# A Simple Transformation for Offline-Parsable Grammars and its Termination Properties 

Marc Dymetman*<br>Rank Xerox Rescarch Centre<br>6 , chemin de Maupertuis<br>Mcylan, 38240 France<br>dymetman@xerox.fr

#### Abstract

We present, in easily reproducible terms, a simple transformation for offline-parsable grammars which results in a provably terminating parsing program directly top-down interpretable in Prolog. The transformation consists in two steps: (1) removal of empty-productions, followed by: (2) left-recursion elimination. It is related both to left-corner parsing (where the grammar is compiled, rather than interpreted through a parsing program, and with the advantage of guaranteed termination in the presence of cmpty productions) and to the Generalized (ireibach Normal Form for DCGs (with the advantage of implcmentation simplicity).

## 1 Motivation

Definite clause grammars (DCGs) are one of the simplest and most widely used unification grammar formatisms. They represent a direct augmentation of context-free grammars through the use of (term) unification (a fact that tends to be masked by their usual presentation based on the programming language Prolog). It is obviously important to ask wether certain usual methods and algorithms pertaining to CFGs can be adapted to DCGs, and this general question informs much of the work concerning DCGs, as well as more complex unification grammar formalisms (to cite only a few areas: Earley parsing, LR parsing, left-corner parsing, Greibach Normal Lorm).
One cssential complication when trying to generalize CFG methods to the DCG domain lies in the fact that, whereas the parsing problem for ClGs is decidable, the corresponding problem for $D C G$ is in general undecidable. This can be shown easily as a consequence of the noteworthy fact that any definite clause program can be viewod as a definite clause grammar "on the empty string", that is, as a DCG where no terminals other than [] are allowed on the right-hand sides of rules. The Turing-completeness of definite clause programs therefore implies the undecidability of the parsing problem for this subclass of DCGs, and a fortiori for DCGs in general. ${ }^{1}$ In order to guarantee good

[^0]computational propertics for DCGs, it is then necessary to impose certain restrictions on their form such as offine-parsability (OP), a nomenclature introduced by Percira and Warren [11], who define an OP DCG as a grammar whose context-free skeleton CFG is not infinitcly ambiguous, and show that OP DCGs lead to a decidable parsing problem. ${ }^{2}$
Our aim in this paper is to propose a simple transformation for an arbitrary OP DCG putting it into a form which leads to the completeness of the direct top-down interpretation by the standard Prolog interpreter: parsing is guaranteed to comerate all solutions to the parsing problem and terminate. The existence of such a transformation is known: in $[1,2]$, we have recently introduced a "Generalized Greibach Normal Form" (GGNF) for DCGs, which leads to termination of top-down interpretation in the OP casc. However, the available presentation of the GGNF transformation is rather complex (it involves an algobraic study of the fixpoints of certain equational systems representing grarmmars.). Our aim here is to present a related, but much simpler, transformation, which from a theoretical vicwpoint performs somewhat less than the GGNF transformation (it involves some encoding of the initial DCG, which the GGNF does not, and it only handles offline-parsable grammars, while the GGNF is defined for arbitrary DCGs), ${ }^{3}$ but in practice is extremely easy to implement and displays a comparable behavior when parsing with an OP grammar.

The transformation consists of two steps: (1) emptyproduction elimination and (2) left-recursion elimination.

The empty-production elimination algorithm is inspired by the ustal procedure for context-free grammars. But there are some notable differences, due to the fact that removal of empty-productions is in general impossible for non-OP DCGs. The empty-

[^1]production elimination algorithm is guaranteed to terminate only in the OP case. ${ }^{4}$ It produces a DCG declaratively equivalent to the original grammar.
The left-recursion elimination algorithm is adapted from a transformation proposed in [4] in the context of a certain formalism ("lexical Grammars") which we presented as a possible basis for building reversible grammars. ${ }^{5}$ The key observation (in slightly different terms) was that, in a DCG, if a nonterminal $g$ is defined literally by the two rules (the first of which is leftrecursive):
\[

$$
\begin{aligned}
& g(X) \rightarrow g(Y), d(Y, X) . \\
& g(X) \rightarrow t(X) .
\end{aligned}
$$
\]

then the replacernent of these two rules by the three rules (where $d t c$ is a new nonterminal symbol, which represents a kind of "transitive closure" of $d$ ):

$$
\begin{aligned}
& g(X) \rightarrow t(Y), d \_t c(Y, X) \\
& d \_t c(X, X) \rightarrow[] . \\
& d \_t c(X, Z) \rightarrow d(X, Y), d \_t c(Y, Z) .
\end{aligned}
$$

preserves the declarative semantics of the grammar. ${ }^{\text {b }}$
We remarked in [4] that this transformation "is closely related to left-corner parsing", but did not give details. In a recent paper [7], Mark Johnson introduces "a left-corner program transformation for natural language parsing", which has some similarity to the above transformation, but which is applied to definite clanse programs, rather than to DCGs. He proves that this transformation respects declarative equivalence, and also shows, using a model-theoretic approach, the close connection of his transformation with left-comer parsing $[12,9,10]$. ${ }^{\text {? }}$

It must be noted that the left-recursion elimination procedure can be applied to any I)C(x, whether OP or not. Henen in the case where the grammar is OP, how cver, it will not lead to a terminating parsing algorithm unless empty productions have been prealably climinated from the grammar, a problem which is shared by the usual left-corner parser-interpreter.

[^2]Dite to the space available, we do not give here correctness proofs for the algorithms presenled, but expect to publish them in a fuller version of this paper. These algorithms have actually been implemented in a slightly extended version, where they are also used to decide whether the grammar proposed for transformation is in fact offline-parsable or nol.

## 2 Empty-production elimination

It can be proven that, if 1$)(\mathrm{GO}$ is an OP OCO , the following transformation, which involves repeated partial evaluation of rules that rewrite into the empty string, terminates after a finite number of steps and produces a grammar DCG without empty-productions which is equivalent to the initial grammar on nonempty strings: ${ }^{8}$
input: an oflline-parsable DC(11.
ontput: a 1 ) CG withont empty rules equivalent to DCG 1
on non-empty strings.
algorithm:
initialize LISTI to a list of the rules of DCG1, set JIST'2
to the empty list.
while there exists an emply rule $\mathrm{BR}: ~ A\left(T^{\prime} 1, \ldots, T k\right) \rightarrow[]$ in LTS'I do:
move FR to 1.LS'L2.
for each rule $\mathrm{R}: \quad B(\ldots) \rightarrow \alpha$ in LSSP1 such that $\alpha$ contains an instance of $A(\ldots)$ (including
new such rules created inside this loop) do:
for each such instance $A(S ' 1, \ldots, S k)$ unifiable with $A(T I, \ldots, T k)$ do:
append to $L A S^{\prime} \mathrm{N}^{\prime} 1$ a rule $\mathrm{R} ': ~ B(\ldots) \rightarrow \alpha^{\prime}$ obtained
from R by removing $A(S 1, \ldots, S k)$
from a (or by replacing it with [] if this was
the only nonterminal in $\alpha$ ),
and by unifying the 'Ti's with the $S i$ 's.
set $)$ (ot to LISl.
Jor instance the grammar consisting in the nine rules appearing above the separation in fig. 1 is transformed into the grammar (see figure):

$$
\begin{aligned}
& s(s(N I, V P)) \cdots p\left(N l^{\prime}\right), v p(V P) . \\
& n p(n p(N, C)) \rightarrow n(N), \operatorname{comp}(C) . \\
& n(n(\text { pcople })) \rightarrow[\text { people }] \text {. } \\
& v p(v p(v(\operatorname{slet} p), C)) \rightarrow[\operatorname{slecp}], \operatorname{comp}(C) . \\
& \operatorname{comp}(c(C, A)) \rightarrow \operatorname{comp}(C), u d v(A) . \\
& \operatorname{adv}(\operatorname{adv}(\text { here })) \rightarrow[\text { here }] . \\
& a d v(a d v(t o d a y)) \rightarrow[t o d a y] . \\
& n p\left(n p(n(y o u)), C^{Y}\right) \rightarrow \operatorname{comp}\left(C^{\prime}\right) . \\
& n p(n p(N, n i l)) \rightarrow n(N) \text {. } \\
& \operatorname{comp}(c(n i l, A)) \rightarrow \operatorname{adv}(A) \text {. } \\
& v p(v p(v(s l e e p), n i l)) \rightarrow[s l e e p] . \\
& s\left(s\left(n p(n p(n(y o u)), n i l), V l^{\prime}\right)\right) \rightarrow v p\left(V P^{\prime}\right)
\end{aligned}
$$

[^3]
## 3 Left-recursion elimination

The transformation can be logically divided into two steps: (1) an encoding of DCG into a "generic" form DCG', and (2) a simple replacement of a certain group of left-recursive rules in DCG' by a certain equivalent non left-recursive group of rules, yielding a top-down interpretable DCG". An example of the transformation $\mathrm{DCG} \longrightarrow \mathrm{DCG}{ }^{\prime} \longrightarrow \mathrm{DCG}^{\prime}$ is given in fig. 2.
The encoding is performed by the following algorithm:
input: an offline-parsable DCG withont empty rules. output: an equivalent "encoding" DCG".
algorithm:
initialize LIST to a list of the rules of DCG.
initialize $\mathrm{DCG}^{\prime}$ to the list of rules (literally):

$$
g(X) \rightarrow g(Y), d(Y, X)
$$

$$
g(X) \rightarrow t(X)
$$

while there exists a rule R of the form
$A(T 1, \ldots, T k) \rightarrow B(S 1, \ldots, S l) \alpha$ in LIST do: remove R from LIS'T.
add to DCG' a rule R':
$d(B(S 1, \ldots, S l), A(T 1, \ldots, T k)) \rightarrow \alpha^{\prime}$,
where $\alpha^{\prime}$ is obtained by replacing any $C(V 1, \ldots, V m)$
in $\alpha$ by $g(C(V 1, \ldots, V m))$,
or is set to [] in the case where $\alpha$ is empty.
while there exists a rule $R$ of the form
$A\left(T^{\prime} 1, \ldots, T k\right) \rightarrow[$ terminal $] \alpha$ in LIS' $d o:$
remove R from LIST.
add to $\mathrm{DCG}^{\prime}$ a rule R ':
$t(A(T 1, \ldots, T k)) \rightarrow[$ terminal $] \alpha^{\prime}$,
where $\alpha^{\prime}$ is obtained by replacing any $C(V 1, \ldots, V m)$
in $\alpha$ by $g(C(V 1, \ldots, V m))$,
or is set to [] in the case where $\alpha$ is empty.

The procedure is very simple. It involves the creation of a generic nonterminal $g(X)$, of arity one, which performs a task equivalent to the original nonterminals $s(X 1, \ldots, X n), v p(X 1, \ldots, X m), \ldots$ The goal $g(s(X 1, \ldots, X n))$, for instance, plays the same role for parsing a sentence as did the goal $s(X 1, \ldots, X n)$ in the original grammar.
Two further generic nonterminals are introduced: $t(X)$ accounts for rules whose right-hand side begins with a terminal, while $d(Y, X)$ accounts for rules whose right-hand side begins with a nonterminal. The rationale behind the encoding is best understood from the following examples, where $\Rightarrow$ represents rule rewriting:

```
vp(vp(v(sleep),C)) }->[sleep], comp(C
\Longrightarrowg(vp(vp(v(sleep),C)))}->[sleep],g(comp(C)
=>g(X) ->[sleep],
    \underbrace
```

```
\(s(s(N P, V P)) \rightarrow n p(N P), v p(V P)\)
\(\Longrightarrow g(s(s(N P, V P))) \rightarrow g(n p(N P)), g(v p(V P))\)
\(\Longrightarrow g(X) \rightarrow g(Y)\),
    \(\underbrace{(\{X=s(s(N P, V P)), Y=n p(N P)\}, g(v p(V P)))}_{d(Y, X)}\)
```

The second example illustrates the role played by $d(Y, X)$ in the encoding. This nonterminal has the following interpretation: $X$ is an "immediate" extension of $Y$ using the given rule. In other words, $Y$ corresponds to an "immediate left-corner" of $X$.

The left-recursion elimination is now performed by the following "algorithm": ${ }^{9}$
input: a DCG' encoded as above.
output: an equivalent non left-recursive DCG".
algorithm:
initialize $\mathrm{DCG}^{\prime \prime}$ to $\mathrm{DCG}^{\prime}$.
in DCG", replace literally the rules:

$$
g(X) \rightarrow g(Y), d(Y, X) .
$$

$$
g(X) \rightarrow t(X)
$$

by the rules:

$$
g(X) \rightarrow t(Y), d_{-} t c(Y, X)
$$

$$
\text { d_tc }(X, X) \rightarrow[] .
$$

$$
d_{-} t c(X, Z) \rightarrow d(X, Y), d_{-} t c(Y, Z)
$$

In this transformation, the new nonterminal d_tc plays the role of a kind of transitive closure of $d$. It can be seen that, relative to DCG", for any string $w$ and for any ground term $z$, the fact that $g(z)$ rewrites into $w$-or, equivalently, that there exists a ground term $x$ such that $t(x) d_{-} t c(x, z)$ rewrites into $w$ is equivalent to the existence of a sequence of ground terms $x=x_{1}, \ldots, x_{k}=z$ and a sequence of strings $w_{1}, \ldots, w_{k}$ such that $t\left(x_{1}\right)$ rewrites into $w_{1}, d\left(x_{1}, x_{2}\right)$ rewrites into $w_{2}, \ldots, d\left(x_{k-1}, x_{k}\right)$ rewrites into $w_{k}$, and such that $w$ is the string concatenation $w=w_{1} \cdots w_{k}$. From our previous remark on the meaning of $d(Y, X)$, this can be interpreted as saying that "consituent $x$ is a left-corner of constituent $z$ ", relatively to string $w$.

The grammar DCG" can now be compiled in the standard way - via the adjunction of two "differential list" arguments---into a Prolog program which can be executed directly. If we started from an offline-parsable grammar DCG0, this program will enumerate all solutions to the parsing problem and terminate after a finite number of steps. ${ }^{10}$

Figure 2: Encoding (DCG') of a grammar (DCG) and left-recursion elimination (DCG").```

[^0]:    *Thanks to Pierre Isabelle and François Perrault for their comments, and to CITI (Montreal) for its support during the preparation of this paper.
    ${ }^{1}$ DCGs on the empty string might be dismissed as extreme,

[^1]:    but they are in fact at the core of the offline-parsability concept. See note 3.
    ${ }^{2}$ The concept of oflline-parsability (under a different name) goes back to $[8]$, where it is shown to be linguistically relevant.
    ${ }^{3}$ The GGNF factorizes an arbitrary DCG into two components: a "unit sub-DCG on the empty string", and another part consisting of rules whose right-hand side starts with a terminal. The decidability of the $D C G$ depends exclusively on certain simple textual properties of the unit sub-DCG. This sub-DCG can be eliminated from the GGNF if and only if the DCG is oflline-parsable.

[^2]:    ${ }^{4}$ The fact that the standard CFG empty-production elimination transformation is always possible is related to the fact that this transformation does not preserve degrees of ambiguity, For instance the infinitely ambiguons grammar $S \rightarrow[\theta] A, A-+$ $A, A \rightarrow[]$ is simplified into the grammar $S \rightarrow[b]$. This type of simplification is generally impossible in a 1$) \mathrm{CG}$. Consider for instance the "grammar" $s(X) \rightarrow[$ number $] a(X)$, $a(\operatorname{succ}(X)) \rightarrow$ $a(X), a(0) \rightarrow[]$.
    ${ }^{5}$ The method goes back to a transformation used to compile out certain local cases of left-recursion from DCG in the context of the Machine Translation prototype CRITTIER [3].
    ${ }^{6} \Lambda$ proof of this fact, based on a comparison of proof-trees for the original and the transformed grammar, is given in [2].
    ${ }^{7}$ His paper doos not state termination conditions for the transformed program. Such termination conditions would probably involve some generalized notion of olline-parsability [ 6,5 , 13]. By contrast, we prove termination only for DCGs which are OP in the original sense of Pereira and Warren, but this case seems to us to represent much of the core issuc, and to lead to some direct extensions. For instance, the DCG transformation proposed here can be directly applied to "gaided" programs in the sense of [4].

[^3]:    ${ }^{8}$ When DCC: is not OF , the transfomation may produce an infinite mumber of rules, but a simple extension of the algorithm can detect this situation: the transfomation stops and the grammar is declared not to be OP'.

[^4]:    ${ }^{9}$ In practice, this and the preceding algorithm, which are dissociated here for exposition reasons, are lumped together.
    ${ }^{10}$ There exist of course DCGs which do not contain empty productions and which are not OP. They are characterized by the existence of cycles of "chain-rules" of the form: $a_{1}(\ldots) \rightarrow a_{2}(\ldots)$. , ..., $a_{m-1}(\ldots) \rightarrow a_{m}(\ldots)$, with $a_{m}=a_{1}$. But, if we start with an OP' DCGO, the empty-production elimination algorithm cannot produce such a situation.
