-MT2-1.8B on the identical 200 pair TVsub test split and decoding setup. Lower is better for TER.

The zero shot Hy-MT2-1.8B baseline trails our fine-tuned adapter by 26.03 sacreBLEU, 14.44 chrF, and 19.03 TER points. This gap is far larger than any of the pairwise differences examined in Section 6.3.1 among the ten fine-tuned configurations and we would expect it to remain significant under the same paired bootstrap procedure given its magnitude relative to the per configuration standard deviations in Table 5 (∼2.1–2.4 sacreBLEU), though we did not run the baselines themselves through the bootstrap analysis. We take this gap as confirming that the gains we report in Table 7 come from the QLoRA fine-tuning step itself rather than from the base model's pretrained translation ability alone. The un-adapted 1.8B model also underperforms the un-adapted 7B model by 4.19 sacreBLEU, which is expected given the roughly fourfold difference in parameter count; notably, our fine-tuned 1.8B adapter still exceeds the larger zero shot 7B model by a wide margin (37.63 vs. 15.79 sacreBLEU) which suggests that at least on this in-domain subtitle test split, domain specific QLoRA adaptation of the smaller model is considerably more effective than relying on the base model's scale alone.

We did not fine-tune the 7B variant ourselves at full scale, both for the hardware reasons discussed in Section 4.2 and because it falls outside the scope stated in Section 7. Thus, we cannot say whether QLoRA fine-tuning would narrow, preserve, or widen this gap for the larger model. We treat the zero shot Hy-MT2-7B number here strictly as a scale reference point rather than as a competitive baseline system.

### 6.6 Results

Table 7 reports our final metrics, produced by loading the best early-stopped adapter and decoding the 200 pair TVsub test split with the configuration in Section 4. This test split is drawn from the same TVsub distribution and preprocessing pipeline as our training data and therefore serves as an in-domain diagnostic of whether fine-tuning succeeded, rather than as an estimate of performance on the shared task's official, historical costume drama test videos, which come from a different source and distribution. We did not have access to references for the official test set and so could not compute an analogous score there. The reported numbers should be read strictly as an internal validation, and, per Section 6.3.1, as a nominal point estimate whose ranking against nearby configurations is not statistically established at this test set size.

| Metric | Score |
|---|---|
| BLEU | 38.56 |
| sacreBLEU | 37.63 |
| chrF | 52.76 |
| TER | 53.93 |

Table 7: Fine-tuned Hy-MT2-1.8B on the 200 pair TVsub test split, multi-reference scoring.

### 6.7 Sentence-Level Score Distribution

Table 7 reports corpus-level metrics, which can mask how consistently the model performs across individual segments. We additionally computed per-sentence sacreBLEU (13a tokenization) for all 200 test pairs (Table 8). The mean sentence-level score (43.43) is noticeably higher than the corpus-level sacreBLEU in Table 7 (37.63), which is expected: corpus BLEU aggregates n-gram counts across the whole set rather than averaging per-sentence ratios, so it is pulled down by low-scoring segments in a way a simple mean is not. The max of 100.0 reflects exact or near exact matches on short, common phrase subtitle lines (Table 12). Only 2 of 200 segments scored zero, both discussed in Section 6.8.

### 6.8 Qualitative Examples

Table 12 (Appendix A) presents representative best and worst predictions, ranked by per-sentence sacreBLEU, from the same 200 pair evaluation set.

| Statistic | Value |
|---|---|
| Median sentence BLEU | 33.73 |
| Mean sentence BLEU | 43.43 |
| Max sentence BLEU | 100.0 |
| BLEU = 0 count | 2 / 200 |

Table 8: Per-sentence sacreBLEU statistics on the 200 pair TVsub test split.

For each example, we show the Chinese source sentence with a Pinyin romanization, the model hypothesis, and the first available English reference (each segment has up to three references).

The highest scoring examples are short, common conversational utterances where the model closely matches the reference in both wording and meaning. The lowest-scoring examples in contrast illustrate well known limitations of reference based evaluation. Short idiomatic expressions (e.g., 讨厌啦, *tǎoyàn la*) and proper nouns (e.g., 安洁丽戏院, *Ānjiélì xìyuàn*) receive low sentence-level sacreBLEU despite producing fluent English, because the model selects different lexical realizations than the reference. Similarly, longer conversational sentences may preserve the intended meaning while differing substantially in wording, resulting in lower n-gram overlap. These examples highlight that BLEU family metrics can underestimate translation quality when acceptable paraphrases differ lexically from the available reference translations.

## 7 Experimental Scope

The primary objective of this paper is to present and validate a reproducible, resource efficient QLoRA fine-tuning pipeline for Hy-MT2-1.8B within the context of the WMT26 Video Subtitle Translation shared task, rather than to provide an extensive benchmarking study across different model scales, prompting strategies, metadata-conditioning approaches, or hyperparameter configurations. This work focuses on establishing the effectiveness and reproducibility of a single, validated training and decoding pipeline, together with zero shot baselines (Section 6.5) and a comparison against nine further locally trained configurations, including a bootstrap significance analysis of that comparison (Section 6.3), that contextualizes how much of the observed effectiveness is attributable to fine-tuning, training configuration, and decoding choice, rather than to the base model, its scale, or resampling noise at this test set size.

Several exploratory experiments were conducted during development. However, these results became invalid following the correction of the SGM multi-reference parsing error described in Section 3, which had corrupted the dev-set sacreBLEU used for early stopping and checkpoint selection as well as the final test report. This rendered previous comparisons unreliable and necessitated complete retraining for any meaningful evaluation. We prioritized revalidating one end-to-end configuration using the corrected evaluation pipeline over re-running every exploratory configuration from scratch given the substantial computational cost of end-to-end fine-tuning under our available hardware constraints (a single 23.7GB GPU). Every run for which this paper reports a metric, SubVision itself, the nine locally trained configurations of Section 6.3, the zero shot baselines of Section 6.5, and the reduced-budget ablation sweeps of Section 6.4, was executed after this fix, against the corrected reference set, so none of them carry the invalidation concern that applies to the pre-fix exploratory numbers we chose not to report. The local configurations differ from SubVision in that they were trained and evaluated in a separate local environment, whereas SubVision additionally incorporates the SGM `<DOC>`-boundary offsetting fix at both the development-split scoring used for checkpoint selection and the final test scoring, which the nine local runs also apply post-fix but which was validated first in the external run.

Consequently, the experimental results presented in this paper are limited to the final, verified system (Sections 4–6.8), the nine locally trained comparison configurations and their bootstrap significance analysis (Section 6.3), and the two zero shot baselines described above. A comprehensive empirical investigation of alternative prompting strategies, metadata-conditioning methods, and length- or display-aware decoding constraints beyond repetition penalty and no-repeat n-gram size is left for future work.

## 8 Limitations

**Limited evaluation size and domain coverage.** Automatic evaluation is performed on 200 referenced TVsub segments drawn from the same general distribution as the training data. This makes the evaluation useful for validating the fine-tuning pipeline, but limits the strength of conclusions about performance on the official WMT26 test distribution. We cannot quantify how well the reported TVsub scores transfer to the shared task test data because reference translations for the official test data are not provided to participants.

**No metadata conditioning.** The submitted system does not use the per-video descriptions, character lists, or glossaries provided by the shared task. Such metadata could help resolve character names, domain specific terminology, and ambiguities that cannot be resolved from an individual subtitle line. Our reduced-budget exploratory evidence for metadata conditioning is based only on a small number of hand-inspected examples and

is therefore insufficient to establish whether metadata would improve aggregate translation quality.

**No cross line or document level context.** Each subtitle line is translated independently. Consequently, the system does not explicitly enforce consistency of terminology, character names, or register across a video, and it cannot reliably resolve pronouns or ellipsis that require neighboring subtitle lines.

**No length or display aware decoding.** The decoding uses a fixed 160-token generation budget but does not explicitly optimize for characters per line, number of lines, reading speed, or other display constraints. We therefore evaluate translation quality primarily through reference based MT metrics rather than through a dedicated subtitle readability or display compliance evaluation.

**Single decoding configuration per model.** The same repetition penalty, no-repeat n-gram constraint, and beam size are used across the reported systems. This isolates the effect of the adapter and training configuration, but does not establish that the selected decoding configuration is optimal for every model or training setup.

**Limited precision at $n = 200$.** The paired bootstrap analysis with 200 test segments distinguishes only a small number of the pairwise differences among the ten trained configurations. The submitted configuration is not statistically distinguishable from the other nine. Accordingly, we interpret the choice of the submitted configuration primarily through its nominal score and engineering properties rather than as evidence of a statistically established optimum.

## 9 Conclusion

We presented SubVision, a QLoRA fine-tuning pipeline that adapts the 1.8B-parameter Hy-MT2 multilingual translation model to Chinese–English subtitle translation using the TVsub corpus, and the corresponding official test inference pipeline used to produce our WMT26 Video Subtitle Translation submission. The fine-tuned model on an in-domain TVsub test split reaches sacreBLEU 37.63, chrF 52.76, and TER 53.93 under a fixed decoding strategy (beam search, beam size 4, repetition penalty 1.15, no-repeat 3-gram constraint, 160-token generation budget), compared to zero shot NF4 baselines of 11.60 sacreBLEU for the un-adapted Hy-MT2-1.8B and 15.79 sacreBLEU for the larger un-adapted Hy-MT2-7B under identical prompt and decoding conditions. The large improvement over the un-adapted 1.8B model provides evidence that the observed gain comes from QLoRA fine-tuning rather than from the base model alone. We additionally compared SubVision against nine further locally trained configurations that vary training pair count, LoRA rank, sequence length, and generation budget, all evaluated under the same decoding setting. A paired bootstrap analysis of this comparison shows that, at 200 test segments, SubVision's nominal top ranking is not statistically distinguishable from several nearby configurations. We report this finding alongside the point estimates rather than presenting the ranking as an established result. Our shared-task submission applies the same fine-tuned model, prompt, and decoding configuration directly to the organizer-provided official test files, translating each subtitle line independently and without access to per-video metadata. We cannot report an automatic score for the actual submission because reference translations for the official test data are not provided to participants and we have described this gap explicitly rather than presenting the TVsub numbers as if they characterized official test performance. The next steps include incorporating the task's provided per-video metadata into the prompt, adding cross-line context, evaluating length or display aware decoding constraints, and extending the statistical analysis in Section 6.3.1 to the reduced-budget ablation sweeps of Section 6.4.

## Open Weights

The QLoRA adapter weights (`adapter_config.json`, `adapter_model.safetensors`; ~74 MB), tokenizer files, and chat template are publicly available under the Apache 2.0 license at `https://github.com/praaajg/wmt26-hymt2`. These are adapter only weights (LoRA rank 16) unlike a merged checkpoint, intended to be loaded on top of the frozen, 4-bit-quantized `tencent/Hy-MT2-1.8B` base model via a PEFT-compatible runtime, consistent with the training and inference pipeline described in Sections 4 and 5.

# Laniqo at WMT26 Video Subtitle Translation Shared Task: Multi-Objective Fusion of Pareto-Optimal Candidates

**Kamil Guttmann**[1,2], **Artur Nowakowski** [1,2]
[1] Laniqo, Poznań, Poland
[2] Faculty of Mathematics and Computer Science, Adam Mickiewicz University, Poznań, Poland
{name}.{surname}@laniqo.com

## Abstract

This paper describes Laniqo's submission to the WMT26 Video Subtitle Translation Shared Task, translating subtitles from Simplified Chinese into English, Thai, Indonesian, Malay, and Traditional Chinese under a 20B-parameter, open-license model constraint. Our system optimizes translation quality and subtitle compliance entirely at inference time, without fine-tuning, by combining hedged multi-prompt candidate generation, language-identification and compliance pruning, multi-objective Pareto reranking, reasoning-based candidate fusion, and a fallback/compression step. We screened four open-weight models and compared the two strongest, `Qwen3.5-9B` and `Gemma-4-12B-it`, across the full pipeline on the complete test corpus. `Gemma-4-12B-it` reached significantly higher compliance rates in every target language, thus it was chosen as our final system.

## 1 Introduction

We describe Laniqo's submission to the WMT26 Video Subtitle Translation Shared Task. The shared task constrained model size to under 20B parameters in total and required participants to release their models under an open license, but placed no constraints on the methods or data used. We participated in all five translation directions, translating video subtitles from Simplified Chinese into English, Thai, Indonesian, Malay, and Traditional Chinese, across 100 videos of varying length. Each video was accompanied by additional metadata.

Subtitle translation differs from general-domain machine translation (MT) in that focusing on adequacy and fluency alone is not sufficient. Viewers must be able to read each subtitle within the time it is displayed, so translations are subject to a maximum reading speed, measured in characters per second (CPS). Subtitles must also fit on screen, subject to a maximum number of characters per line (CPL) and no more than two lines per cue. These constraints compete with translation quality: a semantically faithful translation that exceeds the character or line limits is not a usable subtitle, and neither is a translation compressed to the point of losing its meaning. Producing subtitles therefore requires jointly optimizing translation quality and compliance with hard length and display constraints.

We address this joint optimization problem entirely at inference time, on top of an off-the-shelf instruction-tuned Large Language Model (LLM), without any fine-tuning. Our pipeline consists of the following steps:

1. **Multi-prompt candidate generation**: We generate multiple candidate translations per subtitle cue, combining four prompt variants with hedged sampling to obtain a diverse candidate pool.

2. **Compliance pruning**: We discard wrong-language candidates and those that violate the CPS/CPL constraints the most.

3. **Multi-objective Pareto Reranking**: We compute the Pareto non-dominated set of remaining candidates across translation-quality and compliance objectives.

4. **LLM candidate fusion**: A further LLM inference pass selects, rewrites, or merges candidates from the Pareto set into a single translation.

5. **Fallback and compression**: A final pass retranslates or compresses any cue that still fails a hard requirement.

## 2 Related Work

Prior work treats reading-speed and display constraints as objectives to optimize jointly with translation quality rather than applying them post hoc.

*Proceedings of the Eleventh Conference on Machine Translation*, pages 2608–2615
October 28-29, 2026 ©2026 Association for Computational Linguistics

Matusov et al. (2019) learn subtitle segmentation from human-authored breaks alongside industry length and duration constraints, while Petrick et al. (2025) integrate length control into the translation model itself and optimize every component of their IWSLT 2025 subtitling track (Abdulmumin et al., 2025) submission against reading-speed and line-length limits.

We instead impose these constraints at decoding time, leaving the model untouched. Minimum Bayes Risk (MBR) decoding selects the candidate that minimizes expected risk with respect to a single utility metric, computed over a set of sampled translations (Kumar and Byrne, 2004). This framing optimizes for one reward at a time. In earlier work, we introduced Pareto-Optimal Decoding (Guttmann et al., 2025), a reranking strategy that instead selects the candidate that jointly satisfies multiple, potentially competing objectives by computing the Pareto-non-dominated set over several metrics. In this paper, we generalize Pareto-Optimal Decoding from balancing translation quality against terminology accuracy to balancing translation quality against other constraints.

Both MBR decoding and reranking benefit from diverse candidate pools, but constructing that diversity at scale is costly. Epsilon sampling (Freitag et al., 2023) produces high-quality diverse candidates, but requires sampling budgets in the hundreds to thousands of candidates per input to be effective. Khairi et al. (2025) show that this budget can be reduced substantially without sacrificing robustness via hedged sampling: combining a small number of temperature-sampled candidates with one greedy decoded candidate protects against the variance introduced by high-temperature sampling, particularly for non-English languages. We adopt hedged sampling and extend it across multiple prompt variants (e.g., with and without preceding context or metadata) as an additional, cheap source of candidate diversity and robustness against noise introduced by this contextual information.

Selecting a single best candidate from a generated pool discards potentially useful information contained in the remaining candidates. Khairi et al. (2026) propose Fusion-of-N (FusioN) as an alternative to Best-of-N (BoN) selection: instead of picking one candidate, an LLM judge synthesizes their complementary strengths into a new output. On WMT24++ (Deutsch et al., 2025), FusioN outperforms BoN across languages, and even surpasses oracle selection in German, Russian, and Chinese. In machine translation specifically, the Hunyuan-MT-Chimera model (Zheng et al., 2025) adopts the same principle, training a dedicated fusion model to synthesize several translation candidates generated under varying decoding settings into one output. We adopt this method but, unlike Zheng et al. (2025), use the same off-the-shelf model for both candidate generation and fusion additionally conditioning on the candidates' compliance and quality scores to enforce subtitle-length constraints.

## 3 Approach

### 3.1 Candidate Generation

For each subtitle cue, we generate a total of 25 candidate translations distributed across four prompt variants: a base sentence-level prompt (V1), a variant that adds the album synopsis[1] as metadata (V2), a variant that adds the preceding cues as context (V3), and a batch variant that translates a document-level window of 5 cues in a single call (V4). Following Khairi et al. (2025), we use hedged sampling to form the 25-candidate pool: 4 candidates come from one greedy decode per prompt variant, while the remaining 21 candidates are sampled across the variants at temperature 0.7 and min-p 0.2. We do not enable reasoning at this stage and reserve it for the candidate fusion step, where it has the most leverage, since applying it to the generation of every candidate would multiply the compute cost drastically.

### 3.2 Compliance Pruning

High-temperature sampling occasionally yields candidates in the wrong language – typically English – regardless of the requested target. QE metrics cannot catch this: they are not conditioned on the target language and will score a fluent English candidate as highly as, or higher than, the correct-language candidates for the same source segment.

We therefore prune the candidate pool with two filters applied in sequence. The first filter, based on the `lingua-py`[2] library, keeps a candidate only if its target language is among the three top-ranked detected languages with confidence threshold of 0.3. Indonesian and Malay, being mutually intelligible and often confused by the identifier, are scored jointly and pass if either clears the threshold. Candidates under five characters are exempted since

[1] A short description of the video series to which a given episode belongs.

[2] https://github.com/pemistahl/lingua-py

language identification is unreliable at that length. A length-based filtering step runs second, removing the least CPS/CPL-compliant of the remaining candidates up to 50% of the original candidate set size.

### 3.3 Multi-Objective Reranking

For each cue, we compute the Pareto-non-dominated set of the remaining candidates over four objectives: `xCOMET-XL-QE` (Guerreiro et al., 2024), `MetricX-24-XL-QE` (Juraska et al., 2024), and CPS/CPL compliance scores. The two compliance scores are zero for a fully compliant candidate and negative otherwise, in proportion to how far the candidate's reading speed (CPS) or longest display line (CPL) exceeds the per-language cap.

Averaged over the full test corpus, the non-dominated set contains 1.9 candidates per cue (minimum 1, maximum 11), out of a mean of 13 candidates surviving pruning.

### 3.4 Candidate Fusion

No single candidate in the Pareto set is guaranteed to satisfy both the quality and the compliance objectives. We therefore pass the whole set to the model, annotated with each candidate's quality and compliance scores, and prompt it to rewrite or merge candidates into one translation that combines their strengths.

Additionally, fusion is applied over a window of 12 consecutive cues in a single prompt, with an instruction to keep the fused translations coherent across the window. To preserve coherence across window boundaries, each prompt also includes the last 3 cues already fused in the previous window as read-only context. Crucially, fusion operates strictly on text assignments within existing cue time slots: the original timecodes are strictly preserved, ensuring no audio-visual timing mismatch for the viewer.

### 3.5 Fallback & Compression

If the fusion output for a cue is empty, contains untranslated source text, or is identified as being in a wrong language, we fall back to the best compliant candidate from the Multi-Objective Reranking step, selected by an average of the four normalized scores. If this still fails, we retry generation: for wrong-language cues, we show the model its own broken translation and ask it to redo the translation in the correct language, while empty cues are regenerated from scratch with a fresh greedy decode.

A compression pass is applied if the resulting text still exceeds the CPS cap by a margin of 30%. Separately, to satisfy the line-length and line-count constraints, any line still over the per-line cap is split into two based on punctuation or the nearest word boundary to the midpoint.

## 4 Experimental Setup

### 4.1 Data

For preliminary experiments, we used the demo episode released by the task organizers, consisting of 231 cues. The test set consists of 100 videos, 41,837 source segments in total (mean 418.4, min 41, max 2188 segments per video). No reference translations were released to the public. Each video is accompanied by metadata used to identify and locate it on the source streaming platform: a video ID and title, an album ID and title, an album description, internal content identifiers, and overseas/domestic URLs linking to the hosted video on streaming platforms. Among these fields, the album description is the one source of context relevant to translation, so it is the only field we use in our approach.

### 4.2 Models

The shared task's constrained track required participants to use openly licensed models with fewer than 20B parameters. We screened four models meeting these requirements:

- **Hy-MT2-7B**[3] – a translation-specialized model built on Tencent's Hunyuan architecture, suggested by the task organizers.
- **Qwen3.5-9B**[4] – a general-purpose multilingual LLM from the Qwen family, with substantial Chinese-language training data.
- **Sailor2-20B**[5] – built on Qwen2.5, developed specifically for Southeast Asian languages, including Thai, Indonesian, and Malay.
- **Gemma-4-12B-it**[6] – Google's general-purpose instruction-tuned multilingual LLM.

Table 2: Model screening: xCOMET-QE (QE), CPS/CPL compliance, and parse-failure rate, averaged over six prompt configurations and all five target languages (dev episode, 231 cues each). Per-prompt and per-language breakdowns in Appendix A.

All four are used off the shelf as instruction-tuned checkpoints, with no additional fine-tuning.

### 4.3 Evaluation

We report referenceless quality estimation (QE) scores using xCOMET-XL-QE and MetricX-24-XL-QE. Pombal et al. (2025) show that reusing the same metric for both decoding and evaluation can overstate quality gains, so we additionally report scores from ReMedy-9B-22 (Tan and Monz, 2025) as a non-interfering metric. We additionally report compliance with reading-speed and line-length constraints as the percentage of cues within the applicable characters-per-second (CPS) and characters-per-line (CPL) caps, using the per-language caps in Table 1, chosen to reflect common subtitling practice.

## 5 Results

### 5.1 Model screening

We screened all four models on the dev episode across six prompt configurations – V1–V3, and V4 at window sizes 5, 10, and 15 – in all five target languages, measuring xCOMET-QE, CPS and CPL compliance, and response parse failure rate. Averaged results are described in Table 2 while detailed per-prompt and per-language results are given in Appendix A.

Hy-MT2-7B is weakest on both compliance axes and has the highest parse-failure rate. Despite roughly double the parameter count, Sailor2-20B trails Qwen3.5-9B on both compliance metrics and only matches it on quality. Qwen3.5-9B leads on average compliance and xCOMET-QE, while Gemma-4-12B-it has the lowest average xCOMET-QE of the four but is the only model that never fails to provide a parsable response. We therefore carried Qwen3.5-9B and Gemma-4-12B-it forward.

### 5.2 Multi-Objective MT Fusion

We compared five candidate-selection strategies on top of the same Qwen3.5-9B Pareto-filtered candidate pool: max-xCOMET-QE selection, max-averaged-metrics selection, base document-level fusion with no metric information shown to the model, fusion with metrics, and fusion with metrics plus reasoning (Table 3).

Max-xCOMET-QE selection, by definition, reaches the highest xCOMET-QE of all variants, but only the second-lowest CPS compliance, since selecting purely for translation quality does not account for length restrictions. Max-averaged-metrics selection leads on MetricX-QE – again one of its own selection criteria – and reaches 81.9% CPS compliance, making it the strongest strategy that requires no second inference pass. Base fusion, which sees no scores, has the lowest CPS compliance of the five, suggesting that the model does not infer translation length from the text alone. Including the scores raises CPS compliance to 83.7%, and enabling reasoning to 88.1%.

ReMedy-QE – the only metric used nowhere in the pipeline – orders the fusion variants almost inversely, scoring base fusion highest. A manual check showed that this may be an artifact of per-cue evaluation, as fusion occasionally reorders adjacent cues to translate multi-cue sentences more naturally. Finally, we adopt fusion with metrics and enabled reasoning, trading 0.02 ReMedy-QE for 14 points of CPS compliance.

### 5.3 Final results

Table 4 reports compliance and quality at each pipeline stage. Both models gain most of their CPS compliance between V1-greedy and Fusion, with a smaller further gain at Final, and CPL compliance reaches exactly 100% at Final by construction. The three quality metrics do not agree on the pipeline's overall effect: xCOMET-QE and MetricX-QE improve from V1 to Final for both models, while ReMedy-QE declines – likely reflecting Fusion's window-level rewriting, which redis-

| Variant | xCOMET-QE | MetricX-QE | ReMedy-QE | CPS% | CPL% |
|---|---|---|---|---|---|
| Max-xCOMET selection | 0.9354 | 3.583 | 0.8821 | 79.31 | 100.00 |
| Max-avg-metrics selection | 0.9193 | 3.257 | 0.8999 | 81.90 | 100.00 |
| Base fusion | 0.8956 | 3.459 | 0.9085 | 74.03 | 97.06 |

| Reasoning fusion + metrics | 0.9184 | 3.595 | 0.8880 | 88.14 | 100.00 |

Table 3: Multi-objective MT fusion ablation: xCOMET-QE, MetricX-QE, ReMedy-QE, CPS, and CPL compliance for each candidate-selection strategy, averaged across all 5 languages (`Qwen3.5-9B` candidates, dev episode, 231 cues).

| Stage | CPS%↑ | CPL%↑ | xCOMET↑ | MetricX↓ | ReMedy↑ |
|---|---|---|---|---|---|
| **`Gemma-4-12B-it`** | | | | | |
| V1 | 75.40 | 96.11 | 0.9191 | 2.9705 | 0.9407 |
| Fusion | 92.73 | 99.69 | 0.9304 | 2.9485 | 0.9330 |
| Final | 93.37 | 100.00 | 0.9296 | 2.9669 | 0.9312 |
| **`Qwen3.5-9B`** | | | | | |
| V1 | 65.86 | 92.97 | 0.9173 | 2.9686 | 0.9394 |
| Fusion | 84.49 | 98.87 | 0.9341 | 2.8209 | 0.9318 |
| Final | 85.95 | 100.00 | 0.9321 | 2.8684 | 0.9269 |

Table 4: Compliance and quality at each pipeline stage (V1-greedy, raw Fusion, Final), averaged over the five target languages (full test corpus, 41,837 cues per language).

tributes content across adjacent cues in ways a per-cue reference-free metric penalizes even when the combined meaning is preserved. The metrics do agree on where quality is lost, scoring Fusion above Final, consistent with the fallback and compression stages trading quality for length compliance.

Table 5 compares the two models at the Final stage, with a paired bootstrap significance test on each metric. `Gemma-4-12B-it` wins `CPS` compliance significantly in every language (+0.7 to +12.2 points). The three quality metrics disagree with each other: `xCOMET-QE` and `MetricX-QE` mostly favor `Qwen3.5-9B` (both favor `Gemma-4-12B-it` only on Thai), while `ReMedy-QE` favors `Gemma-4-12B-it` on Indonesian and Malay too.

We chose `Gemma-4-12B-it` for submission because its `CPS` advantage was significant and consistent across every language, while no quality metric consistently favored either model – though `ReMedy-QE`, the one quality metric not used anywhere in reranking or fusion and therefore free of metric interference, favored `Gemma-4-12B-it` on three of the five language pairs.

## 6 Conclusion

We described Laniqo's submission to the WMT26 Video Subtitle Translation Shared Task, a pipeline that optimizes translation quality jointly with reading-speed and line-length constraints entirely at inference time, on top of an off-the-shelf instruction-tuned model. Our submitted system, based on `Gemma-4-12B-it`, reaches 91–100% `CPS` and 100% `CPL` compliance across the five target languages, against 69–98% `CPS` for single-cue greedy decoding.

Two findings generalize beyond this task. First, most off-the-shelf reference-free quality metrics are target-language agnostic and fail to penalize off-target generations, frequently ranking fluent wrong-language outputs above valid translations. Incorporating dedicated language identification as an additional evaluation dimension is therefore essential to complement bare QE metrics. Second, enforcing hard compliance carries a clear quality cost: all three of our quality metrics score the pre-compression output at or above the final output in every language, as post-hoc compression forces a direct trade-off between adequacy and reading-speed limits.

# paramanandaAI@WMT26 Video Subtitle Translation: QLoRA Fine-Tuning with Test-Time Metadata Prompting

**Shiv Ram Saud, Sundeep Dawadi, Sunil Regmi**
Department of Artificial Intelligence, Kathmandu University
{saudshivram373, sundeepdwd}@gmail.com, sunilregmi233@gmail.com

## Abstract

Subtitle translation poses challenges distinct from general-purpose machine translation model trained on web corpus. The outputs must fit strict display constraints as the text is predominantly spoken dialogue, local slangs, proper names, cultural nuances. In the "WMT26 Chinese → English task" all test videos belong to the historical costume drama genre, where period vocabulary cannot be resolved from a single line in isolation. We address these challenges with a two-part system. We fine-tune `Hy-MT2-1.8B` (Zheng et al., 2026) on 500,000 Chinese-English subtitle pairs from the TVsub corpus (Wang et al., 2018) using 4-bit QLoRA (Dettmers et al., 2023), and at test time we inject show-level metadata (title, episode name, summary) into a structured system prompt to ground character names and period terms. On an in-domain 200-pair development split, QLoRA fine-tuning raises BLEU from 6.93 to 31.29 (+24.4 points) which demonstrates the value of domain adaptation over the base multilingual model. Across four prompt configurations evaluated via LLM-as-judge on 20 sampled test translations the metadata-augmented, previous context-free variant (`structured_noctx`) wins 14 of 20 judged dialogues and is sent for submission. The fine-tuned model weights are released under Apache 2.0 at `ShivRamSaud/hy-mt2-1.8b-wmt26`.

## 1 Introduction

Subtitle translation occupies a specific need based niche within machine translation(MT) where output must be concise enough to fit on screen, the source is predominantly spoken dialogue rather than written prose, and the meaning of individual lines is often inseparable from the show's setting. Consider the Chinese term 仵作: without domain context, a general-purpose MT system might render it as "mortician" or leave it untranslated. With knowledge that the show features a female forensic coroner in an imperial court, the same system can produce the contextually correct "coroner" (Matusov et al., 2019). The WMT26 Video Subtitle Translation task (https://www2.statmt.org/wmt26/video-subtitle-translation.html) makes this domain signal explicit and each test video is accompanied by a metadata record containing the video title, album title, and album description.

Our system, **paramanandaAI**, is built around two complementary components. First, we adapt the multilingual model `Hy-MT2-1.8B` to the subtitle register through parameter-efficient fine-tuning on a large subtitle corpus, so that the model's generation style matches the short, colloquial dialogue of the test set. Second, at inference time we condition translation on the video-level metadata via a structured system prompt for the drama-specific context needed.

Our primary contributions are as follows:

- We demonstrate that QLoRA fine-tuning on 500K in-domain subtitle pairs yields a +24.4 BLEU improvement over the base

*Proceedings of the Eleventh Conference on Machine Translation*, pages 2616–2622
October 28-29, 2026 ©2026 Association for Computational Linguistics

multilingual model on a held-out development split, showing that domain adaptation yields higher gains than general purpose bigger model in constrained envrionment.

- We design a test-time metadata prompting scheme and found the metadata-augmented, context-free configuration as the best-performing submission strategy.
- We release the fine-tuned model weights under Apache 2.0, providing a reproducible, domain-adapted baseline for subtitle translation research.

Section 2 reviews related work. Section 3 describes our training data, fine-tuning procedure, and inference pipeline. Section 4 presents experimental results. Section 5 analyzes system behavior through qualitative examples and error patterns. Section 6 concludes, and Section 6 lists limitations.

## 2 Related Work

Our work sits between three research threads: subtitle machine translation, parameter-efficient fine-tuning, and prompt-based adaptation of large language models.

**Subtitle machine translation.** Subtitle translation imposes constraints like length, timing, and a colloquial register, making it different from document or sentence-level MT (Matusov et al., 2019). NMT models specifically customized for subtitling outperform general-purpose systems by better accounting for display length and reading speed. The TVsub corpus (Wang et al., 2018), which we use for fine-tuning, provides large-scale Chinese-English subtitle pairs captures the colloquial style and turn-taking structure typical of the WMT26 test domain.

**Document-level context in MT.** A natural extension of subtitle MT is to leverage cross-sentence context for consistency. Maruf et al. (2021) survey the field and find that local context can improve coherence, but also introduce noise when the surrounding lines are themselves erroneous or topically unrelated to the current line. This tension is directly relevant to our context-window experiments in Section 4.4.

**Parameter-efficient fine-tuning.** LoRA (Hu et al., 2022) fine-tunes large models by injecting trainable low-rank matrices into frozen weight projections, dramatically reducing GPU memory requirements. QLoRA (Dettmers et al., 2023) extends this by additionally quantizing the frozen base model to 4-bit NF4 with double quantization, enabling fine-tuning of billion-parameter models on consumer-grade hardware. For our setup of two 12 GB GPUs using QLoRA is the only viable fine-tuning strategy; full-parameter training of a 1.8B model would exceed available memory.

**LLM prompting and instruction tuning.** Instruction tuning (Ouyang et al., 2022) has become a standard approach for aligning language models with task-specific behavior, and our chat-format fine-tuning template follows this paradigm. Recent work has shown that large language models can translate effectively with few-shot in-context examples (Agrawal et al., 2023) and that adaptive prompting with domain-specific terminology improves translation accuracy in specialized settings (Moslem et al., 2023). We build on these findings by injecting show-level metadata as a structured system prompt at test time.

## 3 Method

### 3.1 Training Data

We train on the TVsub corpus (Wang et al., 2018), which contains 2.15 M Chinese-English subtitle pairs . From this corpus we randomly sample 500,000 pairs (fixed seed 42) and format each as a single chat record:

> `system:` Translate the following Chinese subtitle to English.
> `user:` {Chinese subtitle}
> `assistant:` {English translation}

Training on subtitle dialogue directly exposes the model to the colloquial style that dominates the WMT26 test set. Metadata is **not** used during training and was introduced only at test-time inference (Section 3.3).

### 3.2 QLoRA Fine-Tuning

We use the base `Hy-MT2-1.8B` (Zheng et al., 2026) model then attach LoRA (Hu et al., 2022) adapters of rank $r$=16 and scaling factor $\alpha$=32 with dropout 0.05 to all attention and

MLP projection matrices (q, k, v, o, gate, up, down projections). Only the adapter weights are updated during training; the quantized base weights remain frozen.

After training, the adapters are merged into the base weights, producing a single merged bfloat16 checkpoint (∼3.58 GB) that requires no PEFT runtime or adapter loading at inference. Table 1 summarizes the training configuration.

| Hyperparameter | Value |
|---|---|
| Base model | tencent/Hy-MT2-1.8B |
| Quantization | NF4 + double quant (4-bit) |
| LoRA rank $r$ / $\alpha$ | 16 / 32 |
| LoRA dropout | 0.05 |
| Target modules | q, k, v, o, gate, up, down proj |
| Trainable params | 6.5M (0.36% of 1.8B) |
| Training pairs | 500,000 |
| Epochs | 1 |
| Max sequence length | 512 tokens |
| Per-device batch | 8 |
| Gradient accum. | 4 (effective batch: 64) |
| Learning rate | $2\times10^{-4}$ |
| Compute precision | bf16 |
| Hardware | 2× NVIDIA RTX 3080 Ti (12 GB) |
| Wall-clock time | ∼5 hours |

Table 1: Training hyperparameters of the submitted model.

### 3.3 Test-Time Metadata Prompting

At test-time inference, each subtitle entry is translated as a single chat turn. The system message is populated with the video's metadata record:

> You are translating Chinese subtitles for a historical costume drama.
> Show: {album_title}. Episode: {video_title}.
> Synopsis: {album_desc}.
> Translate naturally, preserving character names and period register.

Table 2 shows a concrete instance. The description establishes the setting like a female forensic coroner, a sickly prince, an imperial murder investigation etc which disambiguates period terms such as 仵作 (coroner) and 王爷 (prince) that are underspecified in any individual subtitle line.

| Field | Content |
|---|---|
| `video_title` | 病娇王爷仵作妻 _11 |
| `album_title` | 病娇王爷仵作妻 |
| `album_desc` | 女法医孔柒柒在血月之夜意外穿越到男友写的小说之中，成为京城相府养女，穿越后的孔柒柒丢失了穿越前的部分记忆，并卷入了一起溺水谋杀案，在案件中孔柒柒结识了病弱失势的肺痨王爷沐之曦。 |
| `subtitle` | 说好一起来查沈万两的案子 |

Table 2: Metadata example from test video `a0046jl5d6d`. The synopsis provides domain context necessary to translate period-specific terms accurately.

Figure 1 illustrates the full inference pipeline. The metadata and Chinese subtitle are combined into a single prompt that is passed to the fine-tuned model. The output is written back to the SRT file with the original entry index and timestamp preserved.

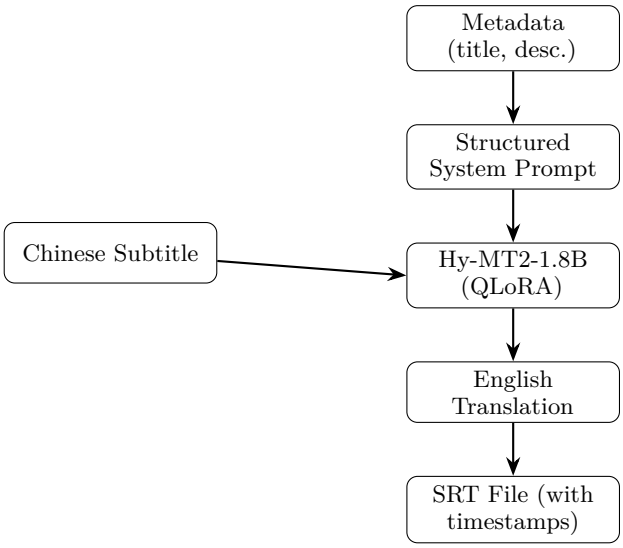

Figure 1: Test-time inference pipeline. Metadata is injected into a structured system prompt and, together with the Chinese subtitle, passed to the fine-tuned model. Each subtitle entry is translated independently.

Generation uses temperature 0.3, top-$p$ 0.9, and a repetition penalty of 1.05, capped at 128 new tokens. We use nucleus sampling rather than beam search considring subtitle dialogue benefits from natural, varied phrases (Agrawal et al., 2023). The 128-token cap is deliberately generous relative to typical subtitle length (10-20 words) and extension later is applied uniformly across all four prompt configurations.

## 4 Experiments

We conduct two complementary evaluations. First, we measure the effect of QLoRA fine-tuning using automatic metrics on an in-domain development set (Section 4.1). Second, we use an LLM-as-judge protocol on test videos to select among four prompt configurations before final submission (Section 4.3).

### 4.1 Dev-Set Evaluation

**Setup.** We used held out 200 subtitle pairs from the devset in TVsub dataset. Considering this data from the TVsub dataset, the reported scores are an in-domain diagnostic and should be interpreted as an upper bound on expected test-set performance rather than wmt26 blind test estimate. We evaluate corpus-level BLEU (Papineni et al., 2002) via SacreBLEU (Post, 2018), chrF (Popović, 2015), and TER (higher BLEU and chrF indicate better quality; lower TER is better). The baseline is the unmodified `Hy-MT2-1.8B` model evaluated under identical conditions with same plain system prompt, same generation parameters, same dev set and without QLoRA fine-tuning.

**Results.** Table 3 presents the main comparison. The base model scores BLEU 6.93, reflecting a large domain gap between the model's pretraining distribution and the subtitle register. QLoRA fine-tuning raises BLEU to 31.29, a +24.4 point improvement, with consistent gains across all three metrics. The sentence-level distribution in Table 4 further illustrates the improvement where the base model produces 22 out of 200 sentences with BLEU 0 (catastrophically wrong translations) when compared to only 3 for the fine-tuned model, indicating that fine-tuning eliminates most complete failures. There are some examples with BLEU scores of 100 which were primarily in very short translations.

| Model | BLEU↑ | chrF↑ | TER↓ |
|---|---|---|---|
| Base Hy-MT2-1.8B | 6.93 | 29.76 | 87.17 |
| **Fine-tuned 1.8B(our)** | **31.29** | **42.94** | **76.51** |
| Δ | +24.4 | +13.2 | −10.7 |

Table 3: Dev-set automatic metrics. QLoRA fine-tuning on TVsub yields substantial gains across all three metrics.

| Statistic | Base | Fine-tuned |
|---|---|---|
| Median sentence BLEU | 7.31 | 23.64 |
| Mean sentence BLEU | 10.63 | 34.92 |
| Max sentence BLEU | 66.87 | 100.00 |
| BLEU = 0 count | 22 / 200 | 3 / 200 |

Table 4: Sentence-level BLEU distribution on the 200-pair dev set.

In the WMT26 Video Subtitle Translation shared task, system outputs were evaluated using an LLM-as-a-Judge protocol with a 100-point deduction-based rubric across four dimensions (Accuracy and fidelity: 40 points maximum, Fluency and readability: 35 points maximum, Cultural and stylistic adaptation: 20 points maximum, Subtitle text conventions: 5 points maximum), which was subsequently verified and corrected by human reviewers. Participating in only the Chinese-to-English (en) direction, Ours(paramanandaAI) achieved a mean score of 55.645.

### 4.2 Comparison with Larger Baselines

To contextualize our fine-tuned 1.8B submission against a larger model, we evaluate `Hy-MT2-7B` (Zheng et al., 2026) on the same 200-pair dev split under the same plain-prompt conditions. We test both the full bfloat16 model and a 4-bit quantized variant to assess quantization degradation at the 7B scale.

| Model | BLEU↑ | chrF↑ | TER↓ |
|---|---|---|---|
| Hy-MT2-1.8B (base) | 6.93 | 29.76 | 87.17 |
| Hy-MT2-7B (bf16) | 7.94 | 32.47 | 86.32 |
| Hy-MT2-7B (4-bit) | 7.57 | 31.83 | 86.14 |
| **Fine-tuned 1.8B(our)** | **31.29** | **42.94** | **76.51** |

Table 5: Comparison of base models at different scales with our fine-tuned 1.8B submission on the 200-pair dev set.

The 7B base model improves marginally over the 1.8B base (BLEU 7.94 vs. 6.93), while our fine-tuned 1.8B surpasses both by a wide margin. This shows that domain-specific fine-tuning provides suitable alternative in subtitle translation than using larger pretrained model on zero-shot configuration, and that 4-bit quantization of the 7B model causes negligible degradation relative to full precision (Dettmers et al., 2023). Yet, Applying QLoRA to the 7B model to properly isolate

the effect of model scale exceeded our hardware constraints (2× 12GB GPUs).

### 4.3 Prompt Configuration Selection

For test submission we evaluate four prompt configurations along two axes: *system prompt style* (plain vs. structured with metadata) and *context window* (no context vs. three previous translations prepended).

| Config | Description |
|---|---|
| `simple_noctx` | Plain system prompt, no context |
| `simple_ctx3` | Plain system prompt + 3 prev. translations |
| `structured_noctx` | Metadata prompt, no context |
| `structured_ctx3` | Metadata prompt + 3 prev. translations |

Table 6: The four prompt configurations evaluated for test submission.

We sample 20 videos from the test set and generate translations under all four configurations. For each video, we sample 10 subtitle entries and present them as a blind 4-way comparison (labeled A/B/C/D and suffled to prevent positional bias) to an external LLM judge (`llama-3.3-70b-versatile` via Groq). The judge ranks the four outputs on three criteria: *fluency* (grammaticality and naturalness), *faithfulness* (semantic accuracy relative to the Chinese source), and *subtitle display suitability* (conciseness and on-screen readability). The system identities are not revealed to the judge.

`structured_noctx` wins 14 of 20 judged dialogues and is selected for submission. Its advantage is attributable to the metadata grounding (Section 4.4 discusses why context windows hurt).

### 4.4 Context Window Analysis

The `ctx3` variants prepend the three most recently translated entries to the system prompt as reference context, with the hypothesis that cross-sentence consistency would improve. The judge evaluation shows the opposite: both `ctx3` variants underperform their `noctx` counterparts.

In subtitle dialogue where consecutive lines frequently belong to different speakers. When a preceding entry is translated incorrectly, that error is fed as reference to subsequent entries, amplifying the mistake.

These findings are consistent with Maruf et al. (2021), who show that local context can degrade MT quality when it is noisy or topically discontinuous.

## 5 Analysis

### 5.1 Qualitative Examples

Table 7 shows three subtitle entries from the same test video, each illustrating how the synopsis grounds a term that would otherwise be ambiguous. All three examples are drawn from video `a0046jl5d6d` (drama 病娇王爷仵作妻), whose metadata is shown in Table 2.

| | |
|---|---|
| **Example 1** | |
| Source | 说好一起来查沈万两的案子 |
| Synopsis | Female forensic coroner investigates imperial murder case |
| Output | We agreed to investigate Shen Wanliang's case together. |
| **Example 2** | |
| Source | 仵作验过了 |
| Synopsis | Same: forensic coroner in imperial court setting |
| Output | The coroner has completed the examination. |
| **Example 3** | |
| Source | 王爷的病如何了 |
| Synopsis | Sickly prince Mu Zhixi, imperial court drama |
| Output | How is the Prince's illness? |

Table 7: Three subtitle translations from the same test video, illustrating how the synopsis grounds domain-specific terms.

In Example 2, 仵作 is a historical term for a court-appointed forensic examiner. Without the descriptive context, a general-purpose system would likely produce "mortician" or leave the term untranslated; with the synopsis identifying the protagonist as a female forensic coroner, the model produces the contextually accurate "coroner." Similarly, 王爷 in Example 3 could be rendered as "lord," "royal uncle," or omitted, but the synopsis identifies a specific prince character, leading to the unambiguous "Prince."

### 5.2 Error Analysis

We identify three recurring error patterns in the WMT26 blind submission:

1. **Post-processing needs** The model had failures that stem primarily from pipeline deficiencies. Many errors were dominated by untranslated source script retention

(43% of videos), and surface formatting leaks such as unescaped HTML entities (`apos;`), subword markers (`@-@`), and uncapitalized sentence starts. Additionally, in our dev set model produced repeated words like ha ha. The untranslated Chinese text were mostly in parenthesis, song lyrics with musical notes ( ♪ ... ♪ ), and short proper names, martial art terms, episode header and formal greeting. By category speech with spoken idioms and slang were mostly affected. During submission these errors weren't handled explicitly showing exactly how model performed on those setting.

2. **Dialogue particle loss.** Chinese dialogue particles (*吧*, *呢*, *啊*) encode conversational attitude like tentativeness, persuasion, surprise and that is difficult to preserve in English. For example, a source line ending in *吧* (a softening particle used in suggestions) may be translated as a flat declarative rather than a suggestion, losing the interpersonal nuance. This is a known challenge in Chinese-to-English MT (Matusov et al., 2019) and likely requires explicit pragmatic-awareness training to address systematically.

3. **Synopsis-absent degradation.** For test videos with a very short or absent `album_desc` field, the metadata prompt reduces to little more than the show title, providing insufficient domain signal. In those cases, the model's output qualitatively resembles that of the plain-prompt baseline, suggesting that the metadata content is the primary source of domain disambiguation for period-specific vocabulary.

## 6 Conclusion

We presented **paramanandaAI**, a system for Chinese-to-English subtitle translation combining QLoRA fine-tuning with test-time metadata prompting. Fine-tuning `Hy-MT2-1.8B` on 500K TVsub subtitle pairs yields a +24.4 BLEU improvement over the unmodified base model on an in-domain development set, and larger 7B baselines without fine-tuning remain far behind, indicating that domain adaptation fine-tuning in resource constraint is a more effective lever than larger general pupose translation models scale for this task.

A structured metadata prompt grounds period-specific vocabulary and character names that would otherwise be ambiguous from a single subtitle line. LLM-as-judge evaluation over 20 test videos suggests that this configuration (`structured_noctx`) outperforms plain prompting and context-window variants alike. Future work should explore length-aware decoding techniques to eliminate over-long subtitle outputs, and evaluate metadata prompting against a held-out test set with automatic metrics to precisely quantify its contribution independently of fine-tuning. Additionally, post processing and analysis of punctuation errors, missing translation and repetition penalty should be explored.

## Limitations

- **In-domain dev set.** The 200-pair development split is drawn from the same TVsub distribution as the training data. The reported BLEU, chrF, and TER scores therefore represent an in-domain upper bound and may overestimate performance on the WMT26 held-out test set, which consists of historical costume dramas rather than the mixed drama genres in TVsub. Additionally, lack of pre-processing of training set and post-processing of model outputs should be considered.

- **No ablation of metadata vs. fine-tuning.** The base model was evaluated under the plain prompt only. The relative contribution of the metadata prompt versus QLoRA fine-tuning on the test set cannot be disentangled without evaluating the base model under the metadata prompt, which we did not do.

- **LLM-as-judge validity.** The judge protocol was not validated against human annotator agreement, and the evaluation covers only 20 videos with 10 sampled entries each. The selection of `structured_noctx` should be interpreted

as an informed preference rather than a statistically significant finding.

- **No length or timing constraints.** The system does not enforce subtitle display-length limits or timing synchronization, both of which are important for production use. We use generation constraint of max Tokens to assume the desired length of generation to be small.
- **Metadata hallucination risk.** The metadata prompt introduces a risk that the model incorporates synopsis details not present in the source line. This failure mode was not systematically evaluated.

## Open Weights

The merged bfloat16 checkpoint (∼3.58 GB), tokenizer, and model card are publicly available under the Apache 2.0 license at:

`https://huggingface.co/ShivRamSaud/hy-mt2-1.8b-wmt26`

No PEFT runtime or adapter loading is required for inference.

## Abstract

We present the training-free subtitle translation system developed by Team ~rupiah for the WMT26 Video Subtitle Translation shared task. The system translates Chinese subtitles into English and Indonesian using Hy-MT2-7B while preserving the source cue indices and timestamps. To support discourse and terminology consistency, each cue is conditioned on episode metadata, preceding source cues, translation history, and an automatically constructed episode glossary. At inference time, the system generates candidates at six temperatures, removes exact duplicates, filters candidates containing Han characters, and selects a hypothesis using reference-free CometKiwi quality estimation. A deterministic lexical-recovery step then replaces glossary terms that remain untranslated in the selected hypothesis. In the preliminary official evaluation over 100 videos per direction, ~rupiah ranks fifth of eight systems for Chinese-to-English and third of four for Chinese-to-Indonesian. Rubric-level results indicate that the largest performance gap relative to the top-ranked system is in accuracy and fidelity, whereas the gaps in fluency and subtitle conventions are smaller. Reference-based scores over 89 videos per direction provide additional diagnostics of the complete pipeline. These aggregate evaluations do not isolate the contribution of individual components. [1]

## 1 Introduction

The WMT26 Video Subtitle Translation shared task requires systems to translate Chinese subtitles into English and Indonesian while allowing the use of associated textual metadata (WMT). Although individual subtitle cues are usually short, their interpretation often depends on information beyond the current cue. Pronouns may refer to entities introduced in preceding dialogue, names and titles may recur throughout an episode, and the appropriate register may depend on relationships between speakers or the broader narrative setting. Independent cue-level translation can therefore produce locally plausible outputs that become inconsistent when read as a sequence. In addition to these linguistic requirements, the translated output must remain a valid SubRip (`.srt`) file aligned with the structure and timing of the source subtitles.

These requirements motivate a system that separates linguistic processing from subtitle-format handling. The primary problem addressed by ~rupiah is the lack of episode-level information available to an independent cue-level translator. The system consequently treats each video as a sequential translation episode. Source cue indices and timestamps are parsed and retained separately, while translation is performed using the current cue together with episode metadata, preceding source cues, translation history, and an episode-specific terminology mapping. The system uses cue-level translation without task-specific fine-tuning; adaptation is performed entirely at inference time through prompt construction, contextual conditioning, terminology guidance, and candidate selection.

A second consideration concerns decoding. The hypothesis assigned the highest probability by a translation model is not necessarily the hypothesis preferred under an external translation-quality criterion (Eikema and Aziz, 2020). Instead of relying on a single sampled translation, the system constructs a small candidate set using the same translation model at multiple temperatures. The resulting hypotheses are deduplicated and subjected to a source-script check before being scored by a reference-free quality-estimation model. This procedure is applicable at test time because it does not require access to a reference translation. The context mechanism provides information relevant to discourse-level decisions, while the candidate-

selection procedure permits comparison among several possible translations. The present evaluation measures these mechanisms as parts of the complete pipeline and does not establish their individual effects.

Terminology consistency is handled at two points in the pipeline. Before cue translation, an episode glossary is constructed and relevant entries are included in the translation prompt. After quality-estimation selection, a narrow lexical-recovery procedure checks whether a glossary source term remains verbatim in the selected non-Chinese hypothesis and, when applicable, replaces it with its mapped target rendering. These two uses of the glossary address recurring expressions without modifying the model parameters or the underlying decoding algorithm.

This paper reports the submitted systems for Chinese-to-English (zh→en) and Chinese-to-Indonesian (zh→id). First, we describe a training-free subtitle translation pipeline that conditions cue-level generation on episode metadata, preceding source cues, translation history, and episode terminology while preserving the source subtitle structure. Second, we present an inference-time candidate-selection procedure based on temperature sampling, exact deduplication, Han-character filtering, and reference-free CometKiwi scoring. Third, we report the system's preliminary official ranking and rubric-level results over all 100 videos per direction, together with reference-based diagnostics over the 89-video subset for which references were available.

## 2 Related Work

### 2.1 Context in Subtitle and Document Translation

Subtitle translation combines sentence-level translation with discourse context and presentation constraints. Earlier work on neural machine translation for subtitles has investigated contextual modeling and segmentation as part of adapting translation systems to subtitle-specific requirements (Matusov et al., 2019). Studies of professional subtitling have further examined how contextual and extra-textual information, including film metadata, contributes to translation decisions (Vincent et al., 2024). Such information is particularly relevant for short dialogue cues, for which the local text may not identify the intended referent, the relationship between speakers, the appropriate interpersonal register, or the established rendering of a recurring entity.

The system described in this paper retains cue-level generation but augments each cue with information from the surrounding episode. Its prompt may include task-provided metadata, preceding source cues, and translation history. This design differs from strictly independent sentence translation because earlier dialogue decisions can inform subsequent cues. However, the rolling translation history does not include future cues. Episode-level information may nevertheless enter through metadata and glossary construction, which are prepared separately from the sequential cue history.

### 2.2 Terminology Consistency

Terminology consistency is important when names, organizations, titles, places, and other expressions recur across an episode. Lexically constrained decoding can enforce required target strings directly within the decoding process (Hokamp and Liu, 2017). Our approach does not alter the decoding search algorithm. Instead, it uses an episode-specific source-to-target terminology mapping during prompt construction and after candidate selection.

Relevant glossary entries are supplied to the translation model as target-rendering guidance. After quality-estimation selection, the system applies a narrow deterministic recovery procedure when a mapped source expression remains verbatim in a non-Chinese hypothesis. The recovery procedure does not perform general terminology correction: it may miss terminology errors expressed through paraphrases, inflectional variants, or alternative incorrect translations. The glossary therefore acts as both prompting context and a limited post-selection safeguard rather than as a hard decoding constraint.

### 2.3 Candidate Generation and Quality-Estimation Selection

Maximum-probability decoding does not necessarily select the translation preferred by an external quality criterion (Eikema and Aziz, 2020). Minimum Bayes risk decoding addresses this discrepancy by selecting a hypothesis according to its expected utility over a candidate distribution. Neural utility functions can improve the relationship between the decoding objective and external translation-quality measures (Freitag et al., 2022). Quality-aware decoding provides a related approach in which multiple hypotheses are generated, evaluated by an external quality model, and

reranked according to the resulting scores (Fernandes et al., 2022).

Our system follows the latter approach. It generates multiple hypotheses using one translator at different sampling temperatures and selects among the surviving candidates using CometKiwi, a reference-free quality-estimation model that requires a source sentence and translation hypothesis but no reference translation (Rei et al., 2022). Unlike minimum Bayes risk decoding, the procedure does not estimate expected utility over the candidate distribution. It directly selects the candidate with the highest CometKiwi score after deduplication and filtering.

Optimizing candidate selection against a learned metric can expose weaknesses in that metric (Amrhein and Sennrich, 2022). Moreover, quality-estimation scoring alone does not enforce a target-script constraint. Before scoring, the system therefore rejects candidates containing Han characters when producing English or Indonesian output. This filter has a deliberately narrow scope: it detects the presence of Han characters rather than the language of the complete hypothesis. Consequently, it cannot identify every off-target output and may reject a legitimate retained Chinese expression. If every candidate is removed, the system applies its documented fallback so that each source cue retains an output candidate.

### 2.4 Terminology consistency

Lexically constrained decoding can enforce required target strings during generation (Hokamp and Liu, 2017). Our mechanism operates through prompt instructions and post-selection replacement, without modifying the decoding search algorithm. A per-episode mapping gives one target rendering for recurring source terms such as character names, organizations, titles, places, and other repeated expressions. Relevant mappings are included in the cue prompt, and a narrow deterministic recovery is applied after candidate selection when a mapped source string remains verbatim in a non-Chinese output.

### 2.5 Candidate generation and QE selection

Decoding by maximum model probability can prefer hypotheses that differ from those favored by translation-quality criteria (Eikema and Aziz, 2020). Minimum Bayes risk (MBR) decoding addresses this problem by choosing a hypothesis according to expected utility over a candidate distribution, and neural utility functions can improve the relationship between decoding and external quality measures (Freitag et al., 2022). Quality-aware decoding provides another route: generate alternatives, score them using an external quality model, and select the best-scoring hypothesis (Fernandes et al., 2022). Recent work has also studied combining rather than simply ranking QE-scored hypotheses (Vernikos and Popescu-Belis, 2024).

We use CometKiwi, a reference-free QE model requiring a source and hypothesis but no reference (Rei et al., 2022). Unlike MBR, this procedure does not estimate utility over a candidate distribution: it directly maximizes a reference-free QE score. Metric-guided decoding can expose weaknesses in the optimized metric (Amrhein and Sennrich, 2022), motivating a separate Han-character check before scoring.

| Item | Documented configuration |

| Sampling | `top_p`=0.6, `top_k`=20, repetition penalty 1.05 |
| QE selector | `Unbabel/wmt22-cometkiwi-da` |
| Output | Source indices/timestamps preserved 1:1 |

Table 1: Inference configuration for the two evaluated directions.

## 3 System Components and Methodology

### 3.1 End-to-end architecture

The system converts Chinese subtitle cues into English or Indonesian cues. Each cue contains an index, start and end timestamps, and dialogue text. The indices and timestamps are retains separately, this approach are to make sure only dialogue and textual context reach the translator. Figure 1 shows the subtitle parsing, metadata extraction, and the cue-level translation loop. The episode glossary is used during prompting and again after QE selection. Solid arrows show cue processing and iteration process, whereas dashed arrow represented the glossary use. Earlier cue translations are fed into later prompts through a rolling history. The inference settings are listed in Table 1. The remaining reproducibility details are given in Section 6.

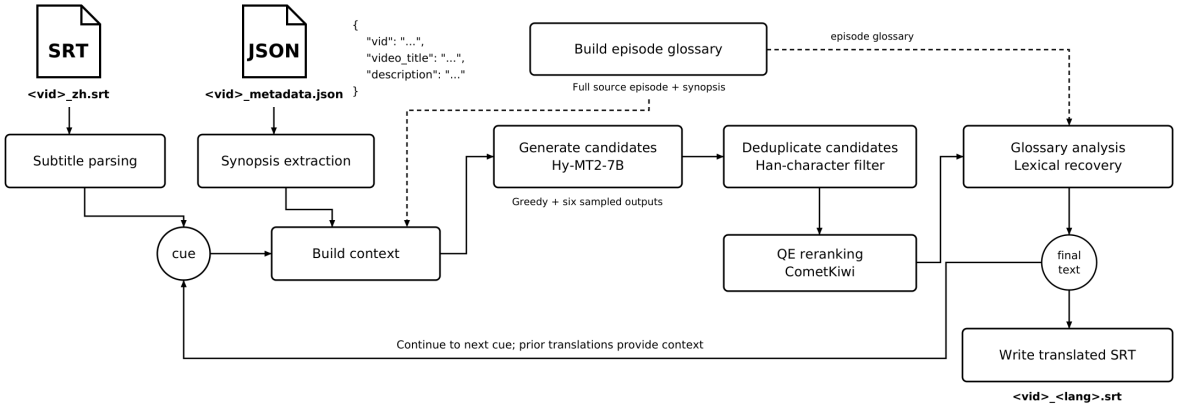

Figure 1: Subtitle translation pipeline. The context construction are provides by the Source SRT cues and JSON synopsis metadata. The episode glossary add the terminology for prompting and post-selection lexical recovery. Hy-MT2-7B generated-candidates are deduplicated and filtered before CometKiwi reranking. The feedback path shows that we use iterates over ques and use prior translation, but it does not show when we update the history store. We keep the original indices and timestamps when rebuilding the SRT.

### 3.2 Base translation and serving

Hy-MT2-7B is the sole translation generator and the model is served through vLLM (Zheng et al., 2026; Kwon et al., 2023). We are not performs any task-specific fine tuning, so there will be no training corpus, optimizer, or adaptation schedule for the submitted system. The user message contains the full translation instruction, and target languages are written out in full.

**Generation settings.** For each cue, the model generates one sampled candidate at each of the six temperatures listed in Table 1. All the candidates use `top_p`=0.6, `top_k`=20, `repetition_penalty`=1.05, and `max_tokens`=512, the difference are only in the temperature. So candidate diversity comes from a single translation model and a single cue prompt, not from an ensemble of generators.

### 3.3 Context-aware prompting

Let $x_i$ be source cue $i$ and $t$ the target language. The cue prompt is represented as

$$p_i = [I_t; M; G_i; x_{i-h:i-1}; (x, y)_{i-r:i-1}; x_i], \quad (1)$$

where the brackets denote conceptual prompt components, $I_t$ is the target-language instruction, $M$ is task-provided title/synopsis metadata, $G_i$ is the set of relevant terminology entries, $x_{i-h:i-1}$ denotes a bounded window of preceding source cues, and $(x, y)_{i-r:i-1}$ denotes preceding source cues paired with their selected translations. Unselected sampled candidates do not enter history. The exact history update point is among the configuration details listed in Section 6.

**Roles of the context sources.** Each context source does a different job. Metadata gives a stable episode-level description that can disambiguate setting or character relationships. The preceding source cues includes nearby context that may resolve short or elliptical dialogue. Previously selected source-target are able to reveal target-side lexical and stylistic choices already in place, so later decisions can take them into consideration. Terminology entries give explicit preferred renderings for recurring terms. This make the two histories are capped to the prompt budget and contain earlier cue.However, the restriction are only applies into rolling history, the glossary construction are not affected by the restriction. This approach are to make sure the glossary construction could reads from the whole episode.

**Target-specific instruction.** For the Indonesian instruction, we additionally add a colloquial but clean register and provide guidance on interpersonal address. For example, to distinguish peer-oriented *aku/kamu* from more formal forms such as *Anda* or *Bapak/Ibu* when the relationship calls for them. The instruction exposes these choices to the models, with the the surrounding dialogue gives it evidence for choosing among them.

### 3.4 Episode terminology and lexical recovery

Before cue-level translation, the system performs a single LLM pass over the entire source episode.

The synopsis metadata acts acts as a seed, helping the model build a mapping from source terms to their preferred target renderings. This mapping is meant to cover recurring proper names, organizations, titles, places, and other repeated expressions in the episode. or a cue containing a mapped term, the relevant entry is included in $G_i$ in Equation 1. This approach help the translator already has the preferred rendering before it starts generating.

**Post-selection lexical recovery.** The *Glossary Analysis* stage in Figure 1 act as a second, narrower mechanism. After QE selection, it checks whether a mapped source string presents verbatim in a non-Chinese target. When it finds an exact match, it simply replaces that string with the mapped rendering. The recovery step is intentionally limited, where it does not perform any morphological inflection, semantic entity linking, or general rewriting. As the results, it can miss terminology errors expressed through paraphrases and produce awkward morphology after the replacement.Let $R_G$ denote this recovery operation. The emitted text is $\hat{y}_i = R_G(y_i^*)$, which may differ from the QE-selected candidate $y_i^*$. The selection score applies to $y_i^*$, so any QE score attributed to the emitted output must be computed on $\hat{y}_i$.

### 3.5 Candidate generation, filtering, and QE

**Candidate search and deduplication.** For prompt $p_i$, the raw candidate set contains one sampled hypothesis $y_i^\tau$ for each temperature in $T = \{0.6, 0.7, 0.8, 0.9, 1.0, 1.1\}$:

$$C_i = \{y_i^\tau \mid \tau \in T\}, \qquad \widetilde{C}_i = \mathrm{dedup}(C_i). \quad (2)$$

The raw pool therefore contains at most six hypotheses, and order-preserving deduplication can reduce it further when different temperatures yield identical text.

**Han-character filtering.** Before QE scoring, a target-specific filter $F_t$ removes out candidates that containing Han characters for English and Indonesian. The goal is not to judge whether a translation is semantically adequate, but to catch one narrow and easily observable failure, where source-script leakage into a non-Chinese output. Since the filter relies on script rather than acting as a general language detector, it may keep Latin-script text that is in the wrong language, and it may also reject legitimate cases where a Chinese name or quotation is intentionally retained. If applying the filter would remove every candidate, the system falls back to the unfiltered deduplicated pool $\widetilde{C}_i$, ensuring that every source cue still has at least one output candidate.

**QE selection and model reuse.** Each of the remaining candidate then scored with `Unbabel/wmt22-cometkiwi-da` using the current source cue and candidate translation (Rei et al., 2022). The checkpoint is loaded just once and then kept in memory for the entire run, so scoring candidates does not require reloading the model for each cue. With $Q(x_i, y)$ denoting the QE score, selection is

$$y_i^* = \arg\max_{y \in F_t(\widetilde{C}_i)} Q(x_i, y), \quad (3)$$

Under the empty-filter fallback of $F_t(\widetilde{C}_i) = \widetilde{C}_i$, all candidates are temperature-sampled. There is no deterministic anchor and samples selected on QE score alone. With that, A fluency-biased QE model may thus favor fluency over adequacy. Equation 3 is a selection rule, not a measured gain, where assessing it requires a controlled comparison against a direct-translation baseline.

### 3.6 Subtitle reconstruction

The parser keeps every source cue index and timestamp. After translation and lexical recovery, only the text field is replaced. The cues are written back in their original order and named using the required `vid_langshort.srt` convention. This reconstruction preserves the source one-to-one in cue count, indexing, and timing. The pipeline can split a cue that exceeds length limits, where on the submitted data this did not occur, so output and source cue counts coincide. Thus, preserving this structure does not establish subtitle usability, where we still found translated cues can still exceed suitable line lengths or reading speeds.

## 4 Inference-Time Optimization

The inference pipeline combines the candidate sampling, translation history, terminology handling, and compute reuse. We describe how they work in Section 3 and summarize the computational consequences here.

**Candidate budget and deduplication.** We sample six decodes, giving at most six candidates per cue. The exact deduplication are able to reduces the number of QE evaluations, but does not recover

generation work that has already performed. After filtering, each cue requires between one and six candidates scoress, the all-filtered fallback able to restore at least one candidate if every generation are filtered out.

**Resident scoring and episode reuse.** We keep CometKiwi loaded across cues, so we avoid reinitializing the checkpoint. The episode glossary is only constructed once and reuse for the whole episode, while translation history is bounded rather than growing with the entire output episode. Our choices are attempt to limit any redundant work, but resident QE also takes up memory and extra context, making the prompt processing more expensive.

**Cost interpretation.** The training-free approach we describes are not involving any task-specific parameter updates. The proposed method currently does not establish any low inference cost. A direct run needs one generation per cue, and the full pipeline adds sampled generation, QE scoring, and episode glossary construction. The optimizations goals are to reduce specific redundant work, even with the benefits are depends on the generation length, candidate duplication, batching, and the serving hardware. No measured runtime or memory advantage is analyze in the paper.

## 5 Evaluation and Results

### 5.1 Evaluation scope and metrics

e evaluate the complete ~rupiah outputs for zh→en and zh→id. The primary evaluation uses the shared task's preliminary official assessment, based on the subtitle quality rubric. The rubric components are Accuracy/Fidelity (40), Fluency/Readability (35), Cultural/Stylistic Adaptation (20), and Subtitle Text Conventions (5). Each video are scored and aggregated to 0–100.[2] These scores are produced by an automatic judge with human verification, and they apply to the actual submitted subtitle files. The secondary evaluation is a reference-based diagnostic (BLEU, chrF, chrF++) computed against ground-truth subtitles, and a reference-free CometKiwi diagnostic (because CometKiwi is also the selector components in our pipeline, we treat it as diagnostic only.

[2]Preliminary results and per-video judgments released by the organizers: https://github.com/jasonNLP/wmt26_video_subtitle_translation.

| English | | Indonesian | |
|---|---|---|---|
| Rank | System (score) | Rank | System (score) |
| 1 | ReopenAI (90.19) | 1 | ReopenAI (87.84) |
| 2 | LensLinguals (75.25) | 2 | laniqo (74.27) |
| 3 | AuditTranslate (74.70) | 3 | **~rupiah (67.60)** |
| 4 | laniqo (74.16) | 4 | BVSLP (62.42) |
| 5 | **~rupiah (70.89)** | | |
| 6 | BVSLP (60.48) | | |
| 7 | paramanandaAI (55.65) | | |
| 8 | SubVision (49.77) | | |

Table 2: Preliminary official mean quality score (0–100), all systems, $n = 100$ videos per direction. Scores from the released organizer results.

The separate reference-score file covers 89 videos (34,250 cues) per direction, so BLEU/chrF/chrF++ describe 89% of the submitted videos. It also flags 1,622 English cues (4.74%) and 1,594 Indonesian cues (4.65%) with `empty_ref`, but, these flags are concern references, not as empty system outputs. BLEU measures n-gram precision with a brevity penalty (Papineni et al., 2002); chrF compares character n-grams and can be less brittle to surface variation (Popović, 2015). We report corpus-level `__ALL__` aggregates rather than averaging per-video scores (Post, 2018).

### 5.2 Official preliminary results

Table 2 ranks ~rupiah on the preliminary official metric: fifth out of eight in English and third out of three in Indonesian, though the Indonesian result reflects a smaller comparison set. In both directions, the top system (ReopenAI) is well separated from the field, while ~rupiah falls within a compact band below it.

### 5.3 Per-dimension analysis

Table 3 decomposes the official score by rubric dimension. ~rupiah and the top system are close on Fluency/Readability, tied on Subtitle Text Conventions, and moderately apart on Cultural/Stylistic Adaptation. Almost all the separation is on Accuracy/Fidelity, where ~rupiah scores about three-fifths of the top system in both directions. Consistent with this, critical mistranslation dominates ~rupiah's deductions, with a per-video penalty an order of magnitude larger than the top system's. The submitted configuration therefore produces fluent, well-formed subtitles whose main limitation is adequacy, as examples of correct, names, and referents that not surface form or timing.

| Dir | System | Acc/40 | Flu/35 | Cul/20 | Conv/5 |
|---|---|---|---|---|---|
| en | ReopenAI | 36.25 | 31.29 | 18.35 | 4.36 |
| | ~rupiah | 22.07 | 29.08 | 15.49 | 4.34 |
| id | ReopenAI | 34.83 | 32.80 | 17.76 | 4.65 |
| | ~rupiah | 22.55 | 29.82 | 14.64 | 4.74 |

Table 3: Mean per-video rubric-dimension scores, ~rupiah vs. the top-ranked system, from the preliminary official judgments. Maxima in headers.

| Target | BLEU ↑ | chrF ↑ | chrF++ ↑ | CometKiwi ↑ |
|---|---|---|---|---|
| English | 16.49 | 39.11 | 37.10 | 0.7515 |
| Indonesian | 11.15 | 38.68 | 35.50 | 0.6882 |

Table 4: Reference-based diagnostics over 89 videos (34,250 cues) per direction, and reference-free CometKiwi. CometKiwi is also the selector and is not independent evidence; see Section 5.1.

### 5.4 Reference-based diagnostics

Table 4 reports the reference-based diagnostics. Because each direction uses its own references, these scores are not directly comparable across languages. They do support the official metric's ordering, where English above Indonesian, however, they do not isolate any individual component.

### 5.5 Evaluation boundaries

The evaluations above characterize the full pipeline and, via Table 2, its standing among submitted systems. But they do not isolate the contributions of context, terminology, or QE selection. So, the no direct-translation baseline or component ablation is included, and CometKiwi serves as both selector and diagnostic. A matched greedy-baseline comparison and a small blinded human assessment, especially of Indonesian register where it remain the necessary next steps, as outlined in the released analysis scaffold.

## 6 Reproducibility and Limitations

### 6.1 Configuration and parameter accounting

We release the code behind our submission. It locks in the pipeline structure, prompt templates, glossary construction, candidate temperatures, filtering, and QE selection. For exact reproduction, read the run-specific settings from the config, where the source- and translation-history window sizes $h$ and $r$, prompt-truncation rules, random seed policy, checkpoint revisions, and vLLM version. The config also states whether the rolling history keeps the QE-selected candidate $y_i^*$ or the recovered output $\hat{y}_i$, so you don't have to infer it from the outputs.

We also use two checkpoints, Hy-MT2-7B for translation and glossary construction and `Unbabel/wmt22-cometkiwi-da` for QE selection. Glossary construction reuses the translator, so there's no third model. That gives roughlt 7B + 0.57B, where around 7.6B parameters, within the WMT26 constrained-track budget of 20B (WMT). Both are counted because both run at inference. Revisions and licenses are in the released code.

### 6.2 Limitations and responsible use

We want to highlight two points, error propagation and local correction. We found a mistaken name or register in the rolling history can bleed into later cues. The Han-character check tests script, not language. Exact-match recovery misses paraphrased terminology and can break morphology. These issues help explain the adequacy gap in Section 5.3: without a deterministic anchor in the candidate pool, QE can favor fluent hypotheses over faithful ones, and the official judgments mainly penalize critical mistranslation, not fluency or formatting. Wrong titles or pronouns can also distort speaker relationships, and preserved timestamps don't guarantee readable speed or line length. Since these failures are about adequacy and register, aggregate metrics should be paired with contextual human review (especially of Indonesian address forms) and and subtitle-usability checks.

## 7 Conclusion

We introduced a training-free subtitle translation system based on Hy-MT2-7B. Episode metadata, dialogue history, and terminology guide cue-level generation. Temperature sampling supplies alternatives for Han-character filtering and CometKiwi selection, while lexical recovery and SRT reconstruction yield the final subtitles without changing cue indices or timestamps. In the preliminary official evaluation, the system ranks fifth of eight in English and third of four in Indonesian. Fluency and subtitle conventions are competitive, but accuracy clearly lags Per-dimension analysis traces almost the entire gap from the top system to adequacy, not surface form. Future works could explore whether QE-guided selection without an adequacy anchor helps or hurts the faithfulness, a matched greedy baseline and a small blinded human assessment would settle it.

## Abstract

We describe ReopenAI's constrained-track submission to the WMT26 Video Subtitle Translation Shared Task. The system translates Simplified Chinese subtitles into English, Thai, Indonesian, Malay, and Traditional Chinese (Taiwan). It combines Hy-MT2-7B and Gemma-4-12B-it without fine-tuning; their unique weights total approximately 19B parameters. Both models receive the complete source subtitle sequence as context and sample two cue-level candidates. Gemma selects one of the four anonymous candidates using a stable random order and its reverse. A selection is accepted only when both judgments identify the same candidate; otherwise a fixed Gemma candidate is used. Official preliminary evaluation ranks ReopenAI first overall and in every target direction, with a macro-average score of 89.357 over 100 videos. On an internal three-video diagnostic totaling 705 cues per target, fusion obtains a 93.8% pooled macro-average acceptable-translation rate, compared with 93.0% for Gemma, 90.0% for Hy-MT2, and 77.0% for Qwen. On a separate 122-cue ablation, full-video context improves Hy-MT2 in all five targets, with gains from 4.1 points in English and Traditional Chinese to 18.0 points in Malay. The system uses no task-specific parallel data, audio, or video frames.

## 1 Introduction

Subtitle translation requires more than independent sentence translation. Full-video textual context can help resolve the referents of pronouns and demonstratives, recover omitted arguments, and maintain discourse and terminology consistency across adjacent cues. However, it cannot fully track speakers when disambiguation requires audio cues, such as voice identity or prosody, or visual evidence. Output must also preserve cue boundaries and remain concise. The WMT26 task evaluates five directions from Simplified Chinese: English, Thai, Indonesian, Malay, and Traditional Chinese as used in Taiwan.

Our system combines the translation-specialized Hy-MT2-7B (Zheng et al., 2026) with Gemma-4-12B-it (Gemma Team, 2026). It supplies full-video Chinese context to every cue-level request, generates four candidates using two models and two seeds, and reuses Gemma for conservative candidate selection. Reusing a checkpoint does not add unique parameters, so the system remains below the constrained track's 20B limit. Our contributions are: (1) a context format that preserves SRT alignment; (2) heterogeneous candidate generation without training; (3) anonymous, reversed-order selection with deterministic fallback; and (4) a single-model comparison and context ablation that document both benefits and failure modes.

## 2 Related Work

Early context-aware NMT established that information beyond the current sentence can improve document translation. Miculicich et al. (2018) model document context with hierarchical attention, while Voita et al. (2018) show on subtitle data that contextual models learn anaphora resolution and improve pronoun translation. For production-oriented subtitling, Matusov et al. (2019) combine domain and style adaptation, inter-sentence context, and learned subtitle segmentation with explicit length and duration constraints. These studies motivate our use of cross-cue context while also highlighting the need to preserve subtitle structure.

Recent LLM-based document translation combines broad source context with segment-level decoding. Hu et al. (2025) prime an LLM with the complete source document and then translate its segments in a multi-turn conversation, retaining prior context while reusing the key-value cache.

*Proceedings of the Eleventh Conference on Machine Translation*, pages 2631–2636
October 28-29, 2026 ©2026 Association for Computational Linguistics

Because useful long-range dependencies can be sparse, Peng et al. (2025) instead retrieve informative local and distant source and target context for each segment. Our method uses the simpler training-free alternative of supplying the complete source subtitle sequence to every cue-level request. This avoids a separate retrieval component, but irrelevant distant cues may still dilute the useful context.

Recent subtitle-specific studies also emphasize metadata, character style, and structure. Pramodya et al. (2025) show that movie metadata such as title, summary, and genre can improve LLM subtitle translation. Ito et al. (2026) derive character profiles and scene descriptions from context to create style-preserving augmentation for movie-specific translation. In an end-to-end speech setting, Cettolo et al. (2026) use a longer-context refinement pass and realign its output to the original subtitle timing. We likewise combine video-level text with cue-level output, but use only the supplied titles and Chinese subtitles: we perform no training, audiovisual processing, or resegmentation, and preserve the given SRT indices and timestamps exactly.

Candidate diversity and quality-aware selection provide the other basis of our system. Shy-hunyuan-MT distills diverse translations and applies multi-reward reinforcement learning (Zheng et al., 2025), whereas IRB-MT uses an unchanged Gemma checkpoint for free-form self-refinement (Grubisic and Korencic, 2025). Kaze-MT ranks a large candidate set with multiple reference-free estimators (Tan, 2025), and KIKIS combines translation and reranking subsystems with long-context decisions (Iwakawa et al., 2025). We instead select verbatim from four candidates with no separately trained ranker, trading possible oracle quality for parameter-budget compliance and auditability.

## 3 Task and Data

The official test package contains 100 Chinese SRT files with 41,837 cues and title metadata for each video. Five target languages produce 209,185 requests per decoding run. We use only these source subtitles and metadata: no reference translations, task-specific training data, external glossary, video frames, or audio. Every output retains the source cue indices and timestamps and follows the required `vid_langshort.srt` naming convention.

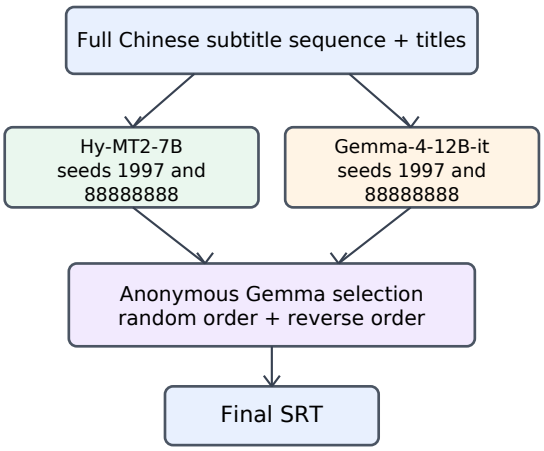

Figure 1: Submitted inference pipeline. Both generators share full-video source context; Gemma selects one anonymous candidate verbatim.

## 4 Method

For source cue $x_i$ in video $v$, we build context $c_v$ from title metadata and all Chinese cues in temporal order. The two submitted models $m \in \{\mathrm{Hy}, \mathrm{Gemma}\}$ decode with seeds $s \in \{1997, 88888888\}$:

$$y_i^{m,s} \sim p_m(y \mid x_i, c_v; s). \tag{1}$$

The four candidates are anonymized and one is copied verbatim to the final SRT. Figure 1 summarizes the pipeline.

### 4.1 Full-Video Context

Each SRT is parsed into cue index, timestamp, and text. Album and video titles are prepended to the complete Chinese cue sequence. Prompts describe this sequence as background for discourse, references, sentence continuation, terminology, tone, and proper names, but require translation of the current cue only. The long prefix is identical across requests for the same video and language, allowing vLLM prefix caching (Kwon et al., 2023).

### 4.2 Candidate Generation

Hy-MT2 receives the context and current cue in one user message. It uses BF16, temperature 0.7, top-$p$ 0.6, top-$k$ 20, repetition penalty 1.05, and a 32,768-token context limit. Gemma receives the context as a system message and the cue as a user message. Thinking is disabled; it uses BF16, temperature 0.7, top-$p$ 0.95, top-$k$ 64, and the same

context limit. Both produce at most 512 new tokens. Diversity therefore comes from model heterogeneity and two independent seeds rather than a large decoding sweep.

Qwen3.5-9B (Qwen Team, 2026) was evaluated as a single-model baseline with full-video context, thinking disabled, temperature 0.7, top-$p$ 0.8, top-$k$ 20, presence penalty 1.5, and at most 128 new tokens. It was not included in the final ensemble: using all three checkpoints would total 28B parameters, and Gemma had the strongest five-language macro average.

### 4.3 Agreement-Gated Selection

Gemma is reused as the selector for two practical reasons. In pilot tests, Hy-MT2 did not reliably complete the constrained task of returning only a candidate label, and adding a separate ranking model would risk exceeding the track's 20B parameter limit. Reusing Gemma keeps the submitted system at 19B unique parameters.

For batches of at most eight cues, the selector sees the Chinese source and four candidates labeled A–D, without model names or seed values. Its prompt prioritizes faithfulness, negation and logical relations, cross-cue coherence, natural subtitle style, and terminology. Rewriting and explanations are forbidden; the response is strict JSON containing cue identifiers and labels.

Let $\pi_i$ be a stable pseudorandom candidate order. Gemma judges $\pi_i$ and its reverse. After mapping labels back to identities, the decision is

$$\hat{k}_i = \begin{cases} k, & g(\pi_i) = g(\mathrm{rev}(\pi_i)) = k, \\ k_{\mathrm{fb}}, & \text{otherwise}, \end{cases} \tag{2}$$

where $k_{\mathrm{fb}}$ is the Gemma candidate generated with seed 1997. Invalid JSON or labels also trigger fallback. Identical candidates bypass the selector. Selection uses temperature 0, and every mapping and decision is recorded in a JSONL audit file excluded from the translation submission.

## 5 Implementation

The Python implementation uses Transformers and vLLM. Generation is batched by video and target language; Hy-MT2 and Qwen use one-way tensor parallelism, and Gemma uses two-way parallelism. Before fusion, every SRT is checked for equal cue count, identical indices and timestamps, and non-empty text. No weights are trained or modified. The release package includes the three baseline scripts and the anonymous fusion program; public model identifiers are `tencent/Hy-MT2-7B`, `Qwen/Qwen3.5-9B`, and `google/gemma-4-12B-it`.

Each generation run is separated by model and seed, so candidate SRTs remain independently inspectable. The fusion stage writes both the final SRT and a JSONL record containing the hidden candidate mapping, the forward and reverse judgments, agreement status, fallback reason, and selected identity. These records are excluded from the translation submission but permit every final cue to be traced to an unmodified model output. Failed validation stops fusion rather than silently repairing indices, timestamps, or missing cues.

## 6 Evaluation

### 6.1 Official Shared-Task Results

The official preliminary findings evaluate submitted systems with three language-aware LLM-based LQA assessments per video, followed by human verification and correction (WMT26 Video Subtitle Translation Shared Task, 2026). ReopenAI was evaluated on all 100 test videos in each target direction and ranked first overall and first in every language. Table 1 reports the top two multilingual systems. ReopenAI's 89.357 macro average exceeds laniqo's 78.265 by 11.092 points. Human-verified assessments were available for 93.36% of all shared-task evaluation units. These 100-point, video-level LQA scores are not directly comparable to the cue-level A+B rates reported below.

| Team | en | th | id | ms | zh-TW | Avg. |
|---|---|---|---|---|---|---|
| ReopenAI | **90.195** | **89.015** | **87.845** | **82.160** | **97.571** | **89.357** |
| laniqo | 74.155 | 79.895 | 74.270 | 69.120 | 93.885 | 78.265 |

Table 1: Official preliminary WMT26 shared-task scores. Each language score is the mean over 100 videos; Avg. is the language macro average. ReopenAI ranked first overall and in every direction.

### 6.2 Internal Evaluation Protocol

To complement the official evaluation with cue-level analysis, we report an internal diagnostic. Three test videos with 122, 199, and 384 cues (705 total) were examined in all five target languages. Cues were graded A (accurate and natural), B (correct with a minor issue), C (noticeable but recoverable error), or D (severe meaning, relation,

| Model | Params | en | th | id | ms | zh-TW | Avg. |
|---|---|---|---|---|---|---|---|
| Hy-MT2 | 7B | 81.7 | 86.7 | 91.3 | 91.9 | **98.3** | 90.0 |
| Qwen3.5 | 9B | 82.0 | 71.9 | 72.6 | 66.0 | 92.8 | 77.0 |
| Gemma 4 | 12B | 87.8 | 90.5 | 94.3 | 94.9 | 97.7 | 93.0 |
| Fusion | 19B | **88.1** | **91.6** | **95.5** | **95.7** | 98.2 | **93.8** |

Table 2: Quality of the single-model baselines and submitted fusion. Values are pooled A+B percentages over three videos (705 cues per language); Avg. is the language macro average.

logic, or language error). A+B is the acceptable-translation rate. Manual grading was conducted by five annotators, one for each target language. All were native Chinese speakers and second-year undergraduates majoring in their assigned target language. Each annotator scored all samples for that language across the three videos while viewing the complete Chinese subtitle sequence and the translations under evaluation. Translations from the different models and methods were anonymized and presented in shuffled order, so annotators were blind to system identity. Several worked examples served as annotation guidance, but no separate calibration round was conducted. Because each language had only one annotator and no items were double-annotated, inter-annotator agreement could not be computed. All three baselines were graded cue by cue on the same sources and outputs. An existing grade was reused when an output string exactly matched a previously graded candidate; changed outputs were judged with the same rubric, and high-risk cross-cue, name, title, and translation-direction errors were manually re-adjudicated. Indonesian and Malay grading also penalizes lexical mixing; Traditional Chinese grading includes Taiwan-oriented character conversion. These scores are diagnostic rather than official task metrics.

### 6.3 Translation Quality

Table 2 compares the three baselines and fusion. Fusion improves over Gemma by 0.3 points in English, 1.1 in Thai, 1.2 in Indonesian, 0.8 in Malay, and 0.5 in Traditional Chinese. Its pooled macro average is 93.8%, 0.8 points higher than Gemma's 93.0%. The direction is consistent across videos: Fusion versus Gemma macro averages are 91.3 versus 90.0 on `a0046j15d6d`, 95.5 versus 95.2 on `j0048kesypr`, and 93.8 versus 92.9 on `z41019npvl9`. Hy-MT2 still leads pooled Traditional Chinese by 0.1 points and remains useful because it occasionally avoids Gemma errors in names, omitted subjects, cue segmentation, and source-preserving conversion. Qwen only edges Hy-MT2 in English; its other results are weaker.

**Selector behavior.** Across all 209,185 cues in the official submission, forward and reverse judgments agreed for 54,030 cues (25.83%); 115,364 (55.15%) triggered the fixed Gemma fallback, and all four candidate strings were identical for 39,791 (19.02%). Among agreement cases, the selector chose a Gemma-origin candidate 45,684 times (84.55%). Excluding 1,787 agreement cases in which the selected string was produced by both model families leaves 44,401 Gemma selections among 52,243 attributable cases (84.99%), with language-specific shares from 77.73% for Traditional Chinese to 89.55% for Thai. This skew does not establish self-preference: model identities were hidden. However, model-specific lexical or stylistic cues may reveal candidate provenance, so the selector-bias concern remains.

### 6.4 Context Ablation

| Context | Lang. | A+B | D | ΔA+B |
|---|---|---|---|---|
| None | en | 71.3 | 17 | – |

Table 3: Five-language Hy-MT2 context ablation on the same 122 cues.

Table 3 shows that full-video context improves Hy-MT2 in all five languages and reduces severe errors in every target. The largest gains are 18.0 points for Malay and 13.9 for Indonesian, followed by 9.0 for Thai; English and Traditional Chinese each improve by 4.1 points. Across the five targets, D-grade errors fall from 65 to 35. The largest gains involve cross-cue syntax and omitted subjects. Context also introduces risks: a model can leak text from the next cue, drift on names or historical titles, or create overlong subtitles. A rhetorical-question error shared by all candidates also showed the limitation of selection without rewriting.

## 7 Conclusion

We submitted a constrained, inference-only system combining Hy-MT2-7B and Gemma-4-12B-it under the 20B limit. Full-video context improves isolated cue translation, heterogeneous generation exposes complementary outputs, and agreement-gated selection preserves auditability because it cannot invent a new translation. Official preliminary evaluation ranks ReopenAI first overall and in every target direction, with an 89.357 macro average over 100 videos. The internal baseline comparison supports Gemma as the final selector and fallback, while the three-video fusion diagnostic shows a 0.8-point pooled macro improvement (93.8% versus 93.0%) over Gemma alone and a higher macro average on every evaluated video. The 122-cue, five-language context ablation shows gains in every target while identifying remaining subtitle-specific risks.

## 8 Limitations

The system uses textual context only and cannot resolve ambiguities requiring visual evidence, voice identity, prosody, or sound effects. Complete context can leak neighboring content, while cue-level selection can mix terminology across a video. The Gemma selector may favor Gemma-like candidates; anonymous labels and reverse ordering reduce identity and position cues but do not guarantee unbiased estimation. The official preliminary scores use human-verified LLM-based LQA rather than exhaustive independent human ratings. Our semantic manual analysis covers all five targets on three videos totaling 705 cues, still a small subset of the 100-video test set. Each target language was evaluated by one annotator without overlapping annotations, so the scores may reflect individual judgment and no inter-annotator reliability statistic is available. Reusing grades for exact string matches also means that not every system output received an independent rating. The manual grades should therefore not be read as official corpus-level scores.

# A Translator–Critic System for Chinese-to-English Subtitle Translation

**Aaryan Yekkisetty**
Peloton Interactive
y.aaryan21@gmail.com
aaryan.y@onepeloton.com

## Abstract

We introduce a text-only system that translates Chinese video subtitles into English using two open-weight models under a 20B-parameter budget. It is our submission to the constrained track of the WMT 2026 video subtitle translation shared task (WMT26 Organizers, 2026), whose rules set that budget. A 7B translation-specialized model generates English candidates, while a quantized 12B instruction-tuned model selects candidates and checks the selected translation for a small set of subtitle-specific accuracy errors. Confirmed errors are converted into focused correction instructions and returned to the translation model for guided retranslation. The system also preserves SubRip subtitle (SRT) indices and timestamps and applies deterministic name-consistency and line-layout processing.

We evaluate the main components through two internal studies scored by an independent large language model (LLM) judge. A synthetic-error experiment shows that the instruction-tuned model is better suited to the critic role than the translation model in our configuration, especially because it produces fewer false alarms on clean translations. An end-to-end ablation shows that contextual prompting provides the largest improvement over a context-free translator baseline; under a paired sign test it is the only component gain we can establish. The system placed third of eight in the official preliminary English evaluation at 74.705, 0.55 points behind second place. Those results are system-level and do not isolate individual components, but they localize the remaining gap to critical accuracy errors, the largest identified category of which is pronoun and referent confusion, which is what the critic was built to detect. This is consistent with the critic's limited context window and single-model candidate pool. Reference translations were never released to participants, so no reference-based metric is computable on this test set.

## 1 Introduction

Video subtitle translation differs from conventional sentence-level machine translation (MT) in several important ways. Subtitle cues are short, often omit punctuation, and frequently contain only part of an utterance. A cue may therefore be difficult to translate correctly without information from neighboring cues, the series synopsis, or previously established character names.

These problems are especially visible in Chinese-to-English translation. Chinese is a pro-drop language in which subject and object pronouns are frequently omitted, particularly in conversational genres, while English translations often require them to be recovered explicitly (Wang et al., 2023); cross-sentence context is therefore necessary rather than merely useful (Voita et al., 2019). Pronoun gender may need to be inferred from context, terms of address may encode social rank (娘娘, roughly "Your Highness"; 皇上, "Your Majesty") and rank-indexed self-reference (本官, used by a ranking consort; 朕, the imperial "we"), and short expressions can have different interpretations depending on the speaker and scene. Character names must also remain consistent across an episode.

The provided test set makes this contextual dependence clear. It contains 41,837 cues across 100 SubRip subtitle (SRT) files. The median cue contains six Chinese characters, and 42.5% of cues contain five characters or fewer. None of the cues ends in terminal punctuation. As a result, punctuation-based sentence reconstruction is not available, and many cues must be interpreted as fragments of a longer exchange.

Providing context to a large language model is straightforward: neighboring cues and metadata can be included in the prompt. However, this introduces a second problem. The model may translate content from neighboring cues or merge sur-

*Proceedings of the Eleventh Conference on Machine Translation*, pages 2637–2651
October 28-29, 2026 ©2026 Association for Computational Linguistics

rounding information into the target line. We refer to this behavior as *context leakage*. The system must therefore use context for interpretation while ensuring that only the target cue is translated.

Our system addresses this problem with a translator–critic pipeline. A translation-specialized model produces candidate translations using the source cue, neighboring cues, and series metadata. A separate instruction-tuned model selects among the candidates and audits the result using eight focused accuracy checks. When an error is confirmed, the translation model receives a short instruction naming the problem and produces new candidates.

The system is implemented with three main design choices, which together form our contribution:

1. **Context is presented as read-only background information.** Only the current cue appears in the translation field.
2. **Translation and criticism use different model families.** The translation-specialized model generates source-based translations, while the instruction-tuned model performs selection and post-editing.
3. **Auditing is decomposed by error type.** Each critic call checks one narrowly defined defect, followed by a second verification step before repair.

In this paper we focus on the submitted pipeline, its implementation under the constraints described above, controlled internal comparisons of its main components, and the official preliminary task results (§7).[1]

## 2 Related Work

**Document-level and context-aware MT.** The observation that sentence isolation is the wrong unit for translation predates LLM pipelines. Tiedemann and Scherrer (2017) extend the translation window across sentence boundaries, and Voita et al. (2019) show that a translation can be correct in isolation and wrong in context, precisely the failure mode that dominates short subtitle cues. Pronoun recovery under Chinese pro-drop has been treated as its own problem (Hardmeier, 2015; Wang et al., 2023). Our context construction (§4.3) is a deliberately minimal instance of this line of work: a fixed symmetric window of neighboring source cues plus album-level metadata, with no learned context selection.

Recent work replaces a fixed window with an agent that accumulates document state. Wang et al. (2025) maintain multi-level memory across a document for online document-level translation, and Ren et al. (2026) internalize document context into model parameters dynamically rather than re-reading it in the prompt. Both maintain learned or parametric document state where we keep a fixed window plus a name memory, and subtitle cues give them less to work with than prose: no cue in the corpus ends in terminal punctuation, so there is no reliable sentence or paragraph segmentation (§3). A document-state agent operating over a whole episode is the most promising direction we did not take.

**Multi-agent and MQM-guided refinement.** Assigning generation and criticism to different agents is an established pattern. Madaan et al. (2023) keep both roles in one model; Wu et al. (2025) distribute translation, evaluation, and revision across a collaborating group for ultra-long literary text. Error-typed feedback in particular has been shown to be more useful than a scalar score: Fernandes et al. (2023) elicit MQM-style error spans from an LLM rather than a single quality number, following the human MQM protocol of Freitag et al. (2021). Our critic is a restricted version of this idea. It does not produce a free-form MQM annotation; it answers eight fixed yes/no questions (§4.5), each in its own call, and a confirmed error is converted into a correction hint rather than an edit. The distinguishing choice is not the use of typed feedback but where repair happens: the translator generates new source-conditioned candidates and the critic selects among them, making limited English-side edits at most (§4.6), which resembles source-aware automatic post-editing (Chatterjee et al., 2020) rather than free rewriting.

**Quality-aware decoding.** Our candidate-and-selection stage (§4.4) occupies the same position in the pipeline as minimum Bayes risk decoding with neural metrics (Freitag et al., 2022) and quality-aware decoding with learned rerankers (Fernandes et al., 2022), which select from a candidate pool using a trained quality model. Our selector is an instruction-tuned LLM given the source, the can-

didates and context, so it is a prompted reranker rather than a learned one. We did not compare against these methods.

## 3 Task and Data

The released test set contains 100 SRT files from 45 series. Each file includes subtitle cues and album-level metadata, including a title and synopsis. We use the Chinese subtitle text, series title, synopsis, and neighboring subtitle cues. We do not use video frames or audio. Table 1 summarizes the corpus.

The corpus covers several genres. Of the 100 episodes, 43 are xianxia or cultivation fantasy, 24 are palace or costume dramas, 16 are reality, variety, or talk programs, nine are modern urban dramas, and eight belong to other categories. Genre labels were assigned by hand over all 45 series from the released `album_title` and `album_desc` fields.

Genre affects the translation problem. Period and fantasy dramas contain rank-sensitive forms of address and specialized terminology, while modern and variety programs rely more heavily on conversational phrasing and real personal names. We therefore avoid assuming that one terminology mechanism will benefit every file equally.

**Development procedure.** No task-specific reference translations were available. During development, we inspected six files and used qualitative model reports to identify recurring errors and refine the pipeline. These files were not used for the quantitative studies reported below.

The critic experiment samples examples from 84 non-development files. The end-to-end ablation uses 14 non-development files selected to cover the main genre groups. We report the two studies separately because they answer different questions: the first evaluates critic behavior on controlled errors, while the second evaluates complete translation outputs.

## 4 System Description

This section describes the submitted system. We first state the two model checkpoints and the parameter budget they have to fit into (§4.1), then follow a single cue through the pipeline in the order the stages run (§4.2–§4.7), and close with how the models are served (§4.8).

### 4.1 Models and parameter budget

The system uses two open-weight checkpoints: Hy-MT2-7B (Zheng et al., 2026; Tencent Hunyuan, 2026), a translation-specialized model; and Gemma-4-12B-it (Google, 2026), an instruction-tuned general-purpose model, used in its 4-bit integer quantization-aware training (INT4 QAT) release.

Both models are used at their released revisions without fine-tuning, adapters, tokenizer modifications, or chat-template changes. Following the checkpoints' tied-embedding configuration, the total parameter count is approximately 19.47B: 7.505B for Hy-MT2 and 11.960B for Gemma. This remains under the constrained track's 20B limit.

Hy-MT2 generates all initial and hint-guided translations. Gemma selects and post-edits translation candidates, performs rule-specific audits, and consolidates repairs. Gemma is not used as a standalone source-to-target translation system.

We use the quantized Gemma release because it runs within the 24 GB of memory available on our graphics processing unit (GPU) instances. Each model is served on a separate endpoint with one GPU.

### 4.2 Pipeline overview

Each SRT file passes through seven stages:

1. parse the SRT and construct contextual information;
2. generate up to three translation candidates;
3. select the best candidate;
4. audit the selected translation;
5. verify detected errors;
6. generate and select repairs when needed;
7. apply deterministic consistency and layout processing.

Cues can be translated concurrently because source-side neighboring cues are available before inference. Whole-file consistency processing is applied after cue-level translation. All prompts are reproduced in Appendix A.

### 4.3 Context construction

For cue $i$, the system uses up to two preceding and two following Chinese cues, together with the series title and synopsis. Neighboring cues are provided as background information and are explicitly marked as context that should not be translated.

Only the current source cue is placed in the translation field. This separation is intended to let the model resolve omitted subjects, pronouns, sentence mood, and short ambiguous expressions without encouraging it to translate surrounding lines.

### 4.4 Candidate generation

Hy-MT2 generates up to three candidates for each cue. The first draw uses temperature 0.7. The second and third draws use higher temperatures, 0.95 and 1.0, with top-$p$=0.95 and top-$k$=40.

The higher temperatures are used because short subtitle cues often produce identical outputs under repeated low-temperature sampling. Candidates are deduplicated exactly. In the production run, 43.97% of cues still produced only one distinct candidate.

If multiple distinct candidates are available, Gemma receives the current Chinese cue, neighboring Chinese context, series metadata, the candidate translations, and available character-name information. It returns a selected or minimally edited English line. The selection prompt emphasizes adequacy, name consistency, pronoun gender, register, brevity, and avoidance of context leakage. If only one distinct candidate is available, the selection stage is skipped.

### 4.5 Rule-specific audit

After selection, Gemma checks the translation for eight error types, listed in Table 2. Each error type is evaluated in a separate call. The categories are a subtitle-specific decomposition of primarily accuracy-related errors, inspired by Multidimensional Quality Metrics (MQM) (Freitag et al., 2021) rather than taken from it: several of the rules are our own task-specific categories with no one-to-one MQM equivalent. Each maps one-to-one onto a repair hint, so that the rule that fires is also what the translator is told when the line goes back for retranslation.

| Rule | Purpose |
|---|---|
| `meaning_preserved` | Detects hallucination, omission, polarity errors, and major semantic distortion. |
| `pronoun_gender_resolved` | Checks whether an English pronoun or subject matches the contextual referent. |
| `no_context_leak` | Detects content copied or inferred from neighboring cues but absent from the target cue. |
| `honorific_register_consistent` | Checks titles, ranked address, and socially marked self-reference. |
| `sentence_mood_match` | Checks question, statement, and command distinctions. |
| `direction_agent_correct` | Detects direction, agent, patient, give/take, or come/go reversals. |
| `person_attribution_correct` | Checks first-, second-, and third-person attribution and terms of address. |
| `no_invented_name` | Detects proper names introduced where the source contains only a title, role, or pronoun. |

Table 2: Error categories used by the critic. The exact question asked for each is reproduced verbatim in Table 7, and the repair hint each produces in §A.6.

The audit focuses on adequacy-related errors rather than general fluency. Hy-MT2 normally produces fluent English, while broad style instructions can encourage unnecessary rewriting.

Each audit call returns a Boolean decision and a short explanation. A positive result is not immediately used for repair. Instead, a second Gemma call independently rechecks the same rule. This verification prompt defaults to "no defect" and confirms a problem only when it can identify concrete offending text.

This second stage is intended to reduce unnecessary repairs. A missed error leaves the translator's original output unchanged, while a false positive may trigger a change to a line that was already acceptable.

### 4.6 Hint-guided repair

When one or more errors are confirmed, each rule is mapped to a short correction instruction. For example, a context-leak error produces an instruction to translate only the current cue; a pronoun error asks the translator to use the referent supported by context; and a mood error asks it to preserve whether the cue is a question, statement, or command.

These instructions are added to the Hy-MT2 translation prompt. The translator then generates two new candidates. Gemma considers the orig-

inal and new candidates and returns one consolidated line intended to address all confirmed defects.

The repaired line is checked once more against the confirmed rules. Remaining issues are recorded rather than repeatedly applying unconstrained repair.

### 4.7 Deterministic output processing

After cue-level translation, code performs three final operations: a whole-file character-name consistency pass; an English ordinal-title normalization, such as changing "Prince Ninth" to "Ninth Prince"; and line wrapping with a soft limit of 42 characters per line and a hard limit of 84 characters per cue.

The system then reconstructs each SRT file while preserving the original cue indices and timestamps. All 41,837 cues were processed without missing subtitle entries, and the output files retained the original indices and timing fields.

### 4.8 Serving and inference volume

Both models are served through vLLM (Kwon et al., 2023) on Amazon SageMaker, with one 24 GB GPU per endpoint.

Over the production run Hy-MT2 was called approximately 130,000 times and Gemma approximately 366,000 times, the latter dominated by the eight audit calls per cue. Appendix B gives the instance types and the exact call breakdown.

The high-volume audit calls use deterministic decoding with native reasoning disabled. Reasoning is enabled only for the lower-volume verification and repair stages.

## 5 Critic Configuration

Two choices in the system above need evidence: that the critic should be a different model from the translator, and that the audit should be decomposed into one call per rule and then gated by a skeptical verification pass. This section measures both on a controlled set of Chinese-to-English cases with known labels, holding the task text fixed within each configuration so that model identity is the only variable in the 7B-versus-12B comparisons.

### 5.1 Controlled evaluation set

The evaluation set contains 600 Chinese-to-English cases: 400 translations with injected errors, 50 for each audit rule; and 200 unmodified controls.

| Configuration | Recall | Clean flag rate |
|---|---|---|
| 7B, one combined call | 49.5% | 58.5% |
| 7B, one call per rule | 81.8% | 77.5% |
| 7B, per rule + verification | 13.5% | 2.5% |
| 12B, one combined call | 88.5% | 12.0% |
| 12B, combined + verification | 84.0% | 2.5% |
| 12B, one call per rule | 98.0% | 12.5% |
| **12B, per rule + verif.*** | 91.5% | 3.5% |

Table 3: Detection recall and clean-control flag rate on the controlled critic set. Each row is one critic configuration run over the same 600 labeled cases; within a configuration both models receive identical task text, while prompt structure differs across configurations as described in §5. Recall is rule-level over the 400 injected errors: the correct rule had to fire. For the flag rate, lower is better. *is the submitted configuration.

Injected errors are created through deterministic English-side transformations. Examples include flipping pronoun gender, inserting or removing negation, reversing an agent and patient, changing sentence mood, flattening an honorific, or inserting content from a neighboring cue.

Eligibility filters are applied before each transformation. For example, a pronoun is modified only when the Chinese source provides evidence about the referent, and an agent–patient reversal is used only when the source supports the original roles. Transformations that would make the English ungrammatical are excluded.

The resulting set tests detection of controlled errors from the system's target taxonomy. It does not represent the full distribution of naturally occurring translation errors.

### 5.2 Configurations

We compare one call containing the complete rubric against one call per rule, with and without skeptical verification. Seven of the eight resulting configurations were run; the 7B combined rubric with verification was not. Both models receive the same task text at temperature zero. We report *recall* over the 400 injected errors, requiring the intended rule to fire, and the *clean-control flag rate* over the 200 unmodified examples. Results are given in Table 3.

### 5.3 Results

In this setup, the instruction-tuned 12B is better suited to criticism than the translation-specialized 7B. Without verification, the per-rule 12B configuration detects 98.0% of injected errors and flags 12.5% of clean controls. The corresponding 7B

setup detects 81.8% of injected errors but flags 77.5% of clean controls.

The main difference is therefore not only error detection. The 12B is substantially more selective on clean inputs. This matters because most production translations are not repaired, and unnecessary intervention can degrade an acceptable subtitle.

For the 12B, decomposing the rubric into separate calls increases observed recall from 88.5% to 98.0%, while the clean-control flag rate remains similar (12.0%→12.5%). Adding skeptical verification reduces recall to 91.5% but lowers the clean-control flag rate from 12.5% to 3.5%. We use this configuration in the submitted system. Note that verification is not a universal precision fix: applied to the 7B it collapses recall from 81.8% to 13.5%, because under a skeptical prompt the specialist clears most of its own initial flags.

The lowest-recall rule in the final setup is `honorific_register_consistent`, at 70%. Honorifics are difficult because their correct rendering depends on genre, speaker status, and local discourse context.

These results should be interpreted as controlled detection measurements. The errors are synthetic, and the clean controls are sampled from system output rather than independently human-verified references.

## 6 End-to-End Evaluation

The second experiment asks whether the complete pipeline translates better than the translation model alone. We build four cumulative configurations over the same held-out cues, score them with an independent judge model, and then look separately at the small subset of cues the critic actually edits.

### 6.1 Systems

We compare four cumulative configurations:

- **S1** **Translator only.** One Hy-MT2 draw without neighboring or synopsis context.
- **S2** + **Context.** One Hy-MT2 draw with neighboring cues and series metadata.
- **S3** + **Candidate generation and selection.** Three Hy-MT2 draws followed by Gemma selection.
- **S4** **Full system.** S3 followed by audit, verification, guided repair, name consistency, and layout processing.

S2 and the first draw of S3 use the same translation prompt, allowing S2→S3 to measure the combined effect of additional candidates and external selection.

The four outputs were generated for 4,563 cues from 14 non-development files. A common subset of 612 cues was scored across all four arms. The critic-edited subset was also examined separately because the critic changes only a small fraction of all cues.

### 6.2 Judge

Neither pipeline model is used as the external evaluator: Hy-MT2 generates the candidates and Gemma performs selection and repair, so scoring with either would be a same-model evaluation, in which a model tends to prefer its own output (Wataoka et al., 2024). We therefore use a separate, larger model, `gpt-5.6-luna`, with high reasoning effort; because the judge plays no part in generating the submission, it is not bound by the shared task's parameter budget. Using a strong language model as an MT evaluator is established practice (Kocmi and Federmann, 2023), including for fine-grained MQM-style error annotation (Fernandes et al., 2023).

Each evaluation item contains the Chinese target cue, neighboring Chinese cues, and two anonymized English renderings. System identities are not shown. Candidate order is reversed in a second evaluation so that each pair is judged in both presentation orders. Identical translations are collapsed to avoid presenting duplicated outputs as independent agreement.

The judge assigns three 0–100 scores (adequacy, readability, and overall quality) and up to two MQM-style errors per candidate (Zheng et al., 2023). Following Freitag et al. (2021), minor and major errors receive weights of 1 and 5; we additionally define a task-specific critical weight of 10 for meaning inversions.

This is a single-model evaluation. We use blinding and order counterbalancing to reduce obvious presentation bias, but the resulting values remain model-based estimates rather than human judgments.

### 6.3 Main results

The largest observed improvement comes from adding series metadata and neighboring source cues (Table 4). The overall score increases by 2.32 points from S1 to S2, while the MQM penalty falls

| System | | Overall | Adeq. | Read. | MQM↓ |
|---|---|---|---|---|---|
| S1 | translator only | 87.18 | 87.47 | 92.93 | 1.63 |
| S2 | + context | 89.50 | 90.11 | 93.52 | 1.27 |
| S3 | + cand. & select | 90.44 | 90.51 | 94.78 | 1.14 |
| **S4** | **full system** | **90.57** | **90.65** | **94.80** | **1.10** |

Table 4: Mean scores from the independent LLM judge over the common evaluated sample of 612 cues. The MQM error penalty column runs the other way: lower is better. Paired transitions are reported separately in Table 5.

| Transition | Δ | 95% CI | W/T/L | $p$ |
|---|---|---|---|---|
| S1→S2 | +2.32 | [+0.94, +3.68] | 189/304/119 | <0.001 |
| S2→S3 | +0.93 | [+0.06, +1.87] | 128/349/135 | 0.71 |
| S3→S4 | +0.13 | [−0.20, +0.41] | 8/600/4 | 0.39 |
| S1→S4 | +3.39 | [+2.04, +4.80] | 223/227/162 | 0.002 |

Table 5: Paired analysis of each transition, measured cue by cue between the indicated system pairs over the 612 cues judged in every arm. Δ is the mean change in overall score. Confidence intervals are percentile bootstrap intervals resampled over cues (4,000 resamples); the cue is the sampling unit, so repeated judgments of one cue are averaged before resampling rather than treated as independent. W/T/L counts cues that improve, tie, and worsen, and $p$ is an exact two-sided sign test on those counts with ties excluded. The sign test ignores effect size and therefore asks a separate question (whether *more* cues improve than worsen), and the two questions disagree for S2→S3.

from 1.63 to 1.27. This supports the use of contextual prompting for short, punctuation-free subtitle fragments.

Candidate generation and selection add a further 0.93 points, and the complete system improves by 3.39 points over the context-free one-pass baseline and by 1.07 points over the context-aware one-pass baseline. As §6.4 shows, only the first and last of these differences survive a paired test.

After reweighting the genre distribution to match all 100 files, the overall scores are 87.82, 89.78, 90.62, and 90.70 for S1 through S4. The corresponding full-system improvements are therefore 2.88 points over S1 and 0.92 points over S2.

These differences are point estimates from one evaluator and should not be interpreted as calibrated human-quality units.

### 6.4 Statistical reliability

Table 5 reports paired bootstrap intervals and sign tests for each transition. The four transitions do not stand on equal evidence, and the ordering in Table 4 should not be read as four established gains.

S1→S2 (context) is the one robust component result: the interval excludes zero and 189 cues improve against 119 that worsen ($p < 0.001$). S1→S4 (the full system) is likewise robust ($p = 0.002$), and the evidence attributes most of it to context. S2→S3 (candidates and selection) is not established: the interval barely excludes zero, but 128 cues improve while 135 worsen ($p = 0.71$), so the positive mean comes from effect size on a minority of cues rather than from broad improvement. That transition is therefore suggestive rather than demonstrated. S3→S4 (the critic) is indistinguishable from noise in aggregate ($p = 0.39$), which is the expected consequence of a mechanism that touches about 2% of cues rather than evidence that it does nothing; §6.5 analyzes the treated cues directly.

These intervals quantify sampling variation over cues for one evaluator, not evaluator bias, and are computed on 612 cues from 14 files.

### 6.5 Effect of the critic

The aggregate S3→S4 difference is small because the critic is deliberately conservative. It changes approximately 2% of cues.

On the 94 cues where the critic changes the translation, 70 receive a higher score, two are tied, and 22 receive a lower score. Thus, 74.5% of all changed cues improve according to the external judge, or 76.1% when ties are excluded. The mean overall change on this subset is +14.8 points.

The gain is concentrated in adequacy (+17.2) rather than readability (+0.1). This is consistent with the critic's design. Its rules focus on meaning, attribution, pronouns, context leakage, and sentence mood rather than stylistic rewriting.

Two examples illustrate the type of correction. 还喃喃自语 ("still muttering to oneself") was initially translated as "muttering to *herself*" and changed to "muttering to *himself*," based on a male referent in the preceding context. 和你妹的事 ("the matter concerning your sister") was initially rendered as "Nothing to do with your sister" and changed to "something about your sister," correcting a polarity error.

The critic is therefore best viewed as a targeted correction mechanism rather than the main source of the system's average improvement. Most of the aggregate gain comes from contextual translation and candidate selection.

## 7 Official Preliminary Results

Official preliminary results became available after the internal evaluations (WMT26 Video Subtitle Translation Organizers, 2026), and they supply the independent evaluator our internal study lacked: a different model family, a different rubric, and all 100 files rather than 14. They assess the submitted system as a whole and do not isolate the contribution of any individual component, but they localize where its remaining headroom is.

### 7.1 Protocol and standing

The official evaluation scores each (team, language, video) unit with `gemini-3.1-pro-preview` under a language-specific translation-quality prompt, three independent runs per video with the median taken, followed by a human verification stage covering 93.4% of units across all five language pairs and 82.4% of the English units. Dimension scores are recomputed in code from itemized defect penalties on a 100-point deduction scale: Accuracy/Fidelity 40, Fluency/Readability 35, Cultural/Stylistic 20, and Subtitle Text Conventions 5.

Our system scored **74.705 in English, placing third** of eight teams in the only direction we entered (Table 6). The second-, third-, and fourth-ranked systems are separated by adjacent gaps of 0.55 points, spanning 1.10 points overall. The gap to ReopenAI is of a different order: −15.49 points, with ReopenAI scoring higher on 92 of the 100 videos.

| Team (English) | Score | Mean points lost per video | | | |
|---|---|---|---|---|---|
| | | Acc. /40 | Flu. /35 | Cult. /20 | Conv. /5 |
| ReopenAI | 90.195 | 3.80 | 3.74 | 1.57 | 0.64 |
| LensLinguals | 75.255 | 15.43 | 4.80 | 3.54 | 0.55 |
| **AuditTranslate** | **74.705** | 16.75 | 5.07 | 3.14 | 0.45 |
| laniqo | 74.155 | 17.22 | 4.80 | 3.52 | 0.32 |
| rupiah | 70.895 | 18.89 | 5.74 | 4.41 | 0.65 |
| BVSLP | 60.480 | n/a | n/a | n/a | n/a |
| paramanandaAI | 55.645 | n/a | n/a | n/a | n/a |
| SubVision | 49.775 | n/a | n/a | n/a | n/a |

Table 6: Official preliminary English-track scores (WMT26 Video Subtitle Translation Organizers, 2026), with rubric-dimension attribution for the five leading systems. Lower is better in the four right-hand columns. Dimension means are computed from the itemized defect penalties, clipped at each rubric maximum, over the units with a parseable itemized assessment (98–100 per team), while the headline score averages all 100; the two are therefore close but not additive, so the dimension columns attribute where points are lost rather than exactly decomposing the score gap.

### 7.2 The gap is one dimension, at one severity, on one phenomenon

Attributing the difference to ReopenAI by dimension gives +12.95 Accuracy/Fidelity, +1.57 Cultural/Stylistic, +1.33 Fluency/Readability and −0.19 Conventions, summing to 15.66 against a 15.49-point score gap. Roughly five sixths of it is Accuracy/Fidelity. Conventions is a five-point band in which every leading system is near ceiling, so the deterministic layout and name processing of §4.7 had little room to matter either way.

Severity localizes the gap further. Counting Accuracy defects by penalty weight, our minor-error count is comparable to the winner's (153 defects at penalty 1 versus their 161), while critical severity-5 defects differ by more than an order of magnitude: 233 versus 19, or 2.33 versus 0.19 per video. The system is not broadly less accurate. It fails badly on a small number of cues, which is also consistent with the score distribution: our median (75.75) is essentially LensLinguals' (76.0), but our 10th percentile is 55.5 against their 64.0, and 14 of our videos score below 60 against their 6. What separates us from second place is the lower tail, not the typical video.

Within those 233 severity-5 Accuracy defects, the largest single category is pronoun, referent and person confusion: 52 defects, 22.3% of the total, costing 2.60 penalty points per video. This is a heuristic count, obtained by keyword rules over the judge's free-text descriptions and subject to errors in both directions; we did not hand-validate the 52 cases, and a 36.5% residual resists the classification altogether.

Cross-cue reference resolution is therefore where our remaining headroom is concentrated, and it is also what the critic's decomposed checks were written for: `pronoun_gender_resolved`, `direction_agent_correct` and `person_attribution_correct` are three of the eight rules in Table 2. That these errors reach the final output is consistent with the audit's evidence being too local: the critic sees the same ±2 cue window as the translator, so a referent established twenty cues earlier lies outside it, whereas ReopenAI supplied the complete subtitle sequence to both generation and selection. The candidate pool may limit it the same way, since all three candidates were drawn from Hy-MT2 alone and a

selector cannot choose a rendering no candidate contains. We cannot separate these explanations from weak audit instructions, over-skeptical verification or repair failure, and the comparison with ReopenAI varies several factors at once; an episode-level window and a two-model candidate pool are the changes we would test first.

One further defect we would not have found without the official records: on cues of three Chinese characters or fewer, output is occasionally displaced by one cue, carrying the following line's content. Measured directly in our submitted files, this affects 83 cues across 46 videos. The judge names the failure independently on a partly overlapping set, charging 33 defects across 27 videos as a translation shift, worth 1.25 penalty points per video. A source-to-target length-ratio check could flag some such cases for review, though it would not reliably catch all of them.

## 8 Discussion

The two experiments above measure what the pipeline buys. This section explains why its main mechanisms are built the way they are, covering read-only context, criticism separated from translation, and repair routed back through the translator, and what that design costs at inference time.

**Why context is useful.** A large fraction of the corpus consists of very short fragments. In such cases, the current cue may not explicitly identify the speaker, the referent of an omitted subject, pronoun gender, whether the line continues a question or command, or the intended interpretation of an honorific or title.

The context-aware configuration improves adequacy more than readability, suggesting that neighboring information mainly helps determine what the cue means rather than how fluent the English sounds.

However, contextual prompting requires strict source boundaries. Neighboring cues are therefore placed in background fields, while only the current cue is placed in the translation field (§4.3). The explicit `no_context_leak` rule provides an additional check.

**Why criticism is separated from translation.** Self-refinement (Madaan et al., 2023) asks one model to critique and revise its own output, and is the closest single-model analogue of what our selection, audit and repair stages do. We separate the roles instead. Hy-MT2 is specialized for translation, while Gemma is better at following structured classification and verification instructions in our controlled experiment. The two-model arrangement uses these capabilities differently: Hy-MT2 generates source-grounded translation candidates; Gemma compares candidates and detects specific defects; and confirmed problems are returned to Hy-MT2 as focused guidance.

This arrangement also avoids asking the translation model to be the only evaluator of its own output (Wataoka et al., 2024). It does not eliminate evaluator bias, but it provides an independent model family for selection and auditing.

**Why repair is routed back through the translator.** Early development tests showed that allowing an editor to freely rewrite a line could introduce unsupported content. We therefore use the critic primarily to identify and describe errors. New source-based candidates are then generated by the translation model with a correction hint, so the mechanism functionally resembles source-aware automatic post-editing (Chatterjee et al., 2020) rather than free rewriting.

The final selection stage can still make limited English-side edits, so the separation is functional rather than mechanically guaranteed. A stricter future version could require the selector to return an exact candidate index.

**Cost and intervention rate.** The audit is computationally expensive because it applies eight checks to every cue, while only a small fraction of cues are repaired. This design prioritizes focused detection and a low false-alarm rate over inference efficiency.

The controlled experiment indicates that a single combined audit call with verification is a cheaper alternative, although it has lower synthetic-error recall than the per-rule configuration. A useful future direction is to compare these configurations directly on final translation quality and GPU cost.

In light of §7 we would now allocate this cost differently. The eight-per-cue audit stage was the largest single consumer of inference in the pipeline, and each call reasoned over a $\pm 2$ cue window too narrow to see the cross-cue referents that dominate our remaining accuracy gap. Spending part of the same budget on full-episode context would let the rules in Table 2 operate on the evidence they need: size the evidence available to each stage before scaling the number of checks it performs. The lim-

itations of the system and of the evidence above are collected in the Limitations section.

## 9 Conclusion

We presented a text-only Chinese-to-English subtitle translation system built from two open-weight models under a 20B parameter limit. A translation-specialized 7B model generates candidates, while a quantized instruction-tuned 12B model performs selection, targeted auditing, and limited post-editing. Confirmed errors are routed back to the translation model through focused retranslation hints.

The internal ablation identifies contextual prompting as the largest source of improvement. Adding series metadata and neighboring cues improves the external judge's overall score by 2.32 points over a context-free translator, and this is the one component gain that a paired sign test establishes. Candidate generation and selection add a further 0.93 points on average, but roughly as many cues worsen as improve, so we describe that transition as suggestive rather than demonstrated. The complete system scores 3.39 points above the context-free baseline on the common evaluated sample.

The official preliminary evaluation placed the system third of eight in English at 74.705, 0.55 points behind second place and 15.49 behind the winner. It assesses the system as a whole rather than isolating components, but it localizes the remaining gap: most of it is Accuracy/Fidelity, most of that is critical severity, and the largest category we identify within it is pronoun and referent confusion, which is what three of the eight audit rules were written to catch.

The system's main practical lesson is therefore about what a critic needs rather than whether to have one. Separating generation from criticism supported targeted repairs, but it required substantial inference (roughly 366,000 critic calls, dominated by eight audit calls per cue), and it did not eliminate harmful edits: 22 of the 94 cues the critic changed scored lower. A critic can confirm only errors it has the evidence to see, and can choose only among renderings some candidate contains. Ours was given a $\pm 2$ cue window and a candidate pool from one model; full-episode context and candidates from both models are the changes we would test first.

## Limitations

**LLM-based quality evaluation.** Our component ablations (§6) use a single independent LLM judge on 612 cues from 14 files, with no bilingual human annotation. Blinding and presentation-order reversal reduce some sources of bias but do not replace human evaluation, and a 14-file sample cannot resolve per-component differences of the size we report. The official evaluation (§7) covers all 100 files, but it is also LLM-based and reference-free, includes no significance testing, and its human stage verified automatic assessments rather than annotating independently. It is also system-level, so it cannot arbitrate between components. All per-component attributions in this paper therefore rest on a single judge and are provisional.

**Synthetic critic errors.** The critic study uses controlled English-side perturbations. These provide known target error categories, but they are more regular than naturally occurring translation errors. The clean controls are also sampled from system output rather than human-verified references.

**Text-only input.** The system does not use video or audio. Visual and acoustic information could help resolve speaker identity, gender, sentence mood, and scene boundaries. The current system relies only on subtitle text and metadata.

**Genre prompting.** Some selection and repair prompts used a historical-drama editor role across all files. This matches much of the corpus but is not appropriate for every modern or variety program. A genre-neutral or metadata-conditioned editor prompt would be preferable.

**Ultra-short cues.** Very short cues remain difficult. Of the 125 cues containing only 是 ("yes"), approximately one quarter were expanded into six or more English words, often because the model used neighboring context too aggressively. A source-to-target length guard or duration-aware shortening stage could reduce such expansions.

**Subtitle timing constraints.** The system preserves timestamps and applies line-length limits (Karakanta et al., 2020), but it does not optimize translations directly for reading speed based on cue duration. Duration-aware generation or shortening would provide stronger subtitle-specific control.

**No reference-based evaluation.** Official task scores are now included (§7), but reference-based evaluation remains impossible on this test set: the organizers never released reference translations to participants, and the official metric is itself a reference-free LLM assessment. We therefore report no BLEU (Papineni et al., 2002), chrF (Popović, 2015) or COMET (Rei et al., 2020) score, and no correlation between our internal judge and a human gold standard, because neither we nor any other participant can compute them. Both evaluations in this paper are LLM-based, from different model families and rubrics; agreement between them is not evidence of agreement with human translators.

**No comparison to quality-aware decoding.** We do not compare our prompted selector against minimum Bayes risk decoding (Freitag et al., 2022) or learned quality-aware reranking (Fernandes et al., 2022) over the same candidate pool (§2). This is the most substantial missing baseline in the paper.

**Critic recall is unmeasured.** We measure critic precision, on synthetic errors (§5) and on the cues it edits (§6.5), but we never measured recall against naturally occurring errors, which the official defect records (§7) suggest is the more informative quantity for this system. The 233 severity-5 defects in those records form a labeled set on which that recall could be measured directly, and it is the evaluation we would run first on any revised version of the critic.

# A Prompts

The main production prompt templates are reproduced below, in call order. Runtime substitutions are shown as ⟨*italic slots*⟩. ⟨*bg*⟩ is the per-file background block: the series synopsis, the episode identifier, and any character-name spellings already established in the file. Cue-specific context is separate, and appears as ⟨*prev*⟩ and ⟨*next*⟩ below. Blank lines present in the originals are elided for space; nothing else is altered. The 12B calls request strict JavaScript Object Notation (JSON); the Hy-MT2 translation calls return plain English text. Decoding: Stage 1 draw 1 at $T$=0.7, draws 2–3 at $T$=0.95 and $T$=1.0 with top-$p$=0.95, top-$k$=40, 256 max tokens; all 12B calls at $T$=0, reasoning mode *off* for select and the audit calls and *on* for re-verify and repair, 512–1024 max tokens.

## A.1 Stage 1: translate (7B)

In Hy-MT2's own documented template, which is written in Chinese. Only the target cue is inside 【待翻译文本】 ("text to be translated"); the neighbors live in 【背景信息】 ("background information") as prose, which is the boundary-preserving structure of §4.3. Line breaks below are inserted to fit the column.

【背景信息】⟨*bg*⟩这句字幕是连续对白的一个片段，上文为：[⟨*prev*⟩]，

下文为：[⟨*next*⟩]。只翻译【待翻译文本】中的这一句，不要翻译上下文，也不要把上下文的内容并入译文。
请结合背景信息将【待翻译文本】翻译为 English，翻译的风格要严格符合【简洁自然、易读的影视字幕】。注意**只需要输出翻译后的结果，不要额外解释**：
【待翻译文本】⟨*source cue*⟩

In English the prompt reads: "[Background information] ⟨*bg*⟩ This subtitle line is one fragment of continuous dialogue; the preceding line is [⟨*prev*⟩] and the following line is [⟨*next*⟩]. Translate only the single line in [text to be translated]; do not translate the surrounding context, and do not merge the content of the context into the translation. Using the background information, translate [text to be translated] into English, in a style that strictly matches [concise, natural, readable screen subtitles]. Note: output only the translated result, with no additional explanation. [text to be translated] ⟨*source cue*⟩"

The style slot is genre-*neutral* ("concise, natural, readable screen subtitles"); register is carried by the synopsis rather than a hardcoded genre claim. The *retranslate* variant is this same prompt with 注意： ("note:") followed by ⟨*hint*⟩, inserted immediately before 【待翻译文本】, where ⟨*hint*⟩ is the concatenation of the per-rule hints of §A.6 for the confirmed defects, most severe first.

### A.2 Stage 2: select and minimally edit (12B)

```
You are the senior editor of English subtitles
for a Chinese historical costume drama. A
translation model produced several candidate
renderings of ONE subtitle line. Choose the
best rendering, and lightly edit it for:
consistency with established names, correct
pronoun gender, period-appropriate register,
and BREVITY (must fit on screen). Do NOT add
meaning not present in the candidates, and
do NOT pull in content from the surrounding
context lines --- they are only for your
understanding.
Background: ⟨bg⟩
Established character-name spellings (keep
consistent): ⟨names⟩
Preceding context (Chinese, do not translate):
[⟨prev⟩]
Following context (Chinese, do not translate):
[⟨next⟩]
TARGET line (Chinese): ⟨source cue⟩
CANDIDATE English renderings:
1. ⟨candidate 1⟩ …
Return ONLY JSON, reasoning first:
{"reasoning": "<brief>", "line": "<the
chosen/edited English line>", "new_names":
["<any English character names you committed
to>"]}
```

The register cue in the opening line is a fixed string applied to every file, including the modern and variety ones.

### A.3 Stage 3: audit call wrapper (12B)

One call per rule; ⟨*defect question*⟩ is substituted from Table 7.

```
Background: ⟨bg⟩
You are auditing ONE English subtitle line
against its Chinese source, for a single
specific defect. Answer only about THIS
defect.
DEFECT TO CHECK: ⟨defect question⟩
Preceding context (Chinese, for reference
only): [⟨prev⟩]
Following context (Chinese, for reference
only): [⟨next⟩]
SOURCE (Chinese): ⟨source cue⟩
ENGLISH draft: ⟨en⟩
Reason briefly, then answer. A CLEAN draft
is the common case --- only report a defect
if it is genuinely present. Return ONLY JSON,
reasoning first:
{"reasoning": "<brief; if defect, quote the
offending words>", "defect": true|false,
"inverts_meaning": true|false}
```

The `inverts_meaning` field escalates `meaning_preserved` from major to critical. A ninth rule, the 84-character line ceiling, runs in code and is trusted without re-verification.

### A.4 Stage 3: skeptical re-verify (12B, system prompt)

This is the verification pass whose effect §5 measures. It is deliberately asymmetric.

```
You are an independent senior reviewer of
English subtitles. A prior reviewer FLAGGED
a line; treat that as an accusation, not a
fact. Re-check the rule from scratch. DEFAULT
to `no defect'. Confirm a defect ONLY if you
can point to CONCRETE OFFENDING TEXT in the
draft that actually violates the rule. If you
cannot cite offending text, or the draft is
a legitimate rendering, the flag was a false
positive --- clear it. Return STRICT JSON
only, reasoning first: {"reasoning": "<one
sentence; if confirming, quote the offending
text>", "defect_confirmed": true|false}.
```

The user turn supplies `RULE FLAGGED`, the prior reviewer's reason, the neighbor context, the source and the draft, and closes with "Independently decide whether a REAL defect exists." The same prompt re-verifies the *repaired* line after repair. On re-verify call failure the original flag is retained, favoring error detection over avoidance of unnecessary repair.

### A.5 Stage 4: consolidated repair (12B)

```
You are the senior editor of English subtitles
for a Chinese historical costume drama.
The current line has the defects listed
below, ranked most to least severe. Produce
```

| Rule key | ⟨*defect question*⟩, verbatim |
|---|---|
| `meaning_preserved` | Does the English MISREPRESENT the source line — a hallucinated detail not in the source, a dropped essential meaning, a negation flip, or a who-did-what-to-whom error? (Escalate to a meaning INVERSION if the core claim is reversed.) |
| `pronoun_gender_resolved` | Chinese drops subjects and 他/她/它 ('he'/'she'/'it', all pronounced *tā*) sound alike. Given the context, is the English subject/pronoun the WRONG gender or person for the referent it must denote? (A subject/pronoun that English grammar requires but Chinese omitted is NOT a defect if it matches the context.) |
| `no_context_leak` | Does the English contain content that belongs to the NEIGHBOR cues (shown as context) and is NOT in the target line itself? |
| `honorific_register_consistent` | Is an honorific/title rendered WRONGLY for the period register (e.g. royal 'We' flattened to 'I', or a rank title dropped/modernized)? |
| `sentence_mood_match` | Does the English change the SENTENCE MOOD vs the source — turning a question into a statement or a statement into a question, or flipping a command into a description? (The source's illocutionary force must survive.) |
| `direction_agent_correct` | Is the DIRECTION or AGENT reversed — moved-here rendered as moved-there, give/take swapped, or the doer and receiver of the action exchanged? |
| `person_attribution_correct` | Is the wrong PERSON doing/saying it — a 3rd-person report ('he will go…') rendered as 1st-person ('I will go…'), or a vocative/address ('Bro, …') rendered as a described subject ('his brother …')? |
| `no_invented_name` | Does the English state a specific PERSON'S NAME (a romanized given/family name) that is NOT present in the source cue — where the source used only a title, role, or pronoun (e.g. 顾总/王爷/他/她/老板: 'Director Gu', 'my lord', 'he', 'she', 'boss')? Rendering a title AS a title is correct; INVENTING or substituting a proper name the source did not give is the defect. (A name that IS in the source is fine.) |

Table 7: The eight audit questions, verbatim. Each is asked in its own call inside the wrapper of Appendix A.

```
ONE corrected line that resolves ALL of
them with the MINIMAL English-side edit.
Prefer picking/assembling from the candidate
renderings; do NOT translate afresh from the
Chinese and do NOT add meaning not supported
by the source or candidates. Keep it concise
(fit on screen).
Background: ⟨bg⟩
Established names (keep consistent): ⟨names⟩
Preceding context (Chinese): [⟨prev⟩]
Following context (Chinese): [⟨next⟩]
SOURCE (Chinese): ⟨source cue⟩
CURRENT line: ⟨en⟩
DEFECTS (fix all, worst first):
  - [⟨severity⟩] ⟨rule⟩: ⟨reasoning⟩ …
CANDIDATE renderings to draw from:
  1. ⟨candidate 1⟩ …
Return ONLY JSON, reasoning first:
{"reasoning": "<brief>", "line": "<corrected
English line>"}
```

The candidate pool at this point is {initial candidates} ∪ {hint-guided retranslations}. If fewer than two distinct strings exist, the call is not made at all: the defects are recorded as residuals and the line is left untouched.

### A.6 Rule-to-hint templates (7B)

The hint sent back to the translator, keyed by confirmed rule. These are what make retranslation *informed* rather than blind resampling.

```
meaning_preserved: Translate only what the
source says --- do not add, drop, or reverse
meaning.
pronoun_gender_resolved: Use the
pronoun/gender that matches the referent
in context.
no_context_leak: Translate ONLY this line;
do not pull in content from the surrounding
lines.
honorific_register_consistent: Render any
title or form of address at a register that
matches the source, and keep it consistent ---
do not flatten, drop, or modernize it.
sentence_mood_match: Preserve the sentence
type of the source: if it is a question,
render it as an English question; if a
command, a command.
direction_agent_correct: Keep the direction
and the doer/receiver of the action exactly as
in the source --- do not reverse who acts on
whom or which way something moves.
person_attribution_correct: Use the correct
grammatical person: if the line REPORTS what
another person said or will do, use third
person (he/she/they), not `I'; keep a vocative
(a term of address) as address, not as a
described subject.
no_invented_name: Do NOT introduce a specific
person's name that the source did not give: if
the source uses only a title/role/pronoun,
render that title/role/pronoun, not an
invented proper name.
```

## B Configuration details

**Models.** `tencent/Hy-MT2-7B` and `google/gemma-4-12B-it-qat-w4a16-ct`, both Apache-2.0, used at their released revisions. No adapters, no tokenizer or chat-template changes, no new weights released.

**Serving.** SageMaker-native vLLM deep learning container (DLC) `vllm:0.23.0` (vLLM Project, 2026), one model per endpoint, one 24 GB GPU per endpoint (`ml.g5.xlarge` /

`ml.g6.xlarge`; A10G / L4). Client fan-out is 16 cue workers per file with 4 nested workers for the per-rule audit calls, and a per-endpoint in-flight cap that scales with the replica count. The cap must scale with replicas, or the client-side semaphore throttles the whole endpoint to one replica's throughput. Retries are exponential (2/4/8/16 s) on *transient* failures only (model errors, service-unavailable, throttling, timeouts, 5xx, connection resets), while a clean empty completion is deliberately *not* retried, since that is a model-output issue rather than an infrastructure one.

**Inference volume.** Over the production run the 7B was called 129,837 times: 125,511 translation draws, three per cue, plus roughly 4,300 hint-guided retranslations. The 12B was called ≈366,000 times: 23,442 candidate selections, 334,696 single-rule audit calls (eight for each of the 41,837 cues), and roughly 8,000 re-verification and repair calls on the cues that were flagged.

**Judge protocol.** `gpt-5.6-luna` at high reasoning effort, one item per call, temperature default; the blinding and counterbalancing are described in §6. Line wrapping is stripped from the judged string, since a line break would identify the arm. Judgment loss to malformed JSON was 2 of 3,258 items (0.06%), in one non-headline comparison.

**Labeled critic set.** The 600 cases of §5 are built from a fixed seed over the 84 non-development files, so the whole set is re-runnable. The 200 controls are half sampled at random from shipped output and half drawn from a cleaner pool. Two rules cannot fill their genre quota, which is a property of the corpus rather than of the sampler: `honorific_register_consistent` and `no_invented_name` have almost no eligible cues in the reality/variety and modern-urban classes.

# One Model, Five Tasks, Two RTX 3090 GPUs: The HSE System for the Sorbian Track of WMT26 Multitask LLMs with Limited Resources

**Michael Diskin**
HSE University
Moscow, Russia
michael.s.diskin@gmail.com

## Abstract

We describe HSE's submission to the Sorbian track of WMT26 Multitask LLMs with Limited Resources, where a single 2B-parameter model must translate between German, Upper Sorbian, and Lower Sorbian and also answer multiple-choice questions, check spelling and grammar, and solve maths problems in both Sorbian languages. Our system is one LoRA adapter on Qwen3.5-2B, trained on the official parallel data, synthetic spelling and grammar examples, a question-answering proxy, and English GSM8K in about nine GPU-hours on two consumer RTX 3090 GPUs. Extended translation-only fine-tuning cost about ten points of question-answering accuracy, reproducing a WMT25 finding, and nearly erased the output conventions of the other tasks; the multitask mixture recovered them at almost no translation cost. The system ranked fourth of four teams. It far exceeded the baseline on translation ($21.7 \rightarrow 61.5$ chrF++) and spell checking ($6.7 \rightarrow 63.6$), but on grammar checking and maths reasoning it learned the answer format without the skill: the grammar score is almost exactly the share of error-free sentences, and maths accuracy did not exceed the baseline. Two negative results may transfer to other low-resource settings. Synthetic holdouts did not predict performance on the official tasks in either direction, and self-translated training problems passed every automatic check yet changed meaning in at least 6 of 20 inspected cases. The model is publicly available.

## 1 Introduction

The WMT26 Multitask LLMs with Limited Resources shared task (Okabe et al., 2026), a successor to the WMT25 shared task on low-resource Slavic languages (Okabe et al., 2025), requires each participant to submit *one* model that handles five tasks. The Sorbian track comprises Machine Translation (MT) in six directions (de↔hsb, de↔dsb, and hsb↔dsb), Multiple-Choice Question Answering (QA), Spell Checking (SC), Grammar Checking (GC), and Maths Reasoning (MR) in Upper and Lower Sorbian. Upper Sorbian (approximately 30,000 speakers) and, especially, Lower Sorbian (approximately 7,000 speakers) are extremely low-resource languages, while the final ranking weights all five tasks equally. Eligible models are restricted to the 2B Qwen3.5 family (Qwen Team, 2026).

Our system is a single LoRA adapter (Hu et al., 2022) on Qwen3.5-2B, trained on official parallel data, synthetic task examples, and English GSM8K within the budget of two consumer GPUs. We quantify the trade-off between MT and the other four tasks that motivates the multitask mixture (§4), show where the recipe works and where the model learns only the answer format (§5), and report why two shortcuts failed: synthetic holdouts as a selection signal and self-translated training problems. Along the way we revisit two WMT25 observations: we reproduce the MT–QA trade-off and identify a lighter training regime in which it did not appear, and our self-translation pilot points to a second possible mechanism behind the negative result that JGU Mainz reported for translated training questions (Saadi et al., 2025). We release the model[1] and document its training and evaluation.

## 2 Related Work

**Sorbian MT and multitask adaptation.** The WMT20–22 shared tasks covered translation between German, Upper Sorbian, and Lower Sorbian (Fraser, 2020; Libovický and Fraser, 2021; Weller-Di Marco and Fraser, 2022). WMT25 evaluated MT and QA jointly for low-resource Slavic languages (Okabe et al., 2025). Its systems exposed a tension between the two tasks: NRC's MT-only system fell below random performance on Upper

October 28-29, 2026 ©2026 Association for Computational Linguistics

Sorbian QA (Larkin et al., 2025), while TartuNLP found that a separate MT fine-tuning stage impaired QA (Purason and Fishel, 2025). TartuNLP used a single-stage multitask mixture (Purason and Fishel, 2025), and JGU Mainz retained parallel data during fine-tuning to prevent forgetting of MT (Saadi et al., 2025). Our system follows this multitask approach in the five-task WMT26 setting.

**Synthetic data for error correction.** Synthetic error generation has been used to train grammatical error correction systems, with downstream quality depending on both the corruption process and the training schedule (Grundkiewicz et al., 2019; Kiyono et al., 2019). Synthetic spelling errors have also been used for spelling correction in resource-scarce Indic languages (Etoori et al., 2018) and Slovene, where training-data construction strongly affected performance (Klemen et al., 2024). Our SC and GC experiments examine both the usefulness of synthetic training examples and the ability of synthetic holdouts to predict performance on the official tasks.

**Translated supervision and mathematical reasoning.** Machine-translated training data have been used for cross-lingual QA (Sorokin et al., 2022) and multilingual mathematical reasoning (Chen et al., 2024). For Sorbian, JGU Mainz translated about 200,000 English multiple-choice questions with its own models; fine-tuning on them slightly reduced QA accuracy, which the authors attribute to the joint MT/QA trade-off (Saadi et al., 2025). The reliability of translated reasoning data remains a concern: Zhu et al. (2024) documented errors in translated GSM8K reasoning traces. Our self-translation pilot examines a related risk in the problem statements themselves: changes in meaning that are missed by checks of answer tags and numerical content. Beyond translation, prior work has explored training on model-generated rationales selected by answer correctness (Zelikman et al., 2022) and synthetic proofs with automated quality checks (Obozov et al., 2025). English-pivoted chain-of-thought training, with reasoning in English and answers in the target language, has also improved mathematical reasoning in Irish (Tran et al., 2026). Our GSM8K supervision instead uses answer-only targets (§5).

| Component | Rows | Weight | Token share |
|---|---|---|---|
| MT (official parallel) | 234,594 | 1 | 81.8% |
| SC (synthetic) | 15,000 | 1 | 3.6% |
| GC (synthetic) | 1,800 | 10 | 3.9% |
| MR (English GSM8K) | 7,094 | 6 | 5.4% |
| QA proxy | 20,000 | 12 | 5.4% |
| Total | 278,488 | — | 100% |

Table 1: The multitask training mixture. Weight is the multiplier applied in the weighted cross-entropy objective; token share is the proportion of weighted supervised tokens.

## 3 Task, Data, and Constraints

**Tasks and metrics.** MT is evaluated in six directions using chrF++ (Popović, 2017), with BLEU (Post, 2018) also reported. QA uses accuracy; SC and GC use the mean of detection and correction exact match, including sentences with no error; MR uses answer exact match. We report all task scores on a 0–100 scale. The Sorbian MR evaluation uses PluraMath (Dementieva et al., 2026), an extension of PolyMath to additional languages. The organizers also evaluate the submitted model on a hidden QA set.

We generated all submitted outputs with the unchanged official lm-evaluation-harness fork (Gao et al., 2026), so that our inference configuration matches the baseline's; the task does not require this. Generative answers are extracted from tags; QA is scored by multiple-choice log likelihood without a chat template, and MR is decoded by sampling at temperature 1. Appendix C gives the prompts, submission format, and stopping diagnostics.

**Data restrictions.** Participants may use any publicly available data but no evaluation-set material in any form, including translations: the Sorbian language-certificate exam questions that form the QA task, PolyMath for MR, and the previous year's test sets.

## 4 Final System

**Architecture and training.** The base model is Qwen3.5-2B (1.9 billion parameters). We add a single LoRA adapter with rank 16, $\alpha = 32$, dropout 0.05, applied to all linear layers (Mangrulkar et al., 2022). We use supervised fine-tuning with weighted cross-entropy, a maximum sequence length of 512, and a global batch size of 32. The initial training lasts two epochs, with a peak learn-

| Model | MT | QA | SC | GC |
|---|---|---|---|---|
| Qwen3.5-2B base | 22.2 | 49.3 | 9.4 | 1.7 |
| MT only | 63.1 | 38.7 | 3.2 | 2.2 |
| Multitask (2 epochs) | 62.9 | 51.6 | 61.6 | 50.0 |
| Final (3 epochs) | **64.2** | **53.4** | **63.9** | 49.9 |

Table 2: Official development results. MT is macro-chrF++ over the six directions; QA is accuracy; SC and GC are the mean of detection and correction exact match. All scores use a 0–100 scale. MR is omitted: with 24 examples per language and sampled decoding (§3), its development scores are too noisy to compare.

ing rate of $2 \cdot 10^{-4}$ and a cosine schedule. Training configuration and resource measurements are given in §6 and Appendix D.

**Why a multitask mixture.** Two development-set observations motivated the mixture (Table 2). First, extended MT-only training (the MT-only row of Table 2) reduced QA accuracy from 49 to 39, reproducing a central WMT25 finding (Okabe et al., 2025). Second—a dimension not present at WMT25—MT training nearly erased the *output conventions* of the other tasks. Even a lighter MT-only adapter, trained for one epoch on balanced parallel data (revisited in §5), reduced SC from 9 to approximately 3 and the valid-tag rate to 68–82%, while no-error answers almost disappeared: the model began to *rewrite* the sentence as if translating it. Multitask mixing was already standard at WMT25 (§2); here we quantify the trade-off across five tasks. Relative to MT-only training, the mixture gives up less than half a chrF++ point on MT while recovering 13 points on QA, 58 on SC, and 48 on GC.

**Mixture composition.** Table 1 gives the composition. All synthetic data were generated from the parallel training corpus, screened against the released development and test texts, and split by source group before generation; the held-out source groups were also removed from the MT component (Appendix B). The synthetic and external components are:

- **SC**: parallel-corpus sentences with a misspelling introduced into one word by a single character edit (diacritic substitution, insertion, deletion, or transposition; half of the examples contain no error), represented in the exact answer format of the task;
- **GC**: 1,800 examples with controlled subject–auxiliary agreement errors, the only class of grammatical phenomena that we could generate confidently from the parallel data alone; this restriction had the largest effect on the final outcome (§5);
- **QA proxy**: multiple-choice translation-selection and lexical cloze examples generated from parallel sentence pairs; and
- **MR**: the English GSM8K training set (Cobbe et al., 2021) with answer-only targets: the assistant turn contains the final number in the task's answer tags and no solution steps. Translating the questions into Sorbian with an internal MT model was rejected on quality grounds (§5).

An LLM agent, not a native speaker, reviewed 48 examples per synthetic family against the source sentence pairs, and all passed; Appendix B gives the construction rules, splits, leakage screens, and review protocol.

**Continued training.** We then continued training the same adapter for one epoch on the unchanged mixture at a learning rate of $5 \cdot 10^{-5}$ and selected the checkpoint at the end of the epoch on the official development set. It improved MT macro-chrF++ by 1.3 points and produced small gains on QA and SC while leaving GC unchanged (Table 2); the gain also transferred to the submission leaderboard, +1.6 BLEU and +1.2 chrF++ over the two-epoch model (§5). Returns were diminishing, so we stopped after one additional epoch.

## 5 Results and Analysis

Table 3 presents the official final results (Okabe et al., 2026), and Table 4 breaks down MT by direction. Development scores overestimated test scores but preserved their ordering. For the final model, development macro-chrF++ was 64.2 against 61.5 on the official test set. For three successive submissions, development macro-chrF++ rose from 56.7 to 62.9 to 64.2, and the leaderboard chrF++ of the same models rose in step from 54.1 to 59.5 to 60.7.[2] Leaderboard scores were never used to choose data, checkpoints, or inference settings. We therefore treat the development set as an optimistic but usable proxy for checkpoint selection.

[2]Leaderboard scores are corpus-level chrF++ over the concatenated output of all six directions, whereas the development and official final scores are means across directions, so levels are not directly comparable between the two.

| Team | MT (chrF++) | QA | SC | GC | MR | Points | Rank |
|---|---|---|---|---|---|---|---|
| HeyBusan | **72.75** | 55.92 | **78.03** | **79.52** | 29.00 | 22 | 1 |
| LT3 | 69.57 | **65.05** | 76.11 | 78.32 | **30.40** | 22 | 1 |
| Hitsz | 63.12 | 57.33 | 73.13 | 62.11 | 18.60 | 16 | 3 |
| HSE (ours) | 61.50 | 46.77 | 63.63 | 50.02 | 5.00 | 9 | 4 |
| baseline | 21.68 | 43.39 | 6.66 | 1.34 | 5.40 | 5 | 5 |

Table 3: Official final results for the Sorbian track, using each team's primary system; QA includes the hidden set. All task scores use a 0–100 scale. Bold denotes the best result for each task.

| Direction | BLEU | chrF++ | Best chrF++ |
|---|---|---|---|
| de→hsb | 30.48 | 56.27 | 70.26 |
| hsb→de | 27.14 | 52.70 | 69.43 |
| de→dsb | 27.14 | 52.72 | 63.06 |
| dsb→de | 29.90 | 54.61 | 69.42 |
| dsb→hsb | 55.78 | 75.50 | 82.38 |
| hsb→dsb | 57.32 | 77.19 | 81.96 |

Table 4: Our system's final-test MT results by direction, with the best track chrF++ score (HeyBusan) for comparison.

**Overall performance.** The gains over the baseline are concentrated in MT and SC (Table 3); the apparent GC gain is examined below. The gap to the leaders was smallest for MT (11 chrF++ points overall and only 5–7 points for the bridge directions hsb↔dsb) and largest for MR and for GC on error-containing sentences.

**QA: the WMT25 MT–QA trade-off appeared only under intensive MT training.** The ten-point QA drop under MT-only training (§4) appeared only under the more intensive configuration of two epochs at the peak learning rate. The lighter MT-only adapter of §4, trained for one epoch on balanced parallel data at half the peak learning rate, did not degrade QA: hsb was unchanged, while dsb improved by approximately 6 points. Because the two conditions also differed in data volume and batch settings, we do not attribute the drop to any single factor. Interpolating the MT-only and multitask adapters recovered part of the MT and QA difference but lost some of the few correct GC predictions on sentences containing errors (Table 5). We kept the multitask model.

**SC: synthetic data were effective.** The system learned to detect and correct misspellings from synthetic edits. On the test set, detection/correction scores were 72/53 for hsb and 73/57 for dsb: correction remained harder than detection in both languages.

**GC: almost all accuracy comes from the no-error half.** Our final GC score was approximately 50. In the test package, the model returned *no error* for 3,712 of the 3,726 GC rows. The narrow synthetic agreement data taught the output format but not how to identify real errors, and the final score is almost exactly the proportion of error-free sentences. The same collapse was visible on the development set, where performance on the error-containing subset was close to zero. By contrast, the two-epoch model achieved 98.5% paired exact match (both fields correct) on the synthetic holdout, which failed to predict transfer.

**MR: correct formatting without correct answers.** The final MR score was 5.0, compared with 5.4 for the baseline: transfer from English GSM8K to Sorbian MR was negligible, and the two alternatives discussed below, the synthetic continuation and self-translated problems, had drawbacks of their own. Because the GSM8K targets contained only the final answer, the model was never trained to write a solution before answering; our experiments do not separate this target choice from the language-transfer problem. In a later run whose GSM8K targets wrapped the answer in TeX dollar delimiters, the LaTeX form that the official prompt invites (Table 5, stopping interventions), answers in that form rose from 2 to 45 of 48 problems, while correct answers rose only from 0 to at most 2.

**Synthetic holdouts: unreliable predictors of task performance.** We tried to improve GC and MR by briefly continuing training on new synthetic data: a morphology-grounded GC generator covering case, gender, number, and person, which yielded only 634 examples, and template-generated Sorbian MR problems, mixed with replay of the original tasks (Appendix B). Selecting the checkpoint by its synthetic-holdout scores picked one that nearly solved the holdouts but lost about 12 SC and 11 GC points on the official development set (Table 5).

After the final submission, we observed the reverse mismatch in SC-only models trained in rounds: after each round, the adapter was merged into the model and a new one was trained, resembling ReLoRA and Chain-of-LoRA (Lialin et al., 2024; Xia et al., 2024). They improved on the final model's official development score of 63.9, reaching 74.0, while all three achieved 80–81% paired exact match on the source-disjoint synthetic holdout. The later evaluation covered SC alone, so retention of the other four tasks was untested and we did not replace the unified model. Together, these experiments show that a narrow synthetic evaluation can both reward changes that fail to transfer and miss improvements on the target task.

**Self-translation: structural checks miss semantic errors.** Our pilot suggests a second mechanism behind the JGU Mainz result (§2). We translated 100 GSM8K problems into both languages with an internal diagnostic MT model (Appendix A). Every translation passed the automatic checks of well-formed tags and matching numbers, yet at least 6 of the 20 manually inspected source pairs had altered semantics (*twice→once*, loss of the question, or a change of referent). For low-resource languages, where large training corpora cannot readily be proofread by native speakers, this pilot supports caution about self-translated training data—especially reasoning data—even when the MT model passes structural checks.

## 6 Efficiency on Consumer Hardware

The final model cost about 6 GPU-hours for the initial two epochs and about 3 for the additional epoch, and the entire experimental trajectory described in this paper, including rejected branches and evaluations, ran on the same two-GPU consumer server. The main trainer changes behind this budget were disabling gradient checkpointing, disabling unused-parameter detection in distributed data parallel training, and compiling the model with `torch.compile`; the production run processed about 52 examples per second at full sequence length and full logits. Two standard optimizations did not pay off for this model. Liger fused cross-entropy (Hsu et al., 2025) saved about 3 GiB but nearly halved throughput, because the 248,000-token vocabulary splits each short step into dozens of small language-model-head chunks, and FlashAttention-2 (Dao, 2024) was slower than PyTorch SDPA on our short sequences. Every adopted change preserved numerical equivalence. Appendix D gives the individual measurements, memory checks, and the power-limit comparison.

## 7 Conclusion

For a five-task track with one 2B model, a single multitask LoRA adapter on public data was enough to beat the baseline by a wide margin on MT and SC within a consumer-GPU budget, but not to acquire the skills behind GC and MR, whose absence coincides with the lack of permitted in-domain training data. The remaining gap is therefore one of skill rather than format: closing it requires training signal for MR and for error-containing GC, and stronger non-bridge MT. Our two failed shortcuts argue for checking transfer on the official tasks early instead of trusting synthetic holdouts or automatic checks of translated data.

## Limitations

**Scope of the claims.** The largest shortcomings are MR and GC on error-containing sentences. Both coincide with the absence of permitted, high-quality in-domain training data, but our experiments do not distinguish data coverage from optimization or model capacity.

**Evidence quality.** Because model selection used a single seed and small official development sets—158 QA questions and 24 MR examples per language, the latter decoded by sampling—we do not treat changes of 0.1–0.5 chrF++ or a few examples as statistically reliable. WMT25 teams also noted the instability of small QA sets (Larkin et al., 2025; Purason and Fishel, 2025). Synthetic data were reviewed with AI assistance but not by native speakers, so systematic generator errors may remain. LLM agents also prepared runs, collected metrics, and maintained logs; scientific decisions and external actions remained with the author.

**Train–test source overlap.** The MT component contains 763 records, about 0.3% and almost all in de→dsb, whose normalized sources also occur among the released MT test sources. These records stayed in the training data, neither removed nor upweighted, and the overlap list itself was not used for anything. We trained no model without them, so their effect on MT scores is unmeasured.

**Inference configuration.** We did not explore task-specific prompts, stop sequences, or decoding

settings. The model frequently continues generating after the first answer; the official parsers extract that answer, leaving track scores largely unaffected. Use outside the harness should stop at the closing tag. Appendix C reports the stopping diagnostics.

## Acknowledgments

This research was supported by the Basic Research Program at HSE University (HSE-BR-2025-025).

We thank the track organizers for the data, evaluation harness, and timely feedback. We also thank Anastasiia Fadeeva for her moral support and invaluable help with the manuscript, and Dmitry Abulkhanov for insightful discussions.

# A Additional Experiments

Several experiments in Table 5 start from the *merged final model*, the final adapter merged into the base weights, and train a fresh adapter on top. Appendix C discusses the stopping behaviour.

## A.1 Settings and Detailed Measurements

**Synthetic continuation.** The 9,600-row mixture contained the 634 morphology-grounded GC ex-

| Experiment | Outcome |
|---|---|
| **Synthetic continuation** Two-epoch multitask model; combined synthetic GC/MR data and five-task replay | The checkpoint selected on synthetic holdouts before official evaluation nearly solved those holdouts, but lost 12.4 SC and 11.1 GC points on the official development set. |
| **Self-translation** 100 GSM8K problems translated into both languages by a diagnostic MT model | All 200 translations had well-formed tags and matching numbers, yet at least 6 of the first 20 manually inspected source pairs had semantic errors (§5). We retained the English MR data. |
| **Adapter interpolation** Exact linear blends of the two-epoch multitask and MT-only LoRA updates | All three blends improved MT on a fixed development slice and QA, but each lost at least one of the few correct GC predictions on error-containing sentences. A rule fixed before the screen allowed no such regression, so we rejected all three on evidence of a handful of rows. |
| **Stopping interventions** (a) Otherwise identical runs with end-of-turn token weights 1 and 4, MR targets with the answer in TeX dollar delimiters in both arms; (b) sequence-unlikelihood penalty on post-tag continuations, with a plain cross-entropy control on the same data | (a) Weight 4 did not improve clean stopping over weight 1. Both arms raised dollar-delimited MR answers from 2/48 to 45/48 with at most 2/48 correct answers and lost 1.0–1.2 chrF++ relative to the merged final model. (b) Clean stopping rose from 23% to 67% on the probe's evaluation slice, while MT lost 0.6 chrF++ and SC lost 4.3 points relative to the merged final model; relative to the control, the unlikelihood term itself cost 0.4 chrF++ and 0.4 SC points. |
| **SC-only training** Three merge-and-retrain rounds; source-disjoint synthetic holdouts | Official development SC rose monotonically from the final model's 63.9 to 74.0, yet synthetic paired exact match plateaued at 80–81% and the synthetic screen rejected every round; the other four tasks were not evaluated. |

Table 5: Additional experiments and their observed outcomes. Task score changes are in points on a 0–100 scale; stopping and paired exact match rates are percentages.

amples, a 1,366-example subset of the template-generated MR training set (Appendix B), and replay of the five tasks. Training lasted 300 steps at a learning rate of $10^{-5}$; the synthetic evaluation selected checkpoint 200.

**Self-translation.** Problems were stratified by length, number count, and answer form. The diagnostic MT model had been trained with official development data and was therefore ineligible for submission.

**Adapter interpolation.** With weights on the multitask LoRA update $\lambda = 0.80/0.90/0.95$, MT macro-chrF++ on a fixed 500-example development slice per direction improved by $1.1/0.8/0.2$, and QA by $5.8/4.5/2.7$ points, respectively, relative to the two-epoch multitask model. On error-containing GC, that model itself had only 3 detection and 2 correction exact matches among 1,000 hsb rows and none among 625 dsb rows; the blends retained at most 2 detection matches and no correction matches.

**Stopping interventions.** Both probes trained a fresh rank-16 adapter on the merged final model for 100 steps. The two weighting arms used the full mixture at a learning rate of $5 \cdot 10^{-5}$ and differed only in the loss weight of the final <|im_end|> token. The unlikelihood run (Welleck et al., 2020) used 5,632 positive examples balanced over 11 generative task labels, each paired with one rejected continuation, at a learning rate of $2 \cdot 10^{-5}$.

**SC-only training.** Starting from the merged final model, we trained and merged a fresh rank-128 adapter in each round (one epoch, learning rate $10^{-4}$). The first two rounds used 60,000 synthetic rows; the third added the previously evaluated 4,000-row holdout and was scored on a new source-disjoint holdout. Data included clean sentences and one- or two-character errors.

## B Synthetic Data Construction and Review

All synthetic families were generated by deterministic local scripts from the released Sorbian MT training files (de–hsb, de–dsb, and hsb–dsb) and, for MR, from the English GSM8K training set. Released development and test rows entered the pipeline only through a collision screen that removes any candidate whose normalized text

matches a released development or test string; they never influenced selection. Each family assigned source rows to train or holdout before generation (20% holdout), and the source groups of every synthetic holdout were removed from the MT component, so the 4,779 holdout rows (2,000 SC, 400 GC, 2,000 QA, 379 MR) share no source sentence with training.

**SC (15,000 train, 2,000 holdout).** Source sentences pass length and cleanliness filters (5–35 words, terminal punctuation, no URLs or markup, no normalized duplicates). An error example alters one word by a single character using one of four families in equal shares: diacritic substitution, insertion, deletion, or transposition. The corrupted form must not occur in the training-corpus vocabulary of the language, and the source word must occur at least twice. Clean and error examples are balanced 1:1 and stratified by sentence length and error position; targets use the exact official answer format.

**GC (1,800 train, 400 holdout).** Source sentences contain exactly one adjacent pair of a nominative subject pronoun and a positive present-tense auxiliary. An error example replaces only the auxiliary with the form of another person/number cell; a clean example keeps the sentence. Each language contributes equal numbers of clean and error examples spread over the six agreement classes according to availability. Random word replacement, case and preposition errors, negative and future auxiliary paradigms, and sentences with zero or several controlled pairs were excluded.

**QA proxy (20,000 train, 2,000 holdout).** Two families in equal shares use the official raw multiple-choice format with four options and uniformly distributed correct positions. Translation selection presents a German sentence and asks for its Sorbian translation among distractors of similar length and punctuation from the same split. Lexical cloze asks for the correct word form among distractors that are known clean forms with the same initial letter, length $\pm 1$, and Levenshtein distance 1–3. Targets are the option number, scored by log likelihood without a chat template as in the official QA task.

**MR (7,094 train, 379 holdout).** GSM8K training problems were screened against the WMT26 MR development and test questions and split by source ID. Each target is the final numeric answer inside the answer tags; the GSM8K solution text was not used.

**Semantic review.** For each family, a fixed stratified sample of 48 examples was reviewed row by row by an LLM agent with a trace to the German or paired-Sorbian source sentence. Acceptance required that the source is a usable sentence, that an error example contains exactly one intended error, and that the target is correct; for QA, that exactly one option is correct and the options are close and fluent. All 48 passed in every family. The only notes concerned loan words and lower-case sentence starts in the released sources, which led to a stricter source filter when the GC set was scaled up.

**Holdout scoring.** Holdouts were scored with the official tag extraction (SC, GC, MR) and raw multiple-choice mode (QA). These scores are checkpoint evidence only and are not comparable to official development scores.

**Data for the synthetic continuation.** Two further generators were built after the primary mixture was fixed and were used only in the short synthetic continuation (Table 5). (i) Morphology-grounded GC: from released sentences and two public morphology resources,[3] an error example replaces exactly one surface form with an attested form of the same lemma and part of speech that differs in exactly one of case, gender, number, or person, and the replacement must break an explicit adjacent nominal or subject–verb agreement relation. The small Upper Sorbian lexicon (3,606 forms) limited the yield to 634 training and 180 holdout examples across both languages after an agent review of a 300-example sample. (ii) Template-generated Sorbian MR: arithmetic word problems instantiated from project-authored templates with paired numbers for both languages and solved by executing the underlying program. Training and holdout templates are disjoint, so the holdout measures wording transfer rather than memorized numbers. The continuation used a 1,366-example subset with targets reduced to the answer tags. No sentence from the MR evaluation data was used.

## C Inference and Submission Format

A test submission comprises 34,815 rows: 26,174 for MT, 415 for QA, 4,000 for SC, 3,726 for GC,

[3] UD Upper Sorbian UFAL r2.18 (CC BY-SA 4.0) and UniMorph Lower Sorbian (CC BY-SA 3.0).

```
Translate the following German text to
Upper Sorbian. Put it in this format
<hsb> Upper Sorbian translation </hsb>.
<deu> {{de}} </deu>
```

```
The following sentence contains at most
one misspelled word. Respond with
exactly these two tags and nothing else:
<wrong> misspelled word </wrong>
<corrected> correct spelling </corrected>
If the sentence has no error, use the
literal string CORRECT in both tags:
<wrong> CORRECT </wrong>
<corrected> CORRECT </corrected>
<sentence> {{input_sentence}} </sentence>
```

```
Answer this mathematical reasoning
question. Place your final answer, using
LateX when appropriate, in this format:
<answer> answer </answer> {{question}}
```

Figure 1: Official harness prompts (verbatim `doc_to_text`, including the original spelling; line breaks were added for typesetting): MT de→hsb, SC, and MR. The GC prompt replaces *misspelled word / correct spelling* with *grammatically incorrect word / correct form*. QA is scored by multiple-choice log likelihood on the raw prompt without a chat template. Answers are extracted from the tags using regular expressions.

and 500 for MR. QA is scored by log likelihood; the remaining 34,400 rows are generated. Figure 1 reproduces the official prompts.

**Termination.** Only 5,222 of the 34,400 generated rows in the final package stop cleanly at the closing tag. The parsers take the first tagged answer, so track metrics are largely unaffected, and a stop sequence at the closing tag would remove the symptom at inference time. Because we kept the official inference configuration unchanged (§3), we briefly tried two training-side fixes (Table 5): upweighting the final end-of-turn token did nothing, while sequence-unlikelihood training on rejected continuations raised the clean-stop rate substantially at a small cost in MT and SC. Those rates were measured on the probes' own evaluation slices and are not comparable to the package count above. Since a stop sequence achieves the same at inference time, we kept the primary model.

## D Configuration Notes

**Production training.** Training used BF16, SDPA, `torch.compile`/Inductor (Ansel et al., 2024), and weighted cross-entropy over full logits. The global batch of 32 comprised a micro-batch of 8 per GPU, two GPUs, and two gradient-accumulation steps. The initial two epochs (17,406 steps) took approximately three hours on two RTX 3090 GPUs at 350 W; in the monitored part of the additional epoch (8,703 steps), reserved memory peaked at 17.0 GiB per card.

**Trainer throughput.** Throughput was measured after warm-up, separately from compilation time, and the longest batch was tested before each production run. On the eager trainer, disabling gradient checkpointing raised single-GPU throughput by 62%, disabling unused-parameter detection in DDP raised throughput by 29%, and gradient bucket views added 5%; the final eager trainer ran at 27.7 examples per second at batch 8, up from 17.8. On a short calibration corpus, `torch.compile` at batch 16 reached 80.7 examples per second, and the production run with full logits and length 512 reached 52.2. These settings differ in data and batch size and are not pairwise comparable.

**Implementation comparisons.** These configuration choices were tuned to our sequence-length profile using short probes that differed only in the setting under test. The production system used PyTorch 2.11/CUDA 12.8. The FlashAttention-2 and Liger comparisons are summarized in §6. The effect of the power limit depended on the batch setting: on the compiled batch-16 setup, increasing the limit from 250 to 350 W improved speed by 11%, whereas on the earlier eager setup it made no appreciable difference.

# HeyBusan at WMT26: A System for the Sorbian Track

**Mikhail Khasykov**
Independent
mkhasykov@gmail.com

## Abstract

We describe our submission (team HeyBusan) to the Sorbian track of the WMT26 Multitask LLMs with Limited Resources shared task. A single Qwen3.5-2B model handles machine translation, question answering, spell checking, grammar checking, and mathematical reasoning in Upper Sorbian, Lower Sorbian, and German. We fine-tuned all model parameters on public data (the official task data plus external corpora) for approximately 55 GPU-hours on one 24 GB consumer GPU. Task-specific decoding then improved the results further without changing the model's weights. Team HeyBusan placed first in machine translation, spell checking, and grammar checking, and tied with team LT3 for the overall track win.

## 1 Introduction

Can a single 2B model, trained on one consumer GPU, handle five tasks across both Sorbian languages? The WMT26 Multitask LLMs with Limited Resources shared task (Okabe et al., 2026) tested exactly this setting. Each team had to use one model for all five tasks, restricted to Qwen3.5-2B (Qwen Team, 2026) or a permitted smaller variant. The tasks cover Upper Sorbian (hsb), Lower Sorbian (dsb) and German: machine translation (MT), multiple-choice question answering (QA), spell checking (SC), grammar checking (GC), and mathematical reasoning (MR). Teams submitted the model's *outputs* and could use different decoding methods for each task; all training data had to be publicly available. The final ranking gives equal weight to all five tasks through per-task rank points (Section 2).

Our submission was built under genuinely limited resources: a single RTX 3090 for everything, with the final model's whole training path taking ≈55 GPU-hours. Our system finished joint first with team LT3, placing first in three of the five tasks. Our contributions:

- a resource-constrained training recipe that handles all five tasks: full-parameter fine-tuning of one 2B model on one 24 GB GPU with public data;
- a task-specific decoding suite on top of the frozen model, led by QA option-order averaging.

## 2 Task setup and constraints

**Tasks and ranking.** Table 1 lists the five tasks, their official metrics and test sizes. The organizers scored the outputs submitted by each team; participants ran inference themselves with full control over prompting and post-processing. The final ranking uses per-task rank points: for each task, the best primary submission earns the maximum number of points. Scores within one point of each other are treated as tied, and teams with equal totals share the final rank.

**Evaluation protocol.** For model selection, we used three sources of development data: the untouched MT development set, held-out 20% subsets of QA/SC/GC, and the organizer-released 48-item MR set. The remaining 80% of QA/SC/GC entered training. The MR set is the Sorbian part of PluraMath (Dementieva et al., 2026), an extension of PolyMath (Wang et al., 2025) to 18 further languages; we used it only for evaluation and used no other PluraMath or PolyMath data. Over these *local validation* sets we averaged the five task metrics into the composite

$$S = \frac{1}{5}\left(\frac{\text{chrF++}}{100} + \text{QA} + \text{SC} + \text{GC} + \text{MR}\right).$$

Results from individual leaderboard submissions are labeled *leaderboard*. The leaderboard reports only per-task scores, so we computed $S$ over those scores ourselves. The final results table uses the organizers' *official* scores.

*Proceedings of the Eleventh Conference on Machine Translation*, pages 2662–2667
October 28-29, 2026 ©2026 Association for Computational Linguistics

| Task | Required output | Official metric | Test size |
|---|---|---|---|
| MT | translation inside <hsb>/<dsb> tags | chrF++ (Popović, 2017) over six directions | 26,174 |
| QA | option number (2–16 options) | accuracy | 415 |
| SC, GC | the incorrect word and its correction, or CORRECT in both fields | mean exact-match accuracy for detection and correction | SC 4,000 GC 3,726 |
| MR | final answer inside <answer> tags | exact-string accuracy (no symbolic equivalence) | 500 |

Table 1: The five tasks. The scorer extracts answers from the required tags; an output without these tags receives a score of zero. Scores are averaged over hsb and dsb (MT: the six directions among de/hsb/dsb).

## 3 Model training

Starting from Qwen3.5-2B, we ran 2,000 steps of multitask SFT, followed by a final 200-step pass that added the previously held-out QA/SC/GC and MT development examples to training. We then set the final weights to a weighted average of the two models — $0.9\times$ this checkpoint + $0.1\times$ the original Qwen3.5-2B — and applied per-task decoding (Section 4).

### 3.1 Training data (all public)

Table 2 lists the six components of the training mix; all source data are public. The external WMT20–22 parallel corpora (Fraser, 2020; Libovický and Fraser, 2021; Weller-Di Marco and Fraser, 2022) were decontaminated against all Sorbian-track MT test inputs and MT dev sentences before use, checking both sides of every candidate pair.[1] We used no data from the WMT25 edition of the task (see Section 6).

Core supervision came from the official task data: the full MT training set plus 80% of the QA/SC/GC development sets, with a hash-based 20% holdout reserved for local validation until we added it back during the final 200 steps. We sampled the parallel corpora into ∼435k directional MT examples, with at most 120k examples from each file.

**SC/GC synthesis.** The official development sets provide only 1,250–2,000 examples per task and language, so we generated additional examples from correct sentences in the official monolingual corpora. Both tasks build on the full-form lexicons: dictionaries that list every recorded form of a word, such as all its case and number forms.

For GC, we replaced one word with a different form of the same word (for example, with a different case, number, or gender ending). Both the original word and its replacement had to belong to exactly one entry in the lexicon. In 70% of cases we took a word right after a preposition or next to a word it must agree with, because there the ending is fixed by the context.

For SC, we changed one word by one or two character edits (one edit in 80% of cases): a diacritic change, or a replaced, swapped, deleted, inserted, or doubled letter. We kept an edit only if the result is not a word: it must be absent from the lexicon and rejected by the hunspell spell checker.

For both tasks, we left about half of the sentences unchanged and labeled them CORRECT, teaching the model not to invent an error in a correct sentence.

**MR synthesis.** We translated GSM8K training questions (Cobbe et al., 2021) into German with the original Qwen3.5-2B, because the model han-

| Source | How it was used |
|---|---|
| Official task data (MT train; 80% of QA/SC/GC dev, 20% held out; 100% of QA/SC/GC dev plus MT dev in the final 200 steps) | core supervision |
| WMT20–22 de–hsb / de–dsb / hsb–dsb (Fraser, 2020; Libovický and Fraser, 2021; Weller-Di Marco and Fraser, 2022) (+304k/+37k/+61k pairs, decontaminated) | main MT training pairs |
| FineWeb-2 hsb/dsb (Penedo et al., 2025) (12.9M/1.9M words) | additional monolingual text |
| Instruction mix, ∼32k rows (Singh et al., 2024; Longpre et al., 2023; Zhao et al., 2024; Lambert et al., 2024; Köpf et al., 2023; Open Assistant contributors, 2023) | general instruction data to reduce forgetting, following (Purason and Fishel, 2025) |
| Dataset generated from the soblex / dolnoserbski full-form lexicons (∼20k rows/task/lang) | synthetic spelling and grammar examples |
| Reasoning chains for German GSM8K-train questions (Cobbe et al., 2021; Zelikman et al., 2022) (2,657 model chains + 785 gold solutions) | filtered examples of mathematical reasoning |

Table 2: Training data.

[1] For example, the WMT22 de–hsb training split contained 7,334 exact matches to MT test inputs.

dles German far better than Sorbian and because all our parallel data pair German with Sorbian. An earlier checkpoint of our own model (from a QLoRA run, before we switched to full fine-tuning) then sampled eight reasoning chains per question at temperature 0.7. Following STaR (Zelikman et al., 2022), we kept at most one chain per question, and only if its final answer matched the gold answer; this retained 2,657 chains. For the 785 questions where no sampled chain reached the gold answer, we used the original English GSM8K solution as the target instead, so for these questions the target is in English while the question stays in German.

### 3.2 Training regime

We used full-parameter bf16 SFT with packed 1,536-token sequences, an effective batch size of 32, paged 8-bit AdamW, and a cosine learning-rate schedule with a peak of $7 \times 10^{-5}$. Training comprised 2,000 main steps and the final 200-step pass, taking ≈55 GPU-hours in total on one 24 GB RTX 3090.

**How we evaluated training choices.** Because 80% of the QA/SC/GC development examples entered training, their full development scores were contaminated; we therefore selected models on held-out local-validation subsets. The merge and the final 200-step pass were each checked with one leaderboard submission, which is not enough to claim a real improvement (Section 6). In total we used 13 of the 20 allowed submission rounds. Table 3 summarizes the five training decisions with one primary number each.

Full fine-tuning clearly beat our tuned QLoRA baseline (all-linear rank-64, NF4-quantized base) with the data mixture, step count and batch size held fixed, and the gain was confirmed on held-out validation data — consistent with what team NRC reported at WMT25 (Larkin et al., 2025). The base-weight merge ($0.1 \cdot$ base $+ 0.9 \cdot$ fine-tune) recovered some QA and math ability (leaderboard QA +2.7 pp, MR +3.2 pp) while slightly reducing the other tasks (MT $-0.2$ chrF++, SC $-1.2$ pp, GC $-0.1$ pp), echoing team TartuNLP's WMT25 merging observation (Purason and Fishel, 2025). The released final weights are at https://huggingface.co/mkhasykov/qwen3.5-2b-wmt26-sorbian.

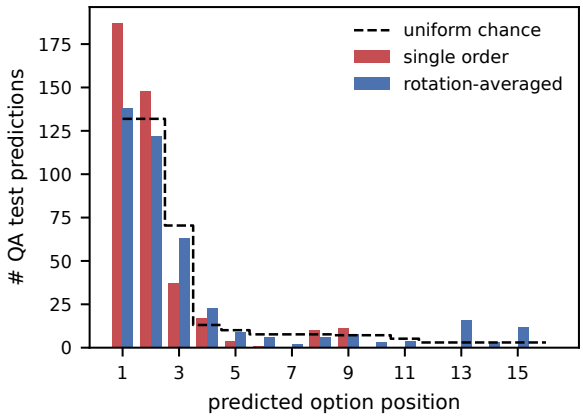

Figure 1: Predicted answer position on the QA test set. With the original option order (red), predictions collapse onto early positions; rotation averaging (blue) moves them toward the dashed line — the distribution expected if every available answer were equally likely.

## 4 Per-task decoding

The metric structure guided decoding (Table 4): MT's graded chrF++ score favored beam search, whereas SC, GC, and MR benefited from sampling votes; SC and GC also benefited from lexical constraints.

**QA position debias.** The model favored answers near the beginning of the option list. With the original option order, it never selected an answer beyond position 9, even though 92 of the 415 test questions had at least 10 options (Figure 1). We therefore rotated each option list so that every answer appeared once in every position. For each answer, we averaged its log-softmax score across these rotations and selected the highest average. This increased accuracy by 6.9 percentage points on local validation ($n$=58) and by **6.5 percentage points on the leaderboard**. Team JGU Mainz reported a similar benefit from permutation-based likelihood averaging at WMT25 (Saadi et al., 2025).

**Lexicon vote filters.** For SC and GC, we generated 16 corrections per sentence and selected the majority prediction (Wang et al., 2023). Before voting, we removed any sample whose proposed correction did not appear in the lexicon. If this removed all 16 samples, we retained the unfiltered set. We applied this filter to both languages for SC and only to Lower Sorbian for GC; the incomplete Upper Sorbian lexicon reduced local-validation accuracy.

**MR in two languages.** For each MR question we first let our model translate the question into

| Decision | Primary evidence | Caveat |
|---|---|---|
| Full fine-tuning instead of QLoRA (Dettmers et al., 2023) | local $S$ +0.111 | the comparison also changes quantization and learning rate |
| External-data bundle (parallel + monolingual + instructions + reasoning pool) | local MT +8.54 chrF++ | the four components were not ablated separately |
| Lexicon-based SC/GC synthesis | local SC +3.0 pp; GC +2.1 pp | the data recipe and task balance changed together |
| Weight averaging with the base model | leaderboard $S$ +0.009 | one leaderboard submission; $w$=0.1 was chosen by a local-validation sweep |
| Final 200-step pass (adds all QA/SC/GC and MT development examples; never MR dev) | leaderboard $S$ +0.003 | one leaderboard submission; cannot separate extra steps from the added data |

Table 3: The five training decisions and the primary evidence behind each. The decisions were made in this order, each on top of the previous ones; every number compares the model with that decision against the model without it, all other settings unchanged. "Local" numbers are on local validation; "leaderboard" numbers come from one leaderboard submission each.

| Task | Final decoding | Evidence |
|---|---|---|
| MT | beam search, 4 beams | local MT +1.5 chrF++ |
| QA | argmax after averaging option log-likelihoods over all rotations of the option order | leaderboard QA +6.5 pp |
| SC | majority vote over 16 answers sampled at $T$=0.7 (each answer: the detected word and its correction), after removing answers whose correction is not in the lexicon | leaderboard SC +3.0 pp |
| GC | the same vote, with the lexicon filter applied to Lower Sorbian sentences only | leaderboard GC +0.4 pp |
| MR | majority vote over 32 samples: 16 from the Sorbian question and 16 from its German translation by our model | local MR +14.6 pp |

Table 4: Final per-task decoding. Each delta compares the final decoding with greedy decoding of the same model.

German. We then sampled 16 answers at $T$=0.7 from the Sorbian question and 16 from the German translation, and took the majority answer over all 32 samples. If the translation lost or changed a number from the question, we discarded it and sampled all 32 answers from the Sorbian question instead.

**Inference cost.** All test outputs were generated on the same RTX 3090 with Hugging Face transformers in bf16. With greedy decoding, all five test sets take about 2–3 GPU-hours. The final decoding is several times more expensive: beam search with 4 beams over the 26,174 MT inputs, 16 samples for each of the 7,726 SC/GC sentences, 32 samples for each of the 500 MR questions (16 for the Sorbian question and 16 for its German translation), and up to 16 option rotations per QA question. In total this took roughly 10–15 GPU-hours, dominated by MR sampling and MT beam search.

## 5 Results

Table 5 shows the official final results. HeyBusan led MT, SC and GC, while team LT3 led QA and MR; the two teams tied at 22 rank points and were declared **joint winners of the Sorbian track**. Official SC/GC scores are computed differently from the leaderboard's display — the official metric averages detection and correction exact match — so the official and leaderboard numbers are not directly comparable.

## 6 Limitations

A single 24 GB GPU limited the study: each training comparison ran once, with no repeated seeds. The QA/SC/GC local holdouts were small (QA $n$=58) and did not always predict leaderboard behavior. The merge and the final 200-step pass were each evaluated with one leaderboard submission, so their small gains may simply be noise. We used

| Team | MT | QA | SC | GC | MR | Pts |
|---|---|---|---|---|---|---|
| **HeyBusan** | **72.75** | 55.92 | **78.03** | **79.52** | 29.00 | **22** |
| LT3 | 69.57 | **65.05** | 76.11 | 78.32 | **30.40** | **22** |
| Hitsz | 63.12 | 57.33 | 73.13 | 62.11 | 18.60 | 16 |
| HSE | 61.50 | 46.77 | 63.63 | 50.02 | 5.00 | 9 |
| baseline | 21.68 | 43.39 | 6.66 | 1.34 | 5.40 | 5 |

Table 5: Official final results of the Sorbian track (Okabe et al., 2026). Primary team submissions are shown with the organizers' baseline for reference; the best team score per task is in bold. Teams HeyBusan and LT3 finished level at 22 rank points and are the joint winners of the track.

13 of the 20 submission rounds and did not tune continuous parameters on the test set.

MR remained our weakest task (official accuracy 29.00) despite the synthetic reasoning data and the two-view decoding. We also overlooked the parallel and monolingual corpora released for the WMT25 edition of the task (about 190k de–hsb and 170k de–dsb sentence pairs), although the rules allowed them; this was an oversight on our part.

## 7 Conclusion

With one 2B model, one consumer GPU, and public data, HeyBusan was a joint winner of the WMT26 Sorbian track. The successful recipe combined full-parameter fine-tuning, additional public data, and task-specific decoding, led by QA option-order averaging.

## Abstract

We describe LT3's submission to the WMT26 shared task on Multitask LLMs with Limited Resources for Upper Sorbian (hsb) and Lower Sorbian (dsb): one QLoRA-fine-tuned Qwen3.5-2B model serves machine translation, multiple-choice question answering, spell checking, grammar checking, and maths reasoning. Our approach centres on three components. First, *retrieval augmentation*: fuzzy-match (FM) exemplars, retrieved by character- and embedding-based similarity from authentic and back-translated sentence pools, are included in prompts at training and inference times. Second, *synthetic task data*: training data for spell- and grammar-checking is generated from dictionaries and monolingual text. Third, a *scoring-based inference system*: the model generates free text only for the open-ended tasks–translation and maths reasoning–while, for the other three tasks, it scores candidates from constrained spaces by ranking multiple-choice options in place and selecting spelling and grammar corrections from dictionary-derived candidates. Our primary system was the joint winner of the Sorbian track, ranking first or second across all five tasks and outperforming the next-best system by 7.7 accuracy points on question answering and 1.4 points on mathematical reasoning. These results show that, for low-resource languages, FM augmentation combined with back-translation can improve MT performance for a relatively small LLM, while inference-level strategies can further improve its performance on other tasks without compromising MT performance.

Dataset · Models

## 1 Introduction

Upper Sorbian (hsb) and Lower Sorbian (dsb) are West Slavic minority languages with scarce digital resources, and the WMT26 shared task on Multitask LLMs with Limited Resources (Okabe et al., 2026) asks a single model of at most two billion parameters to serve five tasks in both languages: machine translation (MT), multiple-choice question answering (QA), spell checking (SC), grammar checking (GC), and mathematical reasoning (MR). For MT, German additionally serves as both source and target language, yielding six translation directions in total.

Our approach centres on three components. The first is **retrieval augmentation**: fuzzy-match (FM) exemplars, retrieved by character- and embedding-based similarity, are included in prompts at both training and inference. This component is motivated by prior work showing that FM augmentation improves neural MT (Bulté and Tezcan, 2019), with further gains in translation performance obtained when back-translation (BT) enlarges the pool from which FMs are retrieved (Tezcan et al., 2024), and that these benefits carry over to fine-tuned LLMs (Moerman et al., 2026). We bring this approach to a multitask LLM setting in new language directions, while changing the role of BT: fine-tuning uses only authentic sentence pairs for FM retrieval, whereas back-translated sentence pairs are also used at inference (Section 4).

The second component is **synthetic task data**: none of the four non-MT tasks comes with task-formatted training data, so we generate it, turning dictionaries and monolingual text into spell- and grammar-checking training pairs and building QA and MR items from monolingual sentences and translated seed problems (Section 5).

The third component is a **scoring-based inference system**. Only MT and MR require the model to write free text. For QA, SC, and GC it uses scoring instead. A deterministic layer lays out the possible answers, QA options in their question context, and SC and GC corrections drawn from dictionaries, and the model picks the answer to which it assigns the highest log-likelihood in place (Sec-

*Proceedings of the Eleventh Conference on Machine Translation*, pages 2668–2681
October 28-29, 2026 ©2026 Association for Computational Linguistics

tion 6).

Our primary system was the joint winner of the Sorbian track, ranking first on QA (65.05, +7.72 accuracy points over the next-best system) and outright on MR (30.40, +1.40), while placing second on the three remaining tasks.

Section 2 introduces the shared task setup. Section 4 describes our MT approach, covering data preparation, fine-tuning, and exemplar retrieval. Section 5 then details how the remaining four tasks are incorporated into training, while Section 6 presents the inference strategies applied after training.

## 2 Shared Task Setup

The WMT26 shared task on Multitask LLMs with Limited Resources (Okabe et al., 2026), continuing the WMT25 series (Okabe et al., 2025), asks one model to serve five tasks in a low-resource setting. We participated in the Sorbian track, covering Upper Sorbian (hsb) and Lower Sorbian (dsb), two West Slavic minority languages. Table 1 lists the five tasks with their output spaces, hidden-test sizes, and official metrics. MT, the only task involving German, runs over six directions (between German, Upper and Lower Sorbian, in both ways), and its hidden-test size is summed over the directions. Per-task scores average the hsb and dsb subtasks. Models must come from the Qwen 3.5 family (Qwen Team, 2026) with at most 2B parameters, the same model must serve all five tasks within a submission, training data must be publicly available, and retrieval augmentation from a clearly defined corpus is permitted at both training and inference. We refer to the task page[1] and the organisers' repository[2] for the full task, data, and rule details. The fine-tuned models we submitted are publicly released[3] together with our code and data (Appendix D).

## 3 Related Work

We highlight four lines of prior work that are utilised in our submission: (i) shared-task efforts around the Sorbian languages, (ii) retrieval augmentation for translation, (iii) language models as scorers of constrained candidates, and (iv) the training dynamics of multitask fine-tuning.

[2] https://github.com/TUM-NLP/llms-limited-resources2026

[3] https://huggingface.co/TomMoeras/wmt26-lt3-sorbian

| Task | Output space | Test | Official metric |
|---|---|---|---|
| MT | free text | 26,174 | chrF++ |
| QA | one option per slot | 415 | accuracy |
| SC | flag + correction | 4,000 | mean det./corr. EM |
| GC | flag + correction | 3,726 | mean det./corr. EM |
| MR | numeric answer | 500 | accuracy |

Table 1: The five Sorbian-track tasks. Test = hidden-test items (MT summed over six language directions, the remaining four tasks summed over hsb and dsb). SC and GC are scored as the mean of detection exact match and correction exact match, so a system must both flag erroneous sentences and reproduce the corrected sentence exactly.

**Sorbian and low-resource shared tasks.** The task setting itself has a history at WMT. Upper and Lower Sorbian entered the evaluations through the unsupervised and very low resource MT tasks (Fraser, 2020; Libovický and Fraser, 2021; Weller-Di Marco and Fraser, 2022), and the step from pure translation to a multitask LLM came with WMT25's joint MT and QA track (Okabe et al., 2025), whose participants adapted Qwen2.5 models with external data and varying fine-tuning strategies (Purason and Fishel, 2025; Larkin et al., 2025; Saadi et al., 2025). Those findings also record a first interaction between the joint tasks: training purely on MT degrades QA. We revisit that interaction along a different axis, training duration within one fixed mixture (Section 5).

**Retrieval-augmented translation.** On the translation side, prior work asks how to make better use of scarce parallel data. One answer is retrieval-augmented translation: FM augmentation concatenates retrieved translation-memory matches to the source and improves NMT (Bulté and Tezcan, 2019), embedding-based retrieval extends the idea beyond edit distance (Xu et al., 2020), and the interaction between source and retrieved match has been studied for domain adaptation, showing that controlling how strongly the model relies on the retrieved match yields further gains (Hoang et al., 2023). The same idea reappears with LLMs as exemplar selection for translation prompting (Agrawal et al., 2023; Vilar et al., 2023), including FMs in adaptive translation (Moslem et al., 2023). A second answer is to generate synthetic data: back-translation (Sennrich et al., 2016) converts monolingual text in the target language into synthetic source-target pairs, although Edunov et al. (2018) show that using such pairs for training can be detrimental in some settings. The two lines of work

converge in Tezcan et al. (2024), who combine FM augmentation with back-translation for NMT, and Moerman et al. (2026), who extend this combination to LLMs. We build on this combination but split it by stage: authentic sentence pairs serve FM retrieval during training, while synthetic pairs obtained through back-translation are added to the pool for retrieval at inference, and we measure each stage's effect (Section 4). To our knowledge, neither this separation nor the role of exemplar provenance in training stability has been studied before.

**Scoring rather than generating.** The non-generation tasks draw on a different tradition, in which a language model scores constrained candidates rather than generating freely. For multiple choice, scoring the likelihood of each option is the standard evaluation convention (Brown et al., 2020), with known calibration caveats (Holtzman et al., 2021; Zhao et al., 2021), and when several questions share one option bank, the choices become a joint-assignment problem, which SCDE (Kong et al., 2020) poses for sentence cloze and solves by exhaustive enumeration. The same generate-candidates-then-score pattern has a long history in spelling correction, where a candidate generator proposes, and a language model decides in context (Kernighan et al., 1990; Brill and Moore, 2000), a recipe carried to Slavic spelling and diacritics by Korektor (Richter et al., 2012). For grammatical error correction, synthetic corruptions substitute for scarce annotated data (Náplava and Straka, 2019), and the acceptability judgement itself can come from a language model (Yasunaga et al., 2021). Even translation decoding has used the same principle, re-scoring hypotheses with a noisy-channel model (Yee et al., 2019). In each of these lines, the scorer is built separately for its task. In our system, a single fine-tuned model plays that role for QA, SC and GC at once (Section 6). We also depart from SCDE in how we find the assignment, computing the best one directly (Kuhn, 1955) instead of trying every combination, and we accept a correction only when real corpus text attests it.

**Fine-tuning dynamics and checkpoint selection.** Finally, packing several tasks into one set of weights raises the question of when to stop training. Koh et al. (2026) document heterogeneous per-task overfitting in multitask supervised fine-tuning (SFT): under one shared budget, sub-datasets reach their optima at different steps. Selecting the stopping point by validation loss has its own pitfall, as Isik et al. (2025) show that held-out cross-entropy can keep improving monotonically while translation quality worsens. Both observations appear in our training trajectories and informed how we selected final checkpoints (Section 5).

## 4 Machine Translation

We first developed the MT component and subsequently built the remaining system components around it. A working MT engine serves the six required translation directions directly, but it also allows us to generate back-translations that enlarge the pool of sentences used for retrieval-based MT, and to translate the English seed problems to generate additional MR training data for Upper and Lower Sorbian languages (see Section 5).

### 4.1 Parallel Data and Back-Translation

The authentic parallel data combines the organiser-provided datasets with public German–Sorbian corpora from earlier WMT editions: the German–Upper Sorbian sets from WMT2020–2022 and the German–Lower Sorbian and Upper–Lower Sorbian sets from WMT2022. Although the available parallel corpora are broadly comparable across language pairs, we observed a clear asymmetry in translation performance: for both the zero-shot base model and models fine-tuned on the available (authentic) parallel datasets, performance was substantially lower when translating from German into either Sorbian variety.

To improve these lower-performing German-source directions, we back-translated additional monolingual Sorbian data provided by the organisers and drawn from public Sorbian corpora into German (Sennrich et al., 2016), using the corresponding fine-tuned Sorbian-source models. This yielded additional synthetic German–Sorbian sentence pairs for the de→hsb and de→dsb directions.

Table 2 summarises the total number of authentic sentence pairs for each translation direction, the additional synthetic sentence pairs generated through back-translation, and the chrF++ scores of both the zero-shot base model and the fine-tuned models on the gold development sets.

### 4.2 Fuzzy-Match Retrieval

In FM augmentation, the model retrieves translations of source sentences similar to the input (fuzzy matches, FMs) from a translation memory (TM)

| | MT data (pairs) | | | chrF++ | |
|---|---|---|---|---|---|
| Direction | Authentic | Synthetic | Total | Base | FT |
| de→hsb | 261,764 | 500,000 | 761,764 | 7.66 | 53.60 |
| de→dsb | 113,680 | 165,738 | 279,418 | 7.58 | 49.37 |
| hsb→de | 261,764 | – | 261,764 | 30.77 | 62.54 |
| dsb→de | 113,680 | – | 113,680 | 25.34 | 59.57 |
| hsb→dsb | 159,193 | – | 159,193 | 40.65 | 73.91 |
| dsb→hsb | 159,193 | – | 159,193 | 42.92 | 73.98 |
| total | 1,069,274 | 665,738 | 1,735,012 | | |

Table 2: The overview of the data sets and the MT performance. Number of authentic sentence pairs, synthetic sentence pairs and total number of sentence pairs per language direction, combined with the chrF++ scores, on the gold development sets, of the zero-shot base model (Base) and of the fine-tuned (FT) models that utilise the authentic datasets.

and leverages them alongside the input to produce MT output. The technique improves neural MT performance (Bulté and Tezcan, 2019), with further gains when the pool from which FMs are retrieved is expanded through back-translation (Tezcan et al., 2024), and has also been shown to improve translation performance in fine-tuned LLMs (Moerman et al., 2026). We build directly on this line and extend it to a multitask LLM setting, with one adjustment: Moerman et al. (2026) used the back-translated pairs during fine-tuning as well, whereas in this work, fine-tuning relies entirely on authentic sentence pairs, while back-translated pairs additionally serve FM retrieval only at inference. The noisier synthetic pairs therefore never reach training, but still provide additional value at inference: using them to expand the FM retrieval pool yields a modest further improvement in chrF scores (see Table 3). In the **training stage**, we sample the number of in-context exemplars per row uniformly from $\{0, 1\}$: a seeded 50% of MT training rows carry exactly one top-1 FM retrieved (only) from the authentic pairs (one-shot), and the remaining rows carry none (zero-shot). This uniform-sampling (0/1) scheme was the most effective configuration in Moerman et al. (2026), drawing on the uniform shot-count sampling of Alves et al. (2023). It differs from the **inference stage**, where every test source retrieves $k = 3$ FMs from the full authentic+BT pool. Retrieval ranks candidates by cosine similarity of MiniLM sentence embeddings (Wang et al., 2020) with FAISS indexing (Johnson et al., 2019) for the German-source directions, and, because the embedding model does not cover Sorbian, by character-set Jaccard similarity for the Sorbian-source directions. Figure 1 walks one example through both stages. The example also illustrates why the enlarged retrieval pool by the synthetic sentence pairs may lead to improvements in translation performance: all three of the retrieved exemplars at inference are synthetic BT pairs, close neighbours that are markedly more similar to the source than anything the authentic-only pool of the training stage offers. Back-translated pairs exist only for the two German-source directions, and there they dominate retrieval: 65.9% of the exemplars retrieved for de→hsb and de→dsb are synthetic BT (72.4% and 60.0% respectively). The four Sorbian-source directions are retrieved from authentic-only pools, so no synthetic pair is ever retrieved for them. Fine-tuning uses none. We validate both design choices at the end of this section.

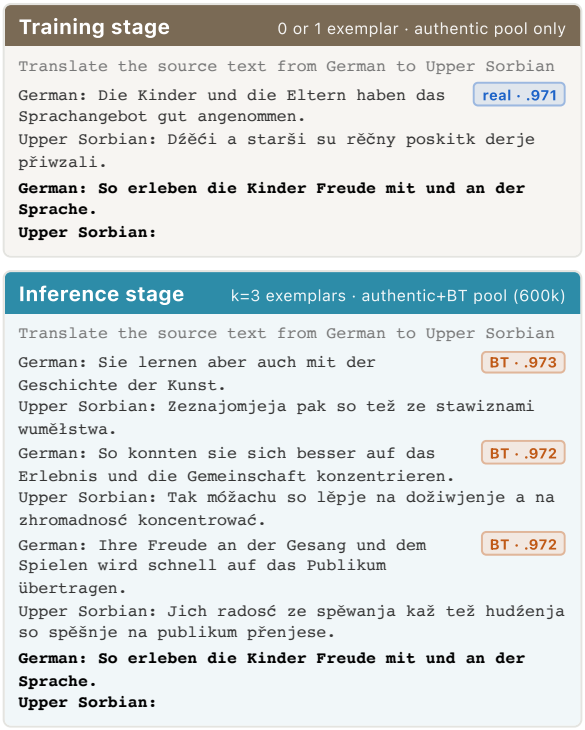

Figure 1: The two retrieval stages on the same deu→hsb development-set source (bold). During training, under uniform sampling (0/1), 50% of the training rows are augmented with one FM retrieved from the authentic TM (real), while the remaining 50% contain no FMs (zero-shot). At inference, we retrieve three FMs from the full authentic+BT TM. For this source, all three highest-similarity FMs originated from back-translated (BT) pairs, where the corresponding cosine similarity score is shown for each FM.

### 4.3 MT Fine-Tuning

The MT training set contains 1,069,344 rows of authentic parallel data only, rendered under the uniform-sampling (0/1) scheme above (one seeded

carrier mask fixes which rows carry an FM). We fine-tune Qwen3.5-2B with QLoRA (Dettmers et al., 2023) at rank 256 (full training configuration in Appendix B).

### 4.4 Validating the Configuration

The choices above, fuzzy rather than random carriers and BT kept out of the fine-tuning rows, were validated on the gold development sets (Table 3). On the base model, in-context FMs used only during inference (not during fine-tuning) reduce MT performance: averaged over all language directions, zero-shot scores 25.82 chrF++, three random exemplars 24.74, and three FMs 24.61. We hypothesise that this is an effect of model scale: in-context learning is known to be effective for MT specifically (Moslem et al., 2023; Moerman et al., 2026), but with larger models, and few-shot ability in general strengthens with model size (Brown et al., 2020). The improvements that follow therefore rely on combining fine-tuning with in-context exemplars, together lifting MT performance by nearly fifty chrF++ points. We compare four fine-tuning recipes, crossing the carrier exemplar selection (fuzzy versus random) with the source of the fine-tuning rows (authentic only versus authentic+BT), and evaluate each recipe at its converged optimum under four inference settings that cross the same two choices on the retrieval side. Figure 2 traces the four recipes across the training schedule. Training to convergence separates them: the recipe of our primary system, fuzzy carriers drawn from authentic rows, improves progressively to a 76.05 plateau at 48k, while the other three peak by 12–15k and then degrade. A plausible reading is that fuzzy carriers keep the exemplar informative, so the copy-and-adapt behaviour they teach keeps improving with more training, whereas random exemplars and synthetic German pairs act as noise that longer training increasingly overfits to. The main improvement thus comes from fuzzy carriers during training, drawn from authentic rows only: at convergence the fuzzy-over-random margin is $+3.63$, and authentic-only rows end $+6.26$ ahead of authentic+BT rows under fuzzy carriers. The inference-side choices matter far less. Retrieving FMs rather than random exemplars adds 0.25 chrF++ on the converged primary recipe, and enlarging the retrieval pool with BT adds a further 0.06, which brings the deployed configuration to 76.11, the best cell of the grid. Notably, the random-trained recipes gain nothing from fuzzy retrieval at inference, so the ability to exploit retrieved exemplars is itself learned during fine-tuning.

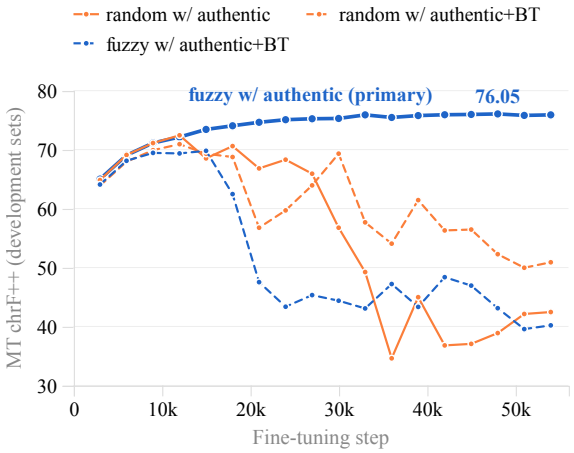

Figure 2: Development-set MT chrF++ of the four fine-tuning recipes averaged over de→hsb and de→dsb (carrier exemplar selection w/ fine-tuning row source), all trained under uniform sampling (0/1). All four curves use the same inference at every checkpoint, $k = 3$ FMs retrieved from the authentic pool, so only the fine-tuning recipe differs. Markers show the evaluated checkpoints. Only the chosen configuration converges upward to a 76.05 plateau, while the other three peak by 12–15k steps and degrade under further training.

## 5 Folding In the Other Tasks

With the MT engine in place, the remaining four tasks are folded into the same model via task-specific fine-tuning.

### 5.1 Synthetic Task Data

For the four non-MT tasks, no training data exists in the task format: the only task-formatted data, the organiser development sets, is reserved for evaluation and selection, and what remains is raw monolingual corpora. We therefore synthesised the training data, using a different strategy per task. For SC, character-level typo injection turns clean sentences into (erroneous, corrected) pairs. For GC, morphological paradigm-swap corruptions generated with the soblex (Baier et al., 2026) and dsb-spell (derbnik, 2024) lexicons play the same role, following the synthetic-corruption route of low-resource GEC (Náplava and Straka, 2019). For QA, cloze-style multiple-choice items are built from monolingual sentences. For MR, public English seed problems (GSM8K (Cobbe et al., 2021) and MATH (Hendrycks et al., 2021), with PolyMath excluded per the track rules) were translated into Sorbian by the best-performing MT engine (Section 4), each paired with a worked so-

| | *Inference* | | | |
|---|---|---|---|---|
| | fuzzy | | random | |
| *Fine-tuning* | auth. | auth. +BT | auth. | auth. +BT |
| *no fine-tuning (zero-shot 25.82)* | | | | |
| base model | 24.61 | – | 24.74 | – |
| *authentic* | | | | |
| fuzzy | 76.05 | **76.11** | 75.80 | 75.80 |
| random | 72.42 | 72.44 | 72.40 | 72.40 |
| *authentic + BT* | | | | |
| fuzzy | 69.79 | 69.97 | 68.55 | 68.34 |
| random | 70.92 | 70.99 | 70.87 | 70.84 |

Table 3: Development-set MT chrF++, averaged over the six directions, for the base model and for each fine-tuning recipe (carrier selection within row source, evaluated at its converged optimum) under the four inference settings (exemplar selection within retrieval pool, $k = 3$ throughout).

| | | Synthetic | |
|---|---|---|---|
| Task | Original (dev. sets) | hsb | dsb |
| SC | 4,000 | 100,000 | 15,000 |
| GC | 3,250 | 100,000 | 15,000 |
| QA | 158 | 60,000 | 12,000 |
| MR | 48 | 28,147 | |

Table 4: Number of items in the original versus synthesised task data for the four non-MT tasks (hsb and dsb combined). The organiser development sets are the only task-formatted data provided, and they are reserved for evaluation and selection, so all task-formatted training data is synthesised.

lution. The per-language volumes follow the available monolingual data, whose clean-sentence supply is roughly six times smaller for dsb than for hsb. Table 4 contrasts these synthetic volumes with the only original task-formatted data that exists, the organiser development sets.

### 5.2 The Multitask Mix

The base mix combines the 1,069,344 MT training rows of Section 4, the authentic per-direction rows of Table 2 summed over the six directions, with the synthetic data sets generated for the remaining four tasks, as provided in Table 4, upsampled to fixed shares: 1,397,057 rows in total, of which MT 76.5%, MR 7.0%, SC 6.3%, GC 6.3%, and QA 3.9%. One QLoRA run over this mix produces the base multitask model.

### 5.3 Three Fine-Tuning Phases

Fine-tuning proceeds in three phases (Table 5).

**Phase 1: the multitask base model.** Phase 1 trains the base model on the mix above. Tracking all five tasks on the development sets along this run reveals a clear split (Table 6). Three tasks improve for as long as we train, up to our last training step (27,000): MT (+12.1 chrF++), SC (+.165) and GC (+.162), while QA peaks at 9,000 steps and slowly declines thereafter, and MR fluctuates on its small development slice. No single checkpoint is best for every task, so selection goes by the equal-weight average, which climbs to a broad optimum between 18,000 and 27,000 steps, and even QA's early peak costs only .044 from inside that region. Appendix A plots the full trajectory.

**Phase 2: GC continuation.** Even at its phase-1 best, GC remains the weakest task, so phase 2 targets it: starting from the merged phase-1 weights, a short continuation trains on a mixture dominated by GC corruptions produced with the same generator as above, at larger volume (520k rows, 63.4% of an 820k-row mixture). The continuation converts the remaining GC headroom while holding the other tasks (Table 7): GC gains +.116 and saturates within 3,000 continuation steps, SC and MR drift up slightly, QA stays flat, and MT gives up half a chrF++ point. The development-set optimum lies at continuation step 3,500, on the GC plateau. In short, increasing the share of GC data in the training mixture improved GC further at little cost to the other tasks.

**Phase 3: folding in the development sets.** Phase 3 asks whether the scarce organiser development sets can themselves add value as training data: it adds the development sets to the phase-2 mixture (+31,614 rows, rendered in the official evaluation formats so that training examples match the inference format exactly), again starting from the merged phase-1 weights. Both continuations train adapters that merge onto the merged phase-1 weights. A development-folded model can no longer be evaluated or selected on the development sets it has seen, so its effect shows only on the hidden test, where it is worth +.002 aggregate (Section 8), and checkpoint selection needs dedicated protocols. We define three protocols and build three corresponding submission types around them (Section 7). **EarlyStop** picks the checkpoint minimising mean cross-entropy on a frozen held-out slice, using no development and no test signal. **DevTransfer** transfers the checkpoint step from the phase-2 sibling, which never saw the development sets and may therefore be selected on them. **HeldOutDev** simply stops at phase 2. The primary

| Phase | Training mixture | Starts from |
|---|---|---|
| 1 multitask base | 1,397,057 rows | Qwen3.5-2B |
| 2 GC continuation | 300k + 520k GC corruptions (820k) | merged phase 1 |
| 3 development fold | phase-2 mixture + 31,614 devel. rows | merged phase 1 |

Table 5: The three fine-tuning phases. Phases 2 and 3 are QLoRA continuations whose adapters merge onto the merged phase-1 weights. Phase 3 differs from phase 2 only by folding the organiser development sets into the training mixture. Submissions run phase-3 weights except FullStack-HeldOutDev, which stops at phase 2 (Table 9).

| Checkpoint | MT | QA | SC | GC | MR | eqw |
|---|---|---|---|---|---|---|
| 3,000 | 62.54 | .611 | .556 | .474 | .208 | .495 |
| 9,000 | 70.12 | **.620** | .643 | .545 | **.229** | .548 |
| 15,000 | 72.53 | .554 | .682 | .600 | .188 | .550 |
| 24,000 | 74.29 | .576 | .714 | .630 | **.229** | **.578** |
| 27,000 | **74.65** | .589 | **.721** | **.636** | .188 | .576 |

Table 6: Development-set scores along the phase-1 trajectory (best per column in bold), where eqw corresponds to the equal-weight average after the chrF++ scores for MT were divided by 100 for scale normalisation.

system, FullStack-DevTransfer, follows the DevTransfer protocol: it runs phase 3 for 3,500 continuation steps on top of the phase-1 checkpoint (each continuation counts its steps from zero), and transfers the step count from phase 2's development-set optimum.

## 6 Inference Strategies

At inference, the frozen model plays two roles. For the open-ended tasks, MT and MR, it **generates** free text. For the three remaining tasks, it **scores** instead: the output space is enumerable, so a deterministic layer builds the candidates and the model only ranks them by the log-likelihood it assigns. It consults the model's own scores, dictionary resources, and corpus statistics from the same enumerated corpora as the training data. Figure 3 shows why scoring is relatively compute-efficient: while free text generation needs one forward pass per output token, in scoring, a full candidate is scored in a single pass and whole batches of candidates are scored in parallel.

### 6.1 Machine Translation (Generation)

MT decodes greedily with $k = 3$ FMs retrieved from the full authentic+BT pool (the inference stage of Section 4).

| After phase | MT | QA | SC | GC | MR | eqw |
|---|---|---|---|---|---|---|
| 1 (step 24,000) | **74.29** | **.576** | .714 | .630 | .229 | .578 |
| 2 (+3,500 cont.) | 73.81 | .570 | **.731** | **.746** | **.250** | **.607** |
| 3 (+ devel. fold) | hidden test: +.002 (Table 11) | | | | | |

Table 7: Effect of each training phase on the development scores (eqw as in Table 6, best per column in bold). The phase-2 continuation converts GC headroom at little cost elsewhere. Phase 3 trains on the development sets, so its effect is measurable only on the hidden test.

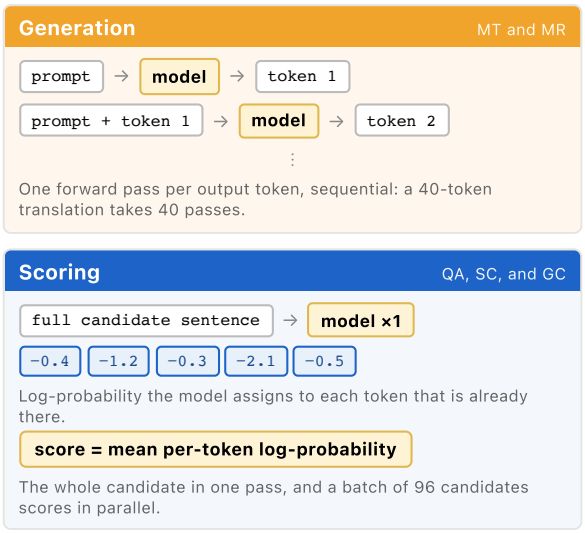

Figure 3: Generation and scoring use the same weights and the same forward computation. Generating runs one sequential forward pass per output token. Scoring runs one pass over a full candidate and reads off the log-probability of every token that is already there (values illustrative).

### 6.2 Question Answering (Scoring)

QA options are never free-generated. We place each option in the question context and score it by the log-likelihood the model assigns to it, following the standard likelihood-scoring convention for multiple choice (Brown et al., 2020). One question, for example, asks for the right reply to *Dźakuju so!* ('Thank you!'), offering exactly two options, *Tu prošu!* ('Here you are!') and *Hdźe su moje knihi?* ('Where are my books?'). Each option follows the answer prompt in turn, and in this example, the model's log-likelihood prefers the first. Items where several questions share one option bank are solved jointly: one development cloze passage has twelve gaps drawing on a single 16-word option bank (four words are distractors), so scoring every word in every gap yields a $12 \times 16$ cost matrix, and an algorithm (Kuhn, 1955) fills all twelve gaps at once with the globally optimal one-to-one assignment, preventing the same option from being spent twice. The same joint setting appears in the

sentence-cloze task of Kong et al. (2020), which resolves it by exhaustively trying candidate assignments, where the assignment algorithm reaches the same optimum directly. Remaining items take the per-slot argmax.

### 6.3 Spell and Grammar Checking (Scoring)

**Spell checking.** SC must find the misspelt word in a sentence and produce its exact correct spelling. The model approaches this as a text generation task: prompted in the tagged format of Appendix C, it outputs the word it considers misspelt together with a proposed correction, and the flagged word is kept. Producing the exact corrected form is where a small model is weakest, so we additionally employ a dictionary layer to compensate. Drawing on the hunspell (Németh, 2026) lexicon for each language, soblex for Upper Sorbian (Baier et al., 2026) and dsb-spell for Lower Sorbian (derbnik, 2024), the engine retrieves candidate corrections for the flagged word: dictionary words within edit distance two of it (Burkhard and Keller, 1973), other inflected forms of the same word, and diacritic variants. Every candidate is substituted into the sentence, the resulting sentences are scored in one batch (Figure 3), and the best-scoring correction wins. This division of labour, where a dictionary proposes candidates and a language model picks among them in context, is the classical noisy-channel approach to spelling correction (Kernighan et al., 1990; Brill and Moore, 2000), applied to Slavic spelling and diacritics by Korektor (Richter et al., 2012). Here the fine-tuned multitask model itself plays the language-model role. One example illustrates how this works. In a sentence containing *twarški*, a word absent from the lexicon, the diacritic generator proposes *twarski* ('construction', adjectival), and the corrected sentence scores a log-likelihood of $-3.84$ against $-4.39$ for leaving the sentence unchanged, so the correction is applied. It matches the gold correction, and for this word the edit-distance and paradigm generators contribute no candidates.

**Grammar checking.** GC uses the same approach as the spell-checking task, but focuses on grammatical forms rather than spellings: the candidates are the inflected forms of the flagged word. Corrections the model flags itself always enter the output, and the engine may add one of its own only when two independent signals agree: its scoring margin is high, and the proposed form actually occurs next to its neighbouring words in the reference corpora (a bigram witness). Prior work accepts a correction whenever a language model scores it above nearby variants, trusting the model's preference alone (Yasunaga et al., 2021). The bigram witness adds a stricter, external requirement: the proposed form must also actually occur next to the same neighbouring words somewhere in the reference corpora. To our knowledge, requiring this corpus attestation on top of the model's own preference is new. The exact decision rule and every fitted threshold are in Appendix B. For example, in … *dokument móže so wot 1. awgust 2022 tež z pomocu widejoweje komunikacije wobkrućić* ('…the document may be confirmed from 1 August 2022 also via video communication', with *awgust* left in the nominative where the ordinal date requires the genitive), the model flags nothing, and the engine proposes *awgust* → *awgusta* from 302 paradigm candidates with a scoring margin of 0.059 and a witness value of 5.013. With the hsb weight of 0.1 the combined evidence reaches 0.561, above the hsb threshold of 0.42, so the correction is applied. *awgusta* is the gold form, so the corpus witness recovers a correct fix that the scoring margin alone would have left in place.

### 6.4 Maths Reasoning (Generation)

MR generates a worked solution and extracts the final numeric answer. Empty or unparseable answers enter a three-stage retry ladder: two strict retries, then one sampled retry at temperature 0.7, and a notation post-formatter normalises bare LaTeX in the answer field. The two strict retries target the two common failure modes, a truncated chain and a missing answer tag (the second appends an explicit answer-now continuation), and the sampled retry is a last resort. On the hidden test, 74.4% of items are answered on the first attempt, 7.2% recovered at the first retry and 18.4% at the second, and none required the sampled retry. For *Jedyn šat žada sej 2 kuli módreje wołmy a poł tak wjele běłeje wołmy. Kelko kulow trjebaš cyłkownje?* the model reasons in English (*The number of white yarn balls is 2/2=1. So the total number of yarn balls is 2+1=3.*) and emits `<answer> 3 </answer>`, the gold answer, without triggering the retry ladder.

### 6.5 Validating the Inference Strategies

Measured under the same development-set protocol as Figure 2, Table 8 isolates the inference strategies within the submission lineage. These infer-

| Submission lineage | MT | QA | SC | GC | MR |
|---|---|---|---|---|---|
| plain decoding | 72.04 | .60 | .71 | .74 | .17 |
| full strategies (as deployed) | 72.05 | .78 | .75 | .77 | .21 |

Table 8: Development-set scores of the submission-lineage weights with and without the inference strategies. The strategies drive QA, SC, GC, and MR, leaving MT nearly untouched.

ence strategies improve the performance of four of the five tasks, with MT remaining essentially unchanged (Table 8).

## 7 Submissions to the shared task

We submitted five systems in a $2 \times 2 + 1$ design (Table 9), **FullStack-DevTransfer** (the primary system), **FullStack-EarlyStop**, **FullStack-HeldOutDev**, **Plain-DevTransfer**, and **Plain-EarlyStop**, built so that pairwise comparisons on the hidden test each isolate one design decision: the inference strategies, the checkpoint-selection protocol, or the use of the development fold. The Plain systems run the same weights as their FullStack counterparts with the deterministic inference layer switched off, isolating the inference strategies of Section 6. With the layer off, every task is answered by free-text generation from the same base prompts (Appendix C): QA and the two checking tasks take the model's generated string directly, with no candidate scoring or dictionary retrieval, and MR runs without the retry ladder. MT is unchanged, since its FM retrieval is part of the translation method rather than of the inference layer. The Plain systems are therefore pure text generation. Contrasting EarlyStop with DevTransfer isolates the checkpoint-selection protocol of Section 5. FullStack-HeldOutDev runs the phase-2 weights, which were never trained on the development sets and are therefore selected directly on them, isolating the development fold.

## 8 Results

**Official results.** Table 10 reports the organisers' final evaluation. Our primary system, FullStack-DevTransfer, was designated joint winner of the Sorbian track. It wins QA (65.05, +7.72 accuracy points over the next-best system) and MR (30.40, +1.40), and places second on MT, SC, and GC. The two tasks on which our submission ranks first, QA and MR, are answered with the additional inference strategies of Section 6. These strategies are also applied to spelling and grammar checking, where our submission ranks second.

| System | Selection | Devel. | Strategies |
|---|---|---|---|
| FullStack-DevTransfer† | DevTransfer | in | full |
| FullStack-EarlyStop | EarlyStop | in | full |
| FullStack-HeldOutDev | direct | out | full |
| Plain-DevTransfer | DevTransfer | in | off |
| Plain-EarlyStop | EarlyStop | in | off |

Table 9: The five submitted systems († = primary). Selection = checkpoint-selection protocol, where direct means selected on the development sets themselves. Devel. = whether the development fold is in the training mixture. Each Plain system shares its weights with the FullStack system above it, so Plain-vs-FullStack contrasts measure the inference strategies alone. We use these system names consistently throughout the paper.

| Team | MT | QA | SC | GC | MR | Points |
|---|---|---|---|---|---|---|
| LT3 (ours) | 69.57 | **65.05** | 76.11 | 78.32 | **30.40** | 22 |
| HeyBusan | **72.75** | 55.92 | **78.03** | **79.52** | 29.00 | 22 |
| Hitsz | 63.12 | 57.33 | 73.13 | 62.11 | 18.60 | 16 |
| HSE | 61.50 | 46.77 | 63.63 | 50.02 | 5.00 | 9 |
| baseline | 21.68 | 43.39 | 6.66 | 1.34 | 5.40 | 5 |

Table 10: Official Sorbian-track results (organisers' final evaluation, metrics as in Table 1, best per task in bold). LT3 and HeyBusan were the joint winners of the track based on the total rank points summed over all tasks.

**Test-scored ablations (proxy metrics).** Table 11 compares the five submitted systems on the hidden test as scored by the submission-phase OCELoT leaderboard, whose **proxy metrics** differ from the official ones (SC and GC as joint both-field accuracy, stricter than the official mean of detection and correction, and MR without mathematical-equivalence checking), so these numbers are never comparable to Table 10. The inference strategies are the dominant factor: switching them off (FullStack-DevTransfer vs Plain-DevTransfer) costs 14.7 QA points, 10.1 SC, 4.6 GC, 6.8 MR, and 0.3 MT (Figure 4). This agrees with the development-set results in Table 8, where we measured the same strategies before the test phase.

Measured at a fixed submission-phase snapshot, before the final SC and MR levers landed, the strategies were worth +.049 on the leaderboard's aggregate score (per-task QA +14.7, GC +4.6, SC +4.4, MR +0.4, MT +0.3). The other two components are small by comparison: checkpoint selection by transfer rather than cross-entropy early stopping is worth +.007 aggregate, and the development fold +.002. MT barely moves across all five systems (68.6 to 69.1), consistent with the strategies leaving generation untouched apart from exemplar retrieval.

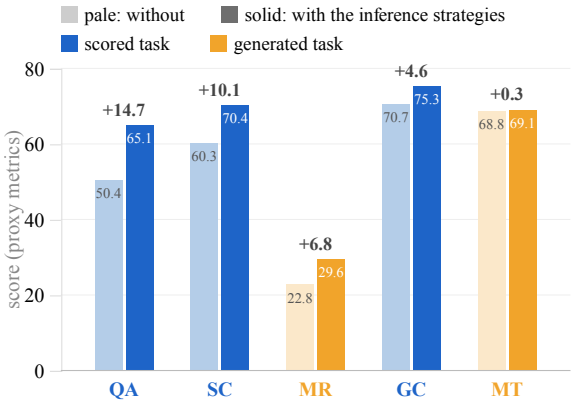

Figure 4: Hidden-test scores per task with and without the inference strategies (Plain-DevTransfer vs FullStack-DevTransfer, proxy metrics). The scored tasks (blue) gain the most, led by QA, while MT, where the strategies only add exemplar retrieval, barely moves. MR (generated) gains through the retry ladder and development-set retrieval guards.

| System | MT | QA | SC | GC | MR |
|---|---|---|---|---|---|
| FullStack-DevTransfer | 69.1 | 65.1 | 70.4 | 75.3 | 29.6 |
| FullStack-HeldOutDev | 69.1 | 63.6 | 64.6 | 75.0 | 24.0 |
| FullStack-EarlyStop | 69.0 | 63.9 | 64.5 | 74.5 | 21.8 |
| Plain-DevTransfer | 68.8 | 50.4 | 60.3 | 70.7 | 22.8 |
| Plain-EarlyStop | 68.6 | 49.4 | 60.9 | 68.9 | 22.2 |

Table 11: Hidden-test scores of the five submitted systems under the submission-phase proxy metrics (defined in the accompanying paragraph), not comparable to the official numbers in Table 10. Plain rows share weights with their FullStack counterparts (Table 9), so the FullStack-vs-Plain gaps measure the inference strategies alone.

## 9 Discussion and Conclusion

Two findings stand out. Firstly, the additional inference strategies help. Our submission ranks first on QA and MR and second on SC, GC and MT. Switching the strategies off costs 14.7 proxy points on QA and 10.1 on SC, while MT, where they only add exemplar retrieval, moves by 0.3 (Figure 4). The largest gains occur on the three scored tasks, which suggests that, for a 2B model, the bottleneck is producing exact surface forms. In other words, it is able to judge whether a word is (in)correct but is not able to give the corrected form without additional help. Letting the model choose between candidate answers, rather than write them, therefore plays to its strength. MR, which remains a generation task, gains instead from the retry ladder and the development-set retrieval.

Secondly, the MT results highlight the importance of both how the model is trained and how retrieval is used at training and inference. The retrieval-based approach only pays off with sufficient training and when exemplars are retrieved from the authentic sentence pool during training. With limited training, fuzzy and random training exemplars perform similarly on the development sets. The difference emerges with longer training: only the fuzzy-on-authentic recipe keeps improving, yielding $+3.63$ chrF++ ahead at convergence, while every other recipe peaks early and degrades (Figure 2). A similar pattern emerges for BT placement: under FM retrieval, authentic-only fine-tuning yields $+6.26$ ahead of BT-containing rows. Both design choices from Section 4 therefore become visible only when training to convergence, highlighting a potential limitation of exemplar-selection studies conducted under small, fixed training budgets. Importantly, this preference for authentic data applies to training, not inference. Across the converged optima, enlarging the inference-time retrieval pool with BT pairs never hurts under FM retrieval and yields modest gains of up to $+0.2$ chrF++, whereas random exemplar selection cannot exploit the larger pool.

To conclude, we fine-tuned a single 2B model to serve five tasks in Upper and Lower Sorbian. We first focused on the translation task: a strong MT model let us back-translate the large monolingual corpora into synthetic parallel data, and that data enlarged the fuzzy-match pool the final model retrieves from at inference. We then folded the remaining tasks into the same weights and answered them by scoring candidates derived from dictionaries and corpora. This combination of retrieval and scoring made our system joint winner of the Sorbian track. All artefacts, code, weights, and data are publicly available (Appendix D).

## Limitations

The main limitation is scope in the sense that everything here is measured on one track, two closely related West Slavic languages, and one 2B base model. We make no claim that the recipe transfers to other language pairs or model scales. More generally, we designed the submission to maximise the shared task's automated metrics. For tasks where human judgement is the real standard, such as MT, a human evaluation could tell a different story than the automated metrics.

Further, we chose several inference thresholds to maximise development-set scores, so some measured gains may not carry over to unseen data, and

the reported gains from these fitted components should be read as upper estimates.

Finally, all cross-system ablations (Table 11) use the submission-phase proxy metrics, which differ from the official metrics for SC, GC, and MR (Section 8), so the two result families are not directly comparable.

## Acknowledgements

We thank the WITAJ-Sprachzentrum for the Sorbian data underlying the task, in particular Beate Brezan, Anita Hendrichowa, and Marko Meskank, with maths annotation by Krystof Persin and language certificate materials by Tomas Solta. We thank the organisers at TUM for running the shared task and for their responsiveness throughout. The computational resources (Stevin Supercomputer Infrastructure) and services used in this work were provided by the VSC (Flemish Supercomputer Center), funded by Ghent University, FWO and the Flemish Government.

## A Training-Length Trade-off

Figure 5 plots the full trajectory behind the cross-task trade-off of Section 5 (Table 6). The run uses the training mixture of Section 5 and the hyperparameters of Table 12 on an annealed schedule truncated at 27k of 36k planned steps, with checkpoints every 3,000 steps, each evaluated on the gold development sets with plain decoding and MT $k = 3$ fuzzy retrieval. Full per-checkpoint numbers accompany the released artefacts (Appendix D).

## B Hyperparameters and Final Configurations

Table 12 lists every fitted inference value of the primary system together with the shared training hyperparameters. The GC engine may act alone (union arbitration) only when margin $+ w \cdot$ witness $\geq t$ with the per-language $(w, t)$ below. The *margin* is the null-margin of the scoring engine: the model's log-likelihood of the sentence with the best candidate correction substituted minus that of the unedited sentence. The *witness* is a corpus bigram-attestation score, witness $=$ bg(candidate) $-$ bg(observed), with bg$(w)$ $=$ $\log(c_{\text{left},w} + 0.5) + \log(c_{w,\text{right}} + 0.5)$, where $c$ counts the bigram of the word $w$ with its left or right neighbour in the reference-corpus bigram table. We fitted the witness weight and threshold via an id-parity cross-fit on the gold development sets.

| Component | Parameter | Value |
|---|---|---|
| MT | decoding | greedy |
| MT | exemplars, training | uniform sampling (0/1), 50% carriers, authentic, cap 100k |
| MT | exemplars, inference | $k = 3$ (authentic+BT) |
| QA | option scoring | in-place log-likelihood |
| QA | shared option banks | Hungarian assignment |
| SC/GC | candidate engine | BK-tree edit distance 2 |
| SC/GC | scoring batch / cands | 96 / 24 |
| GC | paradigm cap | 60 |
| GC | witness hsb $(w, t)$ | $(0.1,\ 0.42)$ |
| GC | witness dsb $(w, t)$ | $(0.4,\ 0.76)$ |
| SC | paradigm cap | 30 |
| SC | diacritic top-up | dsb only, min freq 5 |
| SC | non-word top-up $\tau$ | hsb 0.30, dsb 0.36 |
| MR | retry ladder | 2 strict + 1 sampled ($T$=0.7) |
| MR | development retrieval | similarity $\geq 0.95$ |
| all | LoRA rank / $\alpha$ | 256 / 512 |
| all | learning rate | 2e-5 (phase 1)<br>1e-5 (continuations) |
| all | batch / grad. accum. | 8 / 2 |
| all | sequence length | 1024 |
| all | LR schedule | linear anneal to 0 |
| all | generation seed | 1234 |

Table 12: Fitted inference configuration of the primary system FullStack-DevTransfer. SC/GC engine rows are shared. The two MT exemplar rows are the two retrieval stages of Section 4.

## C Prompt Formats

All prompts are rendered through the model's chat template as single user messages, with thinking disabled. The templates below are verbatim from the released inference code.

**MT.** Exemplars precede the source as plain language-labelled lines. The inference prompt carries $k = 3$ exemplar pairs, and a training carrier prompt carries exactly one (Section 4). Zero-shot training rows omit the exemplar lines entirely.

```
Translate the source text from
{src_lang} to {tgt_lang}

{src_lang}: {exemplar source}
{tgt_lang}: {exemplar target}
...
{src_lang}: {source}
{tgt_lang}:
```

**SC and GC.** Both use a tagged two-field response format, differing only in the error type named in the instruction (misspelled word for SC, grammatically incorrect word for GC):

```
The following sentence contains at most
one misspelled word. Respond with
```

```
exactly these two tags and nothing else:
<wrong> misspelled word </wrong>
<corrected> correct spelling </corrected>
If the sentence has no error, use the
literal string CORRECT in both tags:
<wrong> CORRECT </wrong>
<corrected> CORRECT </corrected>
<sentence> {sentence} </sentence>
```

**QA.** Used for scoring rather than free generation (Section 6): each option is placed after `Answer:` and scored in place.

```
Answer the multiple-choice question with
the number of the correct option only.

{context}
Question: {question}
{n}. {option n}
...
Answer:
```

**MR.**

```
Answer this mathematical reasoning
question. Place your final answer, using
LaTeX when appropriate, in this format:
<answer> answer </answer> {question}
```

**An example.** The MT template rendered on the development source of Figure 1 with its actually retrieved exemplars (line breaks added for layout). The training render shows the carrier case, whose single exemplar is an authentic pair. The inference render carries three FMs, here all back-translated pairs.

## D Reproduction Details

All artefacts are public: the code repository with the primary system's configuration, an end-to-end reproduction script, and a retraining script,[4] the merged weights,[5] and a data repository with the retrieval pools and training sets.[6]

The computational cost is modest: reproducing the primary system end-to-end from the public artefacts, from the fine-tuned weights to all five task outputs, takes about 2 hours on a single H200 GPU. Training and development ran on the VSC infrastructure acknowledged above.

## Abstract

We describe the TUMHN team's systems for the WMT26 Shared Tasks on LLMs with Limited Resources for Slavic Languages. We participated in the Ukrainian track, covering machine translation, question answering, spell checking, grammar checking, and math reasoning tasks. We restructured our training dataset into a chat-style format and fine-tuned the Qwen3.5-2B model for the Ukrainian track in a multitask learning setting. Our model outperforms the baseline on three of the five tasks, with significant improvements on Question Answering, Spell Checking, and Grammar Checking. In Machine Translation, the model shows a slight improvement for the English–Ukrainian direction. For Spell Checking and Grammar Checking specifically, the largest gains were observed in spell or grammatical error detection as opposed to correction. In Math Reasoning, however, our model does not outperform the baseline. The fine-tuned model [1] and training dataset [2] are publicly available on Hugging Face.

## 1 Introduction

Large language models (LLMs) no longer just dominate NLP research; they have found their way into people's everyday lives worldwide. Frontier models such as ChatGPT (OpenAI), Claude (Anthropic), and Gemini (Google) are widely used to assist people in both professional and private contexts, while smaller, typically open-weight models such as Llama (Meta AI), Qwen (Alibaba), and Deepseek (DeepSeek) are used for more individualized applications. Both the training and evaluation of these models are largely biased towards high-resource languages, particularly English (Xu et al., 2025). For lower-resource languages, the number of models that support them declines quickly (Unjum et al., 2026), and even when a model supports a particular lower-resource language, research has shown that performance is better when prompted in English (Zhang et al., 2023). This leaves speakers of lower-resource languages at a disadvantage, limiting their access to this widely used technology. Closing this gap matters regardless of whether a language is high-resource, low-resource, or somewhere in between.

The WMT26 Limited Resources LLM shared task (Okabe et al., 2026) addresses this imbalance, focusing this year on three Slavic languages: Ukrainian, Upper Sorbian, and Lower Sorbian. Ukrainian, though not low-resource, sits in the mid-resource range, with roughly 40M first-language speakers, making progress here beneficial to a large population. Upper and Lower Sorbian, by contrast, are at the extreme low-resource end, both in terms of available data and speaker populations (roughly 30K and 7K speakers, respectively). The shared task evaluates LLM performance across five tasks: machine translation (MT), multiple-choice question answering (QA), spell checking (SC), grammar checking (GC), and math reasoning (MR). Submissions are restricted to Qwen3.5-2B[3] (Yang et al., 2025) as the base model.

In this work, we participated in the Ukrainian track. Our approach uses parameter-efficient fine-tuning, training a single Low-Rank Adaptation (LoRA) (Hu et al., 2021) adapter on all five tasks simultaneously. We sourced training data for the five tasks from various sources, including the Ukrainian datasets provided by the shared task organizers. Ukrainian training data was not available for math reasoning, so we used English data instead, with the expectation that the model would be able to transfer the underlying task knowledge to Ukrainian. (cf. Section 2). We restructured all task data into a

*Proceedings of the Eleventh Conference on Machine Translation*, pages 2682–2688
October 28-29, 2026 ©2026 Association for Computational Linguistics

chat-style format and fine-tuned Qwen3.5-2B for Ukrainian in a multitask learning setting, allowing a single model to handle all five tasks jointly. Our model achieved higher performance in three of five tasks. It outperforms the baseline in question answering, spell checking, and grammar checking. For the latter two, our model performs better at detecting spelling and grammatical errors than at providing corrections. In contrast, our model does not surpass the baseline in math reasoning, likely due to the difficulty of cross-lingual transfer from English-only training data. In machine translation, our model performs slightly better on English–Ukrainian translation but falls behind on Czech–Ukrainian translation.

## 2 Dataset and Tasks

We participated in the **Ukrainian track**, which comprises five NLP tasks that cover different language understanding and generation settings. We convert the data from each task into a unified chat-style format, allowing us to combine all tasks and train a single model jointly on all five tasks. The datasets are summarized in Table 1; this includes both the datasets provided by the shared task and those we have gathered from several external sources.

**MT:** This task covers two translation directions: Czech–Ukrainian (CES-UKR) and English–Ukrainian (ENG-UKR). We sampled a subset of parallel sentences for both language pairs from the Tatoeba corpus (Tiedemann, 2020).

**QA:** We used the data provided by the shared task organizers, which included the MMLU (Yukhymenko et al., 2026) and ZNO (Syromiatnikov et al., 2025) datasets, structured as multiple-choice question answering. We augmented this with a Ukrainian version of SQuAD (Stanford Question Answering Dataset) (Ivanyuk-Skulskiy et al., 2021), semi-automatically translated from the original English SQuAD (Rajpurkar et al., 2016), which is formulated as an extractive QA task.

**GC:** This task requires the model to identify grammatical errors in a given sentence and provide the corresponding correction. Each sentence contains at most one grammatical error in a single word. Some sentences may be error-free, in which case the model should leave the sentence unchanged or output *correct*. For sentences containing an error, the model is expected to identify the erroneous word and provide its correct form. For this task, we use data from the UA-GEC dataset (Syvokon et al., 2023), which covers a range of grammatical and fluency-related errors, as well as spelling and punctuation errors.

**SC:** Each sentence contains at most two spelling errors within a single word. As in GC, some sentences may be error-free and should therefore be left unchanged or marked as *correct* by the model. When an error is present, the model should identify the misspelled word and provide its correct spelling. The training dataset is sourced from UA-GEC (Syvokon et al., 2023).

**MR:** We incorporated data from OlympiadBench (He et al., 2024), which contains mathematics, physics, and multimodal reasoning problems. From this dataset, we selected the text-only, open-ended questions from the mathematics and physics subsets. We additionally used data from MathMist (Sobhani et al., 2025), a multilingual mathematical reasoning benchmark, from which we selected the English subset, as Ukrainian was not available.

Reid and Artetxe (2023) show that parallel data facilitates cross-lingual transfer not only for translation but also for other downstream tasks. Motivated by this finding, we hypothesize that machine translation resources can similarly support the transfer of task-specific capabilities across languages. In our setting, both OlympiadBench and MathMist are in English. We therefore hypothesize that a model can acquire mathematical reasoning ability from English-language examples and transfer this ability to Ukrainian, using English–Ukrainian parallel data as an intermediate signal for cross-lingual adaptation.

In total, we collected 66.9K training samples. The datasets are not evenly balanced, with MT taking the largest proportion of the training data, followed by the SC dataset, as shown in Figure 1. This distribution largely reflects the availability of data across the different Ukrainian datasets. The datasets for each task are merged within each split and shuffled before training[4].

## 3 Methods

We fine-tuned the 4-bit quantized Qwen3.5-2B model (non-thinking mode) using Low-Rank Adap-

[4]For datasets with predefined training and validation splits, we use the provided splits. When no validation split is available, we randomly divide the training data into 80% training and 20% validation sets.

| Task | Source | Train | Test |
|---|---|---|---|
| MT | CES/ENG → UKR Tatoeba (Tiedemann, 2020) | 32,000 | 317 |
| QA | †MMLU (Yukhymenko et al., 2026)<br>†ZNO (Syromiatnikov et al., 2025)<br>UA-SQuAD (Ivanyuk-Skulskiy et al., 2021) | 8,596 | 14,793 |
| SC | UA-GEC (Syvokon et al., 2023) | 17,016 | 2,000 |
| GC | UA-GEC (Syvokon et al., 2023) | 6,929 | 2,000 |
| MR | MathMist (Sobhani et al., 2025)<br>OlympiadBench (He et al., 2024) | 2,417 | 250 |
| | **Total training instances** | **66,958** | |

Table 1: Datasets used for each subtask in the Ukrainian track. † indicates a dataset provided by shared task organizers.

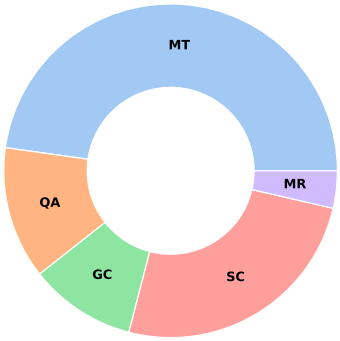

Figure 1: Distribution of training examples across tasks. All datasets are in Ukrainian except for MR, which is in English.

tation (LoRA) with a rank of $r = 32$ on a single NVIDIA H100 GPU for approximately 4 hours. The model was initially trained for 3 epochs and subsequently fine-tuned for an additional 10 epochs[5] , with early stopping (patience of 3). Loss is computed only over the assistant's response tokens. We use a zero-shot strategy with greedy decoding during both training and inference. For reproducibility, we report the hyperparameters in Appendix A, as well as the model instructions used for each task in Appendix B.

**Evaluation:** We report **chrF++** (Popović, 2015) as the main evaluation metric for MT and **BLEU** (Papineni et al., 2002) for comparison. For QA and MR, we report **accuracy**. Finally, for SC and GC, we report **accuracy** separately for detection and correction.

## 4 Results and Discussions

Table 2 shows our model's overall performance compared with the baseline results reported by the shared-task organizers and the two other participating teams, Zolint and koshi. According to the shared-task scoring scheme, Zolint achieves the highest overall score with 19 points, followed by koshi with 12 points. TUMHN obtains 9 points, the same overall score as the baseline, placing us fourth.

Despite obtaining the same overall score, our approach and the baseline exhibit substantially different performance profiles across the individual tasks. Our approach outperforms the baseline in three of the five tasks: QA, SC, and GC. In contrast, the baseline performs better in MT and MR (See Table 3).

**MT:** MT results show a mixed pattern across translation directions. On the CES-UKR subset, the baseline outperforms our model (BLEU 5.38 vs. 3.93; chrF++ 25.44 vs. 19.77). In contrast, our model performs slightly better on ENG-UKR, with BLEU 1.01 vs. 0.55 and chrF++ 12.39 vs. 11.47. Overall, our approach shows small gains on ENG-UKR but larger losses on CES-UKR, leading to a lower aggregate MT score. Moreover, the test set is constructed at the document level, whereas our model is trained at the sentence level. This discrepancy may contribute to the model's low performance, consistent with the findings of Alabi et al. (2025), which report that models trained on sentences often struggle to generalize to longer documents. We notice incomplete translations in CES-UKR, in which the model provides short responses. This is likely due to the training data consisting of short sentences. Nevertheless, this shows an improvement over the baseline, which frequently failed to produce a meaningful translation, often refusing to translate, or generating incoherent output.

**QA:** Our model outperforms the baseline on QA, achieving an overall accuracy of 40.13 versus 36.33 for the baseline (+3.80 points). This improvement holds consistently across both QA domains. On UkrQA, our model reaches 35.82 compared to 30.76 for the baseline (+5.06 points), while on Ukr-MMLU it achieves 44.44 vs. 41.90 (+2.54 points).

**SC:** Our model shows its strongest gain over the baseline in SC, reaching an overall accuracy of 16.50 (+8.12 points). The gain comes mainly from error detection; our model scores 22.20 vs. 8.55 for the baseline, showing it is much better at recognizing misspelled word(s). However, on correction,

[5]We initially trained the model for 3 epochs and evaluated its performance on the dev set for each task. However, the results were not satisfactory; therefore, we continued training on the same dataset for an additional 10 epochs with early stopping.

| | MT (chrF++) | Points | QA | Points | SC | Points | GC | Points | MR | Points | Final Points | Final Rank |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Zolint | **49.86** | **4** | 41.15 | 3 | **66.43** | **4** | **45.18** | **4** | **21.60** | **4** | 19 | 1 |
| koshi | 16.80 | 1 | **46.99** | **4** | 52.50 | 3 | 30.55 | 3 | 0.40 | 1 | 12 | 2 |
| baseline | 18.46 | 3 | 36.33 | 1 | 8.38 | 1 | 2.18 | 1 | 20.00 | 3 | 9 | 4 |
| TUMHN | 16.08 | 1 | 40.13 | 2 | 16.50 | 2 | 6.80 | **2** | 4.40 | 2 | 9 | 4 |

Table 2: Ukrainian track leaderboard: best results are in **bold**.

the gap is smaller (10.80 vs. 8.20). The predominant error pattern observed was that the model flags a word as erroneous but predicts the same word as the corrected output, leaving the erroneous word unchanged.

**GC:** We achieved an accuracy score of 6.80 compared to 2.18 for the baseline (+4.62 points). Looking more closely, this advantage comes mainly from detecting grammatically incorrect instances, where our model reaches 10.35 vs. 2.70 for the baseline, whereas the gap on corrected instances is narrower (3.25 vs. 1.65). Similar error patterns are observed here as in SC, suggesting that the model is more effective at flagging errors than at generating accurate corrections.

**MR:** MR shows the largest performance gap between our approach and the baseline, with an accuracy score of 4.40 versus 20.00 for the baseline. This result shows whether parallel data can support cross-lingual transfer of task capabilities. Our training data combines English math data with English–Ukrainian parallel data and the aforementioned Ukrainian data; therefore, we expected this combination to help transfer mathematical reasoning ability to Ukrainian. While parallel data has been shown to support cross-lingual transfer under certain training setups (Reid and Artetxe, 2023), another study shows that MT training does not necessarily improve cross-lingual representations for downstream tasks (Ji et al., 2024). Our results align with this latter finding: despite joint training on English MR data and parallel data, our approach substantially underperforms the baseline on Ukrainian MR. Furthermore, our MT dataset is derived from Tatoeba, which contains simple sentences. This could explain the lower performance on MR, which is a more complex task that requires a higher level of linguistic proficiency.

## 5 Conclusion

We presented our submission to the Ukrainian track of the WMT2026 Shared Task on LLMs with Limited Resources for Slavic Languages. Our approach consisted of fine-tuning Qwen3.5 2B model jointly on five tasks: machine translation, math reasoning, spell checking, grammar checking, and question answering.

| Task | Subset | Metric | TUMHN | Baseline |
|---|---|---|---|---|
| MT | ces-ukr | BLEU | 3.93 | **5.38** |
| | ces-ukr | chrF++ | 19.77 | **25.44** |
| | eng-ukr | BLEU | **1.01** | 0.55 |
| | eng-ukr | chrF++ | **12.39** | 11.47 |
| | all | chrF++ | 16.08 | **18.46** |
| QA | ukrqa | ACC | **35.82** | 30.76 |
| | ukrmmlu | ACC | **44.44** | 41.90 |
| | all | ACC | **40.13** | 36.33 |
| SC | ukrsc | ACC-D | **22.20** | 8.55 |
| | | ACC-C | **10.80** | 8.20 |
| | all | ACC | **16.50** | 8.38 |
| GC | ukrgc | ACC-D | **10.35** | 2.70 |
| | | ACC-C | **3.25** | 1.65 |
| | all | ACC | **6.80** | 2.18 |
| MR | ukrmr | ACC | 4.40 | **20.00** |

Table 3: Results for the Ukrainian track: We compare TUMHN (our approach) vs. the baseline results reported by the organizers. BLEU, chrF++, and exact-match accuracy are reported. Best scores are presented in **bold**. $ACC-D$ and $ACC-C$ represent accuracy scores for detection and correction, respectively.

Our system ranked fourth among participants, tied with the baseline. Looking at the individual tasks, we outperformed the baseline on QA, SC, and GC, with the largest gains on SC, while falling short on MT and MR. We hypothesized that task knowledge learned from English MR data could transfer to Ukrainian. However, our results do not support this. Performance on MR remains below the baseline, suggesting that cross-lingual transfer alone was insufficient to compensate for the lack of in-language training data.

Overall, we view these results as encouraging. Despite using a modest amount of data and a comparatively short training time, we improved over the baseline on three of the five tasks, demonstrating that this joint fine-tuning approach is a viable strategy for mid-resource languages like Ukrainian under limited compute and data budgets.

## 6 Limitations

Our submission has several limitations that we leave for future work:

- **Single training strategy.** We have only explored joint fine-tuning on all five tasks simultaneously, without comparing against alternative strategies such as sequential or task-specific fine-tuning. Additionally, we only evaluated our model on a single random seed.
- **No task interaction analysis.** We did not analyze how the tasks influence one another during joint training. Some tasks may contribute more positively to overall model capability than others, or even have a negative effect; identifying and prioritizing such beneficial tasks, e.g. through additional data for those specifically, is a promising direction for future work.
- **No translation for MR.** Due to the lack of Ukrainian data for MR, we relied on English data and cross-lingual transfer. We did not explore machine-translating the English MR data into Ukrainian before training, which might have been a more effective approach.

## A Hyperparmeter

Table 4 below summarizes the hyperparameters that we used for fine-tuning; We used greedy decoding in non-thinking mode, with all other decoding parameters kept at their default values in both training and inference.

| Hyperparameter | Value |
|---|---|
| Learning rate | 2e-5 |
| Batch size | 16 |
| Warmup steps | 20 |
| Epochs | †13 |
| Optimizer | AdamW 8Bit |
| Seed | 3407 |
| Temp. | 1.0 |

Table 4: Hyperparameters used for fine-tuning. † The model was initially fine-tuned for 3 epochs and continued fine-tuning for 10 more epochs with early stopping; therefore, in total it was fine-tuned for 13 epochs.

## B Instructions

Table 5 lists the exact instruction used for each of the five tasks, including the expected output format.

| Task | Instructions |
|---|---|
| MT | Translate the following English/Czech text to Ukrainian. Put your output in this format `<ukr> Ukrainian translation </ukr>`. |
| QA | Given a multiple-choice question, select the correct option from the listed alternatives (0–3). Respond ONLY with the number corresponding to the correct answer enclosed in `<answer>` and `</answer>` tags. |
| SC | The following sentence contains at most one misspelled word. Identify the misspelled word, if it exists, and place it between `<wrong>...</wrong>` tags, with the correct spelling in `<corrected>...</corrected>` tags. If there is no error, use the literal string `CORRECT` in both tags. |
| GC | The following sentence contains at most one grammatical error. If an error exists, place the incorrect word inside `<wrong>...</wrong>` and the corrected word inside `<corrected>...</corrected>`. If there is no error, output `CORRECT` in both tags. |
| MR | Answer this mathematical reasoning question. Provide your final answer using appropriate LaTeX formatting when needed, following the template `<answer>...</answer>`. |

Table 5: Instructions used to prompt the model for each of the five tasks during joint training. Each instruction specifies both the task and the expected output format, including the tags used to delimit the model's answer.

# Zolint at WMT 2026: A Multitask LLM Submission for the Low-Resource Ukrainian Track

## Abstract

We present a unified multi-task fine-tuning system submitted to the WMT 2026 Shared Task on Multitask LLMs with Limited Resources (Ukrainian track), covering machine translation, spelling correction, grammar correction, question answering, and mathematical reasoning. Our system is built on Qwen3.5-2B-Instruct and adopts a two-stage training pipeline that gradually introduces heterogeneous tasks while replaying selected data from earlier stages to mitigate catastrophic forgetting. The resulting model achieves a strong balance across all evaluated tasks, consistently outperforming the official baseline and obtaining the best performance on every task except question answering. Our results demonstrate that staged multi-task fine-tuning is an effective strategy for adapting compact multilingual LLMs under limited-resource constraints.

## 1 Introduction

Large language models (LLMs) have achieved remarkable success on high-resource languages, yet their performance remains considerably weaker for low-resource languages such as Ukrainian. The WMT 2026 Shared Task: Multitask LLMs with Limited Resources investigates whether a single Qwen3.5 model with at most 2B parameters can jointly solve diverse Ukrainian NLP tasks, including machine translation, spelling correction, grammar correction, question answering, and mathematical reasoning.

This setting poses a challenging multi-task learning problem. These tasks require different capabilities, ranging from cross-lingual generation and linguistic correction to language understanding and multi-step reasoning. Jointly optimizing such heterogeneous objectives often leads to task interference and catastrophic forgetting, especially for compact language models with limited capacity.

To address these challenges, we propose a two-stage multi-task fine-tuning pipeline. The first stage focuses on English–Ukrainian translation together with spelling and grammar correction to establish fundamental Ukrainian language abilities. The second stage introduces Czech–Ukrainian translation, question answering, and mathematical reasoning while replaying a subset of first-stage data to mitigate catastrophic forgetting.

Besides the staged training strategy, we construct additional spelling correction data from the question answering corpus and observe a consistent positive interaction between the two tasks, suggesting that auxiliary correction supervision benefits language understanding in low-resource settings. We also find grammar correction to be most susceptible to forgetting after continual multi-task training.

Our unified multi-task system achieves a strong balance across all evaluated tasks. Compared with the official baseline, it consistently improves overall performance and achieves the best results on all tasks except question answering. These results demonstrate that carefully scheduling heterogeneous tasks and mitigating forgetting are crucial for adapting compact multilingual LLMs in limited-resource settings. We release our model and code.[1]

## 2 Related Work

### 2.1 Low-resource Multilingual LLMs

Despite modern LLMs' strong multilingual capabilities, their performance on low-resource languages still has substantial room for improvement due to the imbalance of pre-training data. Recent work has explored continued instruction tuning, synthetic data generation, and bilingual supervision to improve multilingual performance, yet significant performance gaps remain for low-resource languages

| Task | Train Set | Dev Set | Description |
|---|---|---|---|
| MT (EN→UK) | 95,140 pairs | 5,108 pairs | Only provided sentence-level dev set. Constructed both sentence- and paragraph-level training data. |
| MT (CS→UK) | 16,946 pairs | 9,424 pairs | Only provided sentence-level dev set. Constructed sentence- and paragraph-level training data and augmented dev set. |
| QA (ZNO) | 7,379 pairs | 613 questions | Augment the training set by shuffling, introducing CoT and comprehension understanding |
| QA (MMLU) | 21,531 questions | 285 questions | Augmented training set with back-translated MMLU data |
| GC | 32,036 sentences | 2,000 sentences | Only provided dev set. Constructed training set by UA-GEC |
| SC | 6,232 sentences | 2,000 sentences | Only provided dev set. Built training set by ourselves |
| MR | 14,895 questions | 24 questions | Only provided dev set. Constructed training set by back-translating English data |

Table 1: Summary of the datasets for the five tasks.

such as Ukrainian (Okabe et al., 2025). The analysis of the WMT 2025 Shared Task systems (Okabe et al., 2025) also revealed difficulties in maintaining complete paragraph-level information during translation, suggesting that context preservation remains an important challenge for low-resource multilingual LLMs.

### 2.2 Multi-task Instruction Tuning

Instruction tuning enables a single LLM to solve diverse downstream tasks through natural language instructions (Chung et al., 2022). However, jointly optimizing heterogeneous tasks often introduces task interference and catastrophic forgetting, particularly for compact models (Luo et al., 2025). The WMT 2025 Shared Task further reports that optimizing translation alone degrades question answering performance, while unrestricted reasoning may negatively affect translation quality (Okabe et al., 2025). These findings motivate staged training strategies that balance linguistic knowledge and reasoning ability during multi-task adaptation.

## 3 Data

In this section, we describe the datasets used for the five tasks. For each task, we introduce the data source, explain the processing strategies, and report the resulting data sets. To enable joint instruction tuning, all datasets are converted into a unified instruction-response format. An overview of the dataset is shown in Table 1.

**Machine Translation (MT).** For EN→UK, we start from the WMT 2025 constrained parallel corpora (ParaCrawl, WikiMatrix, TED, ELRC, and OPUS). Following quality filtering, we apply SDKM-style similarity retrieval (Saadi et al., 2025) using Qwen2.5-3B-Instruct embeddings, obtaining 108k high-quality sentence pairs. We further cluster semantically similar sentences with MiniBatchK-Means to construct 42k pseudo-document training examples for long-context translation.

For CS→UK, we combine public parallel corpora, including NLLB (Team et al., 2022) and OPUS resources (ELRC, Wikimedia, and EUBookshop) (Tiedemann, 2012). To construct paragraph-level data, we use the monolingual corpus from UberText Ukrainian fiction (Chaplynskyi, 2023). Then we segment the text into sentences using Stanza, group consecutive sentences into paragraphs of 300–700 words, and then back-translate them with the LINDAT Ukrainian→Czech system (Popel et al., 2024), yielding together with sentence-level data 16,946 training pairs in total.

All MT data are processed with a unified cleaning pipeline including quality filtering, normalization, deduplication, FastText language identification (Grave et al., 2018), multilingual-e5-small semantic filtering (Wang et al., 2024), and final quality estimation.

**Question Answering (QA).** The official QA dataset is constructed from two sources: the ZNO dataset (Romanyshyn et al., 2024) and the Ukrainian MMLU dataset (Yukhymenko et al., 2026) provided in the WMT2026 shared task. In addition to these official resources, we further enhance the QA data as follows. We first oversample the ZNO training set by a factor of two and randomly shuffle answer options to reduce position bias. We then incorporate additional CoT examples from the training split of NLPForUA/dumy-zno-ukrainian-math-history-geo-r1-o1 (Syromiatnikov and team, 2025). To ensure data integrity and avoid

contamination, we aligned this data with the official training set, filtered out any overlaps with the official development set, and retained only valid training instances with `o1_score = 1`. A deterministic 70%/30% split defines implicit and explicit CoT formats: in implicit CoT, the reasoning trace is included in the input and only the final answer is produced; in explicit CoT, the model generates full reasoning followed by the final answer. For MMLU, we further extend coverage using training split of the cais/mmlu dataset (Hendrycks et al., 2021a). We used Google Translate API to translate English questions into Ukrainian and merged them into the same QA format.

**Grammar Checking (GC).** GC training data are derived from **UA-GEC** (Syvokon and Romanyshyn, 2024), using the `gec-only` annotation layer. Each source–target sentence pair is converted into the shared-task format by aligning erroneous and corrected spans. We keep only sentences with at most one error region, yielding 32,036 training instances. The official GC development set (2,000 instances) is taken from the WMT 2026 Ukrainian shared-task release.

**Spell Checking (SC).** No dedicated Ukrainian spell-checking training corpus was provided by the organizers. We therefore construct SC training data synthetically from **MMLU_UKR** (Yukhymenko et al., 2026): Ukrainian question stems and answer options are taken from the released validation split, and spelling errors are injected automatically (e.g., character swaps, deletions, duplications, and visually confusable Cyrillic/Latin substitutions). About half of the sentences are left unchanged and labeled `CORRECT`. This yields 6,232 training instances. The SC development set (2,000 instances) is released by the organisers.

**Math Reasoning (MR).** MR training data come from two English math datasets separate from the official MR evaluation benchmark: **GSM8K** (Cobbe et al., 2021) (7,473 problems) and **Competition Math** (the MATH dataset) (Hendrycks et al., 2021b) (7,500 problems). We used Google Translate API to back-translate problem statements and reference solutions from English to Ukrainian. Then we cleaned the data to enhance data quality, including converting decimal numbers to equivalent LaTeX format fractions, correcting corrupted answer annotations, enforcing a single final boxed answer, and correcting examples with invalid LaTeX. We also standardize all targets to the format `Answer: \boxed`. Overall, 78 corrupted instances are removed, leaving 14,895 training examples. The official MR development set (24 problems: 12 low-difficulty and 12 medium-difficulty) is released by the WMT 2026 organizers.

## 4 System Architecture & Methodology

All tasks are handled by a single LoRA-finetuned Qwen3.5-2B-Instruct model (Hu et al., 2021) without any task-specific parameters, strictly satisfying the parameter constraint of the shared task. As illustrated in Figure 1, we propose a two-stage fine-tuning framework to adapt the foundation model across multiple tasks, which achieves optimal overall performance.

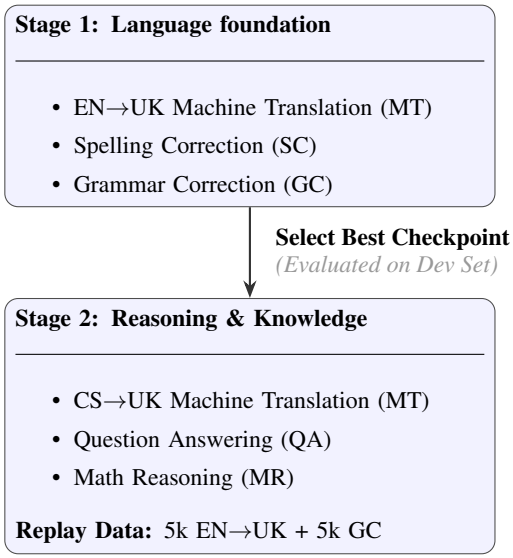

Figure 1: Overview of the simplified two-stage multi-task training framework.

### 4.1 Stage 1: EN→UK MT, SC, and GC

We first fine-tune the model on English→Ukrainian machine translation (MT), spelling correction (SC), and grammar correction (GC). The objective of this stage is to strengthen Ukrainian generation and correction ability before introducing more heterogeneous tasks.

For MT, the model is instructed to translate English sentences into Ukrainian and output only the translation. For SC and GC, we adopt a unified decision-then-correction format. The model first determines whether the input sentence is correct. If no error exists, it outputs `CORRECT`; otherwise, it predicts the incorrect word and its correction in

| | Machine Translation (MT) | | | | Spelling Correction (SC) | | Grammar Correction (GC) | | QA | MR |
|---|---|---|---|---|---|---|---|---|---|---|

Table 2: Performance on development-set. EM-W and EM-C denote exact match on incorrect and corrected words, respectively.

the format `{wrong word} -> {correct word}`. During evaluation, predictions are converted into corresponding word pairs, while correct sentences are mapped to `(CORRECT, CORRECT)`.

The first-stage model is trained for five epochs, with the checkpoint selected according to development performance. However, we observe that the best checkpoint is usually obtained after the first epoch, whereas later epochs often lead to overfitting under the low-resource setting.

### 4.2 Stage 2: CS→UK MT, QA, and MR

Starting from the best checkpoint from the first stage, we continue joint multi-task training by introducing Czech→Ukrainian machine translation, multiple-choice question answering (QA), and mathematical reasoning (MR).

Notably, we split the two MT directions and move the CS→UK task to the second stage for two motivations. First, as Czech and Ukrainian are closely related Slavic languages, CS→UK translation may benefit from a richer representational foundation established during Stage 1. Second, training CS→UK in Stage 2 places it closer to the final checkpoint, thereby mitigating catastrophic forgetting by reducing its exposure to non-MT fine-tuning in subsequent steps.

For CS→UK MT, the model translates Czech text into Ukrainian. For QA, the model predicts the answer option label, and outputs containing the full answer text are mapped back to the corresponding option during evaluation. For MR, the model is encouraged to generate intermediate reasoning, while only the final answer following the token `Answer:` is used for evaluation.

To balance training efficiency and mitigate forgetting, we also empirically set a replay size of 5,000 EN→UK MT examples and 5,000 GC examples from the first-stage datasets during second-stage training. Consequently, the second stage jointly optimizes new tasks with replayed data to preserve prior capabilities while learning new ones.

| Task | Zero-shot | After Stage 1 | Improvements |
|---|---|---|---|
| MT (BLEU) | 15.40 | **17.92** | +2.5 |
| GC (det / corr) | 34.2 / 32.4 | **42.5 / 42.1** | +8.3 / +9.7 |
| SC (det / corr) | 32.5 / 30.6 | **75.2 / 59.3** | +42.7 / +28.8 |

Table 3: Effect of Stage-1 training on the Stage-1 tasks (development set).

## 5 Results and Discussion

**Experimental setup.** We compare four training strategies on the development set. **Baseline** directly evaluates the base `Qwen3.5-2B-Instruct` model without fine-tuning. **Joint** fine-tunes all six tasks jointly. **2-Stage-I** first trains on English→Ukrainian machine translation (EN→UK MT), spelling correction (SC), and grammar correction (GC), and then continues training on the full multi-task mixture with replayed first-stage data. **2-Stage-II** follows the same framework but postpones GC until the second stage. Unless otherwise stated, all results are reported on the development set. Our final submission adopts the 2-Stage-I configuration. Detailed hyperparameter settings are provided in Appendix A.

### 5.1 Results

**Development-set results.** We first evaluate the different training strategies on the development sets. Tables 2 show that ours outperforms over the zero-shot baseline across multiple tasks and all fine-tuned configurations improve substantially over the zero-shot baseline across tasks, confirming the value of task-specific fine-tuning.

Our final system (**2-Stage-I**) substantially improves Ukrainian generation in both EN→UK and CS→UK translation on both BLEU and chrF++. Notably, comparing the Stage-1-only results in Ta-

| **Ours** | **49.86** | **23.66** | **51.53** | **15.43** | **48.18** | 41.15 | **66.43** | **45.18** | **21.60** |

Table 4: Official test-set results on the Ukrainian track of the WMT 2026 Shared Task. For multi-subtask categories (QA, SC, GC), overall macro scores are reported here. Detailed sub-category breakdowns are provided in Appendix C.

ble 3 with the full two-stage results shows that the translation ability acquired in Stage 1 is not degraded by the later reasoning stage.

Among the training strategies, **2-Stage-I** provides the strongest overall balance across heterogeneous tasks, achieving the best performance on SC, QA, and MR while remaining competitive on GC.

**Official test-set results.** Table 4 reports the official test-set results of our final submission. Ours achieves the highest reported scores on all four tasks metrics. For question answering, our system achieves 41.15 EM, below Koshi's 46.99 EM, but remains competitive with the other systems.

Compared with the official baseline, the largest improvements are observed on machine translation and correction tasks, demonstrating that staged multi-task fine-tuning effectively enhances Ukrainian generation and linguistic knowledge. More importantly, the results show that a single compact model can jointly support translation, correction, reasoning, and language understanding without sacrificing overall performance.

### 5.2 Training Strategy Analysis

**Effect of staged-training** Comparing Joint strategy and 2-Stage strategy as shown in Table 2, the 2-Stage method performs better on most tasks. Separating training into two stages lets the model first acquire translation and correction behaviors and only then take on reasoning, rather than trading them off from the start. We therefore adopt the staged setup as our main system.

Our training order follows a language-first approach. We first train the model on translation and correction tasks so that it can better handle Ukrainian before introducing QA and MR. The idea is that a stronger foundation in the target language may make it easier for the model to learn the later reasoning tasks. As shown in Table 3, Stage 1 improves MT, SC, and GC by 59.2% on average over the baseline. Stage 2 extends the model to reasoning and another translation direction. Importantly, most capabilities learned in Stage 1 are also preserved after Stage 2, suggesting that sequential fine-tuning can absorb new tasks without substantially overwriting prior knowledge.

**Task composition and ordering.** Given that we train in two stages, the composition and ordering of tasks within each stage may affect transfer and interference. Rather than randomly partitioning tasks, we explored different combinations and orderings and report the two configurations that performed best overall.

Moving GC from the first stage to the second (2-Stage-I vs. 2-Stage-II) changes both the correction and the downstream reasoning scores, showing that ordering and composition jointly determine which capabilities transfer and which interfere. Two contrasting effects illustrate this. The configuration with the strongest SC performance also achieves the strongest QA performance; since the SC data are derived from the QA corpus, this points to positive transfer between the two. Conversely, the degradation of GC after subsequent training reflects negative interference. Task composition should therefore account for task compatibility rather than treating all tasks as interchangeable.

**Catastrophic forgetting and replay.** To mitigate the GC degradation identified above, we retain a small replay buffer of representative Stage-1 examples and mix them into Stage-2. This allows the model to maintain training signals for previously learned tasks while introducing the new objectives, providing a simple mechanism for reducing capability drift.

We also use more English→Ukrainian than Czech→Ukrainian data to mitigate the MT degradation. Since Czech and Ukrainian are both Slavic

languages and share many lexical and morphological features, Czech→Ukrainian is easier to preserve, letting us spend more of the budget on the more forgetting-prone English→Ukrainian direction.

### 5.3 Output Analysis and Discussion

We qualitatively examined model outputs across all five tasks and group the observed behaviors into three types. Where relevant, we compare the final system (**2-Stage-I**), which is trained on the cleaned math data described in Section 3, with an ablation variant (**MR-Raw**) trained on the uncleaned, raw translated MR data, both are evaluated on the same test set.

**(1) Repetition and degeneration.** The most common failure is repetition, where the model repeats until it reaches the maximum length. This is rare on short inputs but frequent on longer ones. In MR task it occurs in only 5 of 125 low-difficulty items but in 69 of 125 medium-difficulty items. We also observe it in some of longer translation outputs. The problem is that a 2B model, adapted with a small number of parameters, may not always produce a stable stopping point once the output grows long and symbol-heavy. We clean the training data to mitigate it: the raw math solutions (**MR-Raw**) contained calculator markers such as `«48/2=24»`, a highly regular pattern that the model learned to repeat, and removing them in **2-Stage-I** reduces this. However, the remaining failures on hard math problems are driven by long derivations, and may be better addressed at decoding time, for example, by penalizing repetition.

**(2) Format and prompt following.** In general, the simpler tasks generally show strong format compliance. However, a small fraction of correction outputs only contain a dash (`-`)(around 6% for spelling and 8% for grammar). These are often associated with inputs beginning with a dash or bullet, suggesting that the model sometimes copies salient surface tokens from the input rather than producing the requested structured field.

The largest format failures occur in MR. Although low-difficulty instances usually produce directly usable answers, 118 of 250 predictions (47.2%) do not contain the final numerical answer. This partly results from our prompt, which explicitly encourages step-by-step reasoning. While this may benefit mathematical reasoning, it also lengthens generation and can exhaust the token budget before a final answer is produced, especially on harder problems. Combined with the repetition issues discussed above, this creates a trade-off between encouraging reasoning and producing an easily extractable answer.

**(3) Reasoning language and cross-lingual consistency.** We further examined whether the model maintains Ukrainian when generating explanations, given that the task prompts are written in English. Overall, we find little evidence of systematic cross-lingual drift. The natural-language portions of MR outputs are predominantly Ukrainian, including the longer reasoning traces. Apparent Latin-script content is mostly mathematical notation rather than English prose, and Russian-specific characters appear only rarely in MT outputs.

The remaining language errors are not switches from Ukrainian to English or Russian, but local contamination from degenerate generations, such as repeated punctuation, symbols, or emojis. Language consistency is thus not the main bottleneck; improving generation stability and format control is likely to have greater impact.

## 6 Conclusion

We presented our submission to the WMT 2026 Shared Task on LLMs with Limited Resources for Ukrainian. Our system fine-tunes a single Qwen3.5-2B-Instruct model using a two-stage multi-task training strategy with replay to mitigate catastrophic forgetting.

Development-set experiments show that staged training provides a better balance across heterogeneous tasks than straightforward joint optimization. In particular, we observe positive transfer from spelling correction to question answering, while grammar correction remains the task most vulnerable to catastrophic forgetting.

On the official test set, our system achieves the highest reported scores on all evaluated tasks except QA. These results demonstrate that carefully scheduled multi-task fine-tuning enables compact multilingual LLMs to effectively balance diverse tasks under limited-resource constraints.

## A Hyperparameters & Training Specs

In this section, we provide the hyperparameters used for both model training and decoding.

| Hyperparameter | Value |
|---|---|
| Optimizer | AdamW |
| Learning Rate | $2 \times 10^{-4}$ |
| Learning Rate Schedule | Cosine decay with 3% warmup |
| Precision | bfloat16 |
| Batch | $4 \times 8$ |
| Epoch | 5 |
| Max Sequence Length | 3072 |
| Rank | 16 |
| Alpha | 32 |
| Target Modules | `q_proj, k_proj, v_proj, o_proj, gate_proj up_proj, down_proj` |
| LoRA Dropout | 0.05 |

Table 5: Training and decoding hyperparameter configurations.

## B Evaluation Metrics and Settings

To ensure reproducibility, we report the exact tools and parameter settings used for evaluating Machine Translation. Both metrics are computed at the corpus level using the `sacrebleu` library (Post, 2018):

- **BLEU** (Papineni et al., 2002): We compute corpus-level BLEU using `sacrebleu.corpus_bleu` with the default SacreBLEU settings, including the default `13a` tokenizer.
- **chrF++** (Popović, 2017): We compute corpus-level chrF++ using `sacrebleu.corpus_chrf` with `word_order=2`, which incorporates word $n$-gram information in addition to character $n$-grams. All other parameters are left at their SacreBLEU default values.

## C Detailed Test-Set Performance Breakdowns

Table 6 and Table 7 report the detailed sub-metric evaluations on official downstream tasks for the WMT 2026 Shared Task (Ukrainian track).

| | Question Answering | | Math |
|---|---|---|---|
| System | UkrQA EM | UkrMMLU EM | UkrMR EM |
| Baseline | 30.76 | 41.90 | 20.00 |

# HITSZ at WMT 2026: Mixed Continued Pre-training and Supervised Fine-tuning for Low-Resource Sorbian

**Cong Zhang, Yutong Wang, Xuebo Liu*, Min Zhang**
Harbin Institute of Technology, Shenzhen, China
{zhangcong,wangyutong}@stu.hit.edu.cn
{liuxuebo,zhangmin2021}@hit.edu.cn

## Abstract

We describe the HITSZ system submitted to the Sorbian track of the WMT 2026 Shared Task on Multitask LLMs with Limited Resources. The track requires a single Qwen3.5-2B model to jointly perform machine translation (MT), question answering (QA), spell checking (SC), grammar checking (GC), and mathematical reasoning (MR) for Upper and Lower Sorbian. To strengthen the model's limited Sorbian linguistic knowledge while retaining previously acquired capabilities, we first perform mixed continued pre-training (CPT) on Sorbian monolingual and parallel data together with multilingual and task-oriented replay. We then apply full-parameter multitask supervised fine-tuning (SFT) to align the adapted model with the five heterogeneous task formats. Compared with the official Qwen3.5-2B baseline, our primary submission improves MT by 41.44 chrF++ points and improves QA, SC, GC, and MR by 13.94, 66.47, 60.77, and 13.20 points, respectively, ranking third overall in the Sorbian track. Additional analysis shows that removing CPT reduces our five-task development score by 5.24 points, with the largest losses on SC, MT, and GC. We also find that heavily increasing MT supervision does not further improve translation and can degrade other jointly trained tasks.

## 1 Introduction

Large language models (LLMs) have substantially advanced multilingual natural language processing, but their capabilities remain uneven across languages, particularly when high-quality text and task supervision are scarce. Upper Sorbian (hsb) and Lower Sorbian (dsb) are two closely related West Slavic minority languages spoken primarily in eastern Germany, with approximately 30,000 and 7,000 native speakers, respectively (Okabe et al., 2025). Their limited digital resources make it difficult for compact multilingual models to acquire reliable linguistic and downstream-task capabilities. The WMT 2025 shared task studied this problem through joint machine translation (MT) and question answering (QA) (Okabe et al., 2025). WMT 2026 broadens the Sorbian setting to five task families—MT, QA, spell checking (SC), grammar checking (GC), and mathematical reasoning (MR)—which must be handled by a single Qwen3.5-2B model (Okabe et al., 2026; Qwen Team, 2026).

The WMT 2025 systems demonstrate both the potential and the difficulty of low-resource Sorbian adaptation. TartuNLP (Purason and Fishel, 2025) continued training Qwen2.5-3B-Instruct on a mixture of Sorbian monolingual, parallel, and general instruction data, obtaining the highest overall ranking across MT and QA. NRC (Larkin et al., 2025) instead focused primarily on MT with full-parameter supervised fine-tuning and achieved the strongest translation results, but substantially lower QA accuracy, while JGU Mainz (Saadi et al., 2025) jointly adapted MT and QA using parameter-efficient fine-tuning and additional task data. The shared-task findings consequently observed that training purely for MT can degrade the model's original QA capability (Okabe et al., 2025). These studies addressed the two-task MT–QA setting; the addition of SC, GC, and MR in WMT 2026 creates a broader requirement in which language-specific knowledge and general task capabilities must coexist within the same compact model.

We address this requirement with a two-stage adaptation strategy. First, the base model has limited Sorbian linguistic competence, while continued pre-training on a narrow target-language corpus risks catastrophic forgetting of capabilities acquired during pre-training. Replay of general pre-training data has been used in recent MT-oriented continued pre-training to mitigate this effect (Zheng et al., 2025). Motivated by this,

our *mixed CPT* combines Sorbian monolingual and parallel data with English and German replay, directional MT supervision, instruction data, mathematical reasoning examples, and lightweight downstream-task anchors. Second, the five downstream tasks differ substantially in output format, supervision scale, and optimization behavior. Starting from the selected CPT checkpoint, we therefore perform full-parameter multitask SFT with assistant-only loss and explicitly control task exposure rather than allowing the largest training source to dominate the supervised-token budget. Together, the two stages separate the acquisition of stronger Sorbian language competence from the subsequent alignment of that competence with heterogeneous task requirements.

Our primary submission ranks third overall in the WMT 2026 Sorbian track, achieving 63.12 chrF++ on MT, 57.33 on QA, 73.13 on SC, 62.11 on GC, and 18.60 on MR (Okabe et al., 2026). The final submitted checkpoint is publicly available on HuggingFace.[1] Compared with the official Qwen3.5-2B baseline, the system improves all five task scores, with particularly large gains on SC, GC, and MT. Our development experiments further provide two observations. Removing mixed CPT while keeping the downstream SFT recipe unchanged reduces the five-task development score from 57.45 to 52.21, with the largest losses on SC, MT, and GC. In addition, increasing MT to nearly three quarters of the supervised-token budget does not improve translation and reduces performance on several other tasks. These results suggest that effective low-resource multitask adaptation requires both target-language adaptation and careful allocation of supervision across downstream capabilities.

## 2 Data

### 2.1 Mixed Continued Pre-training Data

The base Qwen3.5-2B model has limited exposure to Sorbian because the language is severely underrepresented in large-scale pre-training corpora. We therefore first perform continued pre-training to increase Sorbian linguistic competence before downstream task alignment. However, directly optimizing on a narrow low-resource corpus may cause over-specialization and degradation of previously acquired multilingual capabilities. To address this trade-off, our CPT data combines Sorbian adaptation data with multilingual and task-oriented replay.

[1] https://huggingface.co/worthing-zhang/sorbian-sft-v3-ck3250

| Component | Tokens | Role |
|---|---|---|
| Sorbian monolingual | 110.87M | adaptation |
| Parallel bilingual text | 4.22M | alignment |
| Directional MT replay | 18.60M | MT replay |
| English monolingual | 13.53M | replay |
| German monolingual | 9.29M | replay |
| Sorbian instructions | 7.62M | instruction |
| Mathematical CoT | 6.49M | reasoning |
| Task anchors | 16.12M | task replay |
| **Total** | **186.74M** | |

Table 1: Composition of the mixed CPT corpus. Token counts denote full sequence tokens; assistant-only components contain fewer trainable tokens.

The complete recipe contains approximately 186.74M full tokens and 157.76M trainable tokens. The complete composition is summarized in Table 1.

**Sorbian adaptation data.** Our monolingual pool combines the official WMT 2022, 2025, and 2026 Sorbian resources, including Wikipedia and data released by the Sorbian Institute and Witaj Language Center (Weller-Di Marco and Fraser, 2022; Okabe et al., 2025; TUM-NLP, 2026). Because substantially more Upper Sorbian than Lower Sorbian text is available after cleaning and deduplication, we expose the Upper Sorbian pool once and the Lower Sorbian pool twice. This yields 83.17M Upper Sorbian and 27.70M Lower Sorbian tokens.

We also include 82,514 unique bilingual sentence pairs from the WMT22–26 German–Upper Sorbian, German–Lower Sorbian, and Upper–Lower Sorbian training resources. A separate directional MT replay component covers all six required translation directions. Approximately 60% of its supervised tokens are allocated to Sorbian-to-German translation, 30% to German-to-Sorbian translation, and 10% to translation between the two Sorbian languages. This allocation is a heuristic replay design rather than a separately optimized mixture. We place the largest share on Sorbian-to-German to preserve German-side generation and previously acquired multilingual capability during Sorbian-focused adaptation, retain substantial German-to-Sorbian supervision for target-language generation, and reserve the remaining portion for transfer between the two closely related Sorbian languages.

**Capability replay.** Because continued pre-training on a narrow Sorbian corpus may cause

the model to over-adapt to the target language and forget capabilities acquired during multilingual pre-training, we retain English and German replay data. These replay components are intended to preserve general language modeling ability and previously learned multilingual knowledge while adapting the model to Sorbian. English replay uses FineWeb-Edu and FineWeb (Penedo et al., 2024) together with FineWiki (HuggingFaceFW, 2025). German replay uses the `deu_Latn` subset of FineWeb2 (Penedo et al., 2025) and German FineWiki. These components contribute 13.53M English and 9.29M German tokens.

We additionally construct Sorbian instruction-following data from 955 English instruction–response records drawn from a processed Magpie Pro pool (Xu et al., 2024). Each record is translated into both Upper and Lower Sorbian using Qwen3.7-Max via OpenRouter with temperature 0.2, JSON-formatted output, and reasoning disabled. The translation prompt requires all natural-language dialogue turns to be translated while preserving code, URLs, markup, formulas, variables, placeholders, and option labels. We reserve 50 translated records per language for validation, leaving 905 training records for each Sorbian language. These examples are used only in the mixed-CPT mixture and are repeated three times.

Mathematical replay uses the original English versions of GSM8K (Cobbe et al., 2021), level-1–4 MATH examples (Hendrycks et al., 2021), and 13 MathInstruct subsets (Yue et al., 2023).

We additionally include a lightweight task-anchor component for QA, SC, GC, and MR. These examples expose the model during CPT to the task-specific instruction and output formats that will later be used during multitask SFT: QA anchors use Sorbian question-answering formats, SC and GC anchors use controlled orthographic and grammatical corrections, and MR anchors use Sorbian problem statements with gold or deterministically verified reasoning supervision. MT is handled separately by the directional MT replay described above. The task-anchor component contributes 16.12M full sequence tokens, as shown in Table 1.

Because this stage combines ordinary next-token prediction with assistant-only supervised replay, we refer to it as mixed CPT.

### 2.2 Multitask SFT Data

Although CPT improves Sorbian language representations, it does not directly teach the model to follow the heterogeneous output formats required by the WMT 2026 tasks. We therefore perform multitask supervised fine-tuning to align the adapted model with MT, QA, SC, GC, and MR objectives. Because these tasks differ substantially in data scale and output structure, we construct task-specific supervision and control their effective exposure during training.

| Task | Example exposures | Token share |
|---|---|---|
| MT | 180,356 | 47.25% |
| QA | 78,764 | 3.53% |
| SC | 58,474 | 9.52% |
| GC | 78,554 | 12.58% |
| MR | 37,514 | 27.12% |
| **Total** | **433,662** | **100%** |

Table 2: Effective exposure in the final recipe multitask SFT mixture after sampling and repetition over two epochs.

The final SFT recipe jointly trains all five task families for two epochs. After sampling and repetition, the model receives 433,662 example exposures and approximately 15.61M supervised target tokens.

MT uses the same six-direction symmetric training pool described above. The remaining tasks use task-specific data construction designed to increase Sorbian supervision while preserving the official task format.

**QA.** We construct 20,000 QA examples deterministically from native Upper and Lower Sorbian Wikipedia contexts rather than translating English QA data, with 10,000 examples per language. For each language, 6,000 examples are statement-selection questions and 4,000 are Boolean-verification questions. For statement selection, the correct option is an evidence sentence from the current context, while distractors are drawn from other contexts and verified not to occur in the current context. The number of candidate options varies with difficulty from two to four. For Boolean verification, positive examples use an original evidence sentence, whereas negative examples are created by deterministically modifying a single numeric token by an offset of 1–9 and retaining only statements that do not occur in the original context. All examples preserve the corresponding Sorbian language and include the context, candidate options, answer, and supporting evidence.

**SC.** The final SC pool contains 59,693 accepted examples, including 31,039 synthetically corrupted

sentences and 28,654 unchanged CORRECT examples. Source sentences are drawn from Sorbian monolingual data and MT target-side text. Each corrupted example modifies exactly one token using one or two character-level operations selected from deletion, insertion, substitution, adjacent transposition, and diacritic change. The resulting pool contains 14,748 examples at character edit distance one and 16,291 at edit distance two. For unchanged examples, both the incorrect-word and corrected-word fields are set to `CORRECT`.

**GC.** Our grammar-correction data contains a balanced 40K pool, with 20K examples per language and approximately half of the examples representing already-correct sentences. Most error examples are constructed through rule-based or otherwise controlled single-token perturbations. To improve coverage of under-represented adjective-agreement errors, we replace 2,400 over-represented case-related error examples with adjective-agreement minimal pairs generated by Qwen3.7-Max, using 1,200 examples for each Sorbian language. Generation is constrained to modify exactly one whitespace-delimited token and to introduce a morphological disagreement in case, number, or gender rather than spelling or punctuation noise. Generated pairs are retained only when they satisfy the single-token constraint, have a token-core edit distance of at most three, and contain token cores of at least four characters. The LLM-generated examples therefore form part of the 40K pool rather than an additional dataset; the enhanced GC stratum used in later SFT recipes corresponds to the training-split subset of these same synthetic examples.

**MR.** The final MR dataset contains 18,757 unique examples: 10,363 Sorbian GSM8K examples (Cobbe et al., 2021), 3,558 Sorbian ASDiv/SVAMP examples (Miao et al., 2021; Patel et al., 2021), and 4,836 English MATH examples (Hendrycks et al., 2021).

For Sorbian examples, only the problem statement is translated. The translation is performed using gpt-5.5 with temperature 0.0, without providing answers or reasoning traces to the translation model. The prompt requires preservation of numbers, fractions, percentages, units, and symbolic expressions, followed by deterministic checks on numeric consistency, symbols, language validity, and length ratio.

GSM8K retains its original English gold reasoning traces, while ASDiv/SVAMP reasoning is constructed from deterministically verified equations whose results match the original answers. The MATH portion uses level-1–4 gold solutions in English. External LLMs are therefore used only for Sorbian problem translation rather than for generating mathematical reasoning supervision.

The redistributable portions of our synthetic and derived training data, together with generation prompts, filtering procedures, reconstructed processing scripts, source manifests, and license metadata, are publicly available at `https://huggingface.co/datasets/worthing-zhang/wmt26-sorbian-synthetic-data`. For examples whose upstream licenses or provenance do not permit unambiguous redistribution, we release only reproducibility metadata and processing artifacts rather than the underlying text.

### 2.3 Filtering and Contamination Control

After constructing the heterogeneous training mixtures, we further apply contamination filtering and quality control to reduce the risk of evaluation leakage and unintended overlap with official evaluation material. These procedures are applied throughout data construction before creating the final training views. For downstream task data, we compare source groups against available evaluation material using exact matching, normalized matching, and word 8-gram near-duplicate detection. Matched source groups are quarantined before the final production view, and no matches remain under these checks.

Held-out WMT and Sorbian validation material is also removed from the CPT monolingual pool. PluraMath (Dementieva et al., 2026), which extends PolyMath (Wang et al., 2025) to underrepresented languages and underlies the official Sorbian MR evaluation, is excluded from the complete training lineage. English mathematical sources are independently decontaminated against the corresponding English PolyMath source data.

All train/validation splits are performed at source-group level. These procedures cannot exclude semantic paraphrases or overlap with unseen hidden evaluation data; we discuss this residual risk further in the Limitations.

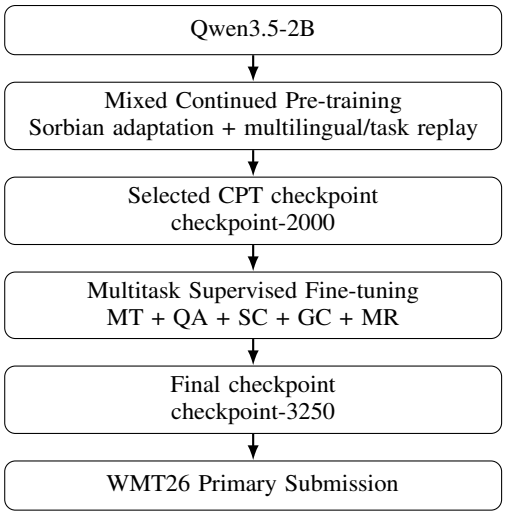

Figure 1: Overview of our two-stage adaptation pipeline. Mixed CPT strengthens Sorbian language competence while replaying multilingual and task-oriented capabilities, after which multitask SFT aligns the model with the five shared-task objectives.

## 3 Methodology

### 3.1 System Overview

Our system consists of two full-parameter adaptation stages, as illustrated in Figure 1. Mixed continued pre-training (CPT) first adapts Qwen3.5-2B to Sorbian while retaining multilingual and general task capabilities. Multitask supervised fine-tuning (SFT) then aligns the adapted model with the five shared-task objectives.

### 3.2 Mixed Continued Pre-training

To increase Sorbian exposure without overspecializing the model to a narrow low-resource corpus, we formulate continued pre-training as a mixed objective. Starting from Qwen3.5-2B, we jointly train on the Sorbian-focused data described in Table 1 together with multilingual and task-oriented replay.

Raw monolingual and bilingual texts are trained with the standard next-token prediction objective. Translation, instruction-following, mathematical-reasoning, and downstream-task examples instead use assistant-only supervised loss. The mixture therefore combines Sorbian language acquisition with capability replay within a single CPT stage.

We include English and German text together with directional MT supervision to reduce capability degradation during language adaptation. Lower Sorbian is also upsampled relative to its naturally available corpus size to reduce the large imbalance between Upper and Lower Sorbian training resources.

The resulting CPT model is used to initialize the subsequent multitask SFT stage.

### 3.3 Multitask Supervised Fine-tuning

Continued pre-training improves the model's Sorbian representations but does not directly align it with the heterogeneous input and output requirements of the five downstream tasks. We therefore perform full-parameter multitask SFT from the selected CPT checkpoint using MT, QA, SC, GC, and MR supervision jointly.

Before SFT, examples from all tasks are normalized into a common instruction–input–output schema. The instruction identifies the task, language direction when applicable, and required response format; the input contains the source sentence, context, question, or candidate options; and the output contains the canonical target response. Each record is then serialized as a single-turn conversation using the Qwen chat template, with the instruction and task input placed in the user turn and the target response placed in the assistant turn. We compute loss only on assistant tokens.

To improve instruction-following stability and permit deterministic answer extraction, the targets follow task-specific structured formats. MT targets contain only the tagged target-language translation. SC and GC targets separately identify the incorrect word and its correction. MR targets contain the verified reasoning supervision followed by a delimited final answer, while QA records preserve the candidate-answer format used for selection. The same instructions and response delimiters are retained during inference.

We train all six MT directions together with the four non-MT tasks in a single model using the final mixture reported in Table 2. Because the task datasets differ substantially in size and response length, we control effective exposure through task-specific sampling and repetition rather than sampling directly in proportion to the available raw data. Detailed construction of the task datasets is described in Section 2 and its corresponding subsections.

### 3.4 Inference

For the generative tasks, inference uses the same task instructions, Qwen chat serialization, and response formats as multitask SFT. This alignment avoids a train–inference prompt mismatch and al-

lows predictions to be recovered using deterministic post-processing rather than unconstrained interpretation of the complete model response.

For MT, we extract the text inside the expected target-language span and use it as the translation. For SC and GC, the incorrect-word and corrected-word fields are extracted separately and written to the corresponding submission fields. For MR, the reasoning trace is removed during post-processing and the delimited final answer is extracted for evaluation. Translation is performed independently at sentence level.

QA does not use free-form generation. We place the context, question, and candidate options in the same task template used during training, compute the conditional log-likelihood of each candidate answer, and select the highest-scoring option. The resulting task predictions are then converted to the official WMT 2026 JSONL submission fields.

## 4 Experimental Setup

### 4.1 Training Setup

Table 3 summarizes the optimization settings used for the two training stages. Both stages update all model parameters.

| Setting | Mixed CPT | multitask SFT |
|---|---|---|
| Epochs | 1 | 2 |
| Max. sequence length | 2,048 | 2,048 |
| Learning rate | $2 \times 10^{-5}$ | $3 \times 10^{-6}$ |
| Warmup | 3% | 3% |
| LR schedule | cosine | cosine |
| Per-device batch | 16 | 8 |
| Gradient accumulation | 2 | 2 |
| Number of GPUs | 8 | 8 |
| Global batch | 256 | 128 |

Table 3: Training configuration for mixed CPT and the final multitask SFT run.

We use ZeRO-2 (Rajbhandari et al., 2020) and FlashAttention-2 (Dao, 2024) for distributed and memory-efficient training. The final SFT run finishes after 3,388 optimization steps and takes approximately 2.75h on 8 GPUs.

The submitted checkpoint contains approximately 2.21B parameters and is evaluated in BF16 precision.

### 4.2 Inference Setup

For MT, SC, and GC, we disable the model's native thinking mode and perform a single generation pass with the task-specific templates described in Section 3.4. For MR, we enable native thinking and use temperature 1.0, top-$p = 0.95$, top-$k = 20$, and a maximum generation length of 4,096 tokens. The reasoning trace is removed before extracting the final answer. QA is evaluated through candidate conditional log-likelihood and therefore does not use generation hyperparameters.

### 4.3 Evaluation

We use the official WMT 2026 evaluation repository, which is based on the Language Model Evaluation Harness (Gao et al., 2023), for development evaluation and submission generation.

For MT, we report the mean chrF++ score (Popović, 2015) over the six Sorbian translation directions. BLEU is additionally reported in the official results but is not used for our internal checkpoint selection.

For QA, we use candidate-selection accuracy. For MR, we report accuracy using the official evaluation implementation. For SC and GC, our internal checkpoint-selection metric uses the corrected-form exact-match score averaged across Upper and Lower Sorbian.

For model development, we define an internal five-task selection score:

$$S_{\text{dev}} = \frac{M_{\text{MT}} + M_{\text{SC}} + M_{\text{GC}} + M_{\text{MR}} + M_{\text{QA}}}{5}, \tag{1}$$

where all task scores are represented on a 0–100 scale.

$M_{\text{MT}}$ is the mean chrF++ score over the six MT directions. $M_{\text{SC}}$ and $M_{\text{GC}}$ are the mean corrected-form exact-match scores over Upper and Lower Sorbian. $M_{\text{MR}}$ and $M_{\text{QA}}$ are accuracy scores.

This development score is used only for model comparison and checkpoint selection. It is not identical to the official final leaderboard aggregation because the official SC and GC task scores incorporate both error detection and correction.

### 4.4 Checkpoint Selection

All model and checkpoint selection is performed on development data. Blind test results are not used to select the final checkpoint.

For mixed CPT, we evaluate checkpoints between steps 500 and 3000 and select checkpoint 2000 as the common initialization for subsequent SFT experiments.

For the final SFT run, we evaluate checkpoints throughout training. Checkpoint 3250 obtains the

highest value of $S_{\text{dev}}$ among the evaluated checkpoints and is used for the primary submission.

The no-CPT ablation follows the same evaluation protocol. For that run, checkpoint 3000 obtains the highest development selection score and is used in the controlled comparison with the submitted CPT-initialized model.

## 5 Results and Analysis

### 5.1 Official Shared-task Results

Table 4 reports the official primary-submission results for the WMT 2026 Sorbian track. Detailed results by translation direction and language-specific task scores are provided in Appendix A.

As shown in Table 4, our system ranks third overall in the Sorbian track. It obtains the second-highest QA score and the third-highest score on MT, SC, GC, and MR.

Compared with the official Qwen3.5-2B baseline, our primary submission improves MT from 21.68 to 63.12 chrF++, QA from 43.39 to 57.33, SC from 6.66 to 73.13, GC from 1.34 to 62.11, and MR from 5.40 to 18.60. These correspond to absolute improvements of 41.44 points on MT, 13.94 on QA, 66.47 on SC, 60.77 on GC, and 13.20 on MR.

The leaderboard nevertheless indicates substantial remaining headroom, particularly on MT, GC, and MR. We therefore view the submission as a strong improvement over the fixed base model rather than as saturation of the Sorbian track.

### 5.2 Task-Mixture and Supervision Trade-offs in Multitask SFT

We examine how task allocation and supervision design affect multitask adaptation in the low-resource setting. Specifically, we compare three full-parameter SFT recipes initialized from the same selected CPT checkpoint. The comparison focuses on whether heavily increasing ordinary MT supervision improves translation, and whether a more balanced task mixture with task-aligned supervision produces a stronger overall model. Table 5 summarizes the main configuration differences and the selected checkpoint of each recipe.

As shown in Table 5, V1 provides the reference multitask mixture, whereas V2 substantially increases ordinary MT supervision to 73.94% of the supervised-token budget. Despite this increase, MT decreases from 66.01 to 65.53, an absolute reduction of 0.48 points. SC decreases from 69.55 to 64.27, and QA decreases from 69.03 to 67.47, corresponding to reductions of 5.28 and 1.56 points. GC increases from 57.47 to 59.40, but this change coincides with the introduction of refined GC supervision and therefore cannot be attributed to the increase in MT data.

The V1–V2 comparison suggests that allocating most of a fixed supervision budget to the largest task does not necessarily improve that task and may reduce the effective exposure of the remaining tasks. One possible explanation is that MT had already reached diminishing returns under the available supervision, whereas the smaller tasks were more sensitive to reductions in training exposure. Because the MR inference protocols differ, we do not use the V1 MR score or its aggregate development score to assess the effect of the SFT recipe.

V3 corresponds to the final SFT recipe used for our WMT 2026 primary submission. V3 reduces the dominance of MT and restores broader coverage of the remaining tasks. It also retains the refined GC supervision and replaces the previous MR data with the reasoning-oriented supervision described in Section 2.2. Compared with V2, V3 improves MT from 65.53 to 65.84, SC from 64.27 to 68.30, GC from 59.40 to 59.63, MR from 18.75 to 22.92, and QA from 67.47 to 70.55. These correspond to absolute gains of 0.31, 4.03, 0.23, 4.17, and 3.08 points, respectively. The overall development score consequently increases from 55.09 to 57.45, a gain of 2.36 points.

These results provide two practical lessons for low-resource multitask adaptation. Maintaining sufficient exposure for smaller tasks and improving the quality and format alignment of their supervision can be more effective than repeatedly oversampling a comparatively mature task. Since both the task mixture and the MR supervision change between V2 and V3, this comparison should be interpreted as a system-level recipe comparison rather than a controlled single-variable ablation. The complete development trajectories of the V1, V2, and V3 recipes are reported in Tables 9, 10, and 11, respectively.

### 5.3 Ablation Study

We conduct an ablation study to quantify the contribution of the two adaptation stages. We compare four settings: the original Qwen3.5-2B base model, mixed CPT without downstream SFT, multitask SFT applied directly to the base model, and

| System | MT | QA | SC | GC | MR | Points | Rank |
|---|---|---|---|---|---|---|---|
| HeyBusan | **72.75** | 55.92 | **78.03** | **79.52** | 29.00 | **22** | **1** |
| LT3 | 69.57 | **65.05** | 76.11 | 78.32 | **30.40** | **22** | **1** |
| **HITSZ (ours)** | 63.12 | 57.33 | 73.13 | 62.11 | 18.60 | 16 | 3 |
| HSE | 61.50 | 46.77 | 63.63 | 50.02 | 5.00 | 9 | 4 |
| Qwen3.5-2B baseline | 21.68 | 43.39 | 6.66 | 1.34 | 5.40 | 5 | 5 |

Table 4: Official WMT 2026 Sorbian-track results for primary submissions. MT is reported in chrF++; the remaining columns use the official task scores. Bold task scores indicate the best result in each column.

| Recipe | Main configuration |
|---|---|
| V1 | Initial multitask mixture. It uses the initial GC and MR supervision, with non-thinking inference for MR. |
| V2 | MT-heavy mixture, with MT accounting for 73.94% of the supervised-token budget. It uses refined GC supervision and thinking-enabled MR inference. |
| V3 | Rebalanced mixture with MT/QA/SC/GC/MR token shares of 47.25/3.53/9.52/12.58/27.12%. It retains the refined GC supervision and replaces the previous MR data with reasoning-oriented supervision. MR uses thinking-enabled inference. |

| Recipe | Step | MT | SC | GC | MR | QA | $S_{dev}$ |
|---|---|---|---|---|---|---|---|
| V1 | 1750 | 66.01 | 69.55 | 57.47 | 2.08† | 69.03 | 52.83† |
| V2 | 3352 | 65.53 | 64.27 | 59.40 | 18.75 | 67.47 | 55.09 |
| V3 | 3250 | 65.84 | 68.30 | 59.63 | 22.92 | 70.55 | **57.45** |

Table 5: Main configuration differences and selected development checkpoints for the three multitask SFT recipes. Percentages denote shares of supervised training tokens. †V1 uses non-thinking inference for MR; consequently, its MR and aggregate scores are not directly comparable with those of V2 and V3.

the complete CPT→SFT pipeline. For all comparisons, we use the same downstream evaluation protocol and select the checkpoint with the highest development selection score for each setting.

As shown in Table 6, both CPT and SFT provide substantial improvements over the original base model, but they contribute in different ways. Mixed CPT alone improves the five-task development score from 16.84 to 46.77, with particularly large gains on MT, SC, and GC. These improvements indicate that continued pre-training effectively increases Sorbian language competence and provides useful representations for language-dependent tasks.

In contrast, SFT-only achieves a score of 52.21 by directly optimizing the official downstream task formats. Compared with CPT only, SFT provides stronger improvements on MR and QA, showing that task-specific supervision is necessary for learning structured response formats and reasoning-oriented objectives.

The complete CPT→SFT pipeline obtains the best performance with a score of 57.45, outperforming SFT-only by 5.24 points. The remaining gains after SFT initialization are mainly observed in MT (+6.16), SC (+14.20), and GC (+4.67), suggesting that Sorbian-oriented continued pre-training provides linguistic knowledge that cannot be fully recovered by downstream supervision alone.

The effect of CPT is task dependent. While CPT improves language-dependent tasks substantially, it does not directly solve structured reasoning evaluation: CPT-only obtains 0.00 on MR, indicating that the lightweight MR anchors used during CPT are insufficient to learn the task-specific reasoning and answer format without downstream SFT. After SFT alignment, MR performance improves to 22.92. The MR results should still be interpreted cautiously because the development set contains only 48 examples and therefore has coarse score resolution.

This ablation compares complete adaptation stages rather than individual data components. Since removing CPT changes the entire continued pre-training stage, the experiment does not isolate the contribution of individual CPT data sources. Detailed checkpoint trajectories for both CPT and no-CPT runs are provided in Appendices B and C.

### 5.4 Task-level Analysis

The comparisons in Tables 5 and 6 reveal two complementary sources of improvement. Mixed CPT mainly benefits tasks that depend strongly on Sorbian language knowledge: under the same multitask SFT recipe, CPT initialization improves SC from 54.10 to 68.30 (+14.20), MT from 59.68 to 65.84 (+6.16), and GC from 54.96 to 59.63 (+4.67), while producing smaller gains on QA and MR.

The SFT-stage results further show that supervision allocation affects how the adapted capability is distributed across tasks. Increasing MT to 73.94% of the supervised-token budget reduces several other task scores, whereas the rebalanced recipe achieves the strongest overall development result.

| System | MT | SC | GC | MR | QA | $S_{dev}$ |
|---|---|---|---|---|---|---|
| Qwen3.5-2B | 22.04 | 8.42 | 0.38 | 4.17 | 49.21 | 16.84 |
| CPT only | 55.66 | 58.30 | 57.46 | 0.00 | 62.43 | 46.77 |
| SFT only | 59.68 | 54.10 | 54.96 | 22.92 | 69.38 | 52.21 |
| CPT→SFT | 65.84 | 68.30 | 59.63 | 22.92 | 70.55 | 57.45 |
| Δ (CPT→SFT vs. Base) | +43.80 | +59.88 | +59.25 | +18.75 | +21.34 | +40.61 |

Table 6: Ablation study of the two-stage adaptation pipeline. CPT only applies mixed continued pre-training without downstream supervised fine-tuning, SFT only directly fine-tunes the base model on downstream tasks, and CPT→SFT represents the complete system.

Taken together, these results motivate the final two-stage system. Mixed CPT supplies broad Sorbian language adaptation, while the multitask SFT recipe determines how effectively that capability is distributed across the five downstream objectives. In our setting, allocating most of the supervised-token budget to the largest task does not improve that task. Maintaining broader task coverage and using task-aligned supervision instead produces the strongest overall development result.

We treat this interpretation as specific to our training setting. The CPT comparison removes the complete adaptation stage rather than individual CPT components, and the SFT recipes are system-level comparisons rather than controlled single-variable ablations.

## 6 Conclusion

We present the HITSZ system for the WMT 2026 Multitask LLMs with Limited Resources Sorbian track. Our approach adapts Qwen3.5-2B through two complementary stages: mixed continued pre-training combines Sorbian adaptation data with multilingual and task-oriented replay to improve language competence, while multitask supervised fine-tuning aligns the adapted model with MT, QA, SC, GC, and MR objectives. The resulting system substantially outperforms the official Qwen3.5-2B baseline on all five tasks and ranks third overall in the Sorbian track. Our ablation studies show that downstream SFT alone cannot fully replace target-language adaptation: removing mixed CPT decreases the five-task development score by 5.24 points, mainly affecting language-dependent tasks such as SC, MT, and GC. We further find that allocating excessive supervision to the largest task does not improve translation performance and can reduce other task capabilities. These results highlight the importance of combining sufficient target-language adaptation with balanced supervision allocation when adapting compact LLMs to low-resource multilingual multitask settings.

## 7 Limitations

Our experiments are primarily system-development experiments rather than exhaustive controlled studies. In particular, the V1, V2, and V3 recipes differ in more than one design choice, so their comparison supports conclusions about complete training recipes rather than the contribution of individual components. We also train one main run for each recipe and do not estimate variance across random seeds, which is especially relevant for MR because its development set contains only 48 examples.

Our development protocol also differs slightly from the official leaderboard evaluation. SC and GC checkpoint selection uses corrected-form exact match, whereas the official scores combine error detection and correction. In addition, our contamination filtering cannot completely exclude semantic overlap with unseen evaluation material, and LLM-assisted or synthetic data construction may introduce artifacts that are not separately quantified.

# A Detailed Evaluation Results

## A.1 Machine Translation by Direction

Table 7 reports the official MT results of our primary submission for all six Sorbian translation directions.

| Direction | BLEU | chrF++ |
|---|---|---|
| de→hsb | 35.32 | 60.04 |
| hsb→de | 37.42 | 62.42 |
| de→dsb | 26.87 | 52.37 |
| dsb→de | 36.30 | 60.92 |
| dsb→hsb | 49.42 | 70.62 |
| hsb→dsb | 50.50 | 72.35 |

Table 7: Official machine translation results of our primary submission by direction.

Translation between Upper and Lower Sorbian is strongest, exceeding 70 chrF++ in both directions. German-to-Lower-Sorbian is the weakest direction at 52.37 chrF++.

## A.2 Detailed QA, SC, GC, and MR Results

Table 8 reports the official Upper and Lower Sorbian results for the non-MT tasks.

| Metric | HSB | DSB |
|---|---|---|
| QA accuracy | 58.57 | 56.10 |
| MR accuracy | 19.20 | 18.00 |
| SC detection | 81.55 | 78.05 |
| SC correction | 66.95 | 65.95 |
| GC detection | 64.70 | 63.09 |
| GC correction | 60.80 | 59.85 |

Table 8: Detailed official results for Upper Sorbian and Lower Sorbian.

# B Development Checkpoint Trajectories

## B.1 SFT V1

| Step | MT | SC | GC | MR | QA | $S_{dev}$ |
|---|---|---|---|---|---|---|
| 250 | 60.40 | 62.60 | 57.05 | 4.17 | 64.86 | 49.82 |
| 500 | 61.58 | 63.98 | 57.64 | 0.00 | 65.65 | 49.77 |
| 750 | 62.96 | 66.15 | 57.69 | 4.17 | 66.90 | 51.57 |
| 1000 | 65.51 | 69.42 | 57.10 | 6.25 | 68.30 | 53.32 |
| 1250 | 65.81 | 69.55 | 57.37 | 2.08 | 67.63 | 52.49 |
| 1500 | 66.09 | 70.10 | 57.04 | 2.08 | 68.20 | 52.70 |
| 1750 | 66.01 | 69.55 | 57.47 | 2.08 | 69.03 | **52.83** |
| 1782 | 66.02 | 69.80 | 57.27 | 0.00 | 67.98 | 52.21 |

Table 9: Development trajectory for the V1 SFT run. V1 MR uses non-thinking evaluation.

## B.2 SFT V2

| Step | MT | SC | GC | MR | QA | $S_{dev}$ |
|---|---|---|---|---|---|---|
| 500 | 60.83 | 60.02 | 55.68 | 14.58 | 64.13 | 51.05 |
| 1000 | 62.63 | 64.98 | 59.96 | 10.42 | 65.08 | 52.61 |
| 1500 | 64.42 | 63.13 | 58.87 | 18.75 | 65.46 | 54.12 |
| 2000 | 64.65 | 62.02 | 58.19 | 14.58 | 66.96 | 53.28 |
| 2500 | 65.39 | 63.62 | 57.55 | 16.67 | 67.41 | 54.13 |
| 3000 | 65.67 | 63.35 | 59.61 | 14.58 | 67.47 | 54.14 |
| 3352 | 65.53 | 64.27 | 59.40 | 18.75 | 67.47 | **55.09** |

Table 10: Development trajectory for the V2 SFT run.

### B.3 SFT V3

| Step | MT | SC | GC | MR | QA | $S_{dev}$ |
|---|---|---|---|---|---|---|
| 1500 | 63.02 | 65.70 | 58.42 | 12.50 | 68.10 | 53.55 |
| 1750 | 64.82 | 67.95 | 60.76 | 20.83 | 68.84 | 56.64 |
| 2500 | 65.35 | 68.17 | 60.10 | 16.67 | 69.12 | 55.88 |
| 3000 | 65.65 | 67.78 | 60.80 | 20.83 | 70.33 | 57.08 |
| 3250 | 65.84 | 68.30 | 59.63 | 22.92 | 70.55 | **57.45** |
| 3388 | 65.72 | 68.35 | 60.07 | 20.83 | 70.33 | 57.06 |

Table 11: Development trajectory for the final V3 SFT run.

## C No-CPT Ablation Trajectory

Table 12 reports the complete development trajectory of the SFT-only recipe initialized directly from Qwen3.5-2B without mixed CPT. The best development score is obtained at step 3000, which is used in the controlled comparison reported in Table 6.

| Step | MT | SC | GC | MR | QA | $S_{dev}$ |
|---|---|---|---|---|---|---|
| 250 | 40.47 | 35.43 | 40.84 | 12.50 | 65.74 | 39.00 |
| 500 | 45.57 | 43.07 | 46.37 | 14.58 | 66.00 | 43.12 |
| 750 | 48.69 | 43.25 | 49.04 | 14.58 | 67.78 | 44.67 |
| 1000 | 52.35 | 45.45 | 52.23 | 14.58 | 65.91 | 46.10 |
| 1250 | 53.77 | 48.75 | 51.83 | 16.67 | 69.05 | 48.01 |
| 1500 | 54.81 | 52.33 | 54.42 | 14.58 | 68.62 | 48.95 |
| 1750 | 57.33 | 53.12 | 54.78 | 18.75 | 70.60 | 50.92 |
| 2000 | 58.32 | 53.52 | 53.60 | 20.83 | 69.86 | 51.23 |
| 2250 | 59.30 | 52.30 | 53.95 | 20.83 | 69.26 | 51.13 |
| 2500 | 59.51 | 54.30 | 55.05 | 16.67 | 69.26 | 50.96 |
| 2750 | 59.60 | 53.12 | 54.42 | 22.92 | 69.54 | 51.92 |
| 3000 | 59.68 | 54.10 | 54.96 | 22.92 | 69.38 | **52.21** |
| 3250 | 59.91 | 53.40 | 54.72 | 22.92 | 69.60 | 52.11 |
| 3388 | 59.90 | 53.62 | 55.18 | 22.92 | 69.38 | 52.20 |

Table 12: Development trajectory for the SFT-only recipe initialized directly from Qwen3.5-2B without mixed CPT.
