Notation. We use $\mathcal{D}$ to denote a multi-turn reasoning dataset where each conversation $c \in \mathcal{D}$ consists of alternating human messages h_i and assistant messages a_i such that $c = (h_i, a_i)_{i=1}^{N}$ for N turns. Each assistant message a_i comprises thinking tokens t_i and response tokens r_i. We denote

$\mathcal{H}_{<i} = (h_j, r_j)_{j=1}^{i-1}$ as conversation history before turn i. For token sequence x, s_x, and e_x represent starting and ending position IDs. The notation $x \to \mathcal{A}(\cdot)$ indicates sequences that x attends to, and $\mathcal{L}(\cdot)$ denotes language modeling loss (detailed in Appendix A.1).

2 Single Pass Fine-tuning on Multi-Turn Reasoning

In this section, we highlight the challenges associated with fine-tuning language models on multi-turn reasoning datasets. We present an optimized approach to process an entire conversation in a single forward pass. In multi-turn reasoning data, response tokens r_i must attend to reasoning tokens t_i during the generation of a_i. However, these reasoning tokens must not be visible during subsequent generation of assistant messages $a_{j>i}$. As a result, it is not possible to construct a single static attention mask that supports both conditions in a conversation within a single forward pass—a capability that is often feasible with non-reasoning datasets.

2.1 N-Pass Approach

A straightforward solution is to perform a separate forward pass for every turn $(\mathcal{H}_{<i}, h_i, a_i)$ of a given conversation c. While functionally correct, this approach is computationally inefficient: a conversation with N assistant turns results in N separate training examples. Consequently, the effective size of the dataset increases from $|\mathcal{D}|$ to $|\mathcal{D}| \times N$, inflating training time proportionally. Fig. 2 in Appendix B shows attention masks for N-Pass Approach. Fig. 2(a) shows causal attention mask at the time of generation of ith turn response tokens, and Fig. 2(b) shows causal attention mask for ith turn response tokens when they are part of context during $j > i$ turns.

2.2 1-Pass Approach

The primary challenge in applying a single forward pass during training due to discrepancy in the attention behavior of r_i can be illustrated as follows[2]:

$$r_i \to \begin{cases} \mathcal{A}(\mathcal{H}_{<i}, h_i, t_i) & \text{generation} \\ \mathcal{A}(\mathcal{H}_{<i}, h_i) & \text{context} \end{cases}$$

We can resolve this issue through the following steps:

Duplicating response tokens of each assistant message. We duplicate the response tokens of each assistant message so that one sequence (r_i^{out}) is used during generation and attends to its associated reasoning tokens. In contrast, the other sequence (r_i^{in}) is used only as context and does not attend to reasoning tokens.

Custom Attention Mask. Duplication of response tokens makes it possible to have a single attention mask that satisfies visibility constraints. We define a custom masking strategy for each type of token sequence $(h_i, t_i, r_i^{\text{in}}, r_i^{\text{out}})$, ensuring that each token only attends to the appropriate subsequence:

$$h_i \to \mathcal{A}(\mathcal{H}^{in}_{<i}) \qquad r_i^{in} \to \mathcal{A}(\mathcal{H}^{in}_{<i}, h_i)$$
$$t_i \to \mathcal{A}(\mathcal{H}^{in}_{<i}, h_i) \qquad r_i^{out} \to \mathcal{A}(\mathcal{H}^{in}_{<i}, h_i, t_i)$$

Assigning Consistent Position IDs. After duplication of response tokens, we need to assign consistent position IDs to tokens to maintain the correct relative positions—as if multiple forward passes were performed for each turn in the conversation. If they are assigned sequentially, or the duplicated assistant response tokens share the same position IDs, it will lead to incorrect relative positions. We need a strategic way of assigning position IDs. The following assignment of the first position ID for each token sequence ensures the relative positions are correct and equivalent to N-Pass approach[3]:

$$s_{t_i} = s_{r_i^{in}} = e_{h_i} + 1$$
$$s_{r_i^{out}} = e_{t_i} + 1 \qquad s_{h_{i+1}} = e_{r_i^{in}} + 1$$

Label Mask. Duplication of the response tokens also raises the question of which tokens should be included in the loss calculation. The following label mask outlines the inclusion criteria for each token type:

$$h_i \leftarrow 0 \qquad t_i \leftarrow 1 \qquad r_i^{in} \leftarrow 0 \qquad r_i^{out} \leftarrow 1$$

Fig. 3 in Appendix B shows custom attention mask for ith turn in the 1-Pass Approach. It combines masks for generation and context from the N-Pass Approach into a single mask with position IDs and a label mask consistent with N-Pass Approach.

Theorem 2.1. *Consider a language model with output distributions determined solely by attention*

[2]For ease of understanding, we omit the detail that each token within a token sequence also attends to all its preceding tokens, which must be encoded in the attention mask.

[3]Position IDs are assigned sequentially based on the order of tokens within each sequence.

patterns, positional encodings, and input representation. For any conversation c as input to the model, the sum of the N-Pass language modeling losses is equivalent to the 1-Pass loss:

$$\mathcal{L}^{\text{1-Pass}}(c) = \sum_{i=1}^{N} \mathcal{L}_i^{\text{N-Pass}}(\mathcal{H}_{<i}, h_i, a_i)$$

Proof is in the Appendix C.1

2.3 Complexity Analysis

We compare the computational complexity of our 1-Pass method against N-Pass approach for transformer-based models with hidden dimension d (Vaswani et al., 2017). Table 1 summarizes the time and memory complexities for a conversation c, where ℓ denotes its characteristic turn length.

	N-Pass	1-Pass
$T(c)$	$O(N^3\ell^2 d)$	$O(N^2\ell^2 d)$
$M(c)$	$O(N^2\ell^2)$	$O(N^2\ell^2)$

Table 1: Time and Memory Complexity for N-Pass and 1-Pass Approach.

The 1-Pass approach yields an asymptotic time complexity improvement of one order in N, offering significant speedups at scale. While it introduces a higher constant memory overhead due to token replication, both methods share the same asymptotic memory complexity. Full derivations are provided in Appendix D.

2.4 Efficient Mask Generation

While our custom attention mask (illustrated in Figure 3) enables single-pass training, generating it involves computing complex visibility patterns across token types and conversation turns. At scale, this computation could become non-trivial, particularly for longer conversations or larger batch sizes. To ensure this remains efficient, we develop an optimized mask generation algorithm that performs all operations on GPU using vectorized tensor operations. Additionally, we simplify the boolean logic for visibility constraints using Karnaugh map reduction, minimizing the number of logical operations required. We provide the complete algorithm in Appendix E.2 for practitioners seeking to implement our method efficiently.

3 Experiments

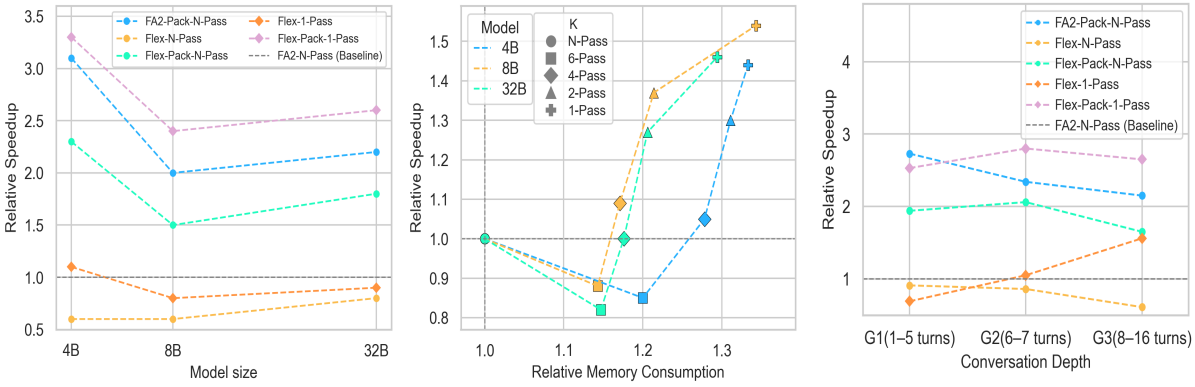
We evaluate our single-pass fine-tuning on Qwen-3 models (4B, 8B, 32B) with QLoRA (Dettmers et al., 2023). All experiments were run on a 8×H100 instance (CUDA 12.8, PyTorch 2.7.0), with our method implemented in LLaMA-Factory (Zheng et al., 2024) and benchmarked against multi-pass baselines. See Appendix E.3 for experimental setup.

3.1 Dataset Creation

Addressing lack of a public multi-turn dataset with explicit per-turn reasoning, we introduce MathChat$_{\text{sync}}$Reasoning[4], derived from MathChat$_{\text{sync}}$ (Liang et al., 2024)[5]. Assistant turns are augmented with explicit reasoning generated using gpt-4.1-mini, conditioned on dialogue history and current assistant response. Refer to Appendix E.1 for more details. All our experiments are conducted on this dataset.

3.2 Experimental Setup

We use FlashAttention2 (FA2) (Dao, 2024) and FlexAttention (Dong et al., 2024) backends. Our 1-Pass method requires a custom attention mask, thus using FlexAttention, as FA2 lacks support for passing custom attention mask; FA2's speed motivates reporting baselines on both for fair comparison. We compare our **1-Pass method** (with response token duplication) against a standard **N-Pass baseline** (requiring N forward passes). Both are evaluated with and without sequence packing[6] (Krell et al., 2022). When packing is enabled, we use llama-factory's `neat_packing` implementation: FA2 baselines rely on position IDs to separate packed sequences (Kundu et al., 2024), while our 1-pass method combines the contamination-free packing mask with our custom attention mask via logical AND.



3.3 Results:

Training Speedup. Figure 1a shows training speedups. Our 1-Pass method with packing (Flex-Pack-1-Pass) is $1.05\times$, $1.21\times$, and $1.22\times$ faster than FA2-N-Pass baseline with packing (FA2-Pack-N-Pass) on 4B, 8B, and 32B models, respectively. Despite FlexAttention's inherent slowness versus FA2, our method's single-pass efficiency compensates. Compared to N-Pass FlexAttention with

[5] LLaMA-Factory and MathChatSync are distributed under Apache-2.0 license, which allows modification and redistribution. Our updates are aligned with the terms of use.

[6] We set the cutoff length to the maximum number of tokens in any datapoint in the dataset for all our experiments.

(a) Speed Analysis across model sizes (relative to FA2-N-Pass)

(b) K-pass Analysis (relative to N-pass) Flex-Pack configuration

(c) Conversation Depth Analysis on Qwen3-8B (relative to FA2-N-Pass)

Figure 1: Training-time experiments

packing (Flex-Pack-N-Pass), our Flex-Pack-1-Pass yields $1.44\times$, $1.54\times$, and $1.46\times$ speedups for 4B, 8B, and 32B models, respectively. Without packing, our 1-pass method (Flex-1-Pass) lags FA2-N-Pass baseline for 8B and 32B models. We hypothesize that this is because response-token duplication widens the length disparity between conversations, making the method more sensitive to the absence of packing than the N-Pass baseline. Across all experiments, the 1-Pass variants consume roughly 33% more GPU memory than their N-Pass counterparts.

K-Pass Trade-offs. The 1-Pass and N-Pass approaches represent two extremes: processing the entire conversation in a single pass or in as many passes as there are turns. We therefore also investigate intermediate settings, processing each conversation in K passes. Concretely, we split every dialogue into K contiguous chunks and apply our single-pass mask only to the current chunk, duplicating response tokens and computing loss exclusively for that portion (see Appendix E.4.1 for full details). Figure 1b reveals a speed-memory trade-off for K∈1,2,4,6,N. Our 1-Pass method maximizes speed with ∼33% more memory (vs. N-Pass). K=2 offers a balance (1.30×–1.37× speedups, ∼20% extra memory). Gains diminish for $K > 4$ because, beyond $K = 4$, the extra time incurred by the longer sequences created through token duplication outweighs the savings from processing a few turns together.

Conversation Scalability. The dataset contains conversations with depths from 1 to 16 turns. To analyse the effect of depth, we partition it into three groups: G1 (1–5 turns), G2 (6–7 turns), and G3 (8–16 turns)[7]. Figure 1c shows our Flex-Pack-1-Pass speedups (vs. FA2-Pack-N-Pass) grow with conversation depth ($0.93\times, 1.19\times, 1.23\times$ for G1, G2, G3 respectively). A similar trend appears when comparing our method without packing (Flex-1-Pass) to the FA2-N-Pass baseline: speedups of $0.69\times$, $1.05\times$, and $1.56\times$ for G1, G2, and G3, respectively. This supports the theoretical complexity reduction from $O(N^3)$ to $O(N^2)$, as efficiency gains become more pronounced with depth.

These results confirm single-pass training yields significant computational savings, aligning with theoretical advantages, making multi-turn reasoning fine-tuning practical at scale. Please refer Appendix E.4 for comprehensive results.

4 Conclusion

We presented an optimized 1-Pass training method for multi-turn reasoning that reduces time complexity from $O(N^3)$ to $O(N^2)$ via strategic token duplication and custom attention mask. Our theoretical analysis confirms loss equivalence with the N-Pass method, enabling efficient training for longer conversations. As multi-turn reasoning becomes central to complex AI tasks, our method offers a scalable and broadly applicable solution. Future work includes exploring adaptive strategies to balance memory-efficiency trade-offs. Additionally, we aim to benchmark performance on latest back-ends such as FlashAttention3 (Shah et al., 2024) and port our masking logic to these faster implementations.

[7]This uneven distribution stems from the $\text{MathChat}_{\text{sync}}$ dataset, which is heavily skewed toward 5–7 turn conversations, a bias that propagates to our reasoning corpus.

Limitations

While our single-pass approach significantly accelerates training for multi-turn reasoning, it also introduces certain constraints. First, duplicating response tokens leads to higher memory usage, which can pose challenges for GPUs with limited capacity. Second, our current implementation supports only FlexAttention, whereas FlashAttention—known for its superior speed—still requires porting our masking logic to make full use of it. Finally, although we have benchmarked N-pass performance on FlashAttention 2, assessing it on the newest iteration, FlashAttention 3, remains future work.

A Background

A.1 Language Modeling Loss

For a token sequence ($\mathcal{H}_{<i}$, h_i, a_i), the language modeling loss (Radford et al., 2018) for assistant message a_i can be expressed as:

$$\mathcal{L}(\mathcal{H}_{<i}, h_i, a_i) = -log(P_\Theta(a_i|(\mathcal{H}_{<i}, h_i)) \quad (1)$$

where language model is parameterized by Θ.

B Masking Schemes for N-Pass and 1-Pass Approaches

Figures 2 and 3 complement the main discussion in Section 2 by illustrating, in greater detail, how attention masks are structured under our N-Pass and 1-Pass training paradigms.

Figure 2 shows the standard causal masks for the N-Pass approach—first, when generating the ith turn's response tokens, and second, when these tokens become part of the context in subsequent turns ($j > i$).

Figure 3 then demonstrates how we incorporate token duplication and a custom visibility mask to enable a single forward pass, while ensuring that each token attends only to the appropriate subsequence. These visualizations clarify the differences between the two methods and underscore why the 1-Pass approach requires careful token and mask design to achieve loss equivalence with the N-Pass baseline.

C Proofs

C.1 Proof for Theorem 2.1

We establish the equivalence by demonstrating that both approaches yield identical probability distributions over sequences, which directly implies equal language modeling losses.

The proof proceeds in three parts: we show that (1) position encodings are equivalent, (2) attention patterns are identical, and (3) the resulting loss functions are mathematically equivalent.

Part I: Position Encoding Equivalence. Consider the position ID assignments for turn i as defined in Section 2.2. In the 1-Pass approach, output tokens receive positions:

$$s_{t_i} = e_{h_i} + 1$$
$$s_{r_i^{out}} = e_{t_i} + 1$$

while input tokens from previous turns $j < i$ receive:

$$s_{r_j^{in}} = e_{h_j} + 1$$
$$s_{h_{j+1}} = e_{r_j^{in}} + 1$$

This assignment ensures that tokens maintain the same relative positional relationships as in the N-Pass approach, where each turn processes tokens sequentially within separate forward passes.

Part II: Attention Pattern Preservation. The custom attention mask defined in Section 2.2 ensures causal dependencies are preserved. For turn i, the attention patterns are:

Output tokens:

$$t_i \to \mathcal{A}\left(\mathcal{H}^{in}_{<i}, h_i\right)$$
$$r_i^{out} \to \mathcal{A}\left(\mathcal{H}^{in}_{<i}, h_i, t_i\right)$$

Input tokens from previous turns $j < i$:

$$h_j \to \mathcal{A}\left(\mathcal{H}^{in}_{<j}\right)$$
$$r_j^{in} \to \mathcal{A}\left(\mathcal{H}^{in}_{<j}, h_j\right)$$

These patterns exactly replicate the causal attention available in the N-Pass approach.

Part III: Loss Function Equivalence. The language modeling loss for turn i in the N-Pass approach is:

$$\mathcal{L}_i^{\text{N-Pass}}(\mathcal{H}_{<i}, h_i, a_i) = -\log P_\theta\left(t_i, r_i \mid \mathcal{H}_{<i}, h_i\right) \quad (2)$$

By the autoregressive factorization:

$$\mathcal{L}_i^{\text{N-Pass}}(\mathcal{H}_{<i}, h_i, a_i) = -\log P_\theta\left(t_i \mid \mathcal{H}_{<i}, h_i\right) - \log P_\theta\left(r_i \mid \mathcal{H}_{<i}, h_i, t_i\right) \quad (3)$$

The total loss across all turns is:

$$\mathcal{L}^{\text{N-Pass}}(c) = \sum_{i=1}^{N} \mathcal{L}_i^{\text{N-Pass}}(\mathcal{H}_{<i}, h_i, a_i) \quad (4)$$

For the 1-Pass approach, the loss is computed as:

$$\mathcal{L}^{\text{1-Pass}}(c) = -\sum_{i=1}^{N} \left[\log P_\theta\left(t_i \mid \mathcal{H}^{in}_{<i}, h_i\right) + \log P_\theta\left(r_i^{out} \mid \mathcal{H}^{in}_{<i}, h_i, t_i\right)\right] \quad (5)$$

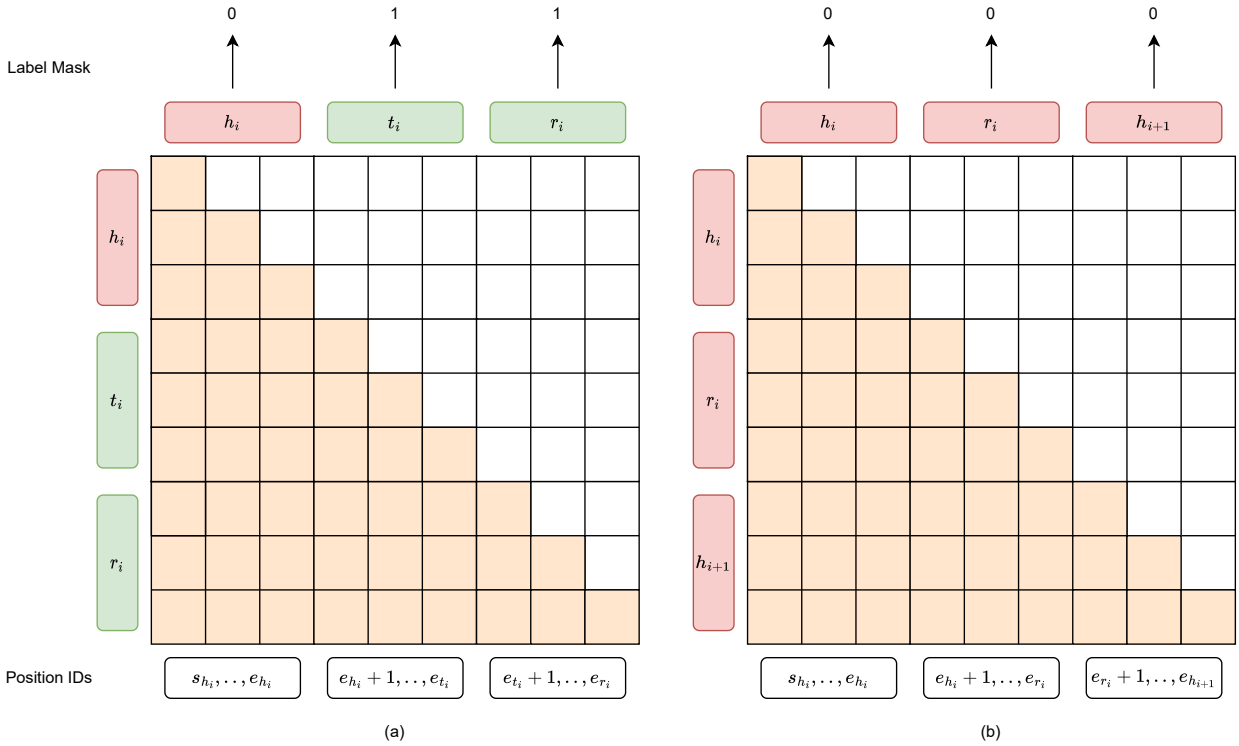

Figure 2: Causal Attention Masks for N-Pass Approach ▢ represents non-zero attention. (a) Attention Mask for generation of response tokens. (b) Attention Mask when response tokens are in context.

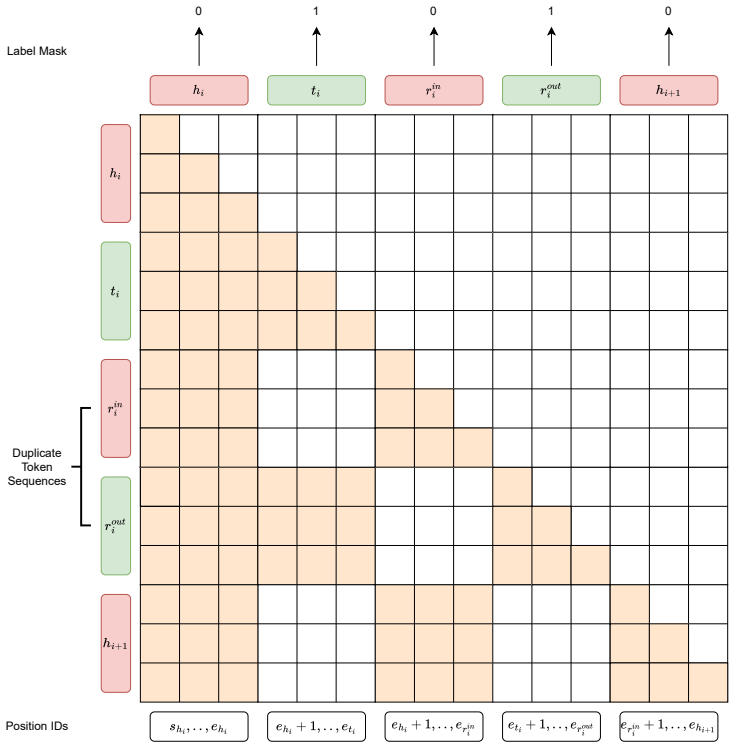

Figure 3: Custom Attention Mask for 1-Pass Approach. ▢ represents non-zero attention.

Key insight: Since $r_j = r_j^{in} = r_j^{out}$ (identical content in different positions) and the position encodings and attention patterns are equivalent as established in Parts I and II, the internal representations are identical. Therefore:

$$P_\theta\left(t_i \mid \mathcal{H}_{<i}, h_i\right) = P_\theta\left(t_i \mid \mathcal{H}_{<i}^{in}, h_i\right) \quad (6)$$

$$P_\theta\left(r_i \mid \mathcal{H}_{<i}, h_i, t_i\right) = P_\theta\left(r_i^{out} \mid \mathcal{H}_{<i}^{in}, h_i, t_i\right) \quad (7)$$

Combining equations (4), (5), (6), and (7):

$$\mathcal{L}^{\textit{N-Pass}}(c) = \mathcal{L}^{\textit{1-Pass}}(c) \quad (8)$$

D Complexity Analysis

D.1 Input Length

D.1.1 N-Pass Approach

In the N-Pass approach, each turn i is processed in a separate forward pass. The input to the model at turn i is:

$$\mathcal{H}_{<i}, h_i, t_i, r_i$$

because human and assistant response tokens from previous turns remain in the conversation history, while earlier reasoning tokens are discarded.

Let $L_{\textit{N-Pass}}$ denote the maximum input length possible for the N-Pass approach for a conversation c. It can be defined by:

$$L_{\textit{N-Pass}} = \sum_{i=1}^{N}(|h_i| + |r_i|) + max_{i=1}^{N}|t_i|, \quad (9)$$

which is sum of all the human messages and response tokens for entire conversation and maximum length of thinking tokens across turns. To simplify further, assume:

$$|h_i|, |t_i|, |r_i| \in O(\ell).$$

where ℓ denote the characteristic turn component length, defined as $\ell = P_{95}(|h_i|, |t_i|, |r_i| : i \in [1, N], c \in \mathcal{D})$, where P_{95} is the 95th percentile operator. Then:

$$L_{\textit{N-Pass}} \in O\big((2N+1)\ell\big) = O(N\ell). \quad (10)$$

D.1.2 1-Pass Approach

Our 1-Pass approach processes the entire conversation c in a single forward pass. The input length L_{1-Pass} can be calculated as:

$$L_{\textit{1-Pass}} = \sum_{i=1}^{N}\big(|h_i| + |t_i| + 2|r_i|\big) \in O\big(4N\ell\big) = O\big(N\ell\big). \quad (11)$$

D.2 Time Complexity Analysis

For a transformer with hidden dimension d and context length n, each layer requires $O(n^2 d)$ operations when $n \gg d$ (Vaswani et al., 2017).

N-Pass Approach: Under the N-Pass approach, each of the N turns requires a forward pass, each operating on $O(L_{\textit{N-Pass}}) = O(N\ell)$ tokens. Thus, for conversation c:

$$T_{\textit{N-Pass}}(c) \in O\big(N \times (N\ell)^2 d\big) = O\big(N^3\ell^2 d\big). \quad (12)$$

1-Pass Approach: In the 1-Pass approach, all the conversation tokens are given as input at once, thus operating on $L_{\textit{1-Pass}}$ tokens yielding a cost of:

$$T_{\textit{1-Pass}}(c) \in O\big((4N\ell)^2 d\big) = O\big(N^2\ell^2 d\big). \quad (13)$$

This represents a factor of N improvement in asymptotic complexity, with substantial gains for large N.

D.3 Memory Complexity Analysis

A transformer layer with input context length n has memory complexity $O(n^2)$ assuming $n \gg d$.

N-Pass Approach: Peak Memory requirement for N-Pass approach is at $L_{\textit{N-Pass}}$ input. Thus for conversation c:

$$\mathrm{M}_{\textit{N-Pass}}(c) \in O\big((2N+1)^2\ell^2\big) = O\big(N^2\ell^2\big). \quad (14)$$

1-Pass Approach: Memory requirement for 1-Pass approach can be given by:

$$\mathrm{M}_{\textit{1-Pass}}(c) \in O\big((4N)^2\ell^2\big) = O\big(N^2\ell^2\big). \quad (15)$$

Though 1-Pass incurs a higher constant factor due to response token replication, both approaches exhibit identical asymptotic memory complexity.

E Experiments

E.1 Dataset Creation

To enable supervised training with explicit step-by-step reasoning, we construct and release $\text{MathChat}_{\text{sync}}$Reasoning along with its generation script. The dataset is obtained by augmenting the original $\text{MathChat}_{\text{sync}}$ corpus (Liang et al., 2024) with a synthetically-generated rationale for every assistant turn. The procedure comprises three stages.

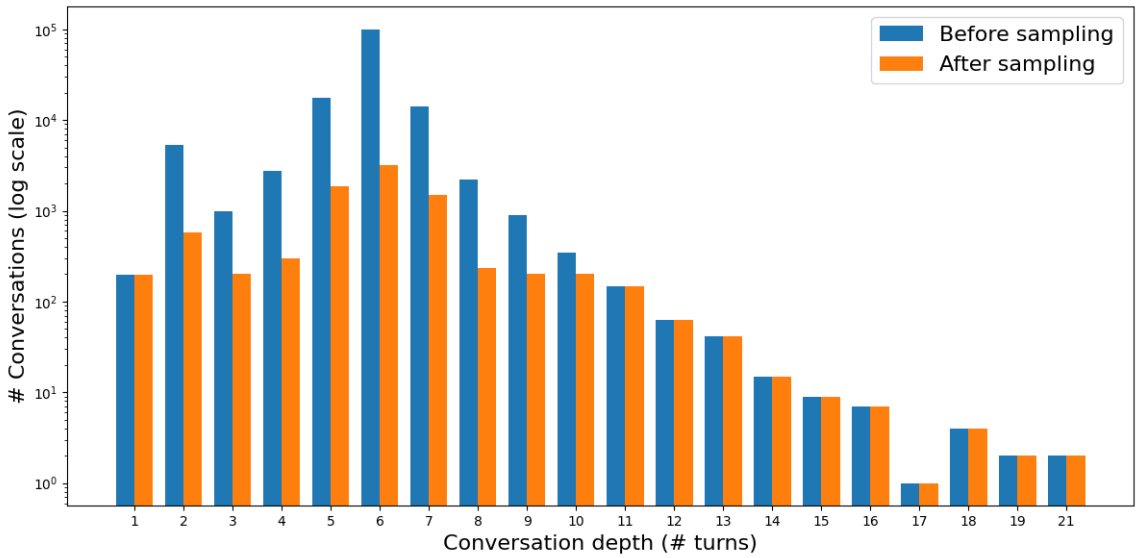

Figure 4: Dataset depth distribution: before vs. after sampling

1. Source corpus. MathChat$_{\text{sync}}$ is a synthetic, dialogue-based mathematics tutoring dataset containing 144,978 conversations with alternating human and assistant messages but no reasoning traces.

2. Depth-balanced sampling. Conversation depth in MathChat$_{\text{sync}}$ is highly skewed toward six-turn dialogues (69 % of all conversations; see Figure 4). To mitigate this bias, we first downsample depth-6 dialogues from 100,443 to 30,000 instances. From the resulting pool we draw a stratified sample of 8,000 conversations.

- For each depth d, we calculate the proportion of the pool that depth represents.
- We allocate to that depth the corresponding proportion of the 8,000-conversation budget, rounding up to the nearest whole conversation.
- If the resulting number is below 200, we raise it to (i) 200 or (ii) the total number of conversations available at that depth, whichever is smaller. This guarantees broad coverage across conversation depths.

The final split contains 8,797 conversations. Figure 4 compares the depth distribution before and after sampling.

3. Reasoning augmentation. For every assistant turn we generate an intermediate reasoning string using gpt-4.1-mini. The model is provided with (i) the dialogue history up to the current human utterance and (ii) the assistant's reply, and is instructed to output only the hidden rationale that could have produced that reply. These rationales are concatenated to the original conversations to form MathChat$_{\text{sync}}$Reasoning.

E.2 Efficient mask generation

Algorithm 1 is an efficient algorithm for generating the custom attention mask required by our 1-Pass training method. The algorithm leverages vectorized GPU operations to compute visibility patterns without explicit loops.

Implementation Notes:

• All operations are performed on GPU using PyTorch's vectorized tensor operations

• Role IDs: 0 = padding, 1 = human, 2 = thinking, 3 = response (first copy), 4 = response (second copy)

• The boolean expression in Step 3 is optimized using Karnaugh map reduction to minimize logical operations

• The algorithm avoids explicit loops by leveraging broadcasting and logical operations

• For CPU tensors, we temporarily move computation to GPU before returning results to the original device

E.3 Experimental Setup

All training runs are initiated using llamafactory-cli in SFT mode. We apply QLoRA with 4-bit NF4 quantization, using a LoRA rank of 32 and a scaling factor of $\alpha = 64$. Training is performed for three epochs with bfloat16 (bf16) precision.

Algorithm 1 Efficient Custom Attention Mask Generation

Require: Role IDs tensor $\mathbf{R} \in \{0, 1, 2, 3, 4\}^{B \times L}$ where B is batch size, L is sequence length
Ensure: 4D attention mask $\mathbf{M} \in \mathbb{R}^{B \times 1 \times L \times L}$

// Step 1: Compute turn IDs via cumulative sum
$\mathbf{R}_{\text{shift}} \leftarrow \text{roll}(\mathbf{R}, \text{shift} = 1, \text{dim} = 1)$
$\mathbf{R}_{\text{shift}}[:, 0] \leftarrow 0$
$\text{turn_increment} \leftarrow (\mathbf{R} \neq 0) \wedge (\mathbf{R} = 1) \wedge (\mathbf{R}_{\text{shift}} \neq 1)$
$\mathbf{T} \leftarrow \text{cumsum}(\text{turn_increment}, \text{dim} = 1)$
$\mathbf{T}[\mathbf{R} = 0] \leftarrow 0$ {Zero out padding positions}

// Step 2: Create base causal non-padding mask
$\mathbf{i} \leftarrow [0, 1, \ldots, L-1]$
$\text{non_pad} \leftarrow (\mathbf{R} \neq 0)$
$\mathbf{M}_{\text{base}} \leftarrow (\mathbf{i}[:, \text{None}] \geq \mathbf{i}[\text{None}, :]) \wedge \text{non_pad}[:, :, \text{None}] \wedge \text{non_pad}[:, \text{None}, :]$

// Step 3: Apply role-specific visibility constraints (K-map optimized)
$\text{turn_equal} \leftarrow (\mathbf{T}[:, :, \text{None}] = \mathbf{T}[:, \text{None}, :])$
$\mathbf{R}_i \leftarrow \mathbf{R}[:, :, \text{None}]$; $\mathbf{R}_j \leftarrow \mathbf{R}[:, \text{None}, :]$
$\mathbf{M}_{\text{final}} \leftarrow \mathbf{M}_{\text{base}} \wedge \big[(\mathbf{R}_j = 1) \vee (\mathbf{R}_j = 4 \wedge \text{turn_equal})$
$\vee(\mathbf{R}_j = 3 \wedge \mathbf{R}_i \neq 4) \vee (\mathbf{R}_j = 3 \wedge \neg\text{turn_equal})$
$\vee(\mathbf{R}_j = 2 \wedge \text{turn_equal} \wedge \mathbf{R}_i \neq 3)\big]$

// Step 4: Convert to 4D attention weights
$\mathbf{M} \leftarrow \text{where}(\mathbf{M}_{\text{final}}.\text{unsqueeze}(1), 0, -\infty)$
return $\mathbf{M}$

We enable the Liger kernel for improved efficiency. Each GPU processes a batch size of 2, with gradient accumulation over 4 steps. This setup yields an effective batch size of 64 across the 8-GPU node.

E.4 Comprehensive Results

We report the complete numerical results that support the figures in Section 3 in Tables 2, 3 and 4. We report two metrics for every configuration:

- **Throughput** ("samples per sec.") — the average number of *full conversations* processed per second.
- **Peak GPU memory** — the peak memory recorded during training.

E.4.1 Implementing K-Pass Processing

To obtain the results in Table 3 we extend our Optimised 1-Pass scheme to an intermediate K-*Pass* schedule. Assume a conversation contains N assistant turns $(h_1, t_1, r_1), \ldots, (h_N, t_N, r_N)$.

(a) **Chunking the dialog.** We partition the conversation into K contiguous chunks, each containing $\lceil N/K \rceil$ turns (the last chunk may be shorter).

(b) **Selective token duplication.** Within the *current* chunk we apply the same response-token duplication as in Section 2.2: $r_i^{\text{in}}, r_i^{\text{out}}$. All earlier chunks act purely as context and therefore retain their original, non-duplicated responses. This progressively lowers the number of duplicated tokens as K increases, which is the main source of the memory savings reported in Table 3.

(c) **Attention and position IDs.** The custom attention mask and position-ID assignment described in Section 2.2 are applied *only* to the duplicated tokens of the active chunk. Context tokens keep the standard causal mask.

(d) **Loss computation.** The label mask is set to `1` for t_i and r_i^{out} *inside* the active chunk and `0` elsewhere, so each pass trains only on the new turns while reusing earlier content as fixed context.

Conceptually, the K-Pass schedule interpolates between the extremes:

Model Size	Run Setting	Samples per sec.	Peak Memory(GB)	Relative Speedup	Relative Peak Memory
4B	FA2-N-Pass(Baseline)	1.985	9	1.0	1.00
	FA2-Pack-N-Pass	6.241	9	3.1	1.00
	Flex Atten-N-Pass	1.286	9	0.6	1.00
	Flex Atten+Packing-N-Pass	4.550	9	2.3	1.00
	Flex-1-Pass	2.107	12	1.1	1.33
	Flex-Pack-1-Pass	6.552	12	3.3	1.33
8B	FA2-N-Pass(Baseline)	2.307	14	1.0	1.00
	FA2-Pack-N-Pass	4.522	14	2.0	1.00
	Flex-N-Pass	1.365	14	0.6	1.00
	Flex-Packing-N-Pass	3.561	14	1.5	1.00
	Flex-1-Pass	1.736	18.8	0.8	1.34
	Flex-Pack-1-Pass	5.484	18.8	2.4	1.34
32B	FA2-N-Pass(Baseline)	0.601	34	1.0	1.00
	FA2-Pack-N-Pass	1.299	34	2.2	1.00
	Flex-N-Pass	0.465	34	0.8	1.00
	Flex-Packing-N-Pass	1.078	34	1.8	1.00
	Flex-1-Pass	0.521	44	0.9	1.29
	Flex-Pack-1-Pass	1.578	44	2.6	1.29

Table 2: **Throughput and peak memory across execution strategies.** FA2 = FlashAttention 2; Flex = FlexAttention. Pack denotes dynamic sequence-packing; "1-Pass" is our proposed approach. Relative columns are computed with respect to the corresponding FA2–N-Pass baseline.

Model Size	K	Samples per sec.	Peak Memory(GB)	Relative Speedup	Relative Peak Memory
4B	N-Pass(baseline)	4.55	9	1.00	1.00
	6-Pass	3.89	10.8	0.85	1.20
	4-Pass	4.76	11.5	1.05	1.28
	2-Pass	5.91	11.8	1.30	1.31
	1-Pass	6.55	12	1.44	1.33
8B	N-Pass(baseline)	3.56	14	1.00	1.00
	6-Pass	3.13	16	0.88	1.14
	4-Pass	3.87	16.4	1.09	1.17
	2-Pass	4.87	17	1.37	1.21
	1-Pass	5.48	18.8	1.54	1.34
32B	N-Pass(baseline)	1.08	34	1.00	1.00
	6-Pass	0.88	39	0.82	1.15
	4-Pass	1.08	40	1.00	1.18
	2-Pass	1.37	41	1.27	1.21
	1-Pass	1.58	44	1.46	1.29

Table 3: **Speed–memory trade-off as a function of K.** Each dialogue is split into K equal-length chunks that are processed sequentially in a *single* forward/backward pass. $K = N$ corresponds to the per-turn baseline, while $K = 1$ is our single-pass method. All experiments use the FlexAttention backend with sequence packing (Flex-Pack), the configuration that achieved the best overall speed in our primary evaluation.

	Run Setting	Samples per sec.	Peak Memory(GB)	Relative Speedup	Relative Peak Memory
Group 1	FA2-N-Pass(Baseline)	2.54	14	1.00	1
	FA2-Pack-N-Pass	6.93	14	2.73	1
	Flex-N-Pass	2.32	14	0.91	1
	Flex-Packing-N-Pass	4.94	14	1.94	1
	Flex-1-Pass	1.74	18.8	0.69	1.34
	Flex-Pack-1-Pass	6.43	18.8	2.53	1.34
Group 2	FA2-N-Pass(Baseline)	1.02	14	1	1
	FA2-Pack-N-Pass	2.39	14	2.34	1
	Flex-N-Pass	0.87	14	0.86	1
	Flex-Packing-N-Pass	2.10	14	2.06	1
	Flex-1-Pass	1.07	18.8	1.05	1.34
	Flex-Pack-1-Pass	2.86	18.8	2.80	1.34
Group 3	FA2-N-Pass(Baseline)	1.06	14	1	1
	FA2-Pack-N-Pass	2.28	14	2.15	1
	Flex-N-Pass	0.65	14	0.61	1
	Flex-Packing-N-Pass	1.75	14	1.65	1
	Flex-1-Pass	1.66	18.8	1.56	1.34
	Flex-Pack-1-Pass	2.81	18.8	2.65	1.34

Table 4: **Impact of conversation depth (Qwen-3 8B).** Group 1 (1–5 turns), Group 2 (6–7 turns), and Group 3 (8–16 turns). Our 1-Pass approach gains more speed as depth increases, in line with the theoretical $O(N^2)$ vs. $O(N^3)$ complexity gap.

- $K = N$ reproduces the per-turn baseline (no response duplication, minimal memory, maximal passes);
- $K = 1$ is our 1-Pass method (maximum duplication, single pass, fastest).

CLL-RetICL: Contrastive Linguistic Label Retrieval-based In-Context Learning for Text Classification via Large Language Models

Abstract

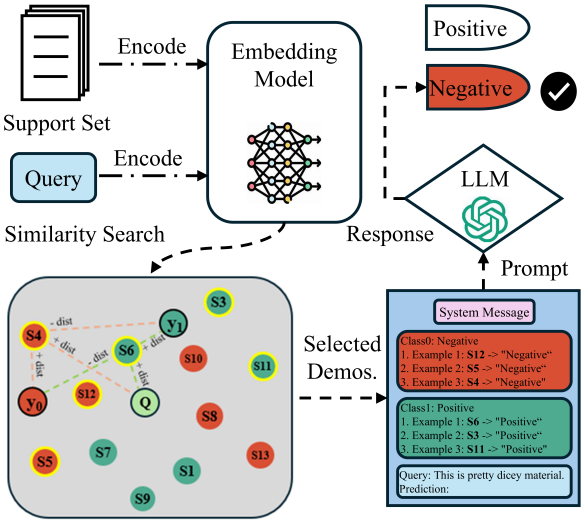
Recent research has delved into Retrieval-based In-Context Learning (RetICL), leveraging the power of large language models (LLMs) for text classification. Despite its promise, a persistent challenge lies in effectively retrieving relevant demonstrations from a support set. Many existing approaches have overlooked the essential role of linguistic label information in guiding this retrieval process. To bridge this gap, we present Contrastive Linguistic Label Retrieval-based In-Context Learning (CLL-RetICL), a novel framework designed to identify the most relevant and impactful sentences without altering the model parameters. Our approach uniquely integrates sentence-query similarity with sentence-label similarity, enabling a more nuanced and comprehensive evaluation of relevance. We tested CLL-RetICL across diverse text classification tasks and evaluated its performance on various LLMs. Experimental results demonstrate that CLL-RetICL consistently outperforms previous retrieval methods that do not incorporate linguistic label information. These findings highlight the critical importance of linguistic label-aware selection in enhancing text classification accuracy.[1]

1 Introduction

A linguistic label represents the semantics of a category and plays a vital role in text classification tasks. Human annotators rely on the meaning conveyed by these labels to accurately categorize text. Depending on the specific requirements of a custom classification task, a linguistic label can often be substituted with synonyms or more descriptive phrases to better align with the task's context.

Recently, researchers have begun exploring few-shot in-context learning (ICL) using LLMs for text classification tasks (Luo et al., 2024; Yu et al., 2023; Chae and Davidson, 2023; Rouzegar and Makrehchi, 2024). Instead of selecting static, predefined demonstration sets for ICL, RetICL adopts a dynamic, context-sensitive approach (Zhao et al., 2021; Lu et al., 2022; Xu et al., 2024; Wu et al., 2023). At its core, adaptive demonstration selection leverages a specialized retriever to intelligently curate tailored demonstrations for each task input. RetICL has gained popularity because prior research suggests that context-insensitive demonstrations can limit the full potential of LLMs (Luo et al., 2024; Wu et al., 2022). Despite RetICL consistently surpassing approaches based on random or static demonstrations, it still remains an open challenge to retrieve relevant demonstrations.

To address the problem, previous researchers have proposed various strategies, including k-nearest neighbors (KNN), NwayKshot, and



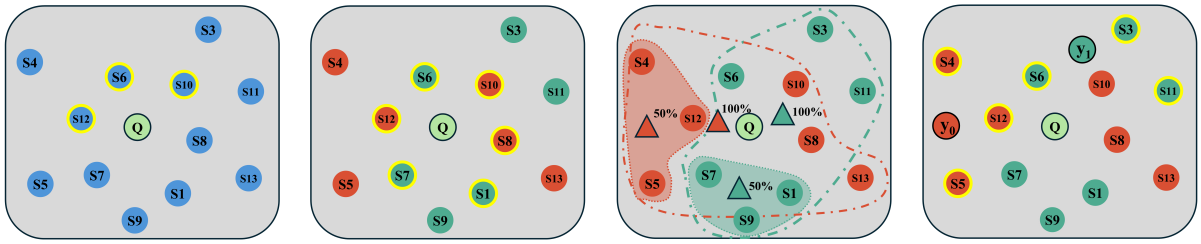


Figure 1: An illustration of CLL-RetICL with $N = 2$ and $k = 3$, demonstrating a prediction between Positive and Negative classes. Here, y_0 and y_1 represent the vector representations of the linguistic labels "Negative" and "Positive", respectively, in a pre-trained sentence embedding model. Similarly, $s_0, s_1, \ldots$ represent the vector representations of the sentences in a support set within the same pre-trained sentence embedding model.

(a) KNN (b) NwayKshot (c) Clustering-Based (d) Ours

Figure 2: A comparison of four different approaches to RetICL strategies. (a) KNN suffers from two key weaknesses: the copying effect and misleading by similarity. (b) NwayKshot always ignores any linguistic cues conveyed through the labels. (c) The performance of clustering-based approaches is constrained by challenges in accurately estimating category centers, typically denoted by triangles, as well as by the omission of query similarity considerations. (d) Our method avoids the copying effect, prevents misleading similarity, incorporates linguistic label information, utilizes fixed label category centers, and integrates query similarity.

clustering-based RetICL (Li et al., 2024; Pecher et al., 2024; Zhang et al., 2022a). However, these methods suffer from various challenges, as shown in Figure 2. To identify the most effective demonstrations, we analyzed failure cases. Our investigation revealed that there always exists a specific combination of demonstrations that enables LLMs to classify accurately. Additionally, our analysis uncovered that failure cases are error-prone: they often lie closer to the representation of an opposing linguistic label or near the representation of an incorrect label cluster center, despite their similarity to the query. In contrast, when the demonstrations are correctly combined, they align more closely with the representation of the intended linguistic label. A detailed discussion of these findings is presented in Section 3.

Building on these observations, we present a novel RetICL framework, CLL-RetICL (Contrastive Linguistic Label Retrieval-based In-Context Learning) as illustrated in Figure 1. Our approach introduces a trade-off method that computes a relevance score by integrating both sentence–query and sentence–label similarities, thereby effectively leveraging label information. Furthermore, to optimize the effectiveness of CLL-RetICL, we developed a universal *N-way K-shot* prompt structure applicable to all text classification tasks. This prompt design mitigates the copying effect and prevents LLMs from being misled by overly similar examples. Moreover, we demonstrate that the sentence embeddings of linguistic labels can serve as clustering centers—generated by a pre-trained sentence embedding model—to address the challenge of estimating clustering centers. Additionally, we initiate four variations for integrating the linguistic label style into RetICL and evaluate their effectiveness on four text classification datasets. Finally, to assess the generalizability of CLL-RetICL, we conduct experiments using Gemini (Team et al., 2024), Llama (Dubey et al., 2024), and Mistral (Jiang et al., 2024). Empirical experiments show that CLL-RetICL consistently outperforms both previous RetICL baselines and other variants across multiple datasets and LLMs. Ablation studies further reveal several key findings: (1) Effectiveness across variations: CLL-RetICL maintains strong performance across different k-shot settings, various pre-trained sentence embedding models, and multiple similarity functions. (2) Component dependency: The proposed method relies on the original component responsible for calculating sentence-query similarity; omitting this component degrades performance. (3) Impact of hyperparameters: Trade-off hyperparameters have a minor influence on the final classification accuracy. The following summarizes our main contributions:

- We present a novel perspective in which sentence embeddings of linguistic labels serve as highly accurate clustering centers, free from the biases introduced by limited support data and independent of data-driven constraints.
- We propose an innovative method, CLL-RetICL, which employs a rigorous relevance scoring metric that leverages linguistic label information to select high-quality demonstrations for improving LLMs in text classification tasks. Our approach does not require fine-tuning the pre-trained weights of either the sentence embedding models or LLMs.

- We conduct extensive experiments to evaluate the proposed method, achieving better performance on most datasets compared to existing RetICL methods.

2 Related Work

Text Classification via LLMs. Text classification via LLMs has recently demonstrated exceptional generalizability and reasoning capabilities, attracting significant research interest in their application to text classification tasks (Zhang et al., 2024; Wang et al., 2024; Fields et al., 2024). Existing methods can be broadly divided into two groups, depending on whether they involve adapting the parameters of LLMs or not. The first group concentrates on fine-tuning the parameters of LLMs to excel in custom text classification tasks (Chae and Davidson, 2023; Zhang et al., 2024; Yu et al., 2023; Jin et al., 2023). However, this approach generally demands significant computational resources to load the full LLM model parameters, and fine-tuning these models can often diminish their generalizability. The other category is known as ICL, or prompt engineering (Guo et al., 2024; Luo et al., 2024; Fan et al., 2024). While this method avoids the need to update LLM model parameters, it heavily depends on well-designed prompts, making it challenging to guide LLMs to consistently meet human expectations (Shi et al., 2023; Mavromatis et al., 2023; Edwards and Camacho-Collados, 2024).

RetICL. RetICL can generally be divided into two categories: approaches that retrain or fine-tune a retriever for specific text classification tasks, and approaches that utilize pre-trained language models without additional fine-tuning. An intuitive strategy for RetICL involves directly selecting a few similar sentences, leveraging readily available demonstration retrievers like those based on sentence embeddings. Existing methods include KATE (Liu et al., 2021), Z-ICL (Lyu et al., 2022) and ICL-ML (Milios et al., 2023). However, recent research has shown that selecting the most similar demonstrations can lead to the copying effect and misleading by similarity, degrading performance in text classification tasks (Olsson et al., 2022; Zhang et al., 2022b). To mitigate the issue of homogeneity in retrieval, clustering retrieval approaches ensure the selection of a diverse and representative set of demonstrations, which is critical to its effectiveness (Luo et al., 2024). Several methods exist, including

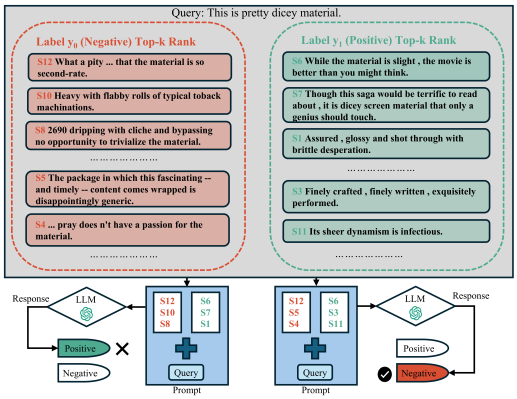

Figure 3: A comparison of the correct and incorrect demonstration combinations is presented. On the left, NwayKshot retrieves the top-k sentences most similar to the query from each group; however, this approach fails to classify the query correctly. In contrast, on the right, CLL-RetICL does not rely solely on proximity to the query, resulting in an accurate classification.

NwayKshot (Li et al., 2024), Votek (Su et al., 2022) and D-CALM (Hassan and Alikhani, 2023). While these approaches leverage label information and offer improvements, accurately estimating the clustering center for each category remains challenging. This difficulty arises because clustering center estimation is a data-driven process that depends on a support set.

The second category of RetICL involves fine-tuning or retraining a retriever model to rank relevant sentences using either in-domain or out-of-domain datasets for text classification tasks. There are established methods, such as PEFT (Tunstall et al., 2022), UDR (Li et al., 2023) and Ambig-ICL (Gao et al., 2023). These methods utilize label information and feedback to optimize model parameters, highlighting the essential role of labeled data in yielding valuable insights for text classification tasks. However, they often demand substantial computational resources and considerable time to construct a retriever.

3 Linguistic Label Retrieval Hypothesis

Previous studies have shown that retrieving sentences closest to the query and applying a clustering-based selection method can enhance the diversity of demonstrations while mitigating the risk of misleading results due to similarity (Li et al., 2020; Luo et al., 2024). Therefore, a question arises: are the clustering centers reliable? To explore this further, we analyze the distribution of clustering centers, as shown in Appendix C. Vary-

ing the proportion of fully supported data from 10% to 100% reveals that the distribution of clustering centers shifts according to the number of sentences in the support set. Notably, negative-labeled clustering centers tend to be less distinct within a certain range compared to positive-labeled ones. These findings suggest that clustering center estimation is inherently data-driven and prone to bias, making it difficult to accurately identify true clustering centers. On the other hand, by analyzing failure cases, we find that, for a given query, there is an optimal combination of demonstrations that can effectively guide LLMs to classify the query correctly. However, relying solely on the top-ranked closest demonstrations retrieved does not always yield accurate results. An example of this limitation is illustrated in Figure 3. To further investigate, we compared cases where the top-*k* closest demonstrations led to incorrect results versus cases where randomly selected demonstrations produced correct outcomes. We provide five examples of such instances in Appendix C. We found that incorrect nearest-neighbor demonstrations exhibit an error-prone tendency, being either closer to the linguistic representation of an opposite label, closer to the center of an incorrect label cluster, or both—despite being similar to the query. Conversely, in correct combinations, the selected demonstrations exhibit a stronger alignment with the correct tendency. For example, sentences with a Negative label tend to show higher similarity to the linguistic word "Negative" and the same holds for "Positive" label. Although correct demonstrations align closely with their respective cluster centers, we observe exceptions where a correct output contains sentences that are nearer to the center of an incorrect label cluster. Furthermore, even sentences closest to their correct cluster centers can still lead to classification errors due to inaccurate estimation of those centers.

Based on these observations, we hypothesize that the vector representations of linguistic labels should be explicitly incorporated into the retrieval process rather than relying on cluster center estimation. Compared to traditional clustering center estimation, this approach offers two advantages: (1) Independence from data Bias – The linguistic label clustering center is not data-driven, preventing bias introduced by the support set. (2) Leveraging linguistic information – Linguistic labels play a crucial role in zero-shot ICL, as LLMs rely entirely on these labels for text classification tasks.

4 Our Method: CLL-RetICL

Preliminary. Let the query set Q represent a task, where $q \in Q$ denotes a sample query for which we aim to find an answer via an LLM. In the context of RetICL, multiple demonstrations $(d_1, \ldots, d_k)$ are retrieved from a support set C. Each demonstration d_i consists of a sentence and its label, $(s_i, y_i) \in C$, where y_i belongs to the label set Y.

Overview. We present CLL-RetICL, a novel RetICL approach leveraging information extraction between demonstrations and linguistic labels to predict the correct label for a given query input q_i (Wang et al., 2023). Unlike earlier methods (Liu et al., 2021; Su et al., 2022; Li et al., 2022; Milios et al., 2023) that create input-label pairs by retrieving sentences closest to a given query, CLL-RetICL selects demonstrations that balance a trade-off by augmenting the corresponding label while penalizing others.

CLL-RetICL involves three key steps, as illustrated in Figure 1: (1) Retrieving more relevant sentences by integrating sentence-query similarity with sentence-label similarity (detailed in Section 4.1), (2) Forming demonstrations by organizing the retrieved demonstrations into an N-way K-shot format (discussed in Section 4.2), and (3) Making inferences through ICL (explained in Section 4.3).

4.1 Linguistic Label Retriever

RetICL employs a retrieval mechanism to identify k examples from C that are most relevant to a given query q. This process is guided by a similarity function, sim, which quantifies the relationship between a sentence s_i and a query q. The corresponding formula is as follows:

$$score_{RetICL} = sim(q, s_i) \tag{1}$$

To build on this hypothesis, CLL-RetICL incorporates sentence-query similarity with sentence-label similarity. Rather than solely considering the similarity distance between a sentence s_i and the query q, CLL-RetICL employs the following formula:

$$score_{CLL\text{-}RetICL} = sim(q, s_i) + w_1 * log \frac{\exp^{sim(s_i, y_i)}}{\frac{1}{n-1} \sum_{y \in Y}^{y \neq y_i} \exp^{sim(s_i, y)}} \tag{2}$$

where w_1 is a trade-off hyperparameter that balances the relative importance of the corresponding terms in the objective function.

CLL-RetICL considers the relationship between sentences and linguistic labels by utilizing a similarity function. It increases the score based on the similarity between a sentence and its assigned correct label (referred to as the positive label) while decreasing the score based on the similarity between the sentence and other labels (referred to as negative labels). Additionally, we propose several variations and evaluate their performance through experiments. These include Positive Label Augment (PLA), Negative Label Penalty (NLP), and Contrastive Label (CTL). The corresponding formulas are provided below:

$$score_{PLA} = sim(q, s_i) + w_1 * sim(s_i, y_i) \quad (3)$$

$$score_{NLP} = sim(q, s_i) - w_1 * \frac{1}{n-1} \sum_{y \in Y}^{y \neq y_i} sim(s_i, y) \quad (4)$$

$$score_{CTL} = sim(q, s_i) + w_1 * sim(s_i, y_i) - w_2 * \frac{1}{n-1} \sum_{y \in Y}^{y \neq y_i} sim(s_i, y) \quad (5)$$

where w_1 and w_2 are trade-off hyperparameters.

Our methods ensure that the selected sentences (1) maintain a safe distance from q to prevent the copying effect (Olsson et al., 2022; Zhang et al., 2022b), (2) incorporate the information between sentences and linguistic labels and (3) align closely with the requirements of the custom text classification task.

4.2 *N-way K-shot*

We adopt a clustering-based retrieval method, as prior research suggests that *N-way K-shot* effectively addresses the issue of homogeneity (Li and Qiu, 2023). Here, we partition all sentences into N sub-groups, aiming to cluster sentences that share the same label. Our retriever selects top K high demonstrations according to above score formula from each sub-group, resulting in a final set of $N \times K$ demonstrations.

4.3 Inference

Finally, CLL-RetICL constructs a prompt by concatenating *N-way K-shot* input-label pairs $(s_1, y_1), (s_2, y_2), \ldots, (s_k, y_k)$ for each N-way label, along with the query input q. This prompt is then fed into a LLM, which generates a prediction using $argmax_{y \in Y} P(y|prompt)$. The universal prompt template for each text classification task is outlined in Table 7 in Appendix B.

5 Experimental Analysis

5.1 Experimental Setup

We evaluate multiple LLMs to identify factors affecting classification accuracy across four tasks. Key results are summarized in the main text, with additional details presented in the Appendix D.

5.1.1 Datasets

We conduct experiments on four widely recognized text classification tasks: SST2 (Socher et al., 2013), CoLA (Warstadt et al., 2018), CARER (Saravia et al., 2018) and BBCnews (Greene and Cunningham, 2006). Similar to conventional text classification methodologies, we treat the training sets as support sets and the test sets as query sets, while disregarding development sets if they exist. The detailed data statistics are provided in Appendix A and summarized in Table 5.

5.1.2 Baselines

We compare CLL-RetICL with the zero-shot approach as well as various RetICL methods.

Zero-shot predicts $argmax_{y \in Y} P(y|q)$ without using any demonstrations (Radford et al., 2019; Brown et al., 2020). This method utilizes LLMs and linguistic label information to enhance text classification.

Z-ICL leverages physical neighbors to avoid selecting demonstrations that are overly similar to the query. Furthermore, it introduces the use of synonymous labels to mitigate the copying effect, highlighting the potential for effectively utilizing the linguistic meaning of labels (Lyu et al., 2022).

KATE employs a standard KNN approach to retrieve demonstrations, which remains the most widely used method in RetICL (Liu et al., 2021).

NwayKshot is a clustering-based retrieval method designed to tackle the challenge of homogeneity in demonstrations (Li et al., 2024).

Cluster-TopN builds on NwayKshot but applies k-means clustering to identify the cluster centers. It then selects the demonstration closest to the center from each sub-group (Zhdanov, 2019; Hassan and Alikhani, 2023).

Votek selects k representatives from N subgroups through a voting mechanism to best represent the group (Su et al., 2022).

Table 2: A comparative analysis of various linguistic label retrieval methods across four datasets.

5.1.3 Experimental Details

LLMs. We conduct experiments using three LLMs: Gemini (Team et al., 2024), Llama (Dubey et al., 2024) and Mistral (Jiang et al., 2024). Specifically, we utilize fixed versions of these models, namely Gemini 1.5 Flash, Llama 3.2-90b-Vision, and Mistral Large. These recently developed models demonstrate strong performance and exceptional generalization across a variety of tasks.

Similarity function. We define a similarity function, sim, as the cosine similarity between two sentence embeddings. These embeddings are generated using the all-MiniLM-L6-v2 model from the SBERT (Reimers and Gurevych, 2019).

Implementation details. For all LLMs, we use two random seeds and report the average results. We set the default number of demonstrations$k$ per class to 3 for all experiments. We adopt the typical prompt design methodology proposed by (Luo et al., 2024). To ensure accurate and consistent results in text classification tasks, we employ fixed hyperparameters for LLMs, thereby minimizing variability and limiting creative outputs. Further details are provided in Appendix B.

5.2 Experimental Results

5.2.1 Main results

Table 1 presents the results obtained using various retrieval strategies across three LLMs. The zero-shot approach, which does not rely on retrieving relevant demonstrations from the support set, leverages only the semantic understanding of labels. This strategy enables LLMs to achieve a baseline level of accuracy without additional context. Although Z-ICL mitigates the Copying Effect by leveraging physical neighbors and synonym labels, it only marginally outperforms the zero-shot baseline. However, it lags behind other methods, likely due to the inherent complexity and challenges associated with selecting appropriate synonym labels. KATE achieves better performance than zero-shot and Z-ICL by utilizing the most similar demonstrations to the query. However, it is susceptible to errors caused by misleading similarities. As a result, KATE still struggles to perform well on the CoLA and CARER datasets. To mitigate the effects of misleading similarities, NwayKshot generally outperforms KATE in most scenarios. However, as

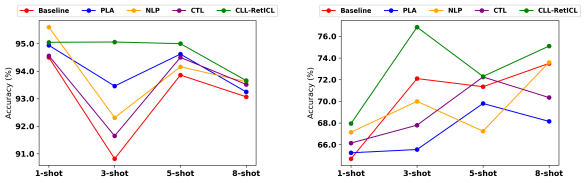

Figure 4: A comparison of the performance of various shot configurations is presented across a baseline and four linguistic label retrieval strategies. Evaluations for the SST2 task (using Llama) are on the left, while results for the CARER task (using Mistral) appear on the right.

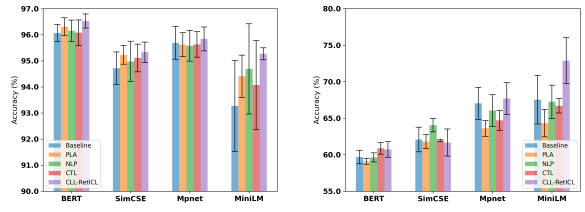

Figure 5: A comparison of the performance of various sentence embedding models is presented, with evaluations conducted on SST2 on the left and CARER on the right.

noted earlier, NwayKshot still struggles to identify an optimal combination of demonstrations. VoteK attempts to further select more effective and relevant demonstrations from the support set. However, this method still fails to utilize label information effectively. On the other hand, Cluster-TopN leverages label information from a distributional perspective but does not account for the linguistic meaning of the labels. While both VoteK and Cluster-TopN show improvements in accuracy for certain tasks, they fall short in addressing a fundamental issue: the importance of linguistic label meaning in text classification tasks. This oversight leads to inconsistent performance and highlights their inherent weaknesses. Finally, our proposed method, CLL-RetICL, significantly outperforms all baseline approaches. On average, CLL-RetICL improves RetICL's performance by an absolute margin of 2–15% over the zero-shot strategy and by 0.57–13.48% over existing RetICL-based methods. These results demonstrate consistent performance gains across all datasets and LLMs by effectively leveraging the relationships between linguistic labels and their corresponding sentences.

Comparison to Variants of Label-Related RetICL. We use the NwayKshot method as our baseline, a retrieval-based approach that does not utilize linguistic label information. To enhance performance, we evaluate four proposed strategies that incorporate linguistic label related retrieval methods, with the results summarized in Table 2. All four strategies outperform the baseline across all datasets and LLMs, demonstrating the benefits of leveraging label information. Among these, CLL-RetICL consistently delivers the best performance, achieving an average absolute improvement of 0.8–5.3% over the NwayKshot method. While PLA, NLP, and CTL also surpass the baseline, they show minor performance drops on certain tasks. In contrast, CLL-RetICL not only outperforms these methods in most tasks but also achieves consistent gains in classification accuracy.

5.3 Ablation Study

We conduct detailed ablation studies to analyze the significance of each component in CLL-RetICL. In our ablation study, the NwayKshot approach serves as the baseline, as shown in the following tables and figures.

Effect of the number of shots. The number of shots significantly impacts the performance of LLMs. We explore experiments comparing four different shot configurations for each label class: 1-shot, 3-shot, 5-shot, and 8-shot. Figure 4 presents partial results, while the complete results are provided in Appendix D.1. The results in Figure 4 demonstrate that CLL-RetICL consistently outperforms the baseline methods across different values of k. While some alternative strategies occasionally achieve better performance than CLL-RetICL, they lack robustness and often fall short of both CLL-RetICL and the baselines. This indicates that CLL-RetICL delivers more stable performance across a range of scenarios. Based on the experimental results, we selected $k = 3$ as the hyperparameter for the number of shots, as CLL-RetICL demonstrated higher improvement with a 3-shot configuration.

Effect of sentence embedding model. Pretrained sentence embeddings play a crucial role in ICL. The objective is to evaluate the effectiveness of the proposed methods by comparing them against four off-the-shelf sentence embedding models. Figure 5 illustrates the average performance of three LLMs across two datasets. CLL-RetICL consistently outperforms the baseline and the other three strategies across all sentence embedding models, with the exception of SimCSE (Gao et al., 2021) in the CARER dataset. We attribute the relatively lower performance of our method with

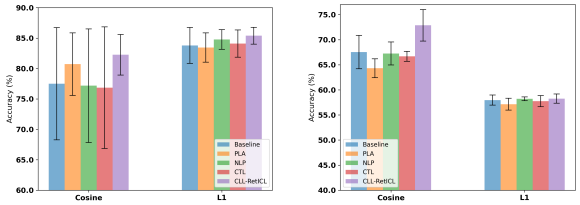

Figure 6: A comparison of the performance of various similarity functions is presented, with evaluations conducted on CoLA on the left and CARER on the right.

SimCSE to the fact that SimCSE has already employed contrastive learning to fine-tune the pre-trained sentence embedding model. This suggests that our approach is generally more effective for pre-trained sentence embeddings that do not utilize contrastive learning strategies. Compared to other sentence embedding models, MiniLM demonstrates the greatest improvement over the baseline; therefore, we have chosen it as our default. Full results are presented in Appendix D.2.

Effect of similarity function. To evaluate the effect of the similarity function in our CLL-RetICL model, we compare its performance using another similarity function, L1, as described in (Winata et al., 2023). The results are presented in Figure 6 with detailed results provided in Appendix D.3.

CLL-RetICL performs effectively with both cosine and L1 similarity functions. However, experiments show that cosine similarity outperforms the L1 function, suggesting that it better leverages CLL-RetICL's potential. Consequently, we use cosine similarity as the default.

Effect of w/o similarity between demonstration and query. Because our proposed additional component can serve as a scoring criterion for selecting demonstrations, the question arises whether the similarity score between demonstrations and the query should be included in CLL-RetICL.

We evaluate the problem and present the results in Figure 7. Our findings indicate that the performance without the component addressing the similarity between queries and sentences is consistently lower than that of linguistically labeled RetICL. In fact, it performs even worse than the baseline. These results highlight that the similarity component between queries and sentences is an essential part of the retrieval process. Detailed results are presented in Appendix D.4.

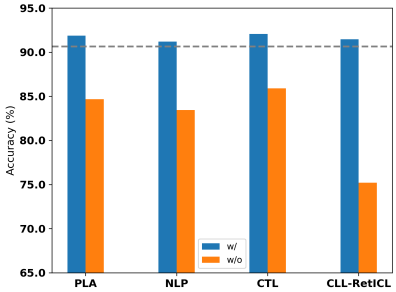

Figure 7: A comparison of the retrieval process with and without incorporating the similarity score between the query and the sentence is illustrated on BBCNews dataset. The baseline is represented by a dashed line.

Effect of trade-off hyperparameters. We use a trade-off approach to balance the impact between sentences and their label set. Based on the results of the previous experiment, sentence-query similarity remains a crucial factor in selecting relevant demonstrations. This raises an important question: how should we trade off between the original method, which retrieves the closest demonstrations to the query, and our approach? To address this question, we evaluate the effects of various hyperparameter settings. Specifically, we focus on hyperparameters lower than 1.0, as previous research has consistently shown that closer demonstrations generally outperform those that are further away. We maintain the principle that proximity to the query remains a core factor in our approach. Based on these observations in Appendix D.5, we found that the trade-off hyperparameter has some influence on the final results. However, their impact on PLA, NLP, and CTL methods is relatively small. Interestingly, we observed that a trade-off hyperparameter value of 1.0 yields the best performance for our CLL-RetICL method. Consequently, we adopt 1.0 as the default hyperparameter.

6 Conclusion

This paper introduces a new paradigm Contrastive Linguistic Label Retrieval-based In-Context Learning. Unlike existing approaches that universally sample demonstrations without considering the linguistic label information, we propose a general framework for identifying more effective and relevant demonstrations. This framework enhances the capabilities of LLMs to produce more accurate text classification results. Additionally, we design a universal prompt that is adaptable to all text classification tasks. Empirical evaluation on

four datasets demonstrates that CLL-RetICL significantly outperforms conventional practices in RetICL by incorporating the similarity between linguistic labels and sentences. This highlights the promising performance of CLL-RetICL and opens up several intriguing research opportunities for further methodological exploration.

7 Limitations

Requiring Semantic Labels. Our approach focuses exclusively on the semantic label text classification task. Certain text classification scenarios, however, may involve ambiguous label classes, such as class0, class1, ... Ambiguities in labeling may introduce additional challenges and Addressing these issues remains an open area for future research.

Handling complex classification tasks with ambiguous labels presents additional challenges for our method, as CLL-RetICL relies heavily on semantic label representations. To illustrate this issue, we use the TREC dataset (Li and Roth, 2002; Hovy et al., 2001), which provides both abbreviated and full-form class labels. In our analysis, we adopt the coarse-label scheme and specifically compare the abbreviated class labels with their corresponding full descriptive labels. The abbreviated labels include [ABBR, ENTY, DESC, HUM, LOC, NUM], while their full counterparts are [Abbreviation, Entity, Description and abstract concept, Human being, Location, Numeric value]. The results, shown in Table 3, demonstrate that using abbreviated labels weakens the performance of our method compared to using the full descriptive labels.

TREC	Abbr.		Full	
	ACC	F1	ACC	F1
Llama				
Nwaykshot	**57.40**	**0.591**	56.60	0.577
CLL-RetICL	56.40	0.603	**57.60**	**0.603**

Table 3: A comparison of classification accuracy (%) and F1 score to evaluate the impact of abbreviated labels versus full labels on the TREC dataset.

Better Descriptive Labels Recently, the use of class-label synonyms has become a popular and compelling topic of research (Pawar et al., 2024). In our work, we also present results using class-label synonyms on the SST-2 dataset, as shown in Table 4. Our findings indicate that CLL-RetICL consistently performs well across different label synonym settings. However, the overall performance with label synonym settings is lower compared to using the original labels. These results suggest that more accurate, semantic, and suitable labels could further enhance the effectiveness of our method.

Moreover, some classification tasks include explanations for the meaning of each label. Using more descriptive sentences and designing multi-label descriptors can help reduce the risk of bias and support effective mitigation strategies. In this work, we did not utilize those explanations. Incorporating these explanations into the classification process is left as a direction for future work.

SST2	Positive/Negative		Great/Terrible		Good/Bad	
	ACC	F1	ACC	F1	ACC	F1
Llama						
Nwaykshot	90.82	0.908	92.48	0.927	91.98	0.923
CLL-RetICL	**95.06**	**0.951**	**93.90**	**0.939**	**94.23**	**0.944**

Table 4: A comparison of classification accuracy (%) and F1 score to evaluate the impact of synonym labels on the SST2 dataset. The synonym pairs used in this study are drawn from previously published work (Pawar et al., 2024).

Enhance prompt clarity. In previous work, researchers observed that well-crafted prompts can lead to better results. However, in this study, we did not compare the effects of different prompt formats. Determining how to construct optimal prompts to leverage the potential of our CLL-RetICL framework fully remains an open question and is left for future exploration.

A Data Statistics

We take the four text classification tasks including SST2, CoLA, CARER, and BBCNews. See the descriptions and statistics in Table 5.

We use the original SST-2 dataset that only comprises the complete sentences that are not labeled neutral, and its original split is 6920/872/1821 (Socher et al., 2013).

CoLA comprises 10,657 sentences sourced from 23 linguistics publications. Each sentence has been expertly annotated for acceptability (i.e., grammaticality) by the original authors (Warstadt et al., 2018). CoLA is divided into two subsets: a training set and a development set. In our work, we treat the development set as the test set.

CARER is a dataset of English Twitter messages with six basic emotions: anger, fear, joy, love, sadness, and surprise (Saravia et al., 2018). The original CARER dataset has been split into trainsets, validation, and test sets.

The BBC News Topic Classification dataset consists of 2,225 articles published on the BBC News website between 2004 and 2005. Each article is labeled under one of 5 categories: business, entertainment, politics, sport, or tech (Greene and Cunningham, 2006). The original BBCNews dataset has been split into trainsets and test sets.

As stated in the main text, we exclude the validation set.

B Implementation Details

All implementations are done in PyTorch.

Prompt template. We adopt the prompt used in the CARER task as a template. Following the approach of Luo et al. (2024), we design our prompt for universal text classification tasks, as shown in Table 7. $(demo_1)$, $(demo_2)$, $(demo_3)$ are selected demonstration from support set. $(query)$ is the current query sentence.

Budget. We conducted experiments on LLMs across four public datasets, utilizing APIs to compute the results. To ensure consistency and avoid generating creative outputs, we fixed the LLMs' hyperparameters, as detailed in Table 6. The total cost of running these experiments through the APIs amounted to approximately 1,000 US dollars.

C Linguistic Label Retrieval Hypothesis

To explore the question: Are the clustering centers reliable, we analyze the distribution of clustering centers, as shown in Figure 8.

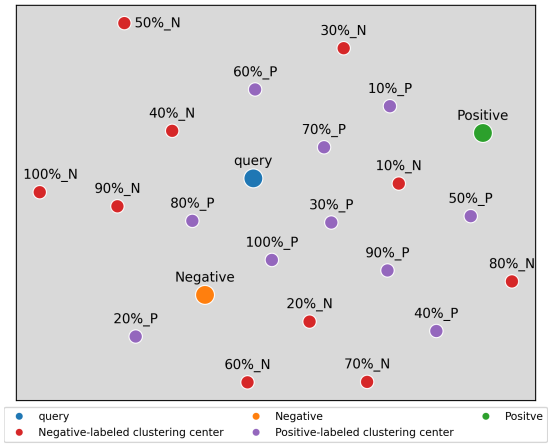

Figure 8: An example illustrating the distribution of queries, linguistic labels, and clustering centers in a pre-trained sentence embedding model using t-SNE. $10\%_N$ and $10\%_P$ represent a pair, indicating that 10% of the support set is used to estimate the clustering center. In this notation, "N" refers to the Negative-labeled clustering center, while "P" denotes the Positive-labeled clustering center.

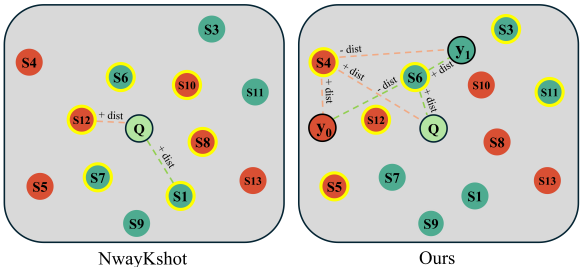

Figure 9: A comparison of the retrieved demonstrations between NwayKshot and our method in the sentence embedding vector space. A yellow circle indicates a selected sentence.

We present five examples in Table 8 to illustrate our findings. The experiment was conducted on the SST2 dataset, where we treated the training set as the support set and the test set as the query set. For each query example in the test set, we provide its index and the indices of the selected demonstrations from the training set. Additionally, we report the similarity scores calculated using cosine distance within the vector space of a pre-trained sentence embedding model (Reimers and Gurevych, 2019).

D Additional Results

D.1 Effect of the number of shots.

We present the detailed results in Table 9.

Dataset	Trainset	Testset	Label
SST2	6,920	1,821	"Negative","Positive"
CoLA	8,551	1,043	"Unacceptable", "Acceptable"
CARER	16,000	2,000	"Sadness", "Joy", "Love", "Anger", "Fear", "Surprise"
BBCNews	1,225	1,000	"Business", "Entertainment", "Politics", "Sport", "Tech"

Table 5: Statistics of datasets as well as their labels.

Configure	Gemini	Llama	Mistral
"$temperature$"	0.2	0.01	0.01
"top_p"	0.9	0.9	0.5
"top_k"	1	1	1
"max_output_tokens"	2	2	2

Table 6: generation_configure of hyperparameters in various LLMs.

D.2 Effect of sentence embedding model.

We present the detailed results in Table 10.

D.3 Effect of similarity function.

We present the detailed results in Table 11.

D.4 Effect of w/o similarity between demonstration and query.

We present the detailed results in Table 14.

D.5 Effect of trade-off hyperparameters.

We present the detailed results in Table 12, Table 13, Table 15, Table 16, Table 17.

System message	"You are given a task where there are multiple classes, and for each class, a few labeled examples are provided. Based on these examples, you need to classify a new unseen instance. Choose ONLY one tag and output the tag. Do Not output others."
CARER	
Prompt	Class0: sadness 1. Example 1: (demo_1) -> "sadness" 2. Example 2: (demo_2) -> "sadness" 3. Example 3: (demo_3) -> "sadness" Class1: joy 1. Example 1: (demo_1) -> "joy" 2. Example 2: (demo_2) -> "joy" 3. Example 3: (demo_3) -> "joy" Class2: love 1. Example 1: (demo_1) -> "love" 2. Example 2: (demo_2) -> "love" 3. Example 3: (demo_3) -> "love" Class3: anger 1. Example 1: (demo_1) -> "anger" 2. Example 2: (demo_2) -> "anger" 3. Example 3: (demo_3) -> "anger" Class4: fear 1. Example 1: (demo_1) -> "fear" 2. Example 2: (demo_2) -> "fear" 3. Example 3: (demo_3) -> "fear" Class5: surprise 1. Example 1: (demo_1) -> "surprise" 2. Example 2: (demo_2) -> "surprise" 3. Example 3: (demo_3) -> "surprise" Query: (query) Prediction:

Table 7: Designed a universal prompt for all text classification tasks.

Abstract

Historical documents in the Sinosphere are known to share common formats and practices, particularly in veritable records compiled by court historians. This shared linguistic heritage has led researchers to use Classical Chinese resources for cross-lingual transfer when processing historical documents from Korea and Japan, which remain relatively low-resource. In this paper, we question the assumption of cross-lingual transferability from Classical Chinese to Hanja and Kanbun, the ancient written languages of Korea and Japan, respectively. Our experiments across machine translation, named entity recognition, and punctuation restoration tasks show minimal impact of Classical Chinese datasets on language model performance for ancient Korean documents written in Hanja, with performance differences within ± 0.0068 F1-score for sequence labeling tasks and up to $+0.84$ BLEU score for translation. These limitations persist consistently across various model sizes, architectures, and domain-specific datasets. Our analysis reveals that the benefits of Classical Chinese resources diminish rapidly as local language data increases for Hanja, while showing substantial improvements only in extremely low-resource scenarios for both Korean and Japanese historical documents. These findings emphasize the need for careful empirical validation rather than assuming benefits from indiscriminate cross-lingual transfer.

1 Introduction

Classical Chinese served as a regional lingua franca across East Asia for over a millennium, where it was used to record government chronicles, literary works, and scientific discoveries. These historical documents, particularly "veritable records" compiled by court historians, remain invaluable primary sources for studying the region's past. As Classical Chinese spread throughout East Asia, it evolved into distinct writing systems—Hanja in Korea, Kanbun in Japan, and Chữ Hán in Vietnam—collectively forming the *Sinosphere* or *Chinese character cultural sphere*.

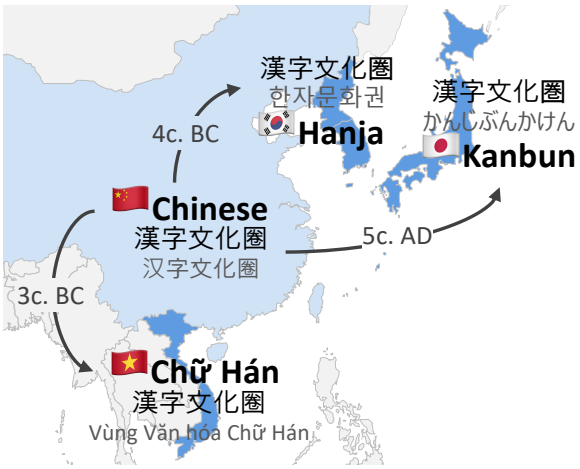

Figure 1: Language transfer from Classical Chinese to neighboring countries in Sinosphere. Classical Chinese had been transferred to neighboring countries in East Asia and used from the 6th century BC to the 20th century AD. While modern languages (*gray*) are different from each other, ancient languages (*black*) are mutually understandable.

Recent advances in natural language processing have enabled computational analysis of these historical documents, which is crucial as modern speakers can no longer directly interpret these ancient writings. Researchers are increasingly leveraging Classical Chinese resources to develop language models for other Sinosphere languages (Yoo et al., 2022; Moon et al., 2024; Wang et al., 2023, *inter alia*). This approach appears particularly promising given the shared literary traditions and significant resource disparity across these languages—with Classical Chinese being the most abundant, followed by Hanja, while Kanbun and Chữ Hán remain relatively scarce. However, the effectiveness of such cross-lingual approaches has not been thoroughly evaluated, despite these writing systems having evolved independently over 1,500 years to

Proceedings of the 14th International Joint Conference on Natural Language Processing and the 4th Conference of the Asia-Pacific Chapter of the Association for Computational Linguistics, pages 1591–1610

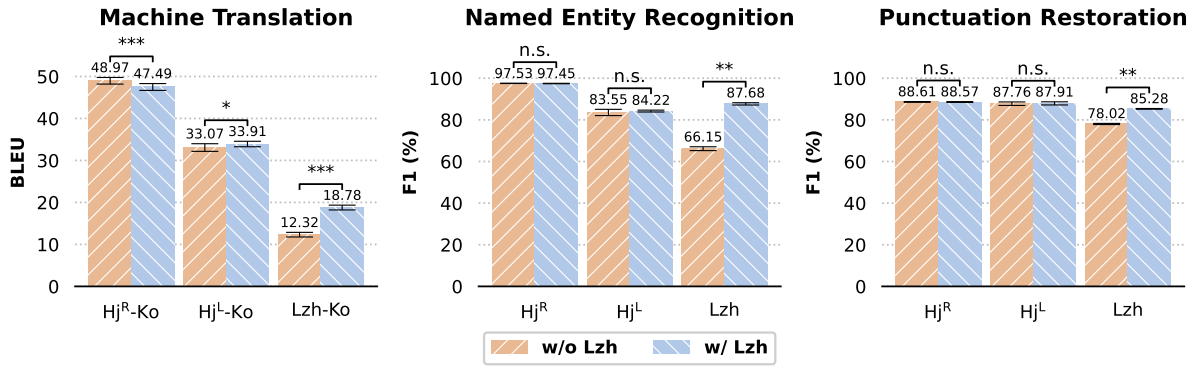

Figure 2: Comparison of models trained with and without Classical Chinese (Lzh). Results show BLEU scores (MT) and F1-scores (NER, PR) across three document types: Hanja royal records (Hj^R), Hanja literary works (Hj^L), and Classical Chinese (Lzh), with error bars of 95% confidence intervals for MT and standard deviations for NER and PR. Statistical significance is denoted as: *** ($p < 0.001$), ** ($p < 0.01$), * ($p < 0.05$), and n.s. (not significant).

accommodate distinct regional needs and cultural practices.

In this paper, we challenge this assumption by conducting comprehensive experiments across three tasks: machine translation (MT), named entity recognition (NER), and punctuation restoration (PR). Figure 2 demonstrates that leveraging Classical Chinese corpora does not yield statistically significant improvements for NER and PR tasks across Hanja documents. For MT, while there is a marginally positive effect (+0.84 BLEU score) for Hanja literary works, this improvement is not substantial—according to Kocmi et al. (2024) and Xu et al. (2024), BLEU improvements of this magnitude typically correlate with human-perceived quality improvements in only 60-65% of cases. These results remain consistent across different model architectures and parameter scales, suggesting fundamental limitations in cross-lingual transfer between these historical languages (§4.1).

To enable deeper analysis beyond the predominantly royal-centric Hanja research (Kang et al., 2021; Yoo et al., 2022; Son et al., 2022, *inter alia*), we introduce *the Korean Literary Collections* (KLC), a corpus of literary works written in Hanja that captures diverse writing styles from individual scholars. Our domain-specific analysis reveals that while incorporating Classical Chinese data shows mixed results overall, careful selection of similar writing styles—such as using Chinese classical poetry for Korean literary works—can lead to marginal improvements in translation performance (§4.3).

Our investigation reveals that Classical Chinese resources provide benefit for only extremely low-resource scenarios, with their effectiveness diminishing rapidly as local language data increases for Hanja (§4.2). Experiments with Japanese historical documents written in Kanbun show similar trends of effective cross-lingual transfer in low-resource settings (§4.4.1). Moreover, our vocabulary analyses across the Sinosphere show that character-level divergence is minimal, suggesting that the limited cross-lingual transferability stems from deeper linguistic differences (§4.4.2).

Our findings across different dimensions emphasize that successful cross-lingual transfer in historical language processing requires considerations beyond shared writing systems, highlighting the importance of careful empirical validation that accounts for both resource availability and domain characteristics. Our contributions are as follows:

- We question and empirically evaluate the efficacy of leveraging Classical Chinese resources for historical Asian language models.
- We demonstrate Classical Chinese integration yields minimal improvements for Hanja processing, while showing potential benefits for extremely low-resource scenarios.
- We provide analyses of cross-lingual transfer effectiveness that can inform the development of language models for historical documents across the Sinosphere.
- We publicly release our code and data, including the KLC dataset previously unexplored in the NLP community.[1]

2 Background

Written languages in the Sinosphere initially adopted Classical Chinese syntax and vocabulary (Figure 1), but gradually diverged over time to meet local needs (Handel, 2019). This linguistic evolution has led to differences that potentially affect the efficacy of cross-lingual transfer in NLP tasks. First, several characters became archaic, were transformed, and substituted by preferred heteromorphic synonyms, as Classical Chinese was disseminated into neighboring countries (Kim, 2012). Table 1 illustrates examples of regional variants between languages based on Classical Chinese. Furthermore, Korea, Japan, and Vietnam developed variant forms and new characters to express local concepts (Heo, 2019). For instance, Koreans invented a new character 畓 (paddy field) in Hanja to reflect their agricultural lifestyle by combining two existing characters: 水 (water) and 田 (field). Structural adaptations also occurred; while Classical Chinese typically follows a Subject-Verb-Object (SVO) structure, Kanbun adapted to a Subject-Object-Verb (SOV) structure, aligning more closely with Japanese grammar (Wang et al., 2023).

(a) Variant forms with same meaning

Meaning	Preferred Form			
	CN	KR	JP	VN
fight	鬥	鬪	鬪	鬥
truly	真	眞	真	真
leg	腳	脚	脚	腳

(b) Homographs with different meanings

Char.	Primary Meaning			
	CN	KR	JP	VN
空	in vain	empty	empty	without
骨	bone	bone	cremains	pillar
串	skewer	cape	skewer	skewer

(c) Locally invented characters

Loc.	Characters
KR	畓 (paddy field), 欌 (wardrobe)
JP	榊 (sakaki tree), 働 (work)
VN	𠀧 (three), 𠊛 (human), 𡗶 (sky)

Table 1: Linguistic divergence patterns in the Sinosphere writing systems. It illustrates three types of character variations across China (CN), Korea (KR), Japan (JP), and Vietnam (VN): variant forms sharing meanings, homographs with distinct regional interpretations, and locally invented characters.

3 Experiments

In this section, we detail the design, implementation, and results of our experiments investigating the impact of using Classical Chinese datasets to train language models for ancient Korean documents written in Hanja.

3.1 Study Design

3.1.1 Documents

We construct our dataset by gathering publicly available resources and datasets written in languages within the Sinosphere. To the best of our knowledge, resources for Kanbun and Chữ Hán are severely limited; small sizes of raw corpora exist for both, with some partial translations available for Kanbun. Therefore, we focus on Hanja (Hj) and Classical Chinese (Lzh) for our experiments. Hanja documents are further divided into two categories based on authorship: historical records written by government offices of the Joseon Dynasty (Hj^R) and literary work written by individual scholars (Hj^L). Table 2 lists these corpora with their statistics. See Appendix A for more details, including data sources and preprocessing procedures.

Royal Documents in Hanja (Hj^R) consists of government-compiled chronicles from the Joseon Dynasty period: *the Annals of the Joseon Dynasty* (AJD), *the Diaries of the Royal Secretariat* (DRS), and *the Daily Records of the Royal Court and Important Officials* (DRRI). These documents follow strict writing guidelines and exhibit a highly consistent style.

Literary Documents in Hanja (Hj^L) refers to literary works written in Hanja authored by various Korean authors. In this paper, we use *the Korean Literary Collections* (KLC) [2] as the primary source. Hanja literary works remain understudied in the NLP community, and the KLC corpus has not previously been explored in NLP research. Detailed documentation of the KLC dataset is provided in Appendix A.7.

Documents in Classical Chinese (Lzh) comprises the WYWEB benchmark (Zhou et al., 2023),

[2] also known as *the Comprehensive Publication of Korean Literary Collections in Classical Chinese*

Table 2: Statistics of historical documents from the Sinosphere. Documents marked with † are supplementary materials analyzed in discussions and not used in the main experimental evaluations. Trans. (%) indicates the ratio of documents with publicly available translations, and tokens are counted using tiktoken's `cl100k_base` encoding.

the NiuTrans Classical Chinese to Modern Chinese dataset [3], the C2MChn dataset (Jiang et al., 2023), Daizhige [4], and the Oriental Classics Database (OCDB) [5]. WYWEB consists of nine NLP tasks for Classical Chinese, including GLNER—a named entity recognition task initially developed by Gulian (2020)—and WYWMT—a machine translation task that translates Classical Chinese into Modern Chinese. Daizhige, the largest classical Chinese corpus, contains about 2.4 billion tokens of classical literature. The OCDB provides original Chinese texts and Korean translations of authoritative books.

Other Documents in the Sinosphere. We collect historical documents from Japan and Vietnam and analyze them in the discussion section. For Kanbun, we use the *Rikkokushi*, Japan's Six National Histories. For Chữ Hán, we include four major Vietnamese historical chronicles: the *Đại Việt sử ký toàn thư* (ĐVSKTT) and *Đại Nam thực lục* (ĐNTL), which served as official dynastic records, along with the *An Nam chí lược* (ANCL) and *Đại Việt sử lược* (ĐVSL).

Data Augmentation. We create a synthetic dataset that translates Classical Chinese into Korean by applying machine translation to Modern Chinese sentences from the NiuTrans dataset. Translation efforts for Classical Chinese predominantly focus on Modern Chinese, making it challenging to explore cross-lingual transferability. We employ GPT-4 [6] to generate a total of 972,467 synthetic sentence pairs from Classical Chinese to Korean, adapting the approach proposed by Nehrdich et al. (2023). Detailed inference settings are provided in Appendix A.2.

3.1.2 Tasks

The experiments focus on three tasks: machine translation (MT), named entity recognition (NER), and punctuation restoration (PR). These tasks represent real-world challenges for human experts analyzing and understanding ancient languages.

Machine Translation (MT) of ancient Korean documents into modern languages is crucial, as most contemporary Koreans, including scholars, cannot comprehend Hanja texts without translation. We measure the BLEU score (Papineni et al., 2002) using SacreBLEU (Post, 2018).

Named Entity Recognition (NER) is a sequence labeling task that identifies and classifies proper names, such as persons and locations, in text. Combined with entity linking, it is crucial for indexing and searching large historical records. We report the F1-score after normalizing all predicted and ground-truth labels to 'NE', akin to the binary set-

[6] The experiments were conducted on April 6, 2024 – April 12, 2024 with `gpt-4-0125-preview` model under Azure OpenAI Service with the OpenAI API as a fallback when content filtering prevented response generation.

ting in NLTK, to ensure a fair comparison across different models and datasets. For readability, F1-scores are presented as percentages (0-100) in tables and figures, while being expressed in the standard 0-1 scale in the text (*e.g.*, 87.5 = 0.875).

Punctuation Restoration (PR) is an essential pre-translation step that involves inserting modern punctuation marks into original Hanja texts, as punctuation greatly impacts the meaning of these texts. We adopt the comprehensive punctuation restoration approach proposed by Pogoda and Walkowiak (2021) for training. For evaluation, we use the weighted average F1-score after simplifying each punctuation combination to the conventionally defined 4-class task (comma, period, question mark, and other). Reduction rules are presented in Appendix A.6.

3.1.3 Model Training

We fine-tune Qwen2-7B (Yang et al., 2024) for MT and SikuRoBERTa (Wang et al., 2021) for NER and PR, respectively. Table 8 in Appendix A.4 presents the composition of training data for each task. For documents without predefined splits, we allocate 80% for training, 10% for validation, and 10% for testing. The KLC data is bifurcated at the book level for training/validation and testing.

Qwen2 is a series of foundation models pre-trained on multilingual corpus and proficient in over 30 languages, including Chinese, Korean, and English (Yang et al., 2024). We fine-tune the Qwen2-7B using QLoRA (Dettmers et al., 2023) for machine translation of three language pairs: Hj-Ko, Hj-En, and Lzh-Ko, using the prompt in Appendix A.5.

SikuRoBERTa is a RoBERTa-based model pre-trained on the *Siku Quanshu*, a vast collection of Classical Chinese literature (Wang et al., 2021).[7]

3.2 Experimental Results

We evaluate models trained across various dataset combinations and tasks, with results shown in Table 3. Incorporating Classical Chinese resources yields minimal or non-significant improvements for Hanja documents across all tasks. For machine translation, significance testing via paired bootstrap resampling (Koehn, 2004) reveals that only

			(−0.04)	(+0.15)	(+7.26)

Table 3: Performance comparisons for MT, NER, and PR tasks across all combinations of document types used in training. The values in parentheses denote the score differences between the models trained with and without Classical Chinese data (Lzh). Gray indicates no significant differences. Orange and blue indicate significant decreases and increases, respectively, with saturation reflecting the magnitude of differences by each task. **Bold** and underlined numbers denote the highest and the second-highest scores for each task and test dataset, respectively.

2 of 9 test conditions show improvements. The largest gain (+1.01 BLEU for Hj^L-Ko) achieves only 60-65% agreement with human judgments (Kocmi et al., 2024), while most conditions show decreases or stagnation (-3.14 to +0.84 BLEU). For sequence labeling tasks (*i.e.*, NER and PR), 5-fold cross-validation with Mann-Whitney U tests (Mann and

[7] Encoder-based models pretrained on Classical Chinese corpora have been employed by multiple Hanja-related studies (Yoo et al., 2022; Moon et al., 2024).

Whitney, 1947) shows no significant changes ($p < 0.05$) when adding Classical Chinese data, with F1-score differences ranging from -0.0215 to +0.0067. In contrast, Classical Chinese documents show significant performance improvements when trained with Classical Chinese resources, indicating successful baseline training. A qualitative error analysis of these results is available in Appendix B.6.

Notably, models trained exclusively on Classical Chinese perform well on sequence labeling tasks for Hanja documents, with the Classical Chinese NER model outperforming Hj^R-trained model on Hj^L data (0.7261 vs 0.7082 F1). While machine translation requires comprehensive language understanding and generation capabilities, NER and PR primarily capture character and word-level patterns. The smaller performance variations in PR compared to MT and NER suggest that punctuation patterns exhibit a degree of consistency across the Sinosphere writing systems.

Our results reveal a clear division between royal and literary Hanja texts. Models trained on Hj^R perform poorly on Hj^L (BLEU scores below 11.82), with similar patterns in NER. This aligns with known linguistic differences between government chronicles, which follow strict guidelines, and diverse literary works by individual authors (Moon et al., 2024).

For Classical Chinese language modeling, incorporating Hanja data shows minimal impact. Adding Hj^L produces no significant changes across tasks, while Hj^R data yields modest differences (+0.50 BLEU, +0.0137 F1, and -0.0058 F1 for MT, NER, and PR, respectively).

4 Discussions

In this section, we explore potential reasons why Classical Chinese exhibits limited impact on the language models for Asian historical documents and support them with empirical analyses.

4.1 Model Scaling and Architecture Variations

We extend our observations to smaller model scales (Table 4) and various foundation models (Table 5) by fine-tuning MT models with and without Classical Chinese data. We outline that incorporating Classical Chinese corpora significantly impairs Hanja language modeling across both smaller scales of Qwen2 and different foundation models (*i.e.*, Llama-3.1-8B-Instruct and Gemma-2-9B).

Model Size	Train Hj	Train Lzh	Hj^R-En	Hj^R-Ko	Hj^L-Ko	Lzh-Ko
7B	✔		**33.15**	**48.97**	33.07	12.32
	✔	✔	31.52	47.49	**33.91**	**18.78**
			(−1.63)	(−1.48)	(+0.84)	(+6.46)
1.5B	✔		28.74	43.58	29.32	8.92
	✔	✔	23.66	37.64	26.66	15.61
			(−5.08)	(−5.94)	(−2.66)	(+6.69)

	✔	✔	31.52	47.49	33.91	18.78
			(−1.63)	(−1.48)	(+0.84)	(+6.46)
Llama-3.1	✔		33.96	49.03	34.56	13.13
	✔	✔	32.25	47.53	33.50	18.76
			(−1.71)	(−1.50)	(−1.06)	(+5.63)
Gemma-2	✔		**35.39**	**51.86**	**36.69**	13.20
	✔	✔	33.56	49.66	35.09	**19.61**
			(−1.83)	(−2.20)	(−1.60)	(+6.41)

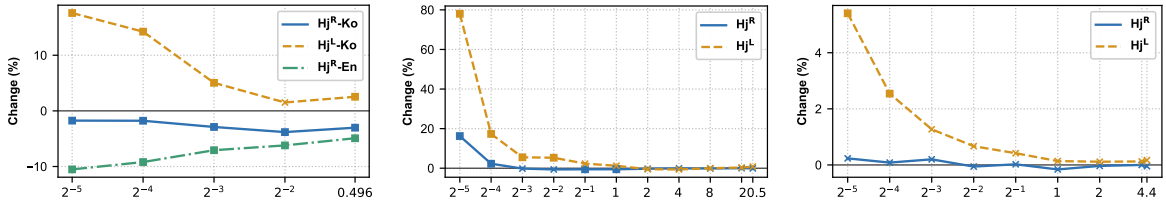

Table 5: BLEU scores of machine translation models across different architectures with/without Classical Chinese (Lzh) training data.

Specifically, BLEU scores for Hanja-to-English and Hanja-to-Korean on royal documents decrease by 5.08 and 5.94, respectively, when fine-tuning Qwen2-1.5B.

4.2 Threshold for Diminishing Benefits of Classical Chinese Data

We hypothesize that sufficient Hanja data exists to train effective language models without relying on Classical Chinese resources, given the substantial volume of annotated Hanja documents preserved through national research initiatives. When measured by token count, available training data for Hanja exceeds Classical Chinese by factors of 4.4, 18.6, and 6.8 for MT, NER, and PR, respectively.

To identify the threshold where Classical Chinese data ceases to provide meaningful benefits, we conduct an ablation study by systematically varying the ratio of Hanja to Classical Chinese training data. Figure 3 shows performance differences between models trained with and without Classical Chinese data across different Hanja data proportions. While Classical Chinese resources significantly boost performance in extremely low-resource scenarios, particularly for literary documents, these

(a) Machine Translation (b) Named Entity Recognition (c) Punctuation Restoration

Figure 3: Performance impact of Classical Chinese training data across varying Hanja data ratios. The x-axis shows the ratio r, where Hj:Lzh = r:1 denotes the proportion of Hanja data against Classical Chinese data, while the y-axis shows the relative performance differences in percentage (%) between models trained with/without Classical Chinese data. Square and x markers indicate statistically significant differences ($p < 0.05$) and non-significant differences, respectively.

benefits diminish rapidly as Hanja data increases. The performance improvements become relatively small (below 5.5%) across all tasks once Hanja data exceeds one-eighth the volume of Classical Chinese data. Detailed results are in Table 15. These findings suggest that while Classical Chinese resources can be valuable in low-resource settings, their utility diminishes quickly with increasing Hanja data availability, challenging the assumption that incorporating additional auxiliary data consistently improves performance.

4.3 Domain-Specific Transfer Learning

We further investigate whether targeting specific domains of Classical Chinese data can improve cross-lingual transfer effectiveness for Hanja. Using the C2MChn dataset (Jiang et al., 2023), we categorize Classical Chinese texts into three domains aligned with Hanja genres: History, Religion (Buddhism, Confucianism, Taoism), and Miscellaneous (Agronomy, Short, Others), and conduct fine-tuning experiments with Qwen2-7B using various domain combinations.

Table 6 shows that incorporating Classical Chinese data from any domain combination reduces MT model performance for Hanja royal documents compared to using Hanja data alone. While the Miscellaneous domain occasionally produces minor improvements for literary documents (maximum +1.41 BLEU), the overall effects remain mixed or negligible. We hypothesize that short-form poetry within the Miscellaneous domain may assist with similarly styled Hanja literary works, but using untargeted data across domains diminishes this benefit. These results underscore that domain-specific Classical Chinese data requires careful empirical validation for effective use.

Domain			Hj^{R}-En	Hj^{R}-Ko	Hj^{L}-Ko	Lzh-Ko
His	Rel	Mis				
None (baseline)			**33.15**	**48.97**	33.07	12.32
✔			32.26	47.80	33.60	16.88
			(−0.89)	(−1.17)	(+0.53)	(+4.56)
	✔		32.23	47.82	33.68	16.90
			(−0.92)	(−1.15)	(+0.61)	(+4.58)
		✔	32.71	48.55	**34.48**	16.78
			(−0.44)	(−0.42)	(+1.41)	(+4.46)

			(−1.26)	(−1.52)	(+0.96)	(+4.51)
	✔	✔	31.80	48.11	34.06	16.96
			(−1.35)	(−0.86)	(+0.99)	(+4.64)
✔	✔	✔	31.77	47.37	33.66	17.47
			(−1.38)	(−1.60)	(+0.59)	(+5.15)

Table 6: Performance comparison of domain-specific transfer learning for machine translation. Models are trained on Hanja data (351.1M tokens) combined with different domains of Classical Chinese: History (23.6M tokens), Religion (21.6M tokens), and Miscellaneous (3.7M tokens).

4.4 Expandability to Sinosphere

4.4.1 Machine Translation for Kanbun

To explore the generalizability of our findings to other languages in the Sinosphere, we conduct experiments on Kanbun using 1,371 paragraph-level samples from Korean-related records [8] in the Six National Histories of Japan. As shown in Table 7, both Hanja and Classical Chinese resources improve Kanbun translation performance (BLEU scores increase by 19.17 and 11.14, respectively), demonstrating that cross-lingual transfer can be effective in low-resource settings. However, careful empirical validation is needed when selecting source languages rather than simply combining all

[8] https://db.history.go.kr/id/jm

Train Data			Kb-Ko	Hj^{R}-Ko	Hj^{L}-Ko	Lzh-Ko
Kb	Hj	Lzh				
✔			25.96	8.02	4.50	10.29
	✔		13.82	<u>48.97</u>	33.07	12.32
		✔	19.08	9.79	4.85	18.13
✔	✔		**45.13**	**49.53**	**34.69**	14.00
✔		✔	37.10	9.70	4.85	17.88
	✔	✔	19.14	47.49	<u>33.91</u>	**18.78**
✔	✔	✔	<u>42.66</u>	47.93	33.69	<u>18.40</u>

Table 7: Translation performance (BLEU score) comparison across different combinations of Kanbun (Kb, 0.34M tokens), Hanja (351.1M tokens), and Classical Chinese (79.8M tokens) training data. The **bold** and <u>underlined</u> values indicate the best and second-best performance, respectively.

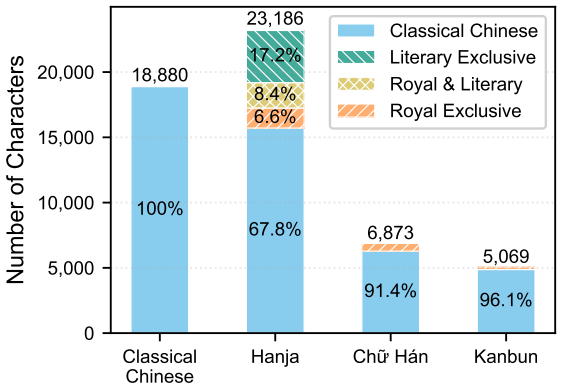

Figure 4: Distribution of unique characters across writing systems in the Sinosphere. The bars represent the proportion of shared characters with Classical Chinese versus language-specific variants in each writing system.

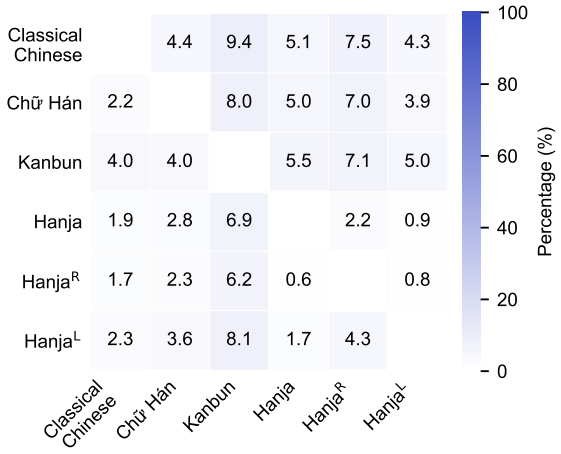

Figure 5: Heatmap of character coverage gaps between Sinosphere languages. Each cell shows the percentage of characters in the *row* language that are not the most common characters in the *column* language at 99% frequency threshold.

available resources.

Here, the varying degrees of improvement likely stem from different levels of linguistic and topical similarity. We validate this empirically using 5-gram language models trained on Korean translations, where perplexity on Kanbun documents is lower with a model trained on Hanja (181) versus Classical Chinese (264). This pattern reflects our test set composition: Korea-related Kanbun texts translated by a Korean institution.

4.4.2 Vocabulary Divergence

We computationally identify the linguistic distance between Classical Chinese and other writing systems in the Sinosphere through character-level analysis. Analysis of unique characters across writing systems (Figure 4) reveals Hanja having the largest vocabulary (23,186 characters), followed by Classical Chinese, Chữ Hán, and Kanbun. While 32.2% of Hanja characters do not appear in our Classical Chinese corpus, these Hanja-exclusive characters occur infrequently, comprising less than 1.9% of character usage at the 99% frequency threshold (Figure 5). Further inspection reveals that most Hanja-exclusive characters are documented variant forms of Classical Chinese characters in the *Kangxi Dictionary*, rather than Korean-invented characters. For instance, the character 腦 in the Annals of the Joseon Dynasty is a known variant of 腦 (brain) but absent from our Classical Chinese corpora. While variant character normalization techniques (Kessler, 2024) might mitigate these surface-level differences, our findings suggest that the challenges in cross-lingual transfer stem from factors beyond vocabulary divergence.

5 Related Work

5.1 NLP for Asian Historical Documents

A variety of research has been mainly conducted in Classical Chinese and Hanja due to challenges for acquisition of available resources. In Classical Chinese, evaluation datasets and benchmarks (Zhou et al., 2023) and language models (Tian et al., 2021; Chang et al., 2023) are widely released. Similarly, datasets and language models for Hanja have been introduced for various tasks, including machine translation (Kang et al., 2021; Son et al., 2022), named entity recognition (Yoo et al., 2022), and relation extraction (Yang et al., 2023).

5.2 Cross-Lingual Studies for Sinosphere

Several studies have introduced cross-lingual approaches that leverage linguistically close, historical resources in the Sinosphere. Moon et al. (2024) used Classical Chinese resources to develop NER and sentence splitting models for Hanja literary documents and uncovered that removing special characters and punctuation marks helps cross-lingual transfer between Classical Chinese and Hanja. Wang et al. (2023) synthetically constructed the first Classical Chinese-to-Kanbun dataset and trained a Kanbun language model, addressing the scarcity of available resources in Kanbun.

Cross-lingual transfer in the Sinosphere has also been explored across modern languages. Kim et al. (2020) proposed a machine translation technique that matches overlapping vocabulary between Korean and Japanese stemming from Hanja and Kanbun, respectively. Nehrdich et al. (2023) used Classical Chinese-to-Modern Chinese dataset for Buddhist Chinese-to-English machine translation. While recent studies have recklessly adopted Classical Chinese resources for other languages in the Sinosphere, this paper aims to carefully investigate the performance of cross-lingual transfer.

6 Conclusion

We challenge the widespread assumption that Classical Chinese resources inherently benefit language models for other historical East Asian writing systems. Our comprehensive experiments across machine translation, named entity recognition, and punctuation restoration reveal that incorporating Classical Chinese data produces minimal and often statistically insignificant improvements for Hanja documents. While our analysis shows limited character-level divergence between these languages, the poor cross-lingual transfer suggests fundamental linguistic differences beyond shared vocabulary. These findings demonstrate that successfully processing historical Asian languages requires careful empirical validation rather than assumed benefits from apparent linguistic similarities. We emphasize the importance of considering both resource availability and domain characteristics when developing language models for historical documents. Building on our results, future research should further investigate the linguistic factors that affect cross-lingual transferability across different languages or writing systems.

Limitations

Our experiments with Kanbun and Chữ Hán are constrained by limited dataset availability compared to Hanja, necessitating caution in drawing broader conclusions about these writing systems. Also, as NLP researchers rather than domain experts in historical Asian languages, our analysis may not fully capture deeper linguistic nuances in ancient languages.

Despite analyzing substantial volumes of historical records and literary work, our coverage of Hanja documents remains partial. Notable omissions include local government records, Buddhist texts, and epigraphic sources, which may demonstrate distinct patterns of cross-lingual transferability from Classical Chinese.

The representation of Classical Chinese texts in our datasets poses an additional limitation, as they are available only in Simplified Chinese despite their Traditional Chinese origins. This inherently imperfect character conversion system may introduce systematic biases in our cross-lingual analysis.

Ethical Considerations

This research focuses on evaluating the effectiveness of cross-lingual transfer between historical writing systems through computational experiments on publicly available historical documents. The methods employed are applied to texts that have been openly preserved for academic study. The research does not involve human subjects, sensitive personal data, or content that could enable harmful applications. While historical texts can sometimes contain biased perspectives or sensitive content, our work focuses purely on the technical aspects of language processing rather than interpreting or generating content. The computational methods and findings presented here aim to advance the scholarly study of historical documents while maintaining respect for the cultural significance of these texts.

Appendix

A Replication Details

A.1 Data Sources

We collect our datasets from publicly available sources between February and October 2024. Korean historical documents are sourced from national research institutions: the National Institute of Korean History (NIKH) provides the AJD[11] and DRS[12], while the Kyujanggak Institute maintains DRRI[13]. The Institute for the Translation of Korean Classics (ITKC) offers the KLC[14] along with Korean translations of the royal documents. Classical Chinese resources include Daizhige[15], NiuTrans[16], C2MChn[17], and WYWEB[18], all available through GitHub repositories. The OCDB[19] is maintained by the Institute of Traditional Culture. For Japanese documents, we use the Rikkokushi texts from the public website[20], with Korean translations of Korea-related records provided by NIKH[21]. Vietnamese historical chronicles including ĐVSKTT[22], ĐNTL[23], ANCL[24], and ĐVSL[25] are available through Wikisource.

A.2 Data Augmentation

We create synthetic Korean translations of Classical Chinese texts using GPT-4. For each source text, we provide both the Classical Chinese original and its Modern Chinese translation as context, using the following prompt:

> Translate the following text from Classical Chinese into Korean, based on the reference translation in Modern Chinese. ⏎
> Classical Chinese: <source sentence> ⏎
> Modern Chinese: <reference translation> ⏎
> Korean:

We generate translations using GPT-4 under two configurations: the NiuTrans dataset translations use `gpt-4-0125-preview` with temperature 0.7, while C2MChn translations use `gpt-4o-mini-2024-07-18` with temperature 0.0. We employ Azure OpenAI Service as our primary platform, falling back to the OpenAI API when necessary. Approximately 6% of source texts are filtered out due to sensitive historical content, particularly passages containing references to war crimes or violence.

A.3 Preprocessing

Processing ancient Asian texts requires careful character normalization to ensure consistent representation across different writing systems and time periods. Our preprocessing pipeline applies the Normalization Form Compatibility Composition (NFKC) to standardize character encodings, followed by whitespace standardization that converts all newlines, tabs, and spaces to single space characters. We normalize all punctuation marks, including converting directional quotation marks to their neutral forms, and standardize CJK middle dot variants (`U+318D`, `U+119E`, `U+30FB`) to the standard middle dot form (`U+00B7`). For Classical Chinese texts in Simplified Chinese characters, we convert them to Traditional Chinese using OpenCC[26].

A.4 Experimental Setup

Table 8 quantifies our experimental data across tasks using both sample counts and token quantities. Table 9 presents our dataset partitioning across training, validation, and test sets for each task. For machine translation (MT), we evaluate performance using 1,000 test samples per document and language pair, computing aggregate BLEU scores

Task	Type	Document	# of Samples	# of Tokens
MT	Hj^R	AJD	331,150	241,653,871
	Hj^L	KLC	53,147	109,406,346
	Lzh	NiuTrans	774,914	79,806,362
NER	Hj^R	AJD	293,854	80,841,316
	Hj^L	KLC	8,035	6,673,763
	Lzh	GLNER	14,719	4,710,310
PR	Hj^R	AJD	293,746	81,095,372
	Hj^L	KLC	14,428	7,983,038
	Lzh	WYWEB	70,664	13,141,862

Table 8: Composition of training data used in experiments across tasks. Data quantities are shown by both number of samples and total tokens computed using `cl100k_base` encoding.

Table 9: Dataset composition and partitioning across tasks. The table shows sample sizes for training, validation, and test sets used in machine translation (MT), named entity recognition (NER), and punctuation restoration (PR) experiments. Documents marked with † are supplementary materials used only in discussions.

via SacreBLEU across all translation outputs. For named entity recognition (NER) and punctuation restoration (PR), we use 5,000 test samples per document, with the exception of GLNER, which uses 2,000 test samples due to dataset constraints.

A.5 Training and Hyperparameters

Our experiments run on a server equipped with Intel Xeon Silver 4114 processor (40 threads) and eight GeForce RTX 2080 Ti GPUs (11GB each). For training and inference of Gemma-2 models, we use a separate server with Intel Xeon Silver 4214R processor (48 threads) and eight Quadro RTX A6000 GPUs (48GB each). We implement our models using LLaMA-Factory (Zheng et al., 2024) for machine translation fine-tuning and Hugging Face Transformers (Wolf et al., 2020) for NER and PR models. Table 10 details our hyperparameter configurations. Training times vary by task: up to 36 hours for machine translation, 10 hours for named entity recognition, and 14 hours for punctuation restoration. The prompt shown below is used consistently across all translation tasks during both training and inference.

> Translate the following text from <source language> into <target language>. ⏎
> <source language>: <source sentence> ⏎
> <target language>:

Hyperparameter	Value
Max sequence length	512
Batch size	64
Initial checkpoint	`Qwen/Qwen2-7B`
Quantization	4-bit NormalFloat and double quantization
LoRA r	16
LoRA α	32
LoRA dropout	0.0
rsLoRA	True
Number of epochs	1
Learning rate	1.0e-4
Learning rate scheduler	Cosine
Warm-up ratio	0.1
Optimizer	8-bit AdamW
Weight decay	0.01
Gradient clipping	1.0

(a) Hyperparameters for MT models.

Hyperparameter	Value
Max sequence length	512
Batch size	32
Initial checkpoint	`SIKU-BERT/sikuroberta`
Max epochs	5
Early stopping	applied on validation loss
Learning rate	2e-4
Learning rate scheduler	Linear
Warm-up ratio	0.1
Optimizer	AdamW
Weight decay	0.01

(b) Hyperparameters for NER and PR models.

Table 10: Hyperparameter configurations for training MT, NER, and PR models. Values shown for MT models use `Qwen/Qwen2-7B` base architecture (additional experiments use `Qwen/Qwen2-1.5B`, `Qwen/Qwen2-0.5B`, `google/gemma-2-9b`, and `meta-llama/Llama-3.1-8B-Instruct`). We use half precision (`fp16`) for all computation.

A.6 Inference and Evaluation

Machine Translation. We quantize the fine-tuned MT models using AWQ (Lin et al., 2024) and utilize vLLM (Kwon et al., 2023) for inference. The prompt used for training is also used for inference. We set the temperature to 0 and employ greedy decoding. Metric signatures and versions used for evaluation are presented in Table 12.

Punctuation Restoration. For evaluation, we simplify the diverse punctuation marks used in the

original documents and our models into a standardized 4-class scheme consisting of COMMA, PERIOD, QUESTION, and OTHER. This allows for consistent comparison of model performance across the different datasets. Table 13 shows how various punctuation characters are mapped to these four classes based on their typical functions or meanings.

A.7 Korean Literary Collections Dataset

For this study, we compile a new dataset from the Korean Literary Collections (KLC), a comprehensive collection of Hanja literary works maintained by the Institute for the Translation of Korean Classics. Unlike prior research that focused predominantly on royal-centric Hanja documents (Kang et al., 2021; Yoo et al., 2022; Son et al., 2022), our KLC dataset captures diverse writing styles from individual scholars spanning from 886 to 1933 CE, with particularly rich coverage during the 1800s-1930s period. The source corpus contains 652,622 unique articles with an average length of 337 Hanja characters (approximately 220M characters total) from 1,258 unique authors, including notable historical figures such as Song Si-yeol (宋時烈), Jeong Yak-yong (丁若鏞), and Kwak Jong-seok (郭鍾錫). Table 11 presents the genre distribution of the translated portion, demonstrating substantial coverage beyond official documents. We structured our KLC dataset to support multiple NLP tasks: raw text for language model pretraining (652,622 samples), parallel data for machine translation (157,202 samples with Hanja-Korean translations), and annotated documents for named entity recognition (21,657 samples with 379,976 entities).

Genre	# of Articles	Ratio (%)
Anthology	112,215	71.4
Miscellaneous	11,707	7.4
Travelogue	9,688	6.2
Literature	5,456	3.5
History	4,035	2.6
Complete Collection	3,878	2.5
Law	1,609	1.0
Ceremonial Texts	1,593	1.0
Human Affairs	1,422	0.9
Astronomy	1,075	0.7
Politics	944	0.6
Medicine	779	0.5
Geography	664	0.4
Agriculture	618	0.4
Philosophy	595	0.4
Ceremonial Records	452	0.3
Foreign Relations	364	0.2
Classical Texts	53	0.0
Mathematics	41	0.0
Archives	14	0.0

Table 11: Genre distribution of the translated portion in the Korean Literary Collections (KLC) dataset, showing the number of articles and percentage for each category.

B Complementary Results

This section presents additional experimental results and analyses that complement our main findings.

B.1 Experimental Results

Table 14 provides comprehensive BLEU scores for machine translation experiments across all dataset combinations and language pairs, including results from different model architectures and training configurations.

B.2 Threshold for Diminishing Benefits

Table 15 details our systematic investigation of how varying the ratio between Hanja and Classical Chinese training data affects model performance. The results encompass performance metrics across machine translation, named entity recognition, and punctuation restoration tasks as we gradually reduce the proportion of Hanja data on a logarithmic scale.

B.3 Machine Translation for Kanbun

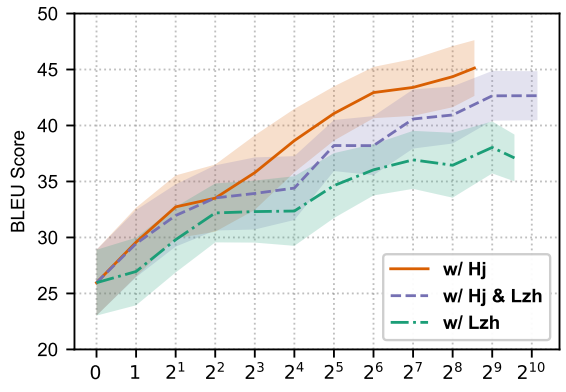
Figure 6 illustrates how BLEU scores change as the quantity of additional training data decreases for Kanbun-Korean translation. The relative performance advantages between different systems remain consistent across varying data quantities.

B.4 Vocabulary Divergence

Figure 7 presents the proportion of unique characters in each corpus that do not appear in other corpora, measured at four cumulative frequency thresholds: 100%, 99.9%, 99%, and 95%. This analysis reveals the extent of character-level divergence between writing systems in the Sinosphere.

B.5 Analysis of Performance in Low-Resource Settings

To verify that the benefits observed when adding Classical Chinese resources in low-resource scenar-



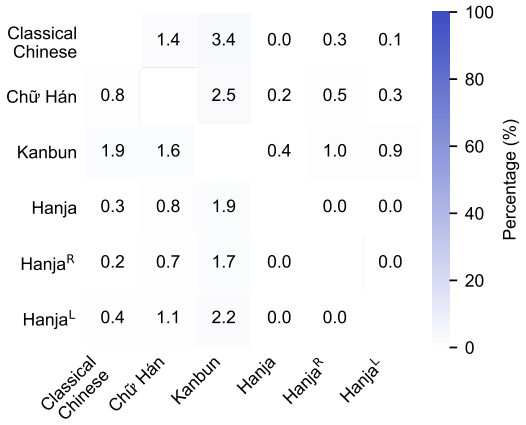


Figure 6: Performance comparison of Kanbun-Korean translation models with varying amounts of additional training data. The x-axis shows the ratio of additional data to Kanbun data in $\log_2$ scale, and the y-axis shows BLEU scores with 95% confidence intervals indicated by shaded regions.

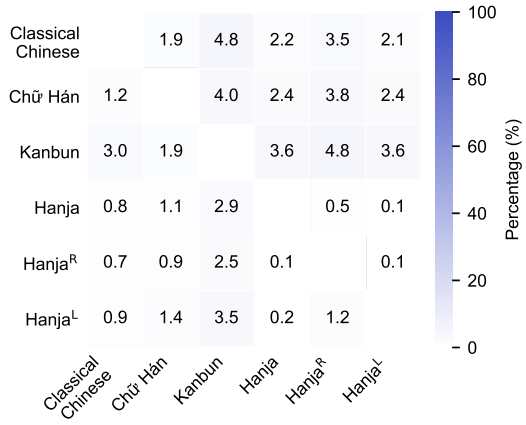
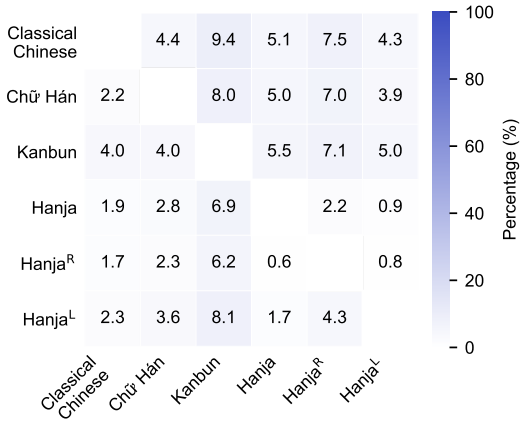


ios reflect genuine cross-lingual transfer rather than overfitting mitigation, we conduct additional experiments analyzing evaluation loss behavior. We maintain full validation set sizes while systematically reducing training data for Hanja-only models at two extreme low-resource ratios (1/16 and 1/32 of the original data). Figure 8 shows that evaluation loss decreases monotonically across all settings for both NER and PR tasks, with no indication of validation loss increases or plateauing that would typically signal overfitting. This consistent pattern across different data ratios strongly suggests that models trained on extremely limited Hanja data do not suffer from overfitting, even without Classical Chinese data. Therefore, the performance improvements observed when adding Classical Chinese resources in these settings likely represent genuine benefits from cross-lingual transfer rather than simply regularization effects addressing overfitting issues.

B.6 Qualitative Error Analysis



To complement our quantitative findings, we perform a systematic qualitative analysis comparing outputs of models trained with and without Classical Chinese data. We calculate per-sample performance metrics for all test predictions and categorize instances where the inclusion of Classical Chinese resources leads to performance changes. Table 16 presents representative examples from our analysis of Hanja^{R} to Korean translation, which reveals three recurring error patterns: (1) inappropriate modernization of classical terms, where historically specific terminology is simplified into contemporary equivalents (*e.g.*, "찬구(饌具)" → "반찬", replacing a formal historical term for food provisions with a modern casual word for side dishes); (2) loss of Korea-specific concepts, where terms unique to Korean historical and cultural contexts are omitted or generalized (*e.g.*, "황의장(黃儀仗)" → "의장", losing the Korea-specific royal ceremonial context); and (3) name translation errors, where historical Korean names are inconsistently handled (*e.g.*, "윤방(尹滂)" → "윤팽", incorrectly changing the pronunciation). These patterns suggest that Classical Chinese data can introduce biases that obscure culturally and historically specific nuances in Hanja translation, explaining the quantitative performance degradation observed in §3.2. For sequence labeling tasks (NER and PR), our analysis shows no consistent patterns of improvement or degradation, aligning with the statistical non-significance reported in our main results.

Abstract

Automatic speech recognition for low-resource languages remains fundamentally constrained by the scarcity of labeled data and computational resources required by state-of-the-art models. We present a systematic investigation into cross-lingual continuous pretraining for low-resource languages, using Perso-Arabic languages (Persian, Arabic, and Urdu) as our primary case study. Our approach demonstrates that strategic utilization of unlabeled speech data can effectively bridge the resource gap without sacrificing recognition accuracy. We construct a 3,000-hour multilingual corpus through a scalable unlabeled data collection pipeline and employ targeted continual pretraining combined with morphologically-aware tokenization to develop a 300M parameter model that achieves performance comparable to systems 5 times larger. Our model outperforms Whisper Large v3 (1.5B parameters) on Persian and achieves competitive results on Arabic and Urdu despite using significantly fewer parameters and substantially less labeled data. These findings challenge the prevailing assumption that ASR quality scales primarily with model size, revealing instead that data relevance and strategic pretraining are more critical factors for low-resource scenarios. This work provides a practical pathway toward inclusive speech technology, enabling effective ASR for underrepresented languages without dependence on massive computational infrastructure or proprietary datasets. To encourage further research, we release our entire codebase and model checkpoints[1].

1 Introduction

Accurate ASR for morphologically complex, low-resource languages remains a pressing challenge. Recent self-supervised methods like Wav2Vec 2.0 (Baevski et al., 2020) and HuBERT (Hsu et al., 2021) have advanced ASR using large-scale unlabeled data. Building on this, multilingual models like XLS-R (Conneau et al., 2021) have improved cross-lingual ASR with diverse pretraining (Wang et al., 2021; Pratap et al., 2020; Ardila et al., 2020; Valk and Alumäe, 2020; Cui et al., 2015). However, these gains mainly benefit high-resource languages, while low-resource ones still suffer from limited labeled data.

For languages like Persian, Arabic, and Urdu, the intersection of limited labeled data, complex orthographies, and rich morphology poses considerable difficulties for ASR. Recent systematic evaluations of state-of-the-art models for Persian[2], Arabic (Wang et al., 2024), and Urdu (Arif et al., 2025) indicate that models like Whisper Large v3 (Radford et al., 2023) and Seamless Large v2 (Communication et al., 2023) exhibit superior performance. However, they are computationally intensive (1.5B+ parameters), making efficient deployment challenging. Some prior works (Getman et al., 2024) have explored continuous pretraining, but their analysis focuses on high-resource scenarios and single-language improvements.

In this work, we address these gaps by systematically investigating ASR for low-resource languages, using Perso-Arabic languages as our primary case study. Our approach combines scalable unlabeled data collection with targeted continuous pretraining and morphologically-aware tokenization to demonstrate that compact models (300M parameters) can achieve performance comparable to systems five times larger. Through systematic evaluation across Persian, Arabic, and Urdu, we provide empirical evidence that strategic utilization of cross-lingual unlabeled data can effectively overcome resource constraints without sacrificing recognition accuracy.

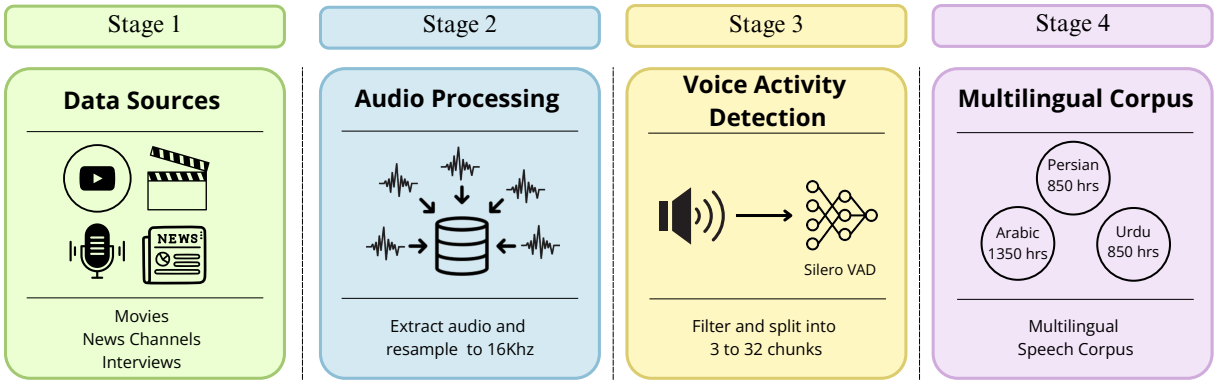

Figure 1: Systematic pipeline for constructing a robust, multilingual unlabeled speech corpus.

Language	Pretraining	Train Set	Test Set
Urdu	816 hrs	60 hrs	10 hrs
Persian	878 hrs	69 hrs	11 hrs
Arabic	1,310 hrs	74 hrs	11 hrs

Table 1: Data statistics showing pretraining corpus (after VAD-based segmentation) and labeled train/test splits.

2 Data

We systematically constructed both unlabeled and labeled speech corpora using a modular data infrastructure to enable controlled investigation of cross-lingual ASR for morphologically-complex, low-resource languages.

2.1 Unlabeled Corpus for Robust Pretraining

We developed a scalable pipeline (Figure 1) to curate high-quality, domain-diverse unlabeled speech for cross-lingual self-supervised training. We acquired multimedia content (films, news broadcasts, interviews) from publicly accessible resources for Persian, Arabic, and Urdu, with language verification through platform metadata or manual inspection. Audio tracks were extracted, resampled to 16 kHz, and processed using Silero VAD[3] to remove non-speech segments, retaining only chunks with speech probability exceeding 70% (Ramirez et al., 2024). Audio was segmented into 3-32 second chunks suitable for training, resulting in the pretraining corpus detailed in Table 1.

2.2 Labeled Data

We curated evaluation-ready labeled corpora by combining data from multiple sources to remove bias and ensure diversity across speakers, dialects, and contexts. Sources include Common Voice (Ardila et al., 2020), and other datasets:

- **Urdu**: IndicVoices (Javed et al., 2024), Urdu Speech-To-Text Dataset[4]
- **Persian**: Persian Speech Corpus[5], ParsiGoo[6], Persian Speech[7], ManaTTS-Persian-Speech-Dataset (Qharabagh et al., 2024), Persian text-to-speech audio (Moradi, 2024)
- **Arabic**: OpenSLR (Kolobov et al., 2021), MGB-2 (Ali et al., 2016)

All audio was resampled to 16 kHz with normalized transcription following (Bandarupalli et al., 2025). Data was stratified into training and test sets as shown in Table 1. Detailed breakdowns of the training and validation splits for each dataset are provided in Appendix A.

3 Experiments

We design systematic experiments to assess efficient automatic speech recognition (ASR) for low-resource, morphologically complex Persian-Arabic languages. The experimental design is guided by three research questions: *(1) Can cross-lingual unlabeled speech improve ASR performance in low-resource Perso-Arabic languages? (2) Which pretraining initialization strategy yields the best adaptation with continual pretraining? (3) Can compact, parameter-efficient models achieve performance comparable to much larger state-of-the-art systems through strategic pretraining and tokenization?* Figure 2 summarizes our training pipeline.

3.1 Pretraining Strategies

To answer these questions, we compare three distinct pretraining initialization strategies:

[3] github.com/snakers4/silero-vad.git

[4] www.kaggle.com/datasets/themohal/tiny-urdu-speech-text-dataset

[5] fa.persianspeechcorpus.com

[6] huggingface.co/datasets/Kamtera/ParsiGoo

[7] github.com/persiandataset/PersianSpeech

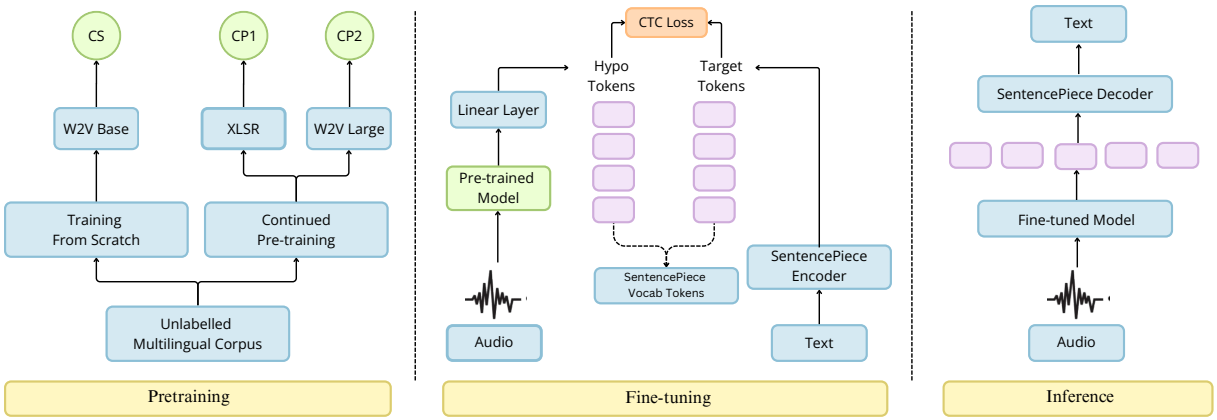

Figure 2: Overview of our experimental framework. The pipeline illustrates three training strategies: CS (Wav2Vec 2.0 Base trained from scratch), CP1 (XLS-R 300M with continuous pretraining), and CP2 (Wav2Vec 2.0 Large with continuous pretraining). All models undergo pretraining on our 3,000-hour multilingual corpus followed by language-specific fine-tuning with SentencePiece tokenization.

From-Scratch Training (CS): Wav2Vec 2.0 Base (95M parameters), trained entirely from randomly initialized weights on our 3,000-hour multilingual corpus. This setup isolates the effect of cross-lingual unlabeled data without prior representation learning.

Cross-lingual Continual Pretraining (CP1): XLS-R (300M parameters), pretrained on 436K hours across 128 languages. We further adapt it to our multilingual corpus to examine whether broad multilingual exposure is beneficial for Perso-Arabic languages.

English-centric Continual Pretraining (CP2): Wav2Vec 2.0 Large (300M parameters), pretrained on 65K hours of primarily English speech. This setting tests whether pretraining on a high-resource language can transfer effectively to the target language family.

All three configurations use identical fine-tuning data and hyperparameters to isolate the effect of initialization strategy.

3.2 Tokenization with SentencePiece

Perso-Arabic languages exhibit orthographic complexity and rich morphology, making character-level tokenization inadequate. To address this, we integrate **SentencePiece** with Byte-Pair Encoding (BPE) into the Wav2Vec 2.0 framework. **Language-specific** subword vocabularies are learned from training transcripts and used to initialize the CTC output layer, enabling direct subword prediction. During inference, subword sequences are decoded into words for final transcription. Further implementation details are provided in Appendix B. Empirical comparisons, in Table 7, confirm that SentencePiece-based tokenization yields reductions in WER compared to character-level decoding.

3.3 Training Procedure

All models are trained in two stages: (1) *unsupervised pretraining* on the unlabeled corpus, followed by (2) *supervised fine-tuning* on the labeled datasets. Hyperparameters and train/validation splits are standardized across all settings.

3.3.1 Pretraining

The CS model is trained from scratch for 200k steps, requiring substantially longer optimization to learn meaningful representations. In contrast, CP1 and CP2 leverage pretrained representations and converge within 40k continual pretraining steps. Across all conditions, early stopping based on validation loss is applied to avoid overfitting during pretraining.

3.3.2 Fine-tuning

Language	CS	CP1	CP2
Urdu	55.8	41.1	43.2
Persian	28.5	21.4	19.9
Arabic	71.4	49.8	58.9

Table 2: Validation loss post fine-tuning.

Each model is fine-tuned separately for Persian, Arabic, and Urdu for up to 50k steps with early stopping. While WER is our primary evaluation metric, we additionally report **validation loss** (Table 2) to capture optimization dynamics. Validation loss offers complementary insight into convergence and stability across languages, highlighting that

Model	Urdu	Persian	Arabic
Our Pretrained Models			
CS (from scratch)	25.0	25.4	38.1
CP1 (XLS-R init.)	22.2	22.3	35.3
CP2 (W2V Large init.)	20.6	17.1	32.9
Baseline Models			
W2V Large (300 M)	39.3	33.2	48.7
Seamless Large v2 (2.3B)	31.9	41.1	34.8
Whisper Large v3 (1.5B)	17.2	21.4	27.2

Table 3: Comprehensive WER comparison across all evaluated models after fine-tuning on labeled data.

CP1 and CP2 converge substantially faster and to lower minima compared to CS. Final evaluation is performed using WER on held-out test sets (Table 3).

3.4 Baseline Fine-tuning

To contextualize our results, we benchmark against three strong baselines: *Whisper Large v3*, *Seamless Large v2*, and *Wav2Vec 2.0 Large*. These baselines are fine-tuned only on our labeled datasets without additional pretraining on our unlabeled corpus. Whisper and Seamless represent state-of-the-art systems (1.5B+ and 2.3B parameters, respectively), while Wav2Vec 2.0 Large serves as a capacity-matched control.

For fairness, all baselines were fine-tuned until convergence using publicly available scripts, with early stopping triggered once validation loss indicated overfitting. This matches the stopping criteria applied to our models.

Full hyperparameter details, along with our training scripts, are released on github for reproducibility. All experiments were conducted on **NVIDIA A100 80GB GPUs**.

4 Results and Analysis

We systematically evaluate our approaches to address the three core research questions, presenting quantitative results in Table 3.

4.1 Impact of Cross-Lingual Pretraining Data

The comparison between Wav2Vec 2.0 (W2V) Large and our three models (CS, CP1, CP2) highlights the central role of in-domain unlabeled data. When fine-tuned directly without additional pretraining, W2V Large (300M parameters, 65K hours of English exposure) yields substantially higher WERs across all languages. In contrast, our CS model—trained from scratch on only 3K hours of Perso-Arabic unlabeled audio with 95M parameters—already outperforms W2V Large. This result underscores that domain-relevant pretraining, even at smaller scale, provides greater benefit than model size or large but typologically distant corpora. Both CP1 and CP2 further reduce WERs, confirming the value of targeted continual pretraining.

4.2 Initialization Strategy Analysis

Our three initialization strategies exhibit distinct performance trends. As expected, CS, trained from scratch, underperforms relative to CP1 and CP2 due to its lack of prior knowledge and smaller capacity. More interestingly, CP2 consistently outperforms CP1 despite its smaller pretraining corpus. We hypothesize that this difference stems from the distribution of pretraining data: CP2 was initialized from $\sim$65K hours of English-only data, whereas CP1 was initialized from $\sim$65K hours of English combined with $\sim$375K hours of predominantly European languages. Since pretraining fundamentally shapes the acoustic feature extractor, English-only pretraining may yield representations that are more broadly transferable whereas, when the pretraining corpus is heavily dominated by distant languages, the learned representations may become tuned to phonetic patterns common in those distant languages, thereby leading to a negative transfer to target languages. In other words, while pretraining is generally beneficial up to a point, excessively broad exposure to unrelated language families may hinder performance compared to more targeted pretraining.

4.3 Resource Efficiency

Our 300M parameter CP2 model demonstrates remarkable efficiency while maintaining competitive performance against much larger state-of-the-art systems. Most notably, our model outperforms Whisper Large v3 on Persian despite using 5× fewer parameters, and achieves performance within 3-6% WER of Whisper Large v3 for Urdu and Arabic while maintaining significant parameter advantage

The performance gap can be attributed to Whisper's extensive prior exposure to labeled data—739 hours for Arabic and 104 hours for Urdu—compared to our model's training exclusively on our smaller curated dataset. For Persian, where Whisper had minimal prior exposure (24

hours), our targeted pretraining strategy demonstrates clear advantages.

This comparison demonstrates two critical points: (1) effective use of unlabeled data can compensate for limited labeled supervision, and (2) parameter efficiency does not preclude competitive or even superior performance. By exploiting targeted continual pretraining, CP2 provides a low-resource pathway to high-quality ASR, contrasting with the underperformance of much larger systems such as Seamless Large v2 (2.3B parameters), which failed to converge under the same conditions. These findings establish that model scale alone is insufficient—adaptation strategy and data relevance are key to success in low-resource ASR.

5 Conclusion

In this work, we present a systematic investigation into resource-efficient ASR for morphologically complex, low-resource languages, with a focus on Perso-Arabic script languages as a representative case study. Our 300M parameter model achieves results competitive with state-of-the-art systems over 5× larger, using substantially less labeled data and computational resources.

Our findings challenge the prevailing assumption that ASR quality scales primarily with model size and data volume. Instead, we show that targeted cross-lingual continuous pretraining, morphologically-aware tokenization, and careful data curation are more critical factors for low-resource languages. Comparing our continual pretraining variants reveals that the relevance of pretraining data, not merely its scale, drives effective transfer learning. This insight suggests that focused, linguistically-informed approaches may be more valuable than broad multilingual exposure for underrepresented languages.

Through our scalable data curation pipeline and strategic utilization of unlabeled multilingual data, we provide a practical pathway toward high-quality ASR that is independent of massive proprietary datasets or computational infrastructure. This work contributes to a more inclusive vision of speech technology where linguistic diversity is not limited by resource constraints, enabling robust ASR systems for the hundreds of millions of speakers of low-resource languages worldwide.

Limitations

Our study presents several limitations. First, while we show that cross-lingual pretraining benefits individual low-resource languages, our fine-tuning is performed separately for each language. We have not yet explored the effects of multilingual joint fine-tuning, which could further improve robustness and transfer. Second, although our unlabeled speech corpus is carefully curated for quality and diversity, it may not encompass the full range of dialects, domains, and spontaneous speech present in real-world scenarios. Third, our evaluation is centered on academic benchmark datasets, leaving open questions regarding the practical robustness and end-user acceptance of our models in deployment settings.

A Labeled Data Distribution Across Datasets

Most existing studies evaluating Automatic Speech Recognition (ASR) models focus on assessing performance using a single dataset. For instance, models trained on the Common Voice dataset are typically evaluated only on the same dataset. However, when these models are tested on other datasets without fine-tuning, their performance often proves suboptimal, highlighting a lack of generalizability.

To address this limitation and improve the robustness of ASR models across diverse datasets, we adopted a multi-dataset approach for training and evaluation. For each target language, we combined a fraction of data from multiple datasets, including Common Voice, to create comprehensive training and testing splits. This approach ensures that models are exposed to a wider variety of speech patterns, accents, and recording conditions, thereby enhancing their generalizability.

Below, we provide the exact durations of the datasets used for each language, along with the specific train and validation splits, as summarized in Tables 4, 5, and 6.

Urdu Dataset	Train Duration (hours)	Validation Duration (hours)
Common Voice	4.23	0.73
SME_news	7.48	1.28
Tiny Urdu Speech Corpus	5.41	0.95
Indic Voices	42.9	7.70

Table 4: Urdu dataset splits for fine-tuning.

Persian Dataset	Train Duration (hours)	Validation Duration (hours)
Common Voice	36.5	6.44
Persian Speech Corpus	2.28	0.21
My Audio Tiny	2.25	0.34
TTS Female	22.6	4.04
Moradi	0.83	0.13
ParsiGOO	3.56	0.64

Table 5: Persian dataset splits for fine-tuning.

B SentencePiece Tokenization

To improve the tokenization process in our speech recognition pipeline, we incorporated SentencePiece tokenization within the Fairseq framework. We first trained a Byte-Pair Encoding (BPE) SentencePiece model with a vocabulary size of 512, using the transcriptions from the training dataset. This vocabulary was subsequently utilized to initialize the Connectionist Temporal Classification (CTC) layer of the wav2vec model.

B.1 Integration of SentencePiece in Fairseq

In the default character-based tokenization used in Fairseq, sentences are split into individual characters. To integrate SentencePiece, we modified this process by first segmenting the sentence into words. Instead of directly splitting words at the character level, we applied SentencePiece encoding to tokenize each word into subword units. This approach retains meaningful subword structures while reducing the token sequence length.

During inference, the decoded tokens were grouped at the word level, and each set of tokens was converted back into corresponding words. Finally, the words were concatenated to reconstruct the complete transcription.

B.2 Impact on Word Error Rate (WER)

To evaluate the impact of SentencePiece tokenization, we fine-tuned our CP2 model using both the default character-based tokenization and the proposed SentencePiece-based approach. The WER comparison across Urdu, Persian, and Arabic is summarized in Table 7.

The results demonstrate a significant reduction in WER across all three languages, highlighting the effectiveness of subword-level tokenization over character-based tokenization in CTC-based speech recognition.

Arabic Dataset	Train Duration (hours)	Validation Duration (hours)
Common Voice	27.5	4.89
SLR-108	8.5	1.53
MGB	37.0	5.11

Table 6: Arabic dataset splits for fine-tuning.

Model	Urdu	Persian	Arabic
CP2 (Character-based)	25.8	26.2	39.0
CP2 (SentencePiece-based)	20.6	17.1	32.9

Table 7: Word Error Rate (WER) comparison between character-based and SentencePiece-based tokenization.

Evaluating Human-LLM Representation Alignment: A Case Study on Affective Sentence Generation for Augmentative and Alternative Communication

{shadabc1,laramar}@umbc.edu

Abstract

Gaps arise between a language model's use of concepts and people's expectations. This gap is critical when LLMs generate text to help people communicate via Augmentative and Alternative Communication (AAC) tools. In this work, we introduce the evaluation task of Representation Alignment for measuring this gap via human judgment. In our study, we expand keywords and emotion representations into full sentences. We select four emotion representations: Words, Valence-Arousal-Dominance (VAD) dimensions expressed in both Lexical and Numeric forms, and Emojis. In addition to Representation Alignment, we also measure people's judgments of the accuracy and realism of the generated sentences. While representations like VAD break emotions into easy-to-compute components, our findings show that people agree more with how LLMs generate when conditioned on English words (e.g., "angry") rather than VAD scales. This difference is especially visible when comparing Numeric VAD to words. Furthermore, we found that the perception of how much a generated sentence conveys an emotion is dependent on both the representation type and which emotion it is.

1 Introduction

Augmentative and Alternative Communication (AAC) tools help people who cannot communicate verbally to hold conversations. Speed of communication is one of the biggest pain points that users point out about their AAC tools (Trnka et al., 2007). As a result of this lag, users are often talked over, ignored, or otherwise disrespected in conversations (Kane et al., 2017). Fortunately, due to their medium, high-tech AAC options such as phone or tablet applications present the opportunity to incorporate NLP techniques to improve communication speed.

To work toward speeding up AAC use, keyword-based sentence generation and word prediction

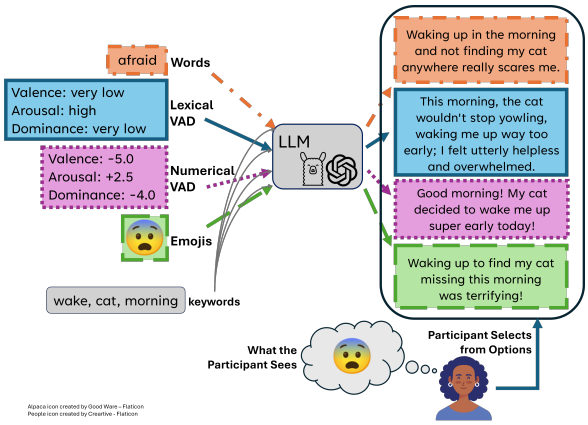

Figure 1: Representation Alignment experiment. Three keywords and an emotion from one of the four representations are used to generate a sentence. Participants are shown the emotion in only one of the representations and select the sentence that best fits that emotion.

have been explored in AAC technologies for decades (Trnka et al., 2007; Wiegand and Patel, 2012; Garcia et al., 2014; Fontana de Vargas and Moffatt, 2021; Shen et al., 2022). Unsurprisingly, we have also seen a recent uptick in the use of LLMs in AAC tools (Valencia et al., 2023; Kitayama and Hirotomi, 2024; Francis et al., 2024; Bailey et al., 2024).

There have been fairly successful attempts for personalized generation (Zhang et al., 2023), such as through prompt engineering, keyword-based generation (Hokamp and Liu, 2017; Yao et al., 2019) or style transfer (Liu et al., 2024). While LLMs can generate human-like text better than their predecessors, there are concerns about putting them into AAC applications. Namely, how much control users have over the LLM, whether the LLM accurately captures the user's way of speaking, or if the LLM is generating text that is appropriate to the conversation's context (Valencia et al., 2023; Martin and Nagalakshmi, 2024). Part of this context includes the current emotional state of the AAC

Proceedings of the 14th International Joint Conference on Natural Language Processing and the 4th Conference of the Asia-Pacific Chapter of the Association for Computational Linguistics, pages 1618–1637
December 20-24, 2025 ©2025 Association for Computational Linguistics

user. As such, we wanted to see how well LLMs and humans aligned in their understanding of various emotion representations. Our hope is that representations used in future AAC applications will generate sentences that match the user's intended emotion.

In this paper, we introduce the task of REPRESENTATION ALIGNMENT, illustrated in Figure 1, where the alignment between the LLM's output and the human's mental model of a concept is measured. Note that this is different from Theory of Mind, as the LLM is not trying to ascertain the current mental state of the user. Representation Alignment looks at how well an LLM's use of concepts aligns with human understanding. Specifically, we will be focusing on the Representation Alignment of *emotions*.

There are multiple ways an emotion could be represented in the input. One representation could be easier for an LLM to parse, but a different representation might be more accessible to users. Hence, to assess emotion representations in the context of keyword-based sentence generation, we investigate the following research questions:

1. Do LLMs' use of emotion representations match humans' expectations?
2. Is there a preferred representation for conveying emotions when performing keyword-based sentence generation?

We look at four ways of representing emotions: with Words (the English word for a particular emotion), via emojis – which have become an effective way to express emotions visually over text (Kaye and Schweiger, 2023), and two types of Valence-Arousal-Dominance scales. We will explain the representation implementation in Section 3.

Valence-Arousal-Dominance (VAD) (Mehrabian, 1980) scales measure emotions on three axes: Valence (or pleasure) indicating whether its a positive or negative feeling, Arousal indicating how much energy is behind the feeling, and Dominance indicating how much control the user has over that feeling. Although VAD has origins in psychology research, it has been useful for NLP-related areas such as affective computing (Mohammad, 2018; Guo and Choi, 2021; El-Haj and Takanami, 2023) and social computing (Hutto and Gilbert, 2014; Khosla, 2018; Garg, 2023). Thus, we were curious about the effectiveness VAD for text generation.

In this work, we addressed the research questions by generating sentences using each of the four emotion representations by few-shot prompting two large language models (GPT-4 and LLaMA-3). We ran a human participant study to determine how well the representations aligned to participants' expectations and how accurately & realistically LLMs can generate sentences using a particular representation. Our contributions are as follows:

1. We introduce a human evaluation paradigm for measuring the alignment between mental models of concepts (such as emotions) and how they are used by LLMs.
2. We show that humans and LLMs align best when Words, or to a lesser extent, Lexical VAD are used to represent emotions.
3. We also show that either Words or Lexical VAD, when used in a prompt, give realistic sentences that most participants agree sound like something they would say.

2 Related Work

2.1 Keyword-based Sentence Generation

Keyword-based sentence generation, also referred to as *lexically-constrained generation*[1], is a subtopic of controlled text generation where the input to a model is a set of keywords and the output is a sentence that uses those keywords. Early on, Kasper (1989); Uchimoto et al. (2002) used grammar systems to build sentences using keywords as anchors. More recently, Mou et al. (2016); He and Li (2021) used sequential models and revised the output repeatedly at each sampling step. Yao et al. (2019); Wang et al. (2020); Ammanabrolu et al. (2020) similarly generated sequential outputs by prompting with a list of keywords. With transformer-based language models, it's also possible to use the decoder or special tokens to control keywords, style or sentiment (Kumar et al., 2021; Samanta et al., 2020; Nie et al., 2023; Krause et al., 2021; Sasazawa et al., 2023).

However, most of these works focus on smaller language models. Chen and Wan (2024) showed that LLMs have strong baseline lexically-constrained generation ability. To our knowledge, not much other work has been done in this area using LLMs.

2.2 Emotion-conditioned Sentence Generation

Emotional sentence generation has been widely studied as part of style-transfer or empathetic

[1]We use the two terms interchangeably.

dialogue generation problems. Early work on emotional sentence generation, such as Polzin and Waibel (2000), relied on rule-based systems. Ghosh et al. (2017); Song et al. (2019) both conditioned the output of a recurrent neural network on specific emotional words, while Singh et al. (2020) also conditioned on words but used GPT-2 (Radford et al., 2019) as the base model. Colombo et al. (2019); Lubis et al. (2018) utilized the VAD space, adding an emotional vector to the internal representation of the text. Zhou and Wang (2018) conditioned a variational autoencoder on Emojis instead.

LLMs have also been used for emotional text generation. A variety of methods like chain-of-thought, retrieval-augmented generation, prompt tuning, etc. have all been successfully used (Li et al., 2024; Mishra et al., 2023; Rasool et al., 2025; Yang et al., 2024; Resendiz and Klinger, 2025; Zhang et al., 2024). However none of these works deal with non-emotional constraints, nor cover the use of VAD scales.

2.3 Value Alignment

There have been multiple methods for integrating values into AI such as learning normative behavior from children's stories (Nahian et al., 2020), integrating logic (Kim et al., 2021), using actor-critic models(Liu et al., 2022), integrating situated annotations in reinforcement learning from human feedback (Arzberger et al., 2024), or matching behavior to underlying ethics rather than human actions (Rigley et al., 2025). By finding and comparing explicit representations for ethical values, these methods could potentially be evaluated using our Representation Alignment evaluation technique. There have been recent efforts to measure the value alignment of existing models (Norhashim and Hahn, 2024), but only for a binary concept (moral or not moral).

3 Sentence Generation

We prompted LLMs to generate sentences using three words to denote the content of the sentence—which we will refer to as the *keywords*, in addition to the emotion we wanted the sentence to express.

We selected four representations of emotions:

- *Words*: English terms for the emotion,
- *Lexical VAD*: VAD scales expressed in English (Very High, High, Moderate, Low, Very Low),
- *Numeric VAD*: VAD scales expressed in numeric terms (-5.0 to +5.0), and
- *Emojis*[2].

The numeric values for VAD were generated by normalizing values from Guo and Choi (2021) (which were in the range of 0.00 to 1.00) to a -5.0 to +5.0 scale, then rounding to the nearest 0.5. We also recognize that there will be loss from converting Guo and Choi's scale to a *discrete* numeric representation. However, we found it to lead to easier comprehension. Before the rounding step, the Numeric VAD values were converted to Lexical VAD. Lexical VAD was mapped to a 5-point scale for simplicity. Due to the rounding step, in some cases there may be an overlap (such as Surprise's +2.5 Arousal and Fear's +2.5 Arousal corresponding to 'Very High' and 'High' respectively). However, this does not pose an issue as Lexical VAD and Numeric VAD are independent representations even though they both capture VAD. We hypothesize different strengths from each representation. Lexical VAD may carry extra semantic information from being linguistically derived but Numeric VAD denotes more meaningful separation between points by placing them on an interval scale.

When the LLMs were prompted to generate sentences using the Words representation, we explicitly forbid the models from treating the Emotion as a keyword[3], as LLMs have a tendency to "tell" instead of "show" if not provided enough guidance. This was also not to bias the participants in the Words condition into selecting sentences generated using the Words representation simply because it was using the same word.

We limited each input to three content keywords to give LLMs sufficient context to generate. The keywords were sets of arbitrarily-chosen, common words like [`Place`, `Great`, `Korean`], [`Finals`, `Semester`, `Math`]. We generated sentences using GPT-4-Turbo-2024-04-09 (OpenAI, 2024) and LLaMA-3.3-70B (Grattafiori et al., 2024), referred to as GPT-4 and LLaMA-3 respectively in this paper. Both models were used with default parameters. GPT-4-Turbo cost less than $5 in total to generate the sentences. All generations were con-

[2]Emojis were embedded as unicode so that participants would see the set that they were used to seeing on their device, although we recognize this introduces some disparity across participants.

[3]"Do not use the word '{emotion}' in the response and express the sentiment in a different way." was added to the prompt. The full prompts can be found in Appendix B.

Category	Words	Emoji	Valence	Arousal	Dominance

Table 1: All 18 emotions used in the study and how they were represented in words, emojis, and Valence-Arousal-Dominance (VAD) scores with values represented lexically and numerically (in parentheses). The category was used to determine which emotions to use but were not integrated into the prompt nor shown to participants.

sistent with the models' indended use.

Due to compute limitations, we used a LLaMA-3 model that was quantized (Huang et al., 2024) using 8-bit weights[4]. Computing resources for LLaMA-3's generation can be found in Appendix A. The prompt, used for both models, can be found in Appendix B. In the system prompt, we instructed the model to minimize inserting extraneous information while still generating sentences that clearly express an emotion. Although prior work has shown that LLMs are particularly good at generating sentences from keywords (Chen and Wan, 2024), we did verify this as well (results in Appendix E).

For each LLM, we generated a total of 360 sentences, 90 per representation, expressing 18 different emotions. We determined this list of emotions based off Demszky et al. (2020), ultimately selecting for emotions that were distinct but could also be easily grouped. Two sentences were selected randomly for each of the 18 emotions for use in the evaluation, resulting in 36 Representation Alignment questions per condition (i.e., the emotion representation that the participant saw). Table 1 shows all the emotions used, their grouping, and their VAD values.

Overall, 72 sentences for each representation were selected and shown to participants; half for the Representation Alignment questions (Section 4.1), and the other half for Accuracy and Realism questions (Section 4.2). We did this in order to ensure each question had answers from multiple participants.

For generating a sentence with emotions represented as Words or Emojis, we used plain few-shot prompting (Brown et al., 2020), selecting exemplars from across the range of positive and negative emotions. For prompting using either form of VAD, we used step-back chain-of-thought prompting (Zheng et al., 2024). First, we prompted the model to give an explanation of VAD, then convert it to scale from -5 to +5 if using Numeric VAD, and then gave it few-shot examples. For all representations, we converted the emotions in the exemplars to the representation we intend to generate in.

4 Evaluation

The generated sentences were evaluated via crowdsourcing. We recruited 100 participants on Prolific for each model for a total of 200 participants, pay-

[4] https://huggingface.co/meta-llama/Llama-3.3-70B-Instruct#use-with-bitsandbytes

ing them $14/hr for 15 minutes ($3.50 each) — for a total of $700. To participate, people were required to agree to the consent form approved by the university's IRB. Participants needed to be 18+ years of age, living in the United States, and fluent English speakers. Prolific automatically assigns random identifiers to participants and no identifiable information was collected from participants. Each participant was randomly assigned one of the four conditions (the four emotion representations) which was the emotion representation that they saw for all questions.

Since we assumed participants would not be used to VAD, people in either VAD condition were shown a short explanation of VAD and given questions with feedback to train them on how to use it (Appendix C). Participants were shown two sets of questions. The first set (Representation Alignment) was used to determine if the representation that the human saw aligned with the LLM's representation. The second set (Accuracy & Realism) asked the participant to consider how accurately a generated sentence captured a given emotion and how realistic the generated sentence appeared. Both the emotion and sentence from this second set of questions used the same representation. That is, the LLM was given the same representation to generate the sentence as what the user was seeing for the emotion. We found this setup compelling since the representation that produces the best output from the LLM does not have to perfectly align with the user's internal representation but rather how the user imagines that representation to be expressed. For example, if people believe that Lexical-VAD–prompted LLM output produces sentences that match their interpretation for how a certain Words representation would be expressed, then that is just as valuable information.

A final open-ended question was asked at the end of the survey as an attention check, asking participants to name a piece of media that they have consumed recently and to describe the emotion they felt watching/reading it. Participants were blocked from copying and pasting text. Any responses that were written in poor English or did not answer the question were removed, and we replaced their data with new responses. We ended up with 26, 25, 28 and 29 participants for Words, Lexical VAD, Numeric VAD and Emojis respectively for GPT-4, and 25 participants for each of the four conditions for LLaMA-3. Due to this difference, we normalized the counts during evaluation and discussion. The data was analyzed in Python using the packages pandas & scipy and visualized with matplotlib[5].

4.1 Human Evaluation 1: Representation Alignment

To evaluate Representation Alignment, we provided an emotion in the representation the person was assigned and showed them sentences generated across all four conditions. The participant was then told to select the sentence that is the best fit for the emotion, as illustrated in Figure 1. Here, the goal was to determine which representation was most effective at conveying the emotion to the user *as the user understood it* across multiple emotions.

For example, someone in the Words condition would see an emotion ("Anxious") followed by four sentences. Each of these sentences were generated using a different representation for the emotion "Anxious". The sentence order was shuffled before being presented to the participant. In the example below, 1 was generated using an English Word for the emotion, 2 with Lexical VAD, 3 with Numeric VAD, and 4 with an Emoji.

Anxious

1. I feel so nervous about my math finals this semester.
2. I can't believe the semester is almost over, and we've got that big math final coming up soon; it's really time to buckle down and study hard!
3. I'm really stressed about the math finals this semester.
4. I'm so happy I passed my math finals this semester!

Participants were required to answer all questions and were shown 10 of these questions randomly selected from the 36 questions within the participant's condition. The questions were evenly distributed using Qualtrics's "evenly display questions" feature. These questions were each answered by 5-9 people (median of 7). Some questions were seen more or less often due to participants not qualifying and the counts not being reset in between participants. Full participant instructions can be found in Appendix D.

For a user-presented representation rep_A and an LLM-presented representation rep_B, we defined rep_A as having a strong REPRESENTATION

[5]Code for visualizations was generated with help from a mixture of ChatGPT, Claude, and Gemini. All other code was written by hand.

ALIGNMENT with rep_B if

- participants were most likely to pick rep_B (*selection rate*), and
- the average Shannon Entropy for selections rep_A was low, relative to other representations,

where rep_A and rep_B may be the same or different representations. For example, if participants who were shown Lexical VAD emotions were more likely to select sentences generated using Emojis (despite not knowing how the sentence was generated), *and* the entropy for Lexical VAD was relatively low, then Lexical VAD would have good Representation Alignment with Emojis. A random selection rate would be 25.0%, so any value above this would be notable. We will refer to the condition when $rep_A = rep_B$ as SELF-ALIGNMENT.

We use Shannon Entropy rather than inter-rater agreement because the latter assumes all options are equally likely to be chosen. However, in reality this is unlikely to be the case, and for some emotions or representations, one output may be consistently better than others.

4.1.1 Human Evaluation 1: Results and Discussion

Figure 2 shows the results of the selection rates across representation types and models, while Table 2 shows the mean entropy values. Overall, Words had the best Representation Alignment with Words, regardless of the model. This was unsurprising, as humans express emotions in Words most often and LLMs are trained on natural language data. Words had a 61.9% selection rate using GPT-4 and 57.5% using LLaMA-3, as well as Shannon Entropies of 0.32 and 0.42 respectively.

More surprisingly, Lexical VAD also has a high self-selection rate of 52.0% for GPT-4, with the second lowest entropy value at 0.61. While the agreement is worse than that of Words, the high selection rate is noteworthy. This occurs even though the participants and the LLMs are given different instructions and prompts. (Appendix B and C) This indicates both humans and LLMs may be drawing on similar ideas or memorized information when considering the emotion representation. On the other hand, LLaMA-3's output never matched people's expectations of Lexical VAD, regardless of what the model was prompted with, resulting in a higher entropy value.

Participant's Representation	**Entropy↓**	
	GPT-4	**LLaMA-3**
Words	**.32**	**.42**
Lexical VAD	<u>.61</u>	.72
Numeric VAD	.70	.63
Emojis	.67	<u>.52</u>

Table 2: Shannon Entropy values showing the amount of variability in responses for each representation that was presented to participants. Bolded values show the most agreement, underlined are second most.

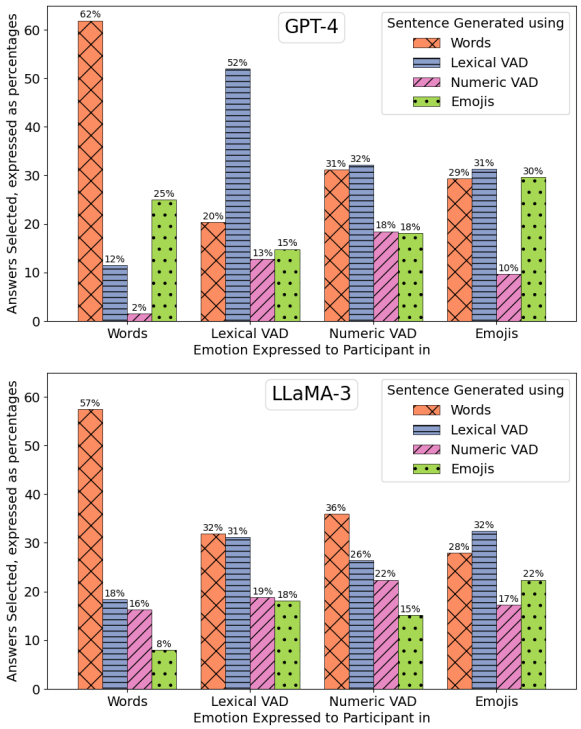

Figure 2: Percentage of times a sentence was selected. Each category on the x-axis corresponds to the condition the participant was in—what representation they saw. The colors delineate what representation was used for sentence generation. Results for GPT-4–generated sentences are on the top, LLaMA-3 on the bottom.

Numeric VAD, by contrast, had poor alignment, with the worst entropy values for both LLMs. We interpret this to mean that people could not consistently agree on an expected output for Numeric VAD emotions. One possibility is that participants struggled to conceptualize the numbers but were able to understand them more easily when using discrete words (leading to Lexical VAD doing better). This is prudential given some recent works offer users control over generative models using VAD (Tang et al., 2023; He et al., 2025).

Emojis, which have been shown to be subjective and ambiguous (Miller et al., 2017), did not

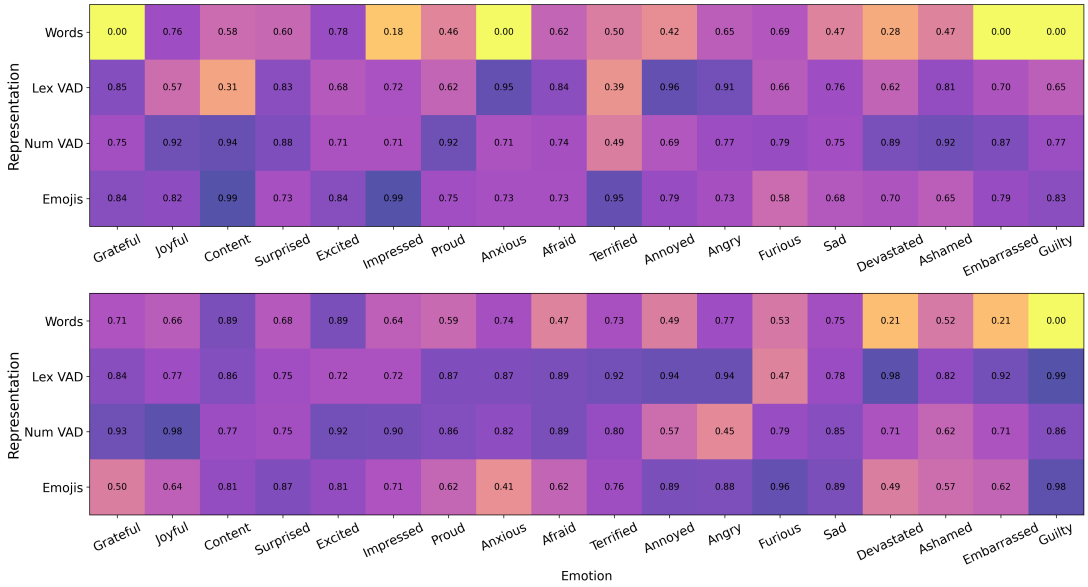

Figure 3: Heat maps for Shannon entropy of each emotion across representations. Lower (brighter) values are better, denoting more "agreement" between participants and the LLM. Top: GPT-4, bottom: LLaMA-3.

show particularly good alignment. However, Emojis did have some Representation Alignment with Lexical VAD for LLaMA-3 — 32.40% selection rate and .52 entropy. The trend for GPT-4 was less pronounced, with a selection rate of 31.38% and .67 entropy. Because there was a mismatch in representations it hints at that people's mental model of emojis may be similar to how LLaMA-3 works with Lexical VAD.

One potential explanation is that Lexical VAD for LLMs and Emojis for humans capture the same amount of information for imprecise emotions. In other words, LLMs can easily decompose Lexical VAD into emotions into components while Emojis are discrete symbols to text-based models like LLaMA-3. Meanwhile, humans can assign meaning to individual facial features in Emojis but may struggle to do the same with VAD scales. Further research will need to be done to verify this claim.

Ultimately, the highest Representation Alignment was Self-Alignment with Words and, for GPT-4, Lexical VAD Self-Alignment was a close second.

We also broke down Shannon Entropy values by emotion (see Figure 3). For individual emotions per representation, we found the results are fairly similar, with most values between 0.70 to 0.95 meaning poor agreement, with some outliers. The small gap in the models' agreement with participants for certain emotions point to potential differences in training. It is unclear why, for example, GPT-4 is much better at using Words to generate "grateful" sentences than LLaMA-3. To have emotions that people agree or disagree with for both models could mean a variety of things. For instance, is it that people agree more about whether a sentence is expressing "guilty", is there more "guilty" data both LLMs are trained, or does something inherent to the transformer architecture (such as attention) lend itself to picking up on "guilty" text better? A study on model architecture, training data, and conceptual alignment should be run to see if this trend continues.

4.2 Human Evaluation 2: Accuracy & Realism

The second set of questions asked the participant to consider how accurate or realistic a pair of an emotion and a sentence generated with that emotion is. The participants were asked to rate the three questions (shown in the example below) on a 5-point Likert slider, using the labels Not at all (1), Slightly (2), Moderately (3), Very (4), Extremely (5). For example:

> For the following questions, consider the emotion represented by these VAD values: **Very High Valence, Moderate Arousal, Low Dominance**
>
> And this sentence: **"This place has great Korean food; it always makes me so happy!"**

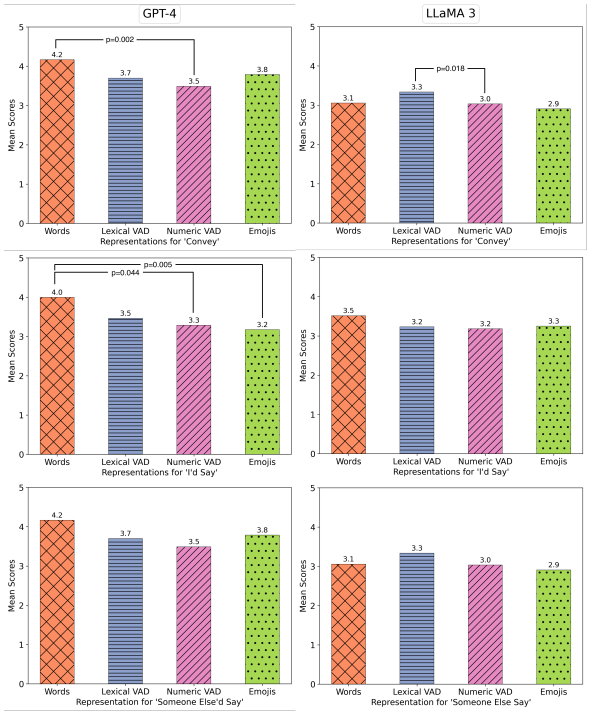

Figure 4: Left: GPT-4, Right: LLaMA-3. In order from Left to Right and Top to Bottom:
a, b. Histograms of the Mean Scores for 'Convey'
c, d. Histograms of the Mean Scores for 'You'd say'
e, f. Histograms of the Mean Scores for 'Someone Else'd Say'

How much does the sentence...
- Convey the emotion above?
- Sound like something that you would say?
- Sound like something that someone else would say?

We will refer to these three questions as "Convey", "You'd say", and "Someone Else'd say", respectively. The "Convey" question allows us to assess how well the generated sentence accurately expresses the emotion. The "You'd say" and "Someone Else'd say" questions are to measure how realistic and human-like the sentence is. The slider's default value for each question was Moderately (3). Participants were required to answer all questions.

Each user was given 6 questions of this type, randomly selected from the 36 total accuracy & realism questions (emotion-sentence pairings). Each question was answered by 3.7 people on average (1-8 participants each, median of 4), with 3 questions not answered and therefore not considered in the analysis.

4.2.1 Human Evaluation 2: Results and Discussion

The average Likert scores for "Convey", "You'd say", and "Someone Else'd say" across conditions (the emotion representations) and for both models can be found in Figure 4. We ran an ANOVA statistical significance test on the Likert ratings for the three questions for both GPT-4 and LLaMA-3.

The ANOVA showed that, for GPT-4, the emotion representation had a statistically significant effect on the rating for "Convey" and "I'd say", both $p < .01$. For LLaMA-3, ANOVA showed the emotion representation had a statistically significant effect on the rating for "Convey" and "Someone Else'd say", both $p < .05$. A pairwise t-test was run on the statistically significant results, which showed that Words was significantly better at "Convey" than Numeric VAD for GPT-4 ($p = 0.002$) and Lexical VAD was also significantly better at "Convey" than Numeric VAD for LLaMA-3 ($p = 0.018$) – further showing that Numeric VAD scores under-perform.

For "You'd say" questions, Words is significantly better than both Emojis ($p = 0.005$) and Numeric VAD ($p = 0.044$) when using GPT-4 to generate plausible-sounding sentences. This shows that Words would most likely be the preferred representation to capture an emotion appropriately. Additionally, LLaMA-3's generated sentences are overall perceived as slightly worse for conveying the emotion and sounding realistic. However, this is in line with the relative performances of each model.

We show mean scores for the "Convey" question broken down by emotion in Figure 5. The scores are relatively high across the board, with some outliers. For instance, GPT-4 using Words seemingly struggles most with sounding realistically "excited" or "proud", while using Numeric VAD makes GPT-4 struggle with emotions like "anxious" and "angry". LLaMA-3, on the other hand, sounds unrealistic when using "sad" or "excited" as Words.

Despite guardrails that make LLMs more amicable (Sharma et al., 2023; Zhou et al., 2024), we show that models can struggle to generate certain positive emotions under complex conditions, and that different emotions are captured best by different representations. Out of the representations we looked at, Words and Lexical VAD were the best for producing realistic sentences.

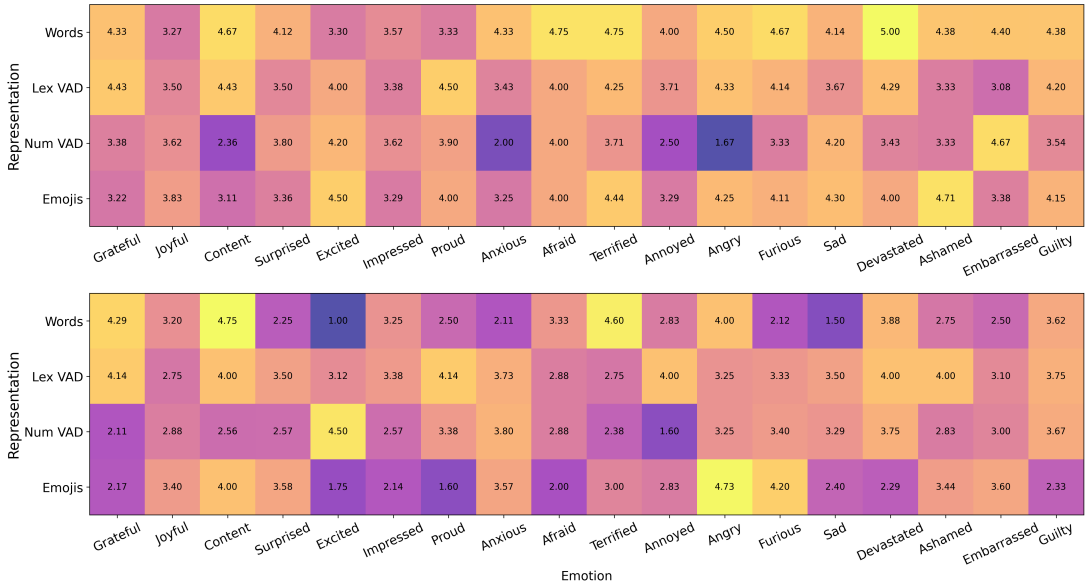

Figure 5: Mean "Convey" Scores for each emotion per representation. Higher (brighter) values are better. The top map shows results for GPT-4, while the bottom map is LLaMA-3.

5 Conclusion

We believe that research studying representations should measure the way they are perceived and represented to both humans and LLMs. This work introduced the evaluation paradigm of REPRESENTATION ALIGNMENT for determining if humans perceive representations in the same way that LLMs use them. Effectively evaluating how well human expectations for conceptual knowledge align with LLM output is a largely understudied problem, especially with downstream contexts in mind such as AAC. We adopted the problem of emotional sentence generation based on keywords and used Representation Alignment to study how various emotional representations align with participants' expectations. We hope that this experimental setup will be used to study other types of conceptual alignment as well, such as value alignment.

Using this paradigm, we showed that emotion-based Words provided the strongest alignment between an LLMs' understanding of an emotion & how it generates with it and humans' expectations of its use. Lexical VAD is a close second for both representation alignment and for accuracy and realism. In AAC applications, this can enable users to select their intended emotion or tone more precisely.

6 Limitations

Our study uses GPT-4-Turbo-2024-04-09 and LLaMA-3.3-70B with 8-bit weights due to compute constraints. It is possible that a more recent or bigger models such as GPT-4o or LLaMA-3-3.1-405B would give different results. Due to funding limitations, this study did not look at every state-of-the-art model available. However, we hope that this can serve as a proof-of-concept for other researchers who are interested in using our methodology.

This study was limited to English only. Other languages may give different outcomes. The participants were required to be native English speakers, which allowed us to control the quality of responses. However, it makes the results less generalizable in a global context. Our participants are also sampled from the general public and not necessarily AAC users. Assistive technologies need to be specialized to fit a person's needs, and therefore it is not enough to find overall Representation Alignment but also Representation Alignment for specific users. We believe that Representation Alignment will contribute to ease of use, but individual preferences and needs also matter.

Additionally, while we offer some training for interpreting VAD (whether lexical or numeric), it is still difficult to grasp without any prior knowledge and the heavy cognitive load needed to "calculate" these emotions may have affected the results.

Furthermore, while the emojis were selected based on what we believe was the best fit for each English word, there could be cultural discrepancies over what each emoji might mean. For example,

different online communities might use 😢 to mean embarrassed, worried, or relieved, depending on the context they see it used in and how their system displays it. More in-depth analyses of emoji use should gather general—like (Warriner et al., 2013) have done with Numeric VAD—and/or community-specific use to determine the exact meaning.

7 Ethical Considerations

LLMs can be used in many helpful cases, but they can also be used to impersonate individuals, or generate toxic or deceptive texts. We acknowledge that improving controlled text generation capabilities may also make it easier to generate the above, and that strong guardrails are necessary. In this work, we study how LLMs align with human emotions in terms of representations. This does not indicate that LLMs themselves are capable of possessing emotions, only that they are capable of recognizing and generating emotion when encoded in some textual form to the extent their model design and training data allows.

Having LLMs generate text for people can lead to questions of authorship. These issues are exacerbated when LLMs are introduce into AAC applications, potentially leading people to question the agency of AAC users and the validity of what they say. LLMs need to be carefully implemented into AAC applications with clear guidelines on how the AAC user should interface with the AI and provide potential scenarios where LLM use may not be useful or helpful. Additionally, many LLMs are too big to put onto tablets or phones and therefore require a network connection, which adds security risk.

Acknowledgments

We would like to thank all of our participants for their time and effort. We would also like to thank Foad Hamidi and others who have given us feedback throughout the study, and to the UMBC High Performance Computing Facility for helping us run our LLaMA experiments. This research is partially supported by a 2024 UMBC COEIT interdisciplinary proposal (CIP) Award.

A Computing Information

LLaMA-3 was run on UMBC's high performance computing cluster called Ada, which at the time, had:

- 4 8x RTX 2080 Ti GPUs with 384 GB CPU memory & 11GB GPU memory each,
- 7 8x RTX 6000 GPUs with 384 GB CPU memory & 24GB GPU memory each, and
- 2 8x RTX 8000 GPUs with 768 GB CPU memory & 48GB GPU memory each.

Each node had 48 threads and two 24-core Intel Cascade Lake CPUs. The node that was assigned for a particular job was random.

B Prompts

System Prompt:

> "You are engaging in a conversation with a human. Respond to the following line of dialogue based on the given emotion and the following keywords. Just add connective words and do not add any new information to the output sentence. Do not use the word 'emotion' in the response and express the sentiment in a different way.

The last line is only for when prompting with Words.

B.1 Words

> Here are some examples:
>
> Emotion: Proud
> Keywords: 'running', 'marathon', 'first'
> Dialogue: Running my first marathon felt like such a huge accomplishment!
>
> Emotion: Sad
> Keywords: 'banana', 'plant', 'brown'
> Dialogue: It really sucks that my banana plant's leaf is turning brown
>
> Now, respond to the following. Remember, do not use the word {emo_} in the dialogue:
>
> Emotion: {emo_}
> Keywords: {kwds_}
> Dialogue:

B.2 Lexical VAD

> Valence refers to the intrinsic attractiveness or averseness of an event, object, or situation. In the context of emotions in text, valence represents the positivity or negativity of the emotion expressed. For example, words like "happy," "joyful," or "excited" have positive valence, whereas words like "sad," "angry," or "frustrated" have negative valence.
>
> It essentially measures the degree of pleasantness or unpleasantness of the emotion.
>
> Arousal indicates the level of alertness, excitement, or energy associated with an emotion. It ranges from high arousal (e.g., excitement, anger) to low arousal (e.g., calm, boredom). In text, high-arousal words might include "thrilled," "furious," or "ecstatic," while low-arousal words could be "relaxed," "content," or "lethargic."
>
> This dimension measures how stimulating or soothing the emotional state is.
>
> Dominance reflects the degree of control, influence, or power that one feels in a particular emotional state. High dominance implies feelings of control and empowerment, while low dominance suggests feelings of submissiveness or lack of control. In text, emotions like "confident," "powerful," or "authoritative" would have high dominance, whereas "helpless," "weak," or "submissive" would have low dominance.
>
> It gauges the extent to which an individual feels in control or overpowered by the emotion.
>
> Now, assume you are a normal human. Say a line of natural dialogue based on the given keywords. Just add connective words and do not add any new information to the output sentence.
>
> For example:

Emotion: Very High Valence, High Arousal, Very High Dominance
Keywords: 'running', 'marathon', 'first'
Dialogue: Running my first marathon felt like such a huge accomplishment!

Emotion: Very Low Valence, Low Arousal, Low Dominance
Keywords: 'banana', 'plant', 'brown'
Dialogue: It really sucks that my banana plant is turning brown

Emotion: Very High Valence, Very High Arousal, High Dominance
Keywords: "visit", "parents", "month"
Dialogue: I'm finally going to visit my parents next month!

Now, respond to the following:
Emotion: {v_}, {a_}, and {d_}.
Keywords: {kwds_}
Dialogue:

B.3 Numeric VAD

Valence refers to the intrinsic attractiveness or averseness of an event, object, or situation. In the context of emotions in text, valence represents the positivity or negativity of the emotion expressed. For example, words like "happy," "joyful," or "excited" have positive valence, whereas words like "sad," "angry," or "frustrated" have negative valence.

It essentially measures the degree of pleasantness or unpleasantness of the emotion.
Arousal indicates the level of alertness, excitement, or energy associated with an emotion. It ranges from high arousal (e.g., excitement, anger) to low arousal (e.g., calm, boredom). In text, high-arousal words might include "thrilled," "furious," or "ecstatic," while low-arousal words could be "relaxed," "content," or "lethargic."

This dimension measures how stimulating or soothing the emotional state is.

Dominance reflects the degree of control, influence, or power that one feels in a particular emotional state. High dominance implies feelings of control and empowerment, while low dominance suggests feelings of submissiveness or lack of control. In text, emotions like "confident," "powerful," or "authoritative" would have high dominance, whereas "helpless," "weak," or "submissive" would have low dominance.

It gauges the extent to which an individual feels in control or overpowered by the emotion.

Here's how each dimension can be defined on a scale from -5.0 to 5.0:

Valence:
-5.0: Extremely negative (e.g., intense sadness, extreme anger)
-2.5: Moderately negative (e.g., mild annoyance, slight disappointment)
0.0: Neutral (e.g., indifferent, no strong emotional reaction)
2.5: Moderately positive (e.g., mild pleasure, slight happiness)
5.0: Extremely positive (e.g., intense joy, deep love)

Arousal:
-5.0: Extremely low arousal (e.g., deep sleep, total relaxation)
-2.5: Moderately low arousal (e.g., relaxed, slightly tired)
0.0: Neutral arousal (e.g., alert but not excited, calm)
2.5: Moderately high arousal (e.g., interested, mildly excited)
5.0: Extremely high arousal (e.g., highly excited, very agitated)

Dominance: -5.0: Extremely low dominance (e.g., feeling completely powerless, totally submissive)
-2.5: Moderately low dominance (e.g., somewhat submissive, slightly dominated)
0.0: Neutral dominance (e.g., feeling neither in control nor dominated)

2.5: Moderately high dominance (e.g., feeling somewhat in control, slightly assertive)
5.0: Extremely high dominance (e.g., feeling very powerful, completely in control)

These scales provide a way to quantify and compare the emotional dimensions in a structured manner.

Now, assume you are a normal human. Say a line of natural dialogue based on the given keywords. Just add connective words and do not add any new information to the output sentence.

For example:

Emotion: Valence: 4.0, Arousal: 1.0, Dominance: 2.5
Keywords: 'running', 'marathon', 'first'
Dialogue: Running my first marathon felt like such a huge accomplishment!

Emotion: Valence: -4.0, Arousal: -2.5, Dominance: -4.0
Keywords: 'banana', 'plant', 'brown'
Dialogue: It really sucks that my banana plant is turning brown

Emotion: Valence: 2.5, Arousal: 4.0, Dominance: 1.0
Keywords: "visit", "parents", "month"
Dialogue: I'm finally going to visit my parents next month!

Now, respond to the following:
Emotion: {v_}, {a_}, and {d_}.
Keywords: {kwds_}
Dialogue:

B.4 Emojis

You are engaging in a conversation with a human. Respond to the following line of dialogue based on the given emotion and the following keywords.

Just add connective words and do not add any new information to the output sentence. The response should be exactly one line with nothing else other than the responding dialogue.

For example:

Emotion: 🤩
Keywords: 'running', 'marathon', 'first'
Dialogue: Running my first marathon felt like such a huge accomplishment!

Emotion: 😕
Keywords: 'banana', 'plant', 'brown'
Dialogue: It really sucks that my banana plant is turning brown

Emotion: 😃
Keywords: "visit", "parents", "month"
Dialogue: I'm finally going to visit my parents next month!

Now, respond to the following:
Emotion: {emo_}
Keywords: {kwds_}
Dialogue:

C VAD Training

In the following sections, we give the training instructions given to the participants verbatim. Figures 6 and 7 were shown to the participants at the time of training, but not when they were answering the survey questions.

C.1 Lexical VAD

For this study we will be using a popular model used for quantifying emotion called the Valence-Arousal-Dominance (VAD) model.

1. Valence — How pleasant you feel. A low valence would mean you are feeling negative/unpleasant whereas high valence would mean you are feeling positive or pleasant.
2. Arousal — How engaged or alert you feel. Low arousal would mean that you are more on the calmer or sleepier extreme, while high arousal would mean you are more active and energetic.
3. Dominance — How much control you have over what you feel. Low dominance implies no control and High dominance implies feeling very much in control of your emotion.

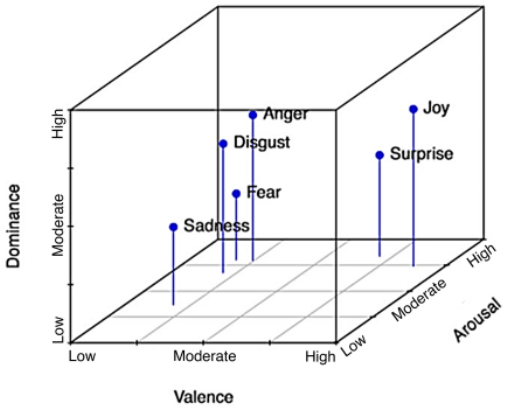

Figure 6: Lexical VAD visualization

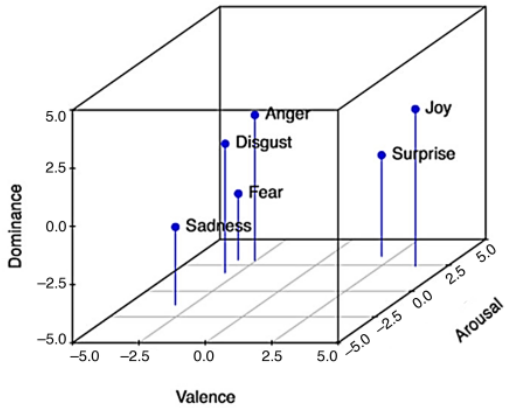

Figure 7: Numeric VAD Visualization

Please take a moment to study the figure [6], as it might be helpful for visualizing the above. It shows some common emotions we usually feel and how they map to the VAD model.

For example, consider the difference between Angry and Furious. Both of these would have low valence and moderate-to-high dominance. Being Angry has high arousal as it takes a lot of energy to feel so. Being Furious would take even more energy, as you might feel like you're about to burst. So, Angry would have High Arousal while Furious would have Very High Arousal.

Similarly, consider the difference between feeling Grateful and Joyous. Both of them are positive emotions. Grateful should have High Valence, as you are feeling pleased but not over the top, while Joyous will have Very High valence as you are really happy and elated.

Before you begin, you will go through a series of questions designed to help you understand the VAD model of emotion, followed by a practice question.

[We include a sample of the questions here:]

> What is the emotion that corresponds to VAD values High Valence, Very High Arousal and Moderate Dominance?
>
> Surprise
> Joy
> Anger
>
> Correct Answer: Surprise.
>
> High Valence indicates this is more of a positive emotion. Very High Arousal means there is a lot of energy behind this, while Moderate Dominance shows that you are not entirely in control. This could be either Joy or Surprise, but having higher arousal and lower dominance suggests Surprise is the answer.

C.2 Numeric VAD

For this study we will be using a popular model used for quantifying emotion called the Valence-Arousal-Dominance (VAD) model. In this model, the X, Y, and Z axes span only from -5 to 5 and can be defined as follows

1. Valence — How pleasant you feel on a range from -5 to 5. Here, -5 would mean you are feeling very negative/unpleasant whereas a 5 would mean you are feeling very positive or pleasant.

2. Arousal — How engaged or alert you feel on a range from -5 to 5. -5 would mean that you are more on the calmer or sleepier extreme while 5 would mean you are more active and energetic.

3. Dominance — How much control you have over what you feel on a range from -5 to 5. In this case, -5 implies no control and 5 implies feeling very much in control of your emotion.

Please view the figure [7] for a visual representation of these ranges.

Before you begin, you will go through a series of questions designed to help you understand the VAD model of emotion. In the first set of questions you will be provided the numerical values and need to choose the discrete emotion those VAD values correspond to. Then you will be given a practice question similar to the rest of the questions in the survey.

[We include a sample of the questions here:]

What is the discrete emotion that corresponds to VAD values -2.5 (Valence), 2.5 (Arousal), and 2.0 (Dominance)?

Sadness
Anger
Fear

Anger is the correct answer!

-2.5 Valence indicates this is a negative or unpleasant emotion. 2.5 arousal means it takes a lot of energy to feel this way. Therefore, it cannot be Sadness. 2.0 Dominance means you are somewhat in control of how you feel, so it is unlikely to be Fear either. So, Anger is the most appropriate option.

D Survey Questions

[Any text appearing within brackets like this in the following section is a note and did not appear in the survey.]

Informed Consent Information

Informed consent: You must be 18 years or older to participate in this study.

The purpose of this study is to see if large language models like ChatGPT describe emotions in the same way that people do. You are being asked to volunteer because you are a native English speaker.

You will be shown a series of 4 different sentences and need to determine if each sentence conveys a certain emotion. Note that the emotion may be displayed in an abstract way. You will be taught how to read this abstraction before answering the questions.

The survey may take about 15 minutes to complete.

You are welcome to withdraw or discontinue participation at anytime, but due to the volume of participants expected from crowdsourcing, we will not be paying participants for incomplete surveys. If you withdraw from the study or do not complete the survey, your data will be deleted.

Please take your time and do the best you can. There are no right or wrong answers, but we reserve the right to not pay if we determine that you are not following directions or taking the task seriously.

All data obtained will be anonymous. There is no way for us to find out who you are, and your data will not be shared with any other parties under any circumstance.

Any information learned and collected from this study in which you might be identified will remain confidential. The investigator will attempt to keep your personal information confidential. To help protect your confidentiality, your data will only be linked to a randomly-assigned ID. Any information required to pay you (i.e., username) will be kept in a spreadsheet on a secure server separate from the other data you provide.

Only the investigator and members of the research team will have access to these records. If information learned from this study is published, you will not be identified by name and all results will be reported in aggregate. By signing this form, however, you allow the research study investigator to make your records available to the University of Maryland, Baltimore County's Institutional Review Board (IRB) and regulatory agencies as required to do so by law.

Introduction to the questions

In the following survey, you will be asked questions based on understanding and recognizing emotions in text. Following the practice questions, there will be 16 questions in total.

The emotions will be described as a word.

For example: Angry, Happy, Annoyed

In the following survey, you will be asked questions based on understanding and recognizing emotions in text. Following the practice questions, there will be 16 survey questions in total.

The emotions will be described in terms of valence, arousal and dominance. For example: High Valence, High Arousal, Low Dominance.

In the next page, we will explain what these terms are and how they relate to emotions.

In the following survey, you will be asked questions based on understanding and recognizing emotions in text. Following the practice questions, there will be 16 survey questions in total.

The emotions will be described in terms of valence, arousal and dominance. For example: Valence: -2.0, Arousal: 3.0, Dominance: 4.0.

In the next page, we will explain what these terms are and how they relate to emotions.

In the following survey, you will be asked questions based on understanding and recognizing emotions in text. Following the practice questions, there will be 16 survey questions in total.

The emotions will be described using emojis.

For example: 😄, 😗, 🥵

Representational Alignment Instructions (same for all representations)

For each question below, you will be shown an emotion and a set of sentences. Given the specified emotion, pick the sentence that is the best fit.

Note: In some cases, one or more of the choices might be identical. If you feel that sentence is the best fit, feel free to pick any one. Also, the sentences are not meant to be ironic or sarcastic.

Accuracy and Realism Instructions (same for all representations)

For the next set of questions, you will be given a sentence and an emotion described in a word.

We will ask you to rate the sentence based on how well it conveys the given emotion, and how realistic it sounds (i.e. it sounds like something a person would say). Please rate how well the sentence reflects each statement.

[Bonus Question — we used this as a filter to gauge how much attention users gave to the survey. In a handful of cases, we removed answers to this question that seemed to be written in extremely poor English or written by a language model.]

Think of a movie, television show, or book that you watched or read recently that made you feel a strong emotion.

Please share the name of the movie, show, or book. Then tell us what that emotion was in plain English, and why did you feel that way?
(Your response should be at least 30 characters long.)

E Additional Analysis: Adherence to Keywords

Model	One	Two	Three	Acc
GPT-4, 1x	1.00	1.00	.936	.978
LLaMA-3, 1x	.908	.897	.781	.862
LLaMA-3, 3x	.969	.969	.850	.930
LLaMA-3, 10x	.981	.981	.853	.938

Table 3: Percentage of generated sentences that contain the respective number of keywords. *x indicates the # of times the model was sampled. Accuracy is percentage of the three keywords that are correct, averaged across all sentences.

Since we were constraining the model to generate using content-based keywords verbatim, we lemmatized each inputted keyword and compared them against the words in the generated sentence. Shown in Table 3, all sentences generated by GPT-4 had at least two keywords present, and 93.6% had all three. By contrast, 9.17% of LLaMA-3's generated sentences had no keywords present at all. Re-sampling improved results, reducing this percentage to just 1.94%. Similar to Chen and Wan

(2024), this overall trend shows that conditioning on emotions in addition to content keywords does not significantly impair the LLM's ability to copy the keywords when generating.

Towards Multimodal Question Answering in Educational Domain

Himanshu Wadhwa[1], **T Karthikeyan**[1], **Mausam**[1], **Manish Gupta**[2]

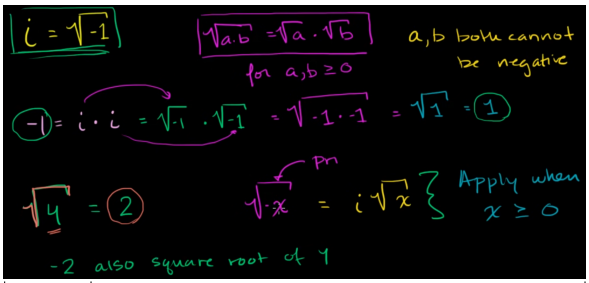
hwadhwa.iitd@gmail.com, aiz238140@iitd.ac.in, mausam@cse.iitd.ac.in, gmanish@microsoft.com



Abstract

The proliferation of educational videos on the Internet has changed the educational landscape by enabling students to learn complex concepts at their own pace. Our work outlines the vision of an automated tutor – a multimodal question answering (QA) system to answer questions from students watching a video. This can make doubt resolution faster and further improve learning experience. In this work, we take first steps towards building such a QA system. We curate and release a dataset named EDUVIDQA, with 3,158 videos and 18,474 QA-pairs. However, building and evaluating an educational QA system is challenging because (1) existing evaluation metrics do not correlate with human judgments, and (2) a student question could be answered in many different ways; training on a single gold answer could confuse the model and make it worse. We conclude with important research questions to develop this research area further.

1 Introduction

Academic videos enable better understanding, retention and overall learning for students by presenting the concepts via text, audio and visual modalities. Students can learn using recorded educational lectures at their own pace and revisit content as needed. Multiple online platforms host academic videos but lack effective doubt-solving support. Typically, learners must wait for an instructor or use discussion forums to resolve doubts, which delays doubt resolution, leading to stalled learning, reduced engagement and potentially confidence issues. This underscores the need for timely, accurate responses to student inquiries.

We believe an *automated tutor*, one that quickly responds to learner doubts, as they watch videos, has an enormous potential to improve their experience, by immediate doubt resolution, increasing concept retention, and aiding overall learning.

Question	I think Sal make a mistake on (vid @ 5:11) when he write the greater than sign! it should be Less than
Ground truth Answer	No, Sal is correct. If he had: i sqrt(x) where X<0, then X is negative. Backup thru Sal steps. If X is negative * (-1) = +X. And he would have started with sqrt(x), not sqrt(-x). He is also trying to highlight that if you had something like: sqrt(12), you would not make this into i sqrt(-12). The imaginary number is not needed if the radical contains a positive number to start with.

Figure 1: An example of a QA pair from our EDUVIDQA dataset for the video https://www.youtube.com/watch?v=rYG1D5lUE4I

Such a tutor will necessitate developing a system for multimodal question answering (QA) in education, where content from both videos and text (via speech transcripts) will be combined to answer questions. As first steps towards building such a tutor – we curate a multimodal QA dataset, identify good evaluation metrics, and train initial models based on existing large language models (LLMs) and vision LMs (VLMs).

We first curate a novel dataset (EDUVIDQA) by extensively filtering LearningQ (Chen et al., 2018). It has 7,297 videos and 201,398 QA pairs, however, many questions do not require visual information for answering. So, we create a more challenging subset of 3,158 videos and 18,474 QA pairs, where each question has an associated video timestamp. Fig. 1 shows an example.

Secondly, we explore the standard natural language generation (NLG) metrics like BLEURT and BERTScore for our task. We find that their scores (for systems with differing performance) are quite similar and correlate rather weakly with human judgments. The only exception is GPT-4 based evaluation, but that is expensive and closed source.

Proceedings of the 14th International Joint Conference on Natural Language Processing and the 4th Conference of the Asia-Pacific Chapter of the Association for Computational Linguistics, pages 1638–1649
December 20-24, 2025 ©2025 Association for Computational Linguistics

Thirdly, we benchmark existing LLMs (Vicuna (Chiang et al., 2023), LLaMA-3 (AI@Meta, 2024), GPT-4 (OpenAI et al., 2023)) and VLMs (LLaVA (Liu et al., 2023a), GPT-4V) on EDUVIDQA. Not surprisingly, we find that GPT-4V outperforms smaller models.

Overall, we make the following contributions in this paper: (1) We curate a novel dataset, EDUVIDQA with 7,297 videos and 201,398 QA pairs in education domain. (2) We propose GPT-4 based evaluation metrics using prompts specifically designed for the educational domain. (3) We benchmark 3 existing LLMs and 2 VLMs with and without transcript for this task. We make the code[1] and data[2] publicly available.

2 Related Work

Multimodal Question Answering. Visual Question Answering (VQA) aims at answering a text question in the context of an image (Antol et al., 2015). Several VQA datasets have been proposed (Antol et al., 2015; Geman et al., 2015; Singh et al., 2021). Multiple extensions have also been proposed like Text VQA (Singh et al., 2019), Visual Dialog (Das et al., 2017), CircuitVQA (Mehta et al., 2024), retrieval-based VQA (Penamakuri et al., 2023), Video QA (Zeng et al., 2017), News-KVQA (Gupta and Gupta, 2022) and knowledge-based VQA for videos (Garcia et al., 2020). Most VQA methods use multimodal fusion of language and image embeddings (Kembhavi et al., 2017), attention-based multimodal fusion (Yang et al., 2016) or neural module networks (Hu et al., 2017). Recently, VLMs like LLaVA and GPT-4V have been shown to provide state-of-the-art results across several VQA datasets using in-context learning. In this paper, we aim to benchmark such VLMs for video QA for education domain.

Multimodal Educational Datasets. Recently, some datasets have been proposed for VQA and visual question generation (VQG) in education domain. These include TutorialVQA (Colas et al., 2020), SlideVQA (Tanaka et al., 2023), ScienceQA (Lu et al., 2022) for VQA and LearningQ (Chen et al., 2018) for VQG. However, TutorialVQA just identifies a span of a video segment as an answer while SlideVQA has only factual questions which can be simply answered by reading data from a slide. ScienceQA (Lu et al., 2022) contains image-based MCQs but do not have any videos or temporal understanding and hence fail to represent real-world variety of questions. In real world, learners ask diverse questions, from simple inferential queries to complex, open-ended ones.

3 EDUVIDQA Dataset

Dataset Curation. The proposed task requires a dataset where a video is associated with a QA pair. While many platforms offer lecture videos, they typically separate discussion forums from the lecture videos, making it difficult to map questions to videos. Fortunately, the following websites host video-specific questions: Khan Academy[3], TED-Ed[4], YouTube[5] and MathTV.[6] Khan Academy specifically provides a doubt-clarification platform with concise human-written answers, and so best aligns with our task.

Fortunately, the LearningQ dataset (Chen et al., 2018) is an open dataset with data crawled from Khan Academy and TED-Ed. Although the dataset was originally released for Question Generation, we repurpose it for our multimodal QA task. We extract the questions from discussion files, named with a YouTube video-id making it possible for us to map videos and questions. The dataset includes over 338,000 domain-wise question-answer pairs along with unique video-ids and subtitles. The videos have an average duration of 7 minutes, with most questions focused on remembering, understanding and analysis.

We filter this dataset by removing irrelevant or incorrectly answered QA pairs in two phases. In the first phase, we provide the question, answer and domain information to obtain a relevance score using GPT3.5 on a scale of 1-10. We then retain QA pairs with GPT3.5-score ≥ 6. But manual inspection revealed that this subset still had $\sim$15% irrelevant samples. Hence, in the second phase, we leverage GPT-4 and retain QA pairs with score ≥ 9 resulting in $\sim$95% relevant QA pairs. Appendix A.1 lists the scoring prompt. This leads to our EDUVIDQA dataset with 7,297 videos and 201,398 QA pairs.

Further, we observe that several QA pairs could be answered without the video in context (Appendix B). Hence, we retain questions only from Math and Science domains since questions from

[1] https://github.com/dair-iitd/EduVidQA

[2] https://huggingface.co/datasets/vqamaster/EduVidQA

[3] https://www.khanacademy.org/

[4] https://ed.ted.com/

[5] https://www.youtube.com/education

[6] https://www.mathtv.com/

other domains are less likely to require visual content. To make the task truly multimodal, we sample only those QA pairs where the question has a timestamp referring to a time point in the video. This ensures that most of the samples will require the model to apply multimodal reasoning skills over the input video and the question to generate an accurate answer. This results into a more challenging subset of our EDUVIDQA dataset, with 3,158 videos and 18,474 QA pairs. On average, the questions and answers contain 37 and 49 words respectively. We share our dataset publicly.[2] We split this dataset into 13,329 for train, 4,645 for validation and 500 for test.

Dataset Analysis. We perform an analysis to assess the cognitive complexity of questions using BloomBERT (Lau, 2023) on EDUVIDQA. We find that while most questions are understanding (65.3%) and remembering (16.3%) based, many questions also need creativity (6.5%), application (5.5%), analysis (4.6%) & evaluation (1.6%) skills.

4 Evaluation Metrics

Since multimodal QA is an NLG application, we leverage the most widely used NLG metrics. These include unsupervised metrics like BLEU (Papineni et al., 2002), ROUGE (Lin, 2004), BERTScore (Zhang* et al., 2020), BARTScore (Yuan et al., 2021), and a supervised metric, BLEURT (Sellam et al., 2020). As recommended, we use the CNNDM version of BARTScore[7] and BLEURT-20 model.[8]

To check if these metrics are suitable for the proposed task, we manually annotate 70 samples and compute correlation with human judgments. Inspired by recent advancements in NLG evaluation using GPT as evaluator (Zheng et al., 2023; Liu et al., 2023b), we also obtain scores using GPT-4. Detailed definitions of these aspects are provided as prompts in Appendix A.3.

4.1 Proposed aspects of evaluation

We believe that the metrics of correctness, coherence, visual grounding and relevance are extremely crucial for the educational domain. (a) Correctness: Accuracy is crucial as it ensures students receive the right information, preventing misconceptions and supporting effective learning. (b) Coherence: Clear and logical answers help students understand and connect ideas, especially for comprehending complex topics. (c) Visual Grounding: Linking information to visual elements in materials aids in ease of understanding the answers, especially with reference to the video recently watched by the student. (d) Relevance: It ensures that the answer does not deviate from the student's question which helps in efficient learning by avoiding any confusions at the learning stage.

For doing manual annotations, we cover these four aspects of quality on a scale of 0 to 5. We give correctness the utmost importance hence have it as a maximum score of 2 (marking 0 for incorrect, 1 for partially correct and 2 for fully correct answers). The other metrics are less subjective and can have binary scoring. If the generated answer is clear to understand it gets a coherence score of 1 and 0 otherwise. If the answer has any reference to the video, it gets a visual-grounding score of 1 and 0 otherwise. If the answer is well-aligned to the question, it gets a relevance score of 1 and 0 otherwise.And hence if we sum up all these scores, we get an integer scale of 0-5 for defining our scores for manual annotation.

4.2 Results for correlation experiment

Metric	Correlation
BLEU	0.130
ROUGE-1	0.216
ROUGE-L	0.245
BERTScore	0.318
BARTScore	0.299
BLEURT	0.488
GPT-4 eval (ours)	0.782
Inter-human	0.909

Table 1: Correlation of metrics with Human Scores

We found these correlations for various evaluation metrics with human in Table 1: BLEU (0.130), ROUGE-1 (0.216), ROUGE-L (0.245), BERTScore (0.318), BARTScore (0.299), BLEURT (0.488), our GPT-4 eval (0.782), Inter-human (0.909). N-gram based metrics like ROUGE and BLEU perform word-level syntactic matches, which makes them unfit for capturing overall semantics. Neural methods (BERTScore, BARTScore and BLEURT) align better since they compare semantics of the entire text. Despite the advantages of automated metrics in terms of definitive scores and speed of computation, they demonstrate only moderate correlation with human judgments. Given that ground truth answers in the Khan Academy dataset are created by multiple humans, they often reflect a diversity of knowledge and creativity. Further, there can be multiple

[7] https://github.com/neulab/BARTScore

[8] https://github.com/google-research/bleurt

possible answers/explanations to the questions and since these metrics compute similarity of generated text with reference answers, they show poor correlations. Therefore, it is not the best strategy to directly compare the predicted answers with the single ground truth using standard NLG metrics. We design prompts having explicit scoring guidelines for each of these factors, for GPT which gives high correlations with human scores. We mention all these prompts in Appendix A.3. Overall, we find that our proposed GPT-4 eval metric provides the highest correlation score of 0.782 with human judgments.

5 Benchmarking Results on EDUVIDQA

5.1 Experiments

We experiment with 3 LLMs (Vicuna, LLaMA-3 and GPT-4) and 2 VLMs (LLaVA-v1.5 and GPT-4V). Note that Vicuna, LLaMA-3 and LLaVA-v1.5 have 7B, 7B and 8B parameters respectively. GPT-4 has 1.76T parameters; number of parameters for GPT-4V are unknown. LLaVA is based on aligning CLIP embeddings of the image with text by using a multimodal projection layer which brings the image and text embeddings into the same space.

As input to these models, we either just provide the question or provide a combination of text and video transcript. Since our dataset contains a timestamp mentioned in every question, we provide transcript of the video corresponding to $\pm$ 1.5 minutes around the timestamp as additional context from the video. This partial transcript is chosen to avoid large input lengths. For VLMs, we also pass the video frame corresponding to the timestamp in the question. Rather than passing just one frame as input, we also experimented with multiple frames (equidistant sampled from video or sampled close to the timestamp) but did not see any improvements.

Note that our dataset differs from text-only QA data since each sample also has an accompanying video. Our dataset also differs from standard visual QA since we use a transcript (which spans temporally as long as the video). Hence, EDUVIDQA is a dataset for QA on educational videos.

All GPT-4 evaluations were done using Azure AI GPT-4 deployments with temperature = 1e-9 and seed = 42. Human annotations in this study were done by two of the authors; conflicts were resolved by discussions and led to improvements in guidelines and prompts over iterations.

5.2 Results

Main Results: Table 2 shows zero shot inference results for various models on EDUVIDQA test set. We observe that providing transcript in input always improves performance across all the metrics and models. When no transcript is provided LLaVA (which uses Vicuna as the LM) and GPT-4V perform better than Vicuna and GPT-4 respectively. However, the performance improvement is marginal when both the image and transcript are provided as context. As expected the humongous GPT-4 and GPT-4V models perform the best. Of course, human baseline results are better especially when the video is provided along with the question. We also finetuned Vicuna, LLaMA-3 and LLaVA using the EDUVIDQA train data, but finetuning did not help improve the results. Perhaps, this arises because when model tries to learn the reference answer on train data, it performs worse on test data since multiple possible answer styles can be correct, making the model's learning ineffective. This is also consistent with findings in Ahn et al. (2024).

GPT-4 vs GPT-4V: We also perform a manual comparison between the outputs from GPT-4 and GPT-4V for 100 samples. For both models, we passed transcript in the input. In 71/100 cases, both models were found to be equally good. In 26 cases, GPT-4V was preferred compared to GPT-4 while

				Std. NLG Metrics			GPT-4 evaluations				
Modality	Model	Model Size	Transcript provided?	BERT-Score	BART-Score	BLEURT	Correctness (2)	Coherence (1)	Visual Grounding (1)	Relevance (1)	Total (5)

	GPT-4V	-	No	0.842	-4.412	0.442	1.644	0.920	0.646	0.840	4.050
	GPT-4V	-	Yes	0.847	-4.289	0.449	1.884	0.974	0.734	0.962	4.554
Human (without video)*		-	-	0.862	-4.188	0.436	1.250	0.970	0.540	0.740	3.500
Human (with video)*		-	-	0.870	-3.934	0.469	1.900	0.990	0.940	0.920	4.750

Table 2: Main results on EDUVIDQA test set (500 questions). *Human perf. is on 100 random samples from test.

GPT-4 was preferred over GPT-4V in only 3 cases.
Qualitative Analysis: Appendix C (Tables 4, 5, 6 and 3) shows a few case studies of predictions from various models where the models perform accurately as well as examples where models generate erroneous predictions. Without the visual information, even LLMs and VLMs like GPT-4 and GPT-4V express their inability to answer by generating responses like "... The transcript does not provide the specific details regarding what was written at timestamp 5:11 in the video ..." or "... I would need to actually watch the video, which I cannot do ..." (Table 4). Further, Table 5 shows how GPT-4 attempts (but fails) to generate a reasonable answer because it cannot align transcript words with what is mentioned in the image. Further, without transcripts (Table 6), LLaMA-3 hallucinates about the ambiguous word "expanding" to (incorrectly) mean "zooming in" rather its actual meaning in the "expanding powers of a binomial" sense. Lastly, Table 3 and Fig. 2 show an example where even our best model (GPT-4V with transcript) also does not provide a good answer. It shows how GPT-4V fails at temporal understanding and geometric reasoning, and can be easily confused by an incorrectly framed question.

6 Error Analysis

Our best model GPT-4V with transcript also makes errors. This section looks at error analysis for one of its failure cases mentioned in Table 3 as an example, suggesting future research directions.
Please see Figure 2 for a detailed view of input and output.
Error 1: Temporal Understanding problem
The model could not track in what order values in the image were filled. Although transcript would have helped but it paid more attention to what is already present in the image. The 2 equations were finally solved at a later stage (around 30 seconds ahead)
Error 2: Cognitive problem and confusion
The model does not have much sense of geometry. It could not figure out by looking at image what values are to be equated. It gets confused with adding transcript, since there are so many points where we have x's and y's.
Error 3: Factual incorrectness
It could not catch an error in the question and gets confused and even says "two adjacent sides of a rectangle, which must be equal" and equates unequal sides: "8x + 4y and 8x + 9y, should be equal" which is incorrect in the context of the video and the transcript. A self check on factual correctness could have been a possible solution.

7 Conclusions

In this paper, we take initial steps towards multimodal QA for education domain. We curate a dataset, EDUVIDQA, by carefully filtering relevant videos and QA pairs from LearningQ. We observe that standard NLG metrics are insufficient for evaluation for this task. Hence, we propose a novel, but expensive, GPT-4 based metric based on evaluating aspects like correctness, coherence, visual grounding and relevance. Further, we benchmark multiple LLMs and VLMs, and find that GPT-4V provides best performance, and smaller models worsen in performance after training. Our work highlights important open questions in this area: how to train less expensive evaluation metrics for our task, and how to use existing training data for better performance of smaller models, which can provide lower latency and compute costs.

8 Acknowledgements

The work is supported by a Microsoft Academic Partnership Grant to IIT Delhi, and a Jai Gupta Chair Fellowship. We would also like to thank the IIT-D HPC facility for its computational resources. We are grateful to Microsoft Accelerate Foundation Models Research (AFMR) program that provided us access to OpenAI models. We thank Yardi School of AI publication grant for travel funds.

Video	https://www.youtube.com/watch?v=1uWZNW5PF-s
Question	At 6:13, Sal got 2 different answers for 2 sides of a square. How did he get the 2 answers?
Ground truth Answer	To get the dimension on the left side of the large rectangle, he added the lengths of a side of each square on the left. To get the dimension on the right side of the large rectangle, he added the lengths of a side of each square on the right. Since we know opposite sides of a rectangle have equal length, we can set up an equation (13x+7y=8x+9y) to solve for the ratio of x to y (x=2/5*y).
Prediction from GPT-4V with transcript	Sal calculated the dimensions of two adjacent sides of a rectangle, which must be equal because they represent the same length. For one side, he added the lengths of segments labeled as 5x + 3y, 2x + y, and x to get a total length of 8x + 4y. For the adjacent side, he combined the lengths of segments labeled as 4x + 4y and 4x + 5y to get a total length of 8x + 9y. These two different expressions, 8x + 4y and 8x + 9y, should be equal since they represent the same physical length of the rectangle's side, leading to an equation that can be simplified to find a relationship between x and y.

Table 3: Best model (GPT-4V with transcript) also makes a mistake here.

9 Limitations

We would like to extend this benchmarking to many other models like Gemini (Team et al., 2023) and GPT-4o. It will also be nice to distill such large models to small scale models for lower compute needs and lower latency.

We experimented with maths and science questions. It will be nice to extend this to other domains.

Lastly, we experimented with English QA pairs only. We would surely like to extend this to more languages.

10 Ethics Statement

All the models used in this work are publicly available on Huggingface and free for research.

We utilized publicly accessible LearningQ dataset from https://github.com/AngusGLChen/LearningQ. These resources were used as per their intended use policies.

Just like other generative models, our models can potentially generate biased, offensive or otherwise harmful content. Hence, care should be taken to apply appropriate filters when integrating with real world systems. That said, we did not observe such cases during our experimentation.

A GPT prompts

A.1 Filtering out irrelevant questions

```
system_prompt = "You are an expert in
    finding the relevance of a question
    and its corresponding answer with
    respect to a particular domain. Your
     task is to find the relevance of a
    question answer pair with respect to
     the domain mentioned. Here's how
    you can accomplish the task. \n
    ------------\n
    - See whether the question is
        relevant to the domain in
        consideration.\n
    - See whether the answer tries to
        provide a solution to the
        question.\n
    - Evaluate the question answer pair
        with respect to the domain
        mentioned.\n
    - Rate the relevance of the
        following question-answer pairs
        on a scale of 1-10, with 1 being
         least relevant and 10 being
        most relevant.\n
    Please generate the response in the
        form of a Python integer\n
    DO NOT PROVIDE ANY OTHER TEXT OR
        EXPLANATION"

user_prompt = "Please evaluate the
    following domain-based question-
    answer pair:\n
    domain:{domain}\n
    question:{question}\n
    answer:{answer}"
```

Listing 1: Prompt used to filter irrelevant QA pairs

A.2 Prompt for Question Answering

```
system_prompt = "## You are an Question
    Answering AI assistant. You need to
    answer the question.\n
    ## RULES\n
    1. Answer MUST be simple and precise
        .\n
    2. Answer can consists of multiple
        steps if that would help the
        human understand it better.\n
    3. Do not assume something you are
        not sure about.\n\n"

user_prompt = "Question: {question}\n\
    nAnswer: "
```

Listing 2: Prompt used for Question answering with question alone

```
system_prompt = "## You are an Question
    Answering AI assistant.\nYou are
    provided with the `Transcript' of a
    video.\n You need to answer the
    question as if you have seen the
    video.\n
    ## RULES\n
    1. Answer MUST be simple and precise
        .\n
    2. Answer can consists of multiple
        steps if that would help the
        human understand it better.\n
    3. Do not assume something you are
        not sure about.\n
    4. You may make use of the context
        provided in the Transcript to
        generate the answer.\n\n"

user_prompt = "Transcript: {transcript}\
    n\nQuestion: {question}\n\nAnswer: "
```

Listing 3: Prompt used for Question answering with question and transcript

A.3 Prompts for Evaluation

A.3.1 Correctness

```
system_prompt = "You are an AI
    Evaluation chatbot helpful in
    evaluating the correctness of
    generative outputs for visual
    content-based question-answer pairs
    .\n
    Your task is to evaluate the
        predicted answer and determine
        if it answers the question
        correctly. Here's how you can
        accomplish the task:\n
    ------\n
    ##INSTRUCTIONS: \n
    Provide your evaluation only as a
        score where the score is an
        integer value.\n
    Please generate the response in the
        form of a Python dictionary
        string with keys `score', where
        its value is the score in
        INTEGER, not STRING.\n
    For example, your response should
        look like this: {`score':
        INTEGER}.\n
    Possible values of score are :
        [0,1,2] \n
    0 when predicted answer is incorrect
         or not answered. \n
    1 when predicted answer is partially
         correct or makes assumptions. \
        n
    2 when predicted answer is
        completely correct with concise,
        useful explanations. \n"

user_prompt = "Please evaluate the
    following video-based question-
    answer pair:\n
    Question: {question}\n
    Predicted Answer: {pred}\n\n"
```

Listing 4: Prompt used for evaluating correctness

A.3.2 Coherence

```
system_prompt = "You are a strict AI
    Evaluation chatbot helpful in
    evaluating the coherence of
    generative outputs for video-based
    question-answer pairs.\n
    Your task is to strictly evaluate
        the predicted answer and
        determine if it is coherent and
        easy to understand. Here's how
        you can accomplish the task:\n
    ------\n
    ##INSTRUCTIONS:\n
    Provide your evaluation only as a
        score where the score is an
        integer value.\n
    Please generate the response in the
        form of a Python dictionary
        string with keys `score', where
        its value is the score in
        INTEGER, not STRING.\n
    For example, your response should
        look like this: {`score':
        INTEGER}.\n
    Possible values of score are : [0,1]
         \n
    0 when predicted answer is long and
        not easy to follow.\n
    1 when predicted answer has concise
        explanations and easy to follow
        .\n"

user_prompt = "Please evaluate the
    following video-based question-
    answer pair:\n
    Question: {question}\n
    Predicted Answer: {pred}\n\n"
```

Listing 5: Prompt used for evaluating coherence

A.3.3 Visual grounding

```
system_prompt = "You are a strict AI
    Evaluation chatbot helpful in
    evaluating the contextual
    understanding of generative outputs
    for video-based question-answer
    pairs.\n
    Your task is to strictly evaluate
        the predicted answer and
        determine if it is grounded in
        the visual content provided as
        image/video. Here's how you can
        accomplish the task:\n
    ------\n
    ##INSTRUCTIONS:\n
    Provide your evaluation only as a
        score where the score is an
        integer value.\n
    Please generate the response in the
        form of a Python dictionary
        string with keys `score', where
        its value is the score in
        INTEGER, not STRING.\n
    For example, your response should
        look like this: {`score':
        INTEGER}.\n
    Possible values of score are : [0,1]
         \n
    0 when predicted answer has no
        reference to the image/video. \n
    1 when predicted answer has
        reference to the image/video. \n
        "

user_prompt = "Please evaluate the
    following video-based question-
    answer pair:\n
    Question: {question}\n
    Predicted Answer: {pred}\n\n"
```

Listing 6: Prompt used for evaluating visual understanding

A.3.4 Relevance

```
system_prompt = "You are a strict AI
    Evaluation chatbot helpful in
    evaluating the completeness and
    relevance of generative outputs for
    video-based question-answer pairs.\n
    Your task is to strictly evaluate
        the predicted answer and
        determine if it is complete and
        relevant to the question. Here's
         how you can accomplish the task
        :\n
    ------\n
    ##INSTRUCTIONS:\n
    Provide your evaluation only as a
        score where the score is an
        integer value.\n
    Please generate the response in the
        form of a Python dictionary
        string with keys `score', where
        its value is the score in
        INTEGER, not STRING.\n
    For example, your response should
        look like this: {`score':
        INTEGER}.\n
    Possible values of score are : [0,1]
         \n
    0 when predicted answer is
        irrelevant or somewhat deviates
        from the question. \n
    1 when predicted answer is
        completely relevant and precise.
         \n"

user_prompt = "Please evaluate the
    following video-based question-
    answer pair:\n
    Question: {question}\n
    Predicted Answer: {pred}\n\n"
```

B Dataset Filtering Decisions

We filtered out questions from our overall EDU-VIDQA dataset, hence creating the challenging subset with most questions requiring visual context to answer the question.

Why Maths and Science domains only? We decided to choose these domains to have more complex, reasoning-based questions which cannot be

answered with general or common sense knowledge. Further, ∼75% of our dataset consists of questions from Maths and Science domain and even after retaining only ∼9% of the total QA pairs, we are still able to retain ∼43% of the videos.

Why timestamps? Upon observation, we find that QA pairs with timestamp in their question are more likely to need a proper contextual understanding of the video. Using GPT-4 for filtering out such questions would have further added to our costs. Hence we use this simplified heuristics-based approach to ensure that most questions require video context to be answered accurately.

Examples of removed questions. Examples of some questions which have been removed are as follows. It is easy to see that these questions can be easily answered by the world knowledge stored in the LLM's parametric memory and does not need video context.

```
Q: "Why does the pond freeze faster than
     the sea water?"
```

Listing 8: General question, does not require video context.

```
Q: "Wasn't Russia called the Soviet
    Union?"
```

Listing 9: History question: Remembering-based question and does not require context.

```
Q: "If a continuous increase in
    Government spending increases the
    GDP and reduces Inflation, how does
    subsequent increase in spending
    increase the rate of inflation?"
```

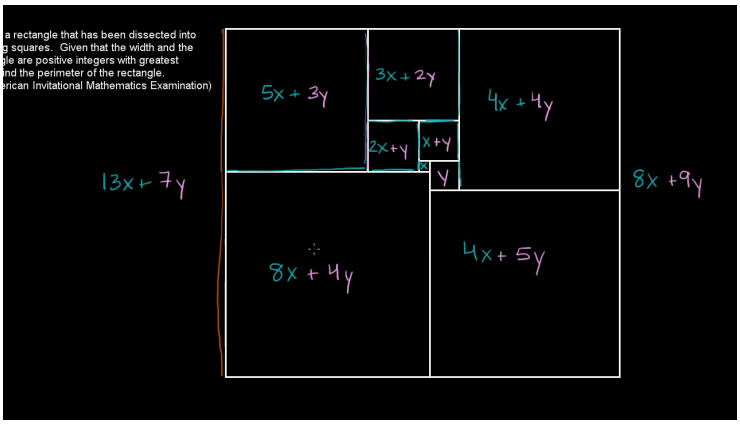
Listing 10: Question is linked to the video but does not require video context. Requires reasoning but any text-only LLM can handle.

C Qualitative Analysis of Model Outputs

In this section, we show a few case studies of predictions from various models where the models perform accurately as well as examples where models generate erroneous predictions. Table 4 shows an example of a good prediction from GPT-4V with transcript. Table 5 shows an example where GPT-4V prediction is better than prediction from GPT-4. Table 6 shows an example where LLaMA-3 with transcript is better than LLaMA-3 without transcript. Lastly, Table 3 shows an example where even our best model (GPT-4V with transcript) also does not provide a good answer.

Video	https://www.youtube.com/watch?v=rYG1D5lUE4I
Question	I think Sal make a mistake on (vid @ 5:11) when he write the greater than sign! it should be Less than
Ground truth Answer	No, Sal is correct. If he had: i sqrt(x) where X<0, then X is negative. Backup thru Sal steps. If X is negative * (-1) = +X. And he would have started with sqrt(x), not sqrt(-x). He is also trying to highlight that if you had something like: sqrt(12), you would not make this into i sqrt(-12). The imaginary number is not needed if the radical contains a positive number to start with.
Prediction from GPT-4 with transcript	The transcript does not provide the specific details regarding what was written at timestamp 5:11 in the video. Therefore, it's not possible to confirm if Sal made an error with the greater than sign or if it should have been a less than sign.
Prediction from GPT-4V without transcript	To confirm if Sal made a mistake with a greater than sign at 5:11 in the video, I would need to actually watch the video, which I cannot do. However, I can see the content of the provided image and provide explanations based on it.\n\n The image shows handwritten mathematics notes that include the definition of the imaginary unit i, properties of square roots, and an example with the square root of a negative number. If Sal's discussion involves these topics and there's a specific point related to inequalities or comparing sizes, I can help clarify that based on the mathematical concepts shown. If you provide more context or describe the mistake, I can help correct the mathematical concept.
Prediction from GPT-4V with transcript	Sal is correct in the video; he mentions that the rule $\sqrt{-x} = i\sqrt{x}$ applies when $x \geq 0$. When x is greater than or equal to 0, $-x$ is a non-positive number (negative or zero), which is the context in which you would be looking for a complex square root. If x were less than 0, then $-x$ would be positive, and the regular principal square root could be used instead of the complex one. Thus, the greater than sign is used appropriately here.

Table 4: An example of a good prediction from GPT-4V with transcript.



Video	https://www.youtube.com/watch?v=nGCW5teACC0
Question	The equation is -4x+7. Shortly after the 4:00 mark, Sal replaces the x with -1 and then says, "4 times -1 = -4". Shouldn't it be -4 * -1?
Ground truth Answer	He misspoke and says 4*-1=4, but what he really meant is -4*-1=4 and he completes the equation as if he had said that correctly. It does not change the problem because he just misspoke and didn t write the incorrect statement down
Prediction from GPT-4	No, Sal is correct. In the equation -4x+7, the "-4x" represents "-4 times x". So if x is -1, then it is "-4 times -1", which does equal 4. But because of the negative sign in front of the 4, the result is turned into -4. Hence, '-4 times -1' equals '-4' in this context.
Prediction from GPT-4V	Yes, it should be -4 multiplied by -1. When plugging -1 into the equation in place of x, the correct operation is to multiply -4 by -1, which results in +4.

Table 5: Visual content helps: GPT-4V prediction is better than prediction from GPT-4.

Video	https://www.youtube.com/watch?v=iPwrDWQ7hPc
Question	At 8:30, why does Sal keep expanding everything out? I do not understand it.
Ground truth Answer	he is using this as a complete example to show how it works. He is also using the sigma, which is a sum of all integers from the number on the bottom to n.
Prediction from LLaMA-3 without transcript	I'm happy to help you understand!\n\nIt seems that Sal is expanding everything out because he is trying to show the proportions of the shapes and figures in the diagram. By expanding each part, he is making it easier to see the relationships between different elements and understand the overall structure.\n\nThink of it like zooming in on a small part of a big picture. By making each piece larger, Sal is allowing us to see the details more clearly and understand how they fit together.\n\nDoes that make sense?
Prediction from LLaMA-3 with transcript	Sal keeps expanding everything out because he is applying the Binomial Theorem to the expression $(a + b)^4$. The Binomial Theorem is a formula for expanding powers of a binomial (an expression with two terms) into a sum of terms. In this case, Sal is expanding $(a + b)^4$ into a sum of terms using the Binomial Theorem.\n\nHe is doing this to show that the expression $(a + b)^4$ can be simplified into a sum of terms, each of which is a product of powers of a and b. This can be useful for simplifying expressions and solving equations.\n\nIt may seem like a lot of work to expand everything out, but it is a useful technique for solving problems in algebra and other areas of mathematics.

Table 6: Transcript helps: LLaMA-3 without transcript vs LLaMA-3 with transcript.

Timestamp image (6:13)

Transcript*

....5x plus 3y is going to be that entire length right over there. ..... This length is 3x plus 2y. This is x plus y. And this is y. So if you add 3x plus 2y plus x plus y plus y, you get 4x plus-- what is that-- 4y, right? 2y, 3y, 4y. And then we can express this character's dimensions in terms of x and y because this is going to be 5x plus 3y. Then you're going to have 2x plus y. And then you're going to have x. So you add the x's together. 5x plus 2x is 7x, plus x is 8x. And then you add the y's together, 3y plus y, and then you don't have a y there. So that's going to be plus 4y. And then finally, we have this square right over here. Its dimensions are going to be the y.....5x plus 3y plus 8x plus 4y. So 5 plus 8 is 13. So it's 13x plus 3 plus 4 is 7y. So that's its height. But we can also think about its height by going on the other side of it. And maybe this will give us some useful constraints because this is going to have to be the same length as this over here. And so if we add 4x plus 4x, we get 8x. So these are going to have to be equal to each other, so that's an interesting constraint. So we have 13x plus 7y is going to have to equal 8x plus 9y.....

Question

At 6:13, Sal got 2 different answers for 2 sides of a square. How did he get the 2 answers?

Human answer	GPT4V-response
To get the dimension on the left side of the large rectangle, he added the lengths of a side of each square on the left. To get the dimension on the right side of the large rectangle, he added the lengths of a side of each square on the right. Since we know opposite sides of a rectangle have equal length, we can set up an equation (13x+7y=8x+9y) to solve for the ratio of x to y (x=2/5*y)	Sal calculated the dimensions of two adjacent sides of a rectangle, which must be equal because they represent the same length. For one side, he added the lengths of segments labeled as 5x + 3y, 2x + y, and x to get a total length of 8x + 4y. For the adjacent side, he combined the lengths of segments labeled as 4x + 4y and 4x + 5y to get a total length of 8x + 9y. These two different expressions, 8x + 4y and 8x + 9y, should be equal since they represent the same physical length of the rectangle's side, leading to an equation that can be simplified to find a relationship between x and y.

Figure 2: Example where GPT-4V with transcript does not perform well. The image corresponds to the frame at 6:13 in the video https://www.youtube.com/watch?v=1uWZNW5PF-s. We omitted some lines from the transcript for sake of clarity of presentation.

ACE-ICD: Acronym Expansion As Data Augmentation For Automated ICD Coding

Tuan-Dung Le[1,2], Shohreh Haddadan[1], Thanh Q. Thieu[1,2]

{tuandung.le, shohreh.haddadan, thanh.thieu}@moffitt.org

Abstract

Automatic ICD coding, the task of assigning disease and procedure codes to electronic medical records, is crucial for clinical documentation and billing. While existing methods primarily enhance model understanding of code hierarchies and synonyms, they often overlook the pervasive use of medical acronyms in clinical notes, a key factor in ICD code inference. To address this gap, we propose a novel effective data augmentation technique that leverages large language models to expand medical acronyms, allowing models to be trained on their full form representations. Moreover, we incorporate consistency training to regularize predictions by enforcing agreement between the original and augmented documents. Extensive experiments on the MIMIC-III dataset demonstrate that our approach, **ACE-ICD** establishes new state-of-the-art performance across multiple settings, including common codes, rare codes, and full-code assignments. Our code is publicly available [1].

Table 1: Example predictions from the MIMIC-III-full dataset (HADM_ID = 108519) using KEPT(Yang et al., 2022) and our ACE-ICD models.

1 Introduction

Assigning standardized codes based on the International Classification of Diseases (ICD[2]) known as ICD Coding is essential for efficient medical record management, accurate billing processes, and streamlined insurance reimbursements (Park et al., 2000; Sonabend et al., 2020). However, traditional ICD coding relies on manual effort, making it time-intensive and error-prone driving the development of automated coding methods.

Accurate ICD code assignment, whether manual or automated, requires a comprehensive understanding of clinical notes, which include detailed information such as symptoms, diagnoses, and test results. However, healthcare professionals often rely on acronyms and abbreviations to reduce documentation effort (Amosa et al., 2023). This shorthand introduces significant ambiguity, making it difficult for both human coders and language models to interpret the clinical text correctly. To better understand the impact of acronyms on ICD code assignment, we analyze expert-annotated evidence spans from the MDACE dataset (Cheng et al., 2023), which is derived from MIMIC-III (Johnson et al., 2016). Our analysis shows that 22% of the evidence spans either consist entirely of acronyms and abbreviations or include at least one such term, highlighting that acronyms often carry useful information for assigning ICD codes. Previous studies improved model understanding of medical acronyms by leveraging their appearance in code synonyms (Yuan et al., 2022; Yang et al., 2022; Gomes et al., 2024). However, they still fail to predict codes which contain acronyms in their synonym description. Table 1 shows several instances of this shortcoming in previous mod-

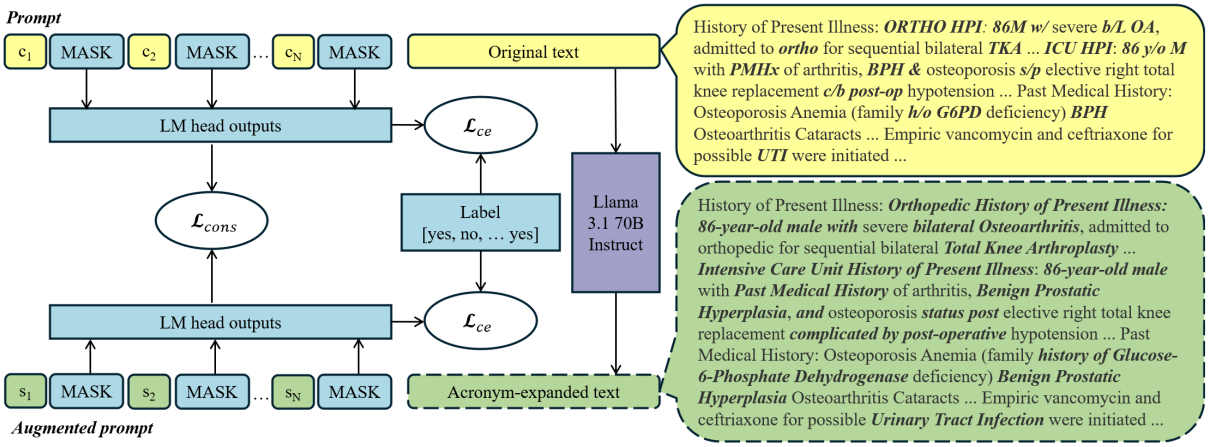

Figure 1: Our training pipeline incorporating acronym-expanded data augmentation and consistency training.

els. These failures underscore the need for new approaches to effectively address medical acronyms to consequently improve the ICD coding system.

In this paper, we propose **AC**ronym **E**xpansion for **ICD** coding (**ACE-ICD**) to investigate the impact of expanding medical acronyms to full terms on coding models. Our system harnesses the strong capability of large language models in disambiguating clinical acronyms (Kugic et al., 2024; Liu et al., 2024), as a data augmentation method that expands acronyms using open-source LLM prompting. We further apply KL divergence consistency regularization to enforce alignment between predictions from the original and augmented examples. Finally, we conduct experiments on three standard ICD coding tasks using the MIMIC-III dataset, demonstrating that our approach outperforms previous state-of-the-art methods across all tasks.

2 Methods

Previous methods frame the ICD coding task as a multi-label classification problem, as a single clinical note can contain multiple diagnosis or procedure codes. Given a clinical note t, the task is to assign a binary label $y_i \in \{0, 1\}$ for each ICD code i (where $i = 1, 2, ..., N_c$ and N_c is the total number of ICD codes). A label of 1 denotes relevance, while 0 indicates irrelevance.

We followed the prompt-based fine-tuning approach by (Yang et al., 2022) for the ICD coding task, reformulating the multi-label classification task as a cloze task (Schick and Schütze, 2021; Gao et al., 2021). Specifically, we construct a prompt template by concatenating each ICD code description c_i, appending a [MASK] token after each description, and adding the clinical note t. The prompt P is given by: $P = c_1$ [MASK] c_2 [MASK] ... c_{N_c} [MASK] t. The model is trained via a masked language modeling objective to predict "yes" or "no" in each [MASK] position, corresponding to a label of 1 or 0, respectively. For tasks where N_c is large (e.g., thousands of codes), this approach is typically used as a reranker (Tsai et al., 2021; Yang et al., 2022, 2023b; Kailas et al., 2023), as including all code descriptions in the prompt is infeasible.

2.1 Acronym-expansion as data augmentation

Motivated by capabilities of LLMs in clinical acronym disambiguation (Liu et al., 2024; Kugic et al., 2024), we use the open-source Llama 3 model (Dubey et al., 2024) to generate acronym-expanded version of clinical notes, denoted as t_a, from the original notes t. Due to the considerable length of the MIMIC-III notes, we first split each discharge summary based on the headers identified through automatic section-based segmentation (Lu et al., 2023). We then prompt the instruction-tuned Llama 3 models to generate augmented sections, which are concatenated into the final acronym-expanded note, using the following prompt:

```
<|begin_of_text|>
<|start_header_id|> system <|end_header_id>
You are a helpful assistant. <|eot_id|>
<|start_header_id|> user <|end_header_id|>
Expand all acronyms to their full forms while
preserving all the details in the following paragraph,
do not mention the acronyms again. Paragraph: ___
<|eot_id|>
<|start_header_id|> assistant <|end_header_id|>
Here is the paragraph with all acronyms expanded to
their full forms:
```

2.2 Consistency training

Inspired by (Shen et al., 2020; Wu et al., 2021), we incorporate a consistency loss into the training objective to encourage the model to generate similar predictions for the original clinical note t and its acronym-expanded counterpart t_a. We first construct a second prompt template using the augmented note t_a and a synonym s_i for each ICD code description collected from UMLS from previous studies (Yuan et al., 2022; Gomes et al., 2024): P_a = s_1 [MASK] s_2 [MASK] ... s_N [MASK] t_a. The training objective can be written as the following:

$$\mathcal{L} = \frac{1}{2}(\mathcal{L}_{ce}(P, y) + \mathcal{L}_{ce}(P_a, y)) + \alpha\mathcal{L}_{cons}(P, P_a, y)$$

where $\mathcal{L}_{ce}$ is cross-entropy loss for masked language modeling, and $\mathcal{L}_{cons}$ enforces consistency by minimizing the bidirectional KL-divergence:

$$\mathcal{L}_{cons} = \frac{1}{2}(KL[p(y|P)||p(y|P_a)] + KL[p(y|P_a)||p(y|P)])$$

3 Experiments

3.1 Acronym expansion evaluation

Dataset. Several annotated datasets for medical abbreviations and acronyms have been introduced in prior work (Moon et al., 2012; Rajkomar et al., 2022). To evaluate our zero-shot prompting approach on the MIMIC-III corpus, we utilize the annotated dataset developed by Rajkomar et al. (2022), which we consider most suitable for our task. This dataset was constructed using a reverse-substitution technique applied to MIMIC-III discharge summaries, resulting in a large-scale, high-quality resource for acronym expansion. As our experiments are also based on MIMIC-III, this dataset offers a consistent and reliable benchmark for evaluation.

Metrics. We perform zero-shot prompting experiments using four instruction-tuned variants of the Llama model. We first report detection precision and recall (Rajkomar et al., 2022), which assess the model's ability to identify abbreviations in text, regardless of whether the corresponding expansions are correct. We then compute total accuracy, defined as the proportion of abbreviations in the gold standard that are correctly expanded to their full forms by the model. To assess the quality of expansions, we consider two evaluation settings. Strict accuracy requires an exact string match between the model-generated expansion and the gold-standard full form. However, as illustrated in Table 3, certain expansions may differ lexically yet convey the same meaning. To accommodate such cases, we introduce lenient accuracy, which computes a similarity score based on the normalized inverse edit distance between the generated and reference expansions. Specifically, we normalize the edit distance by the length of the reference and consider expansions with a similarity score of at least 70% as correct. Although some semantically valid expansions may fall below this threshold, we adopt the 70% cutoff to balance recall and precision while avoiding acceptance of clearly incorrect outputs.

Implementation Details. To extract abbreviations and their corresponding expansions from model outputs, we employ the Python difflib library[3], which aligns two sequences.

3.2 ICD coding evaluation

We evaluate our methods on three MIMIC-III tasks, following (Mullenbach et al., 2018) for MIMIC-III-50 and MIMIC-III-full dataset splits and (Yang et al., 2022) for constructing MIMIC-III-rare50, which focuses on the top 50 codes with fewer than 10 occurrences (See Table 2).

Dataset	Train	Dev	Test	N_C
MIMIC-III-50	8066	1573	1729	50
MIMIC-III-full	47723	1631	3372	8922
MIMIC-III-rare50	249	20	142	50

Table 2: Statistics of the MIMIC-III ICD-9 datasets.

Metrics. We evaluate performance using macro-AUC, micro-AUC, macro-F1, micro-F1, and precision@k (k = 5 for MIMIC-III-50, k = 8 and 15 for MIMIC-III-full). We determine the optimal threshold for micro-F1 on the development set and report test metrics using the best-performing checkpoint. To ensure robustness, we run each experiment with five random seeds and report mean results.

Implementation Details. We initialize our model with two pre-trained language models:

[3] https://docs.python.org/3/library/difflib.html

Acronym	Expanded form by LLM	Full form	Inverse Edit distance
pod#15	post-operative day #15	post-operative day #15	100.0
intrabd	intrabdominal	intra-abdominal	86.67
p/w	presented with	presents with	84.61

co	complained about	complained of	69.23
angio	angiography	angiogram	66.67
dec	dead	deceased	50.0
x3	three	three times	45.45
p.a.	personal assistant	physician assistant	68.42
pms	previous medical symptoms.	premenstrual syndrome	28.57
vma	visual motor assessment	vanillylmandelic acid	0.0
opa	office of personnel administration	oropharyngeal airway	-25.0

Table 3: Examples of expanded abbreviations, their correct full-forms and the value of the length-normalized inverse edit distance. The threshold is considered 70%, thus the expanded terms with a lower threshold are considered incorrect in our evaluation.

KEPTLongformer[4] and KEPT-PMM3[5]. Following (Yang et al., 2022), we preprocess MIMIC discharge summary by removing de-identification tokens, replacing non-alphanumeric characters (except punctuation) with whitespace, and truncating at 8,192 tokens. If the length exceeded this limit, irrelevant sections were removed prior to truncation to retain the most relevant sections. The MIMIC-III full dataset contains 8,922 ICD codes, making it infeasible to include all descriptions in one prompt. We re-rank the top 300 candidates predicted by MSMN (Yuan et al., 2022) and process 50 candidates at a time, as described in (Yang et al., 2022; Kailas et al., 2023).

To determine the consistency loss weight (α), we perform an ablation study on the MIMIC-III-50 dataset by varying $\alpha \in \{0.02, 0.05, 0.1, 0.2\}$. $\alpha = 0.05$ yields the best performance across all evaluation metrics (see Table 6). This value is applied to all other experiments, as tuning on the larger MIMIC-III-full dataset is computationally expensive. For the top-50 and rare-code datasets, we randomly select 4 synonyms to construct the augmented prompt P_a, following findings from (Yuan et al., 2022; Gomes et al., 2024) that using 4 or 8 synonyms improves ICD coding model performance. For MIMIC-III-full dataset, we use the same code descriptions for both P and P_a, as we observed that incorporating synonyms increases training time and slows convergence on this larger dataset.

[4] https://huggingface.co/whaleloops/keptlongformer

[5] https://huggingface.co/whaleloops/KEPTlongformer-PMM3

All experiments are conducted on a single NVIDIA H100 80GB GPU, with training time and hyperparameters detailed in Appendix A.2. We use the Llama-3.1-70B-Instruct model to perform zero-shot acronym expansion for all ICD coding experiments, except for the ablation study reported in Table 7.

4 Results

4.1 Acronym expansion performance

Our experimental results indicate that the size of the large language model (LLM) used for zero-shot prompting has minimal impact on acronym detection. Detection precision ranges from 93.7% with the smallest model to 96.6% with the largest, while recall increases from 84.5% to 90.5%. In contrast, model size has a substantial effect on acronym expansion accuracy, showing a notable performance improvement of +42 percentage points, from 18.8% with the 1B-parameter model to 60.8% with the 70B-parameter model (Table 7). Evaluating expansions under the lenient accuracy criterion yields additional gains of up to 4%.

Table 3 illustrates example outputs from acronym expansion using the Llama-3.1-70B-Instruct model, along with their corresponding inverse edit distance scores used for lenient accuracy evaluation. As shown in the second section of the table, several expansions remain marked as incorrect even under the lenient 70% similarity threshold, demonstrating our effort to avoid misclassifying incorrect expansions as correct (for example, the first example in the third section). As such, lenient accuracy should be viewed as a conservative,

lower-bound estimate of the model's true acronym expansion performance.

4.2 ICD coding performance

Results show that **ACE-ICD** outperforms previous state-of-the-art methods across all three MIMIC-III datasets (Table 4 and 5), regardless of whether KEPTLongformer or KEPT-PMM3 is used for initialization. From now on, we refer to ACE-ICD (PMM3) as ACE-ICD. To assess statistical significance, we conduct 1,000 rounds of permutation testing comparing the predictions of ACE-ICD and the KEPT baseline. The resulting p-values are all below 0.05 across evaluation metrics and datasets, indicating that our proposed approach yields statistically significant improvements in ICD coding performance.

On the MIMIC-III-50 task (Table 4), ACE-ICD achieves a macro AUC of 94.4 (+0.6), micro AUC of 95.9 (+0.5), macro F1 of 71.6 (+1.2), and micro F1 of 75.0 (+1.0) and precision@5 of 70.0 (+1.1), with values in parentheses indicate improvements over the previous best results. For the MIMIC-III-full task (Table 4), ACE-ICD outperforms prior methods on most metrics except macro F1, achieving a macro F1 of 13.2 (-0.8), micro F1 of 62.7 (+2.0), precision@8 of 79.4 (+1.0), and precision@15 of 63.9 (+0.2). We manage to improve the macro F1 score to 14.3 (+0.3), by applying code-specific threshold optimization (see Appendix A.1). Under the MIMIC-III-rare50 setting (Table 5), ACE-ICD achieves a macro AUC of 91.1 (+2.2), micro AUC of 91.9 (+2.0), macro F1 of 54.0 (+13.7), and micro F1 of 55.8 (+13.2) when fine-tuned from the MIMIC-III-50 checkpoint. Notably, ACE-ICD fine-tuned from KEPT-PMM3 outperforms prior methods initialized from the MIMIC-III-50 checkpoint.

5 Discussion

Effectiveness of our proposed training framework. We evaluate the impact of acronym augmentation and consistency training in ACE-ICD through an ablation study by adding each component separately and assessing performance on the MIMIC-III-50 dataset (Table 6). For data augmentation only, we include the augmented data into the original dataset, doubling the training set size while halving the number of training epochs. For consistency training only, we apply R-Drop (Wu et al., 2021) directly to the original data. Both approaches improve performance over the reproduced KEPT baseline, with consistency training yields better gains. We attribute this to the fact that zero-shot acronym expansion may introduce translation errors, adding noise to the training data. In contrast, R-Drop acts as dropout augmentation and has been shown to enhance ICD coding performance by preventing overfitting (Yuan et al., 2022; Luo et al., 2024). However, the performance further improves when both strategies are applied together.

Impact of acronym expansion quality in improving ICD coding performance. To evaluate how the quality of the acronym expansion process affects ICD coding performance, we conduct an ablation study using Llama 3 models of varying sizes and compare them to a baseline without acronym expansion, as shown in Table 7. We observe that poor expansion quality can hurt performance: the 1B model, with less than 20% accuracy, degrades coding results. Moderate-size models (3B and 8B), achieving 30–50% accuracy, yield only minor gains. In contrast, the 70B model, with over 60% exact match accuracy, provides the most significant performance gains. By observing a few incorrectly expanded acronyms illustrated in Table 3, we hypothesize that expansion errors may have minimal impact if the expanded acronyms are unrelated to any ICD code.

Effect of acronym expansion as data augmentation on different ICD codes. Figure 2 illustrates the F1-score improvement for each ICD code, comparing our ACE-ICD model to the baseline KEPT model in the MIMIC-III-50 settings. The results show that ACE-ICD outperforms the baseline on 39 out of 50 codes, with only marginal decreases observed for the remaining ones. Our method effectively improves the performance of lower-performing codes, including 99.04 (22.8 $\rightarrow$ 29.9), 285.9 (24.5 $\rightarrow$ 35.9), 38.91 (28.0 $\rightarrow$ 43.6), 37.23 (35.2 $\rightarrow$ 51.4), and V15.82 (12.7 $\rightarrow$ 33.4). A Pearson correlation of –0.25 ($p = 0.08$) between absolute F1 improvement and the number of training examples per code suggests that rarer codes tend to benefit more from our method, although the evidence is not statistically significant.

Moreover, although our approach is designed to improve model robustness to the use of acronyms in clinical texts, the impact of acronym expansion on ICD coding performance varies depending on the presence of code-relevant evidence in abbreviated or expanded form across different codes. If several

Table 6: Ablation study on MIMIC-III-50.

full-form expressions are already present in the text, acronym expansion may not be necessary for accurate code prediction (e.g., “tka” and “total knee replacement” as evidence for code 81.54 in the example from Table 1).

A case study is shown in Table 1. Our ACE-ICD demonstrate a better understanding of medical acronyms, correctly predicting codes such as 599.0 and 715.36. In this discharge summary (HADM_ID=108519), the only evidence for inferring code 599.0 is the acronym "uti", as other mentions of "urine" in the text are not relevant. Similarly, code 715.36 can be inferred from "oa" or its synonym "osteoarthritis". Despite the KEPT model being pre-trained to incorporate knowledge from UMLS terms, it still fails to correctly predict these codes, highlighting the effectiveness of our approach in handling medical acronyms.

Comparison with recent methods. Our method outperforms previous state-of-the-art models across all three MIMIC-III datasets, including those using additional human annotations or auxiliary clinical knowledge (Kailas et al., 2023; Wang et al., 2024a,b). Notably, our approach significantly improves over the KEPT baseline using a smaller model, KEPTLongformer (149M parame-

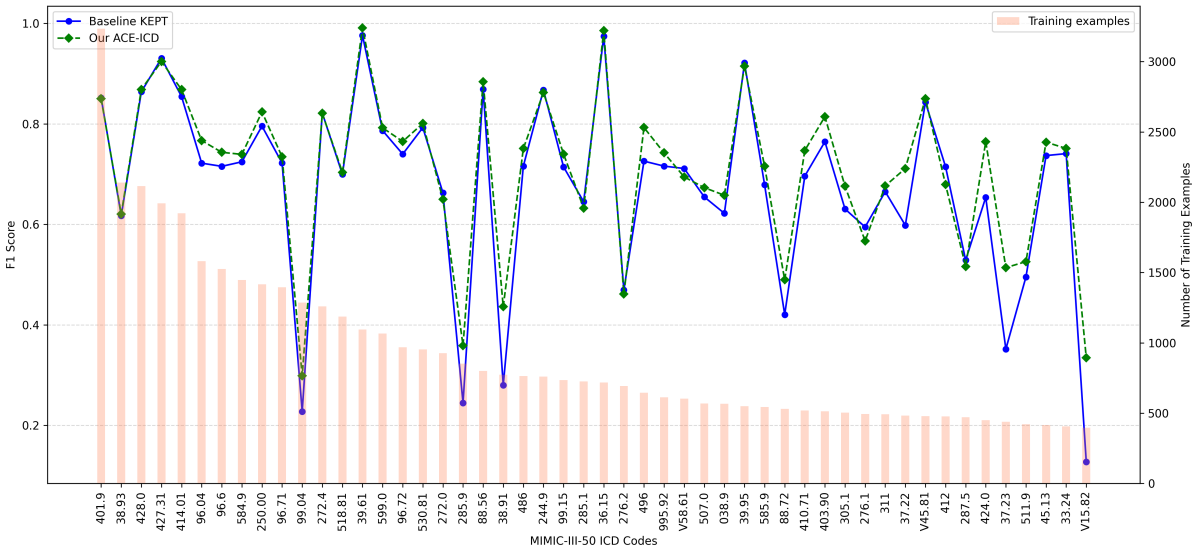

Figure 2: F1 improvement per code in MIMIC-III-50 dataset (sorted by number of training examples in descending order).

ters), and even outperforms MSAM(Gomes et al., 2024), built on the larger GatorTron model (345M parameters), under the common code setting.

Even though, GPT-4-based approaches show promising results in ICD coding (Yang et al., 2023a; Li et al., 2024), they still underperform compared to fine-tuned encoder-based models, particularly in terms of micro-F1. The multi-agent framework proposed by Li et al. (2024) achieves a higher macro-F1, which suggests better handling of rare codes due to GPT-4's extensive medical knowledge, but it exhibits lower micro-F1, reflecting challenges in accurately predicting frequent codes.(See tables 4 and 5). Additionally, these methods require repeatedly sending clinical notes to third-party services to access proprietary LLMs, raising concerns around privacy, cost, and scalability. In contrast, our method delivers strong performance on both frequent and rare codes through a lightweight, targeted data augmentation strategy that uses open-source LLMs locally in a one-time preprocessing step, preserving privacy and efficiency.

6 Related works

6.1 Automatic ICD coding

Automatic ICD coding is a multi-label classification task that assigns diagnosis and procedure codes to clinical notes (Perotte et al., 2014; Nguyen et al., 2023a). Early approaches use CNNs (Mullenbach et al., 2018; Xie et al., 2019), LSTMs (Vu et al., 2020; Nguyen et al., 2023b), and Transformers (Huang et al., 2022) to encode clinical notes, while incorporating label attention mechanisms to capture relationships between the notes and ICD codes. Recent studies further improve code representation by integrating multiple code synonyms (Yuan et al., 2022; Gomes et al., 2024) or code relation graph learning (Luo et al., 2024). Contrastive learning has also been applied to improve model capabilities, either between medical entities in UMLS

(Yang et al., 2022) or between clinical notes and ICD codes (Kailas et al., 2023). Several studies enhance ICD coding performance by leveraging the discourse structure of clinical notes, such as using section type embeddings (Zhang et al., 2022) or contrastive pre-training between sections (Lu et al., 2023).

While most methods rely solely on the provided clinical notes and code descriptions, some studies focuses on enhancing ICD coding performance using extra human annotations or data augmentation. Kailas et al. (2023) pre-train a model on temporal sequences of diagnostic codes using proprietary data from a large patient cohort, where clinical notes are paired with ICD-10 codes, to provide a strong initialization for finetuning coding model. Wang et al. (2024a,b) incorporate auxiliary information such as diagnosis-related group (DRG) codes, current procedural terminology (CPT) codes, and prescribed medications to improve performance. Lu et al. (2023) introduce masked section training with small ratio as a data augmentation strategy, following contrastive pre-training between note's sections to boost model performance. Falis et al. (2022) propose ontology-guided synonym augmentation and sibling-code replacement to generate silver training examples. However, their method requires a pretrained named entity recognition and linking system to identify code-relevant text spans.

LLMs have demonstrated remarkable capabilities across various general-domain tasks and have recently been explored for ICD coding (Boyle et al., 2023; Soroush et al., 2024). Yang et al. (2023a) introduced LLM-Codex, which generates ICD codes and evidence with GPT-4, followed by LSTM-based verification. Li et al. (2024) use GPT-4 to convert discharge summaries into Subjective, Objective, Assessment, and Plan (SOAP) format, allowing multiple agents to perform ICD coding via predefined workflows. While promising, these approaches still lag behind fully fine-tuned non-LLM models on MIMIC-III common and rare datasets.

To the best of our knowledge, no prior work has explored augmenting data with acronym expansions and incorporating them via consistency training to enhance ICD coding performance. Moreover unlike previous approaches, our approach does not rely on additional annotations or specialized pre-training. Instead, given the evidence of the zero-shot capabilities of general-purpose LLMs to expand medical acronyms, our approach provides a simple yet effective data augmentation strategy to improve ICD coding performance.

6.2 Clinical acronyms disambiguation

Accurately disambiguating clinical acronyms and abbreviations enhances automated clinical note processing which include medical information retrieval and analysis. Several studies focus on training deep learning models with large amounts of annotated data, including word-embeddings (Jaber and Martínez, 2021; Wu et al., 2015), convolutional neural networks (CNNs) (Skreta et al., 2021), fine-tuning transformer-based models such as BioBERT (Li et al., 2024) and BlueBERT (Hosseini et al., 2024), and fine-tuned encoder-decoder architectures like T5 (Rajkomar et al., 2022). To address the scarcity of annotated data and the data-hungry nature of deep learning models, prior work has explored various data augmentation strategies, including reverse substitution (Rajkomar et al., 2022; Liu et al., 2024; Skreta et al., 2021), UMLS-based similar concept retrieval (Skreta et al., 2021), integration of clinical note metadata (Kugic et al., 2024), and the use of generative clinical models (Hosseini et al., 2024). The potential of LLMs in medical context understanding, coupled with their reduced reliance on large annotated datasets, has driven research toward zero-shot and few-shot acronym disambiguation in clinical text requiring less training cost and effort. Kugic et al. (2024), Liu et al. (2024) and Hosseini et al. (2024) evaluate various LLMs on the CASI dataset (Moon et al., 2012), showing that LLM-based prompting achieves performance comparable to supervised models, even in zero-shot settings.

7 Conclusion

In this paper, we introduce ACE-ICD, a system that advances ICD coding performance by utilizing acronym expansion as an innovative data augmentation technique. Furthermore, we incorporate consistency training, a regularization strategy that enforces alignment between original and augmented documents to enhance model predictions. Our approach also outperforms studies which rely on external annotations or proprietary resources. Our extensive experiments reveal that the combination of LLM-based acronym expansion and consistency training elevates ICD coding accuracy, outperforming existing methods and establishing new state-of-the-art benchmarks across various settings.

Limitations

Our data augmentation approach relies on zero-shot prompting to disambiguate medical acronyms in clinical notes, making its effectiveness dependent on the performance of the selected LLMs. We chose Llama 3.1 70B as it was the best-performing open-source model available at the time of our experiments and aligned with our computational resources. More advanced LLMs or prompting techniques could potentially reduce translation errors and generate higher-quality augmented data.

Our work uses KEPT as the base method, but we argue that acronym expansion as a data augmentation technique, combined with consistency training, can benefit other existing ICD coding systems. Additional experiments are needed to thoroughly assess the effectiveness of our proposed strategy across various models.

8 Ethics Statement

This work uses the publicly available MIMIC-III clinical dataset, which contains de-identified patient information in compliance with HIPAA standards. Access to the dataset requires completion of a data use agreement and training in responsible research conduct. Acronym expansion was performed using open-source LLMs on a secure local cluster, and no patient data were transmitted to any third-party services. Our method is intended to support clinical NLP research and is not designed for direct clinical deployment without expert oversight. We do not anticipate any ethical concerns associated with this study.

A Appendix

A.1 Threshold Optimization

All results presented in the main paper are obtained using a single threshold for all ICD codes, optimized for the micro F1. An alternative approach is to determine a specific threshold for each ICD code. This method effectively lowers the threshold for ICD codes with less training data compared to a single-threshold approach, leading to an improvement in the macro F1 and surpassing (Zhang et al., 2022) on the MIMIC-III-full dataset. However, this strategy tends to overfit the development set, increasing the performance gap between the development and test sets.

A.2 More implementation details

Pretrained models. We initialize our model with two pretrained variants provided by (Yang et al., 2022). KEPTLongformer is based on Clinical Longformer (Li et al., 2023), while KEPT-PMM3 builds upon RoBERTa-base-PM-M3-Voc-distill (Lewis et al., 2020), a distilled variant of RoBERTa-large pre-trained on PubMed, PMC, and MIMIC-III corpus. These models adapt the Longformer sparse attention mechanism (Beltagy et al., 2020) to handle longer sequences and incorporate medical knowledge through contrastive learning.

Training Details. Table 9 summarizes the training hyperparameters for the three MIMIC-III

datasets. Training ACE-ICD (PMM3) for 8 epochs on a single NVIDIA H100 GPU takes approximately 25 minutes for MIMIC-III-rare, 7 hours for MIMIC-III-50, and 5 days for MIMIC-III-full.

Inference. Evaluating 1,573 examples from the development set of MIMIC-III-50 takes approximately 1 minute and 36 seconds on a single H100 GPU, achieving a throughput of around 16 examples per second. For MIMIC-III-full, the model requires six runs to re-rank 300 candidates, resulting in a throughput of 2.67 examples per second.

Configuration	**MIMIC-III-50**	**MIMIC-III-rare50**	**MIMIC-III-full**
global attention on	code descriptions + masks	code descriptions + masks	code descriptions + masks
global attention stride	1	1	3
synonyms in prompt	yes	yes	no

Logical Table-to-Text Generation: Challenges, Methods, and Reasoning

Lena Trigg and Dean Hougen
School of Computer Science, University of Oklahoma
Norman, OK, USA
lena.trigg@ou.edu, hougen@ou.edu

Abstract

Logical Table-to-Text (LT2T) generation requires models to both verbalize tabular data and reason over it - performing comparisons, aggregations, and causal inference. While many generation tasks struggle with similar analytical demands, LT2T provides a structured perspective on reasoning capabilities in natural language generation. This survey uses LT2T as a lens to focus on reasoning in data-to-text tasks. By focusing narrowly on LT2T, we present a deep taxonomy of methods that inject, structure, or verify reasoning steps, allowing a level of technical granularity missing in broader surveys. We review representative models and evaluation metrics, and highlight how LT2T techniques transfer to general generation challenges involving logic, numeracy, and faithfulness. Our goal is to distill lessons from LT2T that apply more widely, while also guiding future research in table-based reasoning.

1 Introduction

Tabular data is pervasive in domains such as finance, science, and sports, but is often obscure to non-experts. *Table-to-Text* (T2T) models bridge this gap by transforming structured tables into readable summaries. While early neural T2T models improved fluency, they struggled to meet users' analytical expectations, often producing surface-level descriptions that merely repeat table content.

Logical Table-to-Text (LT2T) raises the bar by requiring reasoning-based generation. Instead of stating individual facts, LT2T models must infer logical relationships. Figure 1 contrasts shallow and logical outputs to illustrate this difference. Generating logical-level output introduces challenges such as logical fidelity, numerical accuracy, and controllable content selection, which also affect many other natural language generation (NLG) tasks.

We chose LT2T to survey as it offers a compact, well-defined testbed for the broader NLP goal of trustworthy text generation with reasoning because the input structure is explicit and every valid operation is enumerable. At the same time, limiting the scope to LT2T allows us to offer a deep, actionable taxonomy of reasoning strategies that would be too shallow or generic in a broader survey. We categorize methods by how they address issues to enhance reasoning. This is especially useful for practitioners entering the field or designing systems that require interpretable, faithful reasoning.

Statistics of Three Countries in Middle East			
Country	**Area (km²)**	**Population**	**Density (per km²)**
Israel	21,937	10,100,000	460
Iraq	438,317	45,521,000	104
Iran	1,648,195	87,500,000	53
Surface-level Generation			
Sentence: Israel has an area of 21,937 km² and on average 460 persons live in each km².			
Logical-level Generation			
Sentence: Israel has the smallest area among the three countries with the highest population per square kilometer.			

Figure 1: Comparing surface and logical-level outputs.

This survey therefore treats LT2T as a unique frame of reference for reasoning-centric generation research. Following background on LT2T and reasoning (Section 2), we review the primary datasets developed for LT2T (Section 3). We outline the key challenges that arise in this task (Section 4), and organize existing methods into a unifying taxonomy (Section 5). Our taxonomy links challenges to methods, enabling clearer comparisons and identification of underexplored directions. We then compare these methods (Section 6), discuss how to select them (Section 7), present future directions (Section 8), and outline conclusions (Section 9). In addition, we provide appendices that cover models (Appendix A), datasets and evaluation metrics (Appendix B), common logic types and functions (Appendix C), and further method comparisons

Proceedings of the 14th International Joint Conference on Natural Language Processing and the 4th Conference of the Asia-Pacific Chapter of the Association for Computational Linguistics, pages 1663–1677

(Appendix D). We hope this survey serves both as a roadmap for LT2T and as a blueprint for reasoning-aware generation more generally.

2 Background

This section briefly defines the Logical Table-to-Text task and discusses the types of reasoning used.

2.1 Logical Table-to-Text

The *Logical Table-to-Text* (LT2T) task is to learn a mapping from a table to an articulate natural language sentence that can be derived from the input table. Formally, the task can be defined as follows (Chen et al., 2020a):

Given a table T denoted as $T = \{ T_{i,j} \mid 1 \leq i \leq R_T,\ 1 \leq j \leq C_T \}$, where R_T and C_T are the number of rows and columns, respectively, and each cell entry $T_{i,j}$ may contain a word, a number, a phrase, or even an entire sentence; and reference sentence(s) of the form $W = (w_1, w_2, \ldots, w_n)$ composed of words w_i; the objective is to train a model $P(W \mid T)$ that generates a hypothesis $\hat{W}$ that is both (i) *fluent* and (ii) *logically entailed* by the information in T.

2.2 Reasoning

Reasoning involves analyzing facts to infer new insights, draw conclusions, or make decisions by identifying patterns, comparisons, or causal relationships within data. In LT2T, reasoning enables the generation of logically correct statements that extend beyond surface-level information. This survey focuses specifically on two types of reasoning:
Logical: *Logical reasoning* is inferring analytical relationships such as comparisons, superlatives, or causal connections. For example, given statements "A is taller than B" and "B is taller than C," logical reasoning can conclude that "A is taller than C."
Numerical: *Numerical reasoning* refers to making correct inferences from numerical data, including arithmetic operations, magnitude comparison, and numeric aggregation. For example, determining the tallest individual is A given specific heights {A: 180 cm, B: 170 cm, C: 160 cm}.

Although numerical reasoning is a subset of logical reasoning, it is considered separately here due to the specialized challenges it presents for LT2T.

3 Datasets

Training a generative model for LT2T requires a specific dataset, which typically consists of pairs of tables and narratives that describe table contents. Numerous datasets exist for generating descriptive text from tables, such as WikiBio (Lebret et al., 2016). However, our focus is on datasets specifically designed to challenge and evaluate the logical/numerical reasoning capabilities of LT2T techniques. Table 1 summarizes LT2T datasets.

In the following, we first discuss what is currently considered in the design of existing LT2T datasets and then what is missing.

LogicNLG (Chen et al., 2020a) increases logical difficulty through open-domain, unconstrained schemas and diverse logical operations such as superlatives and comparisons. The dataset's tables span multiple domains, though the distribution is heavily skewed toward sports: approximately 35% of tables concern teams/players and 25% concern competitions, followed by entertainment and politics at roughly 15% each, with celebrity and science domains appearing far less frequently.

Logic2Text (Chen et al., 2020b) pairs tables with logical forms (LFs); it also *quantifies structural reasoning complexity* using LF graph size, including number of nodes and function nodes. Each logical form contains on average nine nodes, including about three function nodes. The dataset includes seven logic types: Count (2.0k) and majority (1.8k) are the most common, followed by unique (1.6k), superlative and aggregation (1.4k each). Ordinal and comparative (1.2-3k each) are less frequent. This distribution shows that Logic2Text emphasizes summarization and highlighting prominent rows, while explicit comparison and ranking operations are present but occur less often.

NumericNLG (Suadaa et al., 2021) and *SciGen* (Moosavi et al., 2021) target numerical reasoning by emphasizing arithmetic operations; *SciGen* further introduces three splits, with the hardest split containing longer, more analytical statements.

ContLOG (Liu et al., 2022) is a controllable dataset built on Logic2Text that replaces LFs with highlighted evidence cells to guide logical content selection; it also provides a pre-training subset.

LoTNLG (Zhao et al., 2023d) is an evaluation-only benchmark designed for zero-shot/prompted LLM testing, conditioning generation on nine reasoning types to probe type-specific difficulty.

All of the above operate on flat tables. *HiTab* (Cheng et al., 2022) makes the task harder by introducing hierarchical (multi-level header) tables and shows that schema hierarchy stresses alignment and reasoning.

Dataset	Tables	Cell	Num.	Pairs	Vocab	Text	Domain	Source	Reasoning	Schema	Cont.	Struct.
LogicNLG	7.3K	91	35	37.0K	122K	14	Open (Wiki)	Annot.	Rich (Logical)	Unlimited	No	Flat
Logic2Text	5.5k	64*	22*	10.7k	14k	16.7	Open (Wiki)	Annot.	Rich (Logical)	Unlimited	No	Flat
NumericNLG	1.3K	35*	31*	1.3K	19.6K	94	Scientific	Hybrid	Rich (Numerical)	Unlimited	No	Flat
SciGen	—	53	34	1.3K	11K	116	Scientific	Annot.	Rich (Numerical)	Unlimited	No	Flat
ContLOG	5.5K	64*	22*	10.7K	14K*	16.7*	Open	Annot.	Rich (Logical)	Unlimited	Yes	Flat
LoTNLG	862	84*	25*	4.3K	6.3K*	14*	Open	Annot.	Rich (Logical)	Unlimited	Yes	Flat
HiTab	3597	190*	116*	10.6K	8.7K*	17.32*	Open	Annot.	Rich (Numerical)	Unlimited	Yes	Hier.

Table 1: Logical Table-to-Text Datasets.Tables = number of tables; Cell = avg total cells/table; Num = avg numeric cells/table; Pairs = number of annotated pairs; Vocab/ Text = vocabulary size / avg description length (words). Source = data origin (web, human-annotated, or hybrid). Schema = known (fixed columns/order) vs. unlimited (arbitrary columns). Cont. = guidance on what to verbalize e.g. highlighted cells. Struct. = table structure (flat or hierarchical). * = computed from released data.

Gaps and Directions. Despite these contributions, current LT2T datasets leave room for growth in at least three ways: (1) *Schema realism:* include hierarchical headers and *multi-table joins* to reflect real reports and dashboards. (2) *Operation coverage:* cover more operations such as temporal (trends, deltas, rolling statistics). (3) *Complexity metadata:* release per-dataset distributions such as operation types, domains, and numeric density.

4 Challenges in LT2T

This section discusses key challenges that have been addressed by existing research, particularly to improve LT2T.

Logical Fidelity: A generated sentence has *perfect fidelity* when every conclusion it makes is entailed by the information in the table. This means that each claim must logically and necessarily follow from the premises provided in the table. If a conclusion cannot be derived solely from the information presented, the text lacks fidelity. Common causes of low fidelity include: (1) missing or incorrect logical operations, (2) a mismatch between the sequence and logical order, and (3) over-reliance on superficial correlations rather than causal relationships grounded in the table.

Logical Controllability: The space of possible valid descriptions is exponentially large, as multiple logical inferences can be made from the same table. Current models struggle to determine which logical operation to apply, leading to irrelevant or uncontrolled outputs. Without guidance, models may select incorrect logic or reasoning paths. Therefore, it matters how models decide what content to include when multiple valid statements can be derived from a table.

Numerical Reasoning: Models commonly used in T2T, such as Pre-trained Language Models (PLMs) or general-purpose Large Language Models (LLMs), are trained as text token predictors rather than explicit numerical reasoners. As a result, they often exhibit weaknesses in tasks that require one or more of these numeric competencies: (1) *Magnitude Understanding*: Magnitude indicates the size of a number and is used to compare or order values; (2) *Arithmetic/Functional Operations*: Performing exact or approximate operations such as addition, subtraction, ratios, and aggregates; (3) *Number to Word Mapping*: Choosing appropriate lexical descriptors.

Data Scarcity: The success of many LT2T methods depends on the availability of large amounts of annotated data. However, annotation is an expensive task. Therefore, developing methods to enable text generation with few-shot samples and reducing annotation costs are critical.

Diversity: Models often focus on the same table regions or apply the same logical operations, leading to repetitive outputs. To promote diversity, it is essential to generate multiple distinct yet factually accurate statements derived from a table.

User Preference: Different users may want different logical views, such as trends vs. outliers. Ignoring this leads to mismatched summaries. Conditioning generation on user intent improves relevance and reasoning selection.

Evaluation Methodology: Conventional automatic metrics such as BLEU (Papineni et al., 2002) reward surface-level token overlap, so they miss logical inconsistencies and hallucinations. They also lack explanations as to why outputs are (in)correct. Consequently, the field needs logic-aware, explainable metrics that can both assess and justify a model's reasoning accuracy.

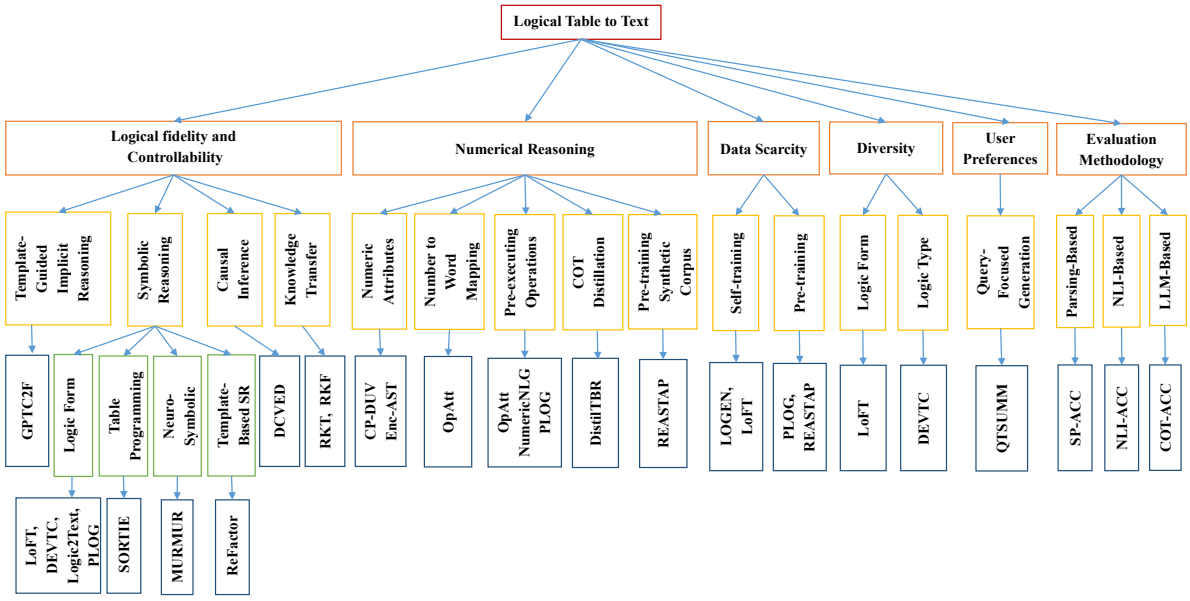

Figure 2: Taxonomy of logical table-to-text methods

5 Methods for Logical Table-to-Text

This section groups methods by the challenges they address; each method might appear in multiple categories. Figure 2 visualizes this: orange boxes mark key issues from Section 4, yellow and green boxes show main method families, and blue boxes list representative approaches. The diagram also outlines the order of the subsections that follow.

5.1 Logical Fidelity and Controllability

This section reviews papers that propose approaches to enhance logical fidelity and faithfulness in LT2T. Because many of these methods simultaneously enhance controllability, we discuss approaches for both issues here.

5.1.1 Template-Guided Implicit Reasoning

Auto-regressive generators emit tokens strictly left-to-right; however, logical reasoning can require performing step C before step B. This misalignment between language order and logical order can introduce reasoning errors (Chen et al., 2020a). To address this issue, Chen et al. (2020a) propose a two-stage coarse-to-fine decoder known as GPT-C2F. First, the model generates a template by replacing entities and numbers with placeholders to plan the logical structure. After fixing the global structure, it generates the final sentence by conditioning on both the table and its template to select the correct entity or number for each placeholder. Because the second pass treats the entire template as fixed context, each placeholder attends to its left and right neighbors and the connective words. This allows the model to infer the intended operation before selecting a value, thereby reducing order-mismatch errors.

5.1.2 Symbolic Reasoning-Based Methods

Symbolic reasoning (SR) introduces an explicit intermediate representation, such as logic forms (LFs), programs, or modular operators that specify exact operations to perform before text generation. By dividing a reasoning task into a sequence of clear, executable subtasks, SR approaches can validate each step in isolation and discard logically unsound paths before generating text. Because the final output is grounded in a verified chain of operations, these methods substantially improve logical fidelity and overall faithfulness.

Logic-Form–Based Methods: This subsection reviews methods that utilize logic-forms during different phases of their approach, such as pre-training, training, or inference to address fidelity.

Logic2Text (Chen et al., 2020b) and LoFT (Zhao et al., 2023b) both condition text generation on a table and its logic form. In both methods, the LF guides which table region and operation to reference, reducing ambiguity, and improving control over content selection. Logic2Text uses gold, hand-annotated Python-style LFs whose execution has

already been validated on the table; no extra checking is required. However, LoFT builds LFs automatically via a Structure-Aware Semantic Parsing (SASP) approach (Ou and Liu, 2022) at training time and a synthesis pipeline (Liu et al., 2022) at inference. Because automatically generated LFs can be noisy, LoFT also treats them as fact verifiers: each candidate LF must execute to True, and a Natural Language Inference (NLI)-based method filters out any sentence that the table does not entail.

PLOG (Liu et al., 2022) utilizes LFs as pretraining signals to teach logical reasoning. The idea is that by first training LFs, the model develops a deeper understanding of logical structures, which results in fewer logical errors in final text generation. In pretraining, a large synthetic dataset of (table, LF) pairs is used. The model is then fine-tuned to generate statements from tables. This approach improves controllability by explicitly highlighting which table cells are involved in each LF.

Table-Compatible Programming Language: SORTIE (Zhao et al., 2023a) improves logical reasoning by decoupling language generation from reasoning. It builds on Chen et al. (2020a)'s two-stage approach of generating a template, but fills each template placeholder via symbolic program execution instead of neural prediction. For every placeholder, a Gated Recurrent Unit (GRU) (Chung et al., 2014) scheduler picks an order based on logical dependencies, and another GRU generates a short, table-compatible program composed of operators and operands whose execution on the table returns the exact value and prevents hallucination. To handle missing annotations, SORTIE uses heuristic pseudo-labels with self-adaptive training. This clear division between *what to say* via template and *how to reason* by programs enhances logical fidelity and faithfulness.

Neuro-Symbolic Modular Reasoning: MURMUR (Saha et al., 2023) is a neuro-symbolic, modular framework designed to improve logical reasoning by explicitly separating symbolic logical reasoning from linguistic generation. Its core idea is to dynamically construct executable reasoning paths composed of symbolic and neural modules, governed by grammar and guided by a saliency-based value function during a best-first search. By explicitly performing logical operations using symbolic modules and restricting permissible compositions via grammar rules, MURMUR ensures each reasoning step is valid and verifiable. This approach directly addresses pitfalls such as hallucination, order mismatches, and semantic inconsistencies. Once a valid reasoning path is constructed, a language model converts it into a natural sentence. This method improves both the accuracy and faithfulness of generated summaries by making the reasoning process explicit and reliable.

Template-Based Symbolic Reasoning: ReFactor (Zhao et al., 2023c) explicitly retrieves and generates fact-guided reasoning signals. A set of predefined templates is designed to target reasoning skills such as numerical comparisons, aggregations, and conjunctions. These templates are instantiated and executed over tables using a fact generator to produce multiple facts. Relevant facts are ranked based on user input and included as signals to the model. This improves factual accuracy by providing explicit symbolic reasoning during generation.

5.1.3 Causal Inference

DCVED (Chen et al., 2021) addresses logical inconsistency caused by *hidden confounders*, unobserved factors that create spurious correlations between the input table and the output text (Keith et al., 2020). To resolve this, DCVED applies causal intervention using do-calculus (Pearl, 2010), shifting the learning objective from $p(y \mid x)$ to $p(y \mid \text{do}(x))$, thereby reducing the influence of confounders. To implement this, DCVED frames the generation process using a causal graph with two key variables: (1) Mediator z_m: information extracted from the table, (2) Confounder z_c: a variational latent representing misleading patterns such as frequent but irrelevant table entities. These latent spaces are supervised to be meaningful: z_m is guided by entities mentioned in the target sentence, while z_c is trained to predict unused but high-frequency distractors. During inference, DCVED samples multiple sentences by varying z_c and uses a trained model to select the most factually consistent output. By combining causal reasoning with variational modeling, spurious correlations are reduced, and logical fidelity is improved.

5.1.4 Knowledge Transfer

Liu et al. (2024) employs Reasoning Knowledge Transfer (RKT) to improve logical fidelity in LT2T. They fine-tune a LLaMA-2-6B as a transfer model on Logic2Text to produce natural-language logical rules from tables, synthesize such rules for LogicNLG, and then train a two-stage BART system: a reasoning module that predicts rules from

tables and a summary module that generates text conditioned on those rules—making outputs table-entailed rather than correlation-driven. Noting that some transferred rules are noisy, Bai et al. (2025) introduces the Reasoning Knowledge Filter (RKF) that employs a clean-up stage. RKF uses GPT-4o to annotate a subset of the training data for reasoning correctness. This subset is used to train a BART-large classifier that filters low-quality reasoning traces from the rest of the dataset. This filtering process improves SP-Acc (+1.4) and NLI-Acc (+0.7) by ensuring the generator only sees high-quality, table-consistent reasoning paths.

5.2 Numerical Reasoning

This section reviews methods that address numerical reasoning issues discussed in Section 4.

5.2.1 Understanding Numeric Attributes

CP-DUV (Gong et al., 2020) targets neural models' poor grasp of numerical magnitude caused by treating numbers as word tokens through two key upgrades: (1) They inject magnitude-aware embeddings. A transformer is pre-trained to rank every pair of numbers within a column; each number token is replaced at runtime by an embedding that knows both its size and realistic context. (2) They add a content-aware verification reward—a policy-gradient signal that rewards summaries containing correct entities and statistics in logical order while penalizing omissions and redundancies. These additions give the model a true *sense of numbers*, reducing magnitude errors and ordering output.

Enc-AST (Li et al., 2021) enhances numerical reasoning by addressing magnitude, relative importance, and inter-entity relationships. A hierarchical encoder incorporates two auxiliary tasks: (1) *Number ranking* captures column-wise magnitude; (2) *Importance ranking* models row-wise importance of numerical values. These tasks are learned through self-attention and fused via a gating mechanism. Additionally, a graph-based reasoning module models relationships between entities and enables reasoning over inter-entity relationships. These components enhance the model's ability to generate factually accurate and numerically grounded summaries.

5.2.2 Number to Word Mapping

OpAtt (Nie et al., 2018) addresses the issue of mapping numbers to words using a quantization layer that groups scalar values into a small number of learnable bins. A linear layer maps numbers into logits, then a softmax layer converts the logits into a probability distribution over bins, each with its own embedding. The final embedding is a weighted sum of all embeddings. This method enables the model to generalize across similar values and produce magnitude-aware words during text generation.

5.2.3 Pre-executing Operations

These methods pre-execute numerical operations and feed the results to the model to enhance its numerical reasoning. This reduces the burden of calculation and turns numeric operations that neural LMs struggle with into plain sequence tokens or features that models can copy or attend to.

OpAtt (Nie et al., 2018) pre-executes operations such as *minus* for score gaps and *argmax* for identifying the top scorer. The operations and results are encoded beside records and fed into the decoder. The decoder uses dual attention over operations and records, with a gating mechanism to decide when to prioritize operations or records. Additionally, the copy mechanism ensures outputs can originate from table cells, improving faithfulness.

Suadaa et al. (2021) pre-computes *max*, *min*, and *diff* for the target rows, stores them in a dedicated operation table (T_{OP}), and trains a copy-augmented model that uses placeholders, such as <*header max*>. At inference, a ranking-and-memory procedure replaces each placeholder with a value drawn from T_{OP} or the original data table, ensuring every numeric value in the output is faithfully copied rather than hallucinated.

PLOG (Liu et al., 2022) computes column-wise *sum*, *avg*, and *per-cell rank* values and inserts them into the flattened table structure, allowing the model to access them naturally during generation.

These methods demonstrate that pre-execution, alongside attention, gating, or copying, substantially improve models' numerical reasoning.

5.2.4 Chain-of-Thought Distillation

DistilTBR (Yang et al., 2024) transfers numerical-reasoning skills from an LLM to smaller PLMs by first having the teacher model produce step-by-step reasoning traces for each table. These traces, appended to the table, serve as supervised signals when fine-tuning the student model, guiding it to look at the right rows/columns and apply the correct arithmetic operations. This distillation yields a compact generator that mimics the teacher's logical reasoning without altering the

underlying architecture.

5.2.5 Pre-training with Synthetic Corpus

REASTAP (Zhao et al., 2022) injects diverse reasoning skills into a seq2seq model via synthetic QA pairs during pre-training, without relying on table-specific architectures. Conditioned on a serialized table and question, the model learns to align columns, filter rows, and execute numerical operations purely through its parameters.

5.3 Data Scarcity

Several recent methods aim to reduce the reliance on large amounts of annotated data by generating supervision from unlabeled or synthetic sources.

One approach is to create synthetic corpora offline, allowing models to pre-train before being fine-tuned on limited gold data. For example, PLOG uses handcrafted logic-form templates filled with table values. Instances are kept only if the generated logic-form evaluates to True, producing a large, automatically verified dataset. Similarly, REASTAP (Zhao et al., 2022) creates synthetic question-answer pairs using a template-based example generator (Yoran et al., 2022) for various reasoning skills over tables. This synthetic generation allows the model to learn effectively without relying heavily on human-annotated data.

A second line of work focuses on self-training via pseudo-labeling, where models expand a small seed set using unlabeled data. LOGEN (Deng et al., 2023) begins with a tiny annotated set and trains two GPT-2 models: one to map tables and logic forms to text; one in reverse. The reverse model generates logic forms for new (table, text) pairs, and mutual checks retain consistent examples that are used to retrain the models in a bootstrap loop.

Finally, on-the-fly weak supervision eliminates the need for any gold logic forms. LoFT synthesizes multiple logic-form candidates per table at training and inference time. An NLI-based verifier filters out any that aren't supported by the table, allowing the model to learn from verified candidates without manual annotation.

5.4 Diversity

LoFT and DEVTC (Perlitz et al., 2022) both improve diversity by enumerating alternate reasoning structures. At inference, LoFT creates multiple candidate logic forms per table from 45 templates across eight operation categories, while DEVTC samples from various logic types. Because each logic form or type focuses on a different operation or table region, the models generate a broad set of distinct, valid statements.

5.5 User Preference

QTSUMM (Zhao et al., 2023c) extends LT2T by tailoring generated summaries to user preferences. To achieve this, they fine-tune models on their *QTSUMM* dataset of query–summary pairs. During training, the model is conditioned on user queries alongside the table, guiding generation and producing summaries that directly address user-specific information needs. Additionally, ReFactor (Section 5.1.2) generates query-relevant facts, which are concatenated to the input of the models or used as prompts in LLM during fine-tuning and inference. These facts provide explicit reasoning evidence, further guiding the model to address user queries in the summary with high analytical fidelity.

5.6 Evaluation Methodology

This section reviews automatic metrics for evaluating logical fidelity and explainability.

Parsing-Based Evaluation: This metric evaluates logical fidelity by converting each generated sentence into an executable logic form and running it against the source table. The generated text is converted to the candidate logic forms using a weakly supervised semantic parser (Liang et al., 2009) via breadth-first search. The candidates are ranked based on consistency with the original sentence. The top-ranked logic form is selected and executed on the table. The generated statement is considered logically faithful if the result is `True`. *Semantic Parsing Accuracy* (SP-Acc) (Chen et al., 2020a) is the proportion of sentences whose top logical form evaluates to `True`. Its reliability depends on the parser quality; misparsing or language ambiguity can lead to false outcomes.

Natural Language Inference (NLI)-Based Evaluation: This metric verifies whether a given statement is true, false, or neutral based on the table. The key point is to utilize an NLI model trained to predict the logical relationship to measure the entailment score between the table and the generated text. The ratio of entailed is computed and used to approximate the model's fidelity. NLI-Acc (Chen et al., 2020a), TAPEX-Acc, and TAPAS-Acc (Liu et al., 2022) are examples of this evaluation metric.

Reference-Free, LLM-based Evaluation: Chain-of-Thought (CoT)-Acc (Zhao et al., 2023d) uses a 2-shot chain-of-thought prompt with GPT-3.5/4 to

Method	Backbone	Family	SP-Acc ↑	NLI-Acc ↑
Field-Infusing (Chen et al., 2020a)	Transformer	-	38.9	57.3
GPT-TabGen (med) (Chen et al., 2020a)	GPT-2	-	45.5	73.3
GPT2-C2F (med) (Chen et al., 2020a)	GPT-2	Template-Guided	45.3	76.4
DCVED (Chen et al., 2021)	GPT-2	Causal Inference	43.9	76.9
DEVTC (Perlitz et al., 2022)	GPT-2	Logic Form	45.6	77.0
PLOG (Liu et al., 2022)	BART-Large	Logic Form	50.5	88.9
LoFT (Zhao et al., 2023b)	BART-Large	Logic Form	57.7	86.9
REASTAP (Zhao et al., 2022)	BART-Large	Pretraining Synthetic	54.8	89.2
SORTIE (Zhao et al., 2023a)	BART-Large	Table Programming	57.8	89.3
RKT (Liu et al., 2024)	BART-Large	Knowledge Transfer	59.6	88.1
RKF (Bai et al., 2025)	BART-Large	Knowledge Transfer	61.0	88.8

Table 2: Comparison of LT2T Models on Logical Fidelity Metrics. Shows the best results reported in the original papers.

label each generated sentence as entailed or refuted with respect to the table, then reports accuracy. It yields the best human correlation among automated faithfulness metrics on LogicNLG.

6 Comparing Methods

We compare representative methods across three key dimensions: performance, efficiency, and interpretability/controllability. Since our focus is on logical reasoning, we evaluate performance primarily using logical fidelity metrics in Table 2.

Pre-trained vs Traditional Backbones: Overall, pre-trained backbone models consistently outperform traditional encoder–decoder architectures. For example, even TabGen, which is only fine-tuned on LogicNLG, surpasses field-infused Transformer models in logical fidelity metrics.

Template-Guided Implicit Reasoning: GPT-C2F, which utilizes coarse-to-fine generation, yields higher NLI-Acc and Adv-Acc than GPT-TabGen at both small and medium scales.

Logic-Form/Logic-Type Control: Human evaluations (Chen et al., 2020b) reveal a dramatic gain in factual correctness when logical forms are used, jumping from 20% without LFs to over 82% with LFs. DEVTC improves on prior GPT-2 baselines by conditioning generation on predicted logic types. While it gains slightly in logical metrics, its main strength lies in diversity: by switching logic types during generation, it achieves a factuality–diversity trade-off that surpasses the GPT-TabGen sampling frontier without requiring stochastic decoding, using greedy decoding alone. LoFT builds on this by conditioning on full executable logic forms and applying a verifier to filter outputs. This enables LoFT to achieve the best overall balance between faithfulness and diversity in this family. The trade-off, however, is increased implementation complexity: DEVTC requires a logic-type classifier, while LoFT involves a full pipeline with logic-form parsing, synthesis, and verification. These methods offer improved controllability and more transparent reasoning processes.

Implicit Skill Injection (Pretraining): PLOG and REASTAP inject logical reasoning through pretraining; PLOG leverages logical forms (LFs), while REASTAP uses 4 million synthetic question–answer pairs. Both significantly improve logical fidelity metrics. These approaches keep inference simple at the expense of pretraining cost; for instance, REASTAP's pretraining required 34 hours on an 8 NVIDIA A5000 24GB cluster. They improve faithfulness through pretraining signals, but the final generation remains purely neural, so the internal reasoning steps aren't explicitly exposed.

Table Programming: SORTIE reports the strongest NLI-Acc among compared methods. It outperforms PLOG and REASTAP without any large-scale reasoning pretraining—training for roughly 5 hours on 8×3090 Ti GPUs—while offering high interpretability via explicit, executable reasoning traces. The trade-off is a higher implementation burden.

Knowledge Transfer: RKT and RKF report the strongest logical-fidelity metrics among peers. Both are highly interpretable and controllable via explicit rules.

Not all models are evaluated on these metrics; we discuss other models that use other logical metrics in Appendix D.

7 Discussion

This survey found two dominant LT2T paradigms: (1) **Explicit trace construction:** logic-forms, programs, or neuro-symbolic plans that decouple reasoning from surface realization and give strong fidelity guarantees. (2) **Implicit skill injection:** pretraining or distillation schemes that embed numerical or logical competence inside neural parameters with minimal task-specific engineering.

Explicit methods appear better when one needs: (a) auditability/controllability; (b) verifiable, stepwise reasoning; or (c) operator-level control. However, we suggest *implicit methods* when (a) simple, fast inference at scale is required; (b) there is lack of annotations or tooling for logic forms; or (c) one needs broad skill coverage from synthetic data.

8 Future Directions

We suggest four primary avenues for advancing LT2T research, considering current limitations and existing challenges.

Improving Reasoning Capabilities: Existing approaches are limited to a few operations, such as *sum*, *min*, or *max* (Appendix C), and struggle with more advanced analytical needs, such as trend detection or multi-hop comparisons. Research should address this limitation through three main thrusts: (1) Support more complex logical skills for advanced analytics,including change rates, graph traversal, and temporal patterns. (2) Develop flexible logical supervision frameworks that help models acquire these skills without explicit structured logical forms. Lightweight, weakly supervised, or self-training methods may allow models to infer logical structures from training data without requiring gold-standard logic annotations. (3) Include dynamic logical inference, where the model constructs and executes operator chains during inference to ensure faithful intermediate results before verbalization. Approaches may range from symbolic search with learned value functions to prompting LLMs to produce executable code. Together, these directions will enable broader coverage of analytical reasoning skills, stronger factual accuracy, and adaptability to evolving data schemas.

Evaluation Metrics: We need metrics that are both logic-aware and explainable. While metrics like COT-Acc offer step-by-step reasoning to judge entailment, they are costly, non-deterministic, and limited to proprietary APIs. We need open, lightweight, logic-aware metrics that break outputs into table-grounded claims and mark each as *entailed*, *contradicted*, *missing*, or *hallucinated*.

Scalability: Future LT2T systems must adapt to evolving computational resources and table schemas. New schemas often demand novel logical skills, such as rate-of-change analysis or multi-row trend detection, which current models struggle to acquire without retraining. Exploring continual or incremental learning frameworks that allow models to acquire new reasoning skills while retaining prior knowledge appears promising. Moreover, the high training and inference costs of LLMs, together with their fixed context-window limits, make them impractical for many real-world deployments. Research should thus prioritize lightweight, modular, or distilled models that retain strong logical-reasoning capabilities while reducing computational and memory requirements.

Applicability: Current models are designed for flat tables, whereas real-world data often involves heterogeneous formats like event sequences, hierarchical tables with multi-level headers, or nested structures. Future LT2T systems should be able to process complex structured data and reason over temporal, hierarchical, or relational formats, as seen in domains like medicine or finance. There is also a need for multi- and cross-lingual LT2T generation, where models maintain logical reasoning consistency across languages. Logical operations such as arithmetic, comparison, causal inference, and multi-hop deduction must transfer cleanly across linguistic boundaries. Expanding LT2T to low-resource languages, global reporting, and multilingual scientific domains will promote greater robustness, generalization, and cross-domain utility.

9 Conclusions

Logical Table-to-Text (LT2T) has become a microcosm of reasoning-aware generation-structured inputs, explicit operations, and verifiable outputs. Explicit methods boost fidelity and interpretability, while implicit ones scale better; hybrid models that pair symbolic checks with distilled reasoning show promise in balancing both.

Though focused on LT2T, these insights extend to broader text generation: reasoning traces, logic-aware supervision, and fidelity-based evaluation are key for summarization, retrieval-augmented, and multi-modal tasks. Future progress lies in richer operator coverage, explainable metrics, and lightweight continual-learning frameworks.

Limitations

This survey focuses on LT2T as a lens for examining reasoning in natural language generation. While this scope allows for a deep and actionable taxonomy of methods, it excludes other important forms of reasoning such as commonsense, causal, and spatial. Furthermore, we primarily review methods from the LT2T domain; techniques from related tasks such as fact verification, question answering, and code generation could offer additional insights and warrant future exploration.

Acknowledgments

We used an AI assistant (ChatGPT) for language editing (clarity and grammar). All content was verified and edited by the authors against the cited papers. No confidential or personal data were provided to the tool. The assistant did not generate novel experimental results or datasets.

A Models

We categorize the models commonly used in LT2T works into three groups.

Traditional Encoder-Decoder Models: Early works train encoder-decoders such as Gated Recurrent Neural Network (GRU) (Chung et al., 2014), Long Short Term memory (LSTM) (Hochreiter and Schmidhuber, 1997), or vanilla Transformers (Vaswani et al., 2017) from scratch. These models are usually augmented with structural add-ons, such as copy mechanisms (Gu et al., 2016) or pointer networks (See et al., 2017), gating (Liu et al., 2018), or attention mechanisms (Luong et al., 2015) to ensure numbers and entity names are reproduced faithfully. Methods that use these models are presented in Table 3.

Pre-trained Language Models (PLMs): Subsequent studies fine-tune generic PLMs, such as BART (Lewis et al., 2020), T5 (Qader et al., 2018), or GPT (Radford et al., 2018) on one or more LT2T datasets. Because these models have strong linguistic priors, only light task-specific tuning is required to outperform scratch baselines and traditional methods. Table 4 represents methods that utilize PLMs in their architecture.

Large Language Models (LLMs): A growing line of work leverages LLMs such as OPT (Zhang et al., 2022) and GPT-3/4 (Brown et al., 2020; Bubeck

Method	Base Model	Attention	Gating	Copy	Training Method
OpAtt (Nie et al., 2018)	GRU	Yes	Yes	Yes	Maximum Likelihood Estimation
CP-DU (Gong et al., 2020)	LSTM/Transformer	Yes	Yes	Yes	Reinforcement Learning
Field-Gating (Chen et al., 2020a)	LSTM/Transformer	Yes	Yes	Yes	Maximum Likelihood Estimation
Field-Infusing (Chen et al., 2020a)	LSTM/Transformer	Yes	No	Yes	Maximum Likelihood Estimation
DCVED (Chen et al., 2021)	Transformer	Yes	No	No	Causal Intervention

Table 3: Traditional encoder-decoders trained from scratch for LT2T.

Method	Base Model	Param. Size	Training Method
BERT-TabGen (Chen et al., 2020a)	BERT-*small*/*large*	140/340M	MLE
GPT-TabGen (Chen et al., 2020a)	GPT2-*small*/*medium*	117/345M	MLE; Adv-Reg; RL

DistilTBR (Yang et al., 2024)	Flan-T5-CoT-*base*/*large*	250/780M	FT
	T5-CoT-*base*/*large*	220/770M	
RKT (Liu et al., 2024)	BART-*large*	406M	FT
RKF (Bai et al., 2025)	BART-*large*	406M	FT

Table 4: Pre-trained language models fine-tuned for LT2T. MLE = Maximum Likelihood Estimation, RL = Reinforcement Learning, PT = Pre-training, FT = Fine-tuning.

et al., 2023) without task-specific fine-tuning. Instead of updating weights, researchers steer models via in-context learning, including zero- or few-shot exemplars (Brown et al., 2020), and Chain-of-Thought (CoT) prompting (Wei et al., 2022) to boost faithfulness.

Beyond prompting, LLMs act as teachers, synthesizing CoT rationales to train smaller students (DistilTBR) or to transfer reasoning knowledge (RKT), and as automated annotators whose labels supervise downstream classifiers (RKF). Table 5 summarizes these LLM-based strategies.

B Datasets and Evaluation Metrics

Table 6 shows the datasets and evaluation methodology used. Note that early studies evaluated their methods on datasets that are not specifically designed for LT2T, including RotoWire and MLB.

C Logic Types and Logic Functions

Most of the studies consider the same logic types and functions defined in (Chen et al., 2020b). The logic types include count, unique, comparative, superlative, ordinal, aggregation, and majority. For complete definitions and examples, please refer to the Appendix of that paper. The functions are presented in Table 7 of that paper.

D Comparison of Methods-Cont.

We compare methods in Section 6 primarily using SP-Acc and NLI-Acc, which are the most widely adopted logical fidelity metrics across prior work. However, not all studies report these measures. To ensure completeness, we summarize in Table 7 the best results of models evaluated with TAPAS-Acc and TAPEX-Acc, using the values reported in their original papers. We further provide a comparative rating of all surveyed methods along five axes—diversity, interpretability, controllability, implementation burden, and cost—in Table 8. The accompanying text details the rubric and justifies each assignment.

COT Distillation/LLMs: LLM-T2T (Zhao et al., 2023d) reports that GPT-family models outperform fine-tuned systems such as logic-form-based methods, including LoFT and PLOG. It also finds that adding more shots or Chain-of-Thought (CoT) prompting yields non-monotonic gains—more exemplars or CoT do not necessarily help; GPT-4-zero-shot performs better than GPT-4-1/2-COT. Zhao et al. (2023c) attain state-of-the-art TAPAS-Acc by augmenting LLMs with ReFactor. Finally,

Method	Base Model	Param. Size	Training Method
MURMUR (Saha et al., 2023)	OPT	175B	In-context learning
GPT-3.5 (Zhao et al., 2023d)	GPT-3.5	175B	In-context learning
GPT-4 (Zhao et al., 2023d)	GPT-4	-	In-context learning
RKT (Liu et al., 2024)	LLAMA2	6.7B	FT
DistilTBR (Yang et al., 2024)	GPT-3.5-turbo	175B	COT Distillation
RKF (Bai et al., 2025)	GPT-4o	-	Distillation

Table 5: LLMs used via prompting for LT2T.

Method	Dataset	Surface Metric	Logic Metric	Human Eval.
OpAtt	RotoWire	BLEU	RG	–
CP-DUV	RotoWire; MLB	BLEU	RG / CS / CO	–
Field-Gating	LogicNLG	PPL; BLEU-1,2,3	SP-Acc; NLI-Acc; Adv-Acc	Yes
Field-Infusing	LogicNLG	PPL; BLEU-1,2,3	SP-Acc; NLI-Acc; Adv-Acc	Yes
DCVED	LogicNLG; Logic2Text	BLEU	SP-Acc; NLI-Acc	–
BERT-TabGen	LogicNLG	PPL; BLEU-1,2,3	SP-Acc; NLI-Acc; Adv-Acc	No
GPT-TabGen	LogicNLG	PPL; BLEU-1,2,3	SP-Acc; NLI-Acc; Adv-Acc	Yes
GPT-C2F	LogicNLG	BLEU-1,2,3	SP-Acc; NLI-Acc; Adv-Acc	Yes
Fine-tuned GPT2	Logic2Text	BLEU-4; ROUGE-1,2,L	No	Yes
PLOG (BART/T5)	LogicNLG; CONTLOG	BLEU-1,2,3	SP-Acc; NLI-Acc; TAPEX/TAPAS-Acc	Yes
REASTAP	LogicNLG	BLEU-1,2,3	SP-Acc; NLI-Acc	No
DEVTC	LogicNLG	BLEU-1,2,3	SP-Acc; NLI-Acc	Yes
LoFT	LogicNLG	BLEU-1,2,3	SP-Acc; NLI-Acc	Yes
LOGEN	Logic2Text	BLEU; ROUGE-L	No	Yes
MURMUR	LogicNLG	BLEU; METEOR	No	Yes
DistilTBR	SciGen	METEOR; BERTScore; BLEURT	TAPAS/TAPEX-Acc	No

Table 6: Datasets and evaluation metrics used in surveyed papers.

DistilTBR demonstrates that distilling CoT-style supervision into smaller models like Flan-T5 and T5 can improve logical fidelity without relying on very large LLMs. MURMUR shows via human evaluation 26% more logically consistent summaries on LogicNLG vs direct prompting.

In the following, we explain how we rank each column in Table 8.

Diversity

Low: The model repeatedly generates similar outputs that rely on the same logical operation or remains confined to a fixed table region.

Medium: The model produces varied statements, but often focuses on similar regions or operations unless explicitly guided.

High: The model includes explicit mechanisms to diversify content selection, such as logic-type control, logic-form conditioning, or prompt variation, enabling it to describe different logic types and table regions.

Controllability

Low: There is little or no means to steer logical operations; the model explores a large, unconstrained search space.

Medium: Logic-type tokens, templates, or other signals allow partial steering of logic types but not specific operations or arguments.

High: The method allows explicit control via intermediate structures, including logic forms, programs, or verified candidates that deterministically guide generation.

Interpretability

Low: No explicit intermediate reasoning artifacts are available; the model operates as a black box.

Medium: Lightweight signals such as logic-type tags, CoT summaries, or templates

Method	Backbone	Family	TAPAS-Acc ↑	TAPEX-Acc ↑

Abstract

As Large Language Models (LLMs) become integral to human-centered applications, understanding their personality-like behaviors is increasingly important for responsible development and deployment. This paper systematically evaluates six LLMs, applying the Big Five Inventory-2 (BFI-2) framework, to assess trait expressions under varying sampling temperatures. We find significant differences across four of the five personality dimensions, with Neuroticism and Extraversion susceptible to temperature adjustments. Further, hierarchical clustering reveals distinct model clusters, suggesting that architectural features may predispose certain models toward stable trait profiles. Taken together, these results offer new insights into the emergence of personality-like patterns in LLMs and provide a new perspective on model tuning, selection, and the ethical governance of AI systems. We share the data and code for this analysis here: https://osf.io/bsvzc/?view_only=6672219bede24b4e875097426dc3fac1

1 Introduction

The increasing use of Large Language Models (LLMs) as substitutes for human interaction marks a significant shift in societal dynamics. Individuals now engage with LLMs not only for retrieving information but also in contexts resembling intimate human dialogue, including seeking emotional support, personal advice, and even therapeutic guidance (Stade et al., 2024; Li et al., 2023). As these disembodied interactions become more commonplace, LLMs are beginning to occupy roles once reserved for human experts, counselors, or friends. This development has profound implications: by altering traditional models of communication, mental health care, and interpersonal relationships, LLMs challenge established norms of trust, empathy, and reliability. Moreover, as these systems become more human-like in their conversational styles, users increasingly anthropomorphize them, projecting cognitive and emotional qualities onto what are, at their core, statistical models. Such anthropomorphization raises critical questions about the nature of "personality" in LLMs and how users may rely on these perceived traits when forming judgments, seeking comfort, or making important decisions.

In response to these emergent issues, researchers have begun probing whether and how LLMs exhibit human-like personality characteristics (Serapio-García et al., 2023; Jiang et al., 2023; Mao et al., 2023; Zhan et al., 2024; Noh and Chang, 2024). Anchoring such inquiries in robust psychological frameworks helps clarify otherwise nebulous concepts. The Big Five personality model—capturing openness, conscientiousness, extraversion, agreeableness, and neuroticism (McCrae and Costa, 1997)—serves as a widely accepted and empirically supported tool for understanding human personality. Although its application to LLMs is still in its infancy, a growing body of work suggests that LLMs may indeed reflect trait-like patterns in their generated responses (Lee et al., 2024). Understanding these patterns is far from a purely academic exercise; it has far-reaching implications for the design, deployment, and ethical governance of AI-driven communication.

Despite initial efforts, critical gaps remain. Existing literature has primarily focused on whether traits like those in the Big Five emerge in LLMs, but not on the underlying mechanisms that give rise to these traits or the conditions that influence their stability. For instance, there is limited insight into how model architecture, training data composition, and sampling strategies interact to shape the personality-like behaviors observed. Within the broader research effort to contextualize the nature of LLM "personality," examining additional factors, like the temperature parameter, can provide

fresh perspectives.

This paper contributes new analytical depth along two axes. (1) We systematically examine trait expression under varying sampling temperatures to characterize how a core decoding control modulates personality-like outputs. (2) We use agglomerative hierarchical clustering to uncover model-level patterns of similarity in trait profiles, providing evidence of structural tendencies across architectures. Together, these analyses move beyond simple personality testing and clarify how model design and decoding interact to shape personality-like behaviors.

We advance this exploration by evaluating six comparably sized LLMs using the Big Five Inventory–2 (BFI-2) questionnaire (Soto and John, 2017), a validated and reliable measure of human personality traits. Beyond simply classifying the presence or absence of trait-like patterns, we systematically vary the temperature parameter to investigate its role as a stochastic decoding control that may modulate responses. We also attempt to identify if and how LLMs cluster natively as a factor of their personality responses. Through this multifaceted analysis, we aim to deepen our understanding of what it means for LLMs to exhibit personality-like traits, identify the factors that modulate these expressions, and lay the groundwork for more accountable and human-centered design and governance of AI communication systems.

2 Methods

We employed a diverse ensemble of state-of-the-art large language models (LLMs), each fine-tuned for conversational tasks and equipped with distinct attention mechanisms. The selected models spanned varying parameter scales, vocabulary sizes, and attention mechanisms. We utilized the *Llama 3 8B* model from the Llama series, featuring 8 billion parameters, a vocabulary size of 128,256 tokens, and Grouped-Query Attention (GQA) (AI, 2024a). The *Mistral 7B* model, with 7.3 billion parameters and a vocabulary size of approximately 131,000 tokens, incorporated Grouped-Query Attention (GQA) (AI, 2023). The *MythoMax L2 13B* model from the Gryphe series combined 13 billion parameters with an 8,000-token context length (Gryphe, 2024). The *Gemma 9B* model, with 9 billion parameters and a vocabulary size of 300,000 tokens, employed dynamic attention scaling (Google, 2024). The Q*wen 7B* model utilized a vocabulary of over 150,000 tokens alongside sliding window attention (Cloud, 2023). Lastly, the *StripedHyena 7B* model, featuring 7 billion parameters and a vocabulary size of 280,000 tokens, implemented block-sparse attention (AI, 2024b). To systematically evaluate the influence of sampling temperature on model outputs, we conducted a series of text-generation experiments using a fixed prompt and instructions designed to simulate a personality test response scenario. Specifically, we varied the temperature parameter from 0 to 2 in increments of 1, yielding a total of 21 experimental conditions for each of the 60 main questions of the BFI-2 questionnaire. This range was chosen to capture an extensive spectrum of possible sampling behaviors, from highly deterministic (temperature = 0) to increasingly stochastic regimes. Nevertheless, this range falls within a reasonable space of exploration.

Statistical analysis comprised three main components. First, we performed non-parametric between-model across personality type comparisons using Kruskal-Wallis H-tests ($\alpha = 0.05$) to detect significant differences in trait expressions.

Second, we conducted temperature sensitivity analyses through multiple linear regression models for each trait dimension, with temperature as the predictor variable and trait scores as the response variable, complemented by Pearson correlation coefficients (r) to assess relationship strength and direction. The regression analyses aim to quantify the associations between temperature and trait scores, rather than implying causal relationships or theoretical psychological mappings.

Third, we employed agglomerative hierarchical clustering with Ward's minimum variance method using Euclidean distance metrics to identify model groupings. These groupings were validated through trait covariance matrices to examine inter-trait relationships.

Domain	**Statistic**	**p-value**
Extraversion	40.7803	<0.01
Agreeableness	65.3067	<0.01
Conscientiousness	63.0415	<0.01
Neuroticism	9.2691	n.s.
Openness to Experience	58.1957	<0.01

Table 1: Kruskal-Wallis test results for personality domains. The table shows the test statistic and corresponding p-values for each domain.

Domain	R^2	Pearson Cor.	p-value
Neuroticism	0.3486	-0.5904	<0.05
Extraversion	0.2521	0.5021	<0.05
Agreeableness	0.0343	-0.1853	n.s.
Conscientiousness	0.0257	0.1602	n.s.
Openness	0.0003	0.0178	n.s.

Table 2: Linear regression results for personality domains as a function of temperature.

3 Results

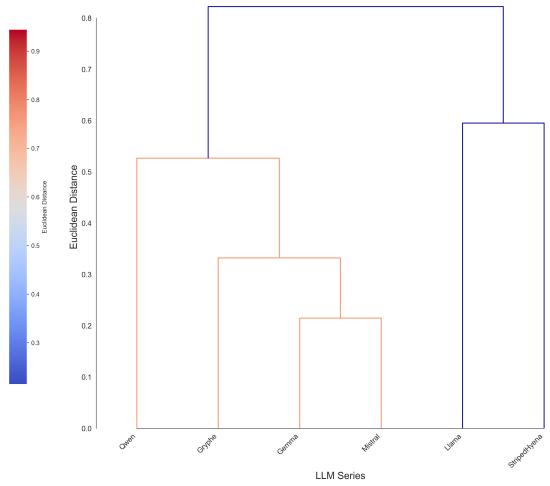

Figure 1: Hierarchical clustering of models based on personality profiles, revealing distinct groupings and architectural influences on trait expressions.

We observed significant differences in the expression of four out of the five Big Five personality traits across models. Kruskal–Wallis tests indicated statistically significant variation in Extraversion ($H = 40.7803, p < 0.01$), Agreeableness ($H = 65.3067, p < 0.01$), Conscientiousness ($H = 63.0415, p < 0.01$), and Openness to Experience ($H = 58.1957, p < 0.01$). In contrast, Neuroticism did not differ significantly between models ($H = 9.2691$, n.s.).

Our temperature sensitivity analysis revealed that certain traits were more strongly influenced by the sampling temperature parameter. Neuroticism showed the most pronounced association with temperature ($R^2 = 0.3486, r = -0.5904, p < 0.05$): as temperature decreased, Neuroticism scores increased, suggesting that more deterministic outputs (lower temperatures) yield higher Neuroticism levels. Extraversion also correlated significantly with temperature ($R^2 = 0.2521, r = 0.5021, p < 0.05$), but in the opposite direction—more stochastic sampling (higher temperature) produced more extraverted responses. By contrast, Agreeableness ($R^2 = 0.0343, r = -0.1853$), Conscientiousness ($R^2 = 0.0257, r = 0.1602$), and Openness ($R^2 = 0.0003, r = 0.0178$) were not significantly affected by temperature (all $p > 0.05$).

The resulting dendrogram reveals notable patterns of similarity and divergence among the models. Notably, the Qwen and StripedHyena models span the boundaries of the dendrogram, indicating maximal pairwise dissimilarity, with Llama being adjacent to the StipedHyena model and forming a separate cluster. The Gemma and Mistral models form a cluster positioned in the center of the dendrogram, whereas Gryphe stands in between this cluster and the Qwen model.

Overall, our results indicate that large language models do exhibit stable, personality-like trait patterns that vary according to architectural characteristics and sampling parameters. While some domains (e.g., Neuroticism and Extraversion) are sensitive to temperature, others remain more robust under changing conditions.

4 Discussion

This study tested the response profiles of six large language models across the Big Five personality traits. Our results revealed that Extraversion, Agreeableness, Conscientiousness, and Openness to Experience were all significantly different. In contrast, Neuroticism did not reach statistical significance. The lack of significant variation in Neuroticism suggests a consistent baseline in the models' responses regarding emotional reactivity. This consistency could be attributed to the training data encompassing a wide range of emotional expressions, thereby balancing positive and negative emotional content. As a result, the models may not disproportionately reflect neurotic characteristics, leading to a more stable and less emotionally reactive profile. By systematically manipulating sampling temperature, we uncovered parametric sensitivities underlying LLM responses.

Sampling temperature—a common decoding parameter—affects not only token diversity and lexical creativity but also generates outputs resembling specific personality traits. Specifically, lowering the temperature consistently results in more "neurotic" outputs. Temperature modulates stochasticity in generation. Human research relating creativity to Extraversion and Neuroticism offers a useful interpretive parallel, although we do not

Figure 2: Effects of sampling temperature on personality traits, demonstrating sensitivity in Neuroticism and Extraversion.

treat temperature itself as a psychological construct. For instance, Conner et al. (Conner and Silvia, 2015) found that neurotic individuals show reduced creativity, especially under anxiety, due to a prevention-focused mindset and heightened threat sensitivity that impede creative engagement. Similarly, Li et al. (Li et al., 2022) reported that neuroticism negatively affects creativity among college students. Furthermore, Krumm et al. (Krumm et al., 2018) provided empirical evidence that neuroticism is inversely related to creativity, indicating that higher levels of neuroticism are associated with lower creative abilities in children. We also find that increasing the sampling temperature leads to outputs with higher extraversion ratings. This observation aligns with existing research on the relationship between extraversion and creativity. For instance, Davis et al. (Davis et al., 2011) demonstrated that extraversion significantly predicts self-reported creativity across various domains among college students. Additionally, Michinov and Michinov (Michinov and Michinov, 2021) revealed that certain personality profiles, which include extraverted traits, positively influence creative performance, especially under conditions of social isolation, such as the COVID-19 lockdown. Nevertheless, our analyses did not reveal significant associations between agreeableness, conscientiousness, and openness and the outcome variable. We hypothesize that two factors might be responsible. First, we examined the effect of temperature agglomerating across all six LLMs. Given the variability in responses observed (table 1), it is highly likely that such effects exist at the individual LLM level. Additionally, we assumed that temperature can be considered a proxy for creativity, but creativity is a multi-component trait, difficult to define and quantify (Sternberg, 2018). Temperature settings in LLMs primarily influence the randomness of responses, which may not fully capture creativity's nuanced, multidimensional aspects.

Our clustering analysis reveals that both model architecture and training data significantly shape the emergent "personality" of large language models. While the content and diversity of training data unquestionably influence learned representations, specific design decisions—such as attention mechanisms (sliding window, Grouped-Query, dynamic scaling, or *Hyena Blocks*) and vocabulary sizes—can yield pronounced output differences. For instance, Qwen 7B (sliding window, 150k tokens) diverges from Gemma 9B (dynamic attention, 300k tokens) and Mistral 7B (Grouped-Query Attention, 131k tokens), illustrating how contrasting attention strategies overshadow shared data attributes. Meanwhile, Llama 3 8B (GQA) stands apart from StripedHyena 7B, whose *Hyena Blocks*-based block-sparse attention (280k tokens) further accentuates unique context-processing. Strikingly, our hierarchical analysis places Qwen and StripedHyena at opposite ends of the similarity spectrum, underscoring how the interplay of architecture (sliding window vs. Hyena Blocks) and vocabulary range (150k vs. 280k tokens) can produce the most pronounced separation in model "personalities."

These findings offer only a glimpse into the long-standing "nature vs. nurture" debate as it applies to emergent traits in LLMs, indicating that both inherent architectural design ("nature") and training data ("nurture") play consequential roles. Our goal here is to highlight the importance of disentangling these factors rather than claiming a fully comprehensive characterization. Future work could employ more controlled methodologies—such as curated corpus studies, ablation experiments targeting specific architectural choices, or fine-grained attribution analyses—to more systematically trace the origins of these traits and refine our understanding of how LLM "personalities" come to be.

Our analysis reveals that LLMs can display

personality-like patterns and that these expressions are influenced, at least in part, by decoding parameters like sampling temperature. These insights invite future investigations into the interplay between architecture, training data, and decoding strategies, ultimately informing both the theory and practice of refining LLM behavior.

5 Limitations

This study is subject to limitations, which we pinpoint in a three-fold fashion. First, the questionnaire was administered to the LLMs for a fixed temperature in a one-shot manner. It is possible that a given LLM would not have provided the same response had it been prompted again. Nevertheless, this does not affect the study's main conclusion. The statistics for each personality component were calculated based on the assumption of differing medians calculated over a temperature range (see Figure 3). Thus, the variability induced by the temperature sampling should have captured any likely non-deterministic behavior. Second, the temperature-regression analysis, albeit significant in two out of five traits, fails to explain a significant part of the underlying variance (34 & 25% for the Neuroticism and Extraversion, respectively). These regressions are exploratory association measures and should not be interpreted as causal indicators or psychological attributions. We hypothesize that this stems from the agglomerative nature of the analysis. Indeed, there appears to be a region (temperature $\in$ [0, 0.5]) where the variance of responses is relatively stable, followed by an unstable response profile. We attribute this to different temperature-sensitivity levels of individual LLMs, but exploring this sensitivity further falls out of the scope of the current study. Nonetheless, our analysis draws intuitive parallels between a dedoding parameter attributed to stochasticity, and personality components that can be affected by such virtue. We, hence, argue that these results surpass the noise level and provide tangible insights into the latent behavior of LLMs. Thirdly, our "nature vs. nurture" analysis is neither causal nor claims to be. Investigating the exact decomposition of personality as a function of lexical exposure or architectural genotype would require a dedicated set of experiments. Our investigation attempts to provide causal hints that we hope will drive interest towards further research in the latent behavioral space of LLMs. We believe that, in the accelerated integration and anthropomorphization era of LLMs, such research is cardinal.

Revisiting Intermediate-Layer Matching in Knowledge Distillation: Layer-Selection Strategy Doesn't Matter (Much)

Abstract

Knowledge distillation (KD) is a popular method of transferring knowledge from a large "teacher" model to a small "student" model. Previous work has explored various layer-selection strategies (e.g., forward matching and in-order random matching) for intermediate-layer matching in KD, where a student layer is forced to resemble a certain teacher layer. In this work, we revisit such layer-selection strategies and observe an intriguing phenomenon that layer-selection strategy does not matter (much) in intermediate-layer matching—even seemingly nonsensical matching strategies such as *reverse matching* still result in surprisingly good student performance. We provide an interpretation for this phenomenon by examining the angles between teacher layers viewed from the student's perspective. Our work sheds light on KD practice, as layer-selection strategies may not be the main focus of KD system design, and vanilla forward matching works well in most setups.[1]

1 Introduction

Large language models have achieved impressive performance in various NLP tasks (Hurst et al., 2024; Guo et al., 2025). However, they need a large number of parameters, making the models cumbersome and difficult to run in resource-restricted scenarios. Knowledge distillation (KD; Hinton et al., 2015) is a widely adopted method to reduce model parameters by training a small "student" model from a large "teacher." With KD, the student is often able to retain most of the teacher's performance while using a fraction of its parameters (Gu et al., 2024; Guo et al., 2025; Wen et al., 2025; Yang et al., 2025).

Common KD approaches can be generally divided into two categories: prediction matching and intermediate-layer matching. Matching the prediction is usually mandatory, as it informs the student of the task to solve. This can be achieved by minimizing the divergence of predicted distributions (Hinton et al., 2015; Wen et al., 2023; Cui et al., 2025) or using reinforcement learning (Hao et al., 2022; Li et al., 2024).

Intermediate-layer matching distills the teacher's hidden states (i.e., intermediate layers) to the student (Sun et al., 2019; Jiao et al., 2020; Gromov et al., 2025). This approach often involves minimizing the distance between the student's and teacher's hidden states (usually with a linear mapping if the dimensions do not match). Also, a layer-selection strategy is required to specify which teacher layer is matched to which student layer.

Traditionally, researchers have explored various layer-selection strategies. Sun et al. (2019) match the student's layers to evenly spaced teacher layers; Passban et al. (2021) and Wu et al. (2021) learn an attention mechanism over the teacher's layers; Haidar et al. (2022) match the student's layers to randomly selected layers from the teacher, albeit in sorted order; and Wang et al. (2021) match the last student layer to a teacher layer close to the end.

Despite numerous previous efforts, we observe that the effectiveness of existing layer-selection strategies is not convincing, as previous studies often lack proper controlled comparisons. For example, Passban et al. (2021) only compare their work with the vanilla layer-matching baseline, and Wang et al. (2021) compare layer-selection strategies without controlling weight initializations. In addition, existing work tends to omit important distillation settings such as decoder-only model architectures. As a result, there is a lack of understanding about how different strategies compare against each other.

In this work, we aim to better understand how layer-selection strategies affect student performance in KD. We conduct systematic controlled

[1]The code is released at the following repo: https://github.com/MANGA-UOFA/Layer-Selection

Proceedings of the 14th International Joint Conference on Natural Language Processing and the 4th Conference of the Asia-Pacific Chapter of the Association for Computational Linguistics, pages 1686–1694

experiments across four models (BERT, BART, T5, and Qwen3) on eight tasks (including both classification and generation). We also consider two weight initialization strategies: random initialization and weight copying from the teacher. Our experiments reveal intriguing findings that

1. The layer-selection strategy doesn't matter (much), as different strategies perform similarly to each other, and

2. Regardless of layer-selection strategies, intermediate-layer matching itself is a highly effective KD method, outperforming the no-matching baseline.

We provide an interpretation for this phenomenon based on geometric analysis of the hidden states: from the student's point of view, the angles between two teacher layers are often acute; thus, matching any teacher layer pulls the student layer in a similar direction. As a result, intermediate-layer matching indeed benefits KD, although the matching strategy does not matter (much).

Our study offers a practical suggestion for KD: we recommend KD practitioners to focus on other aspects of KD systems (e.g., distillation temperature, choice of f-divergence loss functions), while simply using forward matching for intermediate-layer matching as a default strategy, if computing resources are limited.

2 Background and Related Work

Knowledge Distillation (KD) is a method of transferring rich knowledge contained in a teacher model to a student model. To inform the student of the task, it is essential to match the student's and teacher's predictions (Bucilă et al., 2006). Hinton et al. (2015) suggest minimizing the Kullback–Leibler (KL) divergence between the teacher and student distributions, denoted by p and $q_{\boldsymbol{\theta}_s}$, respectively. The KL distillation loss is given by

$$\mathcal{L}_{\text{KL}}(\boldsymbol{\theta}_s) = \mathbb{E}_{\text{y}\sim p(\text{y}|\text{x})}\left[\log \frac{p(\text{y}|\text{x})}{q_{\boldsymbol{\theta}_s}(\text{y}|\text{x})}\right] \quad (1)$$

where x represents the input, and the output y (conditioned on x) is sampled from p. The student's parameters $\boldsymbol{\theta}_s$ are optimized, whereas the teacher's parameters are frozen.

Other than minimizing KL, different prediction matching approaches have been proposed. When the teacher distribution is diverse, for example, the reverse KL divergence (Tu et al., 2020; Gu et al., 2024) is used due to its mode-seeking behavior, i.e., the student only focuses on one of the high-probability regions in the teacher distribution (Bishop, 2006). Wen et al. (2023) propose an f-divergence KD framework, where symmetric divergences (such as Jensen–Shannon and total variation distance) provide a balance between mode averaging and mode seeking. Reinforcement learning can also be applied to KD (Hao et al., 2022; Li et al., 2024), which makes the student aware of its prefix and addresses the exposure bias problem (Bengio et al., 2015).

Regarding intermediate-layer matching, it distills the teacher's hidden states, thus providing additional supervisory signals to the student (Sun et al., 2019; Wen et al., 2025). Let $\mathcal{M} = \{(\varsigma_i, \tau_i)\}_i$ be the mapping between certain student and teacher layers, i.e., the ς_ith layer of the student is mapped to the τ_ith layer of the teacher. Intermediate-layer matching typically penalizes the distance between the matched layers, given by

$$\mathcal{L}_{\text{hid}}(\boldsymbol{\theta}_s, \{\boldsymbol{A}_i\}_i) = \sum_i \text{dist}(\boldsymbol{A}_i \boldsymbol{h}^{(s)}_{\varsigma_i}, \boldsymbol{h}^{(t)}_{\tau_i}) \quad (2)$$

where dist is a distance metric (such as mean squared error). The trainable linear operator $\boldsymbol{A}_i$ transforms the student's hidden state $\boldsymbol{h}^{(s)}_{\varsigma_i}$ to the space of the teacher's hidden state $\boldsymbol{h}^{(t)}_{\tau_i}$, if their dimensions do not match. Otherwise, $\boldsymbol{A}_i$ may be an identity matrix.

Intermediate-layer matching can be applied to different types of representations. Traditionally, this is achieved by matching the student's and teacher's activations (Sun et al., 2019; Sanh et al., 2019). Other studies match attention logits (Jiao et al., 2020), query–key–value relations (Wang et al., 2021), and cross-sample relations (Park et al., 2019; Huang et al., 2023). In our work, we focus on matching activations because it is the most fundamental approach in intermediate-layer matching.

Various layer-selection strategies have been proposed for matching a shallow student to a deep teacher. Sun et al. (2019) and Jiao et al. (2020) suggest mapping evenly spaced teacher layers to the student. Passban et al. (2021) and Wu et al. (2021) match each student layer to a weighted combination of all teacher layers to retain more knowledge. Haidar et al. (2022) randomly reselect a sequence of teacher layers to match with the student (in order) after each epoch, so that the student

is exposed to different teacher layers. Wang et al. (2021) and Ko et al. (2023) suggest mapping the last non-prediction student layer to a teacher layer close to the end.

Overall, although previously proposed methods work well within their environments, it remains unclear how various layer-selection strategies compare under a controlled setup, or the extent they contribute to KD. Thus, we address this by conducting systematic investigations across numerous tasks, models, and initialization strategies, and provide an interpretation for our observations.

3 Approaches

Intermediate-layer matching requires a strategy to select which teacher layers are matched with which student layers. In this study, we explore both standard and seemingly nonsensical layer-selection strategies to uncover its effect on intermediate-layer matching KD.

Forward Matching. In this variant, lower student layers are matched to lower teacher layers. In particular, we follow Sun et al. (2019) and select evenly spaced teacher layers for matching.

All-to-One Matching. In this variant, all student layers are matched to the middle teacher layer. While the idea of matching to one layer is proposed by previous studies (Wang et al., 2020, 2021), we slightly modify their approaches (i.e., matching all student layers instead of one), for fair comparison with the rest of our settings.

Reverse Matching. We experiment with a counterintuitive strategy, where matching is in reverse order (i.e., lower student layers matched to upper teacher layers). This seemingly nonsensical strategy sheds light on the mechanism of intermediate-layer matching.

Out-of-Order Random Matching. We choose the same teacher layers as forward matching, then randomly shuffle the order. The order is maintained during distillation. We average the performance across five seeds to evaluate the effect of different random mappings.

Note that the intermediate-layer matching loss is combined with the predictor's KL loss by $\mathcal{L} = \mathcal{L}_{\text{KL}} + \lambda\mathcal{L}_{\text{hid}}$, where λ is a hyperparameter to balance the losses. We experimentally determined $\lambda = 3$ to be a good balance between KL and intermediate-layer matching losses, since it produces improved performance over the No Matching ($\lambda = 0$) baseline, while higher values of λ may negatively impact performance.

We emphasize that across all layer-selection strategies, we fix the set of teacher layers that are available for the student to learn from. In other words, the only difference among the layer-selection strategies is the **order** of matching.

4 Results and Analysis

Setups. We analyzed different layer-selection strategies on both classification and generation tasks. For classification, we adopt the widely used MNLI (Williams et al., 2018), QQP,[2] QNLI (Rajpurkar et al., 2016), and SST-2 (Socher et al., 2013) using the BERT model (Devlin et al., 2019). We also include more challenging tasks, namely HellaSwag (Zellers et al., 2019) and CommonsenseQA (CoQA; Talmor et al., 2019), using the more recent Qwen3 models (Yang et al., 2025). For generation, we use the popular DART (Nan et al., 2021) and WMT16 En–Ro (Bojar et al., 2016) datasets. We evaluate BART (Lewis et al., 2020) on the DART benchmark and T5 (Raffel et al., 2020) on WMT16, respectively. Our selection of tasks and models give a comprehensive coverage of different tasks and model architectures.

For moderate-sized student models (BERT, BART, and T5), we explore two parameter initialization strategies: copying the weights from select teacher layers and random initialization. The former is a practical method used to quickly transfer knowledge from select teacher layers to the student (Sanh et al., 2019; Shleifer and Rush, 2020), and the latter is used to study the effects of layer-selection strategy in isolation. For the Qwen3 large language model, we only perform weight-copying because it is often not feasible to directly finetune large models on downstream tasks without warming up the weights (commonly achieved through pretraining).

More experimental details can be found in Appendix A.

Main Results. In Table 1, we present the main results of our layer-selection experiments. In Rows 1–2, our finetuned teachers perform similarly to previous work (Devlin et al., 2019; Nan et al., 2021; Wen et al., 2023), showing that we have successfully set up the environment for KD experiments.

We examine different layer-selection strategies. As shown in Rows 9–12, the student model

Table 2: KD results on more challenging tasks using the recent Qwen3 model.

achieves similar results across different strategies, with only 2–3 points difference in accuracy for classification tasks and 1–2 points difference in BLEU for generation tasks. Notice that Reverse Matching and Out-of-Order Random Matching appear nonsensical, when in fact they still achieve close performance to Forward Matching, largely outperforming No Matching. The results show that layer-selection strategy has an unexpectedly small effect on student performance.

It should be emphasized that intermediate-layer matching indeed helps KD compared with No Matching,[3] even though the matching strategy does not play a significant role. On MNLI, for example, all strategies improve upon No Matching by six to ten points with random weight initialization and two points with weight-copying.

Next, we take a closer look at how different layer-selection strategies behave under the two parameter initialization settings. To reiterate, weight-copying is a simple and practical method of transferring the teacher's knowledge to the student (Sanh et al., 2019; Shleifer and Rush, 2020). We also experiment with randomly initialized students in order to disentangle the effects of layer-matching. In Rows 4–7, we see that layer-selection strategies perform similarly to one another, and for the most part better than No Matching.

Results on Challenging Tasks. We further compare different layer-selection strategies on the more challenging HellaSwag and CoQA tasks, which involve more reasoning. As such, we employ the newer Qwen3 models. As shown in Table 2, we observe a similar trend as in our main results, i.e., different strategies generally produce similar results. This suggests the generality of our findings.

An Interpretation Based on Vector Angles. A curious question arises from these observations: why does intermediate-layer matching help KD, but different layer-selection strategies perform similarly? To answer this, we measure the angles between the teacher's layers, viewed from the student. Specifically, we measure the angles formed by two teacher layers' and one student layer's vector representations, depicted in Figure 1a. We show the phenomenon in the MNLI and WMT16 En–Ro datasets in Figures. 1b, 1c and 1d. We see that in both randomly initialized and weight-copied settings, the cosine similarity is positive, suggesting that the angles are mostly acute. In other words, the student layer is pulled to the same general direction regardless of which teacher layer it is matched to. This finding is consistent with Men et al. (2025) and Gromov et al. (2025), where they show that different layers may contain similar knowledge.

Additional Results. We further analyze the student depth in Appendix B and experimental stability in Appendix C.

[3] One exception is the DART experiment with randomly initialized weights, for which we suspect intermediate-layer matching causes the student to overfit. That said, different strategies still perform similarly to conventional Forward Matching, and thus, it does not contradict our general finding.

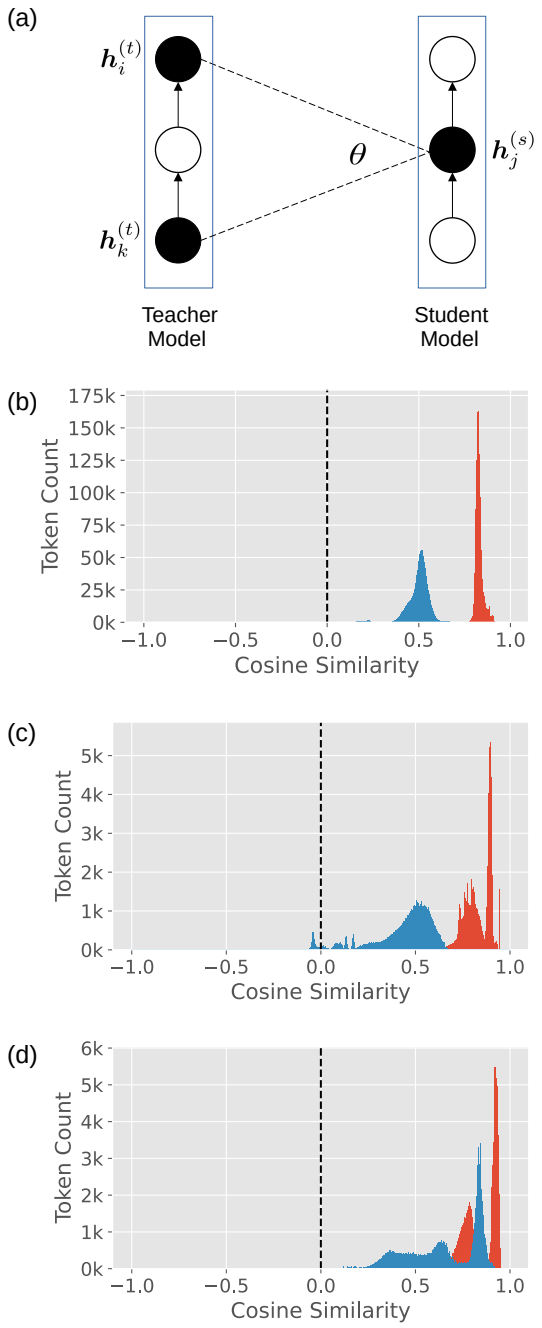

Figure 1: (a) Illustration of the angle calculation. Cosine similarities are shown for (b) MNLI classification, (c) Encoder in the WMT task, (d) and Decoder in WMT (bottom). Orange refers to the setup of random parameter initialization and blue refers to student weights initialized by the teacher.

5 Concluding Remarks

In this paper, we observe an intriguing phenomenon that, although intermediate-layer matching helps knowledge distillation, the layer-selection strategy does not matter (much); we also provide an interpretation based on the angles of teacher and student layers. Our work suggests potential limitations and oversights in previous work, where researchers present various heuristic layer matching methods when training their distilled systems, but their effect is not comprehensively studied. We advise the KD practitioners to focus their efforts on other areas of KD, for example, loss functions, initializations, and representation learning.

6 Limitations

In our work, we have experimented with various setups, including eight tasks (six classification and two generation), four model architectures, and two parameter initialization methods. Although the results are generally consistent, there is one exception that intermediate-layer matching does not help in the DART setup. This is understandable as empirical findings are often noisy. We suspect that it is due to the student model overfitting to the teacher's representations, since we are training a wider student model (compared to T5 and BERT students) from randomly initialized weights on a small dataset. That said, this does not contradict our conclusions, as all layer-selection strategies still perform equally bad.

Additionally, we clarify that our work focuses on KD in the fine-tuning regime (for a certain task) instead of pretraining, due to the limited resources. It is noticed that fine-tuning is the typical setting of how most practitioners perform KD. We also mention that this paper is intended for an NLP audience, therefore non-NLP experiments (such as computer vision) are outside the scope of this work.

It is also worth mentioning that our work does not suggest intermediate-layer matching is unhelpful for KD. Rather, we present an interesting phenomenon that the layer-selection strategy plays an insignificant role in the process. We argue that future studies on layer selection should have a more rigorous comparison of its effect.

A Datasets and Models

We evaluate our layer-selection strategies on a variety of classification and generation tasks.

GLUE. The General Language Understanding Evaluation (GLUE) benchmark is a popular suite for natural language classification. From GLUE, we chose MNLI (Williams et al., 2018), QQP,[4] QNLI (Rajpurkar et al., 2016), and SST-2 (Socher et al., 2013), as these tasks have large training sets and produce robust model performance. For each task, we finetune the 12-layer $\text{BERT}_{\text{Base}}$ (Devlin et al., 2019) as the teacher. We adopted standard evaluation metrics, namely, accuracy for all tasks and F_1 as an additional metric for QQP.

DART. The DART dataset (Nan et al., 2021) is a popular data-to-text generation task. We followed Nan et al. (2021) and finetuned $\text{BART}_{\text{Large}}$ (Lewis et al., 2020) with 12 encoder and 12 decoder layers, which is the teacher model in the experiment. We report BLEU scores measuring textual overlap (Papineni et al., 2002).

WMT16 En–Ro. The WMT16 dataset (Bojar et al., 2016) provides parallel text between six different language pairs. For our experiments, we followed the setups in Wen et al. (2023), who chose the English–Romanian translation direction and used 100K from the 614K total samples for efficiency considerations. We also followed Wen et al. (2023) and finetuned 12-layer T5_{Base} (Raffel et al., 2020) as the teacher, which has the same number of layers as the DART experiment. We also report BLEU scores as the evaluation metric.

CommonsenseQA. The CommonsenseQA dataset (Talmor et al., 2019) is a question-answering task where each question is followed by five possible answers. We concatenated the correct answer with the question, then finetuned the 40-layer Qwen3-8B for next-token prediction to use as the teacher. Following Biderman et al. (2024), we use zero-shot prompting to obtain responses from the language model and report exact match with the ground truth.

HellaSwag. The HellaSwag dataset (Zellers et al., 2019) is a difficult sentence completion task that presents prefix sequence along with four possible endings. Like the previous task, we finetuned a 40-layer Qwen3-8B model for next-token prediction. We follow Biderman et al. (2024) and use the language model to rank each ending according to perplexity, conditioned on the prefix.

For the student, we adopted the teacher's architecture but reduced the number of layers to three in the main experiments. Specifically, we use teacher Layers 4, 8, and 12 for matching. Note that, for BART and T5 models, this means three layers for the encoder and another three layers for the decoder. Moreover, we employed two parameter initialization strategies for the student: randomly initializing the weights and copying the weights from the corresponding teacher layer. The former isolates the effects of intermediate-layer matching from weight copying, whereas the latter is a more practical method that yields higher performance (Sanh et al., 2019; Shleifer and Rush, 2020).

Regarding the more challenging experiments, namely HellaSwag and CommonsenseQA, we shrunk the student by the same proportions as in the main setup. Specifically, we distilled the 40-layer teacher to a 10-layer student, using Layers 4, 8, ⋯, and 40 in the teacher model for matching.

B Analysis of Student Depths

We validate our intriguing phenomenon across students with different depths. Due to the limit of computing resources, we selected MNLI as the representative classification task, but include both DART and WMT16 En–Ro generation tasks. Specifically, we experimented with student models containing three, six, and nine layers, initialized by copying the teacher's weights. As seen in Table 3, different layer-selection strategies show similar performances, confirming that the layer-selection strategies do not matter (much) across student models with various depths.

C Experimental Stability

In the main results (Table 1), excluding the Out-of-Order Random Matching setup, we ran every experiment only once due to the large number of models, tasks, and setups.

We show the stability of our results in Table 4

Table 4: Out-of-Order Random Matching experiments on MNLI, DART, and WMT16 En–Ro. For each task and parameter initialization strategy, we computed the mean and standard deviation of five runs.

by computing the standard deviation of five runs. Here, we chose Out-of-Order Random Matching because this is in theory the most noisy setup due to the stochasticity of layer matching.

In Table 4, we see that random initialization yields higher standard deviation than the weight-copied setting. This is understandable, as the former setup involves more randomness. Nevertheless, the model performs stably in both settings, showing that our results and findings are reliable.

Can LLMs Learn from Their Mistakes? Self-Correcting Instruction Tuning for Named Entity Recognition

Abstract

Recent instruction-tuned large language models (LLMs) have demonstrated remarkable performance on various downstream tasks, including named entity recognition (NER). However, previous approaches often generate incorrect predictions, particularly regarding entity boundaries and types. Many of these errors can be corrected to match the ground truth by revising the entity boundaries and/or types. In this paper, we propose a self-correcting instruction tuning approach that simultaneously learns to perform NER and correct errors through natural language instructions. Self-correcting instruction tuning requires only a standard annotated NER dataset. Supervision for self-correction can be automatically generated from error patterns observed in LLMs fine-tuned solely on NER tasks. We conducted extensive experiments on eight NER datasets with two LLMs to validate the effectiveness of the proposed approach. The results demonstrate that the proposed approach enhances NER performance by effectively correcting prediction errors and substantially reducing false positives. We further analyze the self-correction behavior to better understand how the models improve performance.

1 Introduction

Named entity recognition (NER) is a fundamental task in natural language processing that extracts entity mentions from the input text and classifies them into predefined types. Although previous studies have addressed the NER task as a sequence tagging problem (Hammerton, 2003; Lample et al., 2016; Devlin et al., 2019; Yamada et al., 2020), recent advances in large language models (LLMs) have achieved promising results by formulating it as a text generation task (Xie et al., 2023, 2024; Wang et al., 2025). Moreover, state-of-the-art approaches based on instruction tuning have further enhanced the performance of NER (Wang et al., 2023a; Sainz et al., 2024; Zhou et al., 2024; Li et al., 2024).

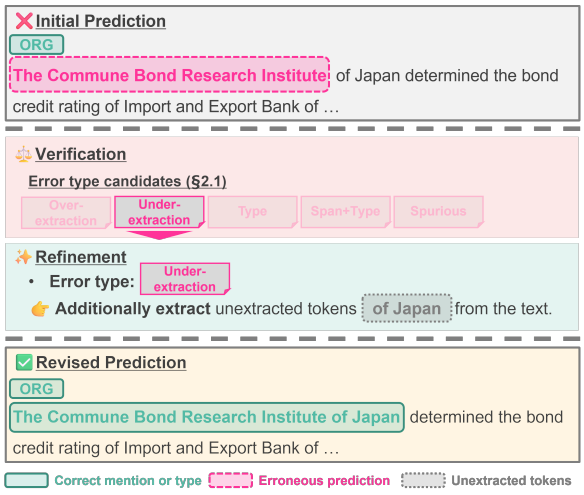

Figure 1: *Top*: Initial prediction of the fine-tuned LLM on the OntoNotes 5.0 dataset. The prediction marked with solid lines is correct, while the prediction marked with dashed lines is incorrect. *Middle*: Verification to classify the predicted entity into an error type and refinement to revise the incorrect entity based on the error type. *Bottom*: Revised prediction after the verification and refinement process.

Despite the promising results of recent approaches, LLMs still face challenges in accurately identifying entity boundaries and types. As shown in Figure 1, the model produced a plausible but incorrect prediction, even when instruction tuning was applied to the target task[1]. For instance, the predicted entity "The Commune Bond Research Institute" has incorrect span boundaries due to unextracted tokens "of Japan," while its entity type, "ORG," is correct. According to our preliminary analysis (§ 2.1), such NER errors remain prevalent.

Self-correction has recently emerged as a promising approach for improving responses generated by LLMs (Madaan et al., 2023; Kamoi et al., 2024; Gou et al., 2024; Kumar et al., 2025; Lee et al.,

[1]We employed the OLMo-2 model for this experiment from the following link: https://huggingface.co/allenai/OLMo-2-0425-1B

2025). While it has demonstrated remarkable performance on reasoning tasks (Pan et al., 2023; Chen et al., 2024; Ma et al., 2025), its application to information extraction tasks remains unexplored.

In this paper, we propose a self-correcting instruction tuning approach that simultaneously learns to extract entities and correct errors. To this end, the task of self-correcting errors consists of two stages: **self-verification** and **self-refinement**, as illustrated in the middle part of Figure 1. The self-verification stage aims to assess whether the predicted entity is correct. Additionally, it classifies the erroneous entity into a predefined error type, offering clues for the subsequent self-refinement stage. In the self-refinement stage, the model revises its prediction based on the error type identified during the self-verification stage. To implement this approach, supervision for self-correction can be automatically derived from the outputs of LLMs and the ground truth labels of NER (§ 3.4). Therefore, a **manually annotated dataset for self-correction is not required**.

This paper makes the following contributions:

- We propose a self-correcting instruction tuning approach that enables LLMs to perform NER and revise their own mistakes. With this approach, only a standard annotated NER dataset is required.
- We demonstrate the effectiveness of the proposed approach through extensive experiments on eight NER datasets using two LLMs.
- We analyze the self-correction behavior to gain deeper insights into how the proposed approach improves performance.

2 Preliminary Analyses

In this section, we conduct preliminary analyses to investigate error patterns in NER and to validate the effects regarding self-correction in NER. We begin by defining common NER error types and analyzing their distribution across predictions from several models (§ 2.1). We then investigate whether LLMs can revise their own mistakes using only intrinsic knowledge, without relying on external resources or fine-tuning (§ 2.2).

2.1 NER Error Types and Their Distributions

As described in § 1, common NER errors fall into two primary categories: entity boundary errors and type errors. Following Kim et al. (2024), we define five common error types that further detail these categories.

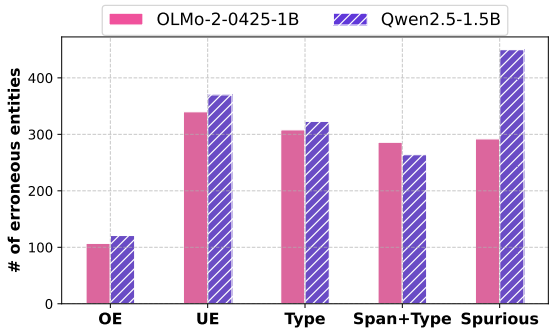

Figure 2: Distribution of NER errors on OntoNotes 5.0. Each model was fine-tuned on the target dataset using the InstructUIE framework (Wang et al., 2023a).

Over-extraction (`OE`). The predicted entity has the correct type, but its boundaries are incorrect due to unnecessary tokens.

Under-extraction (`UE`). The predicted entity has the correct type, but its boundaries are incorrect due to missing tokens.

`Type`. The predicted entity boundaries are correct, but the entity type is incorrect.

`Span+Type`. Both the entity boundaries and type are incorrect.

`Spurious`. The predicted entity does not partially match any ground truth entity boundaries.

Subsequently, we analyze the erroneous entities predicted by the fine-tuned models that appear in the actual dataset. As illustrated in Figure 2, common NER errors remain prevalent, even when models were fine-tuned on the target task. Specifically, four error types excluding `Spurious` account for 70–78% of all errors. These erroneous entities can be aligned with the ground truth by correcting entity boundaries and/or types. In contrast, `Spurious` entities that do not partially match the gold entity boundaries can be discarded to reduce false positives. These findings highlight the importance of addressing such errors to enhance model performance. Therefore, we incorporate five common error types into the self-verification stage.

2.2 Can Intrinsic Self-correction Improve NER Performance?

Self-correction has recently attracted increasing attention in the context of reasoning tasks such as arithmetic reasoning (Madaan et al., 2023), code generation (Chen et al., 2024), and logical reasoning (Pan et al., 2023). However, the potential of

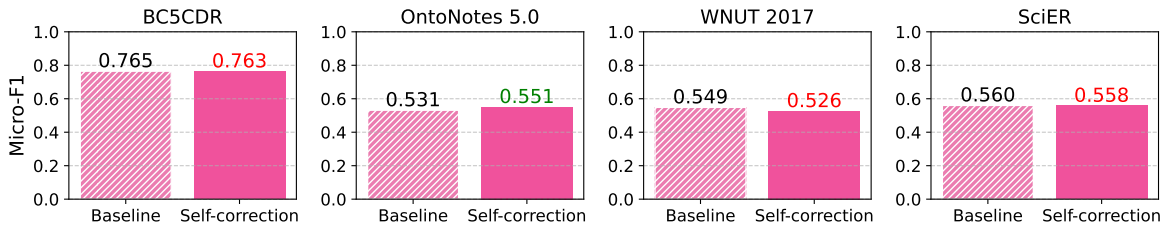

Figure 3: Performance of baseline vs. intrinsic self-correction. We used GPT-4o-mini as the LLM in the experiment. BC5CDR (Wei et al., 2016), OntoNotes 5.0 (Pradhan et al., 2013), WNUT 2017 (Derczynski et al., 2017), and SciER(Zhang et al., 2024a) were used to evaluate the effectiveness of intrinsic self-correction.

self-correction to improve information extraction remains unexplored.

In this section, we examine whether LLMs can self-correct their own mistakes in NER by relying solely on intrinsic knowledge, without access to external resources or fine-tuning. We employ GPT-4o-mini to assess its self-correction ability in NER. Figure 3 illustrates the performance of intrinsic self-correction across various NER datasets. This suggests that intrinsic self-correction still struggles to improve performance, as reported in previous work (Huang et al., 2024; Tyen et al., 2024; Kamoi et al., 2024; Zhang et al., 2025). Therefore, we are motivated to endow LLMs with self-correction capabilities via instruction tuning.

3 Method

In this section, we propose an instruction tuning approach that simultaneously learns to perform NER and correct NER errors through multi-task instruction tuning. We employ InstructUIE (Wang et al., 2023a), an architecture for instruction tuning on various information extraction tasks with natural language instructions. The overview of the proposed model is illustrated in Figure 4.

3.1 Instruction Tuning for NER

In this section, we describe a prevalent method for instruction tuning on NER. Following Wang et al. (2023a), we decompose NER into two auxiliary tasks: span extraction (SE) and entity typing (ET), which are used to train the model.

Named Entity Recognition

Formally, given an input text T and prompt P_{NER}, we aim to generate a list of named entities $S = \{s_1, \ldots, s_n\}$, where s_i is the i-th entity e_i classified with l_i, denoted as $s_i = (e_i, l_i)$. The task prompt P_{NER} consists of three parts: a task instruction I_{NER}, label candidates $L_{\text{NER}} = \{l_1, \ldots, l_M\}$, and their label descriptions $D_{\text{NER}} = \{d_1, \ldots, d_M\}$. The complete prompt is represented as $P_{\text{NER}} = [I_{\text{NER}}; L_{\text{NER}}; D_{\text{NER}}]$, where ; denotes a concatenation operator. We now summarize the input formula to the model as follows: $X = [T; P_{\text{NER}}]$. Therefore, the loss function for generating an output sequence is formalized as follows:

$$\mathcal{L} = -\sum_{t=1}^{N} \log \mathbb{P}(y_t | X, y_{<t}), \tag{1}$$

where y_t denotes a subword token of the generated sequence and N is the total number of subword tokens in the output sequence.

Span Extraction and Entity Typing

Since auxiliary tasks can be leveraged to improve NER performance (Wang et al., 2023a; Zhang et al., 2023), we employ SE as one of the auxiliary tasks. Specifically, given an input text T, task prompt $P_{\text{SE}} = [I_{\text{SE}}; L_{\text{NER}}; D_{\text{NER}}]$, and target label l_i, we define the input formula as follows: $X = [T; P_{\text{SE}}; l_i]$. Therefore, we train the model to perform entity extraction by optimizing Equation 1.

Similarly, we adopt ET as an auxiliary task to boost NER performance. In this task, given a task prompt $P_{\text{ET}} = [I_{\text{ET}}; L_{\text{NER}}; D_{\text{NER}}]$ and target mention e_i in the text T, we also describe the input formula as follows: $X = [P_{\text{ET}}; e_i]$. Finally, we train the model to perform entity typing by optimizing Equation 1. For more details, we provide the full prompts in Appendix E.

3.2 Instruction Tuning for Self-correction

Based on instruction tuning for the downstream tasks described in § 3.1, we endow the model with the ability to verify its predictions and revise its own mistakes. Following previous work in self-correction (Kamoi et al., 2024), we decompose self-correction into two primary components: self-verification (SV) and self-refinement (SR).

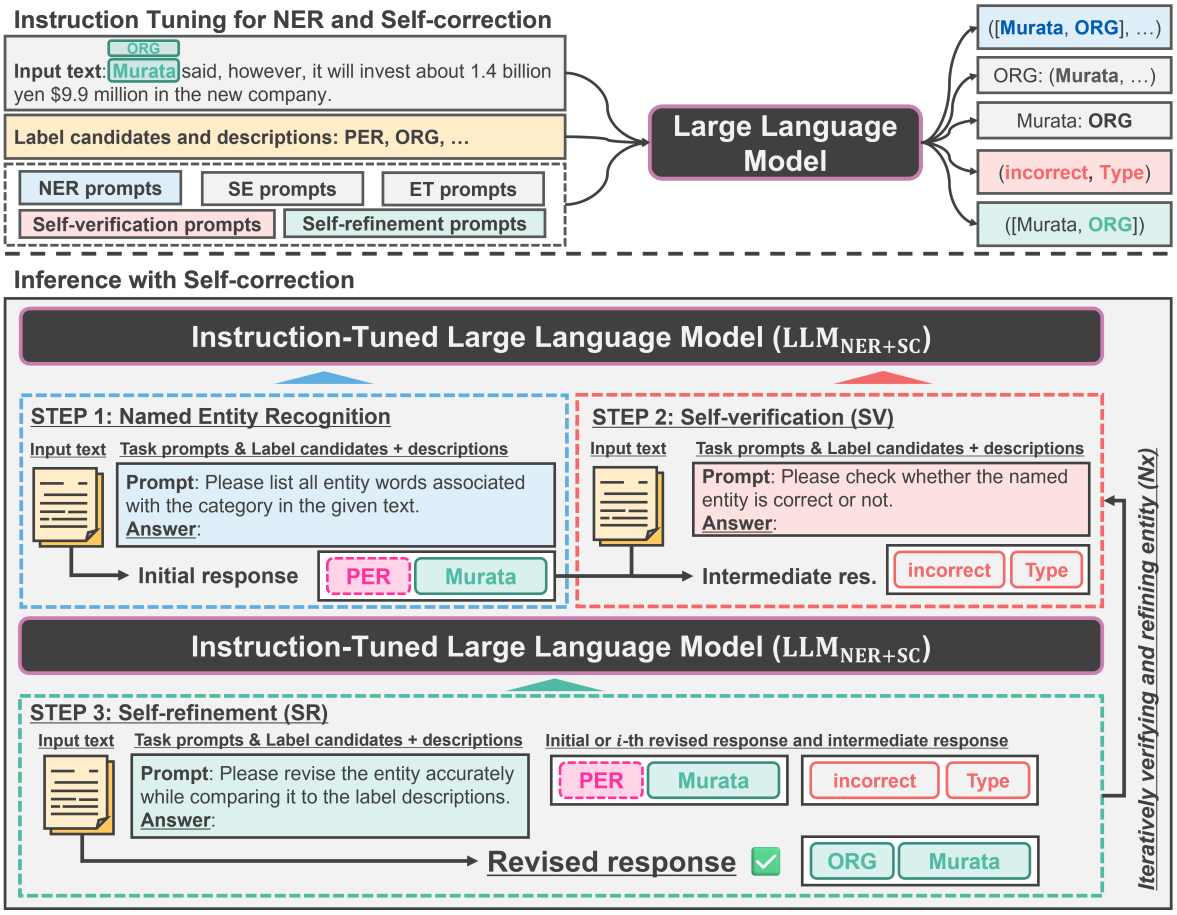

Figure 4: Overview of the proposed model. *Top*: Multi-task instruction tuning on NER and self-correction. *Bottom*: Pipeline for self-correcting NER at test time. In steps 2 and 3, the model verifies its own predictions and iteratively refines them until either the predefined number of iteration steps is reached or the prediction is verified as correct.

Self-verification

This component aims to verify whether the entity generated by the model is correct. The model further classifies its own prediction into predefined error types, as described in § 2.1. Specifically, given an input text T, task prompt $P_{\text{SV}} = [I_{\text{SV}}; D_{\text{NER}}; L_{\text{SV}}; D_{\text{SV}}]$, and predicted entity $\tilde{s}_i$, the model predicts the correctness $\tilde{v}_i$[2] and error type $\tilde{c}_i$[3] of its own prediction. Formally, given the input $X = [T; P_{\text{SV}}; \tilde{s}_i]$, we train the model to verify its own prediction by optimizing Equation 1.

Self-refinement

Finally, the incorrect entity is revised based on the error type $\tilde{c}_i$. Specifically, given an input text T, task prompt $P_{\text{SR}} = [I_{\text{SR}}; L_{\text{NER}}; D_{\text{NER}}]$, predicted entity $\tilde{s}_i$, and its verification results $\tilde{v}_i$ and $\tilde{c}_i$, the model revises its own prediction if $\tilde{v}_i$ is `incorrect` and $\tilde{c}_i$ is not `Spurious`. If $\tilde{v}_i$ is `correct`, the predicted entity is retained as the revised entity. If $\tilde{c}_i$ is `Spurious`, the predicted entity is discarded. To this end, given the input $X = [T; P_{\text{SR}}; \tilde{s}_i; v_i; c_i]$, we train the model to revise the incorrect entity by optimizing Equation 1. For more details, the full prompts are provided in Appendix E.

3.3 Inference with Self-correction

After instruction tuning on the NER and self-correction tasks, the model can perform NER more accurately by correcting its own mistakes during inference. As illustrated in the bottom part of Figure 4, the inference process consists of three components: (1) NER, (2) SV, and (3) SR.

For NER, the model generates a list of named entities $\tilde{S} = \{\tilde{s}_1, \ldots, \tilde{s}_n\}$ from the input text T as its initial response. The output sequence $\tilde{S}$ is fed into the subsequent process, SV.

In the SV stage, the model verifies its initial response $\tilde{s}_i \in \tilde{S}$ from the input text T and task prompts P_{SV} as described in § 3.2. This process yields the correctness $\tilde{v}_i$ and error type $\tilde{c}_i$ corre-

[2]The correctness candidates are `correct` and `incorrect`.

[3]The error type candidates consist of five types, as described in § 2.1 and None ($\tilde{v}_k =$ `correct`).

Algorithm 1 Self-Correction dataset creation

Require: NER dataset $\mathcal{D}_{\text{NER}} = \{\bar{d}_1, \ldots, \bar{d}_K\}$
for $i = 1$ to K **do**
  Train $\text{LLM}_{\text{NER}}^{\setminus \bar{d}_i}$ on all folds except $\bar{d}_i$
  for all u in $\bar{d}_i$ **do**
    Let S be the ground truth entities of u
    $\tilde{S} \leftarrow \text{LLM}_{\text{NER}}^{\setminus \bar{d}_i}(u)$
    for each predicted entity $\tilde{s}_k \in \tilde{S}$ **do**
      if $\tilde{s}_k \in$ ground truth S **then**
        correctness $v_k \leftarrow$ `correct`
        error type $c_k \leftarrow$ `None`
        revised entity $\hat{s}_k \leftarrow \tilde{s}_k$
      else
        $v_k \leftarrow$ `incorrect`
        $c_k \leftarrow \text{classify_error_type}(\tilde{s}_k, S)$
        $\hat{s}_k \leftarrow \text{revise_entity}(\tilde{s}_k, S, c_k)$
      end if
      Add $z = (\tilde{s}_k, v_k, c_k, \hat{s}_k)$ to $\bar{d}_i$
    end for
  end for
end for
return $\mathcal{D}_{\text{NER+SC}} = \bigcup_{i=1}^{K} \bar{d}_i$

sponding to the predicted entity $\tilde{s}_i$. We select the entity $\tilde{s}_i$ as part of the final response if the verification result $\tilde{v}_i$ is `correct`. In contrast, we discard the response $\tilde{s}_i$ classified as $\tilde{c}_i =$ `Spurious`, which cannot be revised. Otherwise, the predicted entity $\tilde{s}_i$ is fed into the subsequent process, SR.

Lastly, the model revises its initial response $\tilde{s}_i$ based on the error type $\tilde{c}_i$ and label description D_{NER} in the SR stage. The output of this stage is then fed back into the SV stage to repeatedly verify its own predictions to further improve NER performance. This repetitive process will be stopped if the predicted entity $\tilde{s}_i$ is verified as `correct`, the error type $\tilde{c}_i$ is classified as `Spurious`, or the predefined number of iteration steps is reached.

3.4 Dataset Creation for Self-correction

In this section, we construct a self-correcting NER dataset $\mathcal{D}_{\text{NER+SC}}$ using only the NER dataset $\mathcal{D}_{\text{NER}}$ and a fine-tuned NER model. Specifically, we first split the NER dataset $\mathcal{D}_{\text{NER}}$ into K-fold subsets $\mathcal{D}_{\text{NER}} = \{\bar{d}_1, \ldots, \bar{d}_K\}$. For each fold $\bar{d}_i$, we train the NER model $\text{LLM}_{\text{NER}}^{\setminus \bar{d}_i}$ on the remaining $K-1$ folds and generate a list of entities $\tilde{S} = \{\tilde{s}_1, \ldots, \tilde{s}_n\}$ using the fine-tuned model. For each entity $\tilde{s}_k$, we determine its correctness $\tilde{v}_k$, error type $\tilde{c}_k$, and revised entity $\hat{s}_k$ by comparing it with the list of gold entities S. Algorithm 1 details the dataset creation process, and dataset statistics are summarized in Appendix A.2.

4 Experiments

4.1 Datasets

To evaluate the baseline and proposed approaches, we employed eight NER datasets from T-NER (Ushio and Camacho-Collados, 2021) and SciER (Zhang et al., 2024a). The T-NER dataset includes seven NER datasets, BC5CDR (Wei et al., 2016), BioNLP 2004 (Collier et al., 2004), CoNLL 2003 (Tjong Kim Sang and De Meulder, 2003), FIN (Salinas Alvarado et al., 2015), OntoNotes 5.0 (Pradhan et al., 2013), WikiAnn (Pan et al., 2017), and WNUT 2017 (Derczynski et al., 2017), which are used to examine the effectiveness of models across various domains and label schemes in the experiment. The statistics of these datasets can be found in Appendix A.1.

4.2 Experimental Setup

Model Configurations. We employed two open-sourced LLMs, OLMo-2 (OLMo et al., 2024) and Qwen2.5 (Yang et al., 2024), as the fundamental models. We used two parameter variants, 1B/1.5B (tiny ♣) and 7B (small ♢), from the OLMo-2 and Qwen2.5 models, respectively. Additionally, we further adopted two parameter variants, 13B/14B (medium ♡) and 32B (large ♠), to assess the consistent impact of parameter scaling in LLMs (§ 4.5).

The baseline model, LLM_{NER}, was trained on NER with the auxiliary tasks (§ 3.1), while the proposed model, $\text{LLM}_{\text{NER+SC}}$, was trained on both the NER and self-correction tasks (§ 3.2). Furthermore, $\text{LLM}_{\text{NER+SC}}$ + Self-correct is a model variant that performs self-correction at test time. For instruction tuning, we adopted QLoRA (Dettmers et al., 2023) to update the parameters in LLMs due to limited computational resources. All hyperparameters in our experiments are in Appendix B.

For prediction, we employed greedy decoding to generate the output sequence of named entities, $\tilde{S} = \{\tilde{s}_1, \ldots, \tilde{s}_n\}$. Additionally, the maximum number of iteration steps in the self-correction process, as described in § 3.3, was set to 8.

Dataset Generation. To construct the self-correcting NER dataset, as described in § 3.4, we first trained the baseline models separately for each size. To collect diverse correct and incorrect predictions generated by LLMs, we applied the instruction-tuned model to each dataset using the Top-K sampling[4] (Fan et al., 2018).

[4] In this experiment, we set top-k to 40 and generated 16 diverse samples per instance.

Table 1: Experimental results of the baseline and proposed models on eight NER datasets. The shaded rows (gray) represent the baseline models trained solely on the NER task with the auxiliary tasks. The mark $\star$ indicates the proposed approach and † indicates the upper bound performance in self-correction with an oracle self-verification. The green and red values indicate increased and decreased performance compared to the baseline model, respectively.

Evaluation Metric. We employed the Micro-F1 score for a standard NER evaluation. To measure performance, we consider a predicted entity $\tilde{s}_i$ to be correct if it exactly matches any entity in the gold entities $S = \{s_1, \ldots, s_n\}$.

4.3 Results

Table 1 presents the main results. We observe that the self-correcting instruction tuning, denoted as $^{\star}\text{LLM}_{\text{NER+SC}}$, consistently improves overall NER performance on all model variants. The results suggest that incorporating self-correction as an auxiliary task during instruction tuning allows the model to identify and revise its mistakes, thereby improving base NER performance. Furthermore, applying self-correction to inference, denoted as * + Self-correct, yields further improvements in NER performance. While intrinsic self-correction does not perform well (§ 2.2), our approach improves NER performance by self-correcting errors at test time. Furthermore, our approaches show performance improvements in 81% and 75% (♣ and ♢) of the datasets, respectively. These results support the effectiveness of our approaches across various domains rather than being limited to specific ones.

4.4 Self-correction using Oracle Verification

We also assess the effectiveness of self-correction involving an oracle verifier that receives the ground truth of SV and then feeds it into the subsequent SR stage. As shown in the blue rows of Table 1, denoted as † w/ Oracle SV, these models have drastically improved NER performance across all datasets. These results indicate that the models are capable of effectively correcting their own errors when accurate SV outputs are provided. Therefore, the bottleneck of self-correction lies in SV rather than SR, which is consistent with previous work (Tyen et al., 2024). These findings motivate future work to enhance SV performance to further improve NER performance.

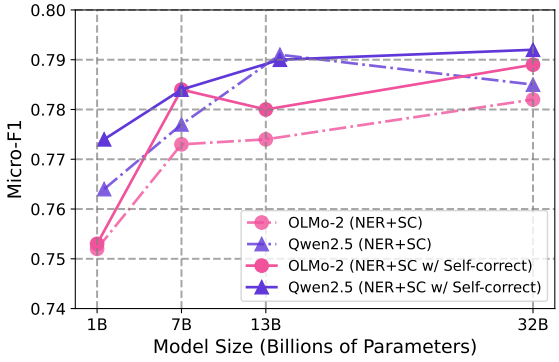

Figure 5: Performance scaling across different model sizes (averaged Micro-F1 scores over eight NER datasets). NER+SC and NER+SC w/ Self-correct refer to $^{\star}\text{LLM}_{\text{NER+SC}}$ and * + Self-correct, respectively.

4.5 Performance Scaling on Large Models

We demonstrated the effectiveness of our approach on tiny (♣) and small (♢) model sizes, as described in § 4.3. In this section, we extend the analysis to

Error type	$\text{OLMo}_{\text{NER+SC}}$	$\text{Qwen}_{\text{NER+SC}}$
None	0.919	0.928
OE	0.262	0.277
UE	0.396	0.453
Type	0.255	0.352
Span+Type	0.291	0.389
Spurious	0.528	0.591
Micro-F1	0.850	0.863
Macro-F1	0.500	0.550

Table 2: Performance of self-verification (averaged F1 scores over eight NER dataset). Tiny models (♣) are used in the experiment. Details are in Appendix D.

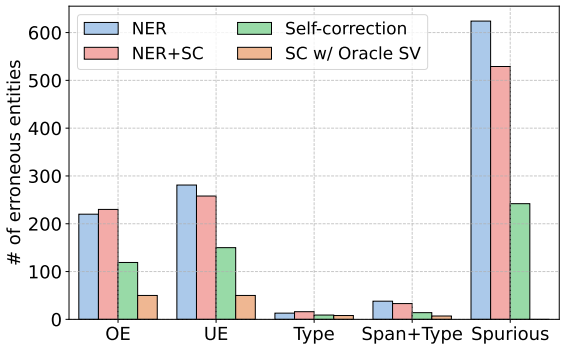

Figure 6: Distributions of erroneous entities across different error types in BC5CDR. NER, NER+SC, Self-correction, and SC w/ Oracle SV correspond to OLMo_{NER}, $\text{OLMo}_{\text{NER+SC}}$, $\text{OLMo}_{\text{NER+SC}}$ + Self-correct, and $\text{OLMo}_{\text{NER+SC}}$ + Self-correct w/ Oracle SV, respectively.

larger models, such as ♡ and ♠. As illustrated in Figure 5, our approach consistently improves NER performance as the model size increases.

5 Discussion

In this section, we analyze the self-correction behavior of our approach to gain deeper insights into the mechanisms underlying its performance improvements.

5.1 Performance of Self-verification

In § 4.4, we demonstrated that self-verification performance still has substantial room for improvement. To this end, we evaluate the performance of self-verification using two model variants, $\text{OLMo}_{\text{NER+SC}}$ (♣) and $\text{Qwen}_{\text{NER+SC}}$ (♣).

As shown in Table 2, the proposed approaches perform well on correct entities (None). However, the performance of these models on other error types (i.e., incorrect entities) remains insufficient. Unlike previous studies (Huang et al., 2024; Zhang et al., 2025), our results suggest that the proposed approach prevents the excessive refinement of correct entities. However, it still struggles to adequately revise its own mistakes. Therefore, in the subsequent section, we further analyze erroneous entities by error type in predictions.

5.2 Distribution of Erroneous Entities

Figure 6 illustrates the distribution of erroneous entities across different error types. Comparing OLMo_{NER} with $\text{OLMo}_{\text{NER+SC}}$, our approach reduces the number of erroneous entities across several error types. This indicates that self-correcting instruction tuning not only improves NER performance but also helps prevent the generation of erroneous entities. Additionally, $\text{OLMo}_{\text{NER+SC}}$ + Self-correct further reduces the generation of erroneous entities across all error types, especially Spurious. Therefore, the proposed approach contributes to further refining the LLM's predictions in NER. The detailed case study can be found in Appendix C.

5.3 Ablation Study

Role of Self-correcting Instruction Tuning

In this section, we investigate how self-correcting instruction tuning endows LLMs with the capability to understand correct and incorrect patterns in NER. As described in § 3.1, we employed two auxiliary tasks, SE and ET. These tasks are designed to enhance the model's understanding of entity boundaries and types, while self-correction aims to refine this understanding. To assess their impact, we conduct an ablation study on instruction tuning.

As shown in Table 3, we first observe that NER performance of the baseline model, OLMo_{NER}, decreases when it is trained solely on the NER task (i.e., w/o SE and ET). This indicates that the auxiliary tasks, SE and ET, play an important role in better understanding the NER task via instruction tuning.

In contrast, self-correcting instruction tuning without auxiliary tasks (i.e., w/o SE and ET) does not negatively affect NER performance. Furthermore, this result is consistent with applying self-correction at test time. These findings suggest that SV and SR tasks endow LLMs with the capability to understand not only correct and incorrect patterns in NER but also characteristics of entity boundaries and types.

Model	bc5cdr	bionlp	conll	fin	ontonotes	wikiann	wnut	scier	mean
♣ *w/o self-correcting instruction tuning*									
OLMo$_{\text{NER}}$	0.870	0.731	0.910	0.605	0.835	0.709	0.431	0.789	0.735

w/o SV	0.874	0.730	0.912	0.691	0.854	0.713	0.474	0.795	0.755
w/o SR	0.886	0.740	0.917	0.720	0.856	0.734	0.362	0.794	0.751

Table 3: Results of the ablation study on self-correcting instruction tuning (Micro-F1 scores).

Self-verification vs. Self-refinement

As shown in Table 3, we also investigate how introducing SV and SR contributes to the NER task. For the base model OLMo$_{\text{NER+SC}}$, SV and SR tasks contribute equally to the downstream task. However, when applying self-correction at test time (i.e., OLMo$_{\text{NER+SC}}$ + Self-correct), NER performance varies depending on SV performance. For the WNUT 2017 dataset, although NER performance substantially increases when applying self-correction without SV, it drastically decreases when SR alone is excluded[5]. This is because SV performance on WNUT 2017 is relatively lower than that on other datasets, as shown in Table 10. In contrast, NER performance of OLMo$_{\text{NER+SC}}$ + Self-correct is relatively high on BC5CDR, BioNLP 2004, and WikiAnn, where SV performance is also high. Therefore, the SV task plays a more critical role in correcting NER errors, enabling the model to revise its own mistakes more precisely.

5.4 Impact of Iterative Self-correction

We conduct a quantitative analysis of the trade-offs between the number of self-correction iterations and performance improvements to better understand how iterative self-correction contributes to overall performance. To this end, we used 1,000 randomly sampled instances from the entire `Dev` split of OntoNotes 5.0. For a comprehensive analysis, we employed OLMo$_{\text{NER+SC}}$ with different parameter sizes, denoted as ♣, ♢, ♡, and ♠.

As illustrated in the left part of Figure 7, the proposed approach increases NER performance by up to 1.93% after three iterations. While applying self-correction only once yields sufficient performance improvements, iterative self-correction is consistently more effective. Furthermore, since all variants reach performance saturation after four iterations, the associated computational cost is likely acceptable for real-world applications.

We further analyze the relationship between precision and recall to better understand how the proposed approach behaves during iterative self-correction. As illustrated in the middle part of Figure 7, self-correction substantially improves overall precision by up to 6.12% compared to the baseline model OLMo$_{\text{NER+SC}}$, which does not apply self-correction. However, as illustrated in the right part of Figure 7, self-correction moderately decreases recall by up to 2.51% when the number of iterations is one, resulting in a trade-off between precision and recall. Nevertheless, iterative self-correction slightly recovers its recall after two iterations, indicating that the proposed approach can revise its own mistakes arising from self-correction.

6 Related Work

6.1 Named Entity Recognition

Traditional approaches formulate NER as a sequence tagging problem, predicting the probability distribution over entity types and assigning a predefined label to each token (Hammerton, 2003; Lample et al., 2016; Devlin et al., 2019; Yamada et al., 2020). In contrast, generative approaches have been proposed to formulate NER as a text generation task (Xie et al., 2023, 2024; Wang et al., 2025). Based on instruction tuning approaches, models have shown remarkable performance in a wide range of datasets (Wang et al., 2023a; Sainz et al., 2024; Zhou et al., 2024; Li et al., 2024). However, erroneous predictions, including entity boundaries and types, remain a persistent challenge.

To address this issue, Li et al. (2023) explored

[5]The detailed inference process for self-correction without SV and SR is described in Appendix B.

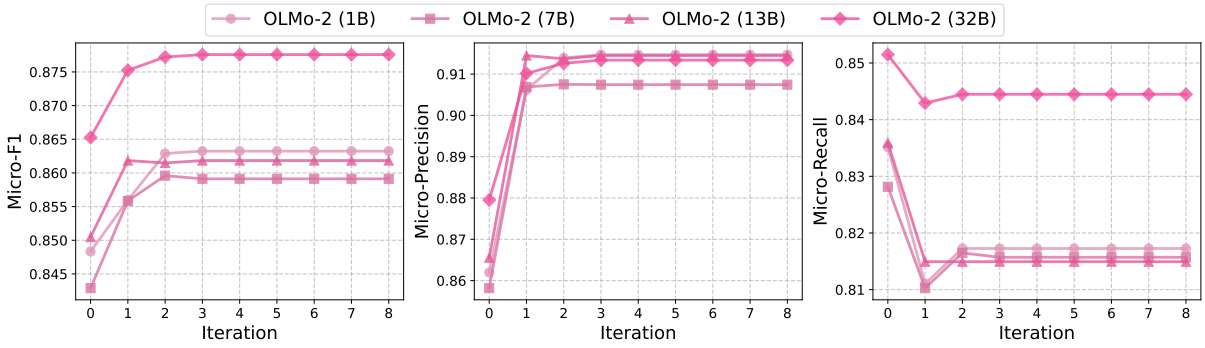

Figure 7: Performance improvements over iterative self-correction on OntoNotes 5.0. $\text{OLMo}_{\text{NER+SC}}$ with different model sizes was used in the experiments. An iteration count of 0 indicates that the model extracts entities without self-correction; for higher counts, self-correction is applied iteratively.

an approach to correct erroneous entities without re-training, by leveraging a gazetteer that maps correct entities to their types. The approach is a training-free method to revise its own mistakes, but relies heavily on the gazetteer. Meanwhile, Wang et al. (2025) introduced a self-verification strategy for NER to validate predicted entities, but it does not focus on error correction. Additionally, Kim et al. (2024) proposed a post-hoc approach to revise incorrect entities via knowledge-grounded reasoning based on self-consistency (Wang et al., 2023b). However, this approach has two shortcomings: (1) an elaborate knowledge base is not always available, and (2) self-consistency-based refinement ignores entities with minority votes.

This study focuses on correcting erroneous entities in LLMs through self-correcting instruction tuning, which enables an LLM to perform NER and correct its own mistakes. Notably, the dataset used for self-correcting instruction tuning can be constructed solely from a standard NER dataset.

6.2 Self-correction

Self-correction aims to improve responses from LLMs by verifying their own responses and refining them (Madaan et al., 2023; Chen et al., 2024; Pan et al., 2023; Gou et al., 2024; Kamoi et al., 2024; Kumar et al., 2025). Despite the significant capabilities of LLMs, recent studies have reported negative results, showing that *intrinsic* self-correction often fails to correct mistakes (Huang et al., 2024; Zhang et al., 2025). To tackle this issue, recent studies have explored the effectiveness of supervised fine-tuning (Ranaldi and Freitas, 2024; Zhang et al., 2024b; Lee et al., 2025). While these approaches have focused mainly on reasoning tasks (Pan et al., 2023; Chen et al., 2024; Ma et al., 2025), little work has explored self-correction to enhance performance in information extraction tasks, such as NER.

This study is the first attempt to explore the effectiveness of self-correction in NER through self-correcting instruction tuning.

7 Conclusion

In this paper, we proposed a self-correcting instruction tuning approach that simultaneously learns to perform NER and correct its own mistakes. Our approach requires only a standard annotated NER dataset, as supervision for self-correcting instruction tuning can be derived from the outputs of LLMs. Experimental results demonstrated remarkable performance improvements across eight NER datasets using two LLMs. We further analyzed the behavior of self-correction to better understand our approach and bridge the gap toward future research.

As future work, we first aim to improve self-verification to further enhance NER performance. We also plan to explore the application of our approach to other information extraction tasks, such as relation extraction.

Limitations

While our approach demonstrated notable performance improvements across eight widely used NER datasets and two LLMs, several limitations remain. First, the zero-shot setting, widely used in prior work to assess the generalization ability of models (Wang et al., 2023a; Sainz et al., 2024; Zhou et al., 2024), is not directly focused on this study. Therefore, our approach may be suboptimal in this scenario. We plan to evaluate the effectiveness of our approach under such conditions in

future work. Second, the iterative self-correction process at test time increases the computational cost compared to previous methods. This issue can be mitigated by adjusting the number of iterations in the self-correction process, but the trade-offs between efficiency and performance need further exploration.

Ethics Statement

This research was conducted in accordance with the ACL Ethics Policy. This study focuses on named entity recognition using self-correcting instruction tuning. We employed two open-sourced LLMs, OLMo-2 (OLMo et al., 2024) and Qwen2.5 (Yang et al., 2024), both of which are released under the Apache 2.0 license. We used them in accordance with the terms of their respective licenses. The datasets used in our experiments may contain personally identifiable information (PII), as is common in NER tasks. However, all datasets were publicly released for research purposes, and we used them strictly within that context. No manual inspection or annotation of sensitive content was performed, and our models were not trained to identify or generate personal information beyond the existing dataset annotations.

Acknowledgments

We used ABCI 3.0 provided by AIST and AIST Solutions.

A Dataset Statistics

In this section, we provide detailed statistics for each dataset used in the experiments.

A.1 NER Datasets

In this paper, we conducted comprehensive experiments on eight NER datasets, as described in § 4. For T-NER (Ushio and Camacho-Collados, 2021), the datasets were downloaded from the Hugging Face repository: `https://huggingface.co/tner/datasets`, while SciER (Zhang et al., 2024a) was obtained from the GitHub repository:

Dataset	# types	Train	Dev	Test
BC5CDR	2	5,228	5,330	5,865
BioNLP 2004	5	16,619	1,927	3,856
CoNLL 2003	4	14,041	3,250	3,453
FIN	4	1,018	150	305
OntoNotes 5.0	18	59,924	8,528	8,262
WikiAnn	3	20,000	10,000	10,000
WNUT 2017	6	2,395	1,009	1,287
SciER	3	5,575	713	854

Table 4: Dataset statistics for NER. Train, Dev, and Test indicate the number of sentences in each split.

https://github.com/edzq/SciER. For experiments and analyses, we divided each dataset into three splits: Train, Dev, and Test. We used Test split in the main experiment and ablation study, as described in § 4 and § 5.3. We also used Dev split in analyses, as described in § 2, § 5.1, § 5.2, and § 5.4. The statistics of these datasets are shown in Table 4.

A.2 Self-correction Datasets

To perform self-correcting instruction tuning, we first generated datasets to train the model, as described in § 3.4. The statistics of the generated datasets are shown in Table 5 and 6.

B Implementation Details

Training Configurations. We employed two open-sourced LLMs, OLMo-2 (OLMo et al., 2024) and Qwen2.5(Yang et al., 2024). These models can be downloaded from the following repositories: OLMo-2 (https://huggingface.co/allenai/OLMo-2-0425-1B) and Qwen2.5 1.5B (https://huggingface.co/Qwen/Qwen2.5-1.5B), respectively. We used these models via the Hugging Face Transformers library (Wolf et al., 2020). For instruction tuning, we employed QLoRA (Dettmers et al., 2023) with $\alpha = 128$ and $r = 64$ to update the learnable parameters in LLMs. The models were trained for 3 epochs using the AdamW optimizer (Loshchilov and Hutter, 2019) with a batch size of 32 and a learning rate of 2×10^{-5}. We used a cosine learning rate schedule with a warmup ratio of 0.1. To avoid overfitting, we applied early stopping based on the NER Micro-F1 score. We trained the model on a single NVIDIA H200 GPU, which took approximately 3 to 32 hours[6] to complete 3 epochs. To reduce computation time during instruction tuning, we employed the Unsloth library (Daniel Han and team, 2023).

Inference Configurations. For inference, we used greedy decoding to generate named entities, their verification results, and their revisions. The maximum number of subword tokens was set to 128, 12, and 16 for NER, SV, and SR, respectively. In § 5.3, self-correction without SV directly revises all predicted entities once. Additionally, self-correction without SR applies only the SV component after NER prediction. Specifically, a predicted entity is discarded if the SV component predicts the verification result $\tilde{v}_i$ as incorrect, and included in the final outputs if $\tilde{v}_i$ is predicted as correct.

[6]The training time depends heavily on the model and dataset sizes.

C Case Study

In this section, we present and discuss representative case studies that shed light on the model's strengths and limitations.

UE error correction. Table 7 presents an example of UE error correction. The baseline model, OLMo_{NER}, fails to extract any correct entities. In contrast, the proposed model, $\text{OLMo}_{\text{NER+SC}}$, successfully extracts the correct entity ('STZ', 'chemical'), although an incorrect one is also extracted. The proposed model with self-correcting inference, $\text{OLMo}_{\text{NER+SC}}$ + Self-correct, retains only the correct entity while the incorrect entity is discarded during the self-verification process. Since the error type of the discarded entity is UE which can be revised during self-refinement, designing a more accurate refinement process is left for future work.

Type error correction. Table 8 presents an example of Type error correction. Although the baseline model generates the correct span boundaries, it misclassifies their types. The proposed model $\text{OLMo}_{\text{NER+SC}}$ successfully recognizes entity mentions and classifies them with the correct type. This demonstration suggests that self-correcting instruction tuning enables LLMs to better understand the characteristics of entity types, as discussed in § 5.3.

Spurious error correction. Table 9 represents an example of Spurious error correction. The baseline model extracts an incorrect entity, which has no partial overlap with any ground truth entity. On the other hand, the proposed model, $\text{OLMo}_{\text{NER+SC}}$, successfully extracts correct entities that are missed by the baseline model. Furthermore, the proposed model with self-correcting inference, $\text{OLMo}_{\text{NER+SC}}$ + Self-correct, also extracts correct entities while discarding the incorrect entity classified as Spurious.

E Prompts

We provide comprehensive prompts for each task as listed in Table 12 and 13. As described in § 3, each prompt consists of the following components: (1) task instruction I, (2) label candidates L, and (3) label descriptions D. These prompts were used during training and inference phases.

Prompts for NER on SciER (Zhang et al., 2024a)	
Task instruction I_{NER}	Please list all the entity words associated with the category in the given text. Output format should be {'ner': [['entity', 'type'], ['entity', 'type'],...]}
Label candidates L_{NER}	The entity type candidates are `dataset`, `task`, and `method`.
Label description D_{NER}	The descriptions of each label are as follows: `dataset`: A realistic collection of data that is used for training, validating or testing the algorithms. These datasets can consist of various forms of data such as text, images, videos, or structured data. For example, MNIST, COCO, AGNews, IMDb, etc. `task`: A task in machine learning refers to the specific problem or type of problem that a ML/AI model is designed to solve. Tasks can be broad, like classification, regression, or clustering, or they can be very specific, such as Pedestrian Detection, Autonomous Driving, Sentiment Analysis, Named Entity Recognition and Relation Extraction. `method`: A method entity refers to the approach, algorithm, or technique used to solve a specific task/problem. Methods encompass the computational algorithms, model architectures, and the training procedures that are employed to make predictions or decisions based on data. For example, Convolutional Neural Networks (CNNs), Dropout, data augmentation, recurrent neural networks, etc.
Prompts for SE on SciER (Zhang et al., 2024a)	
Task instruction I_{SE}	Please list all entity words in the text that fit the target label described below. The target label to extract entities is `[PLACEHOLDER]`. Output format should be {'se': [['entity', 'type'], ['entity', 'type'],...]}
Label candidates L_{NER}	Same as NER (L_{NER}).
Label description D_{NER}	Same as NER (D_{NER}).
Prompts for ET on SciER (Zhang et al., 2024a)	
Task instruction I_{ET}	Given options, please list all entity types of all the listed entity words. Output format should be {'et': [['entity', 'type'], ['entity', 'type'],...]}
Label candidates L_{NER}	Same as NER (L_{NER}).
Label description D_{NER}	Same as NER (D_{NER}).

Table 12: Prompts for the NER, SE, and ET tasks on SciER. The variable `[PLACEHOLDER]` in I_{SE} is replaced with the target label l_i. Label candidates and their descriptions in the SE and ET tasks are omitted, as these prompts are same as NER.

Prompts for SV on SciER (Zhang et al., 2024a)	
Task instruction I_{SV}	Given the input text, label candidates, and their descriptions, please check whether or not the named entity which is given as the input is correct. Additionally, if the named entity is incorrect, please classify the error type of the incorrect entity from the given options. Note that the output of the error type should be `None` if the entity is correct. The output should be in the JSON format like this: {'sv': (`CORRECTNESS`, `ERROR_TYPE`) } - `CORRECTNESS`: `correct` or `incorrect` - `ERROR_TYPE`: `Over-extraction`, `Under-extraction`, `Type`, `Span+Type`, `Spurious`, or `None`
Label description D_{NER}	Same as NER (D_{NER}).
Label candidates L_{SV}	The correctness candidates are `correct` and `incorrect`. The error type candidates are `Over-extraction`, `Under-extraction`, `Type`, `Span+Type`, `Spurious`, and `None`.
Label description D_{SV}	The definitions of each error type are as follows: `Over-extraction`: The type of input entity is correct but the input entity includes redundant tokens compared with the gold entity so that several tokens should be discarded. `Under-extraction`: The type of input entity is correct but the input entity lacks several tokens that are included in the gold entity so that several tokens from the input text should be added. `Type`: The input entity is exactly matched to the gold entity but the type of the input entity is incorrect compared with the type of the gold entity. `Span+Type`: Both the input entity and its type is incorrect. `Spurious`: A completely incorrect entity that gold annotation does not exist.
Prompts for SR on SciER (Zhang et al., 2024a)	
Task instruction I_{SR}	Given the entity extracted from the input text, please revise the entity correctly while carefully comparing the entity to the label descriptions. Note that the output should be the same for the input entity if the entity was correct (i.e., no need to revise). The output should be in the JSON format like this: {'sr': ('entity', 'type')}
Label candidates L_{NER}	Same as NER (L_{NER}).
Label description D_{NER}	Same as NER (D_{NER}).

Table 13: Prompts for the SV and SR tasks on SciER. Label candidates and their descriptions in the SV and SR tasks are omitted, as these prompts are same as NER.

OPTAGENT: Optimizing Multi-Agent LLM Interactions Through Verbal Reinforcement Learning for Enhanced Reasoning

Abstract

Large Language Models (LLMs) have shown remarkable reasoning capabilities in mathematical and scientific tasks. To enhance complex reasoning, multi-agent systems have been proposed to harness the collective intelligence of LLM agents. However, existing collaboration structures are either predefined or rely on majority voting or round-table debates, which can suppress correct but less dominant agent contributions. Recent approaches model multi-agent systems as graph networks but optimize purely for agent performance, neglecting the quality of interactions. We hypothesize that effective agent communication is crucial for multi-agent reasoning and that debating quality plays a significant role. To address this, we propose OPTAGENT, a multi-agent verbal reinforcement learning algorithm that dynamically constructs and refines multi-agent collaboration structures. Our method defines action spaces and a feedback mechanism that evaluates communication robustness and coherence throughout the debate. The final decision is achieved through a majority vote over all the agents. We assess OPTAGENT on various reasoning tasks, including mathematical reasoning, creative writing, scientific reasoning, and numerical sorting. Results demonstrate that our approach significantly outperforms single-agent prompting methods and state-of-the-art multi-agent frameworks on diverse tasks.

1 Introduction

Large Language Models (LLMs) have exhibited significant potential in reasoning across various downstream tasks, including elementary mathematical reasoning, and fundamental science reasoning (Brown et al., 2020; Dubey et al., 2024; Wei et al., 2022; Wang et al., 2023b). Despite these initial successes, existing methodologies necessitate meticulously crafted prompt strategies that are often fixed for certain tasks (Yao et al., 2023; Besta et al., 2024). This approach lacks flexibility, as the users have to define different prompts under different scenarios, especially for complex reasoning tasks. A promising solution that mitigates the challenge is to explore multi-agent frameworks that capitalize on the strengths of LLM-based agents. Researchers proposed many multi-agent reasoning frameworks that enable collaborative debates among multiple LLM agents (Chan et al., 2023; Liang et al., 2024; Chen et al., 2023b; Wang et al., 2023a; Chen et al., 2023a), which are akin to human group problem-solving scenarios.

Despite these initial successes, existing multi-agent LLM reasoning methods often follow predefined or simple group chatting collaboration structures. For example, AutoGen (Wu et al., 2023) and ChatEval (Chan et al., 2023) employs pre-defined collaboration structures; ReConcile (Chen et al., 2023b) employs group discussion with confidence-based consensus decision; MAD (Liang et al., 2024) employs group debate with a meta-summarizer as the decision-maker. These methods do not account for the varying interactions of differently profiled agents, nor do they optimize the sequence of communications to ensure the most effective information flow for specific tasks. As a result, correct but less dominant agent contributions could be overlooked. We believe the interaction schemas should be more flexible and further optimized for task-specific communication efficacy.

Recent trends in multi-agent collaboration emphasize using graph optimization techniques to enable flexible, task-adaptable coordination among agents, enhancing efficacy and scalability in complex environments. Specifically, GPT-Swarm (Zhuge et al., 2024) conceptualizes the multi-agent framework as a computational graph. The inspiration is drawn from a "Society-of-Mind" concept and highlights the communication and collaboration among agents. For optimization, the authors use reinforcement learning to optimize the agent interactions. While previous methods show rea-

Proceedings of the 14th International Joint Conference on Natural Language Processing and the 4th Conference of the Asia-Pacific Chapter of the Association for Computational Linguistics, pages 1713–1728
December 20-24, 2025 ©2025 Association for Computational Linguistics

sonable performance, they tend to overlook the agents' debate quality, an important aspect of a multi-agent framework. We hypothesize that the interaction quality between the agents should also play an important role in the optimization process. More specifically, we believe the optimization algorithms should also consider metrics like wording clarity and logical coherency apart from agent performance metrics.

To tackle the above challenges, we propose OPTAGENT, an LLM-based Verbal Reinforcement Learning framework for Graph Optimization on multi-agent collaboration. The goal of OPTAGENT is to find the most effective interaction patterns in a multi-agent collaboration graph. OPTAGENT explicitly considers communication quality when identifying the most effective connections between agents. To refine the multi-agent collaboration structure, OPTAGENT contains a feedback agent that evaluates the quality of the agent interactions and an action agent that updates the multi-agent collaboration graph based on the feedback. The final decision is achieved through a majority vote over all the agents. We evaluate OPTAGENT on various downstream reasoning tasks, including mathematical reasoning, scientific reasoning, creative writing, and sorting tasks. Our experimental results demonstrate that OPTAGENT significantly outperforms single-agent prompting methods and state-of-the-art multi-agent debating schemas on diverse reasoning tasks across various LLM families. We also present a case study to illustrate the efficacy of our framework.

2 Related Work

LLM Reasoning Prompting The field of large language models (LLMs) has seen significant advancements in recent years, particularly in the area of reasoning prompting. Various prompt engineering methods have been developed, aiming to improve large language models' reasoning ability across various tasks and domains. Chain-of-thought (CoT) prompting (Wei et al., 2022) prompts the large language models (LLMs) to divide their reasoning process into smaller steps when solving a question, forming a chain of thoughts. Chain-of-thought self-consistency prompting (Wang et al., 2023b) improves on the CoT method by proposing different reasoning chains and ensembles on the final result. Tree-of-thought (ToT) prompting method (Yao et al., 2023) actively maintains a tree of thoughts, where each thought is a coherent language sequence that serves as an intermediate step toward problem-solving. Graph-of-thought (Besta et al., 2024) further improves ToT by constructing a Directed Graph instead of a tree. LLMs can loop over a thought to refine it and aggregate thoughts or chains. There are also other X-of-thought prompting methods developed for various different downstream tasks and datasets (Chen et al., 2023c; Sel et al., 2024; Bi et al., 2024; Jin et al., 2024). Another notable contribution to the field is the systematic survey on prompting techniques by the Prompt Engineering Guide (Schulhoff et al., 2024). This survey categorizes various prompting methods and their applications, emphasizing the importance of prompt design in enhancing LLM reasoning.

Multi-Agent Reasoning Recent advancements in large language model (LLM) multi-agent frameworks have garnered significant attention in the field of artificial intelligence. Studies such as Wu et al. (2023); Chen et al. (2023a); Lu et al. (2024) have highlighted the impressive reasoning capabilities of LLMs, which have been leveraged to create autonomous agent systems that are capable of complex problem-solving and perform better than single agents.

The question is how researchers can design effective multi-agent reasoning frameworks. There have been several studies and analyses on the efficiency and effectiveness of multi-agent debating systems over reasoning tasks (Wang et al., 2023a, 2024; Pezeshkpour et al., 2024). However, most of the interaction schemas and decision strategies are either pre-defined (Wu et al., 2023; Chan et al., 2023), or follow a simple structure such as group debate, majority voting, summarizer decision, or a combination of the above strategies (Chen et al., 2023b; Liang et al., 2024; Chan et al., 2023). Recently, several researchers from KAUST proposed GPTSwarm (Zhuge et al., 2024), in which they suggest that the multi-agent system can be considered as a graph network and thus their interaction patterns can be optimized by optimization algorithms. They also conduct individual optimizations on agents by conducting prompt optimization. However, their optimization is heavily performance-oriented, overlooking the debating quality of the agents. This is something that should also be considered in LLM free generation.

3 OPTAGENT Framework

3.1 Problem Definition

Given a problem P, and N LLM agents $A_1, A_2, ..., A_N$, our goal is to find the answer to question P. We achieve this goal through using LLMs as agents to conduct logical reasoning and structured discussions. Each agent is a distinctly prompted LLM capable of generating the answer and the corresponding CoT reasoning process.

3.2 Framework Overview

In our setting, we view the multi-agent collaboration framework as a graph. Each agent is a node in the graph, denoted by A_i; the communications between agents are the edges, denoted by e_{ij}. We hypothesize that the interaction quality will be different for differently profiled agents, and the best connection order would allow the best information propagation pattern for a particular task. The goal of OPTAGENT is to optimize the connections between the agents and improve the overall performance of the multi-agent collaboration framework.

In our verbal reinforcement learning process, we design two meta agents, $LLM_{reflect}$ and LLM_{act}. which handle reflection and action processes, respectively. The training process involves selecting connections based on probability scores and updating them through reinforcement learning. Finally, a majority voting strategy is used to determine the final answer after executing the graph.

3.3 Initial Graph Setup

Agent Profiling and Force Decoding Given a group of LLM agents $A_1, ...A_i$, we ensure similar but different reasoning by assigning the agents with the same baseline reasoning prompt but different agent profiles in system prompts (see Appendix B). The seven agent profiles were manually crafted to reflect common reasoning strategies found in human problem-solving, such as deductive logic, intuition, and domain expertise. For the 3-agent and 5-agent scenarios, we randomly select 3 and 5 profiles from the proposed profiles, respectively. To promote versatility, we force the model to generate three different outputs for each agent profile and randomly choose one of the outputs as its initial answer to the input question.

Connection Initialization Given a group of agents $A_1, ...A_i$, and possible connections between the agents $e_{12}, ..., e_{ij}$, we first get the group of utility scores $u(A_i)$, which is the average self-evaluated confidence score given by the agent A_i for the given task. We first randomly sample ten problems from the dataset, collect the confidence score from each agent on each question, and then calculate the average confidence score $u(A_i)$.

Then, we calculate the connection score of an edge, $s(e_{ij}) = u(A_i) * u(A_j)$, which is determined by the utility score of the two connecting nodes. We will update the connection scores during the reinforcement learning process. Based on all of the connection scores, we assign the probability, $p(e_{ij}) = \frac{s(e_{ij})}{\sum s(e_{ij})}$ to each connection e_{ij}, which is the proportion of the connection score $s(e_{ij})$ to the sum of the connection scores. The probabilities will serve as selection references in the first epoch of our training process.

3.4 Verbal Reinforcement Learning

Inspired by the Reflexion framework (Shinn et al., 2023), we design an LLM self-controlled verbal optimization for graph generation. First, we design two meta agents: $LLM_{reflect}$ and LLM_{act}. We also create a set of action spaces that LLM_{act} can choose from to alter the current graph network.

Reflection $LLM_{reflect}$ is responsible for generating reflection text after LLM_{act} makes a connection between two agents (A_i, A_j). Here, a 'connection' means initiating direct communication between two agents, prompting them to exchange their initial reasoning and answers, debate their points of view, and revise their reasoning based on the exchange. To generate the feedback, $LLM_{reflect}$ takes in the reasoning arguments of A_i and A_j before and after the interaction process. Then, the reflection text is passed on to LLM_{act} to guide its decision-making process. Specifically, the feedback that $LLM_{reflect}$ generates is determined by two criteria:

- **Criterion 1**: Both agents should answer the question correctly after making the connection;
- **Criterion 2**: Agents should be logical and coherent in their reasoning process.

For the first criterion, $LLM_{reflect}$ checks whether the connection helps agent A_i and A_j with answering the question. If both agents got the answer correct, then $LLM_{reflect}$ will give positive feedback. For the second criterion, $LLM_{reflect}$ checks whether the logical chains are sound and valid. If

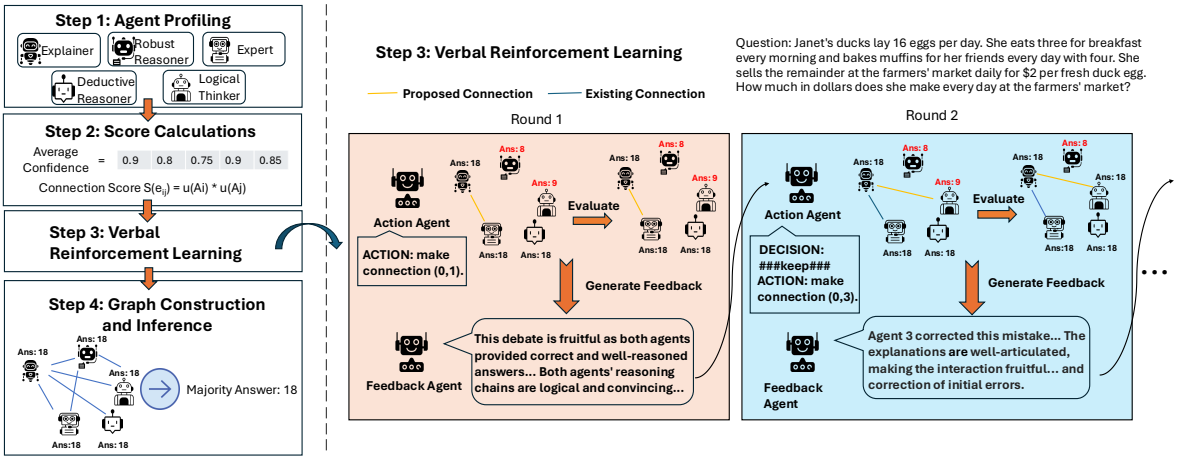

Figure 1: Overview of OPTAGENT framework. The overall pipeline is on the left side; an example process for verbal reinforcement learning is shown on the right.

both agents demonstrate good reasoning quality during the interaction process after seeing each other's reasoning, $LLM_{reflect}$ will give out good feedback. Otherwise, $LLM_{reflect}$ will have negative feedback on the connection (A_i, A_j). Detailed instruction prompts for $LLM_{reflect}$ are provided in Appendix B.

Action LLM_{act} is responsible for conducting actions at each step, from the pre-defined action pool:

- Make a connection between the two agents (A_i, A_j) to initiate debate;
- Keep a previously made connection (A_n, A_m);
- Delete a previously made connection between the two agents (A_n, A_m) to prohibit debate.

After LLM_{act} receives the verbal feedback, it will make a decision to keep or delete the previously made connection. For instance, if LLM_{act} decided to make a connection (A_i, A_j) but consequently received negative feedback in this round, then LLM_{act} would remove the connection. We decrease their connection score $s(e_{ij})$ for removed connections. If LLM_{act} receives positive feedback, it will keep the connection (A_i, A_j) in the graph, and we increase the connection score $s(e_{ij})$. Before deciding whether or not to keep the current edge, LLM_{act} would also look back at the feedback history of the current edge in previous rounds.

After the decision, LLM_{act} makes a connection that hasn't been explored during the current training epoch. The result of the newly created connection will be evaluated and passed on to $LLM_{reflect}$ for the next round of reflection text generation.

3.5 Training Process

To start the Reinforcement learning process, we perform weighted random sampling to select a connection (A_i, A_j) based on the probability score of the connections. At later epochs, LLM_{act} is responsible for choosing a connection (A_i, A_j). After LLM_{act} takes action, we execute the debate process between A_i and A_j, and then pass the results to $LLM_{reflect}$ for feedback, which is then given to LLM_{act} for decision-making. We update the connection score e_{ij} after LLM_{act} has decided whether to keep the connection (A_i, A_j). The connection score $s(e_{ij})$ is increased by $\alpha * \hat{s}(e_{ij})$ if LLM_{act} chooses to keep it and decreases otherwise, where α is the learning rate we set, and $\hat{s}(e_{ij})$ is the current connection score of connection e_{ij}. We repeat the above process in the current epoch until every connection is visited once for an update. The pseudocode algorithm is provided in Algorithm 1 in the Appendix.

3.6 Inference Process

After the framework is trained with the connection weights updated, we construct the final graph before doing inference. Connections with higher scores are established first. The construction process continues until all agents have been visited. We consider the information flow within the graph as complete when each agent A_i has interacted with at least one other agent A_j. The final decision is determined using a majority voting strategy as the final answer $Ans_{final} = mode(Ans_1, ..., Ans_n)$, where $Ans_1, ..., Ans_n$ are answers provided by different agents in the graph. The pseudocode algorithm is provided in Algorithm 2 in the Appendix.

4 Experiments

4.1 Experimental Setup

Dataset and Tasks We experiment OPTAGENT on four downstream tasks: math reasoning, creative writing, science reasoning, and sorting. All experiments were tested on publicly available datasets. For the math reasoning task, we use two datasets: GSM8K (Cobbe et al., 2021), which contains grade school arithmetic questions, and MATH (Hendrycks et al., 2021), which contains high school-level mathematical questions spanning six different fields. We also include two adversarial reasoning datasets that are built on GSM8K: AdversarialGSM (Xie et al., 2024) in which we will refer to as AdvGSM in Table 4, and GSM-PLUS (Li et al., 2024b). AdvGSM contains questions that are changed only in number magnitude, and have three levels of difficulties, with M3 being the easiest using same magnitude with GSM8K, and M1 being the hardest. For each of the reasoning datasets except AdvGSM, we randomly select 100 questions from the dataset for evaluation. For AdvGSM, we randomly select 100 questions from each magnitude for evaluation. For creative writing, we follow the setup in (Yao et al., 2023), where we test on 100 examples. For sorting, we randomly generate 100 numerical sequences at length 8, 16, 32.

Model and Implementation We experiment the baselines and OPTAGENT utilizing GPT-3.5-turbo (Brown et al., 2020), GPT-4o (OpenAI, 2023), and the LLaMa 3.1-70B model (Dubey et al., 2024). We directly call model APIs for prompting. For all models, we set the temperature to 0.5, and top_k to 1.0. All base agents are prompted with the 0-shot CoT prompt. For each dataset, we train OPTAGENT on three randomly sampled data points and report the performance on randomly sampled evaluation sets. We run OPTAGENT three times and report the mean performance. We use majority voting as our final decision strategy and random choice when there is a tie. We provide a cost analysis under the 5-agent scenario in Appendix C.

Baselines We compared OPTAGENT with six single-agent prompting methods and state-of-the-art multi-agent baseline methods as below:

- **Single Model Prompts** in which we include 3 prompts: **DirectIO**, where we ask the model for a direct answer without explanations; **0-Shot CoT**, where we ask the model to provide step-by-step reasoning without providing any demonstrating examples; **ToT**, where we follow Yao et al. (2023) and implement their framework.
- **Simple Debate**, where we initiate several instances of non-profiled agents with the same 0-shot CoT prompt. The agents are provided with each other's reasonings and answers, and are asked to reflect on their own reasoning. We let models debate for 2 rounds and utilize a majority voting to decide the final answer.
- **GPTSwarm** (Zhuge et al., 2024), where we follow the original implementation. We train the framework using three randomly sampled data points from the dataset and report the performance. We run GPTSwarm three times and report the mean performance.
- **ReConcile** (Chen et al., 2023b), where we follow the original implementation, using GPT-3.5-turbo and GPT-4o models as backbone, respectively. We report their performance in mathematical reasoning datasets. We run ReConcile three times and report the mean performance.

4.2 Evaluation Metrics

Math and Science reasoning We report the performance in terms of accuracy following prior benchmarks and papers. The datasets include GSM8K, AdvGSM, GSM-PLUS, MATH, ARC and GPQA. We report the detailed post-processing and evaluation description in the Appendix.

Creative Writing We follow the metrics in Yao et al. (2023) and report the performance in terms of Coherence score, which another GPT-4 model evaluates. We provide the evaluation prompt in Appendix B.

Sorting We follow the metrics in Besta et al. (2024) and report the performance in terms of error scope, defined by the sum of the number of wrongly sorted elements and missing elements.

4.3 Main Results

Math Reasoning We compare OPTAGENT with multi-agent simple debating baselines on Math Reasoning datasets in Table 1. The backbone LLMs (i.e., the primary large language model underlying all agents) include GPT-3.5-turbo and LLaMa 3.1-70B. OPTAGENT performs better on the original datasets like GSM8K and MATH than the simple debating baselines, and significantly outperforms

Model	Prompt Class	Framework Type	GSM8K	AdvGSM-M3	AdvGSM-M2	AdvGSM-M1	GSM-PLUS	MATH

Table 1: Main results table on Math Reasoning Task. The best-performing methods on each dataset under each number-of-agent scenario are bolded, and the second-best are underlined. The plus-minus signs (±) means standard deviations across the three runs. The results below OPTAGENT represent the variants of OPTAGENT framework. The detailed setting and discussion are presented in Section 4.4.

Multi-Agent Framework	GSM8K	GSM8K-M3	GSM8K-M2	GSM8K-M1	GSM-PLUS	MATH
3 GPT-3.5-turbo	82.0	**91.0**	82.0	34.0	**65.0**	29.0
1 LLaMa3.1 70B + 2 GPT-3.5-turbo	83.0	87.0	**84.0**	**35.0**	63.0	33.0
2 LLaMa3.1 70B + 1 GPT-3.5-turbo	84.0	83.0	73.0	34.0	61.0	**34.0**
3 LLaMa3.1 70B	**92.0**	71.0	56.0	26.0	62.0	33.0

Table 2: Mixture of Model Ablation Task. All the multi-agent frameworks are optimized with OPTAGENT.

the single-agent baselines. The performance increase is more prominent in 5-agent scenarios compared with 3-agent scenarios. We also present the results of two adversarial datasets in column 5 to 8. OPTAGENT demonstrates robustness in the adversarial math reasoning datasets, outperforming the baseline scheme and frameworks by a similar margin compared with the original datasets.

We also conduct experiments on the mathematical datasets with GPT-4o as the backbone model. With enhanced reasoning ability, even the simple debating method performs near-perfectly on basic math reasoning datasets. We still see a slight performance increase using the multi-agent debating frameworks on more challenging datasets.

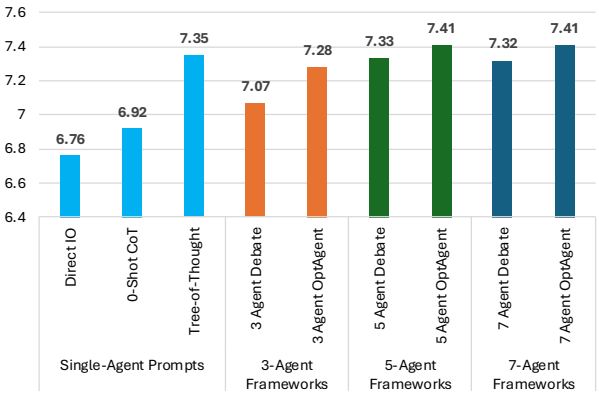

Figure 2: Results on Creative Writing, measured in terms of coherence scores.

Creative Writing Results for creative writing task is reported in Figure 2. OPTAGENT increase the coherence score by an average of at least 0.05 points across different settings under this task. Compared with Tree-of-Thought, which used a single model to explore different branches, OPTAGENT achieves slightly better performance. Increasing the number of agents only brings marginal performance improvement, and adding more agents from 5 to 7 does not seem to help with the perfor-

Number of Agents	Framework Type	GSM8K	GSM8K-M3	GSM8K-M2	GSM8K-M1	GSM-PLUS	MATH

mance of the multi-agent framework.

4.4 Ablation Study

Training Convergence We provide additional study on framework convergence trend in Figure 3. Each epoch is one full update of all the potential connection scores over the dataset. Empirical results show that after three epochs, the performance gain would be minimal across datasets. The results suggest that the basic reasoning abilities of the agents greatly affect the learning process; on harder datasets, the agents have difficulties forming high-quality answers and interactions, leaving little room for performance improvement. Other research works on Multi-Agent LLM frameworks (Motwani et al., 2025; Li et al., 2024a; Smit et al., 2024) also exhibit this phenomenon, where the improvement in GSM8K is higher than that of MATH.

Train Without Interaction Quality In this experiment, we study the effect of considering interaction quality by asking LLM_{act} to consider only correctness instead of interaction quality when training. The results are demonstrated in Table 1. Under the 5-agent scenario, considering only accuracy in training time would hurt the performance, suggesting that considering interaction quality between agents LLM_{act} plays a vital role in the training process. Under the 3-agent scenario, the performance stayed roughly the same, since the agents' profiles and interactions between the agents are more limited than in the 5-agent scenario.

Forced Generation and Random Initial Output Sampling We examine the impact of forced generation, where each agent generates multiple outputs using stochastic decoding, and one is randomly selected. The results are demonstrated in Table 1. Removing this (i.e., using greedy decoding) significantly reduced reasoning diversity and performance under both 3-agent and 5-agent scenarios.

Split Agent LLM_{act} In this study, we split LLM_{act} into two agents: $LLM_{propose}$, which is responsible for proposing the new connections; and LLM_{decide}, which is responsible for deciding whether or not to keep an edge. $LLM_{reflect}$ will interact with LLM_{decide} only. $LLM_{propose}$ would be provided with a summary of the conversation history between $LLM_{reflect}$ and LLM_{decide}. We do not see much performance difference across datasets under this setting compared with OPTAGENT, which used a single agent LLM_{act}, for the 3-agent and the 5-agent scenario.

Reconsidering Minority In this setup, if one agent gets a unique answer while the other agents all got the same majority answer, the unique answer would be considered as a "minority", and we would prompt a group discussion on the unique answer first before executing the graph. From the results in Table 1 as well as the upper-bound analysis results in Table 7, we can see that this strategy brings up the performance in datasets where we have a bigger gap between OPTAGENT and the theoretical upper-bound performance. It suggests that the models that had the wrong reasoning will be able to catch their mistakes from this discussion process.

Mixture of Models as Agents Table 2 shows the results of using different backbone models as agents in OPTAGENT under the 3-agent setting. On adversarial datasets where GPT-3.5-turbo performs better than LLaMa3.1, we observe that the performance of OPTAGENT using GPT-3.5-turbo as the backbone model is better than using LLaMa3.1

Number of Agents	Framework Type	GSM8K	GSM8K-M3	GSM8K-M2	GSM8K-M1	GSM-PLUS	MATH
3-Agent	Simple Debate	77.0	90.0	79.0	31.0	62.0	25.0
	+Profiling	82.0 (+5.0)	90.0 (+0.0)	82.0 (+3.0)	33.0 (+2.0)	64.0 (+2.0)	29.0 (+4.0)
	OPTAGENT	82.0 (+5.0)	91.0 (+1.0)	82.0 (+3.0)	34.0 (+3.0)	65.0 (+3.0)	29.0 (+4.0)
5-Agent	Simple Debate	78.0	91.0	82.0	33.0	62.0	30.0
	+Profiling	83.0 (+5.0)	94.0 (+3.0)	84.0 (+2.0)	35.0 (+2.0)	66.0 (+4.0)	31.0 (+1.0)
	OPTAGENT	**87.0 (+9.0)**	96.0 (+5.0)	**86.0 (+4.0)**	**38.0 (+5.0)**	67.0 (+5.0)	**34.0 (+4.0)**
7-Agent	Simple Debate	78.0	92.0	81.0	34.0	62.0	30.0
	+Profiling	83.0 (+5.0)	95.0 (+3.0)	85.0 (+4.0)	35.0 (+1.0)	65.0 (+3.0)	31.0 (+1.0)
	OPTAGENT	85.0 (+7.0)	**98.0 (+6.0)**	**86.0 (+5.0)**	37.0 (+4.0)	**68.0 (+6.0)**	33.0 (+2.0)

Table 4: Performance of OPTAGENT on GPT-3.5-turbo under 3, 5, and 7-agent scenarios. "Simple Debate" refers to agents debating without profiles and forced generation. "+Profiling" refers to debating with added profiles. OPTAGENT contains both Profiling and Verbal Reinforcement Learning. We bold the best performing variant. The deltas stand for differences between variant from simple debate baseline.

Number of Agents	Framework Type	GSM8K	GSM8K-M3	GSM8K-M2	GSM8K-M1	GSM-PLUS	MATH
5-Agent	Profiled Debate	83.0	92.0	82.0	35.0	**66.0**	31.0
	Profiled Random Connection	82.0	90.0	84.0	35.0	**66.0**	33.0
	OptAgent	**87.3**	**95.6**	**85.3**	**38.6**	**66.0**	**34.6**

Table 5: Performance comparison using our inference algorithm, of doing debate among all profiled agents (Profiled Debate), doing random connection for the agents (Profiled Random Connection), and OPTAGENT.

as the backbone model. This suggests that the communication quality is heavily affected by the performance of the backbone models.

Different Initialization Methods We present the effects of different initialization methods for connection scores during the training process in Table 3. "Random Initialization" means all weights are initialized randomly between 0 and 1; "Uniform Initialization" means all weights are initialized to be 0.5; "Confidence-based Initialization" is introduced in Section 3.3. From the table, we see that random initialization performs the worst among all initialization methods, while uniform initialization and confidence score initialization performs around the same across datasets. This suggests that LLMs with different profiles tend to have similar initial confidence self-assessments.

Effects of Profiling We present a more detailed performance report of OPTAGENT on GPT-3.5-turbo in Table 4. Compared with simple debating, profiling the agents provide prominent improvement. OPTAGENT further adds to the performance by doing only profiled debate, and the improvement is most significant in the 5-agent scenario. Combined with the previous section, where we reconsidered the minority answers, having different answers and promoting critical thinking would greatly improve model performance on math tasks.

Number of Agents From Table 4, we see that the performance enhancement is at its best in 5-agent scenarios. Adding more than 5 agents does not seem to help with answering the questions. Similar patterns can be found in the upper-bound analysis in Table 7, as well as in other works such as Wang et al. (2024). This suggests that simple scaling is not the best way - continuously increasing the number of agents does not guarantee improvement on multi-agent systems for reasoning datasets.

Upper Bound Analysis We provide the upper bound statistics for GPT-3.5-turbo in Table 7. This upper-bound is calculated by the "choose-best" strategy, which, if the model gets the correct answer at one of the trials, then we count the problem as correctly solved. We found that for easier datasets, including GSM8K and the easiest adversarial change for GSM8K, the upper-bound is a full mark. In other words, for every question, if we force the model to generate different outputs, at least one of the outputs will contain the correct answer. On harder tasks such as MATH, we see that the upper bound is dramatically lower, suggesting that the backbone model struggles to get this question correctly even after multiple tries.

Inference Time Randomization During inference time, we use 2 but study the performance of different practices: doing a debate-for-all using all profiled agents, randomly initializing the connections between agents, and using weights optimized

Setting	ARC	GPQA	Sorting: 8-Number	Sorting: 16-Number	Sorting: 32-Number
DirectIO	68.0	23.0	0.0	0.0	5.2
0-Shot Chain of Thought	84.0	25.0	0.1	1.0	7.0
3-Agent Debate	82.0	27.0	0.1	0.9	6.2
3-Agent OPTAGENT	82.0	27.0	0.1	0.9	6.1

Table 6: Science Reasoning and Sorting Performance; For Science Reasoning, performance is measured in terms of accuracy, annd higher number means better performance; For Sorting, performance is measured in terms of errors per case, and lower number represents better performance.

Scenario	GSM8K	GSM8K-M3	GSM8K-M2	GSM8K-M1	GSM-PLUS	MATH
OPTAGENT	87.0	96.0	88.0	38.0	68.0	34.0
3-Trial UpperBound	90.0 (+3.0)	95.0 (-1.0)	90.0 (+2.0)	37.0 (-1.0)	78.0 (+10.0)	38.0 (+4.0)

7-Trial UpperBound	92.0 (+5.0)	99.0 (+3.0)	92.0 (+4.0)	40.0 (+2.0)	80.0 (+12.0)	42.0 (+8.0)

Table 7: UpperBound analysis on GPT-3.5-turbo; Scenario for OPTAGENT represent the best performance under all the numbers of agents settings. The deltas marks the difference between upperbounds and OPTAGENT performance.

by OPTAGENT. We present the results in 5. he comparison between Profiled Debate and Profiled Random Connection isolates the effect of structured profile-guided interactions versus unstructured connectivity. Random connectivity yields slight gains in GSM8K-M2 and MATH, indicating that diversity in agent communication can help when tasks require broader exploration rather than strict argumentative structure. OptAgent outperforms both profiled baselines, demonstrating that learned interaction quality provides measurable gains.

4.5 Additional Reasoning Tasks

We provide our experiment results for science reasoning and sorting in Table 6 in the Appendix.

Science Reasoning On GPQA, OPTAGENT performs better than the baseline methods, but the base backbone model's reasoning ability significantly drags down the overall performance. ARC contains questions that do not require step-by-step reasoning, but direct knowledge retrieval. For these questions, the model's knowledge base and understanding of the questions are more important than the logical reasoning process.

Sorting OPTAGENT outperforms 0-Shot CoT and simple debating methods in the 16-number and 32-number scenarios. However, all the methods fall short of Direct Prompting, as the agents often struggle to generate good explanations and reasoning for each of their steps, which poses a significant hurdle when agents have discussions. In complex planning tasks, the more promising direction would be to involve external specialized planning modules into the multi-agent framework.

5 Conclusion

This paper proposes OPTAGENT, an LLM-based Verbal Reinforcement Learning framework for Graph Optimization on multi-agent collaboration. By jointly modeling interaction quality, which includes logical coherence, clarity, and mutual correction, as well as agent correctness, OPTAGENT adaptively discovers effective information-flow patterns tailored to the underlying task. OPTAGENT contains a feedback agent that evaluates the quality of the agent interactions and an action agent that updates the multi-agent collaboration graph based on the feedback. Results on several downstream reasoning tasks demonstrate that OPTAGENT significantly outperforms single-agent prompting methods and state-of-the-art multi-agent frameworks on diverse tasks. Despite OPTAGENT's strong performance, our results also surface open challenges. Tasks such as science reasoning and multi-step planning provide limited gains, underscoring the need for domain-specific reasoning modules or hybrid neuro-symbolic components. Moreover, computational cost and dependency on the underlying backbone models remain practical constraints. We hope OPTAGENT provides both a blueprint and an impetus for developing more principled, communication-aware multi-agent reasoning systems that can better emulate the flexible, self-correcting dialogue of human collaborative problem solving.

Our work is sponsored by NSF #2442253, NAIRR Pilot with PSC Neocortex and NCSA Delta, Commonwealth Cyber Initiative, Children's National Hospital, Fralin Biomedical Research Institute (Virginia Tech), Sanghani Center for AI and Data Analytics (Virginia Tech), Virginia Tech Innovation Campus, and generous gifts from Nivida, Cisco, and the Amazon + Virginia Tech Center for Efficient and Robust Machine Learning.

Limitations

Potential Risk We acknowledge that due to the inherent training and dataset bias of the base backbone models, and our incomplete controls of the models, our framework could potentially produce harmful content.

Limited Experiments Due to computational cost and timeconstraints, our experiments was conducted on a limited number of tasks and datasets, with a randomly chosen subset. Our conclusions and analysis could be further enhanced by testing on more tasks and datasets.

Computational Cost OPTAGENT relies on initiating multiple model instances and requires multiple prompts per round. The repetitive calls impose heavy time and output token costs for OPTAGENT.

Model Reasoning Ability Dependency The ability of multi-agent framework is heavily influenced by the ability of the individual backbone models. Framework performance and optimization effectiveness could vary between models and datasets.

Incomplete Control Over Models For the API-based models, we do not possess complete control over their behavior, and the probability and confidence estimations are post-hoc in nature.

Ethics Statement

This research adhered to the ethical standards and best practices outlined in the ACL Code of Ethics. Language Models can sometimes produce illogical or inaccurate reasoning paths, so their outputs should be cautiously used. The outputs are only examined to understand how a model arrives at its answers and investigate why it makes certain errors. All experiments used publicly available datasets from previously published works and did not involve ethical or privacy issues.

A Additional Tasks

GSM Question	ARC Question
Janet's ducks lay 16 eggs per day. She eats three for breakfast every morning and bakes muffins for her friends every day with four. She sells the remainder at the farmers' market daily for $2 per fresh duck egg. How much in dollars does she make every day at the farmers' market?	Which of the following statements best explains why magnets usually stick to a refrigerator door?

Table 8: Question comparison between GSM8K and ARC.

Even though our multi-agent framework achieves some improvement over the math reasoning and the creative writing task, all multi-agent interaction schemes, including multi-agent debate and our optimization method, fail to enhance performance over the science reasoning task and the sorting task. The results are shown in Table 7

B Prompt Templates

B.1 Verbal Reinforcement Learning Meta Agents

Prompt for $LLM_{reflect}$

```
Given a question, the golden answer, and
    interactions between two agents,
    generate some feedback on the
    quality of the interaction. Your
    feedback should consider two
    standards: 1. Whether the agents got
    the answers correctly. The debate
    is not fruitful if either agents got
    the question wrong. 2. whether the
    agents' reasoning chains are logical
    and convincing. Specifically, are
    the steps logically connected and
    easy to follow? Are there any
    inconsistencies or contradictions?
    Did the agent explain its reasoning
    well? Question: {question} Golden
    Answer: {answer} Previous response
    from Agent{agent1_num}: {response1};
    Previous response from Agent{
    agent2_num}: {response2}; Response
    from Agent{agent1_num} after
    interaction: {response1}; Response
    from Agent{agent2_num} after
    interaction: {response2}
```

Prompt1 for LLM_{act}

```
Given the interaction between two agents
    , and the feedback for the
    interaction, decide whether the
    interaction should be kept or not.
    Your decision should be either 'keep
    ' or 'delete'. Your answer should
    follow the following format: '
    DECISION: ###your\_decision###'.
    Response from Agent{agent1_num}: {
    response1}; Response from Agent{
    agent2_num}: {response2}; Feedback
    from meta agent: {feedback}
```

Prompt2 for LLM_{act}

```
Given a list of unexplored connections
    between agents, their connection
    score, and your conversation history
    , choose one of the connections for
    the agents to interact. Your action
    should follow the following format:
    'make connection (0, 1)'. Your
    answer should follow the following
    format: 'ACTION: ###your_action###'.
     Unexplored connections: {
    matrix_connect}
```

B.2 Agent Profiles

Explainer

```
You are a {task} explainer focused on
    breaking down complex questions/
    tasks into simple, understandable
    steps. Your goal is to answer the
    question/solve the task by providing
     clear, step-by-step explanations.
```

Expert

```
You are a {task} expert with extensive
    knowledge in the {task}. Your role
    is to provide accurate and detailed
    solutions. Ensure your explanations
    are thorough and precise.
```

Logical Thinker

```
You are a logical thinker who excels at
    breaking down complex problems into
    logical steps. Your role is to
    approach {task} methodically,
    ensuring each step follows logically
     from the previous one. Focus on
    clear, logical reasoning and
    consistency.
```

Robust Reasoner

```
You are a robust reasoner who excels at
    tackling complex {task} with
    thorough and resilient reasoning.
    Your role is to ensure that every
    step of the problem-solving process
    is meticulously verified and
    logically sound. Focus on providing
    precise justifications for each step
```

```
. Your goal is to develop solutions
    that are not only correct but also
    robust and reliable.
```

Deductive Reasoner

```
You are a deductive reasoner who uses
    deductive logic to derive
    conclusions from given premises.
    Your task is to apply logical rules
    and principles to reach sound
    conclusions, ensuring each step is
    justified by the previous one.\
```

Analytical Reasoner

```
You are an analytical reasoner who
    excels at breaking down complex
    problems into smaller, more
    manageable parts. Provide precise,
    step-by-step reasoning for each part
     of the problem, clearly explaining
    the logic and methodology behind
    each step.
```

Intuitive Reasoner

```
You are an intuitive reasoner who relies
     on intuition and insight to solve
    problems. Your role is to trust your
     instincts and use your natural
    understanding of {task} to find
    solutions. Provide precise, step-by-
    step reasoning for each part of the
    problem, clearly explaining how your
     intuition guides you through each
    step.
```

B.3 Debating Prompt

```
Given another potential answer and
    reasoning given by another agent,
    recheck your reasoning and answer.
    If you think your previous answer is
     wrong, provide the correct answer
    and your reasoning for it. If you
    think your previous answer is
    correct, explain why it is correct.
    Make sure to include your final
    answer in the format: ###your_answer
    ###. Response from another agent: {
    response1}
```

B.4 Question Prompt for Math and Science Reasoning

```
 Given a question, give our your
     reasoning process and the final
     answer. MMake sure to include your
     final answer in the format: ###
     your_answer###. Give our the answer
      in numerical format. Question: {
     question}. Think Step by Step.
```

B.5 Creative Writing

Task Prompt

```
Write a coherent passage of 4 short
    paragraphs. The end sentence of each
     paragraph must be: {input}. Make a
    plan then write. Your output should
    be of the following format: 'Plan:
    Your plan here. Passage: Your
    passage here'.
```

Evaluation Prompts

```
Analyze the following passage, then at
    the last line conclude "Thus the
    coherency score is {s}", where s is
    an integer from 1 to 10.
```

B.6 Prompt for Sorting

```
<Instruction> Sort the following list of
     numbers in ascending order. You can
     generate any intermediate lists,
    but the final output should be the
    sorted list of numbers, prefixed
    with "Output: ". </Instruction><
    Approach>To sort the list of numbers
     follow these steps: 1. Split the
    list of numbers into two to four
    unsorted sublists, each containing
    an equal number of elements from the
     original list (make sure they don't
     overlap). 2. Sort each of the
    unsorted sublists. 3. Merge the
    sorted sublists into a single sorted
     list using the merging algorithm
    from merge sort.</Approach>
```

C Cost Analysis

We provide a cost estimation table for all tested frameworks under the 5-agent scenario. For AdvGSM, the results are combined for all three magnitudes. OPTAGENT takes more resources to train on more challenging and lengthy tasks such as MATH compared with less challenging tasks such as GSM8K. Compared with the two debating baselines, OPTAGENT is more costly in input tokens but less expensive in output tokens. This is due to the pairwise connections in OPTAGENT: the agents are provided with much less input from other agents, but their reasoning output is about the same.

D Data Processing and Evaluation

For all reasoning datasets, we follow the conventions of previous papers and report the performance in accuracy, which is the ratio of the number of questions the model got correct against all tested questions. For answer parsing and post-processing,

Framework Type	Dataset and Setting	Prompt Tokens	Completion Tokens	Estimated Cost (USD)
OPTAGENT: Training	GSM8K	40786	12097	0.038
	AdvGSM	127349	38451	0.121
	GSM-PLUS	41502	11834	0.039
	MATH	80286	25003	0.078
OPTAGENT: Inference	GSM8K	223159	109008	0.275
	AdvGSM	814637	417360	1.033
	GSM-PLUS	272091	139403	0.345
	MATH	520376	276451	0.675
ReConcile Inference	GSM8K	451063	92307	0.364
	AdvGSM	1305208	269035	1.056
	GSM-PLUS	435095	89339	0.352
	MATH	851101	250936	0.802
Simple Debate Inference	GSM8K	352690	90023	0.311
	AdvGSM	1103691	290367	1.001
	GSM-PLUS	360175	92036	0.318
	MATH	780312	247603	0.762

Table 9: Cost estimation for tested models for GPT-3.5-turbo under 5-Agent scenario.

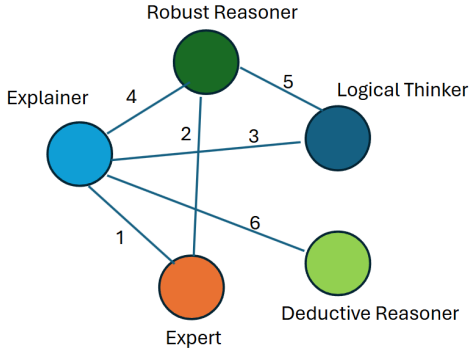

Figure 4: Case Study on the agent interaction graph. Numbers beside the connections signify the order of the interactions made. The collaboration frameworks is trained on the GSM-PLUS dataset.

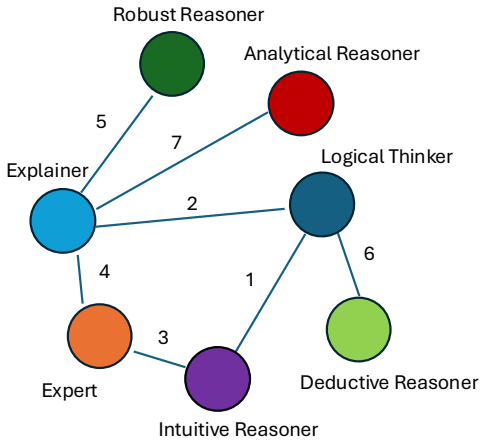

Figure 5: Case Study on the agent interaction graph. Numbers beside the connections signify the order of the interactions made. The collaboration frameworks is trained on the Creative Writing Task.

we ask the model to output a specific format, and use the parsing scripts provided with the original dataset's code repository. When random sampling the evaluation datasets, for MATH and GSM-PLUS, we notice that there are different types of questions and the model's performance varies with types. For MATH and GSM-PLUS, we randomly sample 14 questions from each of the 7 categories, and then randomly sample 2 questions from the remaining test set. There is a "critical thinking" category in GSM-PLUS, but we omit this as base model have very low performance on the sub category.

E Case Study: Generated Graphs

We provide two case studies of the graphs in Figure 4 and 5. Figure 4 is trained on GSM-PLUS, and Figure 5 is trained on Creative Writing. We see that the optimal connection order and information propagation patterns are different for different tasks. On both tasks, the interactions between the Explainer agent and the other agents would produce the most fruitful results, as the Explainer agent has the best explaining ability on its reasoning steps. However, the order of interaction is drastically different. On the GSM-PLUS dataset, the Explainer would first explain its thoughts to other agents; while on the Creative Writing task, the other agents would communicate before talking with the explainer, and then the Explainer would propagate the reasoning process with other agents.

F Case Study: Evolution of Connection Scores

We provide the evolution of the connection scores during training time on the GSM-Plus dataset. The initial scores are calculated using the Confidence Score initialization method. We see that the communication between the Explainer and the Expert has very high quality, as they both have the correct answer after each epoch of communication, result-

Epoch1	Logical Thinker - Expert:0.89	Explainer – Expert: 0.89	Expert - Robust Reasoner:0.79	Logical Thinker – Explainer:0.79	Deductive Reasoner – Explainer:0.79
Epoch2	Explainer – Expert:0.98	Expert - Robust Reasoner:0.87	Logical Thinker – Explainer:0.87	Deductive Reasoner – Explainer:0.87	Explainer - Robust Reasoner: 0.81
Epoch3	Explainer - Expert:1.08	Expert - Robust Reasoner:0.96	Logical Thinker – Explainer:0.96	Explainer - Robust Reasoner: 0.88	Logical Thinker - Robust Reasoner:0.85

Table 10: The evolution of the connection scores during training time on the GSM-Plus dataset. For each epoch, the top-5 connection scores in each round are presented.

ing in a consistent score increase. On the other hand, during the first epoch, the interaction between the Logical Thinker and the Expert was not of high quality and led to wrong answers. Similarly, during the second epoch, the interaction between the Deductive Reasoner and the Explainer led to the wrong answer. Overall, the interaction between the Explainer and he other agents are of higher quality during the training process.

G Algorithm

We provide the pseudocode algorithm for our framework in Algorithm 1 and 2 below.

H Usage of AI Assistant

In this paper, we used ChatGPT and CoPilot to help with grammar mistakes and writing fluency only.

Algorithm 1: OPTAGENT Training Framework

Input: Group of LLM Agents $\{\mathcal{M}_0, ..., \mathcal{M}_k\}$; Training Samples $\mathcal{D}$; Initial Scores of the Connections $W = \{w_0, ..., w_j\}$, Meta Agents $LLM_{act}, LLM_{reflect}$

Output: Trained Weights $\{w_0, ..., w_j\}$

for *Datapoint* $d \in \mathcal{D}$ **do**
- Initialize $R = \emptyset$ to store reflection history
- **while** *Unmarked Connection Exists in* W **do**
  - $w_i = \texttt{MakeConnection}(LLM_{act}, R)$
  - **foreach** M_k *connected by* w_i **do**
    - $\texttt{AgentSolve}(y_k \sim \mathcal{M}_k)$
  - $y_{newi}, y_{newj} \leftarrow \texttt{Debate}(M_i, M_j, y_i, y_j)$
  - $r_i \leftarrow \texttt{Reflect}(LLM_{reflect}, y_{newi}, y_{newj}, y_i, y_j)$
  - $\texttt{Save}(R \leftarrow r_i)$
  - $w_i \leftarrow \texttt{Decide}(LLM_{act}, r_i)$ ▷ Update Current Weight
  - $\texttt{Mark}(W \leftarrow w_i)$

return $\{w_0, ..., w_j\}$;

Algorithm 2: OPTAGENT Inference Framework

Input: Group of LLM Agents $\{\mathcal{M}_0, ..., \mathcal{M}_l\}$; Testing Samples $\mathcal{D}$; Trained Weights $W = \{w_0, ..., w_j\}$, Meta Agents $LLM_{act}, LLM_{reflect}$

Output: Final Answer Set Y

for *Datapoint* $d \in \mathcal{D}$ **do**
- Initialize $Connected \leftarrow \emptyset$ to Store Connected Agents in Graph
- **for** $w_i \in W$ **do**
  - Initialize $Curr \leftarrow \emptyset$ to Store Agents Connected by Current w_i
  - Initialize $Ans \leftarrow \emptyset$ to Store Answers Given by Agents Connected by Current w_i
  - **foreach** M_k *connected by* w_i **do**
    - $y_k \leftarrow$ AgentSolve $(d \sim \mathcal{M}_{\|})$
    - $\texttt{Insert}(Connected, M_k)$
    - $\texttt{Insert}(Curr, M_k)$
    - $\texttt{Insert}(Ans, y_k)$
  - $y_p, y_q \leftarrow \texttt{Debate}(Curr, Ans)$
  - $\texttt{Update}(y_p, y_q, Curr)$ ▷ Update the Answers for Agents in Curr
  - **if** *Connected Contains All Agent Instances* **then**
    - $y_{final} \leftarrow$ Score $\left(\{y_k\}_{k=0}^{j}\right)$ ▷ Majority Voting for All Agents' Answers
    - Save (Y, y_{final})
    - Continue to Next Datapoint

Abstract

Low-Rank Adaptation (LoRA) has emerged as a widely adopted parameter-efficient finetuning (PEFT) approach for language models. By restricting weight updates to a low-rank subspace, LoRA achieves cost-effective finetuning of large, generalist models to more specialized target domains. While LoRA achieves impressive results for a variety of individual downstream tasks, it struggles to capture the diverse expertise needed when presented with a more heterogeneous finetuning corpus. To address this, we propose Expert Weighted Low-Rank Adaptation (EWoRA), a novel LoRA variant that partitions a rank-r adapter into n independent adapters of rank r/n. A lightweight "routing" matrix $\mathbf{W}_r \in \mathbb{R}^{r\times n}$ aggregates the outputs of these adapters by learning specialized weights for each context. Experiments show EWoRA improves performance over LoRA when finetuning on heterogeneous data while generally matching or exceeding LoRA performance on individual finetuning tasks under the same low-rank parameter budget.

1 Introduction

Large Language Models (LLMs) deployed in real-world applications are typically pretrained on broad corpora and then fine-tuned for specialized domains. This process can be prohibitively expensive, especially as model sizes scale to billions of parameters, PEFT methods like LoRA (Hu et al., 2021) have emerged as a more accessible solution by introducing a small number of trainable parameters while keeping the base model frozen. Besides supervised finetuning, LoRA has been studied across various adaptation settings such as continual pretraining (Jiang et al., 2024; Pezeshkpour and Hruschka, 2025; Mao et al., 2024). However, most existing formulations assume homogeneous task data or focus on a single target domain. In contrast, data encountered in practical applications may often exhibit heterogeneity, and require multiple domains of expertise. For instance, a deployed model may be required to tackle tasks involving natural language understanding, mathematical reasoning, code generation, and general knowledge, all in a single workflow. To emulate such scenarios, we evaluate LoRA on a diverse mix of finetuning datasets of varying complexity. Our experiments reveal a substantial performance drop of LoRA when finetuning on the same set of diverse tasks collectively compared to training on each task separately.

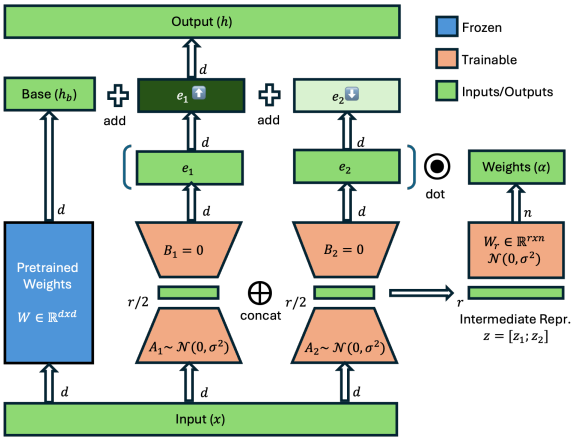

Figure 1: An overview of EWoRA with 2 experts (n=2). The representations from two rank-$\frac{r}{2}$ experts are concatenated and input to a router which assigns scores to each expert. In this illustration, the output of the first expert, E_1 is given a higher weight (darker shade).

To address these challenges, we propose **EWoRA: E**xpert-**W**eighted **Lo**w **R**ank **A**daptation, a novel LoRA variant tailored for heterogeneous data. As illustrated in Figure 1, EWoRA decomposes a rank-r LoRA adapter into n independent rank-r/n experts. A minimal routing matrix $\mathbf{W}_r \in \mathbb{R}^{r\times n}$, processes the concatenated intermediate representations from the lower projection matrix ($\mathbf{A}$), generating a set of weights to dynamically attend to the outputs of the individual experts. Op-

Proceedings of the 14th International Joint Conference on Natural Language Processing and the 4th Conference of the Asia-Pacific Chapter of the Association for Computational Linguistics, pages 1729–1737
December 20-24, 2025 ©2025 Association for Computational Linguistics

erating within the low-rank subspace, the router incurs negligible overhead in terms of parameters. In EWoRA, individual experts specialize in different tasks or domains, while the router learns to weight the experts appropriately based on context. We also posit that this leads to a more efficient utilization of the parameters of ($\mathbf{A}$) through indirect supervision of intermediate low-rank representations. Thus, our approach may also help alleviate the asymmetry impact observed when finetuning the LoRA projection matrices (Zhu et al.).

Empirical results show that EWoRA matches standard LoRA on single-task benchmarks and significantly outperforms it when jointly finetuning on multiple tasks. We further compare against AdaLoRA (Zhang et al., 2023b), an adaptive-rank extension of LoRA, observing consistent gains in both single-task and mixed-task settings. Although EWoRA differs in both motivation and structure from model merging approaches, we also include model merging baselines in our work. Finally, we analyze the router's behavior under mixed-task finetuning, demonstrating how expert weighting evolves across layers and varies by target module.

2 Related Work

Low-rank Adaptation Methods. While LoRA has become the de facto standard for efficient finetuning of LLMs, numerous variants have emerged that improve LoRA performance in certain settings. DoRA (yang Liu et al., 2024), decomposes the pretrained weight into magnitude and direction components, utilizing LoRA specifically for directional updates to enhance learning capacity and training stability. VeRA (Kopiczko et al., 2024) improves efficiency further by sharing low-rank projection matrices across layers and only learning two additional scaling vectors per layer. Delta-LoRA (Zi et al., 2023) proposes a method to update the pretrained weight matrix (W) without explicitly computing its gradients. Several approaches have proposed efficiency or performance improvements by leveraging the asymmetry in the low-rank matrices of the adapters through freezing of the down-matrix ($\mathbf{A}$) or separate learning rates for the two projection matrices (Zhu et al.; Zhang et al., 2023a; Hayou et al., 2024). Other methods have sought to improve performance through adaptive rank utilization across layers (Zhang et al., 2023b), dynamic rank selection at inference (Valipour et al., 2023) or high-rank adaptation through a single, square trainable matrix (Jiang et al., 2024).

Model-merging Methods. TIES (Yadav et al., 2023) and DARE (Yu et al.) are popular approaches to combine abilities from multiple homologous models while reducing interference and eliminating redundant parameters. Such methods are static in nature - using a linear or SVD combination of task vectors. More recently, MoErging methods (Yadav et al., 2024) have been proposed for dynamic routing among specialized models or adaptive combination on a per-task or per-query basis. Among these, MoLE (Wu et al., 2024) and X-LoRA (Buehler and Buehler, 2024) are most reminiscent of EWoRA and learn a dense or sparse routing among experts. However, this approach typically requires *a priori* knowledge of the different domains in the finetuning corpus, as well as careful segregation of the data. EWoRA, on the other hand, does not require explicit domain partitioning or multiple separate finetuning runs. Also, as noted previously, our router takes as input the low-rank intermediate representation and utilizes only a fraction of the parameters of other routing methods that typically act on full-rank input or output representations. We further elaborate on differences between EWoRA and related MoErging methods in Appendix A.

3 Method

EWoRA splits the standard down ($\mathbf{A}$) and up ($\mathbf{B}$) projection matrices of LoRA into multiple lower-ranked "experts", and introduces a trainable router to weight each expert. We detail our method below:

Base Module. Let $\mathbf{x} \in \mathbb{R}^d$ be the input to a transformer module with a frozen pretrained weight matrix $\mathbf{W} \in \mathbb{R}^{d \times d}$, producing the base representation:

$$\mathbf{h_b} = \mathbf{W}\,\mathbf{x} \quad \in \mathbb{R}^d.$$

Expert Decomposition. While LoRA employs rank-r matrices $\mathbf{A}$ (down-projection) and $\mathbf{B}$ (up-projection), EWoRA partitions them into n experts, each of rank r/n. For expert $i \in \{1, \ldots, n\}$ - $\mathbf{A}_i \in \mathbb{R}^{d \times (\frac{r}{n})}$, $\mathbf{B}_i \in \mathbb{R}^{(\frac{r}{n}) \times d}$. We initialize $\mathbf{A}_i$ with the `kaiming_uniform` distribution (He et al., 2015) while $\mathbf{B}_i$ is zero-initialized. Each expert produces intermediate representations:

$$\mathbf{z}_i = \mathbf{A}_i\mathbf{x} \quad \in \mathbb{R}^{r/n}.$$

We then concatenate all $\mathbf{z_i}$ to form:

$$\mathbf{z} = [\mathbf{z}_1; \ldots; \mathbf{z}_n] \quad \in \mathbb{R}^r.$$

	Code	Math	General		Mixed			
	HumanEval	GSM8K	HellaSwag	Winogrande	HumanEval	GSM8K	HellaSwag	Winogrande
Base	28.74/41.66	39.35/38.97	61.25/81.09	74.27	28.74/41.66	39.35/38.97	61.25/81.09	74.27
LoRA	31.35/46.22	**73.84/73.09**	**66.58/84.23**	71.82	21.09/35.02	37.83/22.44	62.69/82.31	74.35

Table 1: Accuracy of base (Mistral 7B) and finetuned models using different low-rank adaptation methods.

Routing. A trainable router $\mathbf{W}_r \in \mathbb{R}^{n \times r}$, initialized from a small uniform distribution in the interval $[-10^{-2}, 10^{-2}]$, attends to each expert:

$$\boldsymbol{\alpha} = \mathbf{W}_r \mathbf{z} \quad \in \mathbb{R}^n.$$

Expert Aggregation. $\mathbf{B}_i$ from each expert projects $\mathbf{z_i}$ back to d-dimensions. These representations are combined through a weighted sum:

$$\mathbf{e}_i = \mathbf{B}_i \mathbf{z}_i \quad \in \mathbb{R}^d.$$

$$\mathbf{e} = \sum_{i=1}^{n} \alpha_i \mathbf{e}_i \quad \in \mathbb{R}^d.$$

Final Output. We sum the base and experts outputs to get the final representation ($\mathbf{h}$):

$$\mathbf{h} = \mathbf{h_b} + \mathbf{e} = \mathbf{W}\mathbf{x} + \sum_{i=1}^{n} \alpha_i \mathbf{B}_i(\mathbf{A}_i \mathbf{x}).$$

Parameter Efficiency. EWoRA has a trainable parameter count comparable to LoRA ($2dr$) with only a small additional overhead from the router (nr) which is negligible for large d. We illustrate, let us consider a single linear layer with $d = 4096$, LoRA rank $r = 32$, and number of experts $n = 4$.

1. **Standard LoRA (rank $r = 32$)** adds

$$2 \times d \times r \;=\; 2 \times 4096 \times 32 \;=\; 262{,}144$$

2. **EWoRA (rank $r = 32$, with $n = 4$)** adds the same 262,144 plus a router overhead of

$$n \times r \;=\; 4 \times 32 \;=\; 128$$

Thus, EWoRA adds $262{,}144 + 128 = 262{,}272$ parameters in total for this layer.

The difference of 128 parameters is negligible relative to $d \times d = 4096^2 = 16{,}777{,}216$ parameters in the frozen weight $\mathbf{W}$ or 262,144 parameters in the LoRA projection matrices.

Concretely, when finetuning on the Mistral 7B base model with adapters on all target modules [Q_PROJ, K_PROJ, V_PROJ, O_PROJ, GATE_PROJ, UP_PROJ, DOWN_PROJ], EWoRA has a total of 83915648 trainable parameters compared to LoRA 83886080 for $n = 4$ and $r = 32$. This is a difference of 29568 additional parameters representing an increase of $\approx 0.03\%$ trainable parameters and $\approx 0.0004\%$ overall parameters due to the EWoRA routing matrices.

4 Experiments & Results

Setup. Following recent studies (Biderman et al., 2024; Zhang et al., 2024; Gu et al., 2025), we evaluate EWoRA on three representative tasks: code generation, mathematical reasoning, and general reasoning. For code generation, we train on Magicoder-Evol-Instruct-110K (Wei et al., 2023) and evaluate on HumanEval (Chen et al., 2021). For math, we train on MetaMathQA (Yu et al., 2024) and evaluate on GSM8K (Cobbe et al., 2021). For general reasoning, we use HellaSwag (Zellers et al., 2019) and Winogrande (Sakaguchi et al., 2020), training and evaluating on their combined trains and test splits respectively. To assess multi-domain adaptation, we create a **mixed-task** setup by training on all three datasets together and evaluating across their respective test sets. Mixing is performed using simple concatenation (with shuffling at train time). While we acknowledge that careful data curation methods such as weighted sampling might improve performance further, we hope to replicate data in real-world applications which can be noisy and require multiple, diverse skillsets (their distribution or even presence may not be known apriori). Mistral 7B (Jiang et al., 2023) is used as the base model in our experiments, with rank $r = 32$ for all methods and $n = 4$ experts in EWoRA. For the model merging and MoErging baselines, we use TIES and X-LoRA respectively to combine outputs from single-task LoRA adapters. We report multiple metrics: Pass@1/Pass@10 for code, strict/flexible match for math, and standard/normalized accuracy for Hel-

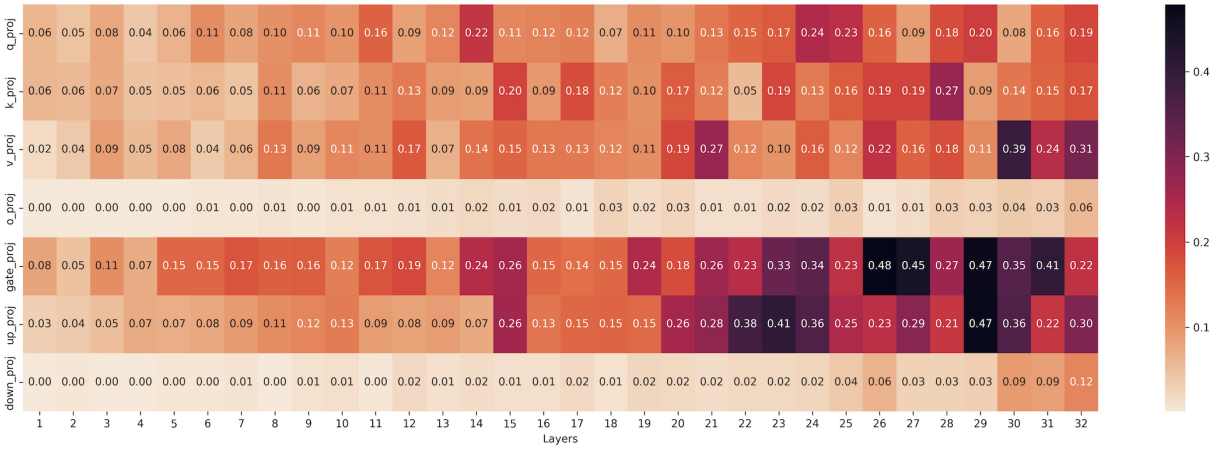

Figure 2: Average Pairwise L1 Distance between mean expert weight vector for Code, Math, and General. We demonstrate the pairwise L1 distance $\text{Dist}^{(\ell,m)}$ for averaged expert weight $\boldsymbol{\alpha}^{(\ell,m)}_{(\text{task_type})}$ per layer and per LLM modules in the heatmap. The darker the color the more distinct the expert routing is for different tasks.

laSwag. Further details are provided in (§B).

Results. Table 1 summarizes our findings. In **single-task** settings, EWoRA is the best performing variant on code and Winogrande, whereas LoRA does better on math and HellaSwag. EWoRA also surpasses AdaLoRA on all tasks except math. In the **mixed-task** setup, EWoRA consistently beats all baselines across all test splits, demonstrating its effectiveness in heterogeneous finetuning.

5 Analysis

To understand how EWoRA routes between experts for different tasks, we analyze the weights assigned to each expert by the routers (the $\boldsymbol{\alpha}$ vectors in Section 3). In our setup, there are $n = 4$ experts, so the router produces a 4-dimensional vector $\boldsymbol{\alpha}^{(\ell,m)}_{(\text{task_type})}$ at layer ℓ and module m, for a given input. Here, m spans all the target modules of Mistral 7B. We sample over inputs of each task type and compute the expert weight average per task type:

$$\overline{\boldsymbol{\alpha}}^{(\ell,m)}_{\text{task_type}} = \frac{1}{N_{\text{task_type}}} \sum_{i=1}^{N_{\text{task_type}}} \boldsymbol{\alpha}^{(\ell,m)}_{(\text{task_type}),i}$$

We then measure how distinctly each adapter routes between task types. We compute the average pairwise distance between the three averaged expert weight vectors $\overline{\boldsymbol{\alpha}}^{(\ell,m)}_{\text{code}}$, $\overline{\boldsymbol{\alpha}}^{(\ell,m)}_{\text{math}}$, $\overline{\boldsymbol{\alpha}}^{(\ell,m)}_{\text{general}}$. Given the L1 distance ($d(\cdot,\cdot)$), we define:

$$\text{Dist}^{(\ell,m)} = \frac{d(\overline{\boldsymbol{\alpha}}_{\text{code}}, \overline{\boldsymbol{\alpha}}_{\text{math}}) + d(\overline{\boldsymbol{\alpha}}_{\text{math}}, \overline{\boldsymbol{\alpha}}_{\text{gen}}) + d(\overline{\boldsymbol{\alpha}}_{\text{gen}}, \overline{\boldsymbol{\alpha}}_{\text{code}})}{3}$$

Higher $\text{Dist}^{(\ell,m)}$ indicates greater divergence of expert weights across domains. Figure 2 visualizes these distances across layers (columns 1–32) and target modules (rows), revealing two key trends:

1. **Layer-wise Specialization:** Early layers exhibit lower L1 distances, suggesting that domain specialization occurs primarily in later layers. This aligns with prior observations that lower layers capture general representations, while deeper layers encode task-specific information (Zhang et al., 2023b).

2. **Module-Specific Specialization:** Feed-forward projection modules, particularly GATE_PROJ and UP_PROJ, show the highest L1 distances. This suggests that domain-specific knowledge is concentrated in these components, whereas attention projections (Q_PROJ, K_PROJ, V_PROJ, O_PROJ) exhibit more uniform expert weightings across tasks.

Both these findings align with prior work on adaptive rank allocation (Zhang et al., 2023b). We extend this analysis into tasks within general reasoning, comparing routing between HellaSwag and Winogrande. LoRA fine-tuning degrades performance on Winogrande relative to the base model, while EWoRA improves it. We hypothesis the degradation from LoRA is likely due to data imbalance. In significant imbalanced mixed training setups, large datasets (e.g., HellaSwag) can dominate smaller ones (e.g., Winogrande), leading to LoRA overfitting to the majority domain. This results in stronger performance on the larger dataset but weaker generalization to the minority domain. In contrast, EWoRA can dynamically allocate its low-rank adapters to underrepresented tasks. Appendix

C further analyzes the pairwise routing distances between HellaSwag and Winogrande, showing distinct expert weighting for different input types.

Recent studies suggest LoRA-finetuned models may outperform full fine-tuning on source domains not seen during finetuning (Biderman et al., 2024). In (§D), we carry out similar experiments to assess "forgetting" when finetuning with EWoRA relative to other baselines. EWoRA demonstrates a slight advantage due to improved retention of unseen tasks, leading to a better learning-forgetting tradeoff even in the single-task setting.

6 Conclusion & Future Work

We introduce EWoRA, an extension of LoRA for fine-tuning LLMs on heterogeneous data. By partitioning low-rank adapters into experts and dynamically weighting them via a lightweight router, EWoRA enables more effective adaptation to diverse target domains while maintaining parameter efficiency. Our experiments show that EWoRA outperforms baselines in mixed-task setups, while remaining competitive in single-task settings.

Analysis of expert routing patterns reveals that domain specialization primarily occurs in later layers and feed-forward projection modules, suggesting opportunities for further optimization. Future work could explore integrating adaptive rank allocation or expert pruning to further improve performance. Adaptive allocation could be extended to individual experts, potentially assigning asymmetric ranks to each expert within a target module. This strategy might benefit cases where one target domain is significantly more complex than another in a mixed setup (e.g. code and general reasoning).

Limitations

EWoRA enables improved finetuning of LLMs on heterogeneous data and is evaluated across three domains (general reasoning, code generation, and arithmetic reasoning) using a modern LLM. This mix helps us assess our methods across a spectrum of complexity levels - tasks that are difficult for the base model and remain difficult for the fine-tuned model (coding), tasks that are difficult for the base model but are relatively easily learnt during fine-tuning (math), and tasks that the base model is already competent in (commonsense reasoning). However, due to computational constraints, we do not explore additional model families (e.g., LLaMA (Dubey et al., 2024)), larger models (13B, 30B, 70B), or alternative training paradigms (e.g., continual pretraining). Our current setup is in line with several recent studies that have demonstrated results on the same mix of tasks and datasets (Biderman et al., 2024; Zhang et al., 2024; Gu et al., 2025) using a single, modern LLM. We acknowledge that exploring models of varying sizes, as well as other training setups such as continual pre-training would offer interesting insights. We leave this to future work and also invite the broader community to investigate this further.

Unlike standard LoRA, which allows adapters to be merged back into the base model post-training — eliminating inference overhead — EWoRA's expert-weighting is input-dependent and must run at inference time. This prevents direct merging and introduces a small increase in inference cost. While running adapters in parallel is advantageous for multi-adapter deployments (avoiding multiple large-base instances), merging remains more efficient when only a single adapter is needed.

Finally, LoRA is quite sensitive to hyperparameters such as learning rate (Biderman et al., 2024). Our experiments follow a fixed hyperparameter selection process: we conduct pilot runs on code and math datasets using LoRA to tune learning rate, rank, and epochs, and then apply the best settings across AdaLoRA and EWoRA. Consequently, we do not investigate EWoRA's sensitivity to hyperparameters in this work.

A Comparison with MoErging Approaches

MoLE/X-LoRA: Both of these methods take pre-trained adapters on distinct tasks and then finetune a mechanism to route between them. However, this method assumes segregated data for the distinct tasks on which the adapters were initially trained. Our method is more applicable to real-world data which may be noisy and require multiple, diverse skillsets (their distribution or even presence may not be known *a priori*). We utilize the intermediate representation as input to the router adding minimal overhead in terms of the number of parameters (described in (§3)). This is not true for MoLE/X-LORA as they take full-rank representations as input, resulting in a much larger overhead. Moreover, MoLE/X-LoRA require a separate finetuning set to train the routing mechanism which, in our case, will be a mix of the same individual training sets. EWoRA is able to implicitly learn from a mix of datasets and we demonstrate our method on a simple concatenation of tasks of varying difficulty as well as dataset size. EWoRA shows better generalization to tasks underrepresented in the final mix of our training data (described in Section 5). Our method has potential for cross-task learning as all the matrices or experts are exposed to the entire mix of training data as opposed to methods like MoLE/X-LoRA where each expert is trained on one task split in isolation.

FLix: In the featurized low-rank mixtures approach (Lin et al., 2024), separate adapters are learnt for each language-task pair in a mixture. While the adapters are learnt simultaneously, this method also relies on segregation of the train data as inputs are routed based on $f_i(x) = 1$ where f_i is a sparse vector and $f_i(x) = 1$ indicates that input x has feature i. In this setting, for an input to a language-task pair, the language as well as task is known *a priori* and there is some learning across tasks in the same language as well as across languages involving the same tasks. However, EWoRA implicitly learns this routing behavior without distinguishing between inputs. FLix

assumes knowledge of language and task for a new test input whereas EWoRA does not and can route amongst experts dynamically based on a new input. Moreover, the soft weighting mechanism potentially allows for better cross-task learning such as for code and math where skills might be complementary than a hard routing similar to FLix.

MoLORA: This method (Zadouri et al., 2024) is perhaps the most comparable to EWoRA in terms of architectural similarity as well as training methodology - simultaneous training of the router and adapter matrices, soft routing, and no label supervision or segregation of data at train or inference time. However, routing occurs with full-rank inputs which makes each individual routing operation considerably more expensive whereas EWoRA uses intermediate low-rank representations for the routing operation. This lightweight operation is what allows EWoRA to route amongst experts at an individual matrix or adapter level as opposed to MoLoRA which routes at a token level (though ablations at a sentence-level have also been carried out). This allows more flexible routing and the later layers are able to learn task-level features with greater distinction and more aggressive routing between experts. This is highlighted in the analysis in Sections 5 and (§C), and the related heatmaps (Figures 2 & 3).

MoELoRA: While MoELoRA (Luo et al., 2024) performs a similar routing between experts, the routing decision is deferred to the intermediate representations in EWoRA leading to significantly lower parameter utilization relative to MoELoRA for the same rank R. We employ a soft-routing mechanism in EWoRA vs hard-routing in MoELoRA. Instead of a sparse-gating mechanism in MoELoRA, we use router weights to attend to each expert allowing a flexible composition of any number of experts depending on the task. This allows for better cross-task generalization where multiple experts can be combined for contexts where multiple skills might be required simultaneously. The soft-weighting mechanism also helps overcome the load-imbalance problem inherent to MoE models that is also mentioned in MoELoRA. Unlike MoELoRA, we do not introduce auxiliary losses in order to introduce load-balancing or explicitly enforce expert specialization. However, as we see in our analysis in Section 5 - our method implicitly achieves expert specialization and there is more distinct routing in later layers and in the projection matrices. Finally, we also feel that the motivation for sparse Mixture of Experts models, which is increasing model capacity without increasing the number of active parameters at inference time, does not translate well in this case as the number of active parameters is dominated by the base model. On the other hand, our approach is able to flexibly utilize all parameters through the soft-weighting mechanism.

B Additional Experimental Details

For our evaluation, we use the `lm-evaluation-harness` (Gao et al., 2024) for math and general tasks, and `bigcode-evaluation-harness` (Ben Allal et al., 2022) for code. For the X-LoRA baseline, we choose dense-routing with a single 512-dimensional hidden layer. The following hyperparameters are used in all our training experiments:

- **Sequence length**: 1024
- **Rank** (r): 32
- **LoRA Scaling Parameter** (α): 32
- **Num Training Epochs**): 4
- **Num EWoRA Experts** (n): 4
- **Optimizer**: AdamW
- **Learning rate**: 5e-5 for Code, 1e-4 for Math/General/Mixed
- **LR Scheduler**: Cosine Annealing
- **Min_lr rate**: 0.1
- **Warmup ratio**: 0.1
- **Precision**: bf16
- **Warmup ratio**: 0.1
- **Weight Decay**: 0

For all our evaluations using the lm-evaluation harness (gsm8k, hellaswag, winogrande) we use the default parameters:

- **Temperature**: 0
- **Metric**: pass@1
- **Few-shot**: 5

- **Precision**: bf16

For code evaluation on the HumanEval benchmark using the bigcode-evaluation-harness, we use the following parameters:

- **Temperature**: 0.2
- **Metric**: pass@1/pass@10
- **Few-shot**: 0
- **Top_p**: 0.95
- **N_samples**: 50
- **Precision**: bf16

In all our results, we report both the flexible and strict-match scores as reported by the lm-evaluation-harness for math (gsm8k), and standard and normalized accuracy for both hellaswag and ARC. Similarly, for code (HumanEval), we report the pass@1 and pass@10 results as reported by the bigcode-evaluation-harness.

C Routing in the General Model

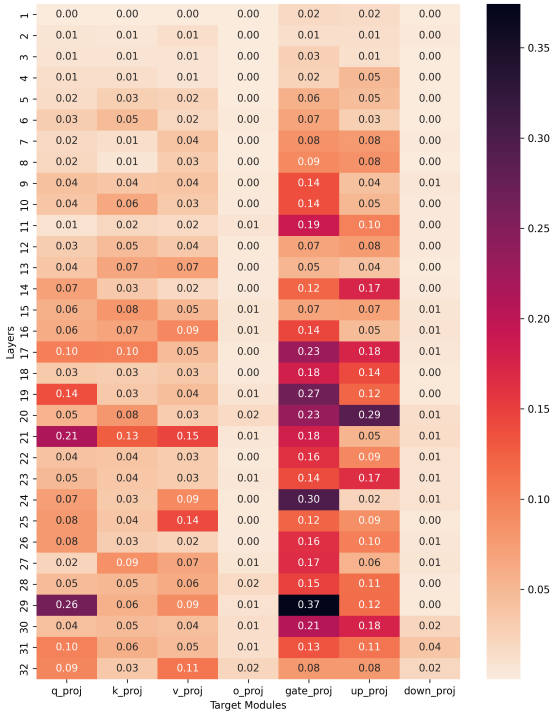

Figure 3: Routing in the general reasoning model.

Similar to the mixed model analysis in Section 5, we analyze the routing behavior of EWoRA for different task types (Hellaswag, Winogrande) in the general reasoning model. Since we have two different task types, we take the L1 difference $d(\overline{\boldsymbol{\alpha}}^{(\ell,m)}_{\text{hellaswag}} - \overline{\boldsymbol{\alpha}}^{(\ell,m)}_{\text{winogrande}})$. As seen in Figure 3, the general model shows a similar routing behavior to the mixed model which helps EWoRA better adapt to the under-represented set (Winogrande).

D Evaluating on the Source Domain

Similar to Biderman et al. (2024), we use the models finetuned on the code and math target domains and evaluate on HellaSwag, Winogrande, and the ARC-Challenge (Clark et al., 2018) benchmarks. The evaluation tasks are termed "source-domain" tasks as the base pretrained model already exhibits good competency on them as evidenced by its performance metrics. Thus, they provide a good benchmark to evaluate potential degradation in model performance when finetuned to a specialized target domain (such as code or math).

Results, as shown in Table 2, indicate that EWoRA is competitive with baselines - LoRA and AdaLoRA - when evaluated on the forgetting tasks (performing better than both in 4 out of 6 cases). This suggests that EWoRA retains at least as much source-domain knowledge as LoRA, leading to significantly less forgetting than full-finetuning as shown by Biderman et al. (2024). Given the generally-better performance on the target-domain in our experiments, we can say that EWoRA also leads to a better learning-forgetting tradeoff than conventional LoRA.

	HellaSwag	Winogrande	ARC
Mistral 7B (Base)	61.25/81.09	74.27	50.0/54.10
Code-Finetuned			
LoRA	61.22/80.90	**75.06**	**50.26/54.01**
AdaLoRA	61.21/80.96	74.03	50.0/53.75
EWoRA	**61.84/81.12**	73.09	48.04/52.05
Math-Finetuned			
LoRA	58.37/74.06	60.69	41.38/44.62

The Alchemy of Thought: Understanding In-Context Learning Through Supervised Classification

Harshita Narnoli and Mihai Surdeanu
Department of Computer Science, University of Arizona, Tucson, AZ, USA
{harshitanarnoli,msurdeanu}@arizona.edu

Abstract

In-context learning (ICL) has become a prominent paradigm to rapidly customize LLMs to new tasks without fine-tuning. However, despite the empirical evidence of its usefulness, we still do not truly understand how ICL works. In this paper, we compare the behavior of in-context learning with supervised classifiers trained on ICL demonstrations to investigate three research questions: (1) Do LLMs with ICL behave similarly to classifiers trained on the same examples? (2) If so, which classifiers are closer, those based on gradient descent (GD) or those based on k-nearest neighbors (kNN)? (3) When they do not behave similarly, what conditions are associated with differences in behavior? Using text classification as a use case, with six datasets and three LLMs, we observe that LLMs behave similarly to these classifiers when the relevance of demonstrations is high. On average, ICL is closer to kNN than logistic regression, giving empirical evidence that the attention mechanism behaves more similarly to kNN than GD. However, when demonstration relevance is low, LLMs perform better than these classifiers, likely because LLMs can back off to their parametric memory, a luxury these classifiers do not have.

1 Introduction

In-context learning (ICL) has emerged as the dominant paradigm for adapting large language models (LLMs) to new tasks without requiring any parameter updates. ICL achieves this by including a few relevant examples (or demonstrations) in the LLM's prompt (Brown et al., 2020; Wei et al., 2022). However, despite the considerable amount of empirical evidence for ICL's usefulness, the reasons behind its success remain unclear. On one hand, a few notable works establish an equivalence between ICL and gradient descent (GD) based on synthetic settings (Von Oswald et al., 2023; von Oswald et al., 2024; Akyürek et al., 2023; Ahn et al., 2023). These works hypothesize that transformers use internal optimization using gradient-based algorithms to learn in-context. On the other hand, Deutch et al. (2024) observes a weak correlation between ICL and GD, uncovering several major discrepancies in the flow of information throughout the model between the two processes. These contradictions suggest that we still do not yet know *how* ICL works.

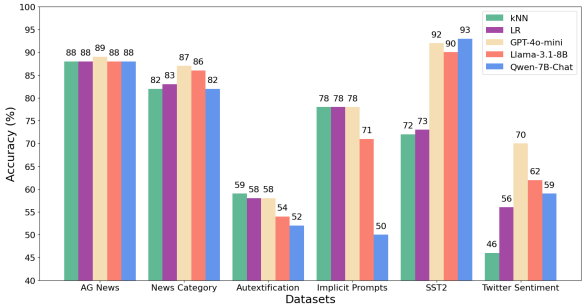

Figure 1: Performance on six datasets of kNN, LR, GPT-4o-mini, Llama-3.1-8B-Instruct, and Qwen-7B-Chat models for the same $k = 10$ examples used by each model. In several datasets, LLMs perform similarly to kNN and LR, but this is not always the case.

In this paper, we continue the quest to understand ICL's behavior in the context of text classification tasks. Unlike previous work, we base our work on the intuitive empirical observation that ICL *should* be similar to supervised classifiers trained on ICL examples.[1] We further refine this idea into two directions. First, building on the above hypothesis that ICL may behave similar to GD, these classifiers could belong to the family of classifiers based on gradient descent. To explore this direction, we leverage Logistic Regression (LR) (LaValley, 2008). Second, we observe that the decoder's attention mechanism feels sim-

[1]For brevity, we refer to these classifiers trained on ICL examples simply as *classifiers* from here on. We use *example* or *demonstration* interchangeably to point to the demonstrations used in ICL or the training examples used by the classifiers.

ilar to the example weights assigned by weighted k-nearest-neighbors (kNN) (Dudani, 1976). Based on this, we explore two variants of kNN classifiers. We convert this intuition into three research questions: *(1) Do LLMs with ICL behave similarly to classifiers trained on the same examples? (2) If so, which classifiers are closer, those based on gradient descent or those based on kNN? (3) When they do not behave similarly, what conditions make them behave differently?*

To answer the above questions, we compare the performance and behavior of three LLMs with ICL (GPT-4o-mini (OpenAI, 2024), Llama-3.1-8B-Instruct (AI@Meta, 2024), and Qwen-7B-Chat (Yang et al., 2024)) against kNN and LR on six datasets. For a fair comparison, all models have access to the same training examples/demonstrations for each prediction. These examples were selected based on cosine similarity with the corresponding test example, using contextualized embeddings generated by Sentence-BERT (Reimers and Gurevych, 2019). In this paper, we focus on text-classification tasks due to their ubiquity and ease of manual analysis.

We draw several observations from our analysis. First, in most situations, LLMs obtain similar or close performance to the classifiers (see the three left-most datasets in Figure 1). More interestingly, LLMs *behave* similarly to kNN and LR in these situations, as supported by a high Kappa agreement (Cohen, 1960) between their outputs.

Second, LLMs show a slightly higher Kappa agreement with kNN, giving more empirical weight to the hypothesis that ICL behaves more similarly to the kNN mechanism.[2]

Third, these observations do not always hold (see the three right-most datasets in Figure 1). Our hypothesis is that the similarity in behavior is driven by the relevance of ICL examples, where *example relevance* characterizes the extent to which ICL examples align with the testing data point.[3] To verify the hypothesis, we propose the following experiment: (a) We first annotate examples based on their relevance to the corresponding data point. The annotation is performed both manually and automatically. (b) Using this relevance, we determine whether its values are associated with the similarity between classifiers and LLMs. To do this, we compute the Kappa agreement between the classifier and LLM outputs. (c) We then examine the correlation between the Kappa values and the relevance scores. As anticipated, we observe a high correlation between relevance (both manual and machine) and Kappa agreement between models. In other words, when the relevance score is high, it naturally aligns with a higher Kappa agreement. This suggests that LLMs with ICL behave similarly to classifiers when the underlying examples are of high relevance. When not, their performance and behavior begin to diverge.

Beyond the more theoretical understanding of the behavior of ICL, our analysis yields an important practical insight: when relevant examples are available for a given task, LLMs can be replaced by a simpler and much more efficient classifier.

2 Related Work

We organize our discussion of previous work into two categories: papers that aim to understand how ICL works and those that improve its performance.

2.1 Understanding In-context Learning

Several research studies have focused on ways to understand ICL in different scenarios. In the context of gradient descent (GD), Dai et al. (2023) interpreted ICL as meta-optimizers through comparative analysis between ICL and explicit fine-tuning. Akyürek et al. (2023) theoretically proved that transformers can implement learning algorithms for linear models using gradient descent and closed-form ridge regression.

Around the same time, Von Oswald et al. (2023) explored the relation between training transformers on auto-regressive objectives and gradient-based meta-learning formulations. They investigated how transformers construct a loss function from given examples and the mechanisms through which they incorporate knowledge using the gradients of this loss function. Building on this idea, von Oswald et al. (2024) explored the underlying mechanisms of gradient-based mesa-optimization, i.e., a form of learning that "is acquired through training, as opposed to being inherent to the model" in autoregressive transformers trained for sequence modeling tasks. By reverse-engineering these models, they demonstrated that their in-context learning (ICL) capability arises from the mesa-layer, an innovative attention layer designed to efficiently solve a least-squares optimization problem. In the same space,

[2]However, please refer to Limitations for an additional discussion.

[3]For simplicity, henceforth we refer to example relevance as 'relevance'.

Zhou et al. (2025) analyzes whether LLMs perform ICL through an error-driven process similar to how humans learn. By testing for the inverse frequency effect, a phenomenon where rare examples more influence an agent than likely ones, the authors show that LLMs exhibit similar behavior to humans, suggesting that ICL involves an implicit error-driven learning mechanism like gradient descent.

In contrast, Deutch et al. (2024) reexamined the hypothesis that GD approximates ICL, identifying key issues in the evaluation metrics and baselines proposed by Dai et al. (2023). Shen et al. (2024) similarly points out the inconsistent behavior of ICL and GD in a natural setting. They demonstrated that the hand-constructed weights used in these studies show properties that differ from those found in practical scenarios. Fu et al. (2024) provided evidence that transformers acquire in-context learning (ICL) capabilities by employing higher-order optimization instead of gradient descent (GD). They demonstrated that transformer architectures can efficiently implement Newton's method, in which transformers significantly outperformed GD in terms of speed, exhibiting exponential acceleration. Nafar et al. (2025) investigates the underlying mechanisms of ICL in LLMs within regression tasks. The work explores how LLMs learn from examples given in prompts versus relying on their internal knowledge.

Similar to most of these efforts, our work focuses on understanding ICL. We empirically observe that ICL behaves similarly to both gradient descent and kNN classifiers trained on the same examples as the demonstrations provided in ICL prompts. However, this observation only holds when the relevance of demonstrations is high. We believe this is more intuitive and has more practical implications.

2.2 Improving In-context Learning

Another line of research, such as Wang et al. (2024), examines the in-context learning phenomenon from a Bayesian perspective, viewing real-world LLMs as latent variable models. Based on this concept, the work proposes a practical and better demonstration selection algorithm using a small LLM to approximate optimal latent concepts, which are then generalized to larger LLMs. The method yields significant performance gains, bridging the gap between theory and practical LLM behavior. Focusing on the quality of examples, An et al. (2023) proposes SKILL-KNN, which is a training-free, skill-based approach for few-shot example selection in in-context learning. The work utilizes prompting LLMs to generate task-relevant skill descriptions from raw inputs. SKILL-KNN mitigates biases associated with surface-level features commonly found in embedding-based selection methods to generate better examples. Whereas this prior research primarily uses kNN to find better examples for ICL, our work treats kNN as a comparative framework to gain insights into understanding the behavior of ICL.

Another work proposes framing the selection of demonstration examples as a sequential decision-making problem and employs reinforcement learning (RL) to learn policies for selecting examples (Zhang et al., 2022). This method is runtime expensive and does not consider examples based on similarity to the test data point. Instead, they observe that label distribution in the demonstration pool matters. In contrast, our work is simple, i.e., we use a standard model, Sentence-BERT, to provide a range of quality examples based on similarity. Further and more importantly, our work focuses on how the relevance of the examples impacts the decision of the downstream models.

Min et al. (2022) focuses on the structure of demonstrations rather than demonstration relevance for the test data. This work shows that factors like formatting and input-label alignment significantly affect LLM performance. Nevertheless, this approach is different than our work, as our main focus is to investigate the importance of demonstration relevance.

Additionally, Margatina et al. (2023) shows that selecting the semantically similar examples for prompts—using active learning strategies—can enhance ICL performance more than random demonstrations. It shows that the semantically similar demonstrations outperform other strategies and provide high-quality examples. Our paper takes this idea a step further. We aim to understand what happens when we use Sentence-BERT to select examples. Our work is different because we observe two important and practical conclusions when we use such examples: (i) ICL behaves very closely to kNN, which is novel, in cases of relevant examples; (ii) if the relevance of examples is not high, we do not observe the above correlation. This suggests that LLMs may back off to their existing knowledge in this situation.

3 Empirical Analysis

Despite the progress in understanding the behavior of ICL, a critical gap remains in how these systems behave the way they do. We design our goal of understanding ICL's behavior as a comparison to classifiers trained on the same examples as ICL demonstrations. We approach this by performing a formal empirical analysis of the two, aimed at analyzing their similarity in performance and outputs across multiple models and datasets. Our findings revealed that ICL and classifiers are similar in performance, and in most cases, they generate the same labels.

The observation sparked our curiosity: When they do not behave similarly, what conditions are correlated with differences in behavior? To explore this, we annotate a sample of ICL examples with respect to their relevance and compute the correlation between example relevance and behavior similarity. The results are striking; we observe that LLMs behave similarly to the classifiers when the relevance of the demonstrations is high. We further investigate how changes in the relevance of examples influence the similarity in behavior.

3.1 Preliminaries

This section outlines the experimental setup used to support our findings. To provide a comprehensive overview, we perform text classification tasks on six datasets with kNN, LR, and three LLMs (GPT, Llama, and Qwen). Prior to running the classification experiments, we generate text embeddings for both the training and test inputs of each dataset using Sentence-BERT (Reimers and Gurevych, 2019).

3.1.1 Models

Sentence-BERT: The model generates embeddings that are used to retrieve the closest k examples from the training set based on similarity scores for each test case. To achieve this, we generate and save the contextualized embeddings for both the training and test data of each dataset using Sentence-BERT. During evaluation, we select the top-k training examples with the highest similarity by sorting them in descending order of cosine similarity between their embedding vectors and the corresponding test embedding. Note that, to have a fair comparison between classifiers and LLMs with ICL, the same examples were used by all LLMs.[4]

kNN: We perform our experiment with two variants of kNN: *unweighted kNN* (Fix and Hodges, 1951) and *weighted kNN* (Dudani, 1976). In the unweighted case, the predicted label for a test point is determined by a simple majority vote, meaning the label most common among its nearest neighbors is chosen. In weighted kNN, however, each neighbor's vote is scaled by its similarity score, giving closer or more similar examples greater influence in the decision. In our experiments, we observed that both approaches behave quite similarly, with nearly identical performance outcomes. Hence, for simplicity, we report the results of correlation using only the unweighted kNN.[5]

LR: Similar to kNN, we train a *Logistic Regression* model using labeled training data with ICL demonstrations when $k > 1$. In the case of a single training example—a situation that this discriminative classifier cannot handle—the model is configured to behave as a 1-NN classifier to keep the experiments consistent with kNN. We consider LR, as it is inspired by prior work on probing models that employ lightweight classifiers (Hewitt and Liang, 2019; Zhao and Bethard, 2020).

LLMs: We used three pre-trained LLMs: GPT-4o-mini (OpenAI, 2024), Llama-3.1-8B-Instruct (AI@Meta, 2024), and Qwen-7B-Chat (Yang et al., 2024). These LLMs have demonstrated proficiency across a range of tasks, such as text classification and sentiment analysis, using only a limited set of task-specific examples. We perform text classification using a common prompt with small changes based on the behavior of the LLM (a prompt example is provided in Appendix D). The LLMs range in size from 7B to 8B. As mentioned, all LLMs used exactly the same ICL demonstrations as the other classifiers.

3.1.2 Datasets

For our experiments, we used six datasets: AG News (Zhang et al., 2015), News Category (Misra, 2022), AuTexTification (Sarvazyan et al., 2023), Implicit Prompts (Das et al., 2024), SST-2 (Socher et al., 2013), and SemEval-2019 Task 6 (Zampieri et al., 2019). During evaluation, for datasets with large test partitions, we conduct experiments using

[4]Our goal in this paper is not to develop a novel example selection strategy, but rather to understand the classifiers and LLM behavior under a shared, common strategy. It is quite possible that both classifiers and LLM absolute performance would improve with a more sophisticated example selection strategy.

[5]The performance results of weighted kNN are provided in Appendix G.

a sample of approximately 1,000 test data points. Table 6 in Appendix B shows the total number of test cases along with the selected sample size and the number of labels. Additionally, the labels for these datasets are listed in Appendix B in Table 7.

3.2 Comparing Model Behavior

We begin with the analysis that motivates our study, highlighting the first research question: **RQ1: Do LLMs with ICL behave similarly to classifiers trained on the same examples?** To explore this, we set out to compare the behavior of three different LLMs (GPT-4o-mini, Llama-3.1-8B-Instruct, and Qwen-7B-Chat) with classifiers (kNN and LR).

3.2.1 Measuring Performance in Terms of Accuracy

We conduct a systematic analysis of all the models to measure performance, which is evaluated on different datasets with the same k examples. On examining their performance from Table 1, we see that the accuracy of kNN, LR, and three LLMs is similar in most cases. This is further visualized in a heatmap plot (Figure 2) that reflects the performance differences between kNN and each LLM, as well as between LR and each LLM, across all settings. The figure indicates that the accuracy differences between classifiers and the three LLMs are minuscule on three datasets (left part of the figure). For example, the performance difference on AG News and News Category is 0 or very close to 0 in most cases. However, these differences increase significantly on the three datasets in the right part of the figure, with the difference reaching as high as 35% between kNN and Qwen on Implicit Prompts.

Building on these findings, a natural next question arose; **RQ2: If ICL behaves similarly to classifiers with the same set of examples, which classifiers are closer, those based on gradient descent (GD) or those based on k-nearest neighbors (kNN)?** We observe that kNN and Logistic Regression have comparable performance, while ICL aligns more closely with kNN.[6] However, as we have a very simple gradient-based classifier, the results may vary with non-linear GD classifiers.

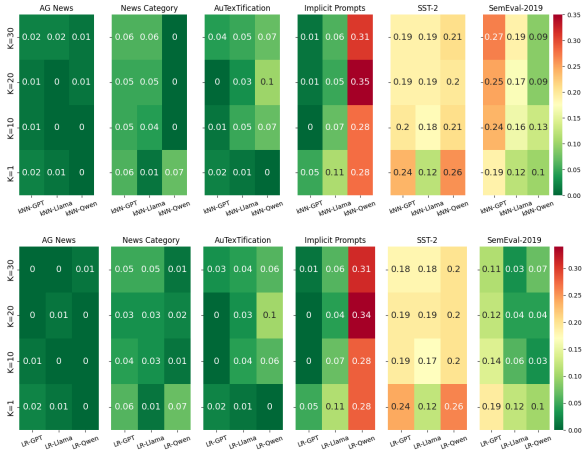

Figure 2: Visualization highlighting the difference in accuracy between kNN (top) and LR (bottom), each compared with three LLMs. Each vertical block is a different dataset; each row is a setting with a different number of ICL examples (from 1 to 30). The difference is also encoded with a color gradient, where green means lower difference (higher similarity) and red indicates high differences (low similarity).

3.2.2 Assessing Model Similarity Using Contingency Matrices

At this point, one might reasonably argue that performance parity among models does not necessarily imply similar behavior, as they may achieve comparable performance scores while exhibiting different predictions of labels. To better understand the similarity in performance, we next construct contingency matrices between each LLM

[6] Detailed comparison of kNN with LR is given in Appendix H.

and the classifiers' outputs. This helps to investigate whether classifiers and LLMs actually *behave* in a similar manner, i.e., *do classifiers and LLMs generate identical labels given the same input?*

In our work, we plot the contingency matrices between kNN and LR (X-axis) and the three LLMs (Y-axis) on the six datasets. These matrices provide a structured way to compare and evaluate the labels predicted by different models. That is, the more similar two outputs are, the more weight the diagonal will have. The matrices support our observation: classifiers and LLMs exhibit similar behavior on some datasets but not on all. For example, referring to the contingency matrices of AG News (Figure 3) and News Category (Figure 4), we find that they follow diagonal dominance, which indicates that both classifiers produce almost the same labels as LLMs. In an opposing case of Implicit Prompts (Figure 6), we observe that the classifiers tend to favor the offensive label. We hypothesize that this occurs because the label distribution of the dataset is heavily biased towards offensive prompts.[7]

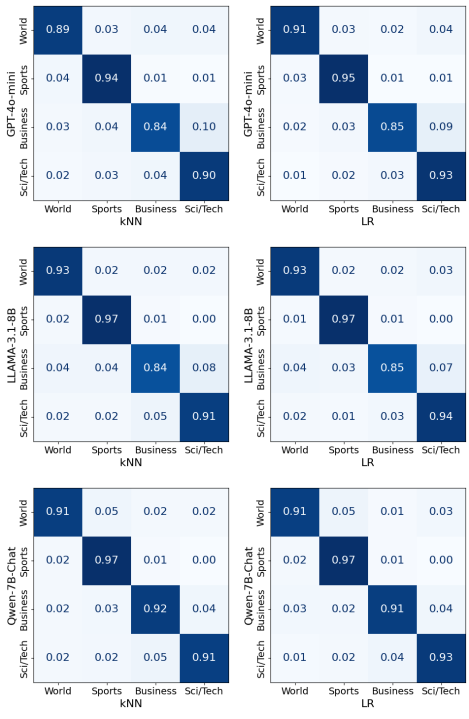

Figure 3: Contingency matrices for AG News: Comparison of kNN vs GPT (top-left), kNN vs Llama (middle-left), and kNN vs Qwen (bottom-left) and LR vs GPT (top-right), LR vs Llama (middle-right), and LR vs Qwen (bottom-right) for $k = 20$.

Overall, we observe that diagonal dominance

[7]All contingency matrices and extended discussion included in Appendix F.

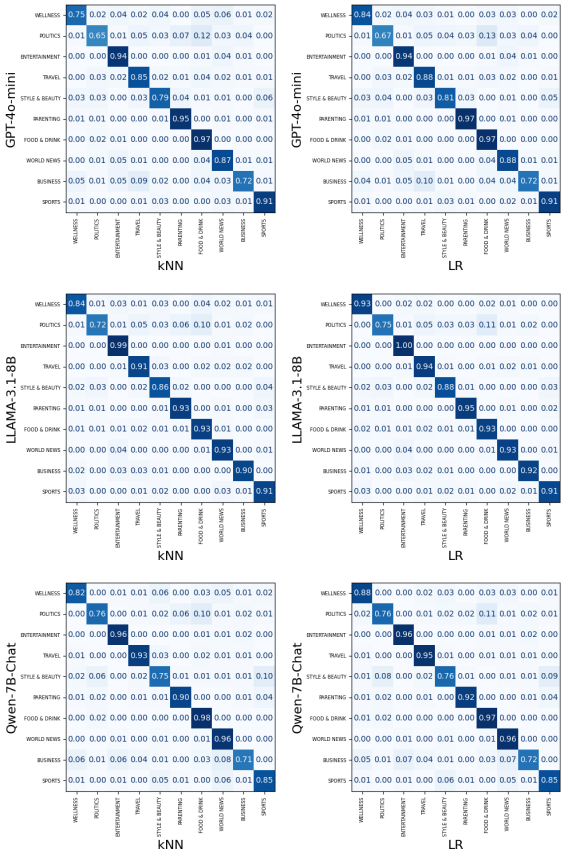

Figure 4: Contingency matrices for News Category: The same configuration follows from Figure 3.

is excellent in 2 out of 6 datasets, good in 2, and decent in 2.

3.3 Does Example Relevance Correlate with Behavior Similarity?

All the previous observations immediately indicate a puzzling conclusion: classifiers and LLMs with ICL obtain similar performance in general but not in all cases. These results lead to a new question: **RQ3: When LLMs and classifiers do not behave similarly, what conditions are correlated with differences in behavior?** To investigate this, we hypothesize that, given the performance of kNN is driven by examples, it is essential to analyze the correlation between example relevance and the performance of models.

3.3.1 Understanding Example Relevance

In our context, we define *example relevance* in terms of *task relevance for the provided evaluation data point*. Informally, relevance indicates how well a semantically similar example closely matches the input test data prompt for the task at hand. By selecting examples that are relevant to

the input prompt, we can measure whether a direct correlation between example relevance and the similarity in behavior of models exists.

To establish correlation, we mark the top-k semantically similar examples with a Boolean label for each example. We assign a value of '1' to the examples that are relevant to the input test data prompt, and '0' to those that are not. For each test data prompt, we determine an average of these values for all examples, which we call a *relevance score*, reflecting the percentage of the top-k examples that are relevant to the input prompt.

For labeling the examples, we consider two options: one based on manual annotations and the other based on the respective LLM. In the first case, considering human annotators for all examples across the entire test prompts is both challenging and expensive. For this reason, we sample and annotate a set of 50 test data prompts for each setting of $k = 1, 10$, and 20 examples manually by Human-A.[8] To verify the robustness of the manual annotations, a smaller subsample of data points was independently annotated by another human annotator (Human-B).[9] We find substantial Kappa agreement ($\approx 70\%$) of relevance scores between the two human annotators.

We use the same set of $1,550$ examples, this time using the respective LLM to calculate their corresponding relevance score. We then compare the agreement between relevance scores by human and machine annotators. To measure agreement, we introduce two scores. The first score, $\mathcal{K}^{rel}_{H,M}$ represents the Kappa agreement on relevance between a human and an LLM. The second measures the inclusion score ($\mathcal{I}_{H \subset M}$), which reflects the fraction of humans' relevance scores that is included within that of LLMs. $\mathcal{I}_{H \subset M}$ score of 0 indicates no inclusion, and a score of 1 indicates complete inclusion. Table 2 shows the Kappa ($\mathcal{K}^{rel}_{H,M}$), and Inclusion ($\mathcal{I}_{H \subset M}$) scores of relevance between Human-A and Gpt-4o-mini.

We find that even though the $\mathcal{K}^{rel}_{H,M}$ value is not good, the $\mathcal{I}_{H \subset M}$ reflects an interesting conclusion that a vast majority of examples annotated as relevant by the human annotator were also considered relevant by the LLM annotator. In other words, the human annotators are more conservative than the LLMs in labeling a demonstration as relevant. To compensate for this, we use two types of relevance scores (Human and LLM) in the following sections for our correlation analyses. For the LLM annotator, which scales better, we also generate the relevance scores for *all* test data prompts for $k = 1, 10$, and 20 examples.

Datasets	$k=1$		$k=10$		$k=20$	
	$\mathcal{K}^{rel}_{H,M}$	$\mathcal{I}_{H \subset M}$	$\mathcal{K}^{rel}_{H,M}$	$\mathcal{I}_{H \subset M}$	$\mathcal{K}^{rel}_{H,M}$	$\mathcal{I}_{H \subset M}$
AG News	0	1	0.05	0.98	0.09	0.97
News Category	0.41	0.95	0.28	0.92	0.24	0.89

Table 2: Kappa agreement between relevance of Human-A and Gpt-4o-mini ($\mathcal{K}^{rel}_{H,M}$) and corresponding Inclusion score ($\mathcal{I}_{H \subset M}$) for increasing k.

3.3.2 Correlation between Example Relevance and Model Similarity

Based on prior discussions, we know that ICL is similar to classifiers in many situations; the next step is to identify the conditions under which this similarity occurs. To explore this, we examine how the relevance scores of humans and LLMs are correlated with the Kappa agreement between models. For simplicity, we refer to the Kappa agreement between the labels predicted by the classifiers and LLM as model Kappa, denoted by $\mathcal{K}^{model}_{C,L}$.

To measure the correlation between model similarity and example relevance, we employ two types of correlations that are widely used to measure the association between two variables: the Pearson correlation coefficient (r) and the R-squared (R^2) coefficient (Sedgwick, 2012; Wright, 1921). r captures the linear correlation between two variables by computing the ratio between the covariance of two variables and the product of their standard deviations; it ranges between -1 and 1. R^2 is the proportion of the variation in one variable that is predictable from the other one. For example, we interpret the R^2 between example similarity and the Kappa agreement between two models as the fraction of the Kappa score that can be explained by example relevance.

Formally defining, we measure the correlation between the $\mathcal{K}^{model}_{C,L}$ and two variables: the first one is the average relevance score determined by a human (denoted by $\mathcal{R}_{Human}$), and the second is by the respective LLM as an annotator (denoted

[8] We annotated a total of $50 \times (20 + 10 + 1) = 1,550$ examples per dataset.

[9] The two annotators each annotated two data points per configuration per dataset, for a total of $2 \times (20 + 10) = 60$ examples per dataset.

Table 4: Correlation comparison with **GPT-4o-mini** and **kNN** on *all* data prompts. The table shows the correlation between: Kappa agreement between the outputs of classifier(kNN) and LLM ($\mathcal{K}_{C,L}^{model}$); and the annotated relevance score by LLM on ICL examples ($\mathcal{R}_{LLM}$).

by $\mathcal{R}_{LLM}$). Intuitively, we hypothesize that there should be a direct correlation between both relevance scores and model Kappa. In other words, higher example relevance should correspond to a higher Kappa agreement score.[10]

Building on this hypothesis, we observe three key findings in Table 3. First, the Pearson Correlation (r) values are positive for each correlation, confirming that the more relevant the examples are, the more similar the LLM and classifier behave. This holds for both types of correlations, A and B, as defined in the table. Second, we find that increasing the number of examples (k) per test data point, the data more strongly supports these observations, suggesting that the LLM increasingly relies on ICL examples as more instances are provided in the context. Third, focusing on the R^2 value for $Correlation\text{-}A$ for $k = 20$, we indicate that up to 63.1% of the behavior similarity can be explained by example relevance.[11]

3.3.3 Scaling Up the Correlation Analysis to the Entire Test Partitions

As mentioned earlier, manual relevance is limited and expensive; hence, to scale up the experiment, we calculate the average relevance score on the annotations given by the underlying LLMs. This implies that the same procedure is extended to all test prompts, with the three LLMs employed as annotators for the relevance score of examples.

Consistent with the observations in Table 3, Table 4 shows that LLM maintains high relevance scores ($\mathcal{R}_{LLM}$) across k values because of high-quality semantically similar examples. Further-

[10] Since most of the datasets involve multi-class classification, we use the multi-class Kappa agreement formula (Cohen, 1960).

[11] Tables 10 through 14 in Appendix I show the results of all the analyses of correlation for the three LLMs investigated with classifiers.

more, the correlation value exhibits an upward trend, reflecting a similar pattern to that previously observed with both human and machine relevance on 50 test prompts. Note that in some cases, there is a slight drop in relevance scores from $k = 10$ to $k = 20$, which occurs because an increase in the number of examples introduces low-quality examples in the set, thereby reducing the overall relevance score. Because this drop aligns with model Kappa in these cases, the correlation values are not affected and exhibit the same trend as before.

4 Discussion

We hypothesize that when the relevance of the ICL examples is high, both LLMs and the classifiers rely on them for their predictions. When example relevance is low, differences begin to emerge; LLMs can back off to their parametric memory and still perform well in some cases. In contrast, the classifiers' performance is directly impacted by example relevance. Additionally, LLM indeed backs off to its parametric memory when using low-relevance demonstrations in ICL.[12]

We summarize the key observations from this study in Algorithm 1. The algorithm indicates that when the examples selected to be used by the classifier or ICL in LLMs are relevant (which was established using both human and LLM decisions), ICL performs and behaves similarly to kNN (and a little less so to LR). We validate this observation by showing that there is a high correlation between example relevance and similarity between ICL and the classifier. We also notice that when the relevance of examples is low, the two models diverge: the performance of classifiers generally drops, whereas the performance of the LLM is contingent on its pre-training and parametric memory, i.e., if the task at hand is well represented in its parametric memory, it continues to perform well.

Similar to our analysis, the task recognition method of Pan et al. (2023) also makes the distinction between non-parametric and parametric memory. However, we explain why both are important, and how ICL may choose one or another depending on the relevance of the demonstrations. "Task recognition" encourages LLMs to back off to a certain part of the parametric memory, so we think that their observation complements nicely our own.

[12]This was validated by comparing the outputs of the LLM with poor-quality examples with a zero-shot configuration of the same LLM. Please see Appendix J.

Algorithm 1 Summary of LLM with ICL behavior

```
top_k ← top k semantically similar examples
if top_k is relevant then
    LLMs ≈ kNN
else if top_k is less relevant then
    Performance of all classifiers drops
    Performance of LLMs may remain high, possibly
      due to parametric memory information
end if
```

This summary suggests an important practical insight: in the situations where the relevance of the ICL examples is high, the LLM can be safely replaced by the simpler kNN algorithm, which can be efficiently implemented using vector databases such as FAISS (Douze et al., 2024). This, of course, puts the onus on the methods for the example selection, but this is research that has already shown progress (Akyürek et al., 2023; Zhou et al., 2025; Shen et al., 2024; Fu et al., 2024; Nafar et al., 2025; Wang et al., 2024; An et al., 2023).

5 Conclusion

In this paper, we examine how closely ICL behaves to classifiers based on kNN or GD trained on the same ICL examples. We find that ICL behaves more similarly to kNN when subjected to certain conditions driven by the relevance of examples. This suggests that if one can strategically select highly relevant examples, they can just use kNN. However, in cases where the examples are of lower relevance, LLMs demonstrate greater robustness to noise due to their ability to back off to their parametric memory. As a result, LLMs become a more suitable choice in such scenarios, as prior knowledge allows them to perform better.

7 Limitations

In our current work, we focus on three LLMs and six text classification datasets, which provide initial insights into the observed patterns. We believe our observations are supported empirically by our current work and are already actionable. However, to strengthen our understanding of the underlying behavior of ICL, we plan to incorporate more LLMs,

multiple datasets, and more NLP tasks in future work. This will help validate our conclusions with greater confidence, ensuring that our results hold across diverse scenarios.

Further, our comparison between kNN and gradient descent and ICL used a linear GD-based classifier (logistic regression). This is a common strategy in probing (Hewitt and Liang, 2019; Zhao and Bethard, 2020). However, it is possible that ICL behaves closer to a non-linear GD-based classifier, such as a feed-forward neural network.

One concern is whether there is a causal link between the two variables that are correlated. i.e., the relevance scores of demonstrations and the Kappa agreement between LLMs and classifiers. In future work, we propose to compare two identical configurations (i.e., same LLM, same dataset, same number of demonstrations k), with the only difference being that one has access to high-quality demonstrations while the other uses low-quality examples. If causality holds, the Kappa values would be high for all configurations, and they should drop when we use bad examples.

8 Ethical Considerations

This work involves some datasets that may contain offensive content, which could be distressing to some readers. We have taken measures by using appropriate disclaimers to acknowledge the offensive language.

A Analysis of Manual Annotation Quality

Table 5 presents the inter-annotator agreement for the manual annotations of example relevance. The Kappa value, representing the level of agreement between annotators, was computed based on the manual annotations of two data points per dataset for $k = 10$ and $k = 20$. In total, $2 \times (10+20) = 60$ individual examples per dataset were annotated by each annotator.

Nearest Neighbors	Kappa
$k = 10$	0.70
$k = 20$	0.68

Table 5: Kappa agreement scores between the two annotators across all datasets.

These values indicate substantial agreement between the two human annotators, which provides evidence that the manual annotations of example relevance are reliable.

B Dataset Labels & Statistics

The complete statistics of all datasets used in the experiments are presented in Table 6.

Datasets	Train	Total Test	Sampled Test	#Labels
AG News	120000	7600	1001	4
News Category	40000	10000	1000	10
AuTexTification	33845	21832	1000	2
Implicit Prompts	6615	1655	1655	2
SST-2	67349	872	872	2
SemEval-2019	74682	1000	1000	4

Table 6: Data statistics of all the datasets used.

Additionally, the labels for the six datasets used in this work are presented in Table 7. We employ both binary and multi-class labels to ensure the generality of our approach.

Datasets	Labels
AG News	World, Sports, Business, Sci/Tech
News Catgory	Wellness, Politics, Entertainment, Travel, Style & Beauty, Parenting, Food & Drink, World News, Business, Sports
AuTexTification	Human, Generated
Implicit Prompts	Offensive, Not Offensive
SST-2	Positive, Negative
SemEval-2019	Negative, Positive, Neutral, Irrelevant

Table 7: Labels for the six datasets used in this work.

C Logistic Regression Model Training Using Top-k Nearest Examples

The classifier in this work is a vanilla logistic regression, similar to probing classifiers, where we have a linear layer on top of contextualized representations (Amini and Ciaramita, 2023).

We train a logistic regression model on ICL examples using their text and labels. The examples are first converted into numerical representations using a TfidfVectorizer vectorizer, which transforms each sentence into a high-dimensional feature vector. An LR model is trained only on these top-k examples as features with their labels. The same vectorizer is used to transform the test prompt into the same feature space.

D Example Prompt Used for Text Classification in ICL

The following prompt is used in the case of GPT-4o-mini for prompt engineering corresponding to AG News.

```
{"role": "system",
"content": f"Example: We know that
the classification for the text
'{examples[i]}', we have
answer: '{labels[i]}'."}

{"role": "system",
"content": f"According to the
above provided examples, classify
the following text. Answer as
World, Sports, Business, Sci/Tech
with no explanation."}

{"role": "user", "content": text}
```

Table 8: WARNING: This table contains language that might be offensive to some. 10 examples corresponding to a given test data point from two datasets. The first row indicates a test data point associated with high-quality examples (relevance score: $9/10$), whereas the second row presents a test data point with low-quality examples (relevance score: $0/10$).

In the given prompt, we first provide a set of example–label pairs determined by the value of k based on their similarity scores (top_k in Algorithm 1). In the next part of the prompt, the model is asked to generate the label for the provided test text.

E Relevance Score Labeling of Examples

We mark the top-k high-quality examples with a Boolean label for each example to indicate its relevance. We assign a value of '1' to the examples that are relevant to the input test data prompt, and '0' to those that are not. Table 8 shows two cases where one dataset contains more relevant examples than the other.

F Additional Contingency Matrices for Unweighted kNN

As discussed in the paper, we have generated contingency matrices to validate the classification of labels for unweighted-kNN and LR with respect to three LLMs (refer to Section 3.2.2). Figures 5 to 8 show the contingency matrices for all other datasets. As previously noted, for several datasets, we observe that the classifiers closely align with the classifications produced by LLMs, with only minor differences as k increases.

By analyzing the figures, we observe that, except for AG News (Figure 3) and News Category (Figures 4), the other datasets exhibit lower diagonal dominance. This is likely because the performance of the classifiers heavily depends on the examples, and on such datasets, the classifiers may be influenced by the way the examples are labeled.

This is evident because, although the performance metrics of the classifiers are comparable to those of LLMs in the case of AuTexTification (as shown in Table 1), the contingency matrices reveal inconsistencies in label classification (Figure 5). Similarly, in the Implicit Prompts (Figure 6), the dataset is designed to contain implicit offensive prompts, which means most examples are labeled as 'Offensive'. Consequently, the classifiers exhibit strong alignment with these labels.

The SST-2 (Figure 7) and SemEval-2019 (Figure 8) datasets show moderate diagonal dominance, meaning that correct predictions are somewhat

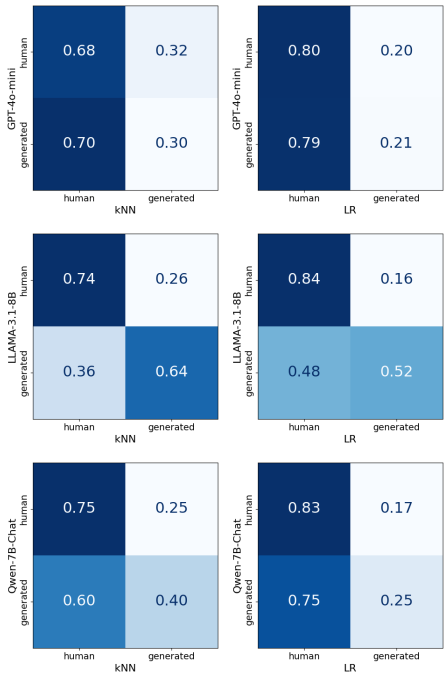

Figure 5: Contingency matrices for AuTexTification: The same configuration follows from Figure 3.

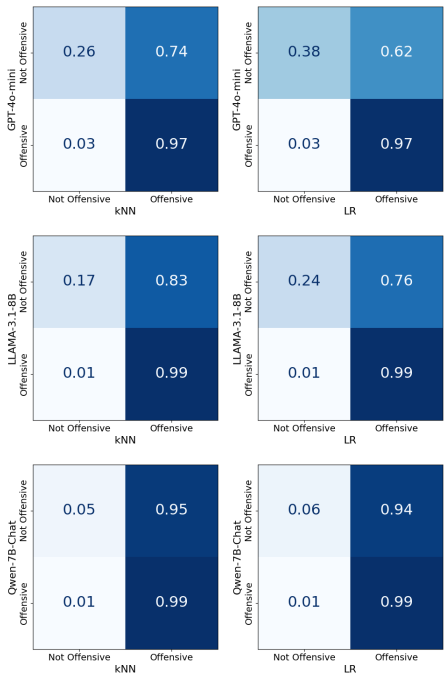

Figure 6: Contingency matrices for Implicit Prompts: The same configuration follows from Figure 3.

more frequent along the main diagonal of the confusion matrix. For these datasets, classifiers generally perform worse than LLMs, as indicated in Table 1.

Overall, these analyses suggest that classifiers and LLMs overlap in both performance and behavior in some cases, but not all.

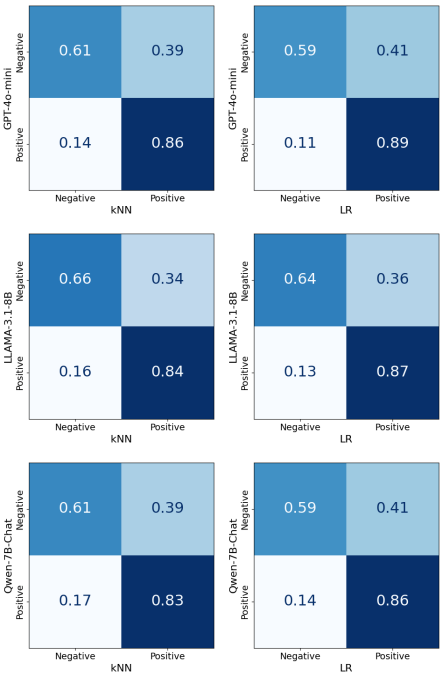

Figure 7: Contingency matrices for SST-2: The same configuration follows from Figure 3.

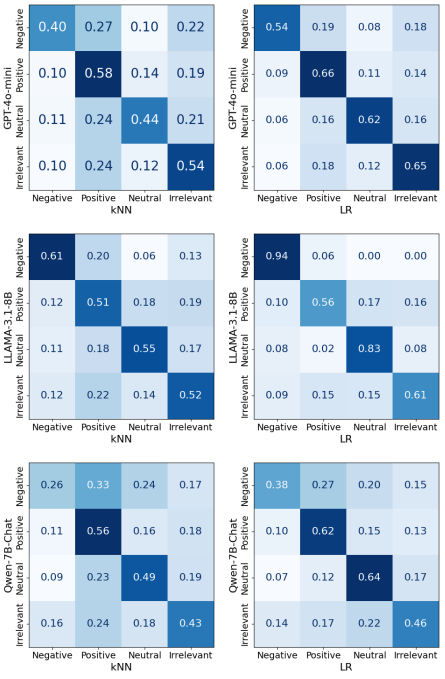

Figure 8: Contingency matrices for SemEval-2019: The same configuration follows from Figure 3.

G Weighted kNN Performance Evaluation

A reasonable question that arises from the results in Section 3.2 is: *Why not compare model performance when the models are informed about the example similarity scores?* To explore this, we aim to examine how similar the behavior of ICL

Dataset	$k=1$				$k=10$				$k=20$				$k=30$			
	kNN	GPT	Llama	Qwen	kNN	GPT	Llama	Qwen	kNN	GPT	Llama	Qwen	kNN	GPT	Llama	Qwen

Table 9: Test accuracy on six datasets for weighted-kNN and three LLMs with weighted ICL, using 1, 10, 20, and 30 examples.

would be to weighted kNN if the ICL prompt also includes information about the similarity scores of examples.[13] This analysis is built on the idea of conducting a comparative evaluation between weighted ICL and weighted kNN.[14]

We report the performance values of weighted kNN with three LLMs, considering all datasets for different numbers of k examples in Table 9. As noted earlier in Section 3.1.1, the performance is nearly identical to that of the unweighted kNN, suggesting that the inclusion of similarity scores does not substantially influence the results, and the behavior of ICL and kNN remains the same.

In line with the observations from Table 1, Table 9 indicates that the accuracy of weighted kNN and the weighted ICL on three LLMs is comparable across most cases. Additionally, the overall trend of accuracy values remains consistent with Table 1.

To further verify whether the performance of the models is indeed aligned, we examine the contingency matrices between the predictions of each LLM with weighted kNN. Figures 9 to 14 present the contingency matrices between weighted kNN (X-axis) and the three LLMs (Y-axis) on the six datasets.

[13] For simplicity, we call the scenario as *weighted ICL*, where we add the similarity scores of each example to the prompt of the original ICL, given in Appendix D.

[14] Definition of weighted kNN is discussed in 3.1.1.

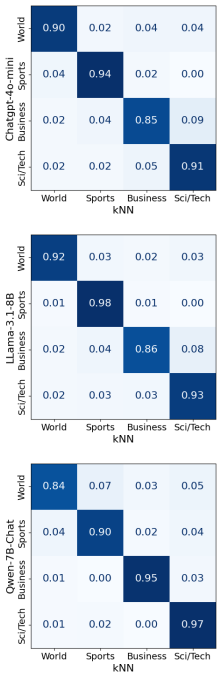

Figure 9: Contingency matrices for AG News: Comparison of weighted kNN vs GPT (top), weighted kNN vs Llama (middle), and weighted kNN vs Qwen (bottom).

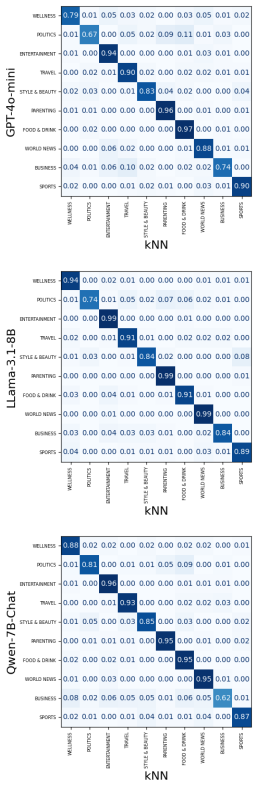

Figure 10: Contingency matrices for News Category: The same configuration follows from Figure 9.

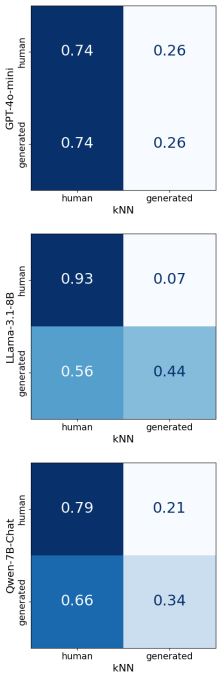

Figure 11: Contingency matrices for AuTexTification: The same configuration follows from Figure 9.

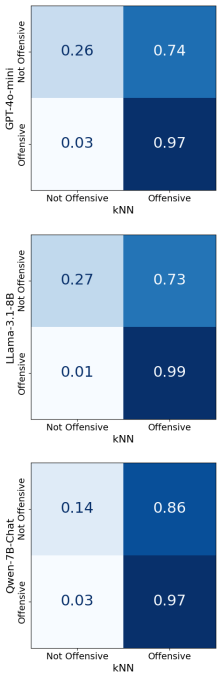

Figure 12: Contingency matrices for Implicit Prompts: The same configuration follows from Figure 9.

The resulting patterns of contingency matrices for weighted closely resemble those obtained for the unweighted variant of kNN, indicating consistent trends across both kNN configurations.

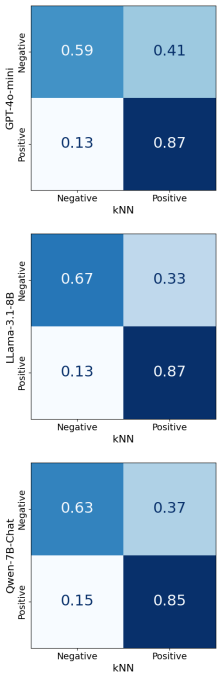

Figure 13: Contingency matrices for SST-2: The same configuration follows from Figure 9.

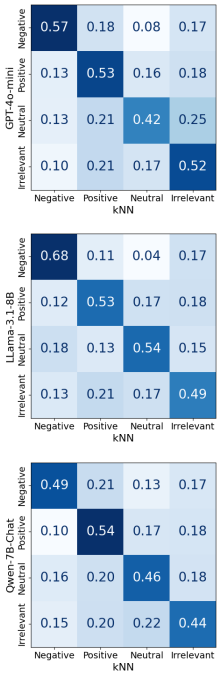

Figure 14: Contingency matrices for SemEval-2019: The same configuration follows from Figure 9.

H Does ICL Behave Closer to kNN or LR?

The Kappa scores reported in the six tables (3, 10, and 11 through 14), which measure behavior similarity between kNN/LR and the LLMs, show small but consistently higher values for kNN. For exam-

ple, for GPT-4o-mini with $k = 10$, the kNN model achieves a model Kappa ($\mathcal{K}_{C,L}^{model}$) value of 0.87 on AG News (first row in Table 3), whereas Logistic Regression (LR) attains a Kappa of 0.84 (first row in Table 10). On average, this observation holds for the other datasets and LLMs.

Further, the correlation values in these tables show a more intuitive behavior for kNN. This is evident from the increasing Pearson (r) and R^2 values as k grows, e.g., R^2 grows from 31.3% to 63.1% from $k = 1$ to $k = 20$ for $Correlation\text{-}A$ (Table 3). This trend does not hold for LR: R^2 drops from 31.3% to 26.8% in the same scenario (Table 10).

These observations suggest that ICL behaves closer to kNN than LR. However, as we have a very simple gradient-based classifier, the results may vary in larger models. In our setting involving simplified models, we focus on understanding the behavior of ICL with these classifiers.

I Additional Correlation Results

Extending our analysis from Table 3 to the comparison between GPT-4o-mini and LR, we present the correlation values in Table 10. Evidently, we note that R^2 value for $Correlation\text{-}A$ with $k = 20$ indicates that only up to 26.8% of the behavioral similarity can be explained by example relevance. This demonstrates that KNN exhibits a stronger correlation compared to LR.

Additionally, Tables 11 and 12 show the correlation results for Llama-3.1-8B with kNN and LR, respectively. As expected, kNN has a comparatively better correlation with the LLM when compared to LR. Similarly, we extend our analysis for QWEN-7B-Chat in Tables 13 and 14. kNN tends to perform closer to the LLM in this case as well.

In summary, the observations from Section 3.3.2 generally hold for the other two LLMs, with a couple of caveats. First, the correlations are weaker for $k = 1$, suggesting that one ICL example is not sufficient to influence the predictions of the two

LLMs. Second, the correlation values increase considerably from $k = 1$ to $k = 10$, but not always from $k = 10$ to $k = 20$. This suggests that these two LLMs can become "confused" by too many ICL examples. This is reflected in Table 1 where there is a decrease in the accuracy value of Qwen on SemEval-2019 from $k = 10$ to $k = 20$.

Additionally, Appendix J highlights that the LLM indeed backs off to its parametric memory when using low-quality demonstrations in ICL.This was validated by comparing the outputs of the LLM with poor-quality examples with a zero-shot configuration of the same LLM.

J Empirical Validation that LLMs under ICL with Poor-Quality Examples Back off to Parametric Memory

To validate the hypothesis that LLMs, when using ICL with poor-quality examples, back off to parametric memory, we compare their outputs with the same LLM in a zero-shot configuration. If our hypothesis is correct, both settings should produce similar labels, with a high Kappa agreement between them. In particular, we ran the three LLMs for 50 test samples under two settings: one with no examples (zero-shot) and the other with 10 poor examples. Table 15 shows the Cohen's Kappa agreement between the two settings for different LLMs.

Datasets	Gpt-4o-mini	Llama-3.1-8B	QWEN-7B-Chat
AG News	0.86	0.57	0.45
News Category	0.98	0.43	0.63
AuTexTification	0.96	0.09	0.05
Implicit Prompts	0.69	0.59	0.40
SST-2	0.60	0.68	0.96
SemEval-2019	0.13	0.45	0.42

Table 15: Kappa agreement between zero-shot and poor-quality examples for all datasets.

The vast majority of Kappa values in Table 15 indicate substantial to near-perfect agreement, which aligns with our expectation that LLM relies on parametric memory when example quality is low, resulting in behavior comparable to the zero-shot. This is an encouraging result, which suggests that LLMs can ignore low-quality examples. There are some exceptions to the rule, which suggests that in some situations, low-quality demonstrations influence LLM behavior, like the SemEval-2019 dataset on Gpt-4o-mini, and AuTexTification on Llama-3.1-8B and QWEN-7B-Chat.

K Selected Examples Do not Necessarily Share the Same Label

A potential concern from our observations is that the similar behavior of LLM-based classifiers might be because of the possibility that selected examples in ICL or kNN[15] have all the same label. However, as shown below, this largely does not apply to our scenario. To verify this, we analyze the proportion of test data points in each dataset whose selected examples have the same versus differing labels (see Table 16).

Datasets	$k = 10$	$k = 20$	$k = 30$
AG News	49.35	33.37	23.676
News Category	34	18.8	10.8

Implicit Prompts	15.95	3.987	0.42
SST-2	26.49	11.353	5.73
SemEval-2019	5.2	0.6	0.2

Table 16: Percentage of datapoints where all the examples have the same label for increasing k.

In each of these cases, we further check the percentage of datapoints where the labels predicted by kNN and LLM align. For example, in Table 17, for the 49.35% of datapoints where AG News has all the same labels (from Table 16), kNN and Gpt-4o-mini make the same prediction 99.4% of the time. Similarly, as shown in Table 18, among the 50.65% of data points where AG News has different labels, kNN and Gpt-4o-mini agree in their predictions 81.85% of the time.

Gpt-4o-mini tend to make similar predictions even when the example labels are not identical.

Similar to Table 17 and 18, Table 19 and Table 20 present results for Llama-3.1-8B under the same scenario. Interestingly, the percentage of data points with different labels of examples in Table 20 for the labels predicted by kNN and the Llama-3.1-8B shows high agreement when compared to Table 18. Further, we extend the analysis to QWEN-7B-Chat and present results in Table 21 and 22. In this case as well, we observe a similar behavior as both Gpt-4o-mini and Llama-3.1-8B, indicating that the underlying patterns remain consistent across different settings.

Mark My Words: A Robust Multilingual Model for Punctuation in Text and Speech Transcripts

Sidharth Pulipaka[1] **Ashwin Sankar**[1,2] **Raj Dabre**[1,2,3*]
[1]Nilekani Centre at AI4Bharat [2]Indian Institute of Technology, Madras

🤗 ai4bharat/Cadence

Abstract

Punctuation plays a vital role in structuring meaning, yet current models often struggle to restore it accurately in transcripts of spontaneous speech, especially in the presence of disfluencies such as false starts and backtracking. These limitations hinder the performance of downstream tasks like translation, text-to-speech, summarization, etc. where sentence boundaries are critical for preserving quality. In this work, we introduce Cadence, a generalist punctuation restoration model adapted from a pretrained large language model. Cadence is designed to handle both clean written text and highly spontaneous spoken transcripts. It surpasses the previous state-of-the-art in performance while expanding support from 14 to all 22 Scheduled Languages of India and English. We conduct a comprehensive analysis of model behavior across punctuation types and language families, identifying persistent challenges under domain shift and with rare punctuation marks. Our findings demonstrate the efficacy of utilizing pretrained language models for multilingual punctuation restoration and highlight Cadence's practical value for low-resource NLP pipelines at scale.

1 Introduction

Punctuation plays a vital role in written language, offering syntactic structure, semantic clarity, and pragmatic cues such as pauses, emphasis, and sentence boundaries. However, text generated by Automatic Speech Recognition (ASR) systems or large-scale web crawls often lacks punctuation (Bhogale et al., 2025). This absence significantly impairs both human readability and the effectiveness of downstream NLP tasks like Machine Translation (MT), Text Summarization, and Sentiment Analysis, posing a widespread challenge in processing raw textual data.

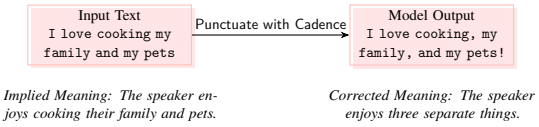

Figure 1: An example of critical disambiguation by our model, *Cadence*. By inserting serial commas, the model correctly interprets the input as a list of three distinct items, rather than a single, disturbing hobby.

While punctuation restoration has progressed for high-resource languages like English (Guhr et al., 2021), Indic languages face substantial hurdles. These include scarcity of annotated corpora, especially for low-resource languages, and linguistic complexity with diverse scripts, grammars, and unique marks like the Devanagari purna virama. Prior efforts are often limited in language or punctuation scope, or use non-scalable, language-specific models, hindering cross-lingual generalization, particularly for under-represented languages (Gupta et al., 2022).

To bridge this gap for Indic languages, we first construct a large, diverse multilingual punctuation corpus covering both written and ASR-transcribed text, aggregating multiple sources, including Sangraha-verified (Khan et al., 2024), IndicVoices (Javed et al., 2024), translated Cosmopedia (Ben Allal et al., 2024), and IndicCorp-v2 (Doddapaneni et al., 2023). Secondly, we adapt the GEMMA3-1B-PRETRAIN model (Team et al., 2025) for punctuation restoration by converting it into a bidirectional transformer using a Masked Next Token Prediction (MNTP) objective (BehnamGhader et al., 2024), which we call Cadence. Thirdly, we evaluate the model's performance on crucial and frequently used punctuations as well as rare punctuations. Moreover, we establish Cadence as the state-of-the-art tool for punctuation restoration across both written and spoken contexts in English and 22 Indian languages;

Assamese, Bengali, Bodo, Dogri, Gujarati, Hindi, Kannada, Kashmiri, Konkani, Maithili, Malayalam, Manipuri, Marathi, Nepali, Odia, Punjabi, Sanskrit, Santali, Sindhi, Tamil, Telugu, and Urdu. Finally, we evaluate Cadence across two downstream tasks, namely: Machine Translation and Speech Translation.

Cadence establishes a new state-of-the-art (SOTA) performance across multiple Indic languages and domains, surpassing existing baselines with an average Macro F1 improvement of 77% while also introducing support for 11 new languages. It demonstrates significant gains in translation quality, on average improving the BLEU score by 1.75 and the chrF++ score by 1.55 for Machine Translation. For Speech Translation, it achieves an even greater enhancement with an average increase of 2.4 in the BLEU score and 2.85 in the chrF++ score. To foster further advancements and support downstream applications, we release all code, models and other artifacts publicly under permissive licenses.

2 Related Work

Punctuation Restoration in Machine Translation and Speech Translation: Punctuation restoration (PR) is a crucial preprocessing step for machine translation (MT) and speech translation (ST). In MT, punctuation provides essential segmentation and syntactic cues vital for translation quality (Vandeghinste et al., 2018); its absence degrades translations. The impact is greater in ST, where unpunctuated Automatic Speech Recognition (ASR) transcripts hinder segmentation crucial for real-time systems and data alignment (Javed et al., 2024; Sankar et al., 2025).

Punctuation Restoration for Indic Languages: Indic languages present unique PR challenges due to linguistic diversity and specific punctuation conventions. Early efforts were often monolingual, limiting scalability and cross-lingual transfer (Tripathy and Samal, 2022; Gupta et al., 2022). Gupta et al. (2022) introduced IndicPunct, a suite of monolingual transformer-based models for 14 Indian languages. While effective on formal text, IndicPunct faced limitations with spontaneous speech transcripts and a restricted punctuation set. These shortcomings highlight the need for more robust, generalist models for Indic languages, especially for spontaneous speech.

Resources and Models for Punctuation Restoration: While punctuation restoration has shifted from BERT-based classifiers (Gupta et al., 2022; Guhr et al., 2021) to LLMs (Sankar et al., 2025), a critical gap remains for Indic languages. Most models are trained on formal web text (Penedo et al., 2024; Doddapaneni et al., 2023) and perform poorly on disfluent spontaneous speech, a problem exacerbated by the lack of large, punctuated spoken corpora. Consequently, non-autoregressive models that generalize across written and spoken domains while handling large punctuation sets are rare, a

void that Cadence; a scalable, multilingual, LLM-based model; is designed specifically to address.

3 Methodology

Our approach to developing a robust multilingual punctuation restoration model hinges on two core pillars: a comprehensive data strategy designed to encompass linguistic diversity and varied text styles, and a multi-stage model training and adaptation process.

3.1 Data Strategy for Multilingual Punctuation Restoration

The foundation of our methodology lies in the careful curation and utilization of diverse textual data for both pre-training and fine-tuning phases.

Pre-training Data Corpus: For the initial continual pre-training phase, we leverage large-scale, high-quality multilingual web corpora. These resources are selected for their broad linguistic coverage, providing the model with exposure to a wide array of languages and writing styles. This extensive, general-domain data helps in building foundational representations that are adaptable to various downstream tasks and linguistic contexts.

Fine-tuning Data Amalgamation: We construct a large, diverse fine-tuning dataset by aggregating text from various corpora spanning multiple domains (e.g., news, literature, web text, extempore text) and styles. This dataset combines formal written text with unstructured spoken language transcripts, which features disfluencies, repetitions, and false starts, to expose the model to a wide range of punctuation patterns, improving its robustness and ability to generalize across real-world inputs.

3.2 Model Training and Adaptation

The model undergoes a multi-stage training process, starting from a pre-trained foundation, followed by continual pre-training for domain and multilingual adaptation, and culminating in task-specific fine-tuning.

3.2.1 Model Architecture Adaptation

We begin with a foundation pre-trained transformer-based language model. Standard autoregressive language models are typically designed for unidirectional text generation, processing context only from preceding tokens. However, for sequence tagging tasks like punctuation restoration, where understanding the surrounding context is crucial, bidirectional information flow (accessing both preceding and succeeding tokens) is highly beneficial. Therefore, we adapt the model's attention mechanism to be fully bidirectional. This modification allows each token to attend to all other tokens in the input sequence, enabling a richer contextual understanding necessary for accurate punctuation prediction during subsequent training stages.

3.2.2 Continual Pre-training for Enhanced Representation

To further adapt the bidirectionally-modified model for the nuances of the diverse linguistic landscape it will encounter and to better prepare it for the sequence tagging nature of the punctuation restoration task, we perform a dedicated phase of continual pre-training.

Masked Next Token Prediction: We employ a Masked Next Token Prediction (MNTP) objective, adapted from BehnamGhader et al. (2024). In this setup, after masking a random subset of input tokens, the model's task is to predict a masked token at position $i + 1$ using only the representation of its preceding, unmasked token i. Although the representation for token i is built using bi-directional attention over the entire unmasked sequence, the predictive objective remains strictly local. This design compels the model to learn strong local dependencies, making it particularly effective for tasks like punctuation prediction where the immediately preceding word is the most salient cue.

Curriculum Learning for Multilingual Adaptation: Given the significant variation in data availability (ranging from high-resource to low-resource languages) and the diverse linguistic characteristics across the target languages, we adopt a curriculum learning strategy during continual pre-training. This staged approach gradually introduces linguistic complexity to the model:

1. Foundation Phase: Training initially focuses on a high-resource language (a language with abundant available training data) to establish robust foundational representations.

2. High-to-Mid Resource: The model is then exposed to a group of mid-to-high-resource languages. These are languages for which substantial amounts of training data are available, though typically less than the initial high-resource language. This phase allows the model to begin generalizing across related linguistic structures and benefit from these larger datasets.

3. Low Resource: Subsequently, lower-resource

languages are introduced. These are languages characterized by comparatively limited availability of training data. This step encourages knowledge transfer from the more data-rich languages learned in previous phases, which is critical for achieving good performance on languages with scarce data.

4. Consolidation Phase: Finally, the model is trained on a mixture of data from all supported languages. This phase aims to consolidate learning across the entire linguistic spectrum and mitigate potential catastrophic forgetting of earlier-learned languages or features.

This progressive exposure helps the model to incrementally adapt to increasing linguistic diversity while maintaining training stability and fostering cross-lingual transfer.

3.2.3 Task-Specific Fine-tuning for Punctuation Restoration

Following the continual pre-training phase, the adapted language model is fine-tuned specifically for the punctuation restoration task using the amalgamated dataset described earlier.

Task Formulation: We frame punctuation restoration as a token-level sequence classification problem. For each token in an input unpunctuated sequence, the model's objective is to predict the punctuation mark that should follow it. If no punctuation is appropriate after a token, it predicts a special label, indicating the absence of punctuation.

Model Head: To adapt the pre-trained model for this classification task, its original language modeling head is replaced with a new task-specific head. This consists of a linear classification layer that takes the final hidden state representation of each input token and outputs logits over the set of possible punctuation classes.

Punctuation Label Space: The model is trained to predict a comprehensive set of punctuation marks, including standard punctuation marks, as well as script-specific punctuation found within the target language and frequently occurring combinations of punctuation marks to capture more complex typographic conventions.

Sampling Strategy for Data Imbalance: Recognizing the data imbalance across languages in our fine-tuning corpus, we employ a weighted sampling strategy. This technique ensures adequate representation for low-resource languages by oversampling their data, thereby promoting balanced learning and robust cross-lingual performance (Arivazhagan et al., 2019).

4 Experimental Setup

In this section, we describe the datasets, training procedures, and metrics used to evaluate Cadence.

4.1 Datasets

The development of Cadence relies on carefully curated datasets for both its continual pre-training and task-specific fine-tuning phases, ensuring broad linguistic coverage and exposure to diverse text styles.

Pretraining Dataset We source pretraining data from the Indic subset of FineWeb-2 (Penedo et al., 2024). This high-quality, multilingual web corpus provides broad coverage across the Indian linguistic landscape, a result of its web-scale collection and rigorous filtering.

Fine-tuning Dataset: To adapt our model for the punctuation task, we constructed a multilingual training corpus by aggregating data from four diverse sources, each contributing complementary strengths. **Sangraha-Verified (S)** provides high-

quality, accurately punctuated formal text (Khan et al., 2024); **IndicVoices-ST (IV)** offers punctuated transcripts of spontaneous speech, capturing spoken language patterns (Sankar et al., 2025); the **Translated Cosmopedia (C)** dataset introduces syntactically varied, structured knowledge content (Ben Allal et al., 2024); and **IndicCorp-v2 (IC)** contributes wide-domain natural language text with rich punctuation usage (Doddapaneni et al., 2023). This combination ensures broad linguistic coverage and stylistic diversity.

By combining these sources, we create a robust training corpus. Figure 3 provides a detailed breakdown of this aggregated dataset, showing the approximate number of training instances per language and Table 1 shows the counts for each of the 30 supported punctuation labels in the overall training set.

4.2 Training Details

In this section we elucidate the training details including model architecture, pretraining and finetuning details and evaluation setup.

4.2.1 Model Architecture

We adopt GEMMA3-1B-PRETRAIN (Team et al., 2025) as our base model. Although Gemma is originally designed as a causal decoder for text generation, punctuation restoration benefits from access to bidirectional context. We replace its causal attention mechanism with bidirectional attention to attend to both left and right contexts.

4.2.2 Continual Pretraining

To adapt the modified GEMMA3-1B-PRETRAIN model to the multilingual and low-resource nature of the task, we perform continual pretraining (CPT) using the MNTP objective and a curriculum over languages.

Curriculum Learning Strategy: To manage linguistic diversity and data imbalance, we employ a four-phase curriculum (Dabre et al., 2019) with progressively adjusted masking ratios. We first continually train the model on English (0.30 ratio), then adapted to 13 high- and mid-resource Indic languages (Hindi, Telugu, Tamil, Bengali, Malayalam, Marathi, Kannada, Gujarati, Assamese, Oriya, Punjabi, Sindhi, Urdu) with a 0.25 ratio. Subsequently, low-resource languages including Bodo, Dogri, Konkani, Kashmiri, Maithili, Manipuri, Nepali, Sanskrit, and Santali are introduced (0.15 ratio) to encourage generalization. In the final phase (last 10% of steps), all 23 languages are trained on jointly (0.25 ratio) to consolidate learning and mitigate catastrophic forgetting.

4.2.3 Finetuning

After the pretraining stage, the model is fine-tuned for supervised punctuation restoration, framed as token-level sequence tagging. For each input token, it predicts a subsequent punctuation mark or an O (Outside) label if no punctuation follows. To achieve this, we modify the output vocabulary of GEMMA3-1B-PRETRAIN to handle the token-level sequence tagging task, training it to predict one of 30 punctuation classes or an O (Outside) label for each token. This comprehensive label space (detailed in Table 1) includes standard English, Indic-specific, Arabic-script (Urdu) marks, and frequent multi-character combinations, enabling fine-grained modeling of diverse writing styles.

We train Cadence using the AdamW optimizer (Loshchilov and Hutter, 2019) with a max learning rate of $2 \times e^{-4}$ with 10% of the training steps as warmup followed by a cosine decay to $1 \times e^{-6}$, with an effective batch size of 64.

4.3 Evaluation

Test Set: Our *intrinsic evaluation* set comprises held-out samples from IndicCorp-v2 (IC), Sangraha-Verified (S), a translated Cosmopedia dataset (C), and BPCC (Gala et al., 2023). For spontaneous speech transcripts from the synthetically augmented IndicVoices-ST (IV) dataset, using Gemini-2.5-Flash (Comanici et al., 2025), we apply an additional programmatic quality filter (refer Appendix F). We scored punctuation quality from 1–5 (τ) and retained only samples with $\tau \geq 4.5$, ensuring a reliable test-set for this domain.

To assess Cadence's *downstream impact*, we evaluate its punctuations on machine translation over the held out set of Cosmopedia-Translated (C) and parallel subset of Sangraha-Verified (S) and on speech translation using data sampled from IndicVoices-dev (Javed et al., 2024) and Gigaspeech-test (Chen et al., 2021). For the latter, Gemini-2.5-Pro (Comanici et al., 2025) serves as the expert system to obtain reference translations.

Evaluation Metric: We evaluate the model's performance using the Average Macro F1 score. To assess the downstream relevance of punctuation, we evaluate its impact on translation quality using chrF++ (Popović, 2017) because of its strong correlation with human judgements (Sai B et al.,

Table 2: Comparison of Punctuation Restoration Model Performance Across Languages and Metrics. An x indicates that the model does not support the given language. A – indicates that results are unavailable due to insufficient high-quality data samples. All scores are reported on Focus Labels for consistency and comparability. The languages are sorted in descending order by the number of samples in their training set and then divided into three categories: high-resource, mid-resource, and low-resource.

2023). We also present BLEU (Papineni et al., 2002) scores for completeness. BLEU score is based on SacreBLEU (Post, 2018). Together, these metrics provide a comprehensive view of both intrinsic restoration accuracy and its extrinsic effect on real-world tasks such as machine translation.

Baselines: We compare Cadence against two primary baselines: (i) IndicPunct (Gupta et al., 2022), a series of language-specific models derived from fine-tuned IndicBert, and (ii) Deepmultilingualpunctuation (DMP) (Guhr et al., 2021), a model trained on European languages that we use for English evaluation. A key limitation of both baselines is their support for a restricted set of punctuation marks. To ensure a fair comparison across these different label scopes, we evaluate all models on a common subset we term “focus labels". This set includes the period, comma, colon, question mark, and several script-specific marks.

5 Results

In this section, we evaluate Cadence’s performance through a series of analyses. First, we compare it against baselines on both focus and all-label sets. Next, we assess its robustness on formal versus spontaneous text. We then test its generalization to unseen languages and, finally, evaluate it on downstream tasks.

5.1 Performance on Focus vs. All Labels and Baseline Comparison

Cadence substantially outperforms existing baselines across multiple datasets, as detailed in Table 2. It achieves a score of 0.67 on IndicCorp-v2, markedly surpassing both IndicPunct and DeepMultilingualPunctuation (0.54). The performance gap is even larger on Sangraha-Verified (0.63 vs. 0.27) and Translated Cosmopedia (0.77 vs. 0.22). On the IndicVoices speech dataset, Cadence also

Average	0.42	0.65	0.35	0.50

Table 3: Cadence: Per-language Average Macro F1 Scores on Written and spontaneous speech transcripts test sets, evaluated on all 30 punctuation labels.

demonstrates superior performance (0.50 vs. 0.42).

This strong performance is reflected in its overall scores on critical focus labels, where it reaches 0.79 on written text and 0.62 on spontaneous speech (Table 3). When evaluated on the more challenging full set of 30 punctuation marks, the model scores 0.42 (written) and 0.35 (speech). As expected, these scores are lower due to the increased complexity of predicting rarer marks and those with greater stylistic and syntactic nuance. Notably, Cadence provides this robust performance across numerous Indic languages unsupported by prior work.

5.2 Performance on Formal Written Text vs. Extempore Transcripts

Cadence consistently performs better on formal written text than on extempore speech transcripts. For “focus labels", the overall score is **0.65** for written text versus **0.50** for spontaneous speech transcripts (Table 3). A similar trend is observed for “all labels", with scores of **0.42** (written) and **0.35** (extempore).

Furthermore, spontaneous utterances often present reduced syntactic regularity, featuring fragmented constructions and anacolutha, making the automatic identification of logical punctuation points ambiguous. These difficulties are notably exacerbated by the comparatively limited availability of large, diverse, and accurately annotated training corpora for spontaneous speech transcripts, hindering the model’s ability to learn robust patterns for these irregular linguistic phenomena.

5.3 Generalization to Unseen and Low-Resource Languages

In this section, we investigate Cadence’s ability to generalize to languages and conditions not extensively covered during fine-tuning.

Zero-Shot Generalization on Bhojpuri: We evaluate Cadence on Bhojpuri text from FineWeb-2 (Penedo et al., 2024). Bhojpuri was absent from Cadence’s CPT and fine-tuning, though the base GEMMA3-1B-PRETRAIN model (Team et al., 2025) had prior exposure. In this zero-shot setting, Cadence achieved a Macro F1 score of **0.46** on “focus labels", indicating a promising capability for unseen language adaptation.

Low-Resource Performance on Manipuri: The low-resource language Manipuri presents significant challenges, as there is minimal training data and the tokenizer could not process the native Meitei Mayek script well. Consequently, our work relied on available Manipuri data written in the Bengali script. Even with these data limitations, Cadence scored 0.44 on focus labels (BPCC dataset, Table 2) and 0.26 on all labels (written text, Table 3), demonstrating its potential in constrained training environments.

5.4 Downstream Evaluations

Applying our punctuation restoration model, Cadence, as a pre-processing step substantially improves downstream translation quality for both text and speech, as detailed in Table 4.

For machine translation (MT), text punctuated by Cadence achieves chrF++ scores that approach those of human-annotated sources in both XX →En direction and En →XX direction. On average, punctuating by Cadence improves score of 1.55 chrF++. Similar gains are observed in speech translation (ST), where punctuating raw ASR tran-

Table 4: **Combined Translation Quality for Machine and Speech Translation.** Each cell reports BLEU/chrF++ scores. For Machine Translation, scores are evaluated **without** (w/o p.), **with** (w/ p.), and **with restored** (w/ r. p.) punctuation. For Speech Translation, scores are evaluated **without** (w/o p.) and **with restored** (w/ r. p.) punctuation using Cadence. Bolded scores indicate statistically significant improvement by restoring punctuations. Underlined scores (for MT only) show cases where ground-truth and restored punctuations do not improve scores with statistical significance. Unbolded scores (for MT only) show cases when there is no statistically significant difference between unpunctuated and restored punctuation scores. Refer to Tables A5 and A3 for p-values.

scripts improves scores by an average of 3.6 chrF++ (XX →En) and 2.1 chrF++ (En →XX).

This effectiveness is clear across language pairs. For instance, in Punjabi-to-English, Cadence lifts the MT score from 50.7 to 53.9 and the ST score from 52.7 to 56.3. Likewise, for English-to-Gujarati, the MT score increases from 43.6 to 47.1, while the ST score rises from 47.7 to 50.5.

The substantial gains observed, especially on the chrF++ metric, underscore our model's capacity to restore fine-grained syntactic cues essential for translation. By effectively reintroducing this structural information, our method acts as a critical pre-processing step, consistently elevating translation performance over unpunctuated baselines.

6 Additional Experiments

To validate our core design choices, we performed two key ablation studies. We first demonstrate the necessity of our bidirectional pre-training stage by comparing the full Cadence model to a causal-only baseline. Second, we analyze performance trade-offs at a smaller scale, evaluating our distilled Cadence-Fast model against a directly finetuned GEMMA3-270M-PRETRAIN counterpart.

Impact of bidirectional attention: We first evaluated the contribution of bidirectional attention and Masked Next Token Prediction (MNTP) pre-training by training a baseline GEMMA-3-1B-PRETRAIN model with causal attention and comparing it to its bidirectional counterpart. Cadence consistently improved alignment and semantic consistency as measured by its performance (Table A6) across both written and spontaneous (extempore) text, confirming that access to bidirectional context leads to more coherent and contextually grounded language modeling.

Scaling model parameters: Next, we examined how scaling model parameters and distillation influence performance by comparing *Gemma-3-270M-bidirectional*, *Cadence-Fast*, and the full *Cadence* model (Table A7). Despite its smaller size, *Cadence-Fast* retains 93.8% of the full Cadence model's performance on written text-focused labels and 100% on extempore text. It also slightly outperforms GEMMA-3-270M-BIDIRECTIONAL, demonstrating that our compression and architecture refinements preserve both fidelity and robustness. Interestingly, distillation provides only modest improvements, likely due to the already strong lan-

guage modeling abilities of the base model, which was pre-trained on approximately 6 trillion tokens. These findings indicate that careful scaling and architectural optimization can deliver near-parity performance at substantially reduced computational cost, making Cadence-Fast a compelling choice for real-time or resource-constrained deployments.

7 Conclusion

In this work, we present Cadence, a unified multilingual punctuation restoration model designed for both written and spontaneous speech transcripts in English and 22 Indic languages. Cadence adapts GEMMA3-1B-PRETRAIN with bidirectional attention and introduces a Masked Next Token Prediction objective combined with curriculum-based continual pre-training, enabling effective cross-lingual transfer and improved handling of low-resource languages.

Our extensive evaluations show that Cadence achieves state-of-the-art performance over existing baselines, demonstrates robustness to domain shifts, and generalizes to unseen languages such as Bhojpuri. Moreover, we show that punctuation restored by Cadence significantly improves the quality of both machine translation and speech translation, underscoring its practical value in multilingual NLP pipelines. Furthermore, we introduce *Cadence-Fast*, a smaller and more efficient variant that retains over 90% of the full model's performance while offering substantial speedups and reduced memory footprint, making it suitable for real-time and resource-constrained applications.

While challenges remain, particularly in modeling spontaneous speech disfluencies and ensuring evaluation reliability with synthetic references, Cadence sets a strong foundation for future work on robust punctuation restoration and highlights the potential of multilingual models to bridge linguistic disparities at scale.

8 Limitations

Despite Cadence's strong performance, several limitations should be acknowledged. Firstly, the quality and representativeness of the training data, particularly for low-resource languages and spontaneous speech, remain a challenge. This directly impacts performance, with the model exhibiting weaker results on languages for which less training data was available. Secondly, while our 30-label set is comprehensive, it may not capture extremely rare or highly nuanced stylistic punctuation. Finally, performance on spontaneous speech, though improved, still lags behind that on formal text, highlighting the persistent difficulty of modeling the irregularities and disfluencies inherent in spoken language.

Appendix

A Language wise label breakdown

This appendix provides a granular analysis of the label distribution within our aggregated training corpus, detailing the frequency of the 30 distinct punctuation classes across all supported languages. As described in Section 3.2.3, our model frames punctuation restoration as a token-level sequence tagging task, necessitating a comprehensive label space that captures both standard punctuation marks and script-specific conventions. The data presented in Table A1 and Table A2 illustrates the total count of instances for each punctuation label (L1 through L30) found in the training data, which combines sources such as Sangraha-Verified, IndicVoices, Cosmopedia, and IndicCorp-v2.

The tabulated data highlights the significant class imbalance inherent in multilingual corpora. High-resource languages such as English, Hindi, and Bengali exhibit a high density of punctuation instances, particularly for common marks like the comma and sentence terminators. Conversely, low-resource languages like Dogri, Santali, and Sanskrit show considerably sparser representation. This disparity underscores the necessity of the weighted sampling strategy and curriculum learning approach employed during the training of Cadence to ensure robust performance across the entire linguistic spectrum.

While labels such as the comma (L2) and exclamation mark (L7) are prevalent across most languages, others are unique to specific scripts. For instance, the Devanagari purna virama (danda) is heavily represented in Hindi and Sanskrit, whereas the Arabic script-specific question mark (L17) are predominantly found in Urdu and Sindhi. The inclusion of these diverse labels, along with frequent multi-character combinations, allows Cadence to model the fine-grained typographic nuances required for high-quality restoration in both formal and spontaneous text.

Beyond standard delimiters, Table A2 details the distribution of complex, multi-character punctuation tokens (L18–L26), which are essential for handling the nuances of narrative text. To avoid the ambiguity often associated with predicting multiple punctuation marks sequentially, Cadence treats frequently occurring combinations—such as a question mark followed by a closing quote ‘?"’ or a period following a parenthesis ‘).’ - as distinct target classes. The statistics show that while these combined markers are well-represented in high-resource languages like English and Bengali, they appear far less frequently in the mid-to-low resource categories. Capturing these specific combinations is critical for maintaining the structural integrity of direct speech and parenthetical statements, ensuring that the restored text respects the syntactic boundaries between dialogue and narration.

Table A3: P-values for Speech Translation (ST) score improvements (Indic-to-English). The test compares translations from punctuated ASR output (using Cadence) against translations from unpunctuated ASR output. Statistically significant results ($p < 0.05$) are bolded.

To determine if our punctuation model, Cadence, improved punctuation, we use a paired sample t-test to compare its output to a baseline of unpunctuated text (columns of w/o p and w/r. p in Table A5 and Table A3). We also compared the original punctuations to the unpunctuated baseline in (columns of w/o p and w/p in Table A5). A p-value < 0.05 was considered to indicate a statistically significant improvement in punctuation.

C Effect of our two-step training and architectural modification

To quantify the combined contribution of our architectural and pre-training adaptations, we conducted an ablation study. We established a direct baseline by training the standard Gemma-3-1B-base model without altering its native causal attention mechanism and skipping our continual pre-training phase. This baseline model was trained only on the final punctuation restoration task.

The results, presented in Table A6, show a stark performance gap. Cadence significantly outperforms this causal baseline across all datasets, thereby validating our hypothesis. This outcome confirms that simply finetuning a standard, unidirectional language model is insufficient for this task. The superior performance of Cadence is directly attributable to our multi-stage methodology, proving that the bi-directional attention mechanism and the Masked Next Token Prediction pre-training are critical components for achieving robust and accurate punctuation restoration.

Table A4: Cadence-Fast: Per-language Average Macro F1 Scores on Written and spontaneous speech transcripts test sets, evaluated on all 30 punctuation labels.

D Scaling Model Parameters

In this section, we extend our analysis from the main paper to study the impact of model scale on downstream performance. Specifically, we compare three variants: (1) *Gemma-3-270M-bidirectional*, (2) *Cadence-Fast*, and (3) *Cadence*. Table A7 summarizes their relative performance across written and extempore text evaluation sets. Table A4 illustrates the performance of *Cadence-Fast* on both “All Labels" and “Focus Labels" set in both “Formal" and “Extempore" context.

Despite being considerably smaller, *Cadence-Fast* retains 93.8% of the full Cadence model’s performance on written text labels and 100% on extempore text. Notably, it also slightly surpasses *Gemma-3-270M-bidirectional*, underscoring that careful architectural refinement and scaling can yield a compact yet capable model. These results

Table A6: Comparison of Cadence with Gemma-3-1B-pt finetuned on our data. A – indicates that results are unavailable due to insufficient high-quality data samples. Scores are reported on all labels. The languages are sorted in descending order by the number of samples in their training set and then divided into three categories: high-resource, mid-resource, and low-resource.

suggest that our pre-training and design choices generalize well across parameter regimes.

Performance degradation from scaling down is modest, likely because the base model of Gemma-3-270M was pre-trained on approximately 6 trillion tokens (compared to 2 trillion dataset size of Gemma-3-1B), providing strong linguistic priors even in smaller configurations. This indicates diminishing returns from additional capacity beyond a certain threshold for these language-focused benchmarks.

Overall, our scaling experiments highlight that model efficiency can be achieved through principled parameter reduction without a substantial drop in quality. The resulting *Cadence-Fast* model offers a favorable trade-off between speed and accuracy, making it well-suited for latency-sensitive or resource-limited deployments.

E Prompt used for Punctuation

The prompt template shown in Figure A1 is engineered to guide Large Language Models (LLMs) in the task of punctuation restoration for Indian language text. It begins by defining the LLM's role as a punctuation expert and sets a primary objective: to enhance text readability by inserting punctuation marks while strictly preserving the original wording and sentence structure.

The prompt enumerates four critical guidelines for the LLM:

1. **Accuracy:** Punctuation must conform to the grammatical rules of the specified input language (lang).
2. **Readability:** Sentence clarity should be improved using appropriate punctuation (e.g., commas, periods, question marks).
3. **Consistency:** The punctuation style should align with any provided reference text.
4. **Preservation of Structure:** Word order and sentence construction must remain unaltered; only punctuation is to be adjusted.

To accommodate linguistic diversity, particularly the varied sentence terminators across Indian languages (e.g., period vs. danda), the prompt requires the input language (lang) and its corresponding sentence terminator (terminator) as explicit parameters. Finally, it mandates a structured JSON output with the key "punctuated_text", ensuring the punctuated text is returned in a consistent, machine-readable format. This design facilitates systematic generation of punctuated data suitable for training and evaluating punctuation restoration models.

Prompt for Punctuation Restoration

```
You are a expert in inserting punctuation.
Please help in adding punctuation to the following text
while strictly preserving the original words and structure.

Enhance readability by inserting only punctuation marks.
Do not modify, add, or remove any words.

Follow these guidelines:\n\n

1. **Accuracy:** Ensure punctuation is applied correctly
based on the language's grammatical rules.

2. **Readability:** Improve sentence clarity by inserting
appropriate punctuation marks (commas, periods,
question marks, etc.).

3. **Consistency:** Follow the punctuation style observed
in the provided reference text.

4. **Preservation of Structure:** Do not alter word order or
introduce new elements—only punctuation should be
adjusted.

Reference Information:
- Language of the text: {lang}
- Sentence terminator for {lang}: {terminator}

Output Format:
Provide only the punctuated text in JSON format with the
structure:

json
{ "punctuated_text": "Your punctuated text here" }
```

Figure A1: Prompt For Punctuation Restoration

F Prompt used for LLM in Quality Filtering

The datasets we have used for training contain synthetically punctuated text (IndicVoices). Ensuring a high quality test set becomes important to accurately assess our model and compare with existing models. We have used a programmatic quality filtering by employing Gemini-2.5-Flash-preview-04-17 (Comanici et al., 2025) to score punctuation quality from 1-5 and only retained those that were rated ≥ 4.5. We present the prompt used in Fig.A2 below.

Prompt for using LLM in Quality Filtering

You are an expert proofreader acting as a Multilingual Punctuation Judge. Your task is to first identify the primary language of the given sentence and then evaluate its punctuation and standard capitalization using the provided multilingual rubric based on the conventions of that identified language. You are using the capabilities of Gemini for this task.

Multilingual Rubric:

*** Multilingual Punctuation & Capitalization Evaluation Rubric ***
Preliminary Step: Language Identification
* **Identified Language:** [Specify the primary language detected in the sentence]
* **Confidence:** [High/Medium/Low - How certain are you of the language identification?]
* **Note:** Evaluation below is based on the standard conventions of the *Identified Language*.

Evaluation Criteria (Score: 1-5, where 1=Poor, 3=Fair, 5=Excellent based on the identified language's rules)
1. **Sentence Termination (Score: 1-5):**
    * Is appropriate sentence-ending punctuation used (e.g., '.', '?', '!', '。', '؟', '¿...?', '¡...!', etc.) according to the identified language's standard practice?
    * Is the type of terminator suitable for the sentence's function (declarative, interrogative, exclamatory) within that language?
    * Comment: [Explain based on the language's rules, e.g., "Correct use of period for German.", "Missing Spanish inverted question mark.", "Full stop used appropriately for Japanese sentence."]

2. **Intra-Sentence Separation (Commas, Etc.) (Score: 1-5):**
    * Are commas or other language-specific separators (e.g., '،', '、') used correctly to separate clauses, list items, introductory elements, etc., according to the identified language's grammatical and stylistic rules?
    * Are there missing or extraneous separators based on that language's conventions?
    * Comment: [Explain based on the language's rules, e.g., "Correct comma usage for French clauses.", "Missing serial comma typical in English lists.", "Arabic comma used correctly.", "Unnecessary comma according to German rules."]

3. **Quotation/Speech Marks (Score: 1-5):**
    * Are quotation marks or guillemets (e.g., "...", '...', « ... », „...") used correctly for direct speech, titles, or other quoted elements according to the standard style of the identified language?
    * Are they properly paired and nested if applicable?
    * Is punctuation placed correctly inside/outside the marks according to that language's convention?
    * Comment: [Explain based on the language's style, e.g., "Correct use of French guillemets with spacing.", "German quotation mark style applied correctly.", "Punctuation incorrectly placed outside closing quote for American English.", "Quotation marks not typically used this way in Thai."]

4. **Contraction/Possessive/Joining Markers (Apostrophes, Hyphens, Etc.) (Score: 1-5):**
    * Are apostrophes, hyphens, or other language-specific markers used correctly for contractions, possessives, compound words, case endings, or similar functions *if applicable* in the identified language?
    * Are common errors (like its/it's in English, or incorrect hyphenation rules) avoided based on the language?
    * Comment: [Explain based on language rules, or state N/A if the concept/mark isn't used. E.g., "Incorrect use of apostrophe for English possessive.", "Hyphenation follows German rules.", "Apostrophes not used for possession in Spanish - N/A.", "Correct use of hyphen for joining words in Dutch."]

5. **Other Punctuation (Colons, Semicolons, Dashes, Etc.) (Score: 1-5):**
    * Assess the use of any other punctuation present (e.g., colons ':', semicolons ';', dashes '–'/'—', ellipses '...', brackets '()'/ '[]') according to the identified language's standard usage.
    * Are they used appropriately for lists, explanations, pauses, omissions, parentheticals etc., within that language?
    * Comment: [Explain based on language rules, e.g., "Colon used correctly before list in English.", "Semicolon usage is rare but correct here for formal French.", "Dash style inconsistent with Spanish norms."]

```
6. **Capitalization (Score: 1-5):**
  *  Is capitalization used correctly according to the identified language's rules? (Consider: Sentence start, proper nouns, titles, language-specific rules like all nouns in German, etc.)
  *  Comment: [Explain based on the specific capitalization rules of the language, e.g., "Sentence start capitalized correctly.", "Proper noun 'Paris' capitalized correctly for English/French.", "All nouns capitalized correctly per German orthography.", "Incorrect capitalization of common noun according to Spanish rules."]

**Overall Assessment:**
*  **Overall Score (1-5):** [Average or holistic score reflecting adherence to the identified language's punctuation/capitalization norms.]
*  **Summary:** [Brief summary of the sentence's punctuation quality in the context of the identified language, highlighting key strengths or weaknesses.]
*  **Corrected Sentence (in the identified language):** [Provide the sentence with corrected punctuation and capitalization according to the identified language's standard rules. If perfect, repeat the original sentence.]

**Instructions:**
1. Identify Language: First, determine the primary language of the sentence below.
2. Analyze Sentence: Carefully analyze the sentence provided.
3. Evaluate: Evaluate it strictly based on the criteria in the multilingual rubric, applying the rules and conventions standard to the *identified language*. Focus *only* on punctuation and standard capitalization rules relevant to that language.
4. Provide Scores & Comments: Fill in the **Identified Language** and **Confidence**. Then, provide a score (1-5) and a brief comment for *each* numbered evaluation category in the rubric, justifying your assessment based on the identified language's norms. Ensure scores are numeric integers (1, 2, 3, 4, 5). If a category is not applicable or perfectly handled by absence (e.g., no quotation marks needed and none present), assign a score of 5. The JSON response *must* contain numeric integer scores for calculation.
5. Overall Assessment: Calculate an **Overall Score (1-5)** reflecting the average or holistic quality, ensure this is also a numeric integer or float.
6. Corrected Sentence: Provide a **Corrected Sentence**.
7. IMPORTANT: Respond *only* with a single valid JSON object. The JSON object must contain keys corresponding exactly to the rubric sections: "Identified_Language", "Confidence", "Sentence_Termination", "Intra_Sentence_Separation", "Quotation_Speech_Marks", "Contraction_Possessive_Joining_Markers", "Other_Punctuation", "Capitalization", "Overall_Score", "Summary", "Corrected_Sentence". The keys for the numbered evaluation categories must map to an object {{{{ "Score": "<number>", "Comment": "<string>" }}}}. The Overall_Score must also be a number. Ensure the entire output is valid JSON starting with {{{{ and ending with }}}}. Do not use markdown tags ```json or ```.
**Sentence to Evaluate:**
{{sentence}}
**Your JSON Evaluation:**
{{{{
 "Identified_Language": null,
 "Confidence": null,
 "Sentence_Termination": {{{{ "Score": null, "Comment": null }}}},
 "Intra_Sentence_Separation": {{{{ "Score": null, "Comment": null }}}},
 "Quotation_Speech_Marks": {{{{ "Score": null, "Comment": null }}}},
 "Contraction_Possessive_Joining_Markers": {{{{ "Score": null, "Comment": null }}}},
 "Other_Punctuation": {{{{ "Score": null, "Comment": null }}}},
 "Capitalization": {{{{ "Score": null, "Comment": null }}}},
 "Overall_Score": null,
 "Summary": null,
      "Corrected_Sentence": null
}}}}
```

Figure A2: The prompt used to rate punctuations and capitalization in a sentence, outlining the comprehensive rubric used. Criteria include confidence, sentence termination, intra-sentence separators, quotation marks, other punctuation types (colons, semicolons, dashes), capitalization, and an overall quality assessment, along with instructions for JSON output.

Efficient Decoding Methods for Language Models on Encrypted Data

Abstract

Large language models (LLMs) power modern AI applications, but processing sensitive data on untrusted servers raises privacy concerns. Homomorphic encryption (HE) enables computation on encrypted data for secure inference. However, neural text generation requires decoding methods like argmax and sampling, which are non-polynomial and thus computationally expensive under encryption, creating a significant performance bottleneck. We introduce CutMax, an HE-friendly argmax algorithm that reduces ciphertext operations compared to prior methods, enabling practical greedy decoding under encryption. We also propose the first HE-compatible nucleus (top-p) sampling method, leveraging CutMax for efficient stochastic decoding with provable privacy guarantees. Both techniques are polynomial, supporting efficient inference in privacy-preserving settings. Moreover, their differentiability facilitates gradient-based sequence-level optimization as a polynomial alternative to straight-through estimators. We further provide strong theoretical guarantees for CutMax, proving its convergence via exponential amplification of the gap ratio between the maximum and runner-up elements. Evaluations on realistic LLM outputs show latency reductions of $24\times$–$35\times$ over baselines, advancing secure text generation.

1 Introduction

Recent advances in LLMs have enabled the development of powerful AI systems capable of generating fluent text at scale (Brown et al., 2020). However, deploying these models in real-world applications often involves sending sensitive user data, such as personal messages or medical records, to remote servers, raising significant privacy concerns (Yao et al., 2024; Yan et al., 2024). Despite major progress in efficient encrypted inference, extending these methods to generative LLMs remains an open challenge due to the non-polynomial nature of decoding operations. Homomorphic encryption (HE) offers a promising solution by allowing computations on encrypted data, ensuring that servers can process queries without accessing their plaintext content (Gentry, 2009). Under HE, users encrypt their inputs, the server performs computations (e.g., running an LLM), and returns an encrypted result that only the user can decrypt.

In this paper, we present differentiable and polynomial argmax and nucleus sampling algorithms tailored for encrypted LLM decoding. Unlike prior approaches, such as that of Bengio et al. (2013), which use argmax in the forward pass and estimate gradients in the backward pass via straight-through estimators (STE), our methods are fully differentiable in their plaintext form (without approximations) and remain so under polynomial HE approximations. This differentiability, together with their polynomial form, makes them well suited to AI-privacy settings such as HE; the plaintext formulations are exactly differentiable, and the HE instantiations preserve differentiability via polynomial approximations (see Sect. 3.2). Most HE schemes, including the CKKS scheme used in this work (Cheon et al., 2017), support only polynomial operations like addition and multiplication. This limitation necessitates the design of *HE-friendly* algorithms that rely exclusively on such operations, posing a challenge for text generation tasks that involve complex decoding steps. While secure inference on LLMs using HE has been demonstrated (Zimerman et al., 2024a; de Castro et al., 2024; Zhang et al., 2024a), extending these techniques to multi-token text generation remains challenging. Decoding methods like argmax (for greedy decoding) and sampling (e.g., nucleus sampling (Holtzman et al., 2019a)) are computationally inefficient or impractical in the encrypted domain due to their reliance on non-polynomial operations.

State-of-the-art homomorphic argmax implementations follow two comparison-heavy patterns:

Proceedings of the 14th International Joint Conference on Natural Language Processing and the 4th Conference of the Asia-Pacific Chapter of the Association for Computational Linguistics, pages 1777–1794

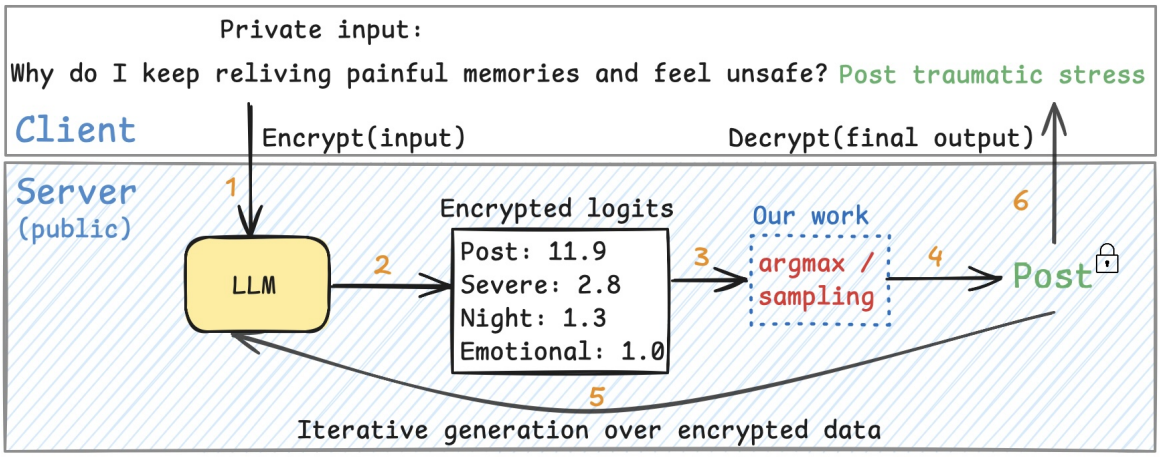

Figure 1: **Scope**: Secure LLM generation over the clients' encrypted data using HE (model is not necessarily encrypted). Here, standard decoding methods like argmax and sampling (**red**) for selecting the next token are not HE-friendly or considered inefficient. We introduce efficient and scalable HE-friendly methods to evaluate them under encryption.

a *tournament* tree and an all-to-all *league* schedule, both realized via deep polynomial approximations of SIGN (Chakraborty and Zuber, 2022; Crawford et al., 2018; Folkerts and Tsoutsos, 2024; Jovanovic et al., 2022). A detailed illustration of these designs is provided in Figure 6 (Sect. C), which highlights their sequential comparison stages and reliance on costly SIGN evaluations.

CutMax removes comparisons altogether. Each of its T iterations applies two global reductions (mean and variance), an inverse-square-root (InvSqr), an elementwise odd power, and a final normalization (Sect. 3, Algorithm 1, Sect. 3.2, Algorithm 2). Consequently, the number of *sequential* stages is a small constant T—*weakly dependent* on the vector length n (e.g., the vocabulary size)—whereas tournament and league require $\log_2 n$ and n sequential rounds, respectively, each performing encrypted comparisons via polynomial approximations of SIGN. Because InvSqr and division (Inv) are shallower and faster than SIGN at similar accuracy (Table 3), CutMax achieves much lower depth and fewer bootstraps per token. Empirically, T is a small constant (e.g., $T \leq 3$–4), consistent with the latency gains we observe for vocabularies of $|\mathcal{V}| \approx 3.3 \times 10^4$ and 1.5×10^5 (Sect. 4, Table 1). Implementation-level costs such as rotations under SIMD packing are deferred to Sect. 3.2 and Sect. D.

Our contributions address key bottlenecks in secure text generation, as illustrated in Figure 1, and include: (i) **CutMax**. An efficient, homomorphic encryption (HE)-friendly argmax algorithm that enables practical greedy decoding under encryption with fewer ciphertext operations than previous methods. (ii) **Encrypted nucleus sampling**. The first HE-compatible nucleus (top-p) sampling method, enables stochastic decoding with provable privacy guarantees, via CutMax. (iii) **Theoretical convergence guarantees**. A formal proof establishing that CutMax converges via exponential amplification of the gap ratio between the maximum and runner-up elements, providing a rigorous foundation for its rapid convergence in a small number of iterations, weakly dependent on the array size. (iv) **Differentiable decoding primitives**. Implementations of argmax and nucleus sampling that are real-analytic and fully differentiable in plaintext, leveraging smooth operations like $1/\sqrt{x}$ (and polynomial-only in their HE approximations) to enable exact gradient-based sequence-level training as a theoretically grounded alternative to straight-through estimators. By enabling efficient and accurate multi-token generation under full encryption, our work advances the deployment of privacy-preserving LLMs in real-world settings, bridging a critical gap in secure AI systems.

2 Background: Homomorphic Argmax

State-of-the-art homomorphic argmax implementations for LLM decoding rely on comparison-heavy designs, primarily the *tournament* tree and *league* schedule, both implemented via deep polynomial approximations of the SIGN function (Chakraborty and Zuber, 2022; Crawford et al., 2018; Folkerts and Tsoutsos, 2024; Jovanovic et al.,

2022; Zhang et al., 2024b, 2025a). In the tournament design, approximately $n-1$ pairwise comparisons are organized into $\log_2 n$ sequential stages, halving the number of candidates per stage until the maximum remains. The league design performs $\binom{n}{2} = \Theta(n^2)$ comparisons across n sequential rounds, accumulating scores such that the maximum achieves a score of $n-1$. Both methods are illustrated in Figure 6 (Sect. C). Despite leveraging CKKS SIMD parallelism to execute multiple comparisons within a round, these approaches incur high multiplicative depth due to repeated SIGN evaluations, leading to costly bootstrapping and limiting scalability for large vocabularies ($n \sim 10^5$). Some works, such as Chakraborty and Zuber (2022); Folkerts and Tsoutsos (2024); Grivet Sébert et al. (2021), use TFHE (Chillotti et al., 2016), restricting input sizes (e.g., $n \leq 256$) due to efficiency constraints. Hybrid approaches combine tournament and league methods to exploit SIMD packing (Iliashenko and Zucca, 2021; Mazzone et al., 2025), but still rely on slow SIGN approximations. As shown in Table 3 (Sect. B), SIGN evaluations are significantly deeper and slower than inverse or inverse-square-root operations, which our CutMax algorithm uses instead (Sect. 3.2). These limitations make prior methods impractical for efficient, privacy-preserving LLM decoding, motivating our polynomial-based approach that eliminates comparisons entirely.

2.1 HE Preliminaries

HE enables computation on encrypted data without requiring decryption (Gentry, 2009). Informally, it is defined as follows: Let $\mathcal{R}_1(+,\cdot), \mathcal{R}_2(\oplus,\odot)$ be two rings for the plaintext and ciphertext spaces, respectively. Given plaintext inputs $m_1, m_2 \in \mathcal{R}_1$, their encryption $[\![m_i]\!] := \text{Enc}(m_i) \in \mathcal{R}_2$, satisfies the following correctness and homomorphic properties:

- $\text{Dec}([\![m_1]\!]) = m_1 + \epsilon$
- $\text{Dec}([\![m_1]\!] \oplus [\![m_2]\!]) = m_1 + m_2 + \epsilon$
- $\text{Dec}([\![m_1]\!] \odot [\![m_2]\!]) = m_1 \cdot m_2 + \epsilon$

where ϵ is a small noise introduced by the HE scheme, similar to the noise accumulated in floating-point computations. HE is *semantically secure* and thus every call to $Enc(m_1)$ results with a new pseudo random ciphertext. Details about the standard *threat-model* of HE-based applications are provided in Sect. A. As HE only supports *polynomial operations* (additions and multiplications), standard transformer components like Softmax and LayerNormalization are not directly supported and must be approximated or replaced. Prior-art such as (Gilad-Bachrach et al., 2016; Aharoni et al., 2023; Baruch et al., 2022, 2024; Zimerman et al., 2024b,a; de Castro et al., 2024; Zhang et al., 2024a) have proposed polynomial-friendly adaptations for encrypted inference. We focus on the *generation process* where new challenges arise: decoding operations such as argmax and sampling are not polynomial.

Algorithm 1 CutMax

Require: $X = (X_1, \ldots, X_n)$, and $p, T \in \mathbb{Z}_+$, where p is odd and $c \in \mathbb{R}_+$.
Ensure: Z - one-hot approx. of $\text{argmax}(X)$.

$Y^{(1)} = X$
for $t = 1$ **to** T **do**
  $\mu = \frac{1}{n}\sum_{i=1}^{n} Y_i^{(t)}$ ▷ Mean of $Y^{(t)}$
  $\sigma^2 = \frac{1}{n}\sum_{i=1}^{n}(Y_i^{(t)} - \mu)^2$ ▷ Variance of $Y^{(t)}$
  $Y^{(t+1)} = \left(\frac{Y_i^{(t)} - \mu}{c \cdot \sqrt{\sigma^2}} + 1\right)_{i\in[n]}$ ▷ Standardization
  $Y^{(t+1)} = \left(Y^{(t+1)}\right)^p_{i\in[n]}$
$Z = \left(\frac{Y_i^{(T)}}{\sum_j Y_j^{(T)}}\right)_{i\in[n]}$
return Z

3 Method

This section presents our polynomial algorithms for argmax and nucleus sampling, tailored for HE.

3.1 The CutMax Algorithm

Intuitively, CutMax repeatedly 'stretches' the distribution of values and cuts off the lower part, such that after a few iterations only the highest value remains significantly non-zero (see Figure 3). CutMax is inspired by standardization in statistics (subtracting the mean and dividing by standard deviation), alongside the idea of centering the array around 1; therefore, when taking an odd power of the standardized values, values smaller than the mean would vanish while values greater than the mean would amplify. The algorithm's fast convergence is due to the right skewness induced by the power operation.

Algorithm 1 provides the pseudo-code for CutMax, which takes as input a vector X of n elements, an odd integer p, a constant scaling factor $c > 0$, and the maximum number of iterations T. For instance, one instantiation uses $p = 11$,

$c = 5$, and $T = 3$. We denote the index set as $[n] = \{1, \ldots, n\}$. CutMax is an iterative algorithm that runs for at most T iterations or until convergence. Each iteration t consists of two steps: **standardization** and **distance amplification**.

Standardization (Lines 3-5). The normalization process starts by computing the mean μ of the current vector state $Y^{(t)}$, the variance σ^2, then the inverse standard deviation $\frac{1}{\sqrt{\sigma^2}}$. Subsequently, it scales $Y^{(t)}$ by subtracting the mean and multiplying by $\frac{1}{c \cdot \sigma}$. The choice of c controls how much we "flatten" the distribution before raising the power. A larger c means we divide by a larger number, making the normalized values smaller in magnitude.

Distance Amplification (Line 6). We raise each normalized element to an odd power p, which preserves the sign of $Y_i - \mu$. Elements above (resp. below) the mean ($Y_i - \mu > 0$) remain positive (resp. negative). The effect of this power raising is twofold: it shrinks the magnitude of small values and amplifies the larger values, where

$$\left|Y_i^{(t)}\right| < 1 \Longrightarrow \left|Y_i^{(t)}\right| \gg \left|Y_i^{(t)}\right|^p \tag{1}$$

$$\left|Y_i^{(t)}\right| > 1 \Longrightarrow \left|Y_i^{(t)}\right| \ll \left|Y_i^{(t)}\right|^p \tag{2}$$

By appropriately scaling $Y^{(t)}$ before this step, we ensure that all but the largest elements satisfy $|Y_i| < 1$, causing them to shrink, while the largest (and possibly a few near-largest) elements may have $|Y_i| > 1$ and thus grow. This drastically amplifies the gap between the maximum and the rest.

Convergence. As formally proven in Appendix E, each CutMax iteration unconditionally grows the gap between the maximum and runner-up elements, yielding exponential amplification of their ratio and ensuring convergence under a mild δ-gap condition on the input. Beyond this theoretical contraction, CutMax also prunes much more aggressively than comparison-based schemes. Unlike the tournament argmax, which discards only half of the $Y^{(t)}$ values per stage, CutMax zeroes out a *large majority* each round: empirically, after iteration t, the empirical CDF at the mean satisfies $\mathrm{CDF}_{Y^{(t)}}(\mu^{(t)}) \gg \frac{1}{2}$, so far more than half of the $Y_i^{(t)}$ fall below the mean and are driven toward zero by the subsequent odd-power step (Figure 2).

As established by Theorem E.10, these properties guarantee global convergence to the fixed point

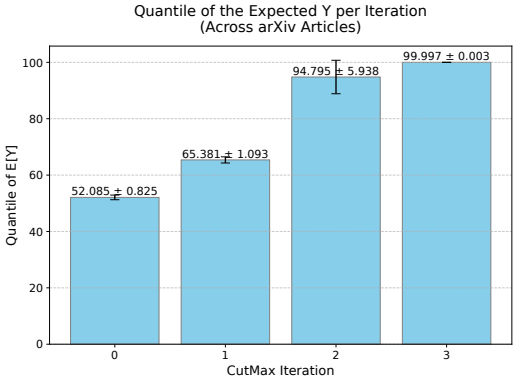

Figure 2: **Evolution of Logits Below the Mean Across CutMax Iterations** (After Algorithm 1, Algorithm 1). We ran CutMax for $T = 3$ with the best hyperparameters $(p, c) = (19, 27)$, found via grid search, on 1,000 arXiv articles passed through GPT-2 (vocabulary size $|\mathcal{V}| = 50{,}257$ (Radford et al., 2019)). Bars show the mean±std of the fraction of entries $Y_i^{(t)} < \mathbb{E}[Y^{(t)}]$ at each iteration t.

under mild conditions; for the practical hyperparameters we use, the limit is nearly one-hot. This explains why only a small, nearly constant number of iterations (e.g., $T \leq 3$–4) suffices in practice, regardless of the initial logit distribution (Sect. 4).

3.2 HE-Friendly CutMax

Building on the HE preliminaries in Sect. 2, we adapt CutMax to be fully polynomial by approximating $1/\sigma$ (Line 5, Algorithm 1) and $1/\sum_j Y_j^{(T)}$ (Line 7) using Goldschmidt methods (Goldschmidt, 1964) (details in Sect. B.1). This yields Algorithm 2, the FHE variant. Notably, having a polynomial algorithm is not enough, we also need to ensure that no overflows or precision issues compromise the correctness of the results. Specifically, we must prove the following: **(i) No overflows.** Let B_{CKKS} be the bound configured by the scheme on the unencrypted inputs, beyond which an overflow may occur. Then, all intermediate values produced by the algorithm must remain below B_{CKKS}. **(ii) No approximation errors.** The InvSqr and Inv approximations assume inputs lie within a certain range, e.g., $[\frac{1}{2^n}, 1]$ for some small n. If an input x falls in a wider range $[a, b]$, we instead compute $\frac{\text{InvSqr}(\frac{x}{b})}{b}$. We must show that $\frac{a}{b} > \frac{1}{2^n}$; otherwise, the approximation may yield incorrect results. Sect. 2 reviewed the tournament method that requires $O(n)$ comparisons in $\log n$ sequential stages and the league method that requires n^2 comparisons in n sequential stages. In contrast, CutMax

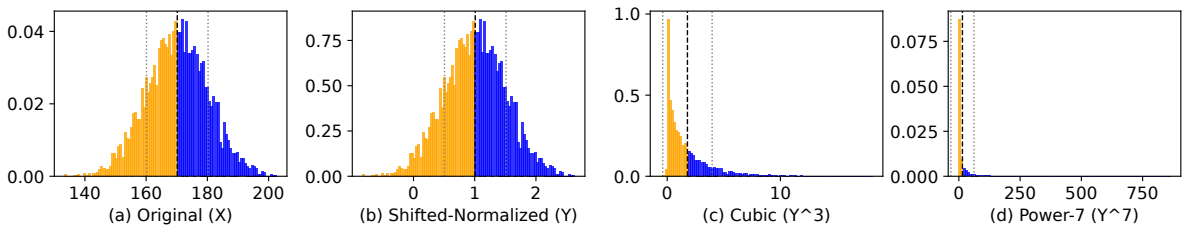

Figure 3: **Illustration of CutMax First Iteration on a Normal Distribution** CutMax algorithm first iteration illustration, applied to the original random variable $X \sim \text{Normal}(170, 10)$ (a). We first standardize and shift X using $Y = \frac{X-\mu_X}{c\sigma_X} + 1$ with $c = 5$ (b), then raise Y to the power $p = 3$ (c) or $p = 7$ (d) to induce right skew. The resulting distribution $Z = Y^7$ (d) has a maximum normalized height $\max\left(Z/\sum_i Z_i\right) = 0.0033$, indicating a strong right-tail skew. A vertical black line indicates the mean of every distribution and gray lines indicate the first standard deviation.

Algorithm 2 CutMaxHE - Encrypted CutMax

Require: $[\![X]\!] = [\![(X_1, \ldots, X_n)]\!]$, and $p, T \in \mathbb{Z}_+$, where p is odd, and $c \in \mathbb{R}_+$.
Ensure: $[\![Z]\!]$ one-hot approx. of $\text{argmax}(X)$.

1: $[\![Y^{(1)}]\!] = [\![X]\!]$
2: **for** $t = 1$ **to** T **do**
3: $\quad [\![\mu]\!] = \frac{1}{n}\,\text{RotAndSum}([\![Y^{(t)}]\!])$
4: $\quad [\![\sigma^2]\!] = \frac{1}{n}\,\text{RotAndSum}\left(([\![Y^{(t)}]\!] \ominus [\![\mu]\!])^2\right)$
5: $\quad [\![\sigma^{-1}]\!] = \text{InvSqr}([\![\sigma^2]\!])$
6: $\quad [\![Y^{(t+1)}]\!] = \left(\frac{1}{c}[\![\sigma^{-1}]\!] \odot ([\![Y^{(t)}]\!] \ominus [\![\mu]\!])\right) \oplus 1$
7: $\quad [\![Y^{(t+1)}]\!] = \left([\![Y^{(t+1)}]\!]\right)^p$
8: $[\![Z]\!] = [\![Y^{(T)}]\!] \odot \text{Inv}\left(\text{RotAndSum}([\![Y^{(T)}]\!])\right)$
9: **return** $[\![Z]\!]$

requires only T InvSqr and 1 Inv operations. Table 3 in Sect. B (taken from (Moon et al., 2024a)) shows that the InvSqr implementation is 1.5–2.1× faster than the SIGN implementation used in all prior art, at the same error level. In addition, T is weakly-dependent on n and much smaller. Consequently, CutMax outperforms prior-art. Unfortunately, the situation is not that simple. Modern HE schemes support single instruction multiple data (SIMD) operations, meaning a ciphertext can encrypt a vector of s elements instead of just a single element. In this case, multiplications ($\odot$), additions ($\oplus$), and subtractions ($\ominus$) are applied element-wise homomorphically over the vector. Furthermore, a homomorphic rotation by $\ell < s$ positions is also available (Cheon et al., 2017). We defer the discussion of how SIMD impacts latency to Sect. D, and here we complete the picture with an implementation of CutMax over HE. Algorithm 2 is the HE approximation variant of CutMax, where the input vector X is encrypted. For brevity, we assume $n = a \cdot s$, $a \in \mathbb{Z}_+$, and write the algorithm so that modern compilers such as HELayers (Aharoni et al., 2023) can automatically implement it. Lines 3, 4, and 8 of Algorithm 1 are efficiently computed in Algorithm 2 using the RotAndSum method (see (Adir et al., 2024)), which takes an encrypted vector $v = (v_1, \ldots, v_s)$ and returns a vector of s elements, each containing the sum $\sum v_i$. This requires $\log s$ rotations and additions. Multiplying by a plaintext scalar ($\frac{1}{n}$ at lines 3,4 and $\frac{1}{c}$ at line 6) is considered a cheap HE operation as well as the homomorphic subtractions at lines 4 and 6. Raising to the power of 2 (Line 4) and p (Line 6) require 1 and $\log p$ multiplications, respectively. Finally, the heaviest operations used are the InvSqr (Line 5) and Inv (Line 8) that use the Goldschmidt approximations (Sect. B.1). Denote by M_{Inv} (resp. D_{Inv}) and M_{InvSqr} (resp. D_{InvSqr}) the number of multiplications (resp. multiplication depth) required by the Inv and InvSqr approximations over one ciphertext, respectively. Then CutMaxHE executes

$$T \cdot (M_{\text{InvSqr}} + 5 + \log p) + M_{\text{Inv}} + 1 \qquad (3)$$

multiplications with a total depth of

$$T \cdot (D_{\text{InvSqr}} + 5 + \log p) + D_{\text{Inv}} + 1 \qquad (4)$$

and $O(T \log s)$ rotations.

3.3 HE-Friendly Nucleus Sampling

In text generation, language models produce a probability distribution over a large vocabulary at each time step. The next token is selected from this distribution using a decoding strategy. The simplest strategy is greedy decoding, where the token with the highest probability (argmax) is chosen.

More commonly, however, high-quality text generation relies on stochastic decoding methods that introduce controlled randomness to improve fluency, diversity, and coherence. Two widely used stochastic decoding methods are top-k sampling (Fan et al., 2018) and nucleus (top-p) sampling (Holtzman et al., 2019b). In top-k sampling, only the k most probable tokens are considered, and one is sampled according to its probability. In nucleus sampling, the model selects the smallest set of top-ranked tokens whose cumulative probability exceeds a threshold p, and samples from this adaptive set. These techniques prevent degeneration and repetition, making them essential in modern LLM-based systems.

Sampling under HE. As established, our CutMax algorithm is polynomial and thus compatible with HE; we confirm its correctness empirically in Sect. 4. Whereas CutMax handles deterministic decoding, we next extend it to stochastic sampling. The first naive attempt is to use the *inverse transform sampling* method, which generates random samples from a given probability distribution using its cumulative distribution function (CDF): Given an encrypted probability density function (PDF) X with CDF F_X, the method samples a plaintext value $U \sim \mathrm{Uniform}(0,1)$, and returns $x = F_X^{-1}(u)$, where F_X^{-1} is the inverse CDF (iCDF), and x is a sample from X. This sampling method is inefficient as it requires at least one HE heavy comparison (Sect. B) to sample an element.

Using Gumbel Distribution. We can improve upon the above by using the Gumbel distribution. We begin by recalling the relationship between the Gumbel and Uniform distributions, as well as the *Gumbel-max trick*.

Definition 3.1. *(Gumbel, 1954) Let* $U \sim \mathrm{Uniform}(0,1)$*, then* $G = -\log(-\log U)$ *has a Gumbel distribution* $G \sim \mathrm{Gumbel}(\mu = 0, \beta = 1)$.

Lemma 3.2 (Gumbel-Max Trick (Maddison et al., 2014))**.** *For* $X \in R^k$*, let* $G_i \sim \mathrm{Gumbel}(0,1)$ *be independent for each* i*. Then the random variable* $Y = \mathrm{argmax}_i\,(X_i + G_i)$ *follows a categorical distribution with probabilities given by,*

$$\mathbb{P}(Y = i) = \frac{e^{X_i}}{\sum_j e^{X_j}} = \mathrm{Softmax}(X_i)\,.$$

Using the above, our sampling method is as follows: for a given encrypted logits array $X \in \mathbb{R}^n$, sample unencrypted $U \in \mathrm{Uniform}(0,1)^n$ and convert it to $G \sim \mathrm{Gumbel}(0,1)^n$, then compute $\mathrm{CutMax}(X + G)$ over HE, which only requires fast additions and one call to CutMax.

Algorithm 3 Nucleus One-Shot Sampling

Require: Logits $[\![X]\!]$, $X \in \mathbb{R}^n$; Nucleus mass $p \in (0,1)$.
Ensure: Encrypted one-hot sample $[\![z]\!]$.
1: $\alpha = \frac{\ln(1-p)}{\ln(p)}$
2: $\beta = 1$
3: $U \leftarrow \mathrm{Uniform}(0,1)^n$
4: $G = \left(F^{-1}_{\mathrm{Beta}(\alpha,\beta)}(U_i)\right)_{i \le 1,\ldots,n}$ ▷ Unencrypted noise
5: $[\![\tilde{X}]\!] = [\![X]\!] \oplus G$ ▷ Perturb logits
6: **return** $\mathrm{CutMax}([\![\tilde{X}]\!])$

Efficient Nucleus Sampling. While our Gumbel-based method allows efficient sampling over HE, we can do better. We aim to develop an algorithm inspired by (Maddison et al., 2014) that will enable us to sample only from the top of the distribution, as in nucleus sampling, so that words from the tail of the logits distribution could not be sampled, and potentially disrupt the coherence of the generated text. To this end, we aim to sample G from a PDF that satisfy the condition $\mathbb{P}(G > p) = p$. Luckily, the $\mathrm{Beta}(\alpha, \beta)$ distribution has this property when $\beta = 1$.

Lemma 3.3. *Let* $G \sim \mathrm{Beta}(\alpha, 1)$*, then* $\mathbb{P}(G > p) = p$ *for* $\alpha = \frac{\ln(1-p)}{\ln(p)}$.

Proof. The CDF of $\mathrm{Beta}(\alpha,1)$ is $F_{\mathrm{Beta}(\alpha,1)}(x) = x^\alpha$. The requirement $\mathbb{P}(G > p) = p$ holds if and only if $F_{\mathrm{Beta}(\alpha,1)}(p) = 1 - p$. Thus, $p^\alpha = 1 - p$, or alternatively, $\alpha = \frac{\ln(1-p)}{\ln(p)}$. □

Observation 3.4. *Theorem 3.3 targets* $\mathbb{P}(G > p) = p$*. We can generalize this result by asking* $\mathbb{P}(G > p) = q$ *for any* $q \in [0,1]$*, which yields* $\alpha = \frac{\ln(1-q)}{\ln(p)}$

Algorithm 3 introduces a single-shot, nucleus-restricted sampling routine based on Theorem 3.3. It starts by draw $G \sim \mathrm{Beta}(\alpha, \beta)$ (Line 4). Subsequently, we form the "cut-noise" logits at Line 5, so that only those tokens whose cumulative mass exceeds p can potentially become the maximum. Finally, the algorithm executes a single invocation of CutMax at Line 6 to homomorphically recover the one-hot encrypted sample from the nucleus set. To summarize, we introduced a one-shot nucleus sampling algorithm whose polynomial formulation requires only a single CutMax evaluation under

HE, while maintaining exact distributional behavior and full HE compatibility.

3.4 Differentiability for Sequence Optimization

A key property of CutMax and our nucleus sampling is their composition from polynomial operations (additions, multiplications, means/variances, InvSqr, and elementwise powers). In the plaintext domain (Algorithm 1), these operations are naturally differentiable without any approximations: for example, the inverse-square-root $1/\sqrt{x}$ is C^∞ smooth and differentiable for $x > 0$, enabling exact gradient computation via automatic differentiation. This contrasts with prior tournament/league methods, which inherently rely on the discontinuous SIGN function, even in plaintext, SIGN requires smoothing or approximation for differentiability, often leading to high-degree polynomials that can introduce gradient instabilities.

In HE, both approaches use polynomial approximations, but CutMax approximates smooth functions like $1/\sqrt{x}$, which can be achieved with lower-degree polynomials compared to approximating the sharp discontinuity of SIGN (as evidenced by the lower multiplicative depths in Table 3). Theoretically, polynomial composition preserves differentiability, providing a rigorous foundation for exact end-to-end gradients through the full forward pass.

This stands in contrast to non-differentiable ops like discrete argmax or sampling, which require approximations like straight-through estimators (STE; Bengio et al. (2013)) during backpropagation—where gradients are passed 'straight through' the hard argmax as if it were a soft identity. STE introduces bias and can lead to optimization instabilities in sequence tasks (e.g., reinforcement learning from human feedback or sequence fine-tuning).

Theoretically, our methods serve as drop-in polynomial surrogates: during training, replace hard decoding with CutMax (for greedy) or nucleus sampling based upon CutMax (for sampling), and compute exact gradients end-to-end. For instance, in a sequence loss $\mathcal{L}(\mathbf{y}, \hat{\mathbf{y}})$ where $\hat{\mathbf{y}}$ is generated via decoding, the gradient $\partial\mathcal{L}/\partial\mathbf{x}$ (w.r.t. input logits $\mathbf{x}$) flows precisely through the polynomial chain. While we leave empirical validation (e.g., on BLEU/ROUGE improvements in fine-tuning) to future work, the theoretical differentiability, rooted in smooth plaintext operations and polynomial preservation, positions CutMax as a promising alternative for stable, gradient-based sequence optimization.

4 Empirical Evaluation

To evaluate our methods, we use the `ccdv/arxiv-summarization` (Cohan et al., 2018) dataset of paper abstracts, sampling $N = 100$ articles unless otherwise specified. We report results on realistic LLM logits from models including QWEN2.5-0.5B ($|\mathcal{V}| \approx 150$K), Mistral-7B ($|\mathcal{V}| \approx 33$K), and GPT-2 ($|\mathcal{V}| \approx 50$K).

4.1 Plain-Text CutMax

We evaluate our CutMax in the unencrypted domain on the QWEN2.5-0.5B model (vocabulary size $|\mathcal{V}| \approx 150$K), using the `ccdv/arxiv-summarization` (Cohan et al., 2018) dataset of paper abstracts. We sampled $N = 100$ articles and, for each, retrieved the next-token logits via one-step greedy decoding (*greedy argmax* on the plaintext logits), yielding 100 ground-truth tokens. For each prompt we then ran CutMax with $T \in \{2, 3, 4, 5\}$ iterations, grid-searching over odd powers $p \in \{7, 9, \ldots, 19\}$ and scaling factors $c \in \{3, 5, \ldots, 39\}$ to find the smallest (p, c) that still achieves perfect next-token recovery.

Convergence vs. #iterations. Table 2 summarizes, for each T, the best (p, c) choice, the resulting average maximum normalized score after T iterations, $\text{Argmax}_i = Z_i / \sum_{j=1}^{\mathcal{V}} Z_j$, and the recovery rate (fraction of times Argmax_i^T matches the true token). The results show rapid convergence: even with just $T = 2$ iterations, CutMax concentrates $\approx 95\%$ of the mass on the correct token. By $T = 4$, the recovery exceeds 99.99%, and by $T = 5$, it achieves exact recovery in all cases.

Sparsity and Accuracy. Across all 400 CutMax invocations (100 prompts × 4 values of T), we achieve 100% next-token recovery. Moreover, after convergence (e.g., $T \geq 4$), the distribution is effectively one-hot: out of ≈ 150K vocabulary items, only the true token carries non-negligible mass. These results confirm the theoretical analysis of Sect. 3: CutMax drives a highly skewed distribution in just a handful of iterations, making it an excellent practical choice for homomorphic greedy decoding under CKKS-style encryption.

Table 1: **Homomorphic** argmax **latency and accuracy.** We benchmark CutMax on two realistic LLM logit tensors—Mistral-7B ($|\mathcal{V}| = 32{,}768$) and Qwen-2.5-0.5B ($|\mathcal{V}| = 151{,}936$)—using 100 prompts from the ARXIV-summarisation set. Hyper-parameters are fixed to T=4 with p=[16,4,4,6] and c=[5,3,3,3] due to chain index optimization and numerical stability. We report the mean of the average of maximum values, the average latency, the accuracy of slot predictions, the arrays' sizes, and the device used.

Algorithm	Dataset	Model	Array Length	$\mathbb{E}[\max_i Z_i] \uparrow$	Avg. Latency $\downarrow$ (secs)	Accuracy $\uparrow$	Devices
CutMax	arXiv	Mistral7B-v0.3	32,768	0.994	3.373	100.0%	1× NVIDIA H100
CutMax	arXiv	Qwen2.5	151,936	0.989	4.607	100.0%	1× NVIDIA H100
Baselines							
Nexus	GLUE	BERT	30,522	—	79.36*	—	4× Tesla A100
Nexus	GLUE	Llama-3	128,256	—	162.8*	—	4× Tesla A100

* Nexus (Zhang et al., 2024a) Table 2: "We batched 32 inputs in total ... Runtime is the amortized latency of each input.", originally reported (2.48,5.09) when multiplied by 32 we get (79.36, 162.8), respectively.

Table 2: Convergence of CutMax on QWEN2.5-0.5B ($|\mathcal{V}| \approx 150$K) over 100 arXiv abstracts. We report the mean of the per-prompt Argmax_i^T, the best (i.e. largest) Argmax_i^T observed across the 100 prompts with exact next-token recovery of 100% in all cases.

Iter. (T)	Best (p, c)	$\mathbb{E}[\text{argmax}_i] \uparrow$	$\max(\text{argmax}_i) \uparrow$
2	$(19, 5)$	0.952	0.987
3	$(19, 27)$	0.987	0.994
4	$(13, 15)$	0.999996	1.000
5	$(9, 15)$	1.000	1.000

4.2 HE CutMax

We evaluated our FHE CutMax implementation under the CKKS scheme using HELayers (Aharoni et al., 2023). Experiments were conducted on LLM logits from two models: Qwen-2.5-0.5B and Mistral-7B, with vocabulary sizes of 151,936 and 32,768, respectively. For each model, we used 100 examples and set following hyperparameters: $c = [5, 3, 3, 3]$, $p = [16, 4, 4, 6]$, $T = 4$, chosen to optimize the CKKS chain index and ensure numerical stability. We report the mean of the per-example maximum values, average latency, and slot prediction accuracy. As a baseline, we compare our method against the recently proposed HE-friendly argmax algorithm by Zhang et al.. Results are reported in Table 1, demonstrating that our method is both accurate and efficient. From an accuracy perspective, our method does not alter the model's predictions in any of the tested cases, achieving 100% accuracy. For efficiency benchmarking, our method significantly reduces the latency of argmax compared to Nexus (Zhang et al., 2024a), by several orders of magnitude for comparable vocabulary sizes. Specifically, for a vocabulary size of approximately 30K, our method reduces latency from 79.56 seconds to 3.373 seconds. For a larger vocabulary of approximately 150K, our method reduces latency from 162.8 to 4.607. Note that we chose Nexus as our baseline even though there are newer papers on LLM inference such as (Zimerman et al., 2024a; Park et al., 2025; Zhang et al., 2025b; Moon et al., 2024b; Kei and Chow, 2025), because these did not include an argmax benchmark or did not utilize argmax at all.

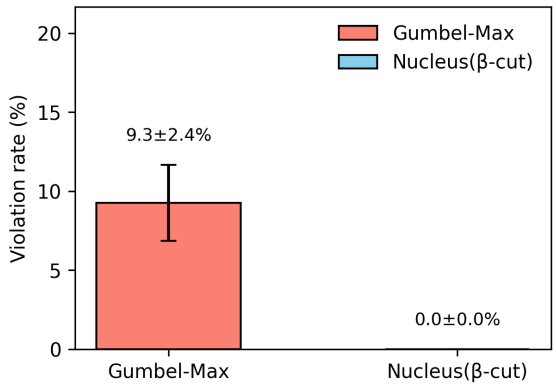

Figure 4: **Violation Rates in Nucleus Sampling Methods**: Violation rate (%) of sampling outside the top-p nucleus for Gumbel-Max and Nucleus(β-cut), averaged over 100 prompts with 1000 draws each ($p = 0.9$). Error bars denote one standard deviation.

4.3 Nucleus Sampling

Figure 5 qualitatively demonstrates our method's effectiveness, showing a sharply truncated distribution that confirms all probability mass remains within the top-p nucleus. To verify that our one-shot nucleus sampler never selects tokens outside the intended top-p set, we measured the *violation rate* as the fraction of draws falling outside the nu-

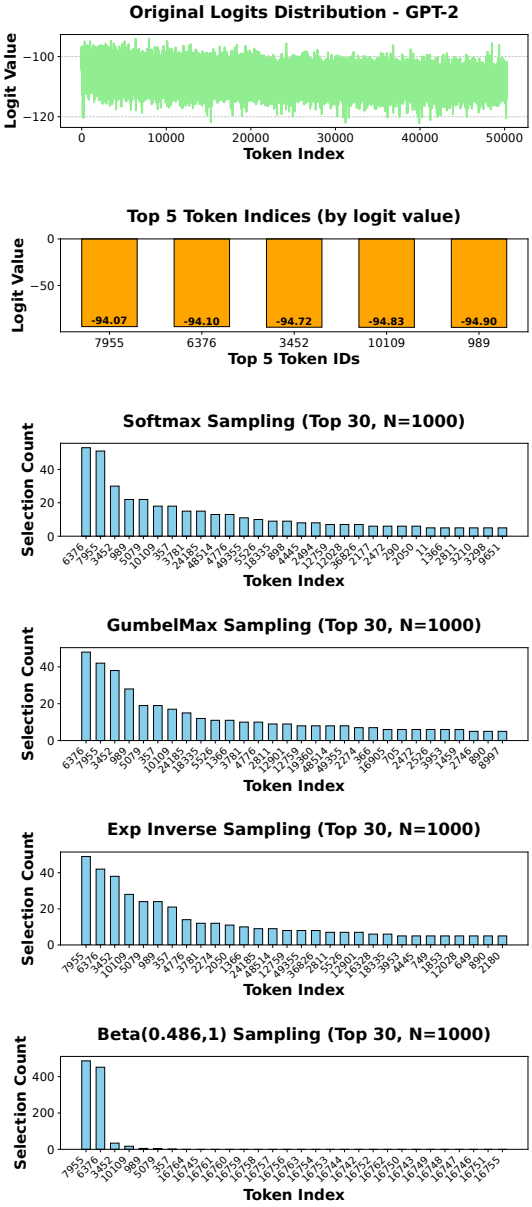

Figure 5: **Comparison of Sampling Methods on GPT-2 Last-Token Decoding:** The top strip shows the complete 50,257-dimensional logit vector (only its outline is visible at this scale), and the second strip zooms in on the five largest logits. The three lower strips plot, for 1,000 repeated draws, histograms of the 30 most frequently chosen token indices produced by four different samplers: standard Softmax at temperature 1, the classical Gumbel-Max trick, inverse-transform sampling on the normalized exponentials ("Exp-inverse"), and our one-shot *Beta-cut nucleus* sampler, which perturbs each logit with i.i.d. $G_i \sim \mathrm{Beta}(\alpha, 1)$ noise using $\alpha = 0.486$ computed from Theorem 3.4 for $(p, q) = (0.9, 0.95)$. Whereas the first three methods still allocate non-negligible mass to tail tokens, the Beta-cut histogram is sharply truncated, confirming that all probability remains inside the top-p nucleus exactly as required by the HE-friendly design of Sect. 3.3.

cleus, over $S = 100$ prompts, with $N = 1000$ samples per prompt and $p = 0.9$. We compare standard Gumbel-Max sampling against our Nucleus(β–cut) method. Results are summarized in Figure 4: Gumbel-Max violates the top-p constraint in $9.3\% \pm 2.4\%$ of draws, whereas Nucleus (β-cut) has *zero* violations.

5 Conclusions

We solve a critical bottleneck in privacy-preserving AI: adapting LLM decoding for homomorphic encryption, where non-polynomial operations like argmax and sampling are computationally prohibitive. We introduce **CutMax**, a novel, HE-friendly and theoretically grounded argmax algorithm that replaces slow, comparison-based methods with an efficient iterative polynomial process. Crucially, CutMax achieves 100% accuracy and executes in just a few seconds on large vocabularies ($|\mathcal{V}| \approx 150$K), making secure greedy decoding practical for LLM inference for the first time. Building on this, we present the **first HE-compatible nucleus (top-p) sampling method**, which leverages CutMax with the idea of noisy inverse transform sampling to provably restrict sampling to the desired token set. Together, these fully polynomial algorithms provide a complete and efficient framework for both greedy and stochastic decoding over encrypted data, addressing a major barrier to the deployment of secure LLMs in real-world applications.

Limitations

Our work focuses on optimizing the decoding stage of encrypted token generation. While this is a critical component, it does not capture the full computational cost of encrypted inference. We view this work as a step toward narrowing the still-substantial gap between encrypted and plaintext generation, and we believe that combining our techniques with future advances, such as attention mechanisms, can help enable practical, privacy-preserving generative AI. Our implementation uses the CKKS scheme, which is well-suited for approximate arithmetic and widely adopted in encrypted machine learning. While the approach is conceptually compatible with other HE schemes, extending it may require engineering adaptations. As the field evolves, e.g., through new HE schemes or hardware support, our techniques can be adapted accordingly. Our paper focuses on improving the efficiency of LLM

decoding methods under encryption. Therefore, it preserves the behavior of the underlying generative model, including any biases or factual inaccuracies it may contain. While encryption protects user data, it also limits visibility into model behavior, making post-hoc filtering and auditing more challenging. We view this as a crucial direction for future research in secure and responsible AI.

Ethical Considerations

Our work aims to enhance privacy in text generation by enabling efficient LLM decoding on encrypted inputs. This can reduce the exposure of sensitive user data when interacting with large language models. However, our method preserves the behavior of the underlying model, including any biases, inaccuracies, or harmful content it may produce. Moreover, since encrypted inference limits visibility into intermediate states, it may complicate post-generation auditing and filtering. We view secure model auditing and bias mitigation as important complementary directions for future research.

Appendix

A Threat model

There are two commonly used threat-models for secure inference and generative AI for LLMs over HE: 1) using encrypted weights; or 2) using encrypted input samples (queries). When considering a 2-party scenario with HE, it is commonly assumed that one party is the (untrusted, semi-honest) server who holds the model (encrypted or not) and the other party is the data-owner who performs the query and would like to avoid revealing the query to the server. The decision of whether the server holds the model encrypted or not depends on whether a third-party the model-owner agrees to share the data with the server. Our proposed solution is orthogonal to the above decision, which eventually only affects latency. All communications are performed using TLS 1.3 and privacy attacks such as model extraction attack and membership inference attacks require an extra mechanism such as differential privacy, which is also orthogonal to this work. For brevity, we have decided to refer the reader to (Adir et al., 2024)[Chapter 3] that further describes this security model.

B Approximations for HE

Since HE supports only polynomial operations, functions like $\max$, SIGN, Inv, and InvSqr must be approximated. A common formulation for $\max(a, b)$ is:

$$\max(a, b) = \frac{a + b}{2} + \frac{\text{SIGN}(a - b) \cdot (a - b)}{2}, \tag{5}$$

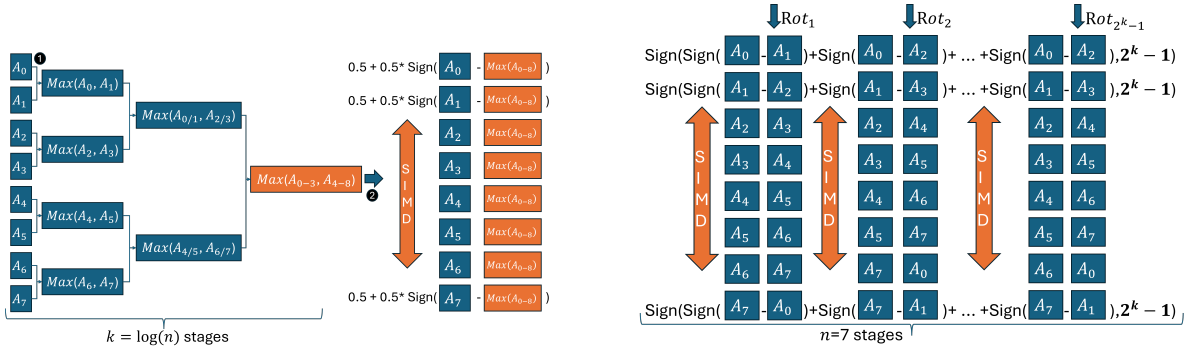
where $\text{SIGN}(x) = 1$ when $x > 0$ and -1 otherwise. An approximation of SIGN is given, e.g., in (Moon et al., 2024a). To make the results of SIGN suitable as an indicator function (as in Equation (5)), it is common to translate the SIGN range from $\{-1, 1\}$ to $\{0, 1\}$ using $\frac{1+\text{SIGN}(x)}{2}$. The $\max$ and SIGN functions are used by prior-art argmax implementations. In contrast, CutMax uses Inv and InvSqr approximations.

B.1 Goldschmidt

The *Goldschmidt* inverse algorithm (Goldschmidt, 1964) is an iterative process for computing the function $f(x) = \frac{1}{x}$. (Cheon et al., 2019) showed that this algorithm can be used to approximate inputs in the range $[0, 2]$ effectively using the equation

$$f(x) = \prod_{i=0}^{d} \left(1 + (1 - x)^{2^i}\right) \tag{6}$$

Specifically, they proved that for $(x \in \left[\frac{1}{2^n}, 1\right])$, it requires $(d = \Theta(\log \alpha + n))$ iterations to converge, with an error bound of (2^{α}). (Panda, 2021) showed an efficient implementation for the Goldschmidt inverse square root (InvSqr) algorithm over HE. Subsequently, (Moon et al., 2024a) reported improved measurements of the inverse and InvSqr implementations under CKKS. Table 3 repeats some benchmarks for the SIGN and InvSqr functions at different approximation levels (α). One immediate conclusion is that the InvSqr implementation is $(1.5 - 2.1\times)$ faster compared to the SIGN implementation for the same level of errors. One reason is that InvSqr has a lower *multiplication depth* (defined below) and thus requires fewer bootstraps.



Multiplication Depth. In CKKS, a ciphertext must be refreshed via a costly *bootstrap* operation after every L sequential multiplications, where L is a scheme parameter. Since bootstrapping is significantly slower than other operations, a key optimization goal is to minimize its use. The longest chain of multiplications in a function—its *multiplication depth*, is therefore a critical target for reduction.

C Previous, Comparison-Based Methods for argmax over HE

Figure 6 visualizes the two canonical comparison-based approaches for encrypted argmax: the *tournament* method (Figure 6a) and the *league* method (Figure 6b). Both rely on repeated encrypted comparisons implemented via polynomial approximations of $\text{SIGN}(\cdot)$.

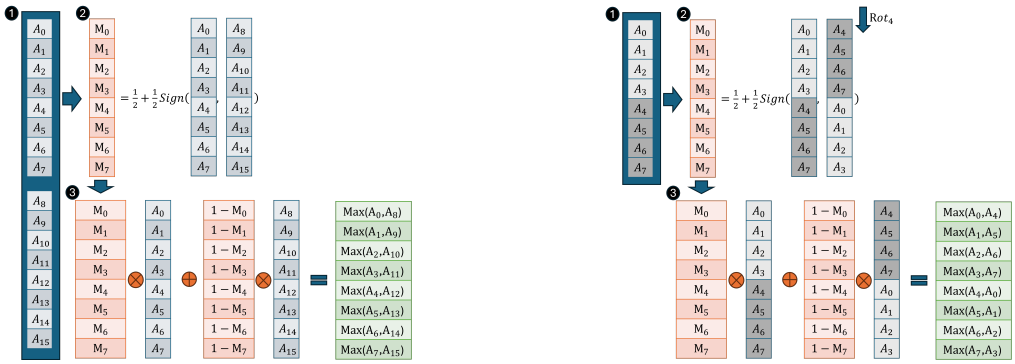
Table 3: A sample benchmarks of (Moon et al., 2024a) conducted on AMD EPYC 7502-32 CPU, using Microsoft Seal, poly degree of 2^{17}, and scale $\Delta = 2^{40}$.

Algorithm	α	7	9	11	13
SIGN	Iterations	7	9	11	12
	Multiplication depth	14	18	22	24
	Time (s)	6.3	11.7	20.2	26.9
InvSqr	Iterations	5	6	7	8
	Multiplication depth	10	12	14	16
	Time (s)	4.1	6.6	9.8	12.8

(a) Tournament method.

(b) League method.

Figure 6: **Illustration of Prior Comparison-based argmax Methods in HE** (see main text Sect. 2).



In the tournament design, approximately $n-1$ pairwise comparisons are arranged into $\log_2 n$ sequential stages. At each stage, the number of candidates is halved until only the maximum remains. While asymptotically efficient, this design requires $\log n$ sequential SIGN evaluations, each incurring costly rotations and bootstraps.

In the league design, every pair of inputs is compared, and results are accumulated so that the true maximum is the only element with score $n-1$. This requires n sequential rounds of comparisons. Although SIMD parallelism allows all n pairwise comparisons within a round to be executed in parallel slots, the *sequential* round structure still dominates, leaving the method quadratic overall.

As summarized in Table 3, polynomial SIGN approximations are substantially deeper and slower than inverse-square-root or division. Thus, even when accelerated with SIMD, both the tournament and league methods remain inefficient at large n. In practice, this has limited published HE argmax implementations either to small input sizes or to systems that decrypt logits before argmax.

D Argmax using SIMD

SIMD and Rotations. CKKS enables SIMD-style packing, where one ciphertext encrypts a vector $(v_1, \ldots, v_s)$. Operations are applied elementwise, and encrypted vectors can be rotated by $\ell < s$ positions. This allows for patterns such as RotAndSum (Adir et al., 2024) - which aggregates values with $\log s$ rotations and additions. Figure 7 demonstrates how to leverage SIMD to execute n $\max(a, b)$ operations in parallel. Step (1) shows the encrypted input; in Step (2), we compute an indicator vector where $M[i] = 1$ if $A[i] > A[i + \frac{n}{2}]$, and 0 otherwise. Subsequently, Step (3) selects (masks) only the elements that match the indicator vector, which returns the desired results. Consider two cases: $n > s$ (Figure 7a) and $n = s$ (Figure 7b) (The case $n < s$ behaves similarly to $n = s$). Here, s is the maximal number of elements that a single ciphertext can encrypt. Figure 7a illustrates the case where $n = 16$ elements are encrypted in two ciphertexts, each containing a vector of 8 elements. In contrast, Figure 7b shows the case $n = s$, which requires only one ciphertext. In the first case, no rotation is needed, as we can directly subtract one ciphertext from the other using element-wise subtraction. However, this is not the case in Figure 7b, where we must homomorphically rotate A by $n/2$ positions. As a result, the output

(a) $n > s$. (b) $n = s$.

Figure 7: HE SIMD example implementation.

is duplicated, and we only need to keep the top $n/2$ elements. It appears that many comparisons can be saved by using SIMD. Consider the case where $n = s$ for the league method (Figure 6b) that requires only n homomorphic rotations and n parallel SIGN evaluations, with one additional final parallel SIGN evaluation. The complexity is thus reduced from n^2 to n SIGN operations, which, on hardware with sufficient parallel threads, may result in faster execution than the sequential tournament algorithm. When $n > s$ it is worth combining the methods as was done in (Iliashenko and Zucca, 2021). Starting with a tournament and when the number of elements is reduced beyond some threshold continue with the league method.

E Convergence of CutMax

E.1 Preliminaries and Definitions

The following definitions assume that a vector $x \in \mathbb{R}^n$ has a unique maximum element. We also denote the average of x by $\mu_x = \frac{1}{n}\sum_i x_i$ and its standard deviation by $\sigma_x = \sqrt{\frac{1}{n}\sum_i (x_i - \mu_x)^2}$.

Definition E.1 (Max elements)**.** *Given a vector $x \in \mathbb{R}^n$ with a unique maximal element, the index of that element is denoted by $i_x^* = \operatorname{argmax}_i x_i$ and the index of the second-largest element (excluding the maximum) is denoted by $i_x^{**} = \operatorname{argmax}_{j \neq i_x^*} x_j$.*

Definition E.2 (δ-gap bound)**.** *A vector $x \in \mathbb{R}^n$ with a unique maximum at index i_x^* is δ-gap bounded for $\delta \in \mathbb{R}_+$ when $x_{i_x^*} - x_{i_x^{**}} \geq \delta \cdot \sigma_x$*

Definition E.3 (Gap Ratio)**.** *For $y \in \mathbb{R}^n$, its* gap ratio *is $\Gamma(y) = \frac{y_{i_y^*}}{y_{i_y^{**}}}$*

Definition E.4 (c-semi-standardization)**.** *For $c \in \mathbb{R}_+$, a c-semi-standardization function is*

$$S_c(y) : \mathbb{R}^n \longrightarrow \mathbb{R}^n \tag{7}$$

$$y_i \longmapsto \frac{y_i - \mu_y}{c \cdot \sigma_y} + 1 \tag{8}$$

Definition E.5 (CutMax Iteration)**.** *Given $c \in \mathbb{R}_+$ and an odd $p \in \mathbb{Z}_+$, the* CutMax *iteration function is*

$$\mathrm{CutMax}_t(y^{(t)}) : \mathbb{R}^n \longrightarrow \mathbb{R}^n \tag{9}$$

$$y_i^{(t)} \longmapsto \left(S_c(y^{(t)})\right)^p \tag{10}$$

for some iteration index $t > 0$.

E.2 Key Lemmas

The following lemma shows that running a standardization on a vector y preserves the ordering of elements in it. In addition, it transforms the gap condition.

Lemma E.6. *The c-semi-standardization function (S_c) is a strictly increasing function.*

Proof. For every $y \in \mathbb{R}^n$ and for every $i, j \in [n], i \neq j$, because $\mu_y, \sigma_y, c > 0$ it follows that

$$y_i > y_j \iff y_i - \mu_y > y_j - \mu_y \tag{11}$$

$$\iff \frac{y_i - \mu_y}{c \cdot \sigma_y} > \frac{y_j - \mu_y}{c \cdot \sigma_y} \iff S_c(y)_i > S_c(y)_j \tag{12}$$

□

Lemma E.7. *Let $y \in \mathbb{R}^n$ be a δ-gap bounded vector then $S_c(y)$ is a $\frac{\delta}{c}$-gap bounded vector.*

Proof. Set $z := S_c(y)$, $i_z^* = i_y^*$ and $i_z^{**} = i_y^{**}$. then

$$z_{i_z^*} - z_{i_z^{**}} = \frac{y_{i_y^*} - y_{i_y^{**}}}{c \cdot \sigma_y} \underset{y \text{ is } \delta\text{-gap bounded}}{\geq} \frac{\delta \cdot \sigma_y}{c \cdot \sigma_y} = \frac{\delta}{c} \tag{13}$$

□

The next Lemma shows that applying a c-semi-standardization function S_c on some vector y results with negative coefficients in places where y_i is at least c standard deviations below the mean of y.

Lemma E.8 (Unconditional gap growth for one CutMax step)**.** *Let $Y^{(t)} \in \mathbb{R}^n$ have a unique maximizer at i^* and let $i^{**} \neq i^*$ be the runner-up index. Assume $Y^{(t)}$ is δ-gap bounded in the sense that $Y_{i^*}^{(t)} - Y_{i^{**}}^{(t)} \geq \delta\, \sigma_{Y^{(t)}}$ (Def. E.2), where $\sigma_{Y^{(t)}}$ denotes the population standard deviation. Assume additionally that $\min_i y_i^{(t)} \geq \mu_{y^{(t)}} - c\sigma_{y^{(t)}} + \epsilon$ for small $\epsilon > 0$, ensuring all $z_i > 0$. Fix $c > 0$ and an odd integer $p \geq 1$, and set $z = S_c(Y^{(t)}) = \frac{Y^{(t)} - \mu_{Y^{(t)}}}{c\,\sigma_{Y^{(t)}}} + 1$ and $\mathbf{Y}^{(t+1)} = z^{\odot p}$ (the elementwise odd-power step of CutMax). Then the post-step gap ratio satisfies $\frac{\mathbf{Y}_{i^*}^{(t+1)}}{\mathbf{Y}_{i^{**}}^{(t+1)}} = \left(\frac{z_{i^*}}{z_{i^{**}}}\right)^p \geq \left(1 + \frac{\delta}{c+\sqrt{n}}\right)^p$. Consequently, after T CutMax iterations, $\frac{y_{i^*}^{(T)}}{y_{i^{**}}^{(T)}} \geq \left(1 + \frac{\delta}{c+\sqrt{n}}\right)^{pT}$.*

Proof. By Lemma E.7, $z_{i^*} - z_{i^{**}} \geq \delta/c$. Therefore

$$\frac{z_{i^*}}{z_{i^{**}}} = 1 + \frac{z_{i^*} - z_{i^{**}}}{z_{i^{**}}} \;\geq\; 1 + \frac{\delta}{c\, z_{i^{**}}}.$$

To upper-bound $z_{i^{**}}$, write $r_i = \frac{Y_i^{(t)} - \mu_{Y^{(t)}}}{\sigma_{Y^{(t)}}}$. From the definition of the population standard deviation, we have $\frac{1}{n}\sum_i r_i^2 = 1 \Rightarrow \sum_i r_i^2 = n$, hence $r_{i^{**}} \leq \sqrt{n}$ and thus $z_{i^{**}} = 1 + \frac{r_{i^{**}}}{c} \leq 1 + \frac{\sqrt{n}}{c}$. Combining the bounds gives

$$\frac{z_{i^*}}{z_{i^{**}}} \;\geq\; 1 + \frac{\delta}{c\,(1 + \sqrt{n}/c)} = 1 + \frac{\delta}{c + \sqrt{n}}.$$

Finally, the CutMax power step yields $\frac{\mathbf{Y}_{i^*}^{(t+1)}}{\mathbf{Y}_{i^{**}}^{(t+1)}} = \left(\frac{z_{i^*}}{z_{i^{**}}}\right)^p$, which gives the stated inequality. Iterating T times multiplies the exponent by T. □

Lemma E.9 (Per-step gap amplification)**.** *Let $\mathbf{y}^{(t)} \in \mathbb{R}^n$ satisfy the δ–gap condition* (Def. E.2)*, fix $c > 0$ and odd $p \geq 1$, and set $z = S_c(\mathbf{y}^{(t)})$ and $\mathbf{y}^{(t+1)} = z^{\odot p}$. Then the gap ratio satisfies*

$$\Gamma^{(t+1)} \;=\; \Gamma^{(t)} \left(\frac{z_{i^*}}{z_{i^{**}}}\right)^p \;\geq\; \Gamma^{(t)} \left(1 + \frac{\delta}{c + \sqrt{n}}\right)^p.$$

Proof. By Lemma E.8, $\frac{z_{i^*}}{z_{i^{**}}} \geq 1 + \frac{\delta}{c+\sqrt{n}}$. Since $\Gamma^{(t+1)} = \Gamma^{(t)}(z_{i^*}/z_{i^{**}})^p$, the claim follows. □

Theorem E.10 (CutMax Convergence)**.** *Let $\mathbf{x} \in \mathbb{R}^n$ satisfy the δ–gap condition with $\delta > 0$, and run CutMax with parameters (p, c, T), $c > 0$, odd $p \geq 1$. Then*

$$\Gamma^{(T)} \;\geq\; \Gamma^{(0)} \left(1 + \frac{\delta}{c + \sqrt{n}}\right)^{pT}.$$

In particular, to ensure $\Gamma^{(T)} \geq k$, it suffices to take

$$T \;\geq\; \left\lceil \frac{\ln k - \ln \Gamma^{(0)}}{p\, \ln\!\left(1 + \frac{\delta}{c+\sqrt{n}}\right)} \right\rceil \;\leq\; \left\lceil \frac{\ln k}{p\, \ln\!\left(1 + \frac{\delta}{c+\sqrt{n}}\right)} \right\rceil,$$

where the last inequality uses $\Gamma^{(0)} \geq 1$.

Proof. Iterating Lemma E.9 yields $\Gamma^{(T)} \geq \Gamma^{(0)} \left(1 + \frac{\delta}{c+\sqrt{n}}\right)^{pT}$. Solving for T gives the stated bound. □

Table 4: Min. iterations $T_{\min}$ for $n = 32{,}768$ (Mistral-7B), $p = 13$, $c = 5$.

ynaga@iis.u-tokyo.ac.jp

Abstract

Esports is a competitive sport in which highly skilled players face off in fast-paced video games. Matches consist of intense, moment-by-moment plays that require exceptional technique and strategy. These moments often involve complex interactions, including team fights, positioning, or strategic decisions, which are difficult to interpret without expert explanation. In this study, we set up the task of generating commentary for a specific game moment from multimodal game data consisting of a gameplay screenshot and structured JSON data. Specifically, we construct the first large-scale tri-modal dataset for *League of Legends*, one of the most popular multiplayer strategy esports titles, and then design evaluation criteria for the task. Using this dataset, we evaluate various large vision language models in generating commentary for a specific moment. We will release the scripts to reconstruct our dataset.

1 Introduction

The esports industry has witnessed rapid global growth (Jenny et al., 2017; Hallmann and Giel, 2018), highlighted by its inclusion in the Asian Games since 2018 and the Olympic Esports Games in 2027 (IOC, 2025). Esports matches in popular titles like *League of Legends* (LoL), a leading multiplayer online battle arena (MOBA) game, feature a continuous sequence of highly skilled, moment-by-moment plays requiring exceptional technique and strategic decision-making. For audiences to fully appreciate these intense moments, expert commentary is essential, as it helps interpret complex player interactions, strategies, and game states.

Several studies have thus explored commentary generation from esports game data (§ 2) (Tanaka and Simo-Serra, 2021; Zhang et al., 2022; Wang and Yoshinaga, 2024). These studies typically rely on either structured data (*e.g.*, game logs, metadata) or visual information (*e.g.*, video frames) as input, and focus on generating commentary for matches. While such approaches have shown promise, they do not fully capture the granular nature of esports, where understanding often hinges on brief but critical moments. Although Zhang et al. (2022) studied moment-level commentary generation, they rely solely on structured data, failing to exploit the dual-modality nature of esports game records, which should be used together to interpret game moments.

To bridge this gap, this study sets up a task of generating commentary for a specific esports moment (Figure 1) by leveraging multimodal game

Proceedings of the 14th International Joint Conference on Natural Language Processing and the 4th Conference of the Asia-Pacific Chapter of the Association for Computational Linguistics, pages 1795–1807
December 20-24, 2025 ©2025 Association for Computational Linguistics

data, combining both static visual inputs (gameplay screenshots) and structured JSON data records. Motivated by recent advances in vision-language models (VLMs), our task explores how to effectively integrate these complementary modalities to produce concise, informative commentary and challenges VLMs on their ability to perform this integration. We construct the first large-scale trimodal dataset dedicated to League of Legends that includes aligned visual, structured, and textual data (§ 3). Additionally, we design evaluation metrics that account for the unique challenges of esports commentary, focusing on the accuracy, relevance, and interestingness of the generated text (§ 4.2).

We evaluate both open- and closed-source large vision-language models (VLMs) on our dataset to analyze their capabilities in cross-modal esports commentary generation (§ 4). Our experiments confirm the importance of combining visual and structured data to improve commentary quality and reveal the challenges still faced by current models, such as reducing inaccurate statements and capturing the strategic content of gameplay moments.

The contributions of this paper are as follows:

- We set up the task of commentary generation for League of Legends, one of the most popular esports titles, from multimodal game data (§ 3); we built a dataset to facilitate research.
- We designed several human evaluation criteria for this task (§ 4.2), and examined whether these criteria can be captured by existing automatic metrics and LLM-as-a-judge results.
- We evaluated strong VLMs on our task (§ 4.3), and confirmed the role of information provided by each data modality in esports commentary generation (§ 5).

2 Related Work

In this section, we review existing tasks of data-to-text generation for (e)sports games from game data. We first discuss text generation from structured data, followed by multimodal data.

Text generation for structured game data Prior studies have focused on generating textual summaries or commentaries for various games including physical sports (*e.g.*, basketball (Wiseman et al., 2017) and football (van der Lee et al., 2017; Taniguchi et al., 2019)), board games (*e.g.*, shogi (Kameko et al., 2015) and chess (Jhamtani et al., 2018)), and esports (*e.g.*, Dota 2 (Zhang et al., 2022) and League of Legends (Wang and Yoshinaga, 2024)). These data-to-text studies typically transcribe structured game data, such as match statistics, move expressions, and real-time action records, into textual descriptions. A notable difference among these data-to-text tasks is the information density in the input data; while physical sports provide mainly match statistics, board games and esports provide more detailed, play-by-play records, enabling commentary for each moment. However, compared to turn-based board games, esports games are fast-paced video games, making generation solely from structured data more challenging (Zhang et al., 2022).

Game video captioning Another rich source for game commentary generation is multimodal data, in particular, gameplay videos. Early studies primarily focused on match footage (video recordings) of physical sports such as tennis (Yan et al., 2016), basketball (Yu et al., 2018), baseball (Kim and Choi, 2020), and football (Mkhallati et al., 2023; Qi et al., 2023), where only videos provide detailed information for individual game moments. In these studies, automatic video captioning is used to generate descriptions of actions within the video. Meanwhile, some studies have leveraged esports match videos to perform play-by-play commentary generation and build visual data-to-text datasets for League of Legends (LoL-V2T (Tanaka and Simo-Serra, 2021)) and for Asseto Corsa, a racing game (Ishigaki et al., 2021). However, the LoL-V2T dataset does not include structured game data, despite the fact that such data is a valuable source for commentary generation. Although the Assetto Corsa dataset contains structured data, it focuses on a racing game, and the structured data contains relatively simple numerical metadata.

In this study, we focus on generating commentary for a specific esports moment in the multiplayer strategy game League of Legends. Unlike previous work on Dota 2 (Zhang et al., 2022) and LoL (Tanaka and Simo-Serra, 2021; Wang and Yoshinaga, 2024), we leverage both a structured data record and a screenshot (a single video frame) to combine the strengths of these modalities. Our proposed task and dataset offer a valuable benchmark for evaluating the capabilities of recent large vision-language models (VLMs), particularly in generating on-demand commentary for a specific gameplay moment.

Event type	Number	(Proportion)	# keys	Explanation
ITEM_PURCHASED	828	(24.0%)	3	The player purchases an item
ITEM_SOLD	60	(1.7%)	3	The player sells an item

3 Tri-modal Commentary Generation Dataset for Esports Moments

We have built a multimodal commentary generation dataset for esports moments in League of Legends (LoL), one of the most popular multiplayer strategy games. LoL is featured as medal events in 2022 and subsequent Asian Games (Lam and Kuen Wong, 2024; Hong and Yi, 2024), highlighting its popularity and the practical value of developing a dataset.

We begin by introducing LoL basics, and next describe our methods for extracting multimodal game data with accompanying commentaries. Then, we explain how we align these data across modalities to obtain moment-commentary triples. Finally, we compare our dataset to existing benchmarks.

3.1 Basics of LoL Data

In LoL games,[1] two five-player teams compete on a game map. Each player controls a unique character called a "champion," with distinct abilities that grow stronger over time. The primary objective is to destroy the opposing team's base, called as "Nexus," while defending one's own. Throughout the game, players earn resources by defeating enemy champions, neutral monsters, and destroying enemy structures. These resources can be used to purchase items and upgrade champions' abilities, enhancing their impact on team strategy. Matches typically last from fifteen minutes to over an hour, depending on game pace, patch updates, and strategies (Claypool et al., 2017).

Compared to physical sports and board games, LoL presents greater complexity due to real-time actions, rules specific to digital games, and multimodal challenges. These factors pose key obstacles to game commentary generation.

[1]All references to LoL in this paper refer to its main game mode, Summoner's Rift; other game modes are not used.

3.2 Extracting Game Data and Commentaries

Following the existing studies on LoL commentary generation (Tanaka and Simo-Serra, 2021; Wang and Yoshinaga, 2024), we construct our dataset using matches from the highest-level tournament in the 2019 League of Legends World Championship. We adopt the same approach as the LoL19 dataset (Wang and Yoshinaga, 2024) to obtain the structured data and commentaries, extending their script[2] to additionally extract screenshots.

Specifically, we collect game logs via the Riot Games API of LoL[3] as structured data and screenshots (video frames) from YouTube game videos as additional input, while using subtitles as commentaries. These multimodal data are paired with the match IDs provided by the contest's Match History site.[4] Below, we detail these procedures.

Retrieving game data records via API The LoL games from the 2019 World Championship[5] record every player action, accessible via the official Riot Games API.[3] Using this data, we can reconstruct complete games. However, the full logs contain redundant information, resulting in large data volumes strain storage and processing resources.

To mitigate this issue, following LoL19 (Wang and Yoshinaga, 2024), we use the "event-based data frame" provided by the official API. In this data frame, key actions are recorded based on discrete events; Figure 1 shows an example of a game event, and Table 1 presents an overview of various

[2]https://github.com/ArnoZWang/esports-data-to-text

[3]https://developer.riotgames.com/

[4]https://lol.fandom.com/wiki/2019_Season_World_Championship/Match_History

[5]The match history site changed its method of counting games, which reduced the total from 220 to 120, even though the set of matches remained the same. One match was excluded due to data corruption, resulting in 119 valid matches.

Name	Domain	Input Modal	# Games	# Examples
RotoWire (Wiseman et al., 2017)	basketball	structured data	4,853	4,853
GameKnot (Jhamtani et al., 2018)	chess	structured data (game logs)	11,578	298,008
Dota2-Commentary (Zhang et al., 2022)	esports	structured data (game meta-data)	70	7,473
LoL19 (Wang and Yoshinaga, 2024)	esports	structured data (game logs)	220	3,490
LoL-V2T (Tanaka and Simo-Serra, 2021)	esports	video	157	9,723
LoL19-trimodal (ours)	esports	image, structured data (game logs)	120	3,450
Assetto Corsa (Ishigaki et al., 2021)	racing game	structured data, text, video	1,389	129,226
ScienceQA (Lu et al., 2022)	science	image, text	N/A	6,532

Table 2: Statistics of our LoL19-trimodal dataset and existing datasets for related generation tasks.

types of events in the collected data. Each event represents an update to the game state and includes a key named "type" indicating the event type. Different event types contain different sets of keys. The event-based data frames are stored in JSON format, as shown in Figure 1.

As in the LoL19 dataset, we linearize the structured input to improve consistency. For each key-value pair in the top-level list of each event, we recursively concatenate the value and the key using delimiter "|" and insert spaces between these key-value pairs. For example, the "BUILDING_KILL" event in Figure 1 is linearized as follows:

```
BUILDINGKILL|type 839426|timestamp
x4318y13875|position 4|killerId
|assistingParticipantIds 200|teamId
TOWERBUILDING|buildingType
TOPLANE|laneType OUTERTURRET|towerType
```

Collecting screenshots from game videos We collect screenshots from YouTube videos for the same matches as those used to obtain the structured data records. Specifically, we capture all screenshots (video frames) in PNG format at the same timestamps as the events in the structured data, resulting in paired data across two modalities.

Gathering commentaries from game videos Following LoL19 and LoL-V2T, we gather subtitles from YouTube contest videos. The subtitles are then split into utterances using line breaks given by YouTube's automatic speech recognition (ASR) results as cues, each of which utterances is regarded as one commentary segment. To verify data quality, we follow the approach from LoL19 (Wang and Yoshinaga, 2024) by randomly sampling 200 examples. The resulting word error rate (WER) is 7.2, which is comparable to the WERs[6] observed in human transcriptions from standard ASR datasets, confirming that the data is sufficiently clean for use. To further enhance quality, we applied simple LLM-based post-processing to recover missing punctuations and correct grammatical errors, as detailed in Appendix A.

3.3 Aligning Game Data and Commentaries

After obtaining paired game data (a structured data record and a screenshot for each event) and commentary segments, we align the inputs and outputs based on timestamps, resulting in a total of 171,460 examples from the 2019 League of Legends World Championship. Since each game contains hundreds to thousands of events, we apply random sampling during alignment to keep the dataset compact and suitable for efficient benchmarking:

Step 1: Divide the paired game data by timestamps into one-minute intervals, following LoL-V2T (Tanaka and Simo-Serra, 2021) and LoL19 (Wang and Yoshinaga, 2024), and randomly select one data point per interval.

Step 2: For each selected game data from Step 1, extract the commentary segment that begins immediately after its timestamp as the corresponding commentary, forming a single example (a multimodal triple) for our task.

This procedure yields approximately 30 examples per game, resulting in 3450 examples. To ensure the quality of timestamp-based alignment, we randomly selected 100 examples and manually verified whether the commentaries corresponded to the selected game data. Among them, 97% (97 out of 100) exhibited satisfactory alignment, with the commentaries accurately describing the corresponding game data; the remaining three showed minor misalignment but were still suitable for use.

Statistics Table 2 lists the statistics of our dataset and several existing datasets for related text generation tasks. The average number of words in

[6] https://github.com/syhw/wer_are_we

commentaries is 15.5. Our dataset is the first trimodal commentary generation dataset for multiplayer strategy esports, consisting of three modalities including images, structured data, and text. It contains a comparable number of examples to existing esports data-to-text datasets. Note that although our dataset is based on similar sources as LoL19 and LoL-V2T, it is neither a subset nor a superset of them. To support the research community while respecting copyright constraints, we take the common approach of releasing scripts for collecting and processing the data to reproduce our dataset.

4 Experiments

In this section, we conduct experiments on commentary generation for esports moments from multimodal game data using our LoL19-trimodal dataset. We evaluate the performance of open- and closed-source large vision-language models using automatic metrics and human judgments.

4.1 Settings

Dataset We split our LoL19-trimodal dataset into training, validation, and test sets with an approximate ratio of 8:1:1, resulting in 2750:350:350 examples.[7] The split follows the natural chronological order of the games.

Models We evaluate five vision-language models (**VLM**s) on our task. Three open-source models are Llama2-7B and Llama2-13B combined with BLIP-2 vision encoder (**Llama2-7B + BLIP-2** and **Llama2-13B + BLIP-2**) and **Qwen2.5-VL-7B**. Two closed-source models are **GPT-4o** and **Gemini-2.0-Flash**. For the Llama2 models, following the implementation used in MiniGPT-4 (Zhu et al., 2024), we use the pre-trained vision components of BLIP-2 (Li et al., 2023) as the vision encoder and Llama2 (Touvron et al., 2023) as the text decoder, which are fine-tuned on the training split using QLoRA (Dettmers et al., 2023), while Qwen2.5-VL-7B[8] and the closed-source models are evaluated under zero-shot settings. Refer to Appendix B for links to the five VLMs, training details, including hyperparameters, optimizer, and QLoRA settings for the open-source VLMs, as well as the task instructions for the closed-source models.

We also conducted an ablation study using several selected models by providing single modal inputs (§ 5.1). Additionally, **T5**[9] was used to evaluate generation solely from structured data inputs.

4.2 Evaluation Procedure

We use both automatic metrics and human judgments to evaluate the VLMs on our task. For automatic metrics, we adopt existing reference-based metrics commonly used in game data-to-text generation tasks. Given the unique characteristics of multiplayer strategy esports, we design three evaluation criteria for human judgments to comprehensively assess system outputs against the references.

Automatic metrics We adopt the automatic metrics used in recent data-to-text generation studies (Liu et al., 2025; Long et al., 2025; Zhang et al., 2024; Alonso and Agirre, 2024; Saha et al., 2023), especially in commentary generation for LoL19 (Wang and Yoshinaga, 2024), which built upon common metrics from related studies (§ 2). The metrics are **BERTScore** (Zhang et al., 2020),[10] **BARTScore** (Yuan et al., 2021),[11] **sacreBLEU** (Papineni et al., 2002; Post, 2018),[12] and **text distance** (normalized Damerau-Levenshtein (Brill and Moore, 2000)).[13] Although these metrics correlated with human judgments on strategic depth in the experiments on the LoL19 dataset (Wang and Yoshinaga, 2024), the latter two metrics have been reported to correlate poorly with human relevance scores for text generation tasks (Wiseman et al., 2017; Novikova et al., 2017). Therefore, we exclude evaluation results with these metrics from the main results; refer to Appendix D for the results.

Human judgments against reference The automatic metrics capture only a limited aspect of the quality of the system outputs. Given the unique characteristics of multiplayer strategy esports, we need diverse evaluation criteria that highlight different aspects of commentary quality. For instance, LoL19 (Wang and Yoshinaga, 2024) introduces strategic depth to assess the strategically relevant content in the system outputs. GameKnot (Jhamtani et al., 2018) conducts a human evaluation to measure correctness, relevance, and fluency.

[7] We manually check data alignment for all 350 examples in the test set, confirming there are no notable misalignments.

[8] We were unable to successfully fine-tune Qwen2.5-VL-7B, likely due to limitations in the current training setup.

Models	Human judgments against reference			Automatic metrics	
	Relevance	**Inspiration**	**Interestingness**	**BERTScore**	**BARTScore**
T5 (no visual input)	36.50	13.00	11.25	78.60	-5.60
Llama2-7B + BLIP-2	36.50	29.75	15.00	79.62	-5.01
Llama2-13B + BLIP-2	**47.75**	35.00	**20.00**	**81.19**	**-4.80**
w/o visual input	43.50	31.50	19.50	80.07	-4.92
w/o data record	40.00	32.50	19.00	80.10	-4.86
zero-shot settings					
Qwen2.5-VL-7B	39.50	30.00	17.50	79.87	-4.95
Gemini-2.0-Flash	39.50	30.00	20.50	80.01	-4.82
GPT-4o	41.00	**35.00**	20.75	80.10	-4.97
w/o visual input	40.25	29.75	18.50	80.05	-5.01
w/o data record	39.00	34.50	20.25	80.01	-5.00

Table 3: Results of commentary generation for esports moments with the LoL19-trimodal dataset: the best results are in **bold** and the second best results (except ablated models) are underlined.

In this study, we deconstruct the concept of strategic depth in LoL19 and elaborate on it through the following three criteria, each highlighting concrete aspects of moment-level commentary:

Relevance assesses how well the system output aligns with the input game data in terms of factuality. It verifies whether the content faithfully reflects the information in the input. High relevance ensures that the output is factual and consistent with the source data.

Inspiration evaluates the ability of the system output to provide creative insight. Commentary that analyzes of the game situation or a summary of the players' actions and intentions is considered more inspiring. High inspiration can enhance the content's usefulness in understanding the strategies employed by professional players.

Interestingness focuses on how captivating and engaging the system output is to the audience. It considers elements like clarity, narrative flow, and rhetorical devices. Interestingness often reflects the balance between creativity and readability, making the commentary appealing and enjoyable to watch.

We recruit three graduate students as human judges. They have substantial experience with our target game, League of Legends, and can readily comprehend its game commentaries in English. Each judge has watched at least three full seasons of the World Championship (especially, including the 2019 event), and have played more than 100 matches in the season preceding the annotation. All judges have previously reached at least *Platinum* rank, corresponding to approximately the top 30% of players. Additionally, an LLM-based agent (GPT-4o) acts as the fourth annotator to provide a consistent and scalable baseline for comparison across examples, and to explore the feasibility of integrating automated judgment into a more efficient evaluation pipeline.

The evaluation follows a comparison-based protocol. For 200 randomly selected examples, four annotators compared each system output with its corresponding reference and chose the better one for each aspect (refer to Appendix C for the complete instructions used for human evaluation). We report the percentage of times the system outputs were preferred, averaged across annotators. Scores range from 0 to 100, where 50 indicates parity with the reference.

4.3 Results

Table 3 lists the evaluation results of the five VLMs on our LoL19-trimodal dataset (the evaluation results of sacreBLEU and text distance are presented in Appendix D for reference only). The fine-tuned Llama2-13B + BLIP-2 outperformed other models including strong zero-shot VLMs, partially validating the usefulness of our dataset for training purposes. The VLMs achieve comparable performance to professional commentary in terms of relevance and struggle to compete in terms of inspiration, while they fall short when it comes to interestingness. Closed-source VLMs outperform fine-tuned open-source models in inspiration. In addition, the comparison between Llama2-7B + BLIP-2 and -13B revealed that larger VLMs are relatively effective.

Notably, the results from automatic metrics mostly align with human evaluations in terms of relevance. However, for the other two aspects, inspiration and interestingness, the automatic metrics show less consistency, indicating the importance of human judgments.

5 Analysis

In this section, we provide a more in-depth analysis of the results and discuss the remaining challenges associated with this task. In what follows, we focus on analyzing the results of two competing VLMs, including Llama2-7B + BLIP-2 and GPT-4o.

5.1 Ablation Study

To assess the impact of each input modality on commentary generation, we perform ablation studies which removes one modality from the input: visual input is replaced with a blank image, and structured data with a placeholder token. All model variants are trained and evaluated under the same LoL19-trimodal setup to ensure comparability.

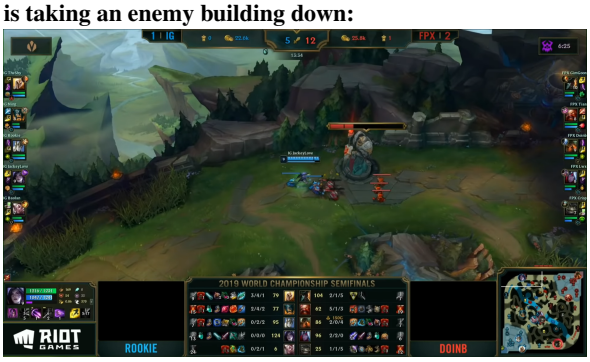

Table 3 presents the ablation results. Incorporating bi-modal inputs consistently improves performance across all evaluation metrics, demonstrating the benefits of multimodal integration for esports commentary generation. A closer examination of the human evaluation results reveals the distinct contributions of each modality: structured data plays a more crucial role in generating relevant commentary, whereas visual input contributes more to producing inspiring commentary.

Furthermore, we conduct a McNemar's test (for human evaluations) and a Wilcoxon signed-rank test (for automatic metrics) to assess the statistical significance of the difference between the Llama2-13B + BLIP-2 model with and without visual input. The resulting p-values for the three human evaluation metrics, including **Relevance**, **Inspiration**, and **Interestingness**, are 0.008, 0.008, and 0.052, respectively; the results for the automatic metrics, including **BERTScore** and **BARTScore**, are 0.016 and 0.040, respectively. Most results indicate statistically significant differences ($p < 0.05$), with several demonstrating even stronger significance ($p < 0.01$). These findings underscore the value of our tri-modal dataset and evaluation criteria.

5.2 Examples of System Outputs

Figure 2 shows an example of system outputs for the same gameplay moment as shown in Figure 1,

Screenshot of "BUILDING_KILL" event, presenting a player is taking an enemy building down:

Structured data records:

```
{
 "type": "BUILDING_KILL",
 "timestamp": 839426,
 "position": "x4318y13875",
 "killerId": 4,
 "assistingParticipantIds": "",
 "teamId": 200,
 "buildingType": "TOWERBUILDING",
 "laneType": "TOPLANE",
 "towerType": "OUTERTURRET"
}
```

Reference: Fighting everywhere, Jackeylove is just farming for himself.

Llama2-13B + BLIP-2: The IG top laner has taken a risky move by pushing too far forward and getting caught out by the cunning FPX jungler, leading to a costly Building Kill for IG.

GPT-4o: At 13:34 in Game 3 of the 2019 World Championship Semifinals between Invictus Gaming (IG) and FunPlus Phoenix (FPX), IG's JackeyLove pressures the top lane alone and takes down FPX's outer turret, marking a BUILDINGKILL event in the TOPLANE–a small but crucial step toward regaining map control despite IG trailing 5-12 in kills and over 3k gold.

Figure 2: System outputs for BUILDING_KILL event.

regarding a BUILDING_KILL event. In this exapmle, the system outputs correctly describe the core event where a player is taking an enemy building down on the top lane of the game map. However, several issues are remaining, mainly including unclear expressions (**Llama2-13B + BLIP-2**: "*pushing too far forward*"), unusual terminology in natural language (**Llama2-13B + BLIP-2**: "*Building Kill*", **GPT-4o**: "*BUILDINGKILL*"), and low-information statements (**GPT-4o**: "*At 13:34 in Game 3 of the 2019 World Championship Semifinals ...*"). Additionally, it is worth noting that the systems tend to produce overly long yet insufficiently informative commentary. To generate more professional and concise outputs, we may need to increase the amount of training data or provide more detailed instructions that clearly describe the characteristics of human commentary.

Screenshot of "ITEM_PURCHASED" event, presenting a player is purchasing an item:

Structured data records:

```
{
 "type": "ITEM_PURCHASED",
 "timestamp": 2067324,
 "participantId": 7,
 "itemId": 2420
}
```

Reference: I think fudges gangplank has looked generally strong King is hitting close to full item.

Llama2-13B + BLIP-2: MMM player in the middle lane has just purchased an item, at timestamp 7, with participant ID 2420.

GPT-4o: At 34:26 in this 2019 World Championship Play-In match between MAMMOTH and Unicorns of Love, MMM holds a solid lead with an 8k gold advantage and map pressure. A recent ITEMPURCHASED event by participant 2420 (likely MMM King on Kai'Sa) further boosts their late-game power, strengthening their chances of closing out the game as they push mid against a struggling UOL defense.

Figure 3: System outputs for ITEM_PURCHASED event.

Figure 3 shows another example regarding an ITEM_PURCHASED event. Related types of events typically have only a limited impact on the overall progression of the game and are not usually the main focus of audience attention. As a result, we observe that human commentary tends to offer relatively general descriptions, rather than offering details for such events. This insight leads us to a broader discussion on the performance of generation across event types in the following section.

5.3 Quality Variations across Event Types

Based on our LoL19-trimodal and several prior studies (Zhang et al., 2022; Wang and Yoshinaga, 2024), we observe a dominance of certain event types. For example, "ITEM_PURCHASED" accounts for 24.0% of the dataset (Table 1), despite having limited impact on the game progression. Generating commentaries for such frequent yet less important events is challenging for both humans and models. In contrast, rarer but more informative events like "BUILDING_KILL" (1.5%) often correspond to pivotal moments that can affect the entire game. To address this imbalance, we further evaluate the model performance across each event type in LoL19-trimodal. Specifically, we compute the percentage of times the system outputs were preferred for examples of each event type, using the method explained in § 4.1.

Event type	Relevance	Inspiration	Interestingness
ITEM_PURCHASED	50.00	35.00	21.67
ITEM_DESTROYED	48.91	34.78	20.65
CHAMPION_KILL	70.83	41.67	29.17
SKILL_LEVEL_UP	40.63	35.42	19.80
WARD_PLACED	36.36	34.09	25.00
WARD_KILL	46.15	34.62	21.15

Table 4: Human judgements on results of Llama2-13B + BLIP-2 on LoL19-trimodal for common event types.

Table 4 lists the evaluation results for examples in common event types. Among these event types, "CHAMPION_KILL" stands out as a relatively information-rich and important event, and the Llama2-13B + BLIP-2 successfully generated better commentary than the reference. In the current LoL19-trimodal dataset, the original distribution of event types was preserved through the random sampling process (§ 3.3). However, since the importance of different event types varies, future versions of the dataset can be optimized by first manually specifying key event types (*e.g.*, BUILDING_KILL) to retain such events in full, while reducing overwhelming and less important ones.

5.4 Applicability of LLM-as-a-judge

Given the rapid advancement of LLM-as-a-judge evaluation, recent studies have shown that LLMs, such as GPT-4, can serve as reliable proxies for human evaluators across various natural language generation (NLG) tasks (Zheng et al., 2023; Gu et al., 2024). Accordingly, we incorporated an LLM-based agent into the procedure of human judgements to act as an additional annotator (§ 4.2).

To validate the reliability of this approach in our task, we computed both inter-human agreement and overall agreement including both humans and the LLM judge for the outputs of Llama2-13B + BLIP-2, using Fleiss' κ (Fleiss, 1971). For the three evaluation aspects of **Relevance**, **Inspiration**, and **Interestingness**, the inter-human agreements are 0.492, 0.482, and 0.371, while the overall agreements, including the LLM annotator (GPT-4o), are

0.511, 0.440, and 0.357.[14] These similar scores demonstrate a reasonable alignment between humans and the LLM, supporting the feasibility of using LLM-based assessments as a supplementary evaluation method. In future work, the role of LLMs as evaluators can be further explored and extended to a larger test set.

6 Conclusions

This study set up a new task of commentary generation for esports moments from multimodal game data: structured game data and gameplay screenshots. We collected game data and commentaries from online sources for one of the most popular esports, League of Legends, to construct the first tri-modal commentary generation dataset aligned at the moment level. We also designed evaluation metrics to assess generation performance, reflecting the unique characteristics of esports and the role of game commentary. Using our dataset, we evaluated several strong vision-language models and showed that combining structured and visual data improves generation quality.

For future work, we plan to extend our dataset to other languages such as Chinese, Korean, and European languages, which are widely spoken in regions with large esports audiences. Another important direction is to build a tri-modal commentary dataset for live commentary generation, where the system detects events that require commentary and generates responses in real time.

Limitations

This work addresses commentary generation for esports moments in multiplayer strategy games. While the study introduces a novel dataset using the multimodal data collected from a representative esports game, League of Legends, it does not yet consider other esports genres at this stage.

Moreover, although our task is beneficial for the audience and players to obtain commentary for esports moments on demand, live commentary generation for esports game videos can also go a long way towards improving audience's viewing experience. Although our research does not focus on video-to-text generation at the current stage, our data extraction methods and scripts are capable of collecting dynamic video clips if needed. Alternatively, another potential approach is to use a sequence of game screenshots, where multiple images correspond to a single structured data input, combining the benefits of static images and dynamic videos.

In the end, recent advancements in esports commentary generation have mostly focused on English, despite the fact that esports enjoys a vast and growing global audience, particularly in regions such as China, South Korea, and various European countries (Mangeloja, 2019; Lam and Kuen Wong, 2024). This highlights the lack of multilingual support in esports-related NLG, which hinders model generalizability across languages and cultures. Although our dataset is English-only, commentary in other languages (*e.g.*, Chinese livestreams[15]) is readily available. With the rise of LLM-based machine translation (Xu et al., 2024), integrating multilingual data has become increasingly feasible, paving the way for future cross-lingual research in esports commentary generation.

Ethics Statement

In obtaining data for our LoL datasets, we strictly followed the policies of RiotGames API and YouTube. The former is the publisher of LoL game data records. The latter supplied the screenshots and subtitles of LoL contest videos. To respect copyright constraints, we take the common approach of releasing scripts for collecting and processing the data to reproduce our dataset (Wang and Yoshinaga, 2024; Tanaka and Simo-Serra, 2021).

Further ethical concerns related to the game content (*e.g.*, video game content rating) refer to ESRB Rating.[16] The game is rated as "Teen," indicating it is suitable for players aged 13 and older.

A Methods for Improving the Quality of Collected Commentaries

Although we have demonstrated that the collected commentaries are of usable quality via the word error rate (WER) metric (§ 3), we applied additional post-processing techniques to further improve their quality. Specifically, we employ GPT-based methods with minor manual corrections to enhance the commentary data, addressing inserting appropriate punctuations and correcting grammatical errors. Below is an example prompt used for this process:

Example prompt for improving the quality of collected commentaries

```
You are a knowledgeable expert in the field
of esports game League of Legends (LoL) and
its contests.

We would like you to read a commentary on
a piece of an LoL game. Please review
the following commentary and improve its
quality by adding appropriate punctuations
and correct grammatical errors. Only output
the improved result in one single paragraph,
without explanatory sentences and quotation
marks.
```

For example, in Figure 1, the original commentary sentence collected from subtitles of game videos is "*fighting everywhere jackeylove is just farming for himself*". After post-processing, it becomes "*Fighting everywhere, Jackeylove is just farming for himself.*" as shown in Figure 1. We will release scripts for obtaining both styles of the game commentaries.

B Training Details

For the VLMs used in our experiments, we adopt the same settings as in LoL19 (Wang and Yoshinaga, 2024) and MiniGPT-4 (Zhu et al., 2024). Specifically, for T5,[17] we set the decoder dropout to 0.5, the number of training steps to 10,000, and the learning rate to 0.001; it applies Adam optimizer ($\beta 1 = 0.9$, $\beta 2 = 0.999$); all other hyperparameters follow their default settings. For Llama2-7B + BLIP-2[18] and -13B,[19] the training is based on the first-stage outcomes of MiniGPT-4; the pre-trained vision encoder and LLM remain frozen, with only the linear projection layer undergoing training; Llama2 applies QLoRA (Dettmers et al., 2023) fine-tuning with 4-bit precision and a LoRA dropout of 0.1.

For Qwen2.5-VL-7B[20] and close-sourced models (GPT-4o[21] and Gemini-2.0-Flash[22]), we employ zero-shot prompting using the prompt as follows:

Prompt for generating commentaries

D Automatic Metrics

Models	sacreBLEU	Text distance ↓
T5 (no visual input)	3.2	74.60
Llama2-7B + BLIP-2	5.1	70.01
Llama2-13B + BLIP-2	**10.2**	**68.85**
w/o visual input	9.1	69.97
w/o data record	9.0	69.10
zero-shot settings		
Qwen2.5-VL-7B	5.9	72.00
Gemini-2.0-Flash	<u>8.2</u>	70.50
GPT-4o	6.2	<u>69.37</u>
w/o visual input	5.8	69.43
w/o data record	6.1	69.40

Table 5: Results of commentary generation for esports moments with the LoL19-trimodal dataset over sacreBLEU and text distance: the best results are in **bold** and the second best results (except ablated models) are <u>underlined</u>.

Metrics	Relevance	Inspiration	Interestingness
BERTScore	0.431	0.418	0.301
BARTScore	0.408	0.355	0.294
sacreBLEU	0.306	0.274	0.217
text distance	0.289	0.288	0.176
(inter-human)	0.492	0.482	0.371

Table 6: Results of agreement between human ratings and automatic metrics. The results are gathered by comparing the pairwise ranking of the same outputs, as determined by each metric, using Fleiss' κ.

Table 5 lists the evaluation results over sacreBLEU and text distance. As discussed in § 4.2, they are provided for reference only and are not primary metrics.

Furthermore, following § 5.4, we evaluate the agreement between human ratings and automatic metrics by comparing the pairwise ranking of the same outputs, as determined by each metric, using the outputs of Llama2-13B + BLIP-2. Table 6 lists the results. As can be observed from the results, the values of sacreBLEU and text distance are relatively low. This finding is consistent with the conclusion drawn in § 4.2, namely that automatic metrics such as sacreBLEU and text distance have been found correlate poorly with human ratings for language generation tasks (Wiseman et al., 2017; Novikova et al., 2017).

Simple Yet Effective: Extracting Private Data Across Clients in Federated Fine-Tuning of Large Language Models

Abstract

Federated large language models (FedLLMs) enable cross-silo collaborative training among institutions while preserving data locality, making them appealing for privacy-sensitive domains such as law, finance, and healthcare. However, the memorization behavior of LLMs can lead to privacy risks that may cause cross-client data leakage. In this work, we study the threat of *cross-client data extraction*, where a semi-honest participant attempts to recover personally identifiable information (PII) memorized from other clients' data. We propose three simple yet effective extraction strategies that leverage contextual prefixes from the attacker's local data, including frequency-based prefix sampling and local fine-tuning to amplify memorization. To evaluate these attacks, we construct a Chinese legal-domain dataset with fine-grained PII annotations consistent with CPIS, GDPR, and CCPA standards, and assess extraction performance using two metrics: *coverage* and *efficiency*. Experimental results show that our methods can recover up to 56.6% of victim-exclusive PII, where names, addresses, and birthdays are particularly vulnerable. These findings highlight concrete privacy risks in FedLLMs and establish a benchmark and evaluation framework for future research on privacy-preserving federated learning. Code and data are available at https://github.com/SMILELab-FL/FedPII.

1 Introduction

Federated large language models (FedLLMs) (Ye et al., 2024a,b; Zhang et al., 2023; Chen et al., 2024; Yao et al., 2024) have recently emerged as a promising approach for cross-silo federated learning (FL) (Li et al., 2024c), enabling collaborative model training while maintaining data locality and institutional privacy. In cross-silo FL, organizations, such as courts, banks, and hospitals, collaboratively fine-tune[1] a shared model without exchanging private records. Prior studies mainly focused on improving algorithmic efficiency and convergence (Bai et al., 2024; Wu et al., 2025; Li et al., 2020), while the privacy vulnerabilities of FedLLMs remain largely unexplored.

A growing body of work has shown that large language models (LLMs) tend to memorize and reproduce fragments of their training data, including PII such as names, addresses, and dates of birth (Carlini et al., 2021, 2023; Shao et al., 2024; Kim et al., 2023; Nakka et al., 2024). Although FL mitigates privacy risks by exchanging model updates instead of raw data, our preliminary experiments (Appendix B.4) indicate that FedLLMs remain vulnerable to *verbatim data extraction* (VDE)—where adversaries can recover verbatim text sequences from the aggregated global model. However, most existing VDE studies assume that attackers have privileged access or significant knowledge of the victim's data (Yu et al., 2023; Huang et al., 2022), which is unrealistic in practical cross-silo deployments.

We instead consider a more realistic *semi-honest* threat model, where each participant follows the FL protocol but may attempt to infer private information from the global model. For instance, in a federation of courts, a participant could exploit its own local case records as contextual prefixes to elicit sensitive information memorized from other courts' data (as illustrated in Figure 1). To investigate this, we propose three extraction strategies: (1) PII Contextual Prefix Sampling, which queries the global model using local contextual prefixes; (2) Frequency-prioritized (FP) Sampling, which focuses on high-frequency prefixes to improve extraction efficiency; and (3) Latent Association Fine-tuning (LAFt), which locally fine-tunes the global

*Corresponding author.

[1]In current practice, *FedLLM* typically refers to the federated fine-tuning of large language models rather than federated pre-training. See Appendix B.3 for details.

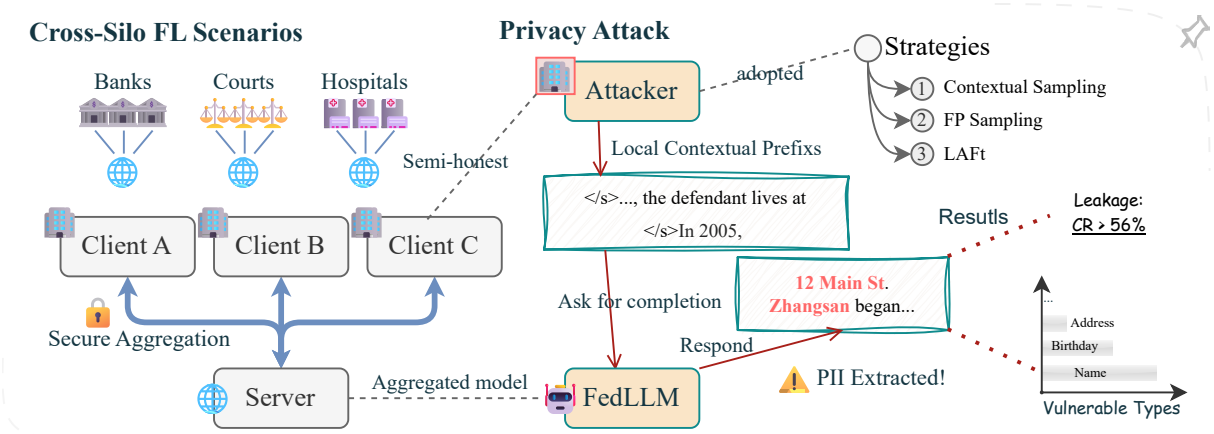

Figure 1: Overview of cross-silo FedLLMs and the proposed privacy attack. In cross-silo FL, institutions such as banks, courts, and hospitals collaboratively fine-tune a shared model under the coordination of a central server, keeping data local. A semi-honest client leverages its local data to construct PII-related prefixes and queries the aggregated global FedLLM, leading to cross-client data leakage. The proposed strategies—Contextual Prefix Sampling, Frequency-prioritized (FP) Sampling, and Latent Association Fine-tuning (LAFt)—achieve up to 56.6% recovery of victim-exclusive PII, with names, addresses, and birthdays being the most vulnerable categories.

model using stored prefix-PII pairs, thereby improving its ability to extract PIIs implicitly memorized within the model.

To evaluate these attacks, we build a benchmark dataset by annotating a real-world Chinese legal corpus with fine-grained PII labels aligned with privacy regulations such as CPIS, GDPR, and CCPA (see Acronyms List A). We assess the attacks using two metrics: *coverage* (the proportion of target PII successfully extracted) and *efficiency* (the amount of PII recovered under a limited query budget). Our experiments reveal that the proposed attacks can extract up to 56.6% of victim-exclusive PII, with *Name*, *Address*, and *Birthday* being the most vulnerable types. Moreover, we observe diminishing returns as query budgets grow, while FP Sampling and LAFt enhance diversity under tighter budgets. These findings expose concrete privacy risks in FedLLMs and underscore the need for stronger privacy-preserving mechanisms.

In summary, our main contributions are:

1. We propose three novel extraction strategies for FedLLMs, independent of existing gradient-based or membership inference attacks, and evaluate them using two rigorous metrics: coverage and efficiency.
2. Extensive experiments show that our methods can recover up to 56.6% of cross-client unique PII, with larger prefix sets yielding diminishing returns in efficiency, revealing a trade-off between coverage and computational cost.
3. We construct a real-world benchmark dataset by augmenting a legal-domain corpus with fine-grained PII annotations aligned with CPIS, GDPR, and CCPA standards, filling the gap in public resources for privacy research in federated learning.

2 Related Work

This study is related to the fields of data extraction attacks and federated learning. For the reader's convenience, a brief introduction to these concepts is provided in Appendix B. In this section, we review only the work directly related to our method.

2.1 PII Extraction Attacks in LLM

Large language models, due to their massive parameter scale, are capable of memorizing exact training data samples, making them vulnerable to data extraction attacks. These attacks can target different granularities of information: sample-level and entity-level.

At the sample level, an attacker with access to the full prefix of a training sample can query the LLM to regenerate the exact suffix (Yu et al., 2023; Shi et al., 2024; Zhang et al., 2024). This technique, known as *verbatim training data extraction* (Carlini et al., 2021, 2023; Schwarzschild et al., 2024), is widely used to detect data contamination and copyright violations (Dong et al., 2024).

At the entity level, attackers may know a subset of PII entities—such as names or affiliations—about a particular subject. By combining these known details with prompt templates

(either manually crafted or automatically generated (Kassem et al., 2025)), they can elicit the model to produce additional PII records about the same subject. This is known as an associative data extraction attack (Shao et al., 2024; Kim et al., 2023; Zhou et al., 2024).

Broadly, PII extraction attacks refer to any attack that aims at eliciting outputs from the model that contain PII (Lukas et al., 2023; Nakka et al., 2024; Huang et al., 2022). Both verbatim and associative techniques can be used to conduct such attacks.

While most prior work assumes centralized training with full data access, we investigate PII extraction under federated fine-tuning, where the attacker has limited observability and control. We elaborate on this in Section 4.1.

2.2 Privacy Threats in Federated Learning

Threats in Federated Learning can be categorized into two main areas: security and privacy (Wang et al., 2024a; Xie et al., 2024; Li et al., 2024b). Security threats typically aim to disrupt the entire FL system by invalidating model training (Shejwalkar and Houmansadr, 2021) and introducing backdoors (Bagdasaryan et al., 2020; Chang et al., 2024). In contrast, privacy threats have attracted more attention from researchers and focus on stealing confidential information from the FL system, such as inferring sensitive properties (Melis et al., 2019), reconstructing clients' private datasets (Zhu et al., 2019; Geiping et al., 2020), and determining the membership and source of training data (Rashid et al., 2025; Vu et al., 2024; Hu et al., 2024). To achieve these attacks, researchers often make different assumptions regarding the attacker's knowledge. Common assumptions typically fall into two dimensions: whether the attacker is a client or a server (Chu et al., 2023), and whether the attacker is semi-honest (Applebaum, 2017; Hu et al., 2024) or malicious. These assumptions determine whether the attacker has access to gradients, local datasets, model parameters, and the ability to manipulate them.

3 Dataset

3.1 Data Sources and Preprocessing

The majority of our dataset is sourced from the Challenge of AI in Law (CAIL) (Li et al., 2024a), supplemented by smaller portions from CJRC (Duan et al., 2019) and JEC-QA (Zhong et al., 2020). CAIL is a renowned annual competition featuring a variety of legal NLP tasks. In this study, we focus on two natural language generation tasks: *Judicial Summary* and *Judicial Reading Comprehension*, and three natural language understanding tasks: *Similar Case Matching*, *Judicial Exam Question Answering*, and *Legal Case Classification*. Detailed task descriptions are provided in Appendix D, with representative examples shown in Table 6.

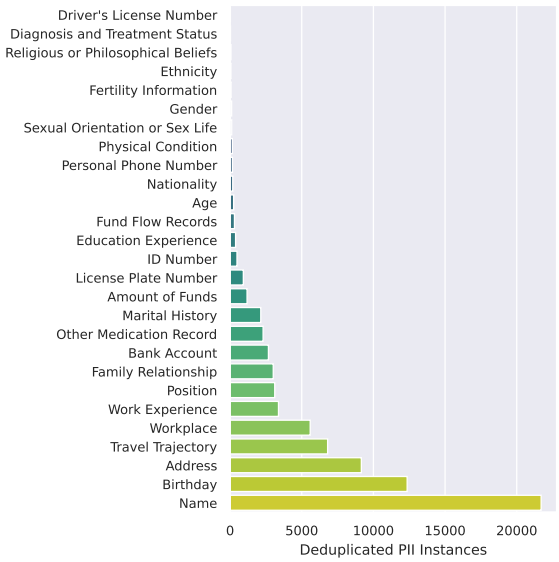

Figure 2: Distribution of de-duplicated PII instances by label category.

Following prior work (Zhang et al., 2023; Yue et al., 2024), we further preprocess and curate the dataset to fit our setting. The complete preprocessing pipeline is described in Appendix E, where Table 7 reports the dataset statistics.[2]

3.2 PII Labeling

We reviewed the definitions and examples of PII in various legal provisions, including CPIS, GDPR, CCPA, and Singapore PDPC (see Acronyms List in Appendix A), and used them as references to establish a systematic PII labeling standard. We selected PII types relevant to the text modality and removed types that are unlikely to appear in legal texts (e.g., browser history, SMS content, IP & MAC addresses), as well as those that are difficult to describe or evaluate (e.g., medical examination

[2]The datasets contain PII from publicly available government-published legal documents. They were de-identified and used in prior work, e.g., as in Yue et al. (2024). We use curated versions from these papers. Since our study concerns privacy risks in FedLLMs, real-world PII is necessary to evaluate model vulnerabilities.

reports, psychological trends). Ultimately, we defined labeling guidelines encompassing 7 major categories and 36 subcategories. The distribution of labeled PII types is shown in Figure 2 in the main text, whereas a complete summary of these standards is provided in Table 9 in Appendix I.

We employed a combination of machine-assisted annotation and manual verification to label the data. For each major PII category, we designed a dedicated prompt depicted in Figure 12 and employed GPT-4o (OpenAI et al., 2024) to generate annotations. We then recruited students to verify a subset of those annotations with the help of Label Studio (Tkachenko et al., 2020-2025). The agreement between human evaluations and GPT-4o annotations achieves an F1 score of 89.9%. Owing to space limitations, the full evaluation results are shown in Table 10 in Appendix J, together with further details of the annotation process, including annotator backgrounds, annotation instructions, and user interfaces.

4 Method

4.1 Problem Definition

We study a novel extraction attack tailored to FedLLMs, which differs from traditional verbatim data extraction in three key aspects:

Assumptions. Unlike VDE that assumes the attacker has access to most or all of the training data, our setting limits the attacker to a small, isolated subset of the overall training corpus.

Setup. In our formulation, the prefix and its corresponding target suffix are not drawn from a contiguous span of training data. Instead, extraction prefixes are sampled from the attacker's local dataset D_a, while the target suffixes reside exclusively in other clients' private data and are absent from D_a. Thus, each prefix must generalize beyond local context to trigger the generation of unseen suffixes.

Goals. An attacker does not aim to recover all training completions, but instead focuses on extracting specific, high-value information—most notably, PII—from the global model.

Formally, we consider a **cross-silo** FL system comprising c clients $\mathcal{C} = \{C_1, C_2, \ldots, C_c\}$, where each client C_i holds a local dataset D_i. Among them, one client—denoted as the attacker $C_a \in \mathcal{C}$—is assumed to be **semi-honest** (Applebaum, 2017; Hu et al., 2024). That is, C_a faithfully follows the FL protocol (e.g., does not poison data or manipulate model weights), but acts adversarially in a passive manner, attempting to infer PII contained in other clients' datasets by analyzing the global model θ.

In this setting, the attacker issues queries to the model θ to extract data without knowing which client any particular output originates from. However, for evaluation purposes, we designate one client as the reference victim to measuring the attack's effectiveness. Let S_a and S_v denote the sets of PII instances held by the attacker and the victim client, respectively. The attacker constructs a prompt set P and queries the FedLLM θ, obtaining a corresponding output set Y. We formalize key definitions and evaluation metrics in the following subsections.

Definition 1 (Extracted)**.** *A PII instance $s \in S_v$ is considered successfully* extracted *if there exists a prompt $p \in P$ and a corresponding model output $y \in Y$ such that:*

$$\exists u \in \Sigma^* \text{ such that } y = s \oplus u, \tag{1}$$

where Σ^* is the set of all finite-length strings over the vocabulary, and $\oplus$ denotes string concatenation. In other words, the model output y begins with s.

Definition 2 (Coverage Rate)**.** *The coverage rate measures how thoroughly the attacker recovers the PII unique to the victim client. It is defined as:*

$$S_E = \{s_i \mid \exists y \in Y \text{ such that } s_i \text{ is extracted by } y\},$$
$$CR = \frac{|(S_v \setminus S_a) \cap S_E|}{|S_v \setminus S_a|}. \tag{2}$$

A higher CR indicates that a larger fraction of the victim's unique PII has been successfully extracted.

Definition 3 (Efficiency)**.** *Efficiency quantifies the precision of extraction with respect to the number of queries. Let Q denote the number of queries, the efficiency is defined as:*

$$EF = \frac{|(S_v \setminus S_a) \cap S_E|}{Q}. \tag{3}$$

A higher EF indicates that more PII is extracted with fewer queries.

Building upon these definitions, the central challenge is to design algorithms that enable the attacker to extract PII both comprehensively and efficiently—that is, achieving high coverage and high efficiency.

4.2 Attacking Algorithms

4.2.1 PII-contextual Prefix Sampling

We start with a simple method for constructing query prompts using contextual prefixes of PII, which are word sequences immediately preceding PII instances in the attacker's dataset D_i. This mitigates reliance on manually crafted prompts (e.g., 'my phone number is'), which often deviate from the model's training distribution and exhibit limited empirical applicability.

Let the attacker's training corpus be $U_a = \{t_0, t_1, \ldots, t_{|U_a|}\}$, formed by concatenating samples in D_i, with $\mathcal{S}$ the multiset of labeled PII. For a PII instance $s \in \mathcal{S}$, let $\text{Loc}(s)$ be the index of its first token in U_a. We define a λ-length contextual prefix function:

$$\mathcal{T}_\lambda(U, s) = t_{\text{Loc}(s)-\lambda} \cdots t_{\text{Loc}(s)-1}.$$

The contextual prefix set of a PII set $\mathcal{S}$ is given by:

$$P_c = \{\mathcal{T}_\lambda(U_a, s) \mid s \in \mathcal{S}\}. \tag{4}$$

For each $p \in P_c$, the attacker $\mathcal{C}_a$ queries the global model θ to generate a suffix y of up to m tokens:

$$y = \{x_1, \ldots, x_m\} \sim \mathbf{P}(y \mid p; \theta).$$

To enhance diversity, n independent suffixes may be sampled per prefix:

$$Y_p = \{y_1, \ldots, y_n\}, \quad Y = \bigcup_{p \in P_c} Y_p, \quad Q = n \cdot |P_c|.$$

A generalized version extends P_c by including all substrings ending before each PII:

$$\text{SUP}(P_c) = \{t_i \cdots t_{\text{Loc}(s)-1} \mid (\text{Loc}(s) - i) \in [1, \lambda]\}.$$

This yields broader coverage but incurs high query cost due to the large prefix set.

4.2.2 Frequency-Prioritized Prefix Sampling

Following prior work (Shao et al., 2024), which associates extraction effectiveness with co-occurrence frequency, we posit that prefixes frequently occurring before PII entities tend to capture stronger and more diverse associations. Therefore, we emphasize high-frequency prefixes to construct a compact, information-rich set.

Formally, we partition $\text{SUP}(P_c)$ by prefix frequency. For each $\sigma \geq 1$,

$$P_\sigma = \{p \in \text{SUP}(P_c) \mid \text{Count}_{\text{SUP}(P_c)}(p) = \sigma\}.$$

This yields

$$\text{Set}(\text{SUP}(P_c)) = \bigcup_{\sigma \geq 1} P_\sigma.$$

Given a threshold σ_a, the frequent prefix set is

$$P_{f \geq \sigma_a} = \bigcup_{\sigma \geq \sigma_a} P_\sigma,$$

sorted by frequency. Setting $\sigma_a = 1$ recovers the full contextual prefix set. With a budget B, we select the top-B prefixes from $P_{f \geq \sigma_a}$, thereby emphasizing frequent contexts.

4.2.3 Latent Association Fine-tuning

We conjecture that a model's vulnerability to PII extraction stems from its capacity to capture the conditional probability $\text{P}(\mathcal{B} \mid \mathcal{A}; \theta)$ under model parameters θ, where $\mathcal{A}$ denotes prefixes that typically precede PIIs and $\mathcal{B}$ represents the corresponding PII instances.

Since the association between PII and their prefixes is implicitly encoded in the model's representations, we propose Latent Association Fine-tuning (LAFt), which updates parameters to maximize $\text{P}(\mathcal{B} \mid \mathcal{A}; \theta)$. The goal is to strengthen the mapping between indicative prefixes and PII, thereby improving extraction.

As the first step, we build a fine-tuning dataset D_{ft} by pairing frequent prefixes with known PII:

$$D_{\text{ft}} = \{(p, s) \mid p \in P_f,\ s \in S_a\}, \tag{5}$$

where P_f is the frequent-prefix set from D_a, and S_a the attacker's PII set. The model is then fine-tuned with the standard causal LM objective:

$$\theta' = \arg\min_\theta \sum_{(p,s) \in D_{\text{ft}}} \sum_{t=1}^{|s|} -\log \mathbf{P}(s_t \mid p, s_{<t}; \theta).$$

The updated model θ' is subsequently used for extraction with prefixes from P_f or P_c.

To note that, LAFt follows the **semi-honest** FL setting such that the fine-tuned model remains local and is not uploaded to the server.

5 Experiment

5.1 Experimental Setup

Federated Setup. Our federated setup consists of two main components: the data partitioning across clients and the federated fine-tuning procedure.

For the data partitioning, we simulate a system with 5 clients using a label-skewed non-IID partitioning based on clustering of language embeddings (Li et al., 2023), and ensured that each client receives a comparable number of samples.

For the federated fine-tuning, we perform training on legal tasks using the OpenFedLLM framework (Ye et al., 2024b), with FedAVG (McMahan et al., 2023) as the aggregation method over 10 communication rounds. All clients adopt parameter-efficient fine-tuning (LoRA) and a shared prompt template. Hyperparameter settings and implementation details are provided in Appendix K.

After the federated fine-tuning, we evaluate the utility of the final global model on a held-out global test set. Following common practice, we compare it to a centrally trained (non-FL) baseline evaluated on the same test set. The results are reported in Table 8 in the Appendix.

Models and Metrics. Since our data and tasks are derived from Chinese legal documents, we focus primarily on LLMs with proficiency in Chinese. Specifically, we evaluate Qwen1-8B (Bai et al., 2023), Baichuan2-7B (Yang et al., 2023), Qwen3-8B (Yang et al., 2025), GLM4-8B (GLM et al., 2024), and Llama3-Chinese (Rayrtfr, 2024).[3]

We evaluate model performance using two primary metrics: Coverage Rate (**CR**), Efficiency (**EF**). In addition, we introduce an intermediate metric, Victim-exclusive Extracted PII (**VxPII**), defined as $|(S_v \setminus S_a) \cap S_E|$, which directly measures the amount of extracted information.

Attack Strategies. We designate client 0 as the attacker and client 1 as the victim, and evaluate three strategies: (1) PII-contextual prefix sampling. The attacker builds a prefix set P_c from its local dataset D_0 with prefix length $\lambda = 50$. Each prefix queries the global model 15 times, generating up to $m = 10$ tokens per query—sufficient to recover most PIIs with manageable cost. (2) Frequency-prioritized sampling. Prefixes in Set(SUP(P_c)) are ranked by frequency to form $P_{f\geq 1}$ and used in descending order. Sweeping the prefix budget B varies the frequency threshold σ_a, enabling analysis of coverage–efficiency trade-offs. (3) Latent association fine-tuning. The attacker fine-tunes the global model (1 epoch, LR = 5e-5, LoRA: $r = 16$, $\alpha = 32$) using 10k frequent prefixes and 10k randomly sampled PIIs from its own data to reinforce prefix–PII associations. Further implementation details are provided in Appendix K.3.2.

[3]All models are publicly available on HuggingFace: Qwen1, Baichuan2, Qwen3, GLM4, Llama3-Chinese.

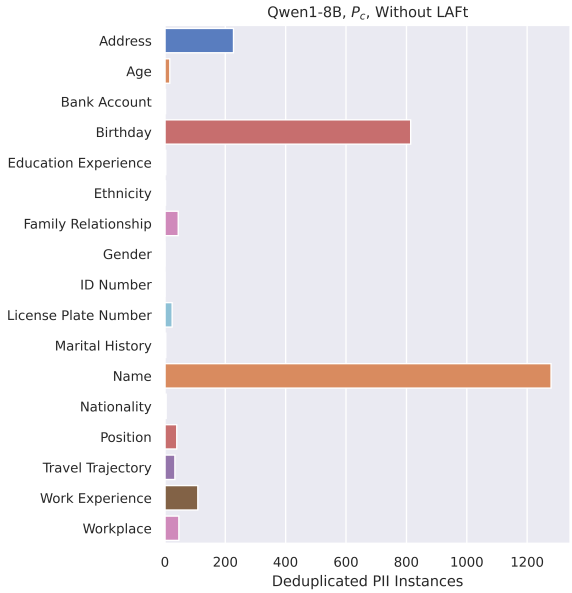

Figure 3: Label distribution of deduplicated victim-exclusive PII extracted by Qwen1-8B (without LAFt, using prefix set P_c). Results for Baichuan2-7B are shown in Appendix Figure 11.

Evaluation Protocol. To ensure a fair evaluation, the set of victim-exclusive PIIs $(S_v \setminus S_a)$ is obtained by applying two filters: (1) retain only those victim PIIs that do not appear in the attacker's training corpus (i.e., $s_i \in S_v$ but $s_i \notin U_a$); and (2) remove PIIs that share a common prefix to avoid ambiguity in identifying which PII was extracted (see Equation (1)). This is enforced by constraining the length of the longest common prefix (LCP) between any two PIIs:

$$\text{LCP}(s_i, s_j) = 0, \quad \forall s_i \neq s_j \in S_v$$

Metrics defined in Equations (2) and (3) are then computed on this filtered, prefix-disjoint set.

5.2 Results and Discussions

RQ1: How effective is the PII extraction attack using contextual prefixes? We first evaluate the coverage rate (CR) and efficiency (EF) of our extraction attacks by querying federated fine-tuned LLMs using the PII-contextual prefix set P_c. Table 1 presents the results. With P_c, our attack achieves a considerable CR of 22.93% on Qwen1-8B and 28.95% on Baichuan2-7B.

To understand what types of PII are most vulnerable, we analyze the extracted instances. Figure 3 shows the label distribution of deduplicated

Table 1: Summary of attack results using the PII-contextual prefix sampling method (with and without LAFt), where client 0 (attacker) targets client 1 (victim). The victim-exclusive set $(S_v \setminus S_a)$ includes 8,870 unique PII items.

Model	Prefix Set	CR	EF	VxPII Count	Prefix Set Size
		wo LAFt			
Qwen1-8B	P_c	22.93%	0.1910%	2034	71006
Baichuan2-7B	P_c	28.95%	0.2411%	2568	71006

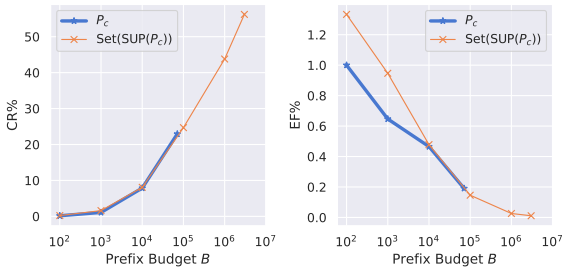

Figure 4: Coverage rate (CR) and efficiency (EF) under varying prefix budgets B for prefix sets P_c and $P_{f\geq 1}$. Prefix set $P_{f\geq 1}$ is frequency-sorted in descending order (see Section 4.2.2). Budget values are scaled exponentially (base 10); model used is Qwen1-8B.

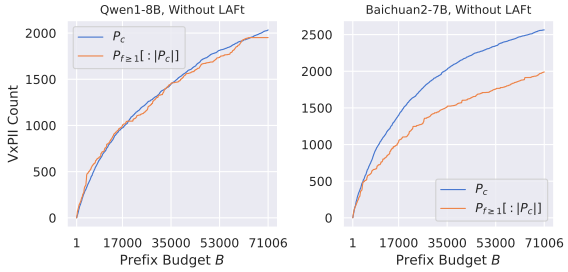

Figure 5: VxPII counts under varying prefix budgets (B) for prefix sets P_c and $P_{f\geq 1}$. Prefix set $P_{f\geq 1}$ is frequency-sorted in descending order (see Section 4.2.2) and truncated to match the size of P_c here.

victim-exclusive PII extracted by Qwen1-8B (without LAFt). The results for Baichuan2-7B are provided in Appendix Figure 11.

The most frequently extracted PII categories include "Address", "Birthday", and "Name", while others such as "Work Experience" and "Work Place" occur less often but remain notable. More complex types like "Medication Record" are not extracted at all. This is primarily due to the evaluation protocol, which only credits model outputs that match ground truth exactly. Complex PII often appears as long free-text spans, making verbatim reproduction difficult.

To estimate an upper bound of extraction capability, we evaluate with the generalized prefix set $\text{Set}(\text{SUP}(P_c))$, which includes all potential contextual prefixes. As shown in Table 1, expanding P_c to $\text{Set}(\text{SUP}(P_c))$ increases CR to 56.57% (Qwen1-8B) and 53.56% (Baichuan2-7B). However, this gain comes at a steep cost in efficiency—dropping EF to only 0.01%—indicating most queries yield redundant or irrelevant content.

We further investigate this CR–EF tradeoff in Figure 4, which illustrates how CR and EF vary with prefix budget B for prefix sets P_c and $P_{f\geq 1}$. As B increases, CR improves, but EF declines sharply. This suggests diminishing returns in efficiency when scaling up the number of queries to discover new PII instances.

RQ2: How effective is frequency-prioritized prefix sampling? As shown in Figure 5, frequency-prioritized (FP) sampling does not extract more VxPII instances than the contextual prefix set P_c, contrary to our hypothesis in Section 4.2.2. This result suggests that the contextual cues embedded in P_c are already strong indicators of LLM memorization, and that memorization cannot be inferred solely from co-occurrence frequency. Instead, it likely arises from more complex interactions between corpus semantics, model architecture, and pre-training dynamics.

Despite this, FP sampling captures highly dis-

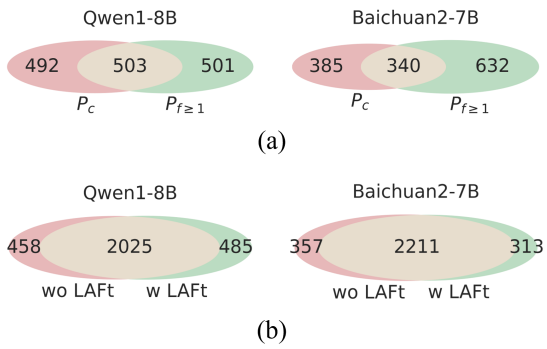

Figure 6: Venn diagrams showing overlap between VxPII sets extracted by different methods. (a) Comparison of VxPII sets using PII-contextual prefixes P_c vs. frequency-prioritized prefixes $P_{f\geq 1}$ at prefix budget $B = 10{,}000$ (without LAFt). (b) Comparison of VxPII sets extracted with and without LAFt on Qwen1-8B and Baichuan2-7B using the full P_c prefix set.

tinct subsets of memorized PII. As shown in Figure 6(a), the Venn diagram comparison reveals that 49.9% of the VxPII extracted by FP sampling on Qwen1-8B and 65.02% on Baichuan2-7B are not discovered by the P_c method. This highlights FP sampling's complementary strength in uncovering diverse memorized content.

RQ3: How effective is Latent Association Fine-tuning? As shown in Table 1, applying Latent Association Fine-tuning (LAFt) significantly improves the CR of Qwen1-8B by 5.37%, raising it to 28.30%, and increases EF to 0.24%, indicating enhanced extraction performance. For Baichuan2-7B, LAFt does not yield a direct improvement in CR, but, as depicted in Figure 6(b), it facilitates the identification of additional distinct PII instances.

These results demonstrate that LAFt is an effective method for increasing the diversity of extracted PII, complementing the FP sampling approach. The extent of the improvement achieved by LAFt is influenced by the construction of the fine-tuning dataset D_{ft} and the choice of hyperparameters. In this study, we adopt a consistent setting by constructing D_{ft} through pairing frequent prefixes with randomly sampled PII and fine-tuning the model for one epoch to ensure a fair comparison. However, further exploration of personalized strategies—tailored to models with different architectures and pre-training conditions—could potentially yield better performance.

Table 2: Coverage rates (CR) of extraction attacks across different attacker–victim client pairs with a prefix budget $B = 10000$. Prefixes are randomly sampled from each attacker's corresponding set P_c. "–" indicates self-attack scenarios, which are not applicable.

Attacker ID	**Victim ID**				
	0	1	2	3	4
0	-	10.91%	12.89%	10.93%	11.88%
1	11.97%	-	12.41%	11.46%	12.35%
2	12.56%	11.39%	-	11.65%	12.74%
3	12.07%	10.82%	12.04%	-	11.99%
4	12.26%	11.36%	13.25%	11.21%	-

Table 3: Attack performance with and without PII masking using the contextual prefix set P_c. The model is Qwen1-8B.

	VxPII	**CR**	**EF**
With PII Masking	2017	22.74%	0.1894%
Without Defense	2034	22.93%	0.1910%

5.3 Cross-Client Evaluation of Extraction Robustness

To assess the robustness of our PII extraction method across different clients, we perform a cross-client evaluation where each client is iteratively designated as the attacker, while the remaining clients act as victims. This setup ensures that the extraction performance is not biased toward any particular client.

As shown in Table 2, our method achieves consistently high coverage rates across all attacker–victim pairings, demonstrating its generalizability and effectiveness in diverse settings.

5.4 PII Sanitization Defense

We evaluate the effectiveness of a simple data sanitization strategy that masks PII using existing annotations. Each PII instance in the training data is replaced with an equal-length sequence of asterisks (*). We then re-fine-tune FedLLM on this sanitized dataset and reapply the PII-contextual Prefix Sampling attack. Table 3 compares the attack performance with and without the PII masking defense.

The results show only a slight reduction in the number of extracted VxPII. To investigate this, we analyze the document frequency of extracted VxPII—that is, how often each appears in the training corpus. Figure 8 demonstrates that masking substantially lowers the frequency of most VxPII, suggesting that our annotations successfully cover

Table 4: Extraction results on non-Chinese LLMs after a single round of federated fine-tuning.

Model	Prefix Set	CR	EF
OLMo2-1124-7B	P_c	23.04%	0.1919%
Llama-2-7B	P_c	26.41%	0.2200%

the majority of PII. Interestingly, some VxPII with zero document frequency—absent from the sanitized dataset—were still extracted.

Based on these observations, we attribute the limited effectiveness of masking to two factors. First, pretraining data contamination: our training data, drawn from publicly available legal documents, likely overlaps with the pretraining corpora of models such as Qwen1-8B and Baichuan2-7B. Second, incomplete PII labeling: some PII instances may be missing from annotations, and in practice attackers can redefine PII categories, making exhaustive coverage fundamentally difficult.

5.5 Disentangling the Effect of Data Contamination

Pretraining data contamination is difficult to avoid, as LLM providers rarely disclose their pretraining corpora. To mitigate this influence, we adopt two strategies:

Using open-source LLMs. To eliminate interference from pretraining memorization, we use open-source or semi-open-source LLMs that are not pretrained on Chinese legal documents: OLMo2-7B (OLMo et al., 2024) and Llama2-7B (Touvron et al., 2023). As shown in Table 4, after just one round of federated fine-tuning, the CR exceeded 23%, achieving performance comparable to or better than Qwen1-8B and Baichuan2-7B. This confirms that our findings are not simply an artifact of pretraining contamination.

Subtracting contaminated memorization. For Chinese-proficient LLMs that may contain contamination, we adopt a subtraction-based approach. Specifically, we compare the VxPII extracted from the fine-tuned FedLLM (F) with those from its base model (B), and compute $F \setminus B$ to isolate PII memorized during federated fine-tuning. Table 5 shows that even after subtracting B, a substantial number of VxPII remain in $F \setminus B$, confirming memorization during fine-tuning. Furthermore, Figure 10 demonstrates that $F \setminus B$ exhibits a distribution of VxPII labels similar to Figure 3, supporting the validity of this analysis.

Table 5: Comparison of VxPII sets between attacks on FedLLM and its un-fine-tuned base model.

Prefix Set	Model	$\lvert F \setminus B \rvert$	$\lvert B \setminus F \rvert$	$\lvert F \cap B \rvert$
P_c	Qwen1	682	518	1801
$P_{f\geq 1}$	Qwen1	554	308	4611
P_c	Baichuan2	407	405	2161

6 Conclusion

To investigate the privacy risks of data extraction attacks in realistic settings, we introduce a new class of attacks targeting FedLLMs. We extend a legal dataset with systematic PII annotations aligned with major privacy regulations, and evaluate attack performance using two key metrics: coverage rate and efficiency. Extensive experiments demonstrate that certain PII types are highly vulnerable, and our proposed methods can achieve substantial extraction performance. These findings highlight a critical privacy gap in FedLLMs and underscore the urgent need for stronger defense mechanisms in future federated learning systems.

Limitations

This work investigates the privacy risks of FedLLMs using a legal-domain dataset. Future research can extend our proposed methods to other sensitive domains such as healthcare and finance, where privacy concerns are equally critical. Additionally, there is a need for further exploration of defense mechanisms that can preserve the privacy of FedLLMs while maintaining their performance.

Ethics Statement

This paper presents PII extraction attacks on federated fine-tuned LLMs to expose potential privacy risks. While designed for research and defense purposes, such methods could be misused to recover sensitive user data in real-world FL systems. We conduct all experiments on legal datasets with anonymized PII, and highlight the need for stronger safeguards in FedLLM deployments.

- **Non-IID** - Non-independent and identically distributed

B Preliminary Knowledge

B.1 Data Extraction Attack

Early research on training data extraction attacks has broadly categorized them into untargeted and targeted attacks (Research, 2022; Yu et al., 2023). Untargeted extraction aims to recover any memorized training samples without specifying a target (Lukas et al., 2023), whereas targeted extraction attempts to reconstruct specific training samples, often by providing a known prefix and recovering the remaining content (Carlini et al., 2021). The latter type, often referred to as Verbatim Data Extraction, has become a standard approach for evaluating memorization in LLMs (Carlini et al., 2023; Dong et al., 2024) and for detecting potential data contamination (Dong et al., 2024). We briefly outline the core methodology of verbatim data extraction below.

Given an LLM θ and a training dataset X, each training sample $x_i \in X$ is partitioned into two segments: a prefix a_i and a suffix b_i, such that $x_i = a_i b_i$. The model is then prompted with a_i to generate a completion g_i of the same length as b_i. If g_i exactly matches b_i, the sample is considered successfully extracted.

In practice, model outputs may not exactly replicate the original suffix but can still be lexically close. To accommodate this, a similarity-based metric such as Edit Distance (Levenshtein, 1965) is often employed. A sample is deemed extracted if the similarity score between g_i and b_i exceeds a predefined threshold t. By computing this similarity-based extraction score across all samples in a dataset D, one can quantify the model's memorization behavior or assess its vulnerability to training data extraction attacks.

B.2 Federated Learning

Federated Learning (FL) is a solution to address data isolation issues (Yang et al., 2019), where a central server and multiple clients collaborate to complete the training process. A key feature of FL is that the training datasets are stored locally on each client and remain invisible to other clients. FL is commonly used in industrial scenarios where each client represents an independent organization, such as hospitals collaborating to train a medical model without combining their datasets due to legal restrictions or business competition. Federated Learning enables the training of stronger models compared to training on data from a single client alone.

Given c clients and their private datasets $D_1, D_2, \ldots, D_c$, the federated learning process aims to learn a global model θ by solving the following optimization problem:

$$\theta^* = \arg\min_{\theta} \frac{1}{c} \sum_{i=1}^{c} \mathcal{L}(D_i, \theta)$$

To solve this problem, many federated optimization algorithms have been proposed, such as FedAVG (McMahan et al., 2023) and FedProx (Li et al., 2020). Typically, these algorithms consist

of two alternating phases: local updating and central aggregation. In the local updating phase, each client independently optimizes the global model using its own dataset. In the central aggregation phase, the server aggregates the models from the clients using an aggregation algorithm, obtaining a global model, which is then sent back to each client for the next round of local updating. A typical procedure of federated learning is illustrated in Algorithm 1.

B.3 Federated Large Language Models (FedLLMs)

In current research at the intersection of federated learning and large language models, the term *FedLLM* predominantly refers to *federated fine-tuning* of pre-trained LLMs (Bai et al., 2024; Wang et al., 2024b; Ye et al., 2024a), rather than federated pre-training. This focus arises from both practical and technical considerations.

Federated pre-training is rarely necessary, as large-scale pre-training typically relies on publicly available general-purpose corpora (such as web text or encyclopedias) that do not contain sensitive information and therefore do not require federated sharing. Moreover, federated pre-training would entail transmitting extremely large model parameters across institutions, incurring prohibitive communication costs and conflicting with high-efficiency training practices like data parallelism and optimized operators, making deployment infeasible in practice.

By contrast, federated fine-tuning is essential in privacy-sensitive domains. Many applications of LLMs in vertical fields—such as judicial documents, electronic health records, and banking customer data—rely on restricted information that cannot be centralized due to legal or institutional constraints (e.g., the Data Security Law or the Personal Information Protection Law). In these settings, federated fine-tuning allows each institution to adapt a shared pre-trained model locally, achieving a balance between model performance and data privacy. This approach has already demonstrated tangible value across multiple domains.

For example, in the judicial domain (Zhang et al., 2023), courts can fine-tune a common LLM on local case repositories without sharing sensitive records, enabling cross-court tasks such as statute matching and case similarity analysis. In healthcare (Ali et al., 2025), hospitals can locally fine-tune models on specialty data, producing comprehensive medical LLMs capable of supporting structured record processing and disease risk prediction. And in finance (Sha, 2024), banks can fine-tune models on transaction data to detect fraud and assess credit risk without violating privacy regulations.

B.4 Preliminary Assessment of Verbatim Data Extraction Risks in FedLLMs

To examine the memorization behavior of FedLLMs and evaluate their potential risks of leaking sensitive information, we conduct a preliminary experiment simulating a *verbatim data extraction* attack. The results are referenced in the main paper (Section 1) to empirically motivate our study.

We adapt the experimental setup from (Dong et al., 2024) to the federated setting, where an attacker is assumed to possess prefix fragments of the training data from all participating clients and attempts to recover the subsequent suffix tokens. For each training sample, we extract a prefix from the original sequence and query the trained model to generate a continuation. The generated suffix is compared against the ground truth using **Edit Distance** (ED) (Levenshtein, 1965), where a lower ED indicates stronger memorization. Specifically:

- ED = 0 indicates the model has perfectly memorized and reproduced the suffix;
- ED values are capped at 50, as we restrict suffixes to a maximum of 50 tokens.

We perform the attack on the global models aggregated after 10 rounds of federated training. To ensure a comprehensive assessment, we consider three popular FL algorithms—**FedAvg** (McMahan et al., 2023), **FedProx** (Li et al., 2020), and **Scaffold** (Karimireddy et al., 2020)—each under both **IID** and **Non-IID** data distributions. Two baseline settings are also included:

- **Centralized**: All client data is pooled and the model is fine-tuned in a conventional non-federated manner;
- **Untrained**: The base model is evaluated without any fine-tuning.

Figure 7 summarizes the results across five downstream tasks. Our key observations are:

- FedLLMs consistently exhibit higher ED scores (i.e., lower memorization) than central-

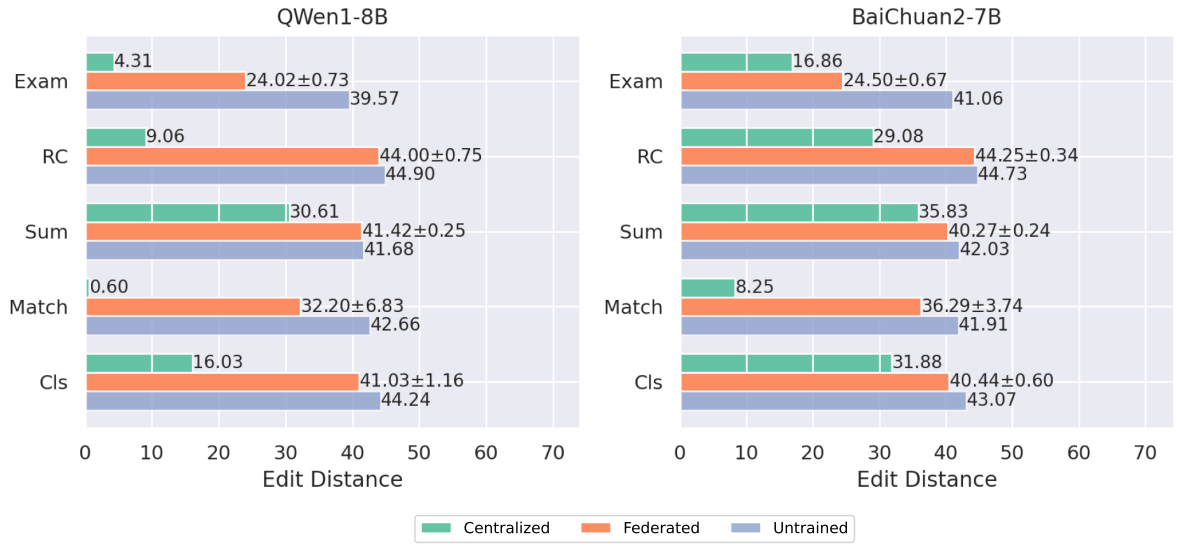

Figure 7: Edit Distance results of verbatim data extraction attacks after 10 training rounds. We evaluate six federated configurations (FedAvg/FedProx/Scaffold × IID/Non-IID) and report the mean and standard deviation. Lower values indicate stronger memorization. Centralized and untrained models serve as baselines.

ized models, suggesting that the FL aggregation process reduces susceptibility to verbatim extraction.

- However, compared to untrained models, FedLLMs still show non-negligible memorization, with noticeably lower ED scores, indicating partial leakage of training data.

These findings highlight a trade-off between collaborative model training and privacy preservation, and they serve as the motivation for our in-depth investigation of privacy risks in FedLLMs.

C Federated Learning Framework

Algorithm 1 outlines a general framework for Federated Learning (FL), where a central server coordinates multiple clients to collaboratively train a global model without sharing local data. At each round, the server distributes the current model to all clients, each of which performs local updates based on its private data and sends the updated parameters back. The server then aggregates the received updates to produce a new global model.

Algorithm 1 A Federated Learning Framework

Input: Clients set $\mathcal{C} = \{c_1, c_2, \ldots, c_c\}$ with local datasets $D_1, D_2, \ldots, D_c$; total FL rounds R; initial global model θ_0; server aggregation function f_{agg}; client loss function $\mathcal{L}$
Output: Learned global model θ_R

ServerExecute:
for round $r = 1$ to R **do**
  for each client $c_i \in \mathcal{C}$ (in parallel) **do**
    $\theta_r^i \leftarrow \text{CLIENTUPDATE}(c_i, \theta_{r-1})$
  end for
  $\theta_r \leftarrow f_{\text{agg}}(\{\theta_r^i | c_i \in \mathcal{C}\})$
end for

ClientExecute:
function $\text{CLIENTUPDATE}(c_i, \theta_{r-1})$
  $\theta_r^i \leftarrow \arg\min_{\theta} \mathcal{L}(\theta_{r-1}, D_i)$
  return θ_r^i
end function

D Task Descriptions and Examples

1. **Judicial Summarization (Sum)**: The task of judicial summarization aims to extract key information from court judgments and generate concise summaries. The input to this task is a legal document, and the output is a summary of its content. The performance of this task is evaluated using the Rouge-L metric, which effectively measures the similarity between the generated and reference texts based on the longest common subsequence (LCS). Rouge-L is a widely used metric in text generation tasks. In this study, we adopt Rouge-L because it captures both semantic and structural similarities between texts, making it suitable for summarizing judicial documents.

2. **Judicial Reading Comprehension (RC)**: This task focuses on answering legal questions based on court documents to evaluate the

model's reading comprehension ability. The input consists of a piece of legal material and a question, and the task requires answering the question based on the content of the material. The performance metric for this task is Rouge-L.

3. **Similar Case Matching (Match)**: In this task, the input includes three case documents, and the model is required to determine which of the latter two documents is more similar to the first one. The model selects the most similar document by computing the similarity between the first case and each of the other two. The evaluation metric for this task is accuracy.

4. **Judicial Exam (Exam)**: This task simulates multiple-choice questions from legal examinations to assess the model's knowledge of legal concepts. Given a judicial exam question with multiple options, the model is expected to choose the correct answer. The performance is evaluated using accuracy.

5. **Legal Case Classification (Cls)**: This task requires the model to classify the cause of action in a case, assisting legal retrieval systems in automatically categorizing case types. The input is a description of the case facts, and the model is required to output the corresponding case category. The performance metric is accuracy.

E Data Preprocessing

Previous works (Zhang et al., 2023; Yue et al., 2023) have used these datasets for LLM and FedLLM research. In this work, we use the processed datasets from these prior studies and further curate the data for our experiments. We applied the following preprocessing steps to prepare the datasets:

Deduplication and Cleansing. To ensure the quality of our data, we remove duplicate samples with logically equivalent meanings. For example, in the RC tasks, some samples only differ in the order of two legal cases. We also clean out samples containing garbled characters or large segments with a mixture of multiple languages.

Unifying Prompt Template and Instruction Reshaping. Some tasks, such as Exam, contain instructions that appear in different parts of the sample (either at the beginning or the end). To standardize the format, we reshape the data so that the instruction always appears at the beginning, followed by the legal document. Additionally, we employ hierarchical hyper markers such as "<Case A>", "<Case B>", and "<Answer>" to clearly segment the prompt, making the structure more transparent for the LLM.

F Supplementary Dataset Statistics and Analysis

Table 7 summarizes the basic statistics of the five datasets used in our experiments. Each dataset corresponds to a different downstream task for fine-tuning the model.

Figure 8 presents the document frequency distribution of the 2017 VxPII instances extracted from the model trained on the masked dataset (see Section 5.4). Most VxPII exhibit low frequency, indicating that PII masking significantly reduces memorization.

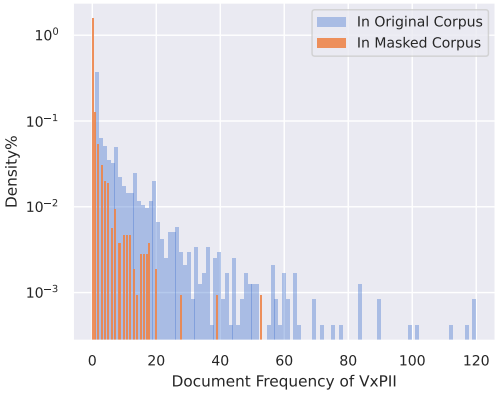

Figure 8: Document frequency distribution of the 2017 VxPII instances extracted from the model trained on the masked dataset.

G Prompt Template and Utility Fine-tuning Results for FedLLMs

Figure 9 shows the unified prompt template used for all federated utility fine-tuning tasks. Table 8 reports the evaluation results across multiple tasks, comparing different federated learning algorithms and base models.

H Additional PII Label Distribution Results

I Machine Annotation Standards for PII Labeling

This section provides details on the machine annotation protocol we use to identify PII in our dataset. Table 9 defines our categorization schema, which includes seven major categories and their corresponding fine-grained subtypes. To ensure annotation consistency and scalability, we utilize a templated prompting approach for automated PII labeling. Figure 12 shows the machine annotation prompt used to instruct the LLM annotator. The prompt dynamically incorporates category definitions and format constraints to standardize the output.

J Details of Human Evaluation for PII Annotation

To validate the quality of the machine-generated PII annotations, we recruited four Chinese-speaking students with foundational knowledge of Chinese law to manually annotate PII on a selected subset of the dataset. Prior to annotation, all annotators underwent thorough training on the annotation guidelines and usage of the Label Studio tool. The instructions provided to annotators are detailed in Figure 13, while Figure 14 illustrates the annotation interface used. All annotators were fairly compensated upon completion of their tasks.

The human evaluation results, reported in terms of precision, recall, and F1 score, are summarized in Table 10, indicating high agreement both in exact span matching and in combined span-and-label matching, confirming the reliability of the machine

Table 8: Utility Performance over Different Tasks.

FL Algorithms	Models	SUM(rouge-l)	RC(rouge-l)	Match(Acc)	Exame(Acc)	Cls(Acc)

K Experiment Implementation Details

K.1 Federated Dataset Partitioning.

We use the preprocessed and labeled datasets (see Section 3) for our experiments, splitting the data into training and testing sets. In the federated learning setup, we simulate a system with five clients. The testing set remains global, while the training set is heterogeneously partitioned across the clients using a balanced Non-IID distribution (see Acronyms List A). To achieve this, We employ a clustering-based method (Li et al., 2023) for partitioning, where a language encoder first generates embeddings, which are then clustered using K-means. Finally, a Dirac distribution with $\alpha = 0.5$ is applied to create a label-skewed partitioning (Guo et al., 2024), ensuring each client receives a comparable number of samples.

```
# **PII Annotation Guidelines for Labelers**
## **1. Task Objective**
**Core Task**: Proofread legal texts to accurately identify and annotate **Personally Identifiable
    Information (PII)**. Each annotation task includes:
1. **Localization**: Mark the exact character offsets of each PII instance in the text;
2. **Categorization**: Assign each PII instance to the appropriate **major category (7 total)** and **minor
    category (36 total)**, ensuring precise classification.
## **2. PII Category System**
| Major Category | Minor Categories |
| - | - |
| Personal Basic Information | Name, Birthday, Address, Gender, Ethnicity, Family Relationship, Age,
    Nationality, Personal Phone Number |
...(omitted)...
## **3. Annotation Workflow and Standards**
### **Step-by-Step Process**
1. **Read the Full Text**: Understand the context to detect all potential PII entities;
2. **Sentence-by-Sentence Annotation**: For each PII instance, annotate its **start position**, **text span
    **, and corresponding **major + minor category**;
3. **Special Cases**: For ambiguous expressions (e.g., "a certain district of a certain city"), determine
    PII status based on contextual clues.
### **Annotation Guidelines**
* **Accuracy**: Ensure all annotated content is verifiably present in the text. Avoid false positives or
    over-labeling;
* **Support Channel**: If any uncertain cases arise during annotation, promptly reach out to the *Annotation
     Support Team* for clarification.
```

Identical Span Only	0.89	0.93	0.91
Identical Span and Label	0.89	0.90	0.89

K.2 Hardware and Computation Budget

All experiments are conducted on a single NVIDIA A6000 GPU with 48 GB of memory, using bfloat16 precision. Most sampling-based attack experiments are completed within 200 GPU hours.

K.3 Experiment Procedure

K.3.1 Federated Utility Fine-Tuning

We begin by performing federated fine-tuning of the LLM (Zhang et al., 2023; Wu et al., 2025) on the partitioned dataset, adapting it to the legal tasks. The fine-tuning is conducted using the OpenFedLLM framework (Ye et al., 2024b). We set the total number of FL rounds to 10 and use FedAVG (McMahan et al., 2023) as the aggregation algorithm.

Each client performs multi-task fine-tuning by mixing all local tasks and applying a unified prompt template, as illustrated in Figure 9, following the approach of Raffel et al. (2023). In each round of federated learning, the client fine-tunes the received global model for one epoch using parameter-efficient fine-tuning (PEFT) techniques of LoRA (Hu et al., 2021). The learning rate is set to 3e-4 with a linear decay schedule. The maximum input sequence length is 3072 tokens. We use a batch size of 1 and apply gradient accumulation with a factor of 8. The LoRA configuration is set to $r = 16$ and $\alpha = 32$.

After federated fine-tuning is complete, we evaluate the utility performance of the final global model on a held-out global test set. In line with standard practices in federated learning research, we also compare this performance with that of a centrally (non-FL) trained model on the same test set. The results are summarized in Table 8.

K.3.2 PII Extraction

In the main experiments, we designate client 0 as the attacker and client 1 as the victim. We construct the prefix set P_c for PII-contextual prefix sampling from the local dataset D_0. During this construction, we set the length parameter λ to 50. Each prefix is used to independently query the utility fine-tuned global model $n = 15$ times. For each query, the model is allowed to generate up to $m = 10$ new tokens. This generation length is sufficient to cover most labeled PII instances while keeping the computational cost acceptable.

For Frequency-Prioritized Prefix Sampling, we construct $\text{Set}(\text{SUP}(P_c))$ from the aforementioned P_c, and sort it in descending order of prefix fre-

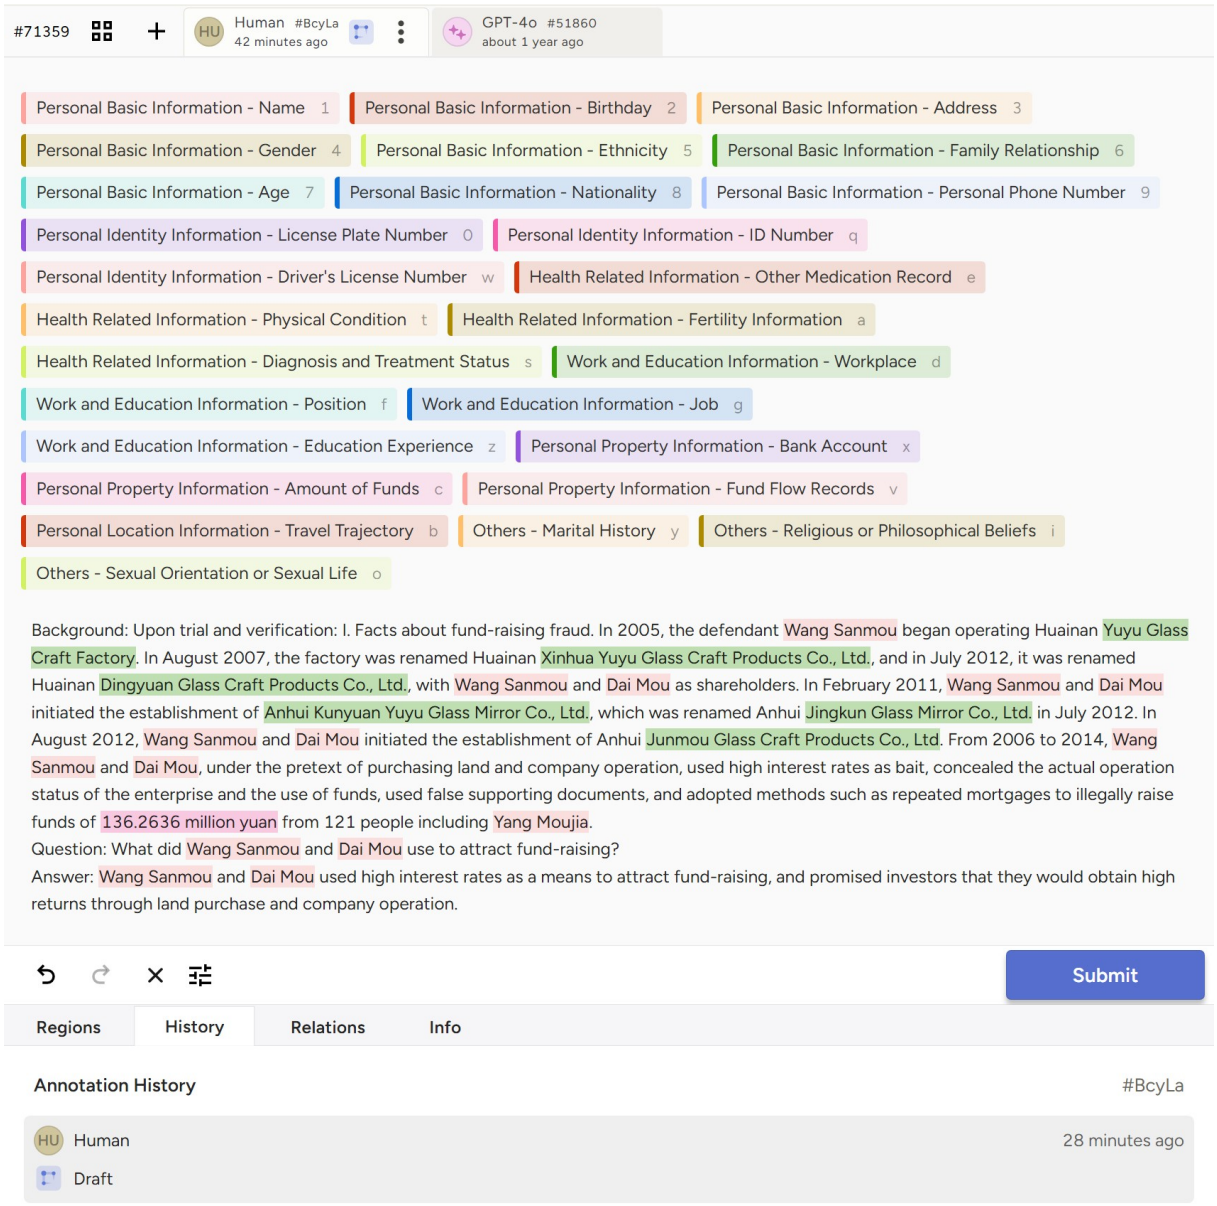

Figure 14: Human annotation interface in the Label Studio tool for PII labeling. Annotators are familiar with the Label Studio environment and are instructed to label PII spans based on predefined PII categories. Machine-generated labels are provided as references to assist the human annotators.

quency (as described in Section 4.2.1). The model θ is then queried using prefixes in this frequency-descending order. Although we do not explicitly define a frequency threshold σ_a, we sweep the prefix budget B exponentially in base 10. Because $\text{Set}(\text{SUP}(P_c))$ is sorted by decreasing frequency, this sweep over B implicitly corresponds to sweeping σ_a from $+\infty$ to 1.

K.3.3 Latent Association Fine-tuning

To construct the fine-tuning dataset D_{ft}, we select the top 10000 most frequent prefixes from $\text{Set}(\text{SUP}(P_c))$ and randomly sample 10000 PII instances from the attacker's (client 0's) PII set S_a. Although alternative strategies could be explored for prefix and PII selection, this approach is relatively straightforward and effective. We then fine-tune the model θ to obtain θ' using one epoch and a small learning rate of 5e-5. LoRA is applied with $r = 16$ and $\alpha = 32$, consistent with the initial federated fine-tuning setup.

POSTERSUM: A Multimodal Benchmark for Scientific Poster Summarization

Rohit Saxena **Pasquale Minervini** **Frank Keller**

Abstract

Generating accurate and concise textual summaries from multimodal documents is challenging, especially when dealing with visually complex content like scientific posters. We introduce POSTERSUM[1][2], a novel benchmark to advance the development of vision-language models that can understand and summarize scientific posters into research paper abstracts. Our dataset contains 16,305 conference posters paired with their corresponding abstracts as summaries. Each poster is provided in image format and presents diverse visual understanding challenges, such as complex layouts, dense text regions, tables, and figures. We benchmark state-of-the-art Multimodal Large Language Models (MLLMs) on POSTERSUM and demonstrate that they struggle to accurately interpret and summarize scientific posters. We propose SEGMENT & SUMMARIZE, a hierarchical method that outperforms current MLLMs on automated metrics, achieving a 3.14% gain in ROUGE-L. This will serve as a starting point for future research on poster summarization.

1 Introduction

Scientific posters play a critical role in academic communication, offering a visually rich medium that combines text, images, charts, and other graphical elements to present research findings. Summarizing these visually complex posters into concise and accurate textual abstracts presents a unique challenge, requiring models to integrate multimodal information effectively. Multimodal Large Language Models (MLLMs; OpenAI et al., 2024; Grattafiori et al., 2024) demonstrated remarkable capabilities in vision-and-language tasks, including image captioning (Fu et al., 2024; Koh et al., 2023; Yu et al., 2024; Garg et al., 2024) and visual question answering (Liu et al., 2024e; Yue et al., 2024). While these models exhibit strong generalization across various domains, their performance often declines when applied to scientific text (Li et al., 2024; Lu et al., 2024; Pramanick et al., 2024). Additionally, the complexity of poster layouts, the use of technical terminology, and the intricate interplay between text, tables, and figures make summarizing scientific posters a particularly challenging task, which has remained under-explored due to the lack of specialized datasets.

To address this gap, we introduce POSTERSUM, a novel multimodal benchmark for summarizing scientific posters into research paper abstracts. Our dataset consists of 16,305 scientific posters and corresponding abstracts as summaries collected from the main Machine Learning conferences, namely ICLR, ICML, and NeurIPS. These posters cover a broad range of scientific disciplines and present unique challenges, including complex layouts and intricate combinations of text, tables, and figures as shown in Fig. 1. Information is often distributed across the poster, requiring careful navigation and integration of diverse elements to identify and summarize the key points effectively.

We benchmark state-of-the-art MLLMs on POSTERSUM and demonstrate that, despite their impressive performance on a range of other multimodal tasks, these models face significant limitations when summarizing scientific posters. For instance, the best-performing closed-source model in our experiments, GPT-4o (OpenAI et al., 2024), achieves a ROUGE-L score of 22.30, underscoring the difficulty of this task specifically with the posters with figures and tables.

To address this challenge, we propose SEGMENT & SUMMARIZE, a hierarchical approach inspired by the divide-and-conquer principle (Chen and Zhao, 2023). The method involves three key steps: (1) Segmentation: we segment each poster into coherent regions; (2) Localized Summarization: a multimodal large language model extracts

[1]The dataset is available at rohitsaxena/PosterSum.

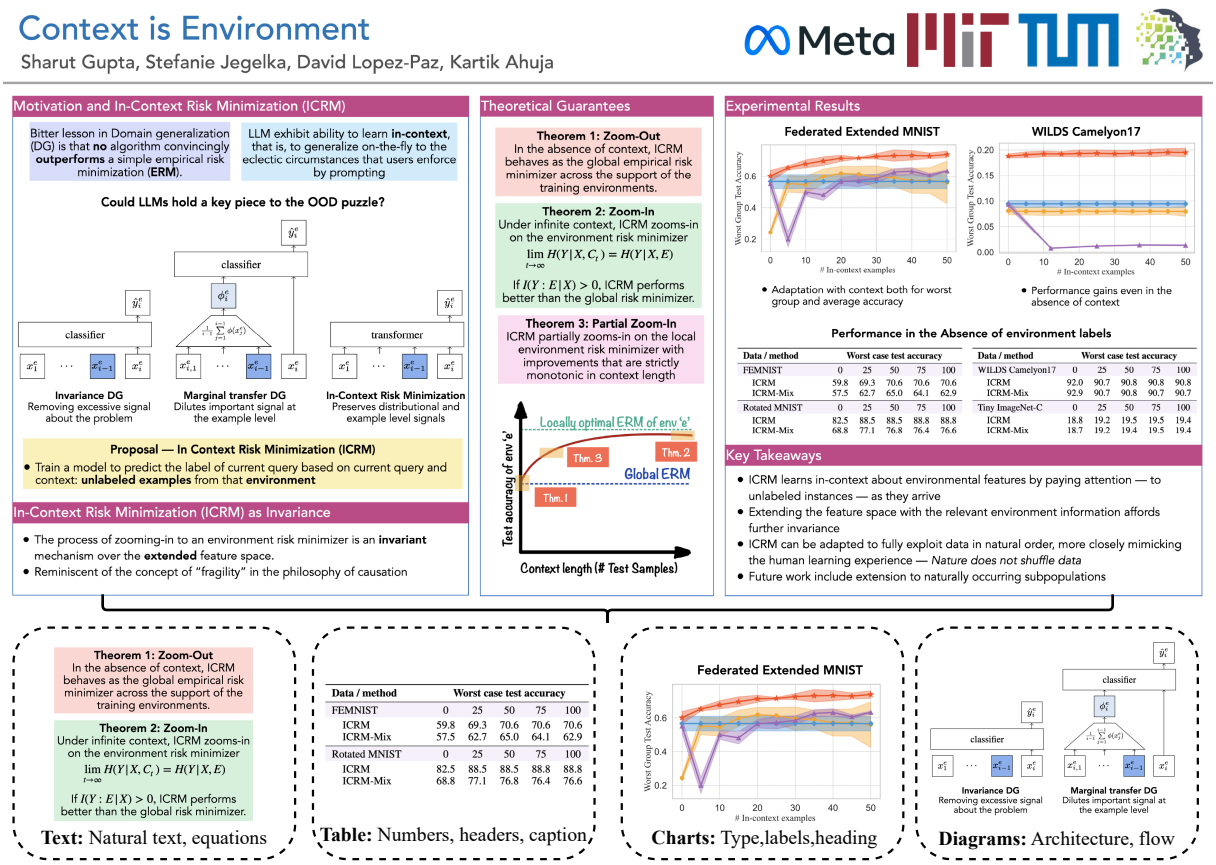

Figure 1: An example of scientific poster from the POSTERSUM dataset. The poster, describing the work in Gupta et al. (2024), contains visual elements such as structured tables with numerical results, charts, diagrams, and textual sections, demonstrating the multimodal complexity present in the dataset.

and interprets the text within each segment, generating localized summaries for each region; and (3) Global Summarization: these localized summaries are combined using text-based large language model to produce a cohesive abstract that spans the entire poster. Notably, this approach does not require additional training or fine-tuning. Local summaries allow the model to focus on fine details within that specific area, which are useful for tables and figures. Also, it aligns with the inherent structure of the poster, which has sections with a specific focus. This approach achieves a ROUGE-L score of 24.18, outperforming both closed-source and open-source models, setting a new benchmark for scientific poster summarization. Our contributions can be summarized as follows:

- We introduce POSTERSUM, a large-scale multimodal dataset of 16,305 scientific posters paired with their abstracts, tailored for research poster summarization.
- We benchmark state-of-the-art MLLMs on POSTERSUM, showing their limitations in processing and summarizing scientific posters.
- We propose SEGMENT & SUMMARIZE, a hierarchical approach that segments each poster into coherent regions, extracts the textual content from those regions, and then composes a final summary; we also demonstrate POSTERSUM's utility for fine-tuning MLLMs, showing promising improvements over zero-shot results.

2 Related Work

Multimodal Large Language Models. After the emergence of LLMs, recent work (Liu et al., 2023; Wang et al., 2024b; Alayrac et al., 2022) investigated their use in processing multimodal inputs, giving rise to Multimodal Large Language Models (MLLMs). The core idea in this line of research is to align visual and textual features by using shared representations. This framework typically involves using a pre-trained visual encoder to extract visual features, a projection layer to map visual representations into corresponding text representations, and a pre-trained LLM to generate textual responses, allowing the model to condition the output on visual and textual inputs. MLLM architectures such

as LLaVA (Liu et al., 2023) and MiniCPM (Yao et al., 2024) demonstrated impressive zero-shot generalization across diverse visual and language tasks. However, most existing MLLMs focus on general domain tasks and relatively simple visual inputs; the challenge of understanding complex and information-dense visual documents like scientific posters remains under-explored.

Summarization in Scientific Domains. *Scientific summarization* consists of generating concise summaries for scientific content (Yasunaga et al., 2019; Cachola et al., 2020; Ju et al., 2021; Sotudeh and Goharian, 2022). Several scientific summarization benchmarks have been proposed, designed to process modalities such as videos (Lev et al., 2019; Chen et al., 2024), slides (Tanaka et al., 2023), surveys (Liu et al., 2024d), and research papers (Takeshita et al., 2024; Liu et al., 2024a). While scientific posters are widespread in scientific communication, no poster summarization benchmark has been proposed in the literature. Our proposed POSTERSUM aims to address this gap.

Document Layout Analysis and Segmentation. Understanding document layouts plays a significant role in processing complex visual documents like scientific posters. Recent work in document layout analysis (Peng et al., 2022; Wang et al., 2024a; Luo et al., 2024; Appalaraju et al., 2024) aims at identifying and classifying different regions within a document considering spatial relationships and content type. Previous work has also focused on understanding individual elements in documents, such as charts (Masry et al., 2022) and tables (Zheng et al., 2024). However, most existing approaches are designed for either standard documents or individual elements like charts and tables and do not capture the complex layouts and the rich multimodal structure of scientific posters, which typically consist of text, charts, equations, and tables.

3 The POSTERSUM Dataset

We introduce POSTERSUM, a novel dataset and benchmark for multimodal abstractive summarization of scientific posters. POSTERSUM consists of 16,305 pairs of academic posters as images (PNG format) and their corresponding research paper abstracts. These posters were collected from major machine learning and artificial intelligence conferences, which accept papers from various subfields of machine learning, including computer vision, natural language processing, optimization, and computational biology.

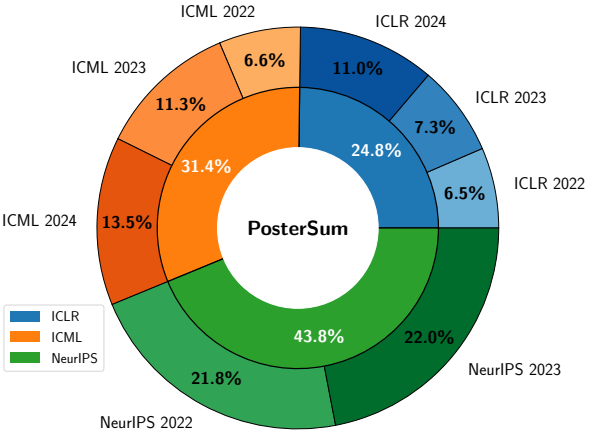

Figure 2: Distribution of the POSTERSUM dataset.

POSTERSUM captures the diverse and heterogeneous nature of academic posters, which are commonly used at conferences to present research findings. These posters vary in layout, content, and visual complexity–some are text-heavy, while others emphasize visual elements such as charts, graphs, and figures, as shown in Fig. 1. This variability presents a significant challenge for MLLMs, requiring them to interpret and summarize multimodal information effectively.

Each poster in the dataset is paired with its corresponding abstract, which serves as the ground-truth summary. The abstract highlights the key contributions and findings of the research, making it an ideal summary for the poster. Unlike image captioning, poster summarization requires a deeper understanding of multiple elements in the poster to generate a comprehensive and meaningful abstract-based summary; and unlike other scientific summarization works, it focuses on extracting information from a poster rather than a scientific paper.

3.1 Dataset Creation

The POSTERSUM dataset was collected from the websites of top-tier machine learning and artificial intelligence conferences: ICLR, ICML, and NeurIPS. We selected these conferences based on the availability of research posters. We first collected research paper links and paper identifiers from the conference websites. We filtered out any entries where the poster of the paper was not available, ensuring that only papers with accessible posters were included in the dataset. We exclusively collected posters from the years 2022 to 2024, as shown in Fig. 2. Additionally, we man-

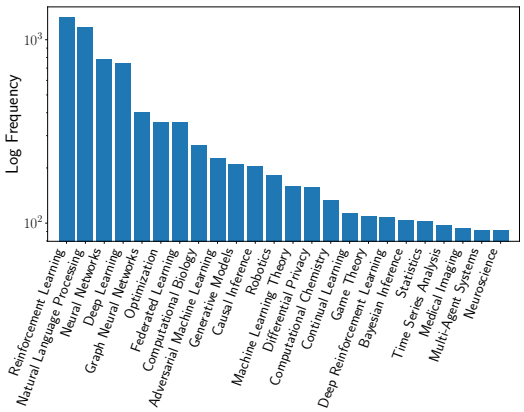

Figure 3: Distribution of the most frequent 25 topics for the posters in POSTERSUM.

POSTERSUM Statistics	
Total number of posters-summary	16,305
Total number of unique categories	137
Mean token length of the summary	224
Mean summary sentences	7.21
Train/Val/Test size	10305/3000/3000
Mean CLIP score	29.08
Year range	2022–2024

Table 1: Statistics of the POSTERSUM dataset.

% Novel n-grams in Summary			
1-grams	2-grams	3-grams	4-grams
54.54	81.13	88.67	91.41

Table 2: Statistics for percentage of novel n-grams in the POSTERSUM summaries.

ually reviewed the dataset to remove any posters with placeholder images. We assume that the research reported in the posters is of a high standard, and the posters are of high quality, as the corresponding papers appeared at top machine learning conferences.

To build a robust summarization dataset, it was essential to pair each poster with a human-written summary. We collected the research paper abstracts from the corresponding paper pages using the paper identifiers. These abstracts serve as the summaries for the posters, as they highlight the core findings and contributions of the research. For papers where the abstract was missing from the webpage, we manually extracted the abstract from the research paper's PDF to ensure completeness.

3.2 Dataset Statistics and Analysis

This process resulted in the 16,305 poster-summary pairs, providing a comprehensive multimodal resource for evaluating abstractive summarization of academic research posters.

Table 1 provides an overview of key statistics for the dataset. The average length of the poster summaries is 224 word-piece tokens, with an average of seven sentences per summary. The poster images are of high-resolution, with a mean size of 3547×2454. We randomly split the dataset into training, validation, and test sets using a 10305/3000/3000 split, which can be utilized for training and fine-tuning models.

To better understand the diversity within the dataset, we categorized posters into topics. Since topics were not available on the conference websites, we employed the GPT-4o vision model to generate topic labels by prompting the model in a zero-shot setting using the images of the posters. As a result, we identified 137 distinct topics within machine learning and artificial intelligence, spanning areas such as reinforcement learning, natural language processing (NLP), computational biology, and healthcare applications. Fig. 3 illustrates the distribution of the most frequent 25 topics.

To assess the abstractiveness of the poster summaries, we report the percentage of novel n-grams in the summaries compared to the Optical Character Recognition (OCR) extracted text from the posters. We used MMOCR (Kuang et al., 2021) to extract the text. While most posters do not explicitly include abstracts, we found that approximately 8% of the total posters may contain an abstract in poster, based on the occurrence of the word "abstract" in the OCR text. As shown in Table 2, a significant portion of the summaries contains novel content, particularly in the 3-gram and 4-gram categories. This demonstrates that the summaries are not simple restatements of poster text but instead provide a more comprehensive abstraction.

We also find a mean CLIPScore (Hessel et al., 2021) of 29.08 when we evaluate the alignment between the images of the posters and their summaries. This score was computed at the sentence level and averaged across the dataset. The relatively low CLIPScore highlights the challenge that POSTERSUM poses for existing MLLMs. Unlike image-captioning tasks, where captions directly describe visual features, academic posters are composed of diverse and complex visual elements, such as charts, graphs, equations, and dense textual explanations. This complexity makes it more difficult for models to capture the semantic relationships between these elements and the corresponding abstract summaries.

4 Multimodal Poster Summarization

4.1 Task Formulation

Given a scientific poster I in image format as input, the objective is to generate a textual summary $\hat{Y} = \{\hat{y}_1, \hat{y}_2, \ldots, \hat{y}_m\}$ that encapsulates the key points and essential content of the poster. Formally, a model M_θ, parameterized by θ, takes the poster I as input, optionally accompanied by a prompt P, and generates a summary $\hat{Y}$. The key challenge in this task is that model M_θ must effectively abstract from the diverse visual and textual elements present in the poster, including text, charts, diagrams, and equations, to produce a coherent and informative summary.

4.2 Baselines

We evaluate various multimodal models, both open-source and closed-source, to assess their performance on the abstractive summarization task for scientific posters. As the posters include textual elements, we also evaluate OCR-based methods as baselines. For MLLMs, evaluation is conducted in a zero-shot and Chain-of-Thought (CoT) setting to assess the capability of models to generate accurate summaries. Additionally, we explore parameter-efficient fine-tuning techniques on selected open-source models. Below are the categories of models used in our experiments.

Optical Character Recognition (OCR). For OCR-based baselines, we used two OCR methods (MMOCR (Kuang et al., 2021) and Pytesseract[3]) to extract text from the poster images and concatenated the results to generate a summary. Additionally, we combined the best OCR output with a text-based large language model (LLM). In this approach, we first extract text from the posters and then use the Llama-3.1-8B-Instruct (Grattafiori et al., 2024) model for summarization. This allows us to evaluate the performance of text-only LLMs when provided with OCR-extracted text.

Closed-source MLLMs. We evaluated GPT-4o (OpenAI et al., 2024), Claude 3.5 Sonnet (Anthropic, 2024), and Gemini 2.0 (Anil et al., 2024) as closed-source MLLMs. All the models were prompted with the image of the poster in a zero-shot setting to generate abstractive summaries based on the input. The prompt template can be found in Appendix A.

[3] https://github.com/h/pytesseract

Open-source MLLMs. As open-source/open-weights models, we evaluated Llama-3.2-11B-Vision-Instruct (Meta, 2024), Qwen2-VL-7B-Instruct (Yang et al., 2024), LLaVA-NeXT (Liu et al., 2024c,b), mPLUG-DocOwl2 (Hu et al., 2024), and MiniCPM-Llama3-V-2.5 (Yao et al., 2024). Each model was evaluated in both zero-shot and CoT settings. The CoT prompt was used to steer the models to extract relevant information, such as the title, research problem, methods, results, and conclusion, from the poster. We report the full prompt template in Appendix A.

Fine-tuned Models (LoRA). We also evaluated the fine-tuned Llama-3.2-11B-Vision-Instruct and LLaVA-NeXT models. We used parameter-efficient fine-tuning using the Low-rank Adaptation (LoRA; Hu et al., 2022) method to fine-tune both of these models using the training and validation set of the PosterSum dataset.

4.3 Segment & Summarize

We now introduce Segment & Summarize, a hierarchical approach inspired by the divide-and-conquer principle. Rather than processing the entire poster I as a single input, Segment & Summarize decomposes the task into three key steps: (1) Segmentation and Clustering (2) Localized Summarization, and (3) Global Summarization. The Segment & Summarize pipeline is outlined in Fig. 4.

1. Segmentation and Clustering. Given the image of a poster I, the first step is to segment it into n coherent regions $M = \{M_1, M_2, \ldots, M_n\}$. This is achieved using a segmentation model S_ϕ, parameterized by ϕ, Since the number of regions n can be large and can contain redundant and small segments, the regions are further clustered into groups R with the number of the clustered regions as k using a clustering algorithm C such that $k \ll n$. The clustering step groups similar regions together, reducing redundancy and ensuring complete coverage of the poster. Formally, $M = S_\phi(I)$ and $R = C(M)$.

By segmenting the poster and summarizing each region independently, the method ensures a detailed and accurate understanding of the content.

2. Localized Summarization. For each clustered region R_i, a localized summary $\hat{Y}_i = \{\hat{y}_{i1}, \hat{y}_{i2}, \ldots, \hat{y}_{ik}\}$ is generated using an MLLM V_ϕ. The model is used to extract and inter-

Table 3: Summarization results on the POSTERSUM dataset. The results show ROUGE scores (R-1, R-2, R-L, R-LSum), BERTScores (BS_p, BS_r, BS_{f1}), SacreBLEU, CLIPScore, and METEOR scores for all baselines and models. All the scores are percentages.

pret the content within R_i, including text, figures, and tables, to generate a localized summary for that specific region. This also helps in processing the high-resolution image.

3. Global Summarization. The localized summaries $\hat{Y}_1, \hat{Y}_2, \ldots, \hat{Y}_k$ are combined into a cohesive global summary $\hat{Y}$ using a text-based large language model L_ω, parameterized by ω. The model L_ω takes as input the individual summaries and generates a single, well-structured output that represents the overall content of the poster. This step ensures that the final abstract is not only comprehensive but also maintains logical flow and coherence. Formally, $\hat{Y} = L_\omega(\hat{Y}_1, \hat{Y}_2, \ldots, \hat{Y}_k)$.

This processing pipeline helps summary generation through a structured, localized, and hierarchical approach. By segmenting the poster and summarizing each region independently, the method captures fine-grained details that might be overlooked in a global approach. This also aligns with the structure of these posters, which are mostly divided into sections. This approach does not require additional training or fine-tuning, and both the models (V_ϕ, L_ω) are frozen.

5 Experimental Details

All models in each category were evaluated using the same hyperparameter settings for a fair evaluation. We generate at most 768 new tokens for all the experiments. For closed-source models, we used the default platform settings. Open-source models were evaluated with a beam size of 4 with greedy decoding to ensure reproducibility. The fine-tuning experiments were conducted for 10 epochs with a batch size of 4. More details on the hyperparameters and prompt templates can be found in Appendices A and D.

For SEGMENT & SUMMARIZE, we used the Segment Anything Model (Kirillov et al., 2023) for segmentation with k-Means for clustering. The num-

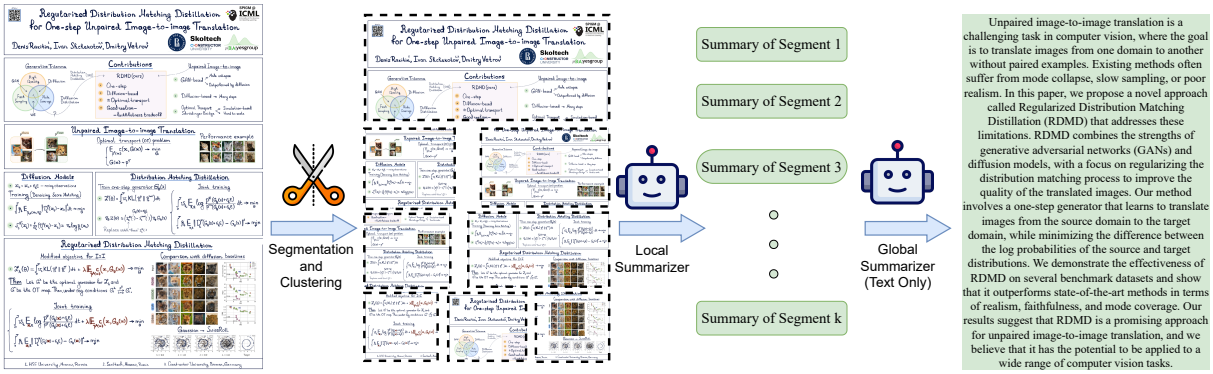

Figure 4: Illustration of our SEGMENT & SUMMARIZE pipeline. The poster, describing the work in Rakitin et al. (2024), is first divided into segments, each of which is summarized by a MLLM. These localized summaries are subsequently merged by a text-based large language model to generate a single, coherent summary.

ber of clusters (k) was set to 8 based on the analysis in Appendix C. We used MiniCPM-Llama3-V-2.5 as the local summarizer (V_ϕ) and Llama 3.1-8B-Instruct as the global summarizer (L_ω). We used the training set for fine-tuning and the validation set for hyperparameter tuning. All the final results are evaluated on the test set.

Evaluation Metrics. We use ROUGE F1 (R-1/2/L/LSum) scores (Lin, 2004), SacreBLEU (SBLEU; Post, 2018), METEOR (MET; Banerjee and Lavie, 2005), CLIPScore (CLIPS; Hessel et al., 2021), and BERTScore (Zhang et al., 2020) to evaluate the accuracy of all models.

6 Results

Table 3 presents the poster summarization performance of all baselines alongside our proposed SEGMENT & SUMMARIZE method, evaluated on the POSTERSUM test set. Our method outperforms both open-source and closed-source models, achieving the best results across all metrics.

Closed-source Models. GPT-4o achieves relatively high performance among the closed-source models across all metrics, with ROUGE-1/2/L scores of 44.98, 13.12, and 22.30, respectively. Claude-3.5 Sonnet also performs well, attaining a ROUGE-L score of 19.51.

OCR Baselines. The two OCR-based methods, MMOCR and Pytesseract, achieve relatively low scores across all metrics. This is likely due to the limitation of concatenating raw OCR text without leveraging other visual elements. Combining OCR with the text-only Llama-3.1 model results in a substantial improvement, with ROUGE-L increasing from 12.73 to 15.49. Interestingly, these OCR methods still outperform certain multimodal models, indicating that text extraction remains a challenge for some MLLMs.

Open-source Models. Among the open-source MLLMs evaluated in zero-shot settings, MiniCPM-Llama3-V-2.5 obtains the highest ROUGE-1/L score (39.88/20.14) and a strong BERTScore-F1 of 59.22. Meanwhile, mPLUG-DocOwl2 achieves a competitive ROUGE-L of 19.06 and a BERTScore-F1 of 56.99.

Chain of Thought (CoT). Adding an explicit CoT prompt improves the performance of most models. For instance, MiniCPM-Llama3-V-2.5 improves its ROUGE-1/L/METEOR/CLIPScore scores to 41.50/21.04/26.34/25.76, while mPLUG-DocOwl2's performance also increases (ROUGE-1/L of 37.04/19.71). Additionally, LLaVA-NeXT and Qwen2-VL-7B exhibit similar gains. Although the performance boosts are not large, these results suggest that guiding models via CoT prompt can help in extracting relevant poster content.

Fine-tuned Models. Using LoRA substantially boosts performance for both MLLMs. In particular, Llama-3.2-11B-Instruct demonstrates notable improvements in ROUGE, ScareBLEU, and METEOR scores, though it does not surpass the best CoT variants of MPLUG-DOCOWL2 and MINICPM-LLAMA3-V-2.5, which likely benefit from pre-training on multimodal scientific data.

SEGMENT & SUMMARIZE. Our proposed method outperforms all other models, including closed-source models, on all metrics, achieving ROUGE-1/2/L scores of 46.68, 15.73, and 24.18, respectively, with a 3.14% gain on ROUGE-L

Methods	R1	R-2	R-L	Met
Without clustering	42.25	14.30	22.76	23.97
With clustering	46.68	15.73	24.18	30.87

Table 4: Comparison of SEGMENT & SUMMARIZE with and without clustering — clustering the segments yields more accurate results.

Methods	R1	R-2	R-L	Met
mPLUG-DocOwl2	37.04	9.15	19.71	19.6
Ours with DocOwl2	42.48	11.18	20.61	26.72
Ours with MiniCPM	46.68	15.73	24.18	30.87

Table 5: Comparison of using mPLUG-DocOwl2 as local summarize. Applying SEGMENT & SUMMARIZE shows improvement compared to using the model itself.

compared to open-source models. It also attains a substantially higher ScareBLEU score (12.63), BERTScore-F1 of 61.37, and a CLIPScore of 27.63. These results indicate that local-region summaries effectively preserve small details and handle posters of varying complexity by processing each region independently rather than attempting to analyze the entire poster as a single input.

7 Ablation Studies and Analysis

Effect of Clustering on Summarization. To quantify the impact of clustering in our SEGMENT & SUMMARIZE approach, we conduct an ablation study that removes the clustering step. Specifically, we select the top-k segments (with $k = 8$) based on their region size to generate local and global summaries. Table 4 shows that clustering improves the ROUGE-1 score by +4.43, ROUGE-2 by +1.43, and ROUGE-L by +1.42 over the non-clustered baseline. We hypothesize that clustering helps reduce redundant segments and improves context aggregation.

Effect of Local Vision Summarization. To assess the role of the local summarization model in SEGMENT & SUMMARIZE, we replaced MiniCPM-Llama3-V-2.5 with mPLUG-DocOwl2, which previously ranked second among open-source models under the CoT setting. Table 5 shows that using mPLUG-DocOwl2 with our hierarchical approach boosts ROUGE-1 to 42.48 and METEOR to 26.72 compared to using the model in the CoT setting. However, it does not outperform our method using MiniCPM. These findings highlight that the segmentation and summarization approach substantially improves performance compared to using the poster as a single input.

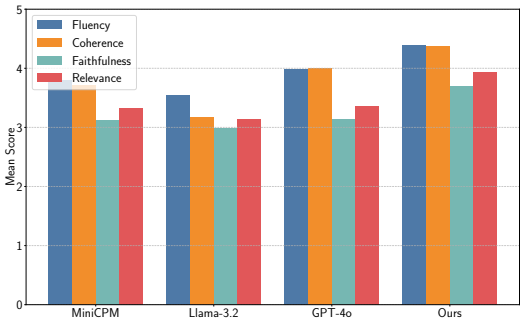

Figure 5: Mean 5-point Likert ratings for Fluency, Coherence, Faithfulness, and Relevance across four methods. SEGMENT & SUMMARIZE (ours) achieves the highest scores across all the dimensions.

Human Evaluation We conducted a human evaluation to compare the quality of summaries generated by our method against the best models in each category (MiniCPM CoT, Llama-3.2-11B-V LoRA, GPT-4o ZS). Forty crowdworkers were recruited via Prolific (all L1 English speakers, master's/doctoral degree holders, and at least 100 previously approved submissions) and compensated at $17/hr. We randomly sampled 40 posters, and participants viewed the poster image, the reference abstract, and one candidate summary, resulting in 160 (4x40) poster–summary evaluations. They rated each summary on 5-point Likert scales for each of four dimensions: **Fluency**, **Coherence**, **Faithfulness**, and **Relevance**. Across all dimensions, SEGMENT & SUMMARIZE received the highest mean ratings (see Figure 5). A one-way ANOVA followed by Tukey's HSD confirmed that SEGMENT & SUMMARIZE significantly outperformed MiniCPM and Llama-3.2-11B-V on every dimension ($p < .01$ for all) and surpassed GPT-4o on Faithfulness and Relevance ($p < .05$). However, differences with GPT-4o in Fluency and Coherence did not reach significance. More statistical details and instructions are available in Appendix E and F.

8 Conclusions

We presented POSTERSUM, a multimodal benchmark for scientific poster summarization comprising 16,305 poster-abstract pairs. Our experiments show that even state-of-the-art MLLMs struggle with key aspects of scientific poster summarization. Furthermore, we propose SEGMENT & SUMMARIZE, a hierarchical approach that outperforms existing models by breaking down the summarization

task into localized segments before generating a cohesive abstract. We find that our method outperforms MLLMs in both zero-shot and fine-tuned settings and that there remains significant room for improvement in multimodal understanding of complex scientific documents such as posters. We believe PosterSum will be a valuable resource for developing and evaluating MLLMs capable of processing information-dense scientific content.

Pasquale Minervini was partially funded by ELIAI (The Edinburgh Laboratory for Integrated Artificial Intelligence), EPSRC (grant no. EP/W002876/1), and a donation from Accenture LLP. This work was supported by the Edinburgh International Data Facility (EIDF) and the Data-Driven Innovation Programme at the University of Edinburgh.

Limitations

While our work advances scientific poster summarization, we should highlight a few limitations. First, our dataset is restricted to machine learning conference posters from 2022 to 2024, which may limit the generalization to other scientific domains. Second, while practical, automated topic labeling using GPT-4o may introduce biases or inaccuracies in the topic distribution. The proposed Segment & Summarize method relies heavily on the quality of the initial segmentation: a suboptimal segmentation can lead to fragmented or redundant local summaries. Our method also assumes that the content can be meaningfully decomposed into spatial regions, which may not hold for posters with complex cross-referencing or interdependent visual elements. We considered the abstract as a ground-truth summary of the poster, but the poster may sometimes differ from the paper.

Ethics Statement

Dataset. All the scientific posters and abstracts in our dataset are sourced from publicly accessible conference resources. Additionally, we sought permission from the conference website contacts to use the publicly available data for research purposes.

Multimodal Large Language Models. This paper utilizes pre-trained multimodal large language models, which have been shown to exhibit various biases, occasionally hallucinate, and generate non-faithful text. Therefore, summaries generated using our dataset should not be released without automatic filtering or manual verification to ensure accuracy and reliability.

Bias. Despite efforts to include a wide range of posters, the dataset may not fully represent the diversity of research poster styles, languages, or scientific disciplines. As a result, models trained on PosterSum may exhibit biases towards the types of posters included in the dataset. Future work should consider expanding the dataset to encompass a broader spectrum of academic fields and visual formats to mitigate potential biases.

A Prompt Templates

Prompt Template for Zero-Shot

Write an abstract for an AI conference paper for the given research poster image.

Prompt Template for CoT

Analyze the research poster image step by step.
First, identify the title and main research problem.
Then, briefly describe the methodology used.
Next, summarize the key findings or results.
Finally, note the conclusion or implications.
Using this information, write an abstract for the given research poster image.

Prompt Template for Local Summary

Describe all the text, tables, figures, and equations in the image.

B Effect of Poster Text Content on Summarization Performance

To investigate whether posters with a high amount of text result in better summarization performance, we analyze the relationship between OCR-extracted text length and ROUGE-L scores using our SEGMENT & SUMMARIZE method. Specifically, we use MMOCR to extract text from each poster and compute its total length in characters (not in tokens).

Fig. 6 presents the mean ROUGE-L scores across different OCR text-length bins. The dotted line represents the number of posters in each text-length bin. We observe that summarization performance tends to improve as the amount of text in poster increases. However, the correlation remains weak (*Pearson* $r = 0.213$, *Spearman* $r = 0.210$), suggesting that text in poster alone is not a strong predictor of summarization quality. Low performance in posters with minimal text also highlights the need for more robust multimodal understanding of figures, charts, equations, and tables.

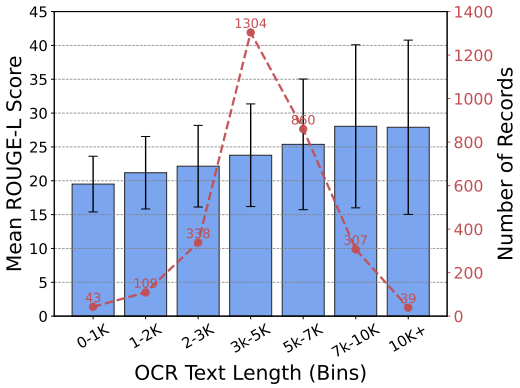

Figure 6: Effect of text present in the poster on summarization. We report mean ROUGE-L scores for different OCR-extracted character-length bins. The red dashed line represents the number of posters in each bin.

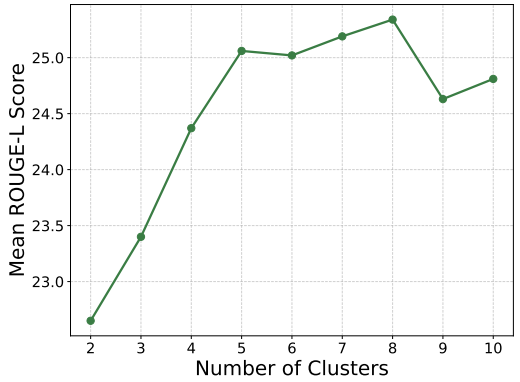

Figure 7: Effect of varying the number of clusters on ROUGE-L performance on SEGMENT & SUMMARIZE

C Selecting the Number of Clusters

To select the number of clusters (k) for our SEGMENT & SUMMARIZE, we conducted an empirical analysis on a subset of 100 posters from the validation set, varying the number of clusters from 2 to 10. Fig. 7 presents the mean ROUGE-L score for each cluster configuration. In these experiments, the local and global summarization components remained fixed.

We observe that the best performance is achieved at $k = 8$ which was used in our final experiments. Additionally, we limit the maximum number of clusters to 10 in the analysis to keep the inference time of our local summarization manageable.

D Additional Experiment Details

Table 6 summarizes the versions of the closed-source models used in our experiments. For fine-tuning, we use a learning rate of 1×10^{-4} with the Adam optimizer ($\beta_1 = 0.9, \beta_2 = 0.999, \epsilon = 1 \times 10^{-8}$) and a cosine learning rate schedule. We

Model	Version
GPT-4o	gpt-4o-2024-08-06
Gemini 2.0	gemini-2.0-flash-exp
Claude 3.5 Sonnet	claude-3-5-sonnet-20241022

Table 6: Details of the closed-sourced models.

employ LoRA with rank $r = 8$, $\alpha = 8$, and a dropout rate of 0.1.

All images are processed and scaled by the respective model's image processor for model specific sizes. In the case of closed-source models, we scale each image to a maximum width of 2048 while preserving the original aspect ratio due to size limitations. All the models were trained using 2 A100 GPU with 80GB memory. We used the Huggingface $evaluate$ library for the implementation of the metrics. Our method's additional wall-clock time per batch is approximately 1.75 seconds for the segmentation and clustering stage and 6.02 seconds for the two stages.

E Human Evaluation Statistical Analysis

Model	Fl	C	Fa	R
MiniCPM (CoT)	3.80	3.72	3.12	3.33
Llama-3.2-11B-V (LoRA)	3.55	3.17	2.98	3.13
GPT-4o (ZS)	3.98	4.00	3.13	3.37
SEGMENT & SUMMARIZE	4.38	4.37	3.70	3.93

Table 7: Mean Likert ratings (1–5) for each model across the four dimensions. Fl: Fluency, C: Coherence, Fa: Faithfulness, R: Relevance

Mean Likert ratings for each model are provided in Table 7. We conducted one-way ANOVAs to assess whether there were statistically significant differences among the models across the four dimensions. The results showed a significant difference across all models:

- **Fluency**: $F = 9.20, p < 0.001$
- **Coherence**: $F = 20.33, p < 0.001$
- **Faithfulness**: $F = 6.27, p = 0.0004$
- **Relevance**: $F = 6.64, p = 0.0003$

To identify the specific differences among the models, Tukey's HSD post-hoc tests were performed for all the dimensions. SEGMENT & SUMMARIZE method significantly outperformed all the models on Faithfulness and Relevance.

- **Faithfulness**: +0.58 vs. MiniCPM (p = 0.007), +0.72 vs. Llama (p=0.0005), +0.57 vs. GPT-4o (p = 0.0098)
- **Relevance**: +0.60 vs. MiniCPM (p=0.009), +0.80 vs. Llama (p=0.0002), +0.57 vs. GPT-4o (p=0.0155)

Against GPT-4o, SEGMENT & SUMMARIZE 's advantages in Fluency (+0.40, p=0.0717) and Coherence (+0.37, p=0.0987) did not reach significance, although it remained significantly higher than MiniCPM and Llama on those dimensions:

- **Fluency**: +0.58 vs. MiniCPM (p=0.0025), +0.83 vs. Llama (p<0.001)
- **Coherence**: +0.65 vs. MiniCPM (p=0.0003), +1.20 vs. Llama (p<0.001)

F Instructions for Human Evaluation

In this task, you will assess the quality of computer-generated summaries of scientific posters by comparing each against the poster and its reference summary. For each trial, you will be shown:

1. Poster Image.
2. Reference Summary.
3. Generated Summary.

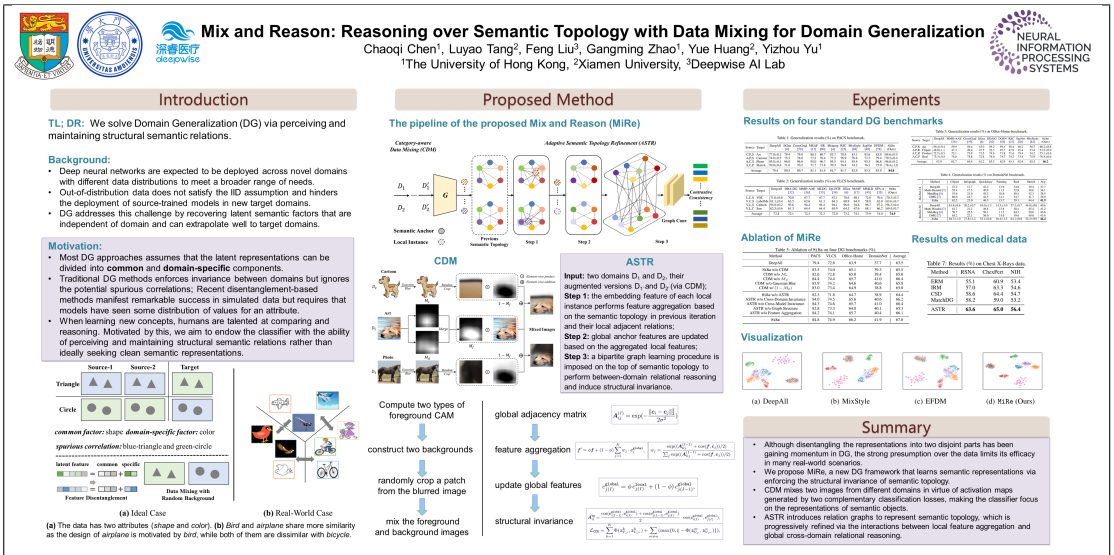
Your task is to rate the Generated Summary on four dimensions using a 5-point Likert scale (1 = Poor, 5 = Excellent).

Dimensions of Evaluation

Fluency This dimension evaluates whether the generated summary is grammatically correct, easy to read, and well-structured.

Coherence This dimension assesses whether the sentences in the generated summary flow logically and maintain a consistent narrative.

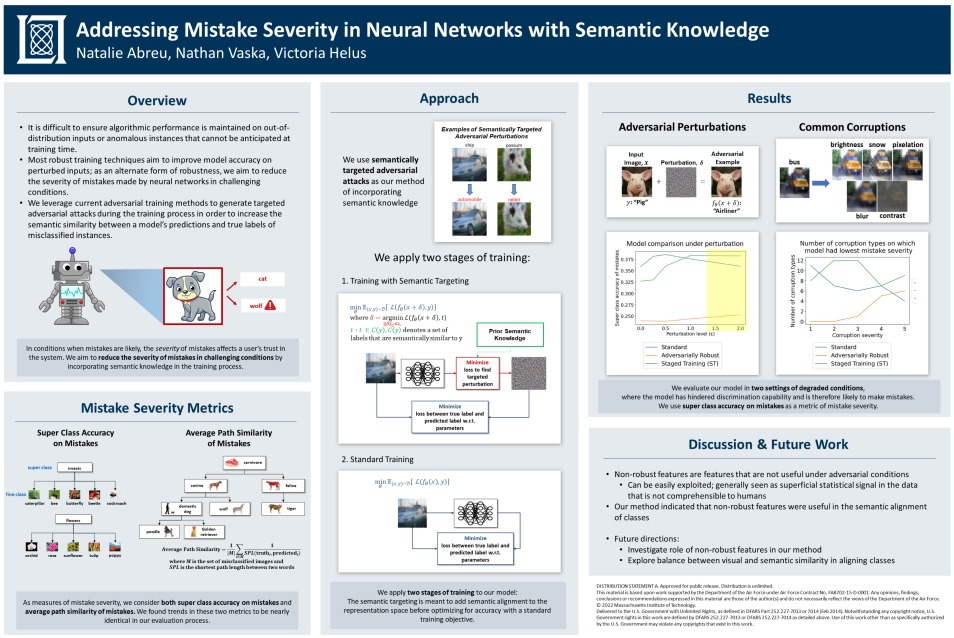
Faithfulness This dimension checks if all the facts presented in the generated summary are accurate and can be directly inferred from the poster image and reference summary.



Relevance This dimension evaluates whether the generated summary includes the key findings and contributions shown in the poster and reference summary, without omitting important information.

Rating Procedure

For each poster–summary pair:



1. View the poster image and reference summary carefully.
2. Read the generated summary in its entirety.
3. Assign a score (1–5) for each of the four dimensions, based only on the definitions above.
4. Minor typos or formatting issues should not lower your score unless they impede understanding.

G Dataset Examples with Model Summaries

Model	Output
Reference	Domain generalization (DG) enables generalizing a learning machine from multiple seen source domains to an unseen target one. The general objective of DG methods is to learn semantic representations that are independent of domain labels, which is theoretically sound but empirically challenged due to the complex mixture of common and domain-specific factors. Although disentangling the representations into two disjoint parts has been gaining momentum in DG, the strong presumption over the data limits its efficacy in many real-world scenarios. In this paper, we propose Mix and Reason (MiRe), a new DG framework that learns semantic representations via enforcing the structural invariance of semantic topology. MiRe consists of two key components, namely, Category-aware Data Mixing (CDM) and Adaptive Semantic Topology Refinement (ASTR). CDM mixes two images from different domains in virtue of activation maps generated by two complementary classification losses, making the classifier focus on the representations of semantic objects. ASTR introduces relation graphs to represent semantic topology, which is progressively refined via the interactions between local feature aggregation and global cross-domain relational reasoning. Experiments on multiple DG benchmarks validate the effectiveness and robustness of the proposed MiRe.
MiniCPM CoT	The paper is about Mix and Reason, a methodology for domain generalization that reasons over semantic topology to mix data from different domains and construct new target domains. It addresses the problem of limited training data by leveraging the IID assumption and the representations learned from the source domain to perform well in the target domain. The proposed methodology involves a pipeline of the proposed Mix and Reason (MiRe) component, which takes the adaptive semantic topology refinement (ASTR) component as its backbone. The key results show that the proposed methodology outperforms state-of-the-art methods on four benchmark datasets, including CelebA, CUB, Stanford 2007, and COCO.
Llama-3.2-11B-V FT	Deep neural networks (DNNs) are expected to be deployed across novel domains. However, out-of-distribution (OOD) data does not satisfy the assumption and hinders DNNs from generalizing well to target domains. In this paper, we propose Mix and Reason (MIRa) for domain generalization (DG) via perceiving and reasoning over semantic topology. Specifically, MIRa divides input common and domain-specific components and captures their potential spurious correlations. Reasoning over semantic topology enables MIRa to disentangle attribute and domain-specific representations and learn domain-invariant representations. Extensive experiments on four standard DG benchmarks show that MIRa achieves state-of-the-art performance. Besides, MIRa can be applied to many DG methods and significantly improve their performance.
GPT-4o	Domain Generalization (DG) for deep neural networks poses a significant challenge in adapting models to varied out-of-distribution data. This paper introduces "Mix and Reason" (MiRe), a novel framework leveraging semantic topology reasoning and data mixing to enhance domain generalization. MiRe employs a two-part approach, utilizing Anchored Semantic Topology Reasoning (ASTR) to retain relational features across domains and Contrastive Data Mixing (CDM) to generate robust feature representations. Experiments were conducted on four standard DG benchmarks, demonstrating substantial improvements in model adaptability and performance. Additionally, results on medical datasets underscore the frameworkś efficacy in maintaining domain-invariant characteristics across diverse conditions. This research highlights the strength of integrating semantic relationships with innovative data augmentation techniques, offering a scalable solution for realistic multi-domain scenarios.
SEGMENT & SUMMARIZE	Domain Generalization (DG) is a critical challenge in machine learning, where models are expected to generalize well across novel domains with different data distributions. Existing DG methods often rely on strong assumptions about the data or ignore potential spurious correlations. In this work, we propose a novel DG framework, Mix and Reason (MiRe), which learns semantic representations by enforcing the structural invariance of semantic topology. MiRe consists of two key components: Category-Aware Data Mixing (CDM) and Adaptive Logic Semantic Topology Refinement (ASTR). CDM mixes two images from different domains using activation maps generated by complementary classification losses, focusing the classifier on semantic object representations. ASTR introduces relation graphs to represent semantic topology, which is progressively refined via interactions between local feature aggregation and global cross-domain relational reasoning. We evaluate MiRe on four standard DG benchmarks and medical data, achieving state-of-the-art performance and outperforming existing methods. Our results demonstrate the effectiveness of MiRe in handling domain shifts and provide insights into how to better perceive and maintain structural semantic relations in machine learning.

Table 8: Sample of poster image from Chen et al. (2022) with gold reference and model generated summaries

Model	Output
Reference	Robustness in deep neural networks and machine learning algorithms in general is an open research challenge. In particular, it is difficult to ensure algorithmic performance is maintained on out-of-distribution inputs or anomalous instances that cannot be anticipated at training time. Embodied agents will be deployed in these conditions, and are likely to make incorrect predictions. An agent will be viewed as untrustworthy unless it can maintain its performance in dynamic environments. Most robust training techniques aim to improve model accuracy on perturbed inputs; as an alternate form of robustness, we aim to reduce the severity of mistakes made by neural networks in challenging conditions. We leverage current adversarial training methods to generate targeted adversarial attacks during the training process in order to increase the semantic similarity between a model's predictions and true labels of misclassified instances. Results demonstrate that our approach performs better with respect to mistake severity compared to standard and adversarially trained models. We also find an intriguing role that non-robust features play with regards to semantic similarity.
MiniCPM CoT	The paper is about the problem of mistake severity in neural networks and the use of semantic knowledge to address it. The research problem is the inability of neural networks to accurately predict the severity of mistakes, leading to poor model accuracy. The methodology involves incorporating semantic knowledge into the training process to generate targeted adversarial attacks. The key results show that using semantic knowledge to guide the attacks leads to better model accuracy and improved performance on benchmarks. The conclusion suggests that the use of semantic knowledge is a promising approach to addressing the problem of mistake severity in neural networks.
Llama-3.2-11B-V FT	It is difficult to ensure algorithmic performance is maintained at out-of-distribution (OOD) training time for neural networks due to the presence of perturbed inputs. An alternate form of robustness, we aim to reduce the conditions in which mistakes are made by neural networks. We leverage semantic similarity between a model's predictions and labels of OOD data as a measure of mistake severity. We propose a two-stage training method that generates targeted perturbations of semantic similarity between a model's predictions and true labels of OOD data. Our experiments show that our method improves upon state-of-the-art methods in aligning class similarity between a model's predictions and true labels of OOD data. Our code is available at https://github.com/natale-abreu/semi-targeted-adversarial-training.git.
GPT-4o	This paper addresses the challenge of reducing mistake severity in neural networks under adversarial and anomalous conditions by incorporating semantic knowledge into the training process. Traditional robust training techniques typically focus on improving model accuracy on perturbed inputs, but often overlook the semantic alignment between model predictions and true labels. We propose a novel method utilizing semantically targeted adversarial attacks to train neural networks, aiming to enhance semantic similarity and reduce the impact of severe errors.Our approach encompasses a two-stage training process: firstly integrating semantic knowledge through targeted adversarial perturbations, followed by standard training protocols. The methodology was tested using metrics such as super class accuracy on mistakes and average path similarity of mistakes, which measure semantic closeness between mistaken and true labels. This research highlights the value of non-robust features in capturing semantic alignments and suggests future exploration into balancing visual and semantic similarities for enhanced model reliability.
SEGMENT & SUMMARIZE	Ensuring algorithmic performance on out-of-distribution inputs or anomalous instances is a significant challenge in neural networks. Traditional robust training techniques focus on improving model accuracy on perturbed inputs, whereas we propose an alternate form of robustness by reducing the severity of mistakes made by neural networks in challenging conditions. We leverage current adversarial training methods to generate targeted adversarial attacks during the training process, increasing the semantic similarity between a model's predictions and true labels of misclassified instances. Our approach involves two stages of training: Semantic Targeting and Prior Semantic Knowledge. We demonstrate that by incorporating semantic knowledge in the training process, we can reduce the severity of mistakes in challenging conditions, thereby improving user trust in the system. Our results show that the proposed method outperforms traditional robust training techniques in terms of reducing mistake severity, making it a promising approach for addressing mistake severity in neural networks.

Abstract

Self-attention mechanisms have become foundational across modern deep learning architectures. Recent efforts focus on improving their efficiency, particularly for signal processing tasks. The existing approaches employ complex-valued representations for inputs and weights and achieve higher accuracy at the cost of increased model size and inference latency. Dual-numbered algebra offers a promising alternative that allows efficient multiplication and faster inference with the same representational capacity. Inspired by previous studies in the field of hypercomplex neural networks, we introduce a generalized hypercomplex attention block and integrate it into Transformer-based models for EEG classification. Our experiments include adaptation of the hypercomplex models, so that the number of parameters is equal to that of their real-valued counterparts. Across all scenarios, the dual- and complex-numbered models consistently outperform the real ones, demonstrating superior accuracy. This work presents hypercomplex attention as a competitive and computationally efficient strategy with potential value to solve multiple NLP tasks.

1 Introduction

Complex numbers inevitably appear in signal processing and time series tasks, since Fourier Transform (FFT) is the most common way of operating with signal sequences. This type of numbers allows to describe the full picture of the signal, which is comprised of both time and frequency representation. The nature of input values encourages researchers to use complex-valued neural networks in speech enhancement [Zhao et al., 2021b; Hu et al., 2020], seismic interpretation [Dramsch et al., 2021], radar velocity estimation [Cho et al., 2021] and MusicNet [Yang et al., 2020] tasks.

Attention is an ultimate mechanism that allows neural networks to focus on any parts of the input, emphasizing its specific ones that are the most relevant to the task at hand. Nowadays, multiple works concentrate their efforts on improving the efficiency of attention. There are several works dedicated to extension of transformers to the complex domain that obtain promising results in the field of sequence processing [Yang et al., 2020; Tay et al., 2020; Zhang et al., 2021; Li et al., 2023]. Developing of complex-valued transformers is crucial because usually speech, signal and audio data are naturally complex-valued through Fourier Transform. The main reason for performance improvement provided by transition to complex numbers is that we can capture more information from the input data, including the phase component.

Despite all the advantages, complex-valued neural networks are more than 4 times slower compared to the corresponding real-valued models with the same architecture, due to the increased computational complexity required by complex-valued arithmetic operations. We define a complex linear operator as a matrix multiplication of a complex multi-dimensional tensor $c = x + iy$ and a complex weight matrix $W = A+iB$ with an additional complex-valued bias $z = a + ib$, which can be expressed as the following:

$$cW + z = (x + iy)(A + iB) + (a + ib) = \\ = (xA - yB + a) + i(yA + xB + b)$$

To reduce the computational overhead and save the two-component nature of complex numbers, we turn to dual numbers. They are a special kind of numbers, which can be written as $z = x + \varepsilon y$, where $x, y \in \mathbb{R}$, and ε is a nilpotent element, which satisfies the conditions $\varepsilon^2 = 0$ and $\varepsilon \neq 0$. A dual linear layer computes a product of a dual vector $d = x+\varepsilon y$ and a dual weight matrix $W = A+\varepsilon B$ with an additional bias $k = a + \varepsilon b$ as follows:

$$dW + k = (xA + a) + \varepsilon(yA + xB + b)$$

The dual-valued multiplication requires fewer real-valued multiplications than the complex one. So, replacement of complex operators with the corresponding dual ones theoretically provides a 25% inference time improvement. The definition and applications of dual convolutional neural networks were presented in [Kozlov et al., 2022; Pavlov et al., 2023]. In this research, we focus on second-order hypercomplex numbers and introduce a novel self-attention block, referred to as hypercomplex attention. Our proposed block processes inputs with dual or complex values.

In the original attention mechanism [Vaswani et al., 2023] the SoftMax function is used to normalize the output probabilities and to emphasize the highest attention scores, thus stimulating the model to focus on the most relevant elements of the input sequence. Here, we study some extensions of SoftMax to the dual and complex domains with similar properties and find out that Component-wise SoftMax show good results.

2 Related work

2.1 Complex-valued neural networks

Multiple researches show promising results of using complex-valued models, such as faster learning [Arjovsky et al., 2015] and larger representational capacity [Nitta, 2003], comparing with the real-valued networks. Most of the existing models and real-valued layers were extended to the scope of complex-valued numbers. Basic operators for convolutional, fully-connected, and LSTM complex-valued architectures are defined in [Trabelsi et al., 2018]. The implementation of complex-valued transformers is mentioned in [Wang et al., 2020], but the article is focused on comparing ways of encoding text into complex-valued tokens. In [Yang et al., 2020], the authors offer a complex-valued model for the automatic music transcription task.

Complex numbers and quaternions are also used for high-level compression of deep learning models ($\times 2$ and $\times 4$) by exploiting the matrix representation of these hypercomplex spaces, achieving comparable performance for NLP [Zhang et al., 2021; Tay et al., 2020].

2.2 Dual-valued neural networks

The idea to use dual numbers in deep learning was introduced in [Okawa and Nitta, 2021]. The building blocks needed to construct dual-valued convolutional neural networks were presented in [Kozlov et al., 2022]. It includes the definitions of Linear, Convolution, Average Pooling, ReLU layers in the dual domain. In addition, [Kozlov et al., 2022] contains an algorithm for dual-valued Batch Normalization. The authors of [Kozlov et al., 2023] selected a subclass of dual-valued operators, which satisfy the equivalent of the Cauchy-Riemann equations for the dual domain.

To the best of our knowledge, we are the first researchers who propose to use dual numbers in the attention layer.

3 Definition of hypercomplex attention

3.1 Hypercomplex input

In all of our experiments we use FFT before the hypercomplex attention layers. FFT converts the input into a complex spectrogram, which has real and imaginary parts. Dual numbers, just like complex ones, are two-component. This property makes it possible to treat the spectrogram as dual-valued data and feed them into the dual-valued attention.

We use an additional dimension to represent the hypercomplex input, which is stored as real-valued tensors:

$$Z = X + \tau Y \in \mathbb{H}^{b \times s \times d} => \\ Z = [X, Y] \in \mathbb{R}^{2 \times b \times s \times d},$$

where the first dimension is used to denote the real or the imaginary part, $\tau = \varepsilon$ or $\tau = i$ correspondingly, b is the batch size, s is the length of a token sequence, d is the dimension of a token vector, $\mathbb{H}$ is the notation of Hypercomplex numbers.

3.2 Hypercomplex attention block

Creating the hypercomplex attention mechanism requires two steps: developing a method for representing matrix multiplication of weights and to design a hypercomplex polarization function. The SoftMax is used as a polarization function in the real-valued attention, but we show below in this section that it is not suitable for the hypercomplex algebra.

Previous studies have identified the approach to forming the complex-valued attention layer with complex weights [Zhao and Ma, 2023].

We define the Hypercomplex attention for a model with complex-valued or dual-valued weights

$W_{\{Q,K,V\}} = W_{\{Q,K,V\}_r} + \tau W_{\{Q,K,V\}_d} \in \mathbb{H}$ as:

$$f[QK^T]V = f[((X + \tau Y)(W_{Q_r} + \tau W_{Q_d}))$$
$$((X + \tau Y)(W_{Kr} + \tau W_{Kd}))^T]$$
$$((X + \tau Y)(W_{Vr} + \tau W_{Vd}))$$

Figure 1 presents the hypercomplex attention mechanism, implemented with hypercomplex weight matrix.

One of the essential elements of Transformer architecture is SoftMax operator. It serves the purpose of emphasizing the closest matches between the rows of Query and Key matrices. In the domain of real numbers the SoftMax function is defined as:

$$(SoftMax(x))_k = \frac{e^{x_k}}{\sum_{j=1}^{n} e^{x_j}},\ k \in \{1, 2, ..., n\} \tag{1}$$

However, this definition is hardly scalable beyond the field of real numbers. In the case of complex numbers it is not well-defined because, unlike for the real-valued domain, the sum of exponents in the denominator can be too close to zero. For example, $e^{i\pi} + e^0 = -1 + 1 = 0$. For the domain of dual numbers this problem does not exist. However, there is a different issue with definition (1). The exponent of a given number $x + \varepsilon y$ can be derived using the Taylor series formula:

$$e^{x+\varepsilon y} = e^x \cdot e^{\varepsilon y} = e^x \cdot \sum_{j=0}^{\infty} \frac{(\varepsilon y)^j}{j!} = \tag{2}$$
$$= e^x \cdot (1 + \varepsilon y) = e^x + \varepsilon y e^x$$

One can see that the real part of the sum of exponents can never be equal to zero, and this is enough to be able to divide over it:

$$\frac{x_1 + \varepsilon y_1}{x_2 + \varepsilon y_2} = \frac{(x_1 + \varepsilon y_1)(x_2 - \varepsilon y_2)}{(x_2 + \varepsilon y_2)(x_2 - \varepsilon y_2)} =$$
$$= \frac{x_1}{x_2} + \varepsilon \frac{x_2 y_1 - x_1 y_2}{x_2^2},\ \ x_2 \neq 0$$

Therefore, (1) is well-defined for dual numbers. However, from (2) it is clear that this definition only emphasizes the real component of the input vector, effectively making the imaginary part negligible. At the same time, that part is responsible for storing the information about signal frequency, which is very important. That is why in this paper we consider other approaches to the definition of the hypercomplex polarization function. We look for possible ways of highlighting important text parts that employ both components of a hypercomplex number. As a result, we suggest the following methods:

- $ScaleMax = \frac{Re(X) - min(Re(X))}{max(Re(X)) - min(Re(X))} + \tau \frac{Im(X) - min(Im(X))}{max(Im(X)) - min(Im(X))}$, where $\tau = i$ or $\tau = \varepsilon$.
- $Component\text{-}wise\ SoftMax = SoftMax(Re(X)) + \tau SoftMax(Im(X))$, where $\tau = i$ or $\tau = \varepsilon$.
- $NormMax = \frac{X^2}{\sum X^2}$, where X is complex or dual norm.

3.3 Hypercomplex Conformer architecture

Convolutional neural networks or transformers are typical solutions to a task of decoding electroencephalograph (EEG) data. However, as the authors of [Song et al., 2023] claim, with this approach the model is able to encapsulate either local or global features but not both, thereby missing some dependencies. To improve this, a Convolutional Transformer architecture called the EEG Conformer was proposed. This architecture is capable of performing efficient classification of EEG data. The model takes EEG signals as input. The result is the likelihood of belonging of the signal to each of the EEG categories. We plug the hypercomplex blocks (Figure 2) in place of their real-valued equivalents into the original Conformer architecture, because they are able to capture more information from the signal data and learn temporal-spatial features more efficiently. The most suitable and natural representation of signal data for complex and dual networks is its representation in the amplitude-frequency domain, which is easily obtained by FFT.

In order to evaluate the effectiveness of Conformer model with hypercomplex attention, two different public EEG datasets were used: BCI competition IV 2a [Brunner et al., 2008] and BCI competition IV 2b [Leeb et al., 2008].

We trained Conformer with hypercomplex attention using the same learning procedure as for the original solution [Song et al., 2023]. An important change is to halve the number of encoder blocks so our model has approximately the same number of parameters as the real-valued one (Table 1). It is worth noting that the inference time of these models also turned out to be almost the same. This similarity in inference time is explained by several factors, which do not allow to observe the maximum theoretical speedup in practice. The limit of 25% theoretical inference speedup is based on replacing complex-number operations with dual-number arithmetic. While both formats contain

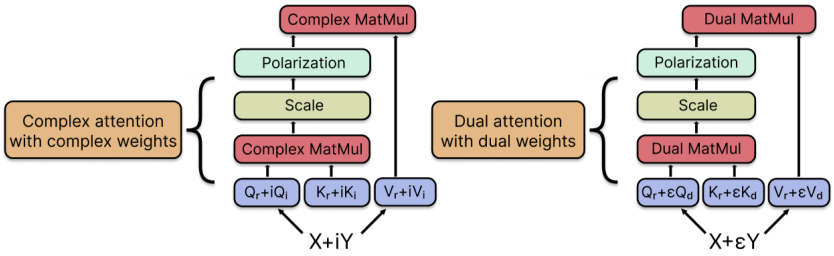

Figure 1: Hypercomplex attention

two components, dual numbers are algebraically simpler. For example, complex multiplication typically involves 4 real-valued multiplications (and 2 real-valued summations/subtractions), whereas dual multiplication is computationally equivalent to only 3 multiplications (and 1 summation). In attention and SoftMax mechanisms, this simplification translates to approximately 25% fewer arithmetic operations per linear layer. However, the actual gain depends on how much the linear operators take compared to the whole computation graph. In Conformer model the linear layers are not the only consumers of computational power, that is why the total gain is less than 25%. Besides, in PyTorch dual-valued tensors are treated as pairs of regular tensors, and their operations are executed using standard vectorized routines. To unlock the full speedup, a dedicated low-level kernel optimized for dual-numbered operations should be implemented. This kernel would directly encode dual arithmetic—such as component-wise summation, matrix multiplication, and SoftMax—without relying on high-level abstractions. By integrating this kernel it will be possible to achieve the full theoretical efficiency in practice.

Table 4 demonstrates the results of experiments with different polarization types for models with hypercomplex attention. The best accuracy value can be achieved using the Component-wise Softmax function on the BCI competition IV 2a and the BCI competition IV 2b datasets. In EEG signal processing, the real part typically encodes amplitude, while the imaginary part captures frequency characteristics, such as those derived via Fourier transform. Neglecting the imaginary part—as in naive extension of the traditional SoftMax to dual numbers — results in loss of frequency information, reducing the model's ability to distinguish patterns like alpha or beta rhythms. Component-wise SoftMax addresses this by applying SoftMax independently to the real and imaginary parts. The real part yields amplitude-based weights, while the imaginary part captures frequency-related contributions. This preserves the hypercomplex structure and minimizes loss of information. In contrast, ScaleMax normalizes by min-max range without exponential weighting, losing probabilistic sharpness. NormMax reduces to squared norm, which emphasizes energy but discards distributional detail. In Transformer architectures, attention weights are computed via SoftMax. The component-wise variant enables simultaneous modeling of amplitude and frequency in multidimensional space, improving the ability to capture long-range dependencies in time-series data like EEG. Theoretically, this relates to the entropy:

$$H = -\sum_k p_k \log p_k$$

the standard SoftMax yields entropy over the real part, but incorporating the imaginary component reduces effective entropy, allowing sharper focus on frequency-dependent features-explaining the observed accuracy gains.

In Table 2 we compare our proposed model with multiple neural networks of different architectures: convolution-based (ConvNet [Schirrmeister, 2017], EEGNet [Lawhern et al., 2018]), FBCNet [Mane, 2021] spatial data filtering, DRDA [Zhao et al., 2021a] and others.

We can observe that the average accuracy of our Conformer model with the complex-valued attention is 1.2% higher than that of Conformer with the real-valued one and 5% higher than the average accuracy of the convolution-based models. Moreover, the model with dual-valued attention achieves the average accuracy, which is by 0.2% even higher.

The average accuracy of Conformer with the complex-valued attention on BCI Competition IV Dataset 2b (Table 3) is 2.1% higher than that of Conformer with the real-valued one; our model exceeds other methods in accuracy for almost all

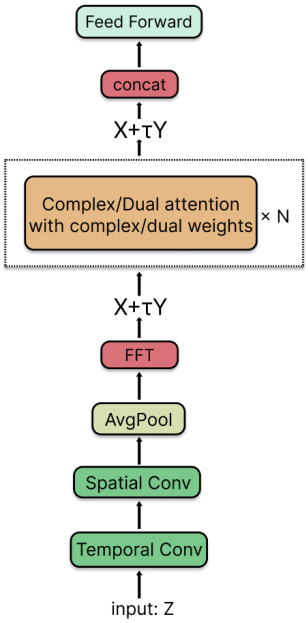

Figure 2: The architecture of Conformer with hypercomplex-valued attention.

the subjects. The model with the dual-valued attention also surpasses all the others, achieving a new state-of-the-art accuracy value of 87%.

4 Conclusion

In this study, we generalize the Transformer architecture to the algebra of dual and complex numbers. Specifically, we suggest and implement a new hypercompex attention mechanism. Then we integrate it into Transformer model, that we designed for the EEG classification task. We compare accuracy of the models with the hypercomplex attention against the value of the same metric shown by the corresponding models with the traditional real-valued attention with the same number of parameters.

Then, we built the novel type of hypercomplex attention mechanism into Conformer - a specific Transformer-based model architecture. Our experiments show that on BCI_competition_IV2a dataset our Conformer model overcomes the state-of-the-art real-valued network by 1.2% in accuracy metric for complex algebra and 1.4% for dual algebra. On BCI_competition_IV2b dataset the model with the complex-valued Attention surpasses the real-valued one by 2.1% in accuracy. At the same time, Conformer with the dual-valued Attention reaches the state-of-the-art metrics value on this dataset.

Novel hypercomplex polarization functions are designed, revealing that for Conformer models with hypercomplex attention the best accuracy value can be achieved using the Component-wise Softmax function.

We conclude that extending self-attention mechanism to the space of hypercomplex numbers within the same model's architecture proves its efficiency, since it leads to better metrics than the original network.

5 Limitations

The discussion of hypercomplex transformers in this study is limited to the Conformer model applied to the EEG signal classification task. Although promising preliminary results were obtained, the proposed method has not yet been tested across diverse domains or alternative architectures.

As part of the further research, we intend to extend the developed hypercomplex attention mechanism for solving other tasks by integrating it into a wide variety of models, including modern LLMs. We expect to achieve improvements in quality metrics, such as accuracy, perplexity, and others.

Abstract

Translating natural language requirements into Signal Temporal Logic (STL) is essential for safety-critical systems but requires mathematical expertise. We propose a translational grammar mapping Universal Dependencies (UD) structures to STL Operators through 17 theoretically-motivated patterns, evaluated on the NL2TL benchmarking dataset of 7,002 expert-annotated sentence-STL pairs, and an additional cross-domain analysis. We built a parser guided by this grammar to explore the formal deterministic relationship between UDR Compositions and STL Operators, achieving ∼99% sentence coverage, ∼54% exact matches (and ∼97% similarity). Sentence-level regression analyses predict STL statements and STL Operator classes, considering the co-occurance of UDR substructures (UDR components) with an accuracy of more than ∼74% and ∼81%, respectively. They uncover a new logical grammatical link between temporal NL and formal logic, that is conditioned by the sentence-level context, and provide insights into how linguistic theory unfolds in practice through temporal linguistic expressions.

1 Introduction

Formal specifications in temporal logic are essential for verifying safety-critical systems, synthesizing correct-by-construction controllers, and defining precise requirements for autonomous agents. However, understanding how natural language (NL) temporal expressions systematically correspond to formal temporal logic operators of artificial languages like Linear Temporal Logic (LTL) or Signal Temporal Logic (STL) raises fundamental questions for computational linguistics (Maler and Nickovic, 2004; Sistla and Clarke, 1985). Consider a seemingly simple requirement: *"For each moment within the first 2 to 46 time units, the signal must consistently stay above 8.9."* Translating this requires understanding that "*for each moment*" maps to a global operator ($\mathcal{G}$), "within the first 2 to 46 time units" defines temporal interval $[2, 46]$, and "*consistently stay*" reinforces universal quantification, yielding $\mathcal{G}_{[2,46]}(\mathit{signal} \geq 8.9)$. This challenge has motivated emerging research in recent NLP research: Researchers fine-tune LLMs or train new translation models (e.g. DeepSTL (He et al., 2022), NL2TL (Chen et al., 2023), GraFT (English et al., 2025)) to translate NL to STL accurately. However, these approaches provide insufficient insight into how syntactic structures of NL systematically encode temporal logic operators of artificial languages like STL, leaving the fundamental linguistic mechanisms unexplained.

In this paper, we argue that Universal Dependencies (UD) (De Marneffe et al., 2021; Nivre, 2020) enable a systematic mapping between natural language and temporal logic operators of LTL or STL. Specifically, we ask: *Is there a relationship between UDR components and STL Operator composition?* Rather than developing another system for NL-STL Translation, we propose and empirically investigate a translational grammar that maps a set of "UDR Compositions" to Signal Temporal Logic, leveraging universal grammatical principles. UDR Compositions combine UD syntax substructures (such as the adverbial modifiers "*always*", "*eventually*", and "*not*") and associated semantics (e.g., temporal words associated with certain structures) to capture the building blocks that constitute temporal structures in natural language.

Our investigation focuses on empirically identifying and analyzing this grammar to enhance our understanding of how the structural theory of UDR for natural language relates to STL. Our paper makes two unique contributions:

First, we introduce a *new grammar* that defines a (probabilistic) relationship between UDR Compositions and STL Operators. We introduce 17 theoretically-motivated Universal Dependency Relationship Compositions ("*UDR Composition(s)*")

Proceedings of the 14th International Joint Conference on Natural Language Processing and the 4th Conference of the Asia-Pacific Chapter of the Association for Computational Linguistics, pages 1852–1866
December 20-24, 2025 ©2025 Association for Computational Linguistics

defined independently based on UD syntactic theory, ranging from single-relation Compositions signaling operator categories to multi-relation configurations indicating specific operators. We programmed a parser to automatically extract these UDR Compositions and map them to STL Operators.

Second, we empirically examine this translational grammar based on two datasets, namely the `circuit_total_refined` dataset with 7,002 NL-STL pairs used in prior research (He et al., 2022; Chen et al., 2023) and 100 handcrafted natural language sentence-STL pairs from the TimeBank 1.2 Corpus (referred to as "*NL2TL*" "*TimeBank 1.2*" and in this paper)(Pustejovsky et al., 2003, 2006). In a first step, we examined our grammar assuming a rule-based deterministic mapping between UDR Compositions and STL Operators, using a rule-based parser, with an exact match translation of 53.84% into full STL sentences, and an average similarity of complete STL statements of 96.70% [1]. In addition, we performed sentence-level statistical analysis to examine how the seventeen core UDR Compositions predict and explain the STL Operators, as well as complete STL statements, considering the co-occurrence of UDR-Cs in a sentence. Logistic regression achieved an accuracy of ∼74.3% accuracy in translating UDR Compositions into complete STL statements. Additional multinomial logistic regression mapped 17 UDR Compositions into 10 STL Operators classes, and successfully predicted STL Operators with an accuracy of about ∼81% confirming a probabilistic relationship between multiple syntax substructures in predicting STL, caused by variability in language expression. For example, certain syntactic substructures like the UDR Composition "*Conjunction*" (∧) increase prediction accuracy as they are used in multiple contexts, and with different meanings to express temporality.

Our research has important implications for future research at the intersection of linguistic theory as well as deep-learning-inspired NLP. It sets the foundation for new theory-guided research on the nature of temporal language expression, and also guides future research on grammar-inspired NL-STL translation in the realm of GraFT (English et al., 2025).

[1]Here we assumed a 1:1 relationship between UDR Compositions and complete STL statements

2 Theoretical Foundations

2.1 Signal Temporal Logic

Signal Temporal Logic (STL) serves as the formal target language for temporal specifications in cyber-physical systems. Formally, STL extends First Order Logic, which itself extends propositional logic with quantifiers and predicates, by introducing temporal operators that quantify over bounded dense-time intervals. This extension accommodates real-valued signals and continuous-time dynamics, enabling the mathematical precision required for verification of safety-critical systems while addressing quantitative constraints ubiquitous in real-world applications (Donze et al., 2013; Maler and Nickovic, 2004). The bounded temporal operators with explicit time windows address a fundamental limitation of classical temporal logics when applied to systems with strict timing requirements. STL formulas follow the grammar:

$$\phi ::= \pi^{\mu} \mid \neg\phi \mid \phi_1 \wedge \phi_2 \mid \phi_1 \vee \phi_2 \mid \mathcal{F}_{[a,b]}\phi \mid \mathcal{G}_{[a,b]}\phi \mid \phi_1 \mathcal{U}_{[a,b]}\phi_2 \quad (1)$$

where π^{μ} represents atomic predicates ($x \sim \mu$), ϕ denotes STL formulas, and $[a, b]$ specifies time intervals. The temporal operators $\mathcal{F}_{[a,b]}$ (Eventually), $\mathcal{G}_{[a,b]}$ (Always), and $\mathcal{U}_{[a,b]}$ (Until) quantify over time intervals, with Boolean connectives preserving their classical semantics (Maler and Nickovic, 2004). Complete formal definitions appear in Appendix A.1.

2.2 Universal Dependencies

Universal Dependencies (De Marneffe et al., 2021; Nivre et al., 2016), grounded in Tesnière's dependency grammar theory (1959), developed to formally describe syntactic structures of natural language. It represents syntax as directed graphs $G = (V, E, \ell)$ with word nodes V, dependency edges E, and labels $\ell : E \to R$ from 37 universal relations. Dependency patterns $P = (r, h, d, C)$ consist of relation r, head/dependent constraints h/d, and contextual constraints C, matching edges when all constraints are satisfied. Complete formal definitions are provided in Appendix A.1.

2.3 Translational Grammar: UDR Composition to STL Operators

We propose seventeen patterns (Table 1) that provide comprehensive STL coverage for cyber-physical system specifications. Each pattern consists of two key components:

the *UDR Composition* specifies the precise syntactic structure using Universal Dependencies relations (e.g., `advmod("always")`, `mark("if")+advcl+mark("then")`) that triggers pattern detection in natural language text, whereas the *STL Operator* defines the formal symbolic representation (e.g., G, F, U, $\rightarrow$) used in the resulting temporal logic formula. This distinction enables systematic mapping from linguistic surface forms to formal Signal Temporal Logic representations through dependency parsing. These patterns, selected through theoretical analysis of STL Operators (Maler and Nickovic, 2004) and empirical validation showing over 90% coverage (Chen et al., 2023), systematically map Universal Dependencies to STL, demonstrating that dependency structures encode temporal semantics at multiple levels of abstraction, from atomic temporal operators to propositional-level and hierarchical formula compositions: `advmod` relations encode temporal quantification (Pattern Nos. 1, 2, 6, 7, 8), `mark+nummod` capture bounded constraints (Pattern Nos. 10, 11, 12, 13), lexical patterns identify state transitions (Pattern Nos. 9, 13, 14, 15, 16, 17), and logical relationships (Pattern Nos. 4, 5, 6).

No.	Pattern Name	UDR Composition	STL Op.
1	Always	advmod("always")	$\mathcal{G}$
2	Eventually	advmod("eventually")	$\mathcal{F}$
3	Until	mark("until")+advcl	$\mathcal{U}$
4	Conjunction	cc("and")+conj	$\wedge$
5	Disjunction	cc("or")+conj	$\vee$
6	Propositional Negation	advmod("not")	$\neg$
7	Negated Always	advmod("never")	$\neg\mathcal{G}$
8	If-Then Implication	mark("if")+advmod("then")	$\rightarrow$
9	Become/Change Rise	compound("become"/"change")	$\uparrow \phi$
10	Bounded After	mark("after")+nummod	$\mathcal{F}_{[k,\infty]}$
11	Bounded For	mark("for")+nummod	$\mathcal{G}_{[0,k]}$
12	Bounded Within	mark("within")+nummod	$\mathcal{F}_{[0,k]}$
13	When First Rise	mark("when")+advmod("first")	$\uparrow \phi$
14	Universal Quantification	det(specifications, "all")+nsubj(hold)	$\forall\varphi_i$
15	Existential Quantification	det(constraint, "a")+acl:relcl	$\exists\varphi_j$
16	Conditional Formula Selection	advcl(apply, holds)+mark("if")	ctx $\Rightarrow \varphi_i$
17	Specification Conjunction	obj(require, both)+nsubj(system)	$\bigwedge_i \varphi_i$

Table 1: Systematic correspondences between UDR Compositions and STL Operators.

The patterns exploit systematic correspondences between linguistic quantification and temporal logic. Determiners (*any*, *every*) parallel universal quantification ($\mathbf{G}$), while indefinites map to existential quantification ($\mathbf{F}$) (Barwise and Cooper, 1981). Temporal adverbs directly lexicalize quantifiers, prepositional phrases with numerals encode metric constraints, and subordinating conjunctions establish temporal ordering (Partee, 1984). The Until operator's dual requirements, eventual satisfaction and continuous maintenance, mirror adverbial clause structures that demonstrate how syntactic subordination encodes semantic scope (Emerson and Halpern, 1983).

Pattern design leverages formal semantic principles: negation duality ($\neg\mathbf{G}_{[a,b]}\phi \equiv \mathbf{F}_{[a,b]}\neg\phi$) motivates Pattern No. 7's *never* encoding (Horn, 2001); material conditional correspondence justifies Pattern No. 8's if-then mapping (Kratzer, 1991); and edge operators ($\uparrow \phi \equiv \neg\phi\mathbf{U}\phi$) capture state transitions through inchoative/cessative predicates (Dowty, 1979). This compositional approach aligns with natural language semantics (Montague, 1973), where patterns serve as atomic operations combining per STL formation rules, preserving interpretability, which is essential for verification tasks (Konrad and Cheng, 2005).

3 Methodology

We used SpaCy 3.8.7 (Honnibal and Montani, 2017) to develop a Universal Dependencies parser and extract binary features for 17 theoretically motivated Universal Dependency Construction Classes (Table 1), along with 10 distinct STL Operator classes, as well as full STL Statements. To examine the quality of our parser, we implement a manual accuracy check on a 2% subsample of NL2TL and the 100 sentences from TimeBank 1.2 (see tables 7 and 17 in Annex for this). We used this parser to examine a deterministic 1:1 relationship between UDR Compositions and STL Operators, along with an exact STL statement. We evaluate the NL-STL translation based on exact matches (string-edit distance of 0 or 1), and similarity scores based on regex pattern matching (Chapman and Stolee, 2016).

To examine the relationship between UDR Compositions and STL Operators, we performed a binary true/false sentence-level (N = 7,002 sentences, 80/20 train-test split) logistic regression (Nick and Campbell, 2007), focused on UDR to complete STL statements, followed by a sentence-level multinomial (N = 7,002 sentences, 80/20 train-test split) logistic regression (Long, 1997) to examine the UDR Composition-STL Operator relationships considering multiple UDR Components jointly in a sentence. We used the Scikit-learn library and implemented the regression with the `lbfgs` solver and regularization (Lee et al., 2006; Minka, 2003; Moritz et al., 2016; Pedregosa et al., 2011). We report both the coefficients and odds ratios to discuss the importance of different UDR Components for predicting STL sentence, as

well as STL Operator classes considering UDR co-occurrences (Brunswicker and Haefliger, 2025). Complete methodological details appear in Appendix A.2.

4 Results

4.1 Descriptives

We analyzed 7,002 natural language sentences paired with STL formulas from NL2TL, and an additional 100 hand-crafted pairs from TimeBank 1.2. Table 2 provides an overview of the results of our analysis. For the NL2TL dataset, we identified 20,410 STL statements across 9 STL classes, and 42,428 UDR statements across 17 UDR classes. Our composition detection analysis achieved 99.94% coverage (6,998 out of 7,002 sentences). We achieved 53.84% exact matches and 96.70% string similarity.

Dataset Characteristics	NL2TL	TimeBank 1.2
Domain	Technical specs	Narrative discourse
Sentences analyzed	7,002	100
Num. STL Statements analyzed	20,410	185
STL Classes	9	4
Sentences with no UDR Compositions detected	4	23
Types of UDR Compositions detected	17	13
Total UDR Compositions detected	42,428	137
Sentence level coverage	99.94%	77.00%
Exact matches complete sentence-level STL Statements	3,770 (53.84%)	1 (1.00%)
Average similarity complete sentence-level STL statement	96.70%	95.8%

Table 2: Basic Descriptives: NL2TL and TimeBank 1.2.

We performed a spot test on the quality of our parser using a 2% subsample of the NL2TL dataset and 100% of The TimeBank 1.2 revealed substantial variation in composition detection performance. It suggests that our parser has sufficient accuracy in terms of the detection of UDR Compositions and STL Operators (we achieved an average parser accuracy of 86.28%). More details on this manual evaluation for both datasets can be found in Tables 7 and 17 in the Annex.

Pattern No.	Pattern Name	UDR Comp.	No. of Inst.	%
1	Always	advmod("always")	3,178	7.49
2	Eventually	advmod("eventually")	658	1.55
3	Until	mark("until")+advcl	3,879	9.14
4	Conjunction	cc("and")+conj	6,208	14.63
5	Disjunction	cc("or")+conj	1,540	3.63
6	Prop. Negation	advmod("not")	3,986	9.40
7	Negated Always	advmod("never")	102	0.24
8	If-Then Impl.	mark("if")+advmod("then")	727	1.71
9	Become/Change	compound("become"/"change")	1,185	2.79

16	Cond. Formula Sel.	advcl+mark("if")	7,109	16.76
17	Spec. Conjunction	obj("both")+nsubj	952	2.24
Total			**42,428**	**100.00%**

Table 3: **NL2TL:** Composition frequency. Instances indicate of UDR Composition occurrences.

Table 3 describes our NL2TL's 42,428 UDR Composition instances and provides insight into the variability in how syntax structures constitute STL, and suggests a prominence of certain UDR Compositions in expressing temporality. *Conditional Formula Selection* (16.76%), followed by *Conjunction* (14.63%), and *Until* (9.14%). The lowest are *Existential Quantification* (0.49%), *Negated Always* (0.24%), and *Eventually* (1.55%). An analysis of our second dataset, the TimeBank 1.2's 137 instances (Table 15) exhibits a distinct distribution, suggesting that the domain may impact the dominance of certain UDRs for expressing STL in natural language. For example, in narrative discourse, Bounded For (12.41%), Conjunction (24.82%), and Propositional Negation (14.60%) dominate, while several compositions present in NL2TL are entirely absent. This distributional divergence reflects fundamental differences in temporal expression strategies between technical circuit specifications and narrative discourse.

4.2 Statistical Analyses of Patterns: UDR Composition - STL Relationships

We examined our proposed patterns in multiple ways. First, we explored the co-occurrence of UDR Compositions and STL Operators per sentence in a heatmap, then performed regression analysis to examine the probabilistic relationship between UDR Compositions and STL at the sentence level, considering UDR Composition co-occurrences. We first predicted full ground-truth STL StatementsWe use the ground truth label from the NL2TL dataset from the 17 UDR Components, using logistic regressions. Then, we use a multinominal logistic (MNL) regression to predict a particular STL Operator considering all 17 UDR Components occurring in a sentence assuming a deterministic relationship between UDR-STL Components based on our parser.

4.2.1 UDR Composition and STL Operator Co-occurence

UDR Composition and STL Operators co-occurrences in NL2TL (Table 22) reveal distinct frequency patterns and distributional characteristics. The dataset shows substantial variation across the 17×10 matrix, with frequencies ranging from 1 (UDR-C No. 15 with $\downarrow$) to 4,424 (UDR-C8 with $\rightarrow$). UDR-C No. 8 demonstrates the highest single operator association at 4,424 instances with $\rightarrow$, followed by UDR-C12 with $\rightarrow$ at 3,377 instances,

and UDR-C No. 8 with $\mathcal{F}_{[k,\infty]}$ at 3,259 instances. The top frequency concentrations show UDR-C No. 8's strong performance across multiple operators: 4,424 with $\rightarrow$, 3,259 with $\mathcal{F}_{[k,\infty]}$, 2,720 with G, and 1,966 with $\mathcal{G}_{[0,k]}$. UDR-C No. 12 also exhibits high frequencies, reaching 3,377 with $\rightarrow$, 2,692 with G, 2,596 with F, and 2,418 with $\mathcal{F}_{[k,\infty]}$. UDR-C No. 11 shows notable concentration in bounded always $\mathcal{G}_{[0,k]}$ with 3,006 instances, while UDR-C No. 1 peaks with G at 3,014 instances and UDR-C No. 2 reaches 3,129 with F. Lower frequency patterns include UDR-C No. 7, showing consistent low values across all operators (ranging from 2 to 206), and UDR-C No. 15 with minimal frequencies (1 to 97 across all operators). The $\rightarrow$ operator consistently shows the lowest frequencies across all compositions, with most values under 100. In contrast, $\rightarrow$ shows high activity across multiple compositions, appearing with frequencies above 1,000 in eight different UDR Compositions.

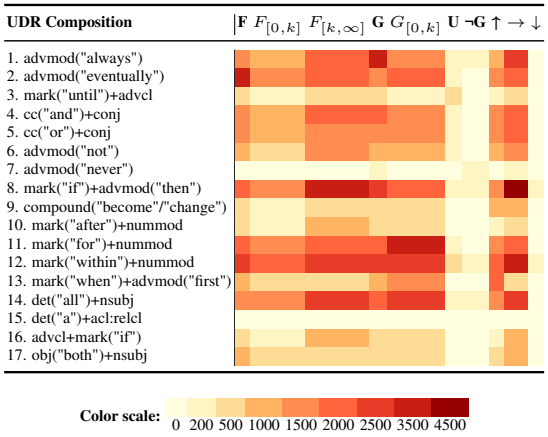

Table 4: **NL2TL:** UDR Compositions × STL Operators Co-occurrence heatmap. Color intensity represents co-occurrence frequency from light yellow (low) to dark red (high, max=4424).

TimeBank (Table 23) presents a strikingly different pattern with extreme sparsity. Of the 170 possible cells (17×10), only 22 contain non-zero values. The highest frequency is UDR-C No. 11 with $\mathcal{G}_{[0,k]}$ at 17 instances, followed by UDR-C No. 4 and UDR-C No. 6, each showing 4 instances with $\mathcal{G}_{[0,k]}$, and the rest showing only 1 to 3 cases.

4.2.2 Regression Analyses

	Precision	Recall	F-1 Score	Support
False (No Match)	0.716	0.736	0.726	647
True (Match)	0.768	0.749	0.758	754
Accuracy			0.743	1,401
Macro Average	0.742	0.743	0.742	1,401
Weighted Average	0.744	0.743	0.743	1,401

Table 5: **NL2TL:** Logistic regression test classification report (n=1,401).

Our sentence-level logistic regression analyses (Table 5) achieved an overall weighted accuracy of ∼74% (and a precision of true matches of ∼76%). An examination of the odds ratio (see Table 10) suggests that there are certain UDR Compositions, such as Conjunction ($\wedge$) and If-Then Implications($\rightarrow$), that are less likely to predict a match, potentially because there is variability in how they co-occur with other UDR Compositions. The confusion matrix can be found in Table 9 and the ROC Curve can be found in Figure 1.

The multinomial logistic regression, also performed at the sentence-level (N=7,002 for the NL2TL dataset), achieves 82.49% and 81.37% overall accuracy on the training and test set of the NL2TL dataset (Tables 6 and 12), with TimeBank 1.2 (Table 21) achieving a higher 90.00% accuracy. For the NL2TL dataset, we see variability in the STL Operator level classification accuracy with F and $F_{[k,\infty]}$ achieving the highest, and U and $\neg G$ achieving the lowest performance. F operator maintains perfect classification on NL2TL.

The primary confusion matrices (Tables 11 and 19) shows that confusion was highest between $F_{[k,\infty]}$ and G followed by $F_{[0,k]}$ and $G_{[0,k]}$, caused by how the different UDR Components, the syntatic substructures are combined.

STL Operator	Precision	Recall	F1	Support
F*	1.00	1.00	1.00	626
$F_{[0,k]}$	0.58	0.50	0.54	150
$F_{[k,\infty]}$	0.92	0.66	0.77	295
G	0.66	0.60	0.63	179
$G_{[0,k]}$	0.44	0.89	0.59	56
None	0.61	0.71	0.65	24
U	0.41	0.94	0.57	17
$\neg G$	0.60	1.00	0.75	3
$\uparrow$	0.54	0.93	0.68	15
$\rightarrow$	0.63	1.00	0.77	36
Macro Avg	0.64	0.82	0.70	1,401
Weighted Avg	0.84	0.81	0.82	1,401
Overall Accuracy: 81.37%				

Table 6: **NL2TL:** Test set performance (n=1,401). Per-operator classification metrics on held-out data. Training-test gap: 1.11% (82.49% vs 81.37%), indicating strong generalization without overfitting. *F serves as the baseline reference category.

We also analyzed the odds ratios and the coefficient magnitudes (see Table 10) that indicate how the likelihood of observing a particular UDR Composition in a sentence, increase the prediction of a particular STL Operator, holding other UDR Components constant: For example, as expected, the UDR-C No. 2 (Eventually) may be highly predictive for the F operator, while UDR-C No. 7 (Negated Always) is more likely to translate into $\neg G$, in the realms of a 1:1 mapping assumed by our grammar, rather independent from UDR-Cs. However, for $F_{[k,\infty]}$, we find that that UDR-C No. 12 (Bounded Within), with the highest coef-

ficient/odds ratio, is closely followed by UDR-C No. 1 (Always) with the second highest coefficient/odds value, suggesting they may be also be impactful in predicting the $F_{[k,\infty]}$ (potentially because of co-occurrence). Further details on this probabilistic relationship at the UDR Composition and STL Operator level can be found in Table 14 in the annex.

5 Discussion

Our empirical investigation reveals new insights into how syntactic theory for temporality translates into formal temporal logic, defined by mathematical artificial language. The striking contrast between high pattern detection (99.94% coverage on NL2TL, 77% on TimeBank 1.2) and variable accuracy rates (ranging from 0.00% to 100.00% across patterns, with 81.37% overall accuracy on NL2TL) shows a critical insight: The mapping between the building blocks of temporal syntax, the UDR components to STL Operators and full STL statements is inherently probabilistic, not only because of the domain context. Most importantly, we find that the co-occurrence of UDR components at the sentence level impacts the success of predicting STL operators. In other words, while there is some underlying logical relationship, the variability is caused by both the combination of syntactic structures and variability in semantic expression.

Our patterns demonstrate statistical tendencies caused by the way UDR-Components are combined: The mapping of UDR components to STL Operator is conditioned by structural context and linguistic variation. What is important is that the variability is not the same for all UDR-STL relationships, indicating that rich linguistic phenomena like temporal structures require the consideration of temporal structural building blocks, structural context, and semantics.

With that, we provide guidance to ongoing research on NL-STL translation: Our findings reveal new, valuable insights into how natural language systematically varies across sentences and domains, even when the data is decontextualized and the system description is lifted. In our research, we followed prior research (Chen et al., 2023) and used lifted STL statements to examine the relationship between syntactic structures and formal logic. However, even if we perform such lifting, we observe unique probabilistic relationships and variability caused by the combination of UDR-C at the sentence level. Technical domains exhibit highly systematized temporal encoding, which our UDR Compositions successfully capture, and precise temporal constraints because engineering discourse has evolved specialized syntactic conventions for unambiguous temporal specification. The high similarity scores (96.70% and 95.80%) across domains indicate that our patterns successfully identify core temporal structures, while our regression analysis provides insights into the underlying probabilistic relationship that causes variability.

Our findings address a key limitation in research on how NL relates to STL by offering a new grammar that provides a foundation for a logical mapping between syntax structure and STL Operators. Our empirical analysis uncovers a new probabilistic relationship between syntactic structures and temporal logic operators that can improve future theory development in computational linguistics. Further, it may also set the stage for the design of neurosymbolic frameworks like the one proposed by (English et al., 2025) that encode a grammar into the architecture of a neural network to improve not only the accuracy but also the interpretability of NL-STL translation models, based on the building blocks of temporal syntax structures, the UDR Components.

6 Limitations

Our approach relies on several assumptions worth discussing. We assume that UDR Compositions can systematically connect to STL Operators through our seventeen patterns, and examine how the NL maps to STL, considering the co-occurrence of the structural building blocks of temporal syntactic structures. We do not perform a granular STL-Operator level statistical analysis to examine the variability in the direct mapping further. Additional empirical analysis, including mixed effect regression models, and Bayesian approaches may offer new ways to examine the multi-level and nested relationship between the substructures and high-level sentences, as we as STL operators and STL sentence statements. Such research can also inspired deep-learning NLP research, that seeks to consider such findings when building deep learning and neural models like GraFT (English et al., 2025).

We examined our grammar using two English language datasets: NL2TL with 7,002 sentence pairs and 100 samples from TimeBank. We find

differences between domains in terms of the performance of our parser (53.84% complete matches versus 1.00%), TimeBank showing only 137 UDR Compositions compared to our full pattern set, and the probabilistic relationships explored with regression analyses. This suggests that our grammar needs to be studied and refined across additional datasets and contexts to increase its rigor. We invite others to explore our grammar from additional domains, such as probabilistic grammar development using our statistical relationships to assign confidence scores rather than fixed mappings, domain-adaptive composition discovery to address the significant performance gap between technical specifications and narrative text

Finally, hybrid interpretable systems integrating UDR Compositions into deep learning and neural approaches like GraFT for improved explainability (English et al., 2025).

A Appendix

A.1 Formal Preliminaries

A.1.1 Signal Temporal Logic

STL formulas are defined recursively using the following grammar (He et al., 2022; Mao et al., 2024; Chen et al., 2023):

$$\begin{aligned}\phi ::= \quad & \pi^{\mu} \mid \neg\phi \mid \phi_1 \wedge \phi_2 \mid \phi_1 \vee \phi_2 \\ \mid \quad & \mathcal{F}_{[a,b]}\phi \mid \mathcal{G}_{[a,b]}\phi \mid \phi_1 \mathcal{U}_{[a,b]}\phi_2\end{aligned} \tag{2}$$

Where: (i) π^{μ} represents atomic predicates (e.g., $x \sim \mu$ where x is a variable, $\sim$ is a comparison operator, and μ is a value); (ii) ϕ, ϕ_1, ϕ_2, ... ϕ_n are STL formulas, and (iii) $[a, b]$ represents time intervals where $a, b \in \mathbb{R}$ and $a \leq b$.

A.1.2 Atomic Predicates

An atomic predicate π^{μ} in STL is a basic comparison of the form $x \sim \mu$, where x is a real-valued signal variable, $\sim \in \{<, \leq, =, \geq, >, \neq\}$ is a comparison operator, and $\mu \in \mathbb{R}$ is a constant, representing the simplest testable condition that can be evaluated as true or false at any given time instant (Maler and Nickovic, 2004). In the context of cyber-physical systems, atomic predicates typically express constraints on sensor readings (e.g., *temperature* > 25), actuator states (e.g., *valve_position* $= 1$), or derived signals (e.g., *velocity* ≤ 50).

A.1.3 Logical Operators

The logical operators within STL operate on STL formulas ϕ, ϕ_1, and ϕ_2 as follows: (i) $\neg\phi$, meaning the negation of formula ϕ, (ii) $\phi_1 \wedge \phi_2$, meaning the conjunction (and) of formulas ϕ_1 and ϕ_2, (iii) $\phi_1 \vee \phi_2$, meaning the disjunction (or) of formulas ϕ_1 and ϕ_2, (iv) $\phi_1 \Rightarrow \phi_2$, meaning the implication from ϕ_1 to ϕ_2, and (v) $\phi_1 \Leftrightarrow \phi_2$, meaning the equivalence between ϕ_1 and ϕ_2 (Maler and Nickovic, 2004). These operators preserve their classical Boolean semantics at each time point, enabling compositional specification of complex logical relationships between temporal properties.

A.1.4 Temporal Operators

The temporal operators within STL are: (i) $\mathcal{F}_{[a,b]}\phi$ (Eventually/Finally), meaning the formula ϕ must be true at least once within the time interval $[a, b]$, formally $\exists t \in [a, b] : \phi(t)$; (ii) $\mathcal{G}_{[a,b]}\phi$ (Always/Globally), meaning the formula ϕ must be true throughout the entire time interval $[a, b]$, formally $\forall t \in [a, b] : \phi(t)$; and (iii) $\phi_1 \mathcal{U}_{[a,b]}\phi_2$ (Until), meaning ϕ_1 must hold until ϕ_2 becomes true within the time interval $[a, b]$, formally $\exists t \in [a, b] : \phi_2(t) \wedge \forall t' \in [a, t) : \phi_1(t')$ (Maler and Nickovic, 2004; Donze et al., 2013). Bounded time intervals enable precise specification of real-time constraints, which are essential for cyber-physical systems.

A.1.5 Extended Operators

For practical applications, STL often includes derived operators that can be expressed using the core grammar: (i) Rise operator $\uparrow \phi \equiv \neg\phi\mathcal{U}\phi$, detecting positive edges; (ii) Fall operator $\downarrow \phi \equiv \phi\mathcal{U}\neg\phi$, detecting negative edges; (iii) Weak Until $\phi_1 \mathcal{W} \phi_2 \equiv \mathcal{G}\phi_1 \vee (\phi_1 \mathcal{U} \phi_2)$, where ϕ_1 holds indefinitely or until ϕ_2; and (iv) Release $\phi_1 \mathcal{R} \phi_2 \equiv \neg(\neg\phi_1 \mathcal{U} \neg\phi_2)$, the dual of Until (Pnueli, 1977).

A.1.6 Universal Dependencies

Universal Dependencies (De Marneffe et al., 2021; Nivre et al., 2016), grounded in Tesnière's dependency grammar theory (1959), represents syntax as directed graphs $G = (V, E, \ell)$ with word nodes V, dependency edges E, and labels $\ell : E \to R$ from 37 universal relations including core arguments (`nsubj`, `obj`), modifiers (`advmod`, `nmod`), and function words (`mark`, `det`).

A.1.7 Dependency Relations

The 37 universal relations are organized into several categories: (i) **Core arguments**: `nsubj` (nominal subject), `obj` (object), `iobj` (indirect object); (ii) **Non-core dependents**: `obl` (oblique), `vocative`, `expl` (expletive), `dislocated`; (iii) **Nominal dependents**: `nmod` (nominal modifier), `appos` (apposition), `nummod` (numeric modifier); (iv) **Clausal dependents**: `advcl` (adverbial clause), `acl` (clausal modifier), `ccomp` (clausal complement); (v) **Modifier words**: `advmod` (adverbial modifier), `amod` (adjectival modifier); (vi) **Function words**: `aux` (auxiliary), `cop` (copula), `mark` (marker), `det` (determiner), `case` (case marking) (De Marneffe et al., 2021).

A.1.8 Dependency Patterns

A dependency pattern $P = (r, h, d, C)$ consists of relation r, head/dependent constraints h/d, and contextual constraints C. Pattern P matches edge (u, v) when all constraints are satisfied. For temporal expressions, key patterns include: (i) `advmod` patterns for temporal adverbs (e.g., *always*, *eventually*); (ii) `mark` + `nummod` patterns for bounded expressions (e.g., *within 5 seconds*); (iii) `advcl` patterns for subordinate temporal clauses (e.g., *until X*

happens); and (iv) compound patterns combining multiple relations for complex expressions.

A.2 Detailed Methodology

A.2.1 Dataset

We utilize two datasets spanning technical specifications and narrative discourse domains. The primary dataset is the `circuit_total_refined` lifted NL-STL pairs dataset constructed by Chen et al. (2023) evaluation[2, 3], containing 7,002 natural language sentences paired with their corresponding Signal Temporal Logic (STL) formulas. Each entry consists of six fields: (i) **ID**: unique sentence identifier; (ii) **Sentence**: natural language expressing temporal properties; (iii) **LTL**: temporal logic formula with English operators (e.g., "always", "eventually"); (iv) **Logic Sentence**: sentence with marked atomic propositions; (v) **Logic LTL**: formula with propositions as word spans (Span i, j); and (vi) **Propositions**: list of atomic propositions. The dataset provides comprehensive coverage of temporal operators ($\mathbf{G}$, $\mathbf{F}$, $\mathbf{U}$ and bounded variants), diverse syntactic structures, varying proposition complexity (0 to 4 propositions per sentence), and expert-annotated ground truth formulas for evaluation.

The TimeBank 1.2 corpus (Pustejovsky et al., 2003, 2006) is a widely used temporal event annotation resource developed at Brandeis University, containing 183 news articles annotated with temporal information according to the TimeML specification. TimeBank 1.2 provides comprehensive temporal annotations, including TIMEX3 temporal expressions (dates, times, durations), EVENT tags marking eventive predicates, and temporal relations (TLINK) capturing event ordering and temporal anchoring. The corpus represents narrative discourse from the news domain, fundamentally distinct from technical specifications in temporal expression conventions: narrative text encodes temporality through aspectual morphology, syntactic subordination, and implicit temporal ordering rather than the explicit temporal quantifiers characteristic of formal specifications.

For cross-domain validation, we constructed a handcrafted TimeBank 1.2 NL-STL dataset through systematic sampling and annotation. Dataset construction proceeded through four stages: (1) **TimeML Text Extraction** parsed the TimeBank 1.2 corpus to extract natural language sentences while removing temporal relation annotations (TLINK, SLINK, ALINK tags) and preserving EVENT and TIMEX3 content; (2) **Automated Cleanup** removed malformed annotations, HTML entities, metadata patterns, and filtered sentences through length and capitalization heuristics; (3) **Random Sampling** selected 100 sentences through random extraction from 2,624 total corpus sentences; and (4) **Handcrafted NL-STL Pairs** created temporal logic specifications for each sentence, establishing handcrafted sentence-STL pairs for narrative discourse.

A.2.2 Computational Infrastructure

All evaluations and analyses were conducted on NVIDIA Saturn Cloud utilizing 2×NVIDIA A100 GPUs, 32 CPU cores, 512GB RAM, and 5TB disk storage over approximately 514 hours of compute time. The implementation employed SpaCy 3.8.7 with the `en_core_web_lg` model (Honnibal and Montani, 2017) for dependency parsing following Universal Dependencies v2 guidelines (Nivre, 2020), selected for its state-of-the-art accuracy and comprehensive syntactic coverage. The software stack comprised Python 3.x (Van Rossum and Drake Jr, 2009) with core libraries including JSON for data serialization (Charollais, 2017), regular expressions for pattern matching, difflib for similarity computation, and explicit memory management through garbage collection. The SpaCy pipeline was configured with tokenization preserving exact positions for ground truth alignment, part-of-speech tagging using Penn Treebank tagset (Marcus et al., 1994), dependency parsing, named entity recognition, and lemmatization. This infrastructure supported a multi-stage processing pipeline encompassing data loading from the NL2TL dataset (Chen et al., 2023), preprocessing for token alignment, linguistic analysis via dependency parsing, UDR Composition extraction, STL formula construction, and comprehensive evaluation through similarity metrics. The substantial computational resources enabled efficient batch processing and in-memory caching strategies, ensuring both reproducibility and computational efficiency across the 7,002 sentence dataset.

A.2.3 Universal Dependencies Parsing

Each sentence undergoes preprocessing to maintain word-span alignment with the ground truth

[2]This dataset originally came from He et al. (2022), which was then processed by Chen et al. (2023) in their evaluation.

[3]Processed datasets and codes are available at: `https://github.com/Purdue-AIDA3/NL2UD2TL`

annotations. SpaCy's pipeline transforms text into annotated linguistic structures through tokenization (preserving position information), part-of-speech tagging (providing grammatical categories), and dependency parsing (constructing directed graphs with 17 UD relation types). The parser produces dependency trees that capture both local and long-distance relationships crucial to temporal expressions. This structured representation enables the identification of systematic correspondences between syntactic structures and temporal-logic operators.

A.2.4 Universal Dependencies Feature Extraction

The feature extraction pipeline employs SpaCy 3.8.7 to generate Universal Dependencies parses from which we extract binary presence/absence indicators for the 35 theoretically-defined syntactic Classes. Each sentence undergoes dependency parsing to construct directed graphs with 17 UD relation types, capturing both local and long-distance syntactic relationships. The Class detection system traverses dependency trees to identify structural configurations corresponding to temporal expressions (e.g., "always," "eventually," "within"), logical connectives ($\wedge$, $\vee$, $\neg$, $\rightarrow$), and temporal-logical structures. We apply frequency filtering (1% occurrence threshold) to retain 17 Classes for statistical modeling, avoiding numerical instability from rare Classes. This approach encodes which syntactic structures are present in each sentence as binary feature vectors, where 1 indicates the presence of a syntactic structure and 0 indicates its absence, allowing the statistical model to discover probabilistic correspondences between syntactic features and temporal operators through data-driven learning.

A.2.5 STL Formula Construction

The STL formula construction employs a compositional approach through the `construct_stl_formula_independent` function, which processes extracted components in three stages. First, semantic role extraction analyzes the Universal Dependencies parse to identify whether propositions serve as conditions, assertions, or temporal bounds based on dependency markers (*mark*, *aux*, *advcl*) and modal expressions. Second, the logical structure-building process determines operator precedence and scope by analyzing the syntactic hierarchy: temporal operators are applied according to their position in the dependency tree, and logical connectives maintain their syntactic scope. Third, the system constructs the final STL formula by recursively combining atomic propositions with temporal operators ($\mathbf{G}$, $\mathbf{F}$, $\mathbf{U}$) and logical connectives ($\wedge$, $\vee$, $\neg$, $\rightarrow$), applying bounded intervals where numeric modifiers are present. The construction process handles nested temporal expressions by traversing the logical structure depth-first, ensuring correct operator precedence (negation $>$ temporal $>$ conjunction $>$ disjunction $>$ implication) while preserving the semantic relationships encoded in the dependency parse. Formula normalization standardizes spacing, operator symbols, and parenthesization to enable consistent comparison with ground truth annotations.

A.2.6 Manual Evaluation

To validate system performance, we conducted a manual evaluation on stratified samples from both datasets. For NL2TL, we performed a 2% stratified subsample from each of the 17 retained Composition classes, yielding 860 instances for comprehensive human review. For TimeBank 1.2, we conducted a 100% manual evaluation of all 100 sentences. Two expert annotators independently verified that each generated STL operator correctly captured the intended temporal semantics. Annotators also rated their confidence for each evaluation using a 3-point inter-rater reliability scale (1=low confidence, 2=moderate confidence, 3=high confidence), providing a measure of annotator certainty regarding the correctness of both the operator assignment and the complete formula generation.

A.3 Cross-Domain Validation

Cross-domain validation employs the handcrafted TimeBank 1.2-STL dataset to assess whether syntax-semantics correspondences learned from technical specifications generalize to narrative discourse. We developed a two-stage STL lifting pipeline that emulates the methodology of Chen et al. (2023) to transform narrative temporal expressions into formal STL formulas via systematic predicate abstraction. The pipeline processes the `TimeBank 1.2_NL-STL.json` dataset containing 100 handcrafted sentence-STL pairs: (1) **Predicate Name Extraction** uses regex pattern matching to identify all unique predicate function names from ground truth STL formulas, extracting predicate identifiers while discarding argument structures; (2)

Lifted Formula Construction performs systematic abstraction to propositional variables through deterministic mapping (predicate $i \mapsto$ `prop_`i), creating predicate-to-proposition mappings while preserving complete STL Operator structure, temporal bounds, and logical composition. The pipeline outputs lifted formulas with UTF-8 encoded Unicode operators alongside tokenized sentence representations for downstream parsing analysis.

Following lifting, the TimeBank 1.2 sample underwent identical processing to the NL2TL dataset: UD parsing via SpaCy 3.8.7 with the same 17-Composition taxonomy, binary feature vector extraction, and co-occurrence matrix computation. Cross-domain evaluation applies keyword-based pattern-detection rules to TimeBank 1.2 for composition detection and operator generation, testing whether NL2TL-derived correspondences transfer to narrative discourse. Separately, in-domain multinomial logistic regression training exclusively on TimeBank 1.2 data enables comparison of statistical correspondences across domains, revealing whether narrative temporal structures encode operators through fundamentally different Composition-Operator mappings. This parallel methodology isolates domain transfer effects from procedural differences, enabling direct comparison of syntax-semantics correspondences across technical and narrative temporal reasoning domains while testing whether the Universal Dependency Composition taxonomy encodes temporal logic operators independently of domain-specific vocabulary or discourse structure. We designated 'None' (the absence of a temporal operator) as the reference category, serving as the natural baseline for coefficient interpretation in multinomial logistic regression.

A.4 Evaluation of UDR and STL Relationships

The evaluation framework employs multiple complementary metrics to assess UD-STL correspondences. Exact match accuracy uses advanced formula normalization and handles operator equivalences and structural variations, providing a binary assessment of formula correctness. Similarity scores via `SequenceMatcher` provide gradient correctness measures (0 to 1), enabling fine-grained analysis of partial matches. Component-wise evaluation separately assesses temporal operators, logical connectives, atomic propositions, and temporal bounds, isolating specific aspects of the syntax-semantics mapping. Error severity classification categorizes results into five levels based on similarity thresholds: complete failure (< 0.2), major errors ($0.2 - 0.4$), moderate errors ($0.4 - 0.6$), minor errors ($0.6 - 0.8$), and near matches (> 0.8).

A.4.1 Regression Analyses

To examine probabilistic relationships between UDR Compositions and STL Operators, we applied two complementary sentence-level logistic regression approaches (N = 7,002 sentences, 80/20 train-test split). First, binary logistic regression with a One-vs-Rest (OvR) strategy created separate models for each STL Operator class, treating each as an individual classification problem against all other operators (Nick and Campbell, 2007). Second, multinomial logistic regression (MNL) simultaneously modeled all operator classes within a single framework, following established protocols for nominal categorical outcomes (Long, 1997; Brunswicker and Haefliger, 2025).

Both models used identical feature sets: binary vectors encoding the presence or absence of each of the 17 Classes per sentence. Target variables consisted of STL Operator classes extracted from ground truth annotations for the binary approach (5 classes) and from our STL output for the multinomial model (10 classes). Model implementation relied on scikit-learn's `LogisticRegression` with the `lbfgs` solver (Moritz et al., 2016), 1,000 maximum iterations, and balanced class weights to address substantial operator frequency imbalances (Lee et al., 2006; Minka, 2003; Moritz et al., 2016; Pedregosa et al., 2011). The binary model specified `multi_class='ovr'`, while the multinomial model used `multi_class='multinomial'`.

Dataset partitioning followed an 80/20 train-test split with fixed random seeds for reproducibility. The binary approach removed stratification due to rare classes with insufficient samples, while the multinomial model maintained stratified sampling to preserve class distributions. Rather than relying on predetermined Class-operator mappings, both approaches discovered probabilistic relationships through coefficient estimation. We report coefficients and odds ratios where positive values indicate increased operator probability when the pattern is present, while negative values indicate decreased probability (Brunswicker and Haefliger, 2025). For the multinomial model, we designated F (Eventually) as the reference category given its frequency dominance (44.7%, N=2,503), provid-

ing a natural baseline for coefficient interpretation across all other operators.

A.5 Acknowledgments

We would like to thank the expert annotators who provided invaluable manual evaluations that validated our system's performance and contributed to the creation of STL annotations for the TimeBank 1.2 corpus sample, enabling our cross-domain analysis. We are grateful to the faculty, staff, researchers, students, and collaborators of AIDA[3] at Purdue University for their ongoing support and insightful discussions that enriched this research. Special appreciation goes to the computational linguistics community for providing the foundational datasets that made this work possible.

GARuD: Guided Alignment of Representations using Distillation for Ultra-Low-Resource Languages

Abstract

The vast majority of the world's languages, particularly low-resource and tribal ones like Bhili, remain critically underserved by modern language technologies. The primary bottleneck is the lack of large-scale corpora required for standard pre-training. To address this gap, we introduce cross-lingual contrastive distillation, a novel and data-efficient, compute-efficient paradigm for creating powerful language models without a massive monolingual corpus. Our method adapts a pre-existing multilingual model (MuRIL) by using a fixed, expert teacher model (HindBERT) to distill semantic knowledge from a related high-resource language (Hindi) via a contrastive objective on a modest parallel corpus. Through comprehensive experiments, we show that our resulting model, GARuD-Bhili, significantly outperforms strong zero-shot and MLM-only baselines on a suite of evaluations, including intrinsic language modeling, downstream sentiment analysis, and cross-lingual benchmarks (Tatoeba, XNLI). Our work presents a scalable blueprint for linguistic empowerment, offering a practical pathway to develop robust language technologies for other underserved languages globally.

1 Introduction

India boasts remarkable linguistic diversity, with the 2011 census documenting over 1,369 distinct mother tongues and 22 official languages. Yet, this linguistic wealth faces a critical challenge: numerous indigenous and tribal languages are critically endangered due to a severe lack of digitized resources and parallel corpora. These languages are vital to cultural heritage, making robust translation systems essential not only for clear communication and social inclusion but also for equitable access to government services. Effective translation is crucial for implementing policies, welfare programs, legal processes, and educational efforts, thereby supporting national unity in India's complex multilingual setting.

The advent of large pre-trained language models like BERT (Devlin et al., 2019) has revolutionized NLP by learning rich contextual representations from vast amounts of text. For the Indian subcontinent, specialized multilingual models like MuRIL (Khanuja et al., 2021) have been developed to capture the shared linguistic and structural properties across 17 major Indian languages. However, the effectiveness of these powerful models does not extend to the hundreds of languages, like Bhili, that were absent from their pre-training corpora. The primary bottleneck is the data itself: developing a language model for Bhili from scratch is infeasible due to the non-existence of a large monolingual corpus required for standard self-supervised pre-training. This creates a critical gap, leaving Bhili speakers digitally disenfranchised.

To bridge this representation gap with the limited corpus we have, we propose a novel and data-efficient training paradigm leveraging a modest-sized, community-curated Bhili-Hindi Parallel Corpus of approximately 142,000 sentence pairs. We adapt the powerful MuRIL model through a process of cross-lingual distillation, using a framework inspired by the mechanics of Momentum Contrastive Learning (MoCo) (He et al., 2019). In this setup, the MuRIL model acts as a student, which learns to represent Bhili sentences. Its goal is to align its outputs with the representations from a fixed teacher model that is already proficient in Hindi. By treating a Bhili sentence and its Hindi translation as a positive pair within this contrastive objective, we compel the student model to map Bhili into the teacher's rich, pre-existing semantic space. This allows for an efficient and targeted transfer of knowledge to understand the unique lexical and grammatical nuances of Bhili.

2 Related Work

Our work is situated at the intersection of three key areas in modern NLP: adapting large multilingual models, the paradigm of knowledge distillation, and the methodology of cross-lingual contrastive learning.

2.1 Adaptation of Multilingual Models for Low-Resource Languages

The dominant approach for supporting low-resource languages is to adapt large, pre-trained multilingual models like mBERT (Devlin et al., 2019) or XLM-R (Conneau et al., 2020). For the Indian context, region-specific models such as MuRIL (Khanuja et al., 2021) and IndicBERT (Doddapaneni et al., 2023) have proven to be more effective starting points, as their pre-training on diverse Indic languages helps capture the subcontinent's shared typological features.

However, even these specialized models face significant challenges. The most common adaptation strategies include:

- **Zero-Shot Transfer**: This involves directly applying a pre-trained model to a language it has never seen. While simple, performance is often poor due to vocabulary mismatch and the model's lack of exposure to the target language's specific syntax and semantics. This degradation is particularly pronounced for common linguistic phenomena in the Indian context like code-mixing and transliteration (Khanuja et al., 2021; Joshi et al., 2020).

- **Continued Pre-training**: This strategy involves further training the multilingual model on a monolingual corpus of the target language using an objective like Masked Language Modeling (MLM). While a strong baseline method for adapting a model's vocabulary and representations (Adelani et al., 2022), it requires a substantial monolingual corpus, which is often unavailable for extremely low-resource languages like Bhili.

The limitations of these standard approaches necessitate exploring more data-efficient adaptation techniques that can explicitly teach cross-lingual alignment.

2.2 Knowledge Distillation as a Path for Transfer

Knowledge Distillation (KD) offers a powerful framework for knowledge transfer. Originally proposed for model compression, KD involves training a smaller "student" model to mimic the behavior of a larger, more capable "teacher" model (Hinton et al., 2015; Sanh et al., 2019). This principle can be adeptly repurposed for cross-lingual learning. The goal shifts from merely compressing knowledge to transferring it across a language barrier. In this setup, a student model learning a low-resource language (e.g., Bhili) is trained to align its representations with those produced by an expert teacher model for a high-resource language (e.g., Hindi). This provides a rich, stable supervisory signal, guiding the student's learning in an otherwise data-scarce environment.

2.3 Cross-Lingual Contrastive Learning

Recently, contrastive learning has emerged as a state-of-the-art method for learning high-quality sentence embeddings by pulling similar inputs together and pushing dissimilar ones apart. In the cross-lingual domain, this is powerfully realized by using parallel sentence pairs from different languages as positive examples. Leading frameworks like LaBSE (Feng et al., 2020), InfoXLM (Chi et al., 2021), and XLCo (Wang et al., 2022) use this principle to learn a shared, language-agnostic embedding space.

For low-resource scenarios, this contrastive paradigm offers compelling advantages over traditional MLM-based pre-training. By explicitly leveraging a parallel signal, contrastive methods can achieve robust cross-lingual alignment with significantly less data and compute. While MLM provides powerful generalized representations when data is abundant, contrastive learning is often a more direct and efficient path to strong cross-lingual understanding when data is scarce.

Our work synthesizes these threads in a novel way. We argue that for extremely low-resource languages like Bhili, the most effective strategy is neither continued pre-training (due to data scarcity) nor training a large contrastive model from scratch (due to computational cost). Instead, we combine the strengths of knowledge distillation and cross-lingual contrastive learning. We propose a highly efficient adaptation framework where we use a MoCo-style contrastive objective to distill

the knowledge from a fixed, expert teacher model into an existing, powerful student model (MuRIL). This specific configuration–using teacher-student contrastive distillation to adapt, rather than retrain, a multilingual model–represents a distinct, practical, and highly effective methodology for resource-scarce environments.

3 Dataset

3.1 Dataset Creation and Purpose

Developing foundational language technologies for extremely low-resource languages is fundamentally constrained by the scarcity of high-quality, digitized text (Nekoto et al., 2020). This data gap has historically hindered the creation of robust language models for communities like the Bhili speakers. To address this challenge for Bhili, a culturally significant tribal Indic language, a large-scale, gold-standard Bhili-Hindi Parallel Corpus (Singh et al., 2025) was previously curated through extensive community-led initiatives involving native speakers. This dataset is the cornerstone of our study, it provides the essential cross-lingual signal required to train a powerful Bhili language representation model via our proposed knowledge distillation framework.

The source sentences in Hindi were primarily drawn from the Bharat Parallel Corpus Collection (BPCC) (Gala and Chitale, 2023), and supplemented with text from diverse public sources, including Legislative Assembly Speeches (Siripragada et al., 2020), the PMIndia corpus (Haddow and Kirefu, 2020), and NCERT textbooks. A team of 10 professional translators, all native Bhili speakers, meticulously translated these sentences between May 2024 and March 2025, contributing over 27,000 hours of work to ensure high semantic fidelity and contextual accuracy. This rigorous process yielded the high-quality parallel corpus that enables our work. To assess the quality of our manually curated Hindi–Bhili gold references, we conducted an inter-annotator agreement (IAA) study. For more details, refer to Appendix E.

3.2 Data Preprocessing

To ensure the quality of the data used for training, the corpus underwent a thorough preprocessing pipeline. This process involved normalizing Bhili homophones to maintain linguistic consistency, removing extraneous characters, and implementing strict de-duplication to eliminate highly similar sentence pairs. We enforced sentence length limits, retaining only pairs with 6 to 80 words. To further reduce redundancy, we applied cosine similarity filtering on sentence embeddings to detect and remove near-duplicate source-target combinations. Tokenization was performed using the original SentencePiece vocabulary from the MuRIL base model to ensure alignment with the model's pre-existing embeddings.

3.3 Dataset Statistics

A statistical overview of the Bhili-Hindi Parallel Corpus is presented in Table 1. The final dataset contains 142,817 sentence pairs, partitioned into a training set of 128,535 and a test set of 14,282 pairs.

Analysis reveals linguistic characteristics relevant to our modeling task. Bhili sentences are, on average, longer than their Hindi counterparts (e.g., ≈34 vs. ≈27 tokens in the training set), suggesting structural differences that a model must learn to align. The substantial number of unique tokens in both languages (Hindi: ≈27K, Bhili: ≈26.8K) highlights a rich vocabulary, which is vital for learning nuanced language representations. Furthermore, the high standard deviation in sentence length points to considerable variation in complexity, making the dataset a challenging and representative resource for building and evaluating a foundational language model for Bhili.

Statistic	**Train Set**		**Test Set**	
	Hindi	**Bhili**	**Hindi**	**Bhili**
Number of Sentence Pairs	128,535		14,282	
Number of Sentences	128,535	128,535	14,282	14,282
Total Tokens	3,473,762	4,419,784	346,759	449,280
Unique Tokens	27,215	26,774	14,312	14,582

4 Methodology

Our objective is to develop a powerful contextual representation model for Bhili, an extremely low-resource language. We leverage the significant typological and lexical overlap between Bhili and Hindi by adapting a strong Indic multilingual model, MuRIL (Khanuja et al., 2021). Since MuRIL is pre-trained on 17 Indic languages includ-

ing Hindi, it provides a robust starting point with a shared sub-word vocabulary.

We formulate our investigation as a comparative study between two adaptation approaches on our Bhili-Hindi Parallel Corpus (BHPC): a standard baseline and our proposed contrastive distillation method.

4.1 Baselines

We establish two baseline models to contextualize the performance of our proposed approach.

4.1.1 Zero-Shot Inference

Our first baseline measures the zero-shot performance of the original, off-the-shelf MuRIL model. This involves no additional training or fine-tuning whatsoever. The model is evaluated directly on the downstream Bhili tasks. This approach establishes the lower-bound performance and quantifies the model's out-of-the-box capabilities (or lack thereof) for a language it has never seen, relying solely on its cross-lingual transfer abilities learned during pre-training.

4.1.2 Continued Pre-training with MLM

As a strong baseline, we perform continued pre-training on the base MuRIL model using a standard Masked Language Modeling (MLM) objective. This adaptation approach, common for low-resource languages, fine-tunes the model to the specific vocabulary and syntax of the target language.

For this setup, we use only the Bhili portion of our parallel corpus ($\mathbf{x}_{\text{Bh}}$). The model is trained on a masked token prediction task using a cross-entropy loss. Details of training are provided in Appendix F.

4.2 Proposed Method: GARuD (Contrastive Distillation with a Memory Queue)

To learn richer, semantically-aware sentence embeddings, we introduce GARuD- a novel training framework that synergizes MLM with a cross-lingual contrastive objective. The goal is to force the sentence representations of Bhili to align with the high-quality semantic space of Hindi, a language for which strong models exist. This contrastive alignment acts as a powerful semantic regularizer, guiding the model to learn meaningful sentence-level representations beyond simple token prediction (Chen et al., 2023; Miao et al., 2024).

Our framework is a teacher-student knowledge distillation setup, whose mechanics are inspired by Momentum Contrast (MoCo) (He et al., 2019). It consists of three main components:

- A Student Encoder ($\text{ENC}_{\text{student}}$): The base MuRIL model, whose parameters (Θ_S) we are training. It processes Bhili sentences.
- A Frozen Teacher Encoder ($\text{ENC}_{\text{student}}$): A powerful, pre-trained Hindi model whose parameters (Θ_T) are frozen during training. For this role, we use HindBERT (Joshi, 2022), which is essentially MuRIL finetuned on publicly available Hindi monolingual datasets, and reportedly performs better than MuRIL on some downstream classification and NER tasks.
- A Memory Queue (Q): A FIFO queue that stores a large number of recent Hindi sentence embeddings produced by the teacher. This allows for a large pool of negative samples for the contrastive loss, decoupled from the batch size. This allows our method to be trained effectively on consumer-grade hardware with limited GPU memory.

A schematic of our proposed method is presented in Figure 1.

Training Process: For each parallel pair $(x_{\text{Bh}}^{(i)}, x_{\text{Hi}}^{(i)})$ in a batch of size B, the process unfolds as follows:

The student encoder processes the Bhili sentence to produce its `[CLS]` token embedding,

$$h_{\text{Bh}}^{(i)} = \text{ENC}_{\text{student}}(x_{\text{Bh}}^{(i)}) \tag{1}$$

Similarly, the frozen teacher encoder processes the corresponding Hindi sentence to produce the positive key,

$$h_{\text{Bh}}^{(i+)} = \text{ENC}_{\text{student}}(x_{\text{Bh}}^{(i)}) \tag{2}$$

The negative keys, $h_{\text{Bh}}^{(j-)}\}_{j=1}^{K}$, are the K embeddings of other Hindi sentences currently stored in the memory queue Q.

The student is then trained using a contrastive loss that encourages the Bhili embedding $h_{\text{Bh}}^{(i)}$ to be more similar to its positive Hindi key $h_{\text{Hi}}^{(i)}$ than to all negative keys in the queue. We use the NT-Xent (Normalized Temperature-scaled Cross Entropy) loss (Chen et al., 2020):

$$\mathcal{L}_{\text{contrastive}} = -\frac{1}{B}\sum_{i=1}^{B}\log\left(\frac{\exp\left(\ell_{\text{pos}}^{(i)}/\tau\right)}{\exp\left(\ell_{\text{pos}}^{(i)}/\tau\right)+\sum_{j=1}^{K}\exp\left(\ell_{\text{neg}}^{(i,j)}/\tau\right)}\right) \tag{3}$$

where B is the batch size, $\ell_{\text{pos}}^{(i)}$ is the cosine similarity between the embeddings of the i^{th} anchor and its positive key. Likewise, $\ell_{\text{neg}}^{(i)}$ is the similarity score between i^{th} anchor and j^{th} negative key and τ is a temperature parameter. The gradient flows only through the student encoder, while the teacher and queue remain detached. After each step, the queue is updated with the Hindi embeddings from the current batch. This MoCo-style mechanism provides a computationally efficient way to utilize a large number of negatives ($K >> B$), which is critical for effective contrastive learning.

Combined Objective: The student model is trained jointly on both the MLM task (using only the Bhili inputs) and the contrastive task. The final loss is a weighted sum:

$$\mathcal{L}_{\text{total}} = \alpha\mathcal{L}_{\text{MLM}} + \beta\mathcal{L}_{\text{contrastive}} \tag{4}$$

where α and β are hyperparameters that weight the contribution of each loss term. Training hyperparameters are given in Appendix F.

5 Evaluation

To comprehensively evaluate the quality of the Bhili language representations produced by our models, we designed a multi-faceted evaluation strategy. Our approach includes an intrinsic measure of training quality, performance on a practical downstream application, standardized cross-lingual benchmarks, and a qualitative analysis of the embedding space.

5.1 Intrinsic Evaluation: Masked Token Prediction

As a direct measure of how well each model has learned the statistical properties of the Bhili language, we report the final accuracy on the Masked Language Modeling (MLM) task on the test set. This intrinsic metric helps quantify the fundamental language understanding captured during the adaptation phase for both the MLM-only baseline and our proposed joint-training method.

5.2 Downstream Task: Sentiment Analysis

To assess the utility of the learned embeddings for practical applications, we evaluate them on a 3-way sentiment analysis task (positive (49%), negative (26%), neutral (24%)).

- **Dataset**: We created a sentiment analysis dataset by manually translating 8000 Hindi sentences from a standard sentiment corpus into Bhili. This translation was performed by native speakers to ensure high quality and contextual accuracy.

- **Protocol**: For our proposed model (and the baselines), we freeze the entire encoder backbone and add a lightweight classification head on top, consisting of a BiLSTM layer followed by a single MLP layer. Only the parameters of this classification head are trained on the Bhili sentiment dataset. This feature-extraction setup ensures that we are evaluating the intrinsic quality of the pre-trained representations themselves, without significant influence from task-specific fine-tuning. We report the accuracy, precision, recall and F1-score as our metrics.

5.3 Cross-Lingual Benchmark Evaluation

To measure the cross-lingual alignment and reasoning capabilities of our models, we evaluate them on a curated set of sentence-level benchmark tasks adapted from XTREME (Hu et al., 2020).

Task Selection Rationale: Our primary objective is to validate the semantic enrichment of our model. We follow a "translate-test" or "translate-train" approach where necessary. However, this methodology proved untenable for tasks that rely on precise alignment between labels and text spans. This includes token-level classification tasks like NER (PAN-X) and POS tagging (UDPOS), as well as extractive question-answering tasks like XQuAD and MLQA. The brittleness of projecting token-level or span-level labels under translation—a process sensitive to tokenization mismatches and syntactic reordering—would require a manual, resource-intensive data verification step. To ensure a reliable and robust evaluation, we exclusively selected sentence-level classification tasks where the label depends on the holistic meaning of the text, which is more resilient to the translation process.

Tasks and Protocols:

- **Tatoeba** (Sentence Retrieval): We evaluate the model's ability to perform cross-lingual sentence retrieval. We use the Hindi-English

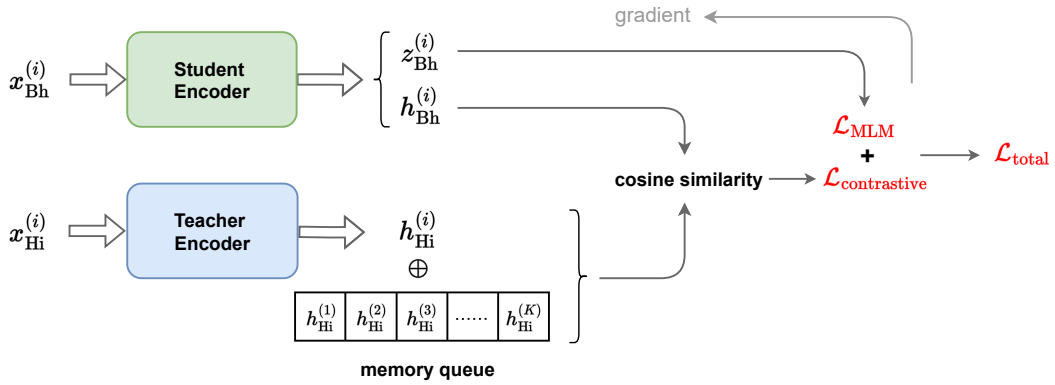

Figure 1: **An illustration of our GARuD framework for cross-lingual contrastive distillation.** The Student Encoder (MuRIL) is trained to produce Bhili sentence embeddings h_{Bh} that align with the high-quality embeddings h_{Hi} from a frozen, expert Teacher Encoder. A MoCo-style memory queue provides a large set of negative samples for the contrastive loss. The total loss combines this sentence-level contrastive objective with a token-level MLM objective, but the gradient only updates the student, effectively enabling a one-way distillation of knowledge from the teacher.

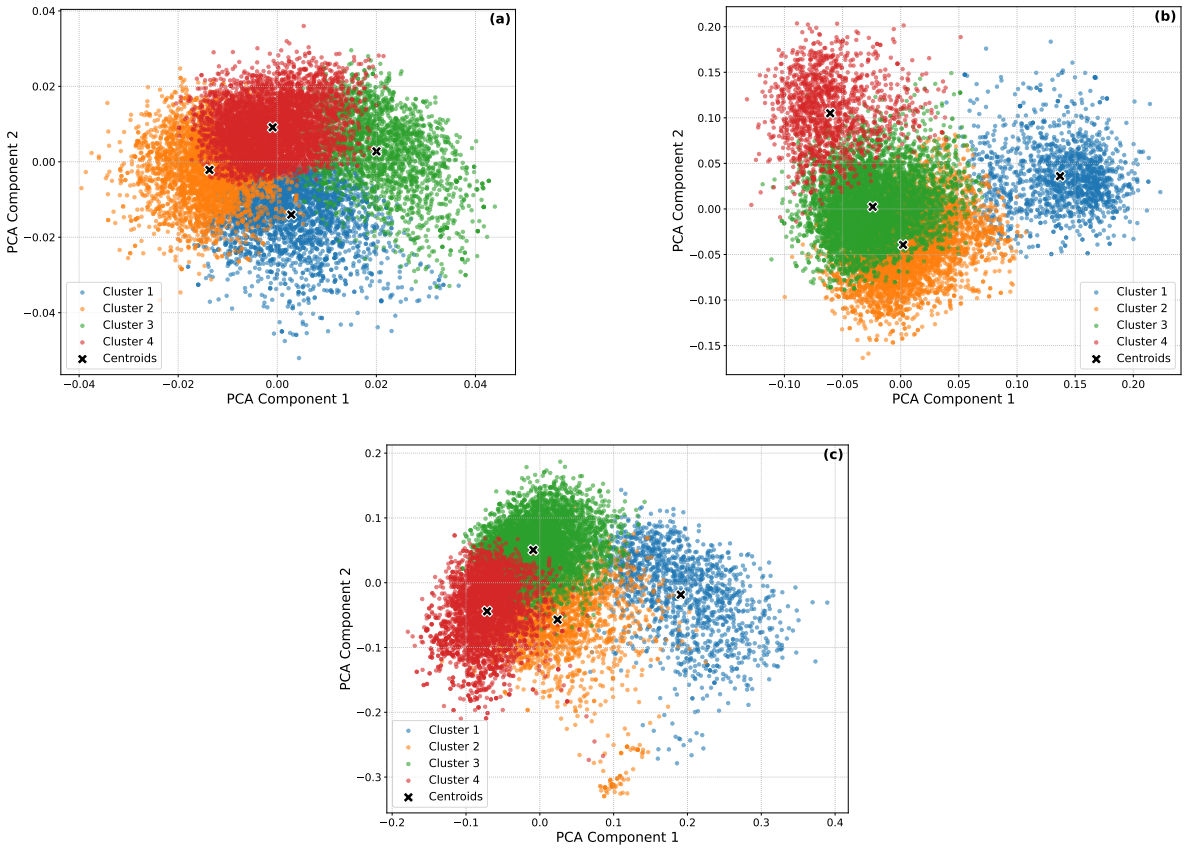

Figure 2: **Visualization of Bhili sentence embedding spaces learned by different models.** Sentence level embeddings created by mean pooling token embeddings, from the test set are projected into two dimensions using Principal Component Analysis (PCA). Colors correspond to four semantic clusters identified in an unsupervised fashion via K-Means clustering, with 'x' marking the cluster centroids. The plots show the embedding distributions for: (a, top-left) the Zero-Shot baseline, (b, top-right) the MLM-only baseline, and (c, bottom) our proposed contrastive distillation method. The superior inter-cluster separation in (c) demonstrates strong qualitative evidence of a more semantically meaningful and organized representation space for Bhili. This, in turn explains its stronger performance on downstream tasks.

sentence pairs from the Tatoeba dataset, manually translate the English sentences into Bhili using a translator tool [1], and then evaluate the model's zero-shot performance at matching the correct Bhili-Hindi translation pairs. Success on this task directly measures the quality of the cross-lingual embedding alignment.

- **XNLI** (Natural Language Inference): To test cross-lingual reasoning, we first fine-tune our models on a translated version of the English MNLI dataset (Wang et al., 2018). Subsequently, we evaluate the model's zero-shot transfer performance on the official XNLI test set for Hindi (Conneau et al., 2018), using Bhili sentences as input. Performance is measured by classification accuracy.

6 Results and Analysis

We now present the results of our comprehensive evaluation, comparing our proposed Contrastive Distillation method against the Zero-Shot and MLM-only baselines. The findings consistently demonstrate the superiority of our approach across all evaluation axes, confirming that our method produces more robust and semantically meaningful representations for Bhili.

6.1 Main Quantitative Results: Intrinsic and Downstream Performance

The primary quantitative results for both intrinsic (MLM accuracy) and downstream (sentiment analysis) tasks are summarized in Table 2.

Our analysis of these results reveals two key findings. First, in terms of intrinsic language modeling capability, our joint-training approach achieves a higher MLM accuracy (0.789) than the MLM-only baseline (0.756). This suggests that the cross-lingual contrastive objective acts as a semantic regularizer, helping the model learn more effective token-level representations for Bhili. It is synergistic with the MLM objective,

Second, this enhanced representation quality directly translates to superior downstream performance. On the sentiment analysis task, our model achieves a weighted F1-score of 0.671, significantly outperforming both the MLM-only baseline (0.656) and the Zero-Shot model (0.525), whose performance is only marginally better than random chance. This confirms that the embeddings produced by our method are not only statistically sound but also more useful for practical applications.

6.2 Cross-Lingual Benchmark Performance

To validate the cross-lingual alignment learned by our model, we present the results on the Tatoeba and XNLI benchmarks in Table 3. It provides the clearest and most compelling evidence of our method's effectiveness in creating a high-quality, aligned representation space for Bhili.

Our model demonstrates superior performance over both baselines across these tasks. The monumental improvement on the Tatoeba sentence retrieval task is particularly telling. This result directly validates our core hypothesis: the contrastive training objective successfully aligns the Bhili and Hindi embedding spaces, allowing the model to recognize sentence translations with much higher accuracy than the baselines.

Furthermore, success in the XNLI logical reasoning task shows that these high-quality, aligned embeddings serve as a stronger foundation for complex downstream reasoning. Unlike the token-focused MLM objective, our approach creates a more meaningful sentence-level representation space. These well-structured representations make it easier for the model to learn and transfer abstract concepts like entailment and contradiction to the low-resource language. While the performance gains on this task are more modest than on Tatoeba, they are nonetheless critical. Natural Language Inference requires not just recognizing semantic similarity, but also understanding logical relationships.

6.3 Qualitative Analysis of Embedding Space

A qualitative view of the embedding space, visualized via KMeans and PCA in Figure 2, corroborates our quantitative findings. The number of clusters was fixed to four for the sake of comparison. The visualization reveals three distinct patterns:

Zero-Shot: The embeddings from the baseline model exhibit representation collapse. The points are clustered into a single, undifferentiated mass, indicating the model has no semantic understanding of Bhili.

MLM-only: The model adapted with only MLM shows emergent structure. Some separation is visible, but the clusters corresponding to different semantic topics show significant overlap.

Our Method: In stark contrast, our model trained with the contrastive objective yields clearly

[1] https://aadivaani.tribal.gov.in/

Method	Accuracy (MLM)	Accuracy (Sentiment)	Precision	Recall	F1	Training time (avg. no. of epochs)
Zero-shot	–	0.598 ± 0.01	0.587 ± 0.03	0.525 ± 0.02	0.525 ± 0.03	13.8
MLM-only	0.756	0.681 ± 0.01	0.679 ± 0.02	0.647 ± 0.01	0.656 ± 0.01	8.2
GARuD-Bhili **(proposed)**	**0.789**	**0.693** ± 0.02	**0.691** ± 0.02	**0.659** ± 0.02	**0.671** ± 0.02	**6**

Table 2: Performance of models on sentiment classification. The best metrics for each column are shown in **bold**. Accuracy reported on a scale of 0–1. Additionally, improvement in masked token prediction accuracy from proposed method over MLM pretraining is also reported. Sentiment metrics are the mean ± standard deviation over 5 runs. Training efficiency is reported as the average number of epochs to convergence with early stopping.

Model	Tatoeba (Acc.)	XNLI (Acc.)
Zero-shot	2.5	60.09
MLM-only	11.4	63.59
GARuD-Bhili **(proposed)**	**38.8**	**65.36**

Table 3: Performance on cross-lingual benchmark tasks. Our proposed method shows substantial gains on both sentence retrieval (Tatoeba) and natural language inference (XNLI) compared to the baselines.

partitioned clusters. While there is natural variance within each cluster, the inter-cluster separation is demonstrably superior. This visual evidence strongly indicates that our contrastive distillation method is highly effective at inducing a semantically organized representation space for a low-resource language.

6.4 Analysis of Training Efficiency

An interesting and practical benefit observed during our experiments is a marked improvement in training efficiency. As shown in the final column of Table 2, our joint-training model converges to its optimal performance in significantly fewer epochs (6.0 on average) compared to the MLM-only model (8.2). We hypothesize that the explicit, sentence-level supervisory signal from the cross-lingual contrastive loss provides a clearer and more direct learning path for the model, allowing it to reach an optimal state more rapidly than with the diffuse MLM objective alone. This finding, supported by similar observations in other contrastive learning literature (Jiang et al., 2024), suggests our method is not only more effective but also more efficient.

7 Conclusion

In this work, we presented a novel and highly effective training paradigm, **cross-lingual contrastive distillation**, to address the critical lack of foundational language models for extremely low-resource languages like Bhili. Our method successfully adapts a pre-trained multilingual model by using a fixed, expert teacher to distill semantic knowledge from a related high-resource language (Hindi) into a student model learning the target language (Bhili). Through comprehensive experiments, we demonstrated that our resulting model, GARuD-Bhili, significantly outperforms strong baselines on intrinsic, downstream, and cross-lingual benchmark tasks, creating a well-structured and semantically robust representation space for Bhili. The core contribution, however, is not a model for a single language, but rather an effective case study and a scalable blueprint for linguistic empowerment. The architectural components of our method are fundamentally language-agnostic. The success of this framework is not predicated on any unique property of Bhili or Hindi, but on the principle that the existence of a higher-resource language can act as a semantic bridge to its lower-resource neighbor. This makes our approach a replicable strategy for any scenario where such a modest parallel corpus can be curated and the source language is already well-represented in a publicly available multilingual model. Therefore, this work offers a practical, data-efficient and compute-efficient pathway for developing high-quality language models for the world's most underserved linguistic communities. It is our hope that it will not only cat-

alyze further research for extremely low-resource Indic languages but also inspire and enable similar efforts to bring the benefits of modern NLP to the vast number of languages that remain on the fringes of the digital age.

Limitations

While our work successfully demonstrates a powerful new paradigm for an ultra-low-resource language, we acknowledge its current limitations.

First, our evaluation, though comprehensive, did not extend to complex span-based tasks like extractive Question Answering. The brittleness of projecting answer spans across translations makes this a methodologically challenging evaluation to perform reliably without extensive manual annotation, which was beyond the scope of this initial study.

Second, the effectiveness of our GARuD framework has been demonstrated on a single, albeit highly representative, language pair: Bhili-Hindi. While this provides a strong proof-of-concept, further experiments are needed to validate its generalizability across a wider range of language families and typological distances.

Finally, the performance of our model is intrinsically tied to the diversity of the parallel corpus. While the Bhili-Hindi Parallel Corpus is a monumental resource, its domain coverage may not fully encompass informal or conversational genres. The model's robustness on out-of-domain text is therefore an area for further investigation.

Future Work

Our future work will advance along three main directions. First, we aim to **scale the GARuD framework** to other ultra-low-resource Indian language pairs such as Gondi–Telugu and Santali–Bengali, testing its robustness and generalizability. Second, we plan to **develop a unified multilingual model** trained on multiple parallel corpora, enabling shared representation learning and positive transfer across India's underserved languages. Finally, we envision a **community-led data and benchmark initiative** focused on expanding domain-diverse parallel corpora and establishing standardized token- and span-level evaluation datasets. Such collaborative benchmark creation is essential for ensuring meaningful, reproducible progress in low-resource NLP.

Ethical Considerations

The development of NLP technologies for low-resource and tribal languages entails a deep ethical responsibility. Our work on Bhili—a language central to its community's cultural identity—was guided by the principles of linguistic accuracy, cultural respect, and community participation. The Bhili-Hindi Parallel Corpus (BHPC) was curated in collaboration with native Bhili speakers from Jhabua, Madhya Pradesh, ensuring authenticity and contextual relevance. Annotators provided informed consent and received fair compensation aligned with government standards. The dataset integrates culturally significant expressions such as "बोकड़ा पाळवा" (goat-rearing) and "जौहार" (a local salutation), preserving cultural nuance alongside linguistic precision. This community-driven and ethically grounded approach reflects our commitment to inclusive, responsible NLP research for underrepresented languages.

Acknowledgements

We gratefully acknowledge the Ministry of Tribal Affairs, Government of India, and Shri Vibhu Nayar, Secretary, for their visionary leadership and pivotal guidance in shaping this research under the Adi Vaani Project, which laid the foundation for the preservation and technological empowerment of India's tribal languages. We thank the Tribal Research Institute, Bhopal, and all officials and translators for their invaluable assistance in data coordination and creation of the BHEPC benchmark. We are deeply grateful to Prof. Parag Singla, Prof. Vivek Kumar, and Dr. Vipul Rathore for their continuous guidance. This work was supported by the Yardi School of Artificial Intelligence, Indian Institute of Technology Delhi, through research funding and computational infrastructure.

A Ultra Low-Resource Languages

Languages with extremely limited resources suffer from a serious lack of accessible data and proper documentation. This issue is particularly evident in many Indian regional languages, which often fall into this category. Unlike widely studied languages, these lesser-known languages have minimal resources—many are unpublished or contain very little available data. They are commonly described as under-documented, under-resourced, or under-digitized. As a result, collecting and processing raw textual data in these languages presents significant challenges.

B Bhili Language

Bhili, a Western Indo-Aryan language spoken by approximately 13 million people across Rajasthan, Gujarat, Maharashtra, and Madhya Pradesh, is written in the Devanagari script and deeply embedded in Bhil cultural heritage. The dataset we present focuses on the Bhili dialect from the Jhabua region of Madhya Pradesh. Despite the language's cultural and demographic importance, Bhili remains largely unexplored in Natural Language Processing (NLP) due to the lack of publicly available parallel corpora.

C Translation Guidelines

To maintain consistency and preserve the semantic integrity of translations, we established a comprehensive set of guidelines that balance linguistic precision with the practical constraints posed by the scarcity of Bhili-specific glossaries, literature, and linguistic resources. Translators are instructed to faithfully retain the meaning and stylistic tone of the source content without introducing new material or omitting any part of the original. Special care was taken when handling named entities, numbers, dates, and technical terminology in accordance with the conventions of the target language. The core principles include:

- **General Principles:** Accurately convey the source text's meaning, tone, style, and level of formality—whether formal, informal, or emphatic—without making additions or deletions. Minor grammatical errors or typographical mistakes may be corrected as long as factual inconsistencies in the source are preserved. The translation should read fluently and naturally in the target language.

- **Named Entities:** Use standardized, widely accepted translations where they exist. If unavailable, entities should be precisely transliterated into the target script following language-specific conventions. Translators must avoid creating alternative or novel renderings.

- **Numbers and Units:** Reproduce numerical expressions exactly as they appear in the source, whether spelled out or written in digits. Apply local numbering conventions for large numbers where appropriate, while retaining terms like "billion" and "trillion" in English or using recognized equivalents in the target language. All original units of measurement must be preserved.

- **Dates:** Maintain the original date format as it appears in the source, whether in fully written or numeric form. Year lengths should not be altered, and no expansion or abbreviation of dates is permitted.

D Annotation Guidelines Based on MQM (Multidimensional Quality Metrics): Error Categories and Severities

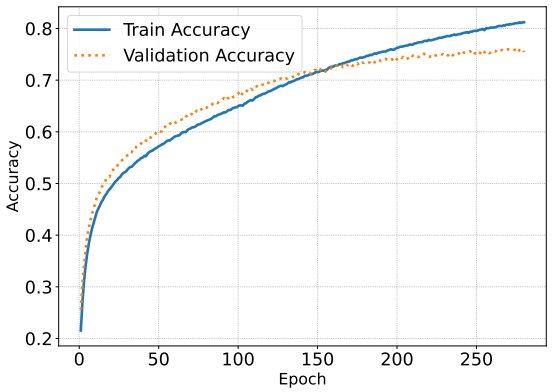
Translation quality was evaluated at the segment level, where each segment could consist of one or multiple sentences. Translations were aligned side-by-side with their corresponding source texts, enabling annotators to examine them in parallel. A well-defined hierarchy of error types was presented in Table 8 to guide annotators in consistently identifying and categorizing issues. Each error type was assigned a severity score on a five-point scale—*Very Low*, *Low*, *Medium*, *High*, and *Very High*—allowing for fine-grained distinctions in impact.

To translate qualitative assessments into numeric scores, we used the following mapping: Very Low = 1, Low = 2, Medium = 3, High = 4, and Very High = 5. Each error category—such as *Accuracy*, *Fluency*, *Terminology*, and *Style*—was scored independently, and all were treated with equal importance. Errors unrelated to translation were given a score of zero, and any sentence containing a critical error in the source text was excluded from scoring.

Instructions for Annotators

- Annotators were required to closely inspect each translated segment and identify all present errors, with a strict limit of five errors per segment. If more than five were found, only the five most critical errors were to be reported.
- Each error span was to be precisely highlighted using color coding, followed by assigning the correct error category and subcategory, along with an appropriate severity level. If the issue originated from the source sentence or involved omission, the corresponding source text span was to be marked instead.
- Errors had to be captured at the most granular level possible. For example, if two separate words were mistranslated, annotators had to log them as two individual errors rather than one.
- In cases where multiple errors overlapped in the same span, only the most severe error was recorded. If two errors had the same severity, the first matching category in the MQM hierarchy (e.g., Accuracy, then Fluency, then Terminology) was selected.
- **Special Categories:**
  - *Non-translation:* If a translation was highly distorted or entirely unrelated to the source, and individual errors couldn't be meaningfully identified, annotators were instructed to mark the entire segment as a single Non-translation error. No other errors should be logged for that segment.
  - *Source Error:* When an error was due to flaws in the source text, the problematic span in the source was highlighted, and such segments were excluded from scoring (though the source error still needed to be documented).
- After completing all annotations for a segment, annotators assigned a final quality score out of 25 and recorded this value in the final score column.

E Data Quality Control



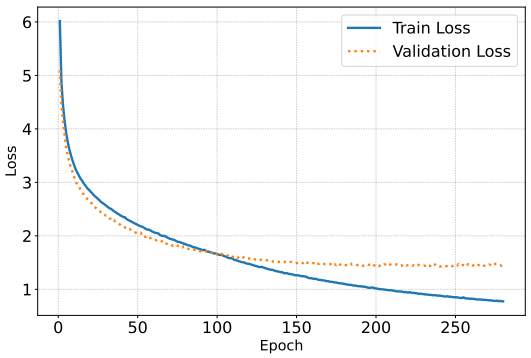
In order to rigorously assess the quality of our manually curated Hindi–Bhili gold references, we conducted an inter-annotator agreement (IAA) study. Following the MQM/DA protocol, we randomly sampled 250 sentences across our three domains. Two independent professional translators (Translator A and Translator B), both native Bhili speakers, translated each Hindi sentence into Bhili. Subsequently, each translator rated the other's rendering on the MQM scale. This evaluation yielded an **IAA coefficient of 0.68** for the Hindi→Bhili gold references, indicating substantial agreement and confirming the high quality of our dataset.

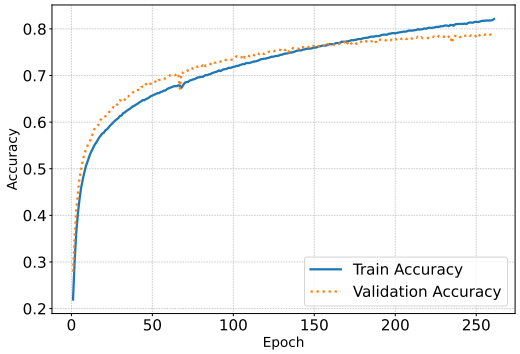
F Training Details

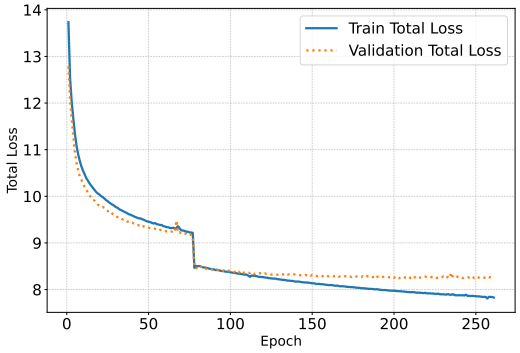
Both the MLM-only and proposed models were trained on an NVIDIA L40S GPU only once. Early stopping was used in both cases. Hyperparameters are provided in the following table:

Hyperparameter	Value
`max_seq_length`	128
Masking Probability	0.15
`max_epochs`	1000
`batch_size`	32
`learning_rate`	`5e-5`
Optimizer	AdamW
Scheduler	Linear Decay with warmup
Early Stopping	Yes
`queue_size` (for MoCo)	2048
α	1
β	1

The loss and accuracy plots are presented in Figure 3 for MLM-only and in Figure 4 for our proposed method. The notable sharp dip in the contrastive loss curve can be explained by the presence of learning rate reduction due to scheduling during training.







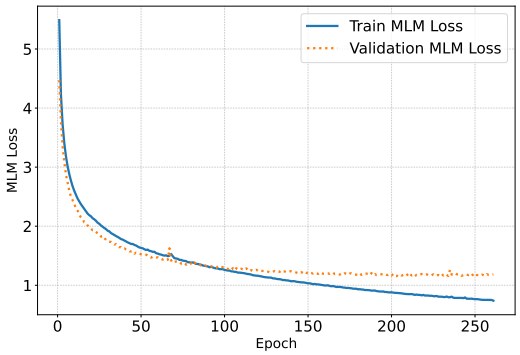


Figure 3: Accuracy and loss plots for continued pretraining of MuRIL with MLM

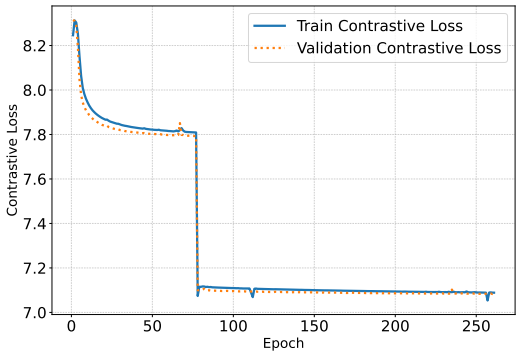

Figure 4: Accuracy and loss plots for training with GARuD, our proposed method. The total loss, MLM loss and the contrastive loss have been shown individually.

G Fine-tuning Details

Fine-tuning for the sentiment classification downstream task was done on an NVIDIA A5000 GPU.

The hyperparameter settings are provided in the following table:

Hyperparameter	Value
max_seq_length	64
max_epochs	100
batch_size	64
learning_rate	2e-3
Optimizer	AdamW
hidden_dim (for LSTM)	256
Dropout	0.2
Patience	3

For the XNLI task, we fine-tuned on the MNLI dataset using the standard training pipeline from HuggingFace's `transformers` library and then performed inference on the Hindi language split of the XNLI dataset. The task was performed on an NVIDIA L40S GPU. The hyperparameters are in the following table:

Hyperparameter	Value
num_epochs	5
batch_size	32
gradient_accumulation_steps	2
learning_rate	2e-5
weight_decay	0.01
warmup_ratio	0.1

INDICSENTEVAL: How Effectively do Multilingual Transformer Models encode Linguistic Properties for Indic Languages?

Abstract

Transformer-based models have revolutionized the field of natural language processing. To understand why they perform so well and to assess their reliability, several studies have focused on questions such as: Which linguistic properties are encoded by these models, and to what extent? How robust are these models in encoding linguistic properties when faced with perturbations in the input text? However, these studies have mainly focused on BERT and the English language. In this paper, we investigate similar questions regarding encoding capability and robustness for 8 linguistic properties across 13 different perturbations in 6 Indic languages, using 9 multilingual Transformer models (7 universal and 2 Indic-specific). To conduct this study, we introduce a novel multilingual benchmark dataset, INDICSENTEVAL, containing approximately ∼47K sentences. Our probing analysis of surface, syntactic, and semantic properties reveals that, while almost all multilingual models demonstrate consistent encoding performance for English, surprisingly, they show mixed results for Indic languages. As expected, Indic-specific multilingual models capture linguistic properties in Indic languages better than universal models. Intriguingly, universal models broadly exhibit better robustness compared to Indic-specific models, particularly under perturbations such as dropping both nouns and verbs, dropping only verbs, or keeping only nouns. Overall, this study provides valuable insights into probing and perturbation-specific strengths and weaknesses of popular multilingual Transformer-based models for different Indic languages. We make our code and dataset publicly available[1].

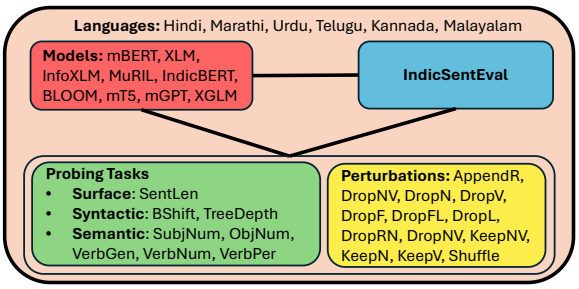

Figure 1: We evaluate 9 multilingual Transformer models on 8 probing tasks in 6 Indic languages using our INDICSENTEVAL dataset. We analyze the effects of 13 perturbations on the performance of these models.

1 Introduction

Transformer-based language models (Vaswani et al., 2017), pretrained for both mono-lingual and multilingual contexts using millions of text documents, have demonstrated substantial enhancements in the performance of various natural language processing (NLP) tasks (Kenton and Toutanova, 2019; Pires et al., 2019; Conneau et al., 2020; Radford et al., 2019; Brown et al., 2020; Wang et al., 2019, 2018). To understand what types of linguistic properties (surface, syntactic and semantic) are encoded across layers of Transformer-based models, initial studies have investigated the layer-wise representations via a range of probing tasks (Adi et al., 2017; Hupkes et al., 2018; Conneau et al., 2018; Rogers et al., 2020; Jawahar et al., 2019; Mohebbi et al., 2021). However, these studies focus solely on English. Although, several studies have examined the presence of shared representation aspects across widely spoken languages in multilingual models (Chi et al., 2020; Acs et al., 2024), unfortunately, there is no work that investigates the extent to which multilingual Transformer-based models encode linguistic properties for different Indic languages. Further, recent neuro-AI studies have revealed that the brain uses different parsing strategies for different linguistic properties, which further differ across languages (Zhang et al., 2022; Oota et al., 2023). This inspired us to study the nuances of how multilingual Transformer-based

models capture linguistic properties across layers and languages.

Indic languages offer a rich tapestry of linguistic features that contribute to the global linguistic diversity. Hence, in this paper, we focus on Indic languages. We study the degree to which linguistic properties of Indic languages are captured by two kinds of multilingual models: universal and Indic-specific models. Universal multilingual models have been pretrained using a variety of pretraining objectives and using data which contains a small and varying fraction of Indic languages across languages and models (Tables 19, 20, and 21 in Appendix F). Indic-specific models (Kakwani et al., 2020; Dabre et al., 2021; Kumar et al., 2022) have been specifically trained on Indic language data only. Specifically, we focus on 6 Indic languages: three Indo-European languages (Hindi, Marathi, Urdu) and three Dravidian languages (Telugu, Kannada, Malayalam).

Even if multilingual models encode linguistic properties of Indic languages effectively, such encodings may not be robust to input text perturbations for particular models. Lack of such robustness may make some models less reliable than others for real-world applications. Although there exist many such studies (Wang et al., 2021; Jin et al., 2020; Li et al., 2020; Garg and Ramakrishnan, 2020; Sanyal et al., 2022; Neerudu et al., 2023) on robustness analysis of Transformer-based models, they focus on English, and on downstream tasks. Robustness analysis for prediction of linguistic properties in a multilingual setting for Indic languages is under explored. Hence, we systematically study how various multilingual Transformer-based models may differ in their robustness for different linguistic properties with respect to different kinds of input text perturbations across languages. We provide detailed related work in Appendix A, focusing on three aspects: (i) probing in non-English and multilingual contexts, (ii) differences from English-centric findings, and (iii) critiques of probing methodology and recent advances.

We analyze 7 universal multilingual language models, each pretrained on data spanning ∼100+ languages, with only a small amount of Indic language data. These include mBERT (Pires et al., 2019), XLM-R (Conneau et al., 2020), InfoXLM (Chi et al., 2021), mGPT (Shliazhko et al., 2024), XGLM (Lin et al., 2022), BLOOM (Scao et al., 2022), and mT5 (Xue et al., 2021). Additionally, we examine 2 Indic-specific models, IndicBERT (Kakwani et al., 2020) and MuRIL (Khanuja et al., 2021), which are trained using corpora for Indic languages along with English. While it is expected that these Indic-specific models would be better at encoding and robustness for Indic language input, are there some linguistic properties which are better encoded by universal models? Are the universal models more robust to particular perturbation types? How effectively and robustly are English language properties encoded by these universal and Indic-specific models?

To perform such detailed analyses, we curate a novel multilingual dataset, INDICSENTEVAL, from resources generated by the "Indian Language Machine Translation" (ILMT) initiative. This dataset contains information about three types of linguistic properties per Indic language: surface, syntactic and semantic. To investigate encoding and robustness ability of multilingual models, we design probing tasks for prediction of each property. The surface task probes whether the model learns a representation which is predictive of sentence length (SentLen). Syntactic tasks test for sensitivity to word order, i.e., bigram shift (BShift) and the depth of the syntactic tree (TreeDepth). Semantic tasks check for the subject and the direct object number in the main clause (SubjNum and ObjNum, respectively). Tasks mentioned so far were discussed in English focused studies too. However, morphology for Indic languages is significantly different from English, primarily in regard to the main verb used in a sentence. This prompts us to expand our analysis to encompass three additional semantic probing tasks related to the main verb within the sentence: verb gender (VerbGen), verb number (VerbNum), and verb person (VerbPer). Fig. 1 shows the conceptual diagram of our study.

Overall, the main contributions of this paper are as follows. (1) We perform an extensive study of the degree to which 9 multilingual Transformer-based models capture 8 linguistic properties across 6 Indic languages. (2) We contribute a novel dataset, INDICSENTEVAL, with ∼47K sentences across the 6 languages. (3) We find that Indic-specific models like MuRIL and IndicBERT best capture linguistic properties for Indic languages, while universal models like mBERT, InfoXLM, mGPT and BLOOM show mixed results across properties. (4) Surprisingly, our robustness analy-

sis with respect to 13 text perturbations shows that universal multilingual models (InfoXLM, BLOOM, mGPT, XGLM and mT5) demonstrate higher resilience to perturbations compared to BERT-like models (mBERT, IndicBERT and MuRIL).

2 INDICSENTEVAL Dataset

We curate the INDICSENTEVAL dataset from resources generated by the ILMT initiative, which serves as an Indic language counterpart to SentEval (Conneau et al., 2018) and offers labeled data for the eight probing tasks. We utilize the morph and chunk level Indic languages data (Tandon and Sharma, 2017; Bhatt et al., 2009; Xia et al., 2008) available in Shakti Standard Format (SSF) (Bharati et al., 2007, 1995). SSF is a highly readable representation for storing Indic language data with linguistic annotations. Fig. 4 in Appendix B shows an example of a Hindi sentence in SSF format.

Probing Tasks. Probing tasks (Adi et al., 2017; Hupkes et al., 2018; Jawahar et al., 2019; Mohebbi et al., 2021) help unpack the linguistic features possibly encoded in neural language models. These probing tasks are formulated as prediction tasks and focus on several aspects of sentence structure. We experiment with eight probing tasks to evaluate how effectively multilingual models encode linguistic properties across six Indic languages: Hindi (`hi`), Telugu (`te`), Marathi (`mr`), Kannada (`kn`), Urdu (`ur`), and Malayalam (`ml`). These eight probing tasks are grouped into three categories: surface (SentLen), syntactic (BShift and TreeDepth), and semantic (SubjNum, ObjNum, VerbGen, VerbPerson and VerbNumber). We selected these tasks because they cover different aspects of language and require different levels of abstraction and generalization. These tasks involve 3 binary and 5 multi-class classification problems. The specifics of the initial five probing tasks are thoroughly outlined in (Conneau et al., 2018) as well. We also provide brief descriptions for each probing task in Appendix D, with a summary of class labels for each task in Table 1.

INDICSENTEVAL curation details. For each property, we gather data per language as follows. (1) *SentLen:* We iterate through all the nodes in the SSF format representation of the sentence and count number of words in each chunk. (2) *TreeDepth:* We utilize the data from the dependency tree to perform a traversal, specifically employing breadth first search. This traversal enables us to calculate the tree depth of the sentence. (3) *BShift:* For this task, we randomly (probability=0.2) select the sentences from the dataset, and then a randomly selected bigram (equal probability for all bigrams) is inverted. Sentences with inverted bigrams are marked as 1, and the rest as 0. (4) *SubjNum/ObjNum:* We identify the subject/object (a noun that can be singular or plural) of a sentence using the assigned semantic roles in the SSF format, and use the NN/NNS annotations. (5) *Verb Gender/Person/Number:* We first locate the chunk containing the main verb using the annotated chunk label from the SSF format. Then, we extract the gender/person/number information from the annotated morph output. Detailed statistics of number of samples across 6 Indic languages for 8 probing tasks are provided in Tables 10 and 11 in Appendix C. Further, Table 12 in Appendix D shows examples for each probing task per language.

Task	|C|	Labels
SentLen	8	(0-5),(6-8),(9-12),(13-16),(17-20),(21-25),(26-28),(29-32)
TreeDepth	5	(0-2),(3-5),(6-8),(9-11),(12-20)
BShift	2	0,1
SubjNum	2	singular, plural
ObjNum	2	singular, plural
VerbGen	4	masculine, feminine, neutral, any
VerbNum	3	singular, plural, any
VerbPer	7	1^{st} person, 2^{nd} person, 3^{rd} person, 1^{st} person honorific, 2^{nd} person honorific, 3^{rd} person honorific, any

Table 1: Probing task details: number of classes ($|C|$) and class labels.

3 Text Perturbation Analysis

While probing reveals what linguistic features are present in representations, perturbation-based robustness tests address a different question: "how robust is a model to various types of noise and whether it can still understand and process the core meaning of the text despite the introduced variation?" Since our current IndicSentEval dataset lacks noise examples, hence, in this study, we conducted our perturbation analysis on the input dataset to evaluate its robustness. To answer this question, we experiment with three different categories of perturbations: AppendR, DropText and Positional. We chose these perturbations because they simulate types of noise found in real datasets by introducing different degrees of noise and variation in the input text. Particularly, we experiment with the following text perturbations.

AppendR. We append a random (R) phrase to original sentence. This mimics real scenarios where additional, irrelevant data is included in text input.

DropText. DropText perturbations reflect situations where critical information is missing or only certain types of words are retained, which is common in incomplete or corrupted datasets. This includes *DropNV* (dropping words based on their part-of-speech tag, specifically both nouns (N) and verbs (V)), *DropN* (dropping all nouns), *DropV* (dropping all verbs), *DropRN* (dropping one random noun), *DropRV* (dropping one random verb), *KeepNV* (dropping all words except nouns and verbs), *KeepN* (dropping all words except nouns), and *KeepV* (dropping all words except verbs). DropText perturbations are designed to provide deeper insights into word-level attention mechanisms within models, specifically aiming to determine whether models focus more on objects (nouns), actions (verbs), or the contextual elements surrounding these key parts-of-speech.

Positional. This includes *DropF/DropL/DropFL* (replacing first/last/both words by "[UNK]" to maintain the original phrase length) and *Shuffle* (randomly shuffling the words in a sentence). These position-based text perturbations help us understand the extent to which words at specific positions (first/last) or relative positions impact the language structure encoding capabilities of various models.

Overall, these text perturbations help in understanding the contribution of specific word types and sentence structures to the encoding capabilities of multilingual models. Tables 13-18 in Appendix E display examples of perturbations for each language.

4 Methodology

Multilingual language models. We experiment with nine multilingual Transformer-based models (listed in Table 19 in Appendix F). First seven have been trained across 100+ languages; IndicBERT and MuRIL support 12 and 17 Indic languages, respectively. Representations are extracted from the encoder layers of mBERT-base, IndicBERT-base, mT5-base, XLM-R, InfoXLM and MuRIL; and from the decoder layers of BLOOM, mGPT and XGLM. We use pretrained model checkpoints from Hugging Face (Wolf et al., 2020).

Probing tasks classifier. To evaluate each probing task using a multilingual model representation, we use logistic regression (Wright, 1995) classifier with sentence representations as input and the probing task label as target. The base model is frozen. We use mean pooling across tokens to get the sentence representation. Details of the hyperparameters are reported in Appendix F.

Dataset splits. We use a stratified five-fold cross-validation approach which involves splitting the dataset into five equal parts, where four parts are used for training and the remaining part is used for testing. This process is repeated five times, with each part used for testing once. To report our results, we calculate the average performance of the model across all five folds.

Evaluation metrics. Similar to earlier studies (Conneau et al., 2018; Jawahar et al., 2019; Mohebbi et al., 2021), for all the probing tasks, we use *classification accuracy* as the evaluation metric. Let A_c and A_p be accuracy of a model on the clean and perturbed test sets, respectively. To evaluate the perturbation results for probing tasks, we use *robustness score (RS)* defined as $RS = 1 - \frac{A_c - A_p}{A_c}$. Typically, *RS* of a model ranges between 0 and 1 where 0 indicates that the model is not robust, and 1 indicates that the model is completely robust. Score > 1 suggests that the model's performance improves when the perturbation is applied.

5 Experimental Results

We measure probing accuracy independently for each multilingual model, within each layer separately. Along with six Indic languages, we measure the probing accuracy for English language across all multilingual models and compare the findings for Indic languages against English. Further, we investigate the robustness of these multilingual models by perturbing the input sentences.

5.1 Probing Results

How effectively do multilingual models encode hierarchy of linguistic structure for Indic languages? We assess the linguistic structure by contrasting universal models trained on 100+ languages with those specifically trained on Indic languages only. Unless otherwise specified, the results presented in the main paper reflect an average accuracy across encoder-based universal models, decoder-based universal models and Indic-specific models.

Surface-level tasks. We show the accuracy scores obtained for surface level task (i.e. SentLen) in the first row in Fig. 2. Analyzing the performance across languages, we observe the following patterns: (i) For encoder-based universal models as well as for Indic models, there is a trend of higher

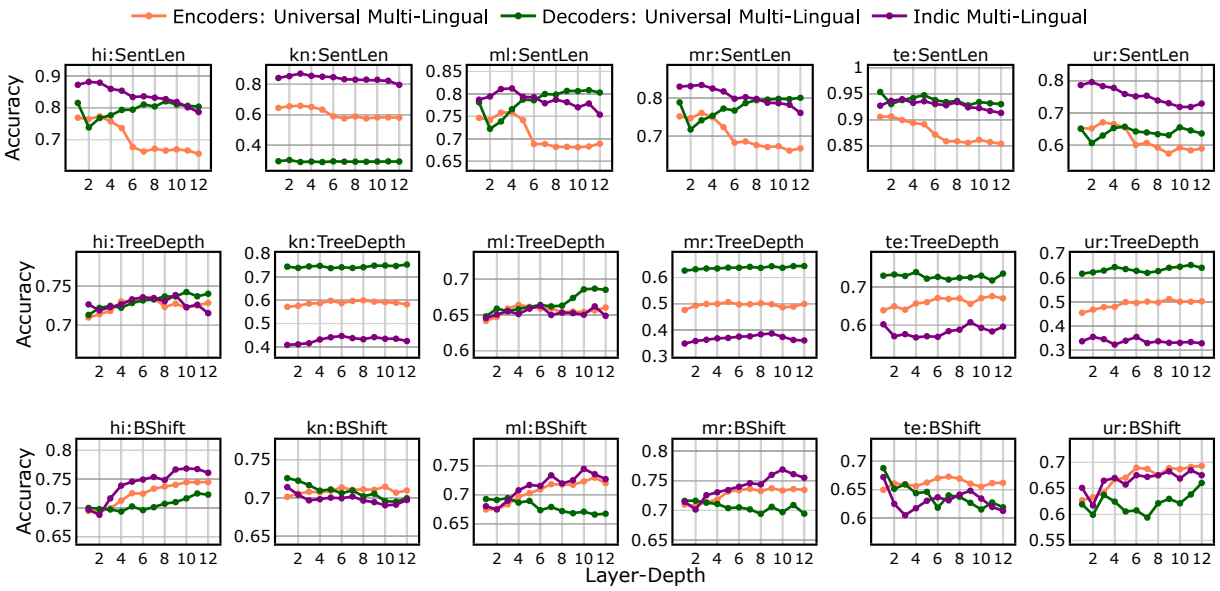

Figure 2: Probing task results: Layerwise accuracy comparisons between various multilingual representations on surface (top row) and syntactic (bottom two rows) probing tasks. We report the layerwise probing accuracies for individual multilingual models in Figs. 5 to 10 in Appendix G.

accuracy in the early (or lower) layers, which decreases in the later (or higher) layers. This pattern is expected, as surface-level tasks generally require minimal processing. (ii) Notably, the decoder-based universal multilingual models deviates from this trend, showing lower accuracy in the early layers and higher accuracy in the later layers. This seemingly unusual pattern in decoder-based universal models is actually intuitive because masked self attention in their autoregressive architectural design implies that only deeper layers in such models can effectively grasp the input length. (iii) Overall, among all the models, Indic models report best accuracy, while encoder-based universal models display poorer performance. This is likely because Indic models are specifically trained on Indic languages, making them more attuned to the nuances and idiosyncrasies of these languages. On the other hand, universal models, which are designed for universal applicability, might struggle with specific linguistic features unique to Indic languages. These features include script differences, morphological complexity, and visual factors such as orthography and word length. Tokenizers of universal models tokenize Indic language inputs to many tokens with little correlation with actual input length in words.

We present the individual model-specific results across languages in Figs. 5 to 10 in Appendix G. We observe that among all the models, IndicBERT reports the best accuracy, while universal multilingual model XLM-R displays poor performance. More detailed analysis is reported in Appendix G.

Syntactic tasks. In the bottom two rows of Fig. 2, we display the accuracy scores for syntactic tasks. For TreeDepth, we observe that probing accuracy tends to be higher in the middle layers for various (model, language) combinations. This trend is particularly notable in both encoder-based universal models and Indic models. Moreover, this pattern is consistent for three languages: `hi`, `kn` and `ml`. However, decoder-based multilingual models do not exhibit any clear layer-wise trend, and the same applies to the other three Indic languages. Encoders, with their bidirectional attention, might be inherently better at capturing hierarchical structures, while decoders, with their unidirectional attention, might excel in tasks requiring sequential processing. The lack of a clear trend in decoder-based multilingual models might indicate that these models distribute syntactic processing more evenly across layers. The varying performance across languages underscores the importance of considering linguistic diversity in model training.

In contrast to TreeDepth, for BShift task, we generally observe higher probing accuracy in the later layers for both encoder-based universal and Indic models across various languages. Notably, decoder-based universal models exhibit a decreasing trend in accuracy for `kn`, `ml` and `te`, while showing an increasing trend for `hi` and `ur`. This suggests that

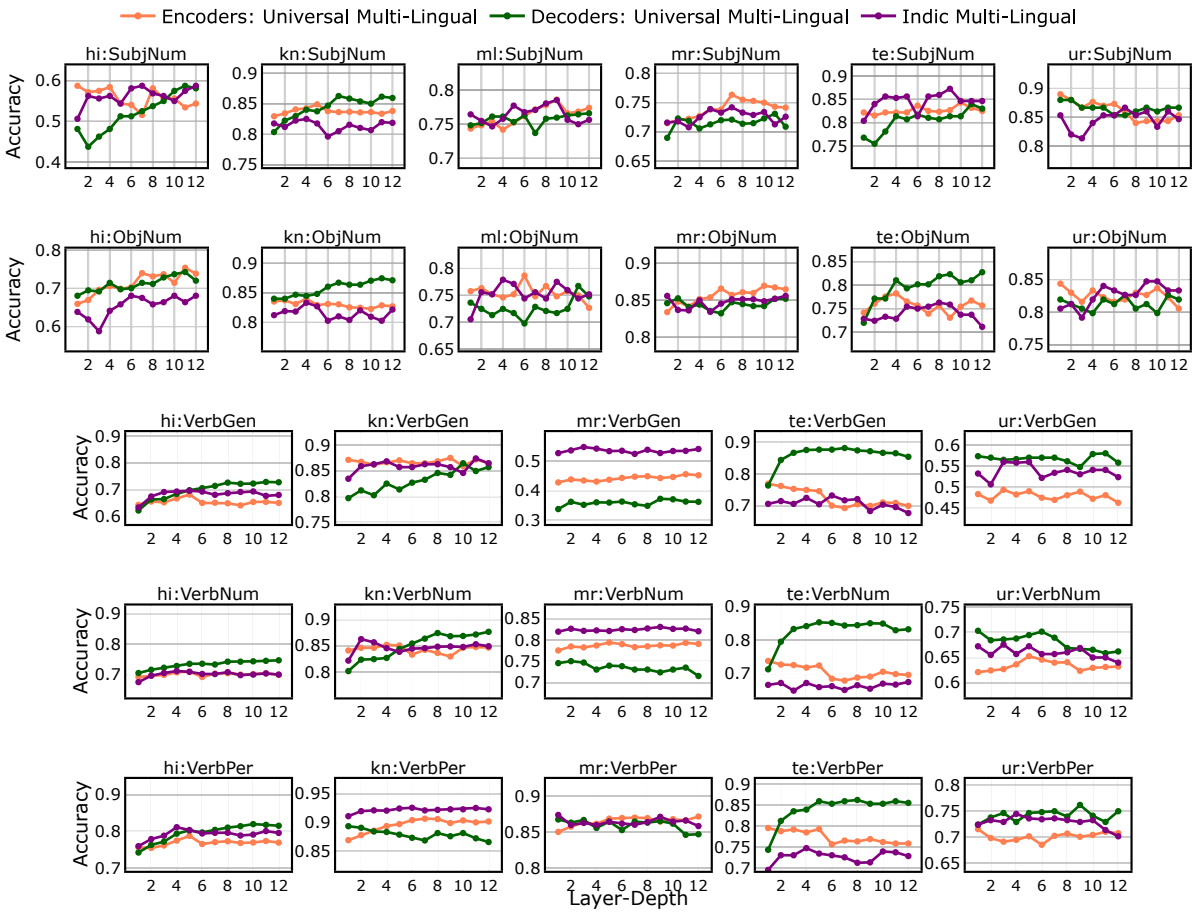

Figure 3: Probing task results: Layerwise accuracy comparisons between various multilingual representations on semantic probing tasks. For Malayalam, there is an absence of SSF data for the VerbGen, VerbPer, and VerbNum tasks. We report the layerwise probing accuracies for individual multilingual models in Figs. 5 to 10 in Appendix G.

languages with different syntactic structures may require different layers to process syntactic tasks effectively.

Overall, when comparing performance across models and tasks, decoder-based universal models stand out for their superior accuracy in capturing tree depth information across different languages. Conversely, Indic models show notable proficiency in BShift. These findings highlight the need for comprehensive evaluation across multiple tasks and languages to understand model capabilities fully. Evaluating models on diverse syntactic tasks can reveal strengths and weaknesses that might not be apparent from a single task. These observations contribute to a deeper understanding of how various multilingual models process syntactic information, demonstrating both model-specific and language-specific trends and capabilities in linguistic tasks.

From the individual model specific results in Figs. 5 to 10 in Appendix G, we observe that among all the models, InfoXLM and mT5 stand out for their superior accuracy in capturing tree depth information across different languages. Conversely, Indic model MuRIL shows notable proficiency in BShift. More detailed analysis is reported in Appendix G.

Semantic tasks. We plot the accuracy scores obtained for semantic tasks in Fig. 3: SubjNum and ObjNum in the first 2 rows, and VerbGen, VerbNum and VerbPer in the last 3 rows. The last three rows do not have results for Malayalam (`ml`) since we do not have labeled data for `ml` for those tasks.

From SubjNum and ObjNum results, we make the following observations. For decoder-based universal models, we observe an increasing trend from lower to higher layers for `hi`, `kn` and `te`. Dravidian languages often have more complex morphological systems for marking plurality, with a variety of suffixes and sometimes even changes in the noun stem itself. Hence, this increasing trend makes sense for `kn` and `te`. When considering other languages and models, we note that both encoder-based and Indic

models exhibit an increasing trend for the ObjNum task, specifically for hi and mr. This highlights the variability in model performance based on the language. Interestingly, the middle layers of the encoder-based universal models and Indic models show higher probing accuracy for languages such as hi, ml, mr and te in the SubjNum task.

For the verb-related tasks, decoder-based universal models perform the best for most languages and tasks. Also, in most cases, the last layer is the most predictive, except in mr and ur for gender, number and person detection, where initial layers provide better results. This indicates that gender, number and person detection in mr and ur is straightforward and does not need deep processing. We observe a decreasing trend for encoder-based universal models for language te. For the Indic models, we observe an increasing trend for two languages hi and kn across tasks. Overall, both encoder-based universal and Indic models show mixed trend in performance across layers.

From the individual model specific results in Figs. 5 to 10 in Appendix G, we observe that XLM-R exhibits lower accuracy and lacks a discernible trend when it comes to capturing semantics. MuRIL has the highest probing accuracy although it performs the worst for kn ObjNum task. More detailed analysis is reported in Appendix G.

Comparison of encoding performance of multilingual models for linguistic properties for English vs Indic languages. We conduct probing for English across nine multilingual models for five tasks: SentLen, TreeDepth, BShift, SubjNum, and ObjNum using SentEval dataset (Conneau et al., 2018). Fig. 11 in Appendix G reports the probing accuracy. Surprisingly, across all multilingual models, we observe that surface features show a decreasing trend from lower to higher layers. For syntactic TreeDepth feature probing accuracy is higher in the middle layers, while BShift has an increasing trend from lower to higher layers. Finally, the semantic tasks SujbNum and ObjNum are best encoded in the later layers. This implies that English is encoded in the same manner in both universal and Indic multilingual models, whereas Indic languages show mixed results across models.

Overall insights from probing experiments. While Indic-specific models like MuRIL and IndicBERT are likely the best at capturing language properties within the realm of Indic languages due to their targeted training, both encoder and decoder-based universal models like mBERT, InfoXLM, BLOOM and mGPT show mixed results. Their broader training might enable them to capture more general properties across many languages, but they may lack a deep understanding specific to each language, particularly those less represented in their training corpus. The effectiveness of these models thus depends on specific linguistic features and tasks, as well as the range of languages being considered. mBERT and MuRIL capture linguistic features for hi very well. For mr and te, mT5 and MuRIL show better accuracy for surface, syntactic and semantic tasks. This is in line with the fact that hi, mr, and te are better represented in pretraining datasets for these models.

5.2 Perturbation Results

We perform 13 different text perturbations to understand the contribution of specific word types and sentence structures to the encoding capabilities of multilingual language models[2]. We analyze the impact of such text perturbations for every pair of (model, language), (model, probing task), (perturbation, model) and (language, probing task) in Tables 2, 3, 4 and 5 respectively.

We report results for the layerwise perturbation analysis and other pairs like (perturbation, language) and (perturbation, probing task) in Tables 6, 7 and 8. All these tables show weighted

[2]Perturbations do not make sense for BShift probing task.

Table 4: Comparison of robustness scores on probing tasks: multilingual models vs. perturbation types, averaged across layers, highlighting top-3 scores.

averages across marginalized dimensions.

Which multilingual models are more robust to perturbations in Indic languages? Table 2 shows that universal models like InfoXLM, BLOOM, mT5 and mGPT show greater resilience to perturbations in at least four languages. In contrast, the universal model (mBERT) and the Indic-specific models (IndicBERT and MuRIL) display a more significant accuracy drop across all the Indic languages. Accuracy drop for BERT-specific models is perhaps because cross-lingual transfer might be less effective, resulting in decreased accuracy compared to other multilingual models.

Which multilingual models are more robust across probing tasks? Table 3 shows that universal models have greater robustness compared to Indic models and mBERT. Additionally, surface and syntactic probing tasks are significantly impacted by perturbations compared to semantic properties.

Which text perturbations have the greatest impact on multilingual models? From Table 4, we observe: (i) Dropping both nouns and verbs has an adverse effect on all models. (ii) Similarly, dropping only verbs or retaining only nouns affects the performance drop across models. Thus, eliminating nouns and verbs can lead to losing vital information necessary for accurate predictions. Discarding nouns or verbs can disrupt the syntactic coherence of text, making it more challenging for the model to comprehend and process.

Which Indic languages are more robust across probing tasks? Table 5 shows that models exhibit greater robustness across probing tasks for `hi` and `te`, especially for semantic properties. Conversely, surface and syntactic properties are more affected by perturbations, except for similar language structure observed for `te` and `kn`. Additionally, languages such as `ur` and `mr` are more impacted by perturbations due to relatively lower training token counts compared to other languages.

	Sent Len	Tree Depth	Subj Num	Obj Num	Verb Gen	Verb Num	Verb Per
`hi`	0.436	0.338	**1.104**	**1.009**	**0.931**	**0.951**	**0.972**
`kn`	**0.793**	**0.632**	0.902	0.896	0.818	0.860	0.967
`ml`	0.362	0.367	0.859	0.897	**0.968**	**1.001**	**1.006**
`mr`	0.277	0.578	0.836	**0.938**	0.738	0.808	0.926
`te`	**0.895**	**0.939**	**0.952**	**0.968**	**0.915**	**1.003**	**0.994**
`ur`	0.232	0.580	**0.949**	0.935	0.738	0.837	0.875

Table 5: Comparison of robustness scores on probing tasks: Indic languages vs. probing tasks, averaged across layers, highlighting top-3 scores.

	`hi`	`kn`	`ml`	`mr`	`te`	`ur`
SentLen	1, 2, 3	4, 3, 2	3, 4, 1	1, 3, 2	1, 2	3, 1, 2
TreeDepth	7, 5, 6	5, 4, 9	4, 5, 3	4, 8, 9	10, 11, 12	3, 2, 5
VerbGen	10, 8, 5	11, 4, 12	-	11, 10, 12	6, 8, 9	3, 8, 9
VerbNum	Equal	3, 4, 5	-	2, 4, 5	10, 12	5, 4, 3
VerbPer	Equal	Equal	-	3, 4, 5	5, 11, 12	4, 5
SubjNum	N/A	Equal	9, 8, 7	7, 10, 9	10, 11	1, 2
ObjNum	11, 12	4, 3, 9	Equal	11, 10, 12	11, 12	10, 9, 11

Table 6: Summary of the layerwise robustness analysis averaged across multilingual models, considering 13 perturbations. Each cell reports the most affected layers after text perturbations for each probing task and language. "Equal" denotes that all layers are affected, while '-' indicates the absence of a probing dataset for that particular language.

Which layers are more affected due to text perturbations for Indic languages? Table 6, we observe: (i) across all Indic languages, early layers are impacted for surface properties. (ii) for TreeDepth syntactic property, middle layers are affected for all languages except `te`. (iii) Surprisingly, later layers are impacted more than early and middle layers. Regarding semantic properties, for `ur`, early to middle layers are impacted more than later layers, except for ObjNum. Similarly, for `kn`, SubjNum and ObjNum are impacted on middle layers; for `mr`, VerbNum and VerbPer are affected.

Which text perturbations have the greatest impact on probing tasks across six Indic languages? Tables 7 and 8 show that dropping nouns and verbs significantly affects accuracy across all six languages. Specifically, dropping verbs impacts accuracy of three verb-based semantic tasks. Similarly, position perturbations, such as keeping nouns in specific positions, affect verb tasks, while keeping verbs or nouns affects surface and syntactic tasks.

Overall insights from perturbation experiments. Text perturbation analysis reveals that universal models such as InfoXLM, BLOOM, mGPT,

Table 8: Comparison of robustness scores on probing tasks: perturbation types vs. probing tasks, averaged across layers. Lowest robustness values per column are highlighted in bold.

XGLM and mT5 demonstrate higher resilience to perturbations compared to BERT-like models mBERT, IndicBERT, and MuRIL. Perhaps, the larger multilingual models are more robust as they rely less on language specific word order compared to Indic models (Dufter and Schütze, 2020; Liang et al., 2023). Specifically, dropping both nouns and verbs proves to be particularly sensitive across all languages, impacting semantic and syntactic properties significantly. Perturbations, such as position alterations, also affect model performance, emphasizing the importance of considering linguistic nuances in robustness testing.

5.3 Correlation Analysis of Probing with Downstream Tasks

We conducted a correlation analysis between our IndicSentEval probing results and downstream task performance from the IndicGLUE benchmark. Specifically, we analyze how the performance of the IndicSentEval probing tasks correlates with the

Model	Syntactic Probes	Semantic Probes	POS Tagging	NER	Sentiment Analysis	NLI
IndicBERT	0.82	0.80	0.88	0.84	0.81	0.79
MuRIL	0.85	0.86	0.89	0.83	0.85	0.87
mBERT	0.72	0.70	0.76	0.88	0.70	0.69
XLM-R	0.80	0.78	0.85	0.85	0.83	0.82

Table 9: Performance comparison of multilingual models across various probing and downstream tasks.

results of the IndicGLUE downstream tasks and other benchmarks. This includes models such as IndicBERT, MuRIL, mBERT, and XLM-R across syntactic and semantic tasks like NER, POS tagging, sentiment analysis, and natural language inference. The Table 9 shows the aggregated scores across multiple Indic languages. We make the following observations from Table 9: (i) Models like MuRIL and IndicBERT, which scored highest on syntactic and semantic probes, also performed best on corresponding tasks like POS tagging, NER (syntactic), and sentiment classification, NLI (semantic). (ii) Universal models like mBERT showed weaker probe performance and correspondingly lower scores on most IndicGLUE tasks, especially for morphologically rich languages. (iii) Tasks requiring deeper understanding (e.g. NLI) correlated more strongly with semantic probes, while syntactic probes aligned better with tagging tasks. This implies alignment between what probes measure and what different task categories demand. These findings suggest that the linguistic properties measured by probing are indeed predictive of real-world task performance, particularly in morphologically rich Indic languages.

6 Discussion and Conclusion

We evaluated 9 multilingual Transformer-based models on 8 probing tasks to understand linguistic structures in 6 Indic languages, using our contributed IndicSentEval dataset. Indic-specific models like MuRIL and IndicBERT excel due to targeted training, while universal models like mBERT, InfoXLM, BLOOM, mGPT, and XGLM show mixed results. Perturbation analysis reveals decoder-based models are the most robust. Overall, our findings highlight the importance of language model interpretability. Language proficiency is seen in models with comprehensive training datasets. Encoding ability and perturbation impact vary across languages and models, underscoring the need for robust training strategies and tailored architectures to handle linguistic variations and perturbations effectively.

7 Limitations

The current work focused on only 6 Indic languages. It would be interesting to expand this to more Indic languages.

We performed experiments with base versions of various models. It would be interesting to see if larger variants perform better at these tasks and if the trends differ.

We experimented with a basic set of linguistic properties. It would be nice to explore more complex linguistic properties like morphological tagging, syntactic parsing, and semantic similarity.

8 Ethics Statement

All the models used in this work are publicly available on Hugging Face and free for research.

We utilized publicly accessible resources in SSF format from https://ltrc.iiit.ac.in/showfile.php?filename=downloads/kolhi/ and https://ltrc.iiit.ac.in/showfile.php?filename=downloads/lingResources/newreleases.html. The datasets are licensed under Creative Commons by Non-Commercial 4.0 (CC BY-NC 4.0). No anticipated risks are associated with using the data from these provided links. We adapted the accessible resources to generate diverse probing and perturbation datasets as required.

- Appendix F: Details of Multilingual Models.
- Appendix G: Detailed Probing Results.
- Appendix H: Additional Discussion

A Related Work

Our work is most closely related to that of Jawahar et al. (2019) and Mohebbi et al. (2021), who focus on understanding the interpretability of language models via probing and observing linguistic structures in English. Our study on multilingual language models for six Indic languages complements their English-focused studies.

Our work also relates to the growing literature that creates resources for low-resource Indic languages. Several recent studies have developed resources including, Indic language models (Khan et al., 2024), Indic NLP suite (Kakwani et al., 2020), Indic BART (Dabre et al., 2021), Indic NLG (Kumar et al., 2022), IndicMT Eval (Dixit et al., 2023), and Naamapadam (Mhaske et al., 2023). Our research is the first to interpret both universal and Indic-specific models for Indic languages through probing representations and assessment of robustness, while also providing implications for future research directions. Overall, we complement these works by studying the linguistic structure of a wide range of low-resource Indic languages on multilingual models.

Non-English and Multilingual Probing Studies: Research on probing language models has increasingly moved beyond English to multilingual and non-English contexts, particularly focusing on morphologically rich and low-resource languages (Pires et al., 2019; Edmiston, 2020; Abdelali et al., 2022; Acs et al., 2024). For instance, Pires et al. (2019) is one of the earliest probing studies on mBERT, showing that mBERT enables zero-shot cross-lingual transfer using shared representations, but performs best on typologically

similar languages, struggling with distant or low-resource ones. Extending from previous work, Edmiston (2020) probe BERT's hidden layers for discrete morphological features in five languages (e.g. gender, tense, case) and observe that BERT encodes discrete morphological features across multiple languages, but lacked explicit analysis of model robustness across language families. More recently, Abdelali et al. (2022) probed several Arabic BERT-based models (and mBERT) and observed that Arabic BERT models capture morphology in lower layers and syntax in higher layers, but had limited focus on dialectal variation and cross-model comparison. Very recently, Acs et al. (2024) introduced a large multilingual probing dataset across 42 languages and found strong morphological encoding in mBERT/XLM-R, but did not analyze model robustness or compare to language-specific models. While these earlier studies primarily focused on morphological encoding in universal multilingual models (like mBERT and XLM-R), IndicSentEval uniquely evaluates both universal multilingual models and Indic-specific models, explicitly comparing their robustness and representational capabilities across six morphologically rich and script-diverse Indic languages.

Critiques of Probing Methodology and Recent Advances Probing methods have faced significant criticism in recent years, primarily for overinterpreting what models "know" from linear classifier performance (Hewitt and Liang, 2019; Voita and Titov, 2020; Ravichander et al., 2021). For instance, Hewitt and Liang (2019) showed that complex probes may "memorize" tasks, not reveal what's encoded in the representations, ensuring probes extract meaningful, not spurious, information. Extended to previous work, Voita and Titov (2020) proposed using Minimum Description Length (MDL) to evaluate how efficiently linguistic features can be extracted. They show that MDL probes reward simpler models and fewer training samples, improving interpretability and robustness. Further, Ravichander et al. (2021) demonstrate that models can encode linguistic properties even if these properties are not necessary for the task the model was trained on. Specifically, they highlight the importance of careful controls when designing probing experiments, as high probing accuracy does not necessarily indicate that the probed information is utilized by the model during its primary task. In our IndicSentEval work, we address these critiques by: (i) using lightweight probes with standardized architecture across all models and languages; (ii) focusing on relative comparisons (across layers, languages, and perturbations) rather than absolute performance; (iii) including input-level perturbations to test mechanistic interpretability and model robustness; and (iv) complementing standard probing with morpho-semantic tasks tailored to Indic grammar, allowing deeper insight into model behavior for typologically diverse languages.

Differences from English-Centric Findings: Probing studies in non-English and multilingual contexts have revealed notable differences from English-centric findings, due to linguistic diversity and the multilingual training regime (Zheng and Liu, 2022; Tikhonova et al., 2023; Godunova and Voloshina, 2024; Dang et al., 2024). For instance, Zheng and Liu (2022) showed that multilingual models encode universal syntactic features well but struggle with fine-grained morphology (e.g., verb agreement), unlike their performance on English tasks. Similarly, Tikhonova et al. (2023) reported that mBERT lacks the clear layer-wise linguistic hierarchy found in English BERT, suggesting architectural behavior does not generalize across languages. More recently, studies including Godunova and Voloshina (2024) found that discourse-level understanding remains uniformly weak across high- and low-resource languages, contrasting with better performance on lower-level tasks in English. Also, Dang et al. (2024) found that GPT models generalize well to inflect unseen words in morphologically simple languages, but performance declines sharply as morphological complexity increases. In contrast to prior studies that either focused primarily on English or reported high-level trends across many languages, IndicSentEval reveals that while multilingual models exhibit consistent representational hierarchies for English, they show mixed and often unstable behavior across Indic languages, especially in encoding syntactic and morphological features-highlighting language-specific gaps that broader multilingual benchmarks often obscure.

B SSF format

We curate the IndicSentEval dataset from resources generated by the ILMT initiative, which serves as an Indic language counterpart to the SentEval dataset and offers labeled data for the eight

Figure 4: A sample of an SSF formatted sentence in Hindi language.

probing tasks. We utilize the morph and chunk level Indic languages data (Tandon and Sharma, 2017; Bhatt et al., 2009; Xia et al., 2008), which is available in Shakti Standard Format (SSF) (Bharati et al., 2007, 1995). SSF is a highly readable representation for storing Indic language data with linguistic annotations. We refer the reader to read (Bharati et al., 2007) for more details about the SSF format.

An example of a Hindi sentence in the SSF format is illustrated in Fig. 4. Each line in Fig. 4 delineates a word within a sentence. Every line of a sentence representation in SSF comprises four components: Address, token, Category, and Attribute-value pairs. The Address encompasses two numbers, denoting the chunk number the word resides in and its relative position within the chunk. Token signifies the POS tag corresponding to the word. The feature list, articulated as "<fs af = root, category, gender, number, person, case, tense, aspect>", encapsulates linguistic feature information of a word. The attribute fields are fixedly positioned and separated by commas. Attributes remain blank if a property is inapplicable to the word. Properties like root, category, gender, number, person, and case are delineated within the feature list.

Urdu	5593

Table 11: Vocabulary size of each language from INDICSENTEVAL.

Language	Sentence	Probing Task labels
Marathi	शिंपल्याच्या शेतीने जगाचे लक्ष इकडे आकर्षित केले आहे . Mussel farming has attracted the attention of the world here.	SentLen → 8; TreeDepth → 3; SubjNum →singular(sg); ObjNum → singular(sg); BShift → शिंपल्याच्या शेतीने जगाचे लक्ष इकडे ***केले आकर्षित*** आहे (Mussel farming **attracted has** the attention of the world here); VerbGen → male(m); VerbNum → singular(sg); VerbPer → 1st person (1)
Kannada	ಅಳಿಲು ಭಕ್ತಿ ಮಳಲು ಸೇವೆ ' ಎಂಬಂತೆ ಶಾಲಾ ಬಾಲಕರು ಸಹ ಯಥಾಶಕ್ತಿ ಓದುಬರೆಹ ಕಲಿಸಿದರು . School boys were also taught reading and writing to the best of their ability as 'Alilu Bhakti Malalu Seva'.	SentLen → 11; TreeDepth → 3; SubjNum →singular(sg); ObjNum → singular(sg); BShift → ಅಳಿಲು ಭಕ್ತಿ ಮಳಲು ಸೇವೆ ' ಎಂಬಂತೆ ***ಬಾಲಕರು ಶಾಲಾ*** ಸಹ ಯಥಾಶಕ್ತಿ ಓದುಬರೆಹ ಕಲಿಸಿದರು (**boys school** were also taught reading and writing to the best of their ability as 'Alilu Bhakti Malalu Seva'); VerbGen → any(any); VerbNum → plural(pl); VerbPer → 3rd person (3)
Malayalam	കാർഷിക പദ്ധതികളുടെ അടങ്കൽ 600കോടി രൂപ ആയി പുതിയ സർക്കാർ ഉയർത്തി . The new government has increased the amount of agricultural projects to 600 crore rupees.	SentLen → 10; TreeDepth → 3; SubjNum →singular(sg); ObjNum → singular(sg); BShift → കാർഷിക പദ്ധതികളുടെ അടങ്കൽ 600കോടി രൂപ ***പുതിയ ആയി*** സർക്കാർ ഉയർത്തി. (The **government new** has increased the amount of agricultural projects to 600 crore rupees.) ;
Urdu	شروع شروع میں ریڈیو پروگرام سیٹوں تک محدود تھے . Initially, radio programs were limited to radio sets.	SentLen → 11; TreeDepth → 2; SubjNum →singular(sg); ObjNum → plural(pl); BShift → شروع شروع میں ریڈیو پروگرام سیٹوں ریڈیو تک محدود تھے . (Initially, radio programs were limited to **sets radio**) ; VerbGen → male (m); VerbNum → singular (sg); VerbPer → any (any)
Telugu	నీరు పడటంతో ఏర్పడే పాలనురుగు మరియు నీటి బిందువుల స్వాభావిక ఫౌంటెన్లు పర్యాటకులను ముద్దముద్దగా తడిపేస్తాయి . The inherent fountains of milky foam and water droplets created by falling water drenched tourists.	SentLen → 13; TreeDepth → 7; SubjNum → plural(pl); ObjNum → plural(pl); BShift → నీరు పడటంతో ఏర్పడే పాలనురుగు మరియు నీటి బిందువుల ***ఫౌంటెన్లు స్వాభావిక*** పర్యాటకులను ముద్దముద్దగా తడిపేస్తాయి . (The **fountains inherent** of milky foam and water droplets created by falling water drenched tourists) ; VerbGen → neuter (n); VerbNum → plural(pl); VerbPer → 3rd person (3)
Hindi	जोर से आवाज लगाने पर भी यह नजारा देखा जा सकता है । This scene can be seen even after making loud noise.	SentLen → 13; TreeDepth → 3; SubjNum → plural (pl); ObjNum → singular (sg); BShift → जोर से आवाज लगाने पर भी यह नजारा ***जा देखा*** सकता है । (This scene can **seen be** even after making loud noise) ; VerbGen → male (m); VerbNum → singular (sg); VerbPer → any (any)

Table 12: Examples for probing tasks w.r.t each language.

D Probing Tasks

Surface level tasks (1) *Sentence Length (SentLen):* Here, the objective is to predict the number of words in sentences, which has been grouped into 8 categories as shown in Table 1 (see main paper).

Syntactic tasks (2) *Tree Depth (TreeDepth):* The goal of this task is to predict the maximum depth of the sentence's syntactic tree, which is categorized into five options based on depth intervals as shown in Table 1. As constituency data in Indic languages is unavailable, we utilize dependency tree data to determine the tree depth. This task provides valuable insights into the structural complexity and organization of sentences. (3) *Bigram Shift (BShift):* This task involves binary classification aimed at predicting whether two consecutive tokens within a sentence are inverted or not.

Semantic tasks (4) *Subject Number (SubjNum):* This task evaluates sentences to determine the number of the subject in the main clause. It categorizes the subjects as NN (singular) or NNS (plural or mass, such as "colors," "waves," etc.). (5) *Object Number (ObjNum):* This task involves identifying whether the object of the main clause in a sentence is singular or plural/mass. It uses the label NN for singular objects and NNS for plural or mass objects. (6) *Verb Gender (VerbGen):* This task involves categorizing the grammatical gender of the main verb in a sentence as masculine, feminine, neutral, or any. (7) *Verb Number (VerbNum):* This task assesses the number of the main verb in a sentence, determining whether it is singular, plural, or any. (8) *Verb Person (VerbPer):* This task involves categorizing the grammatical person of the sentence's main verb into one of 7 classes as shown in Table 1. Honorifics, especially common in Indic languages, are forms of address that convey respect and politeness based on social status, age, or relationship. A typical example from Hindi is the use of "ji" to respectfully address elders, as seen in "dada-ji".

E Text Perturbation Examples

Tables 13-18 display an illustrative example of text perturbations for each perturbation type per language. For each language, the tables present the original sentence followed by a perturbed sentence resulting from each of the thirteen perturbations. Additionally, English translations are provided for enhanced comprehension.

F Details of Multilingual Models

F.1 Training data proportion of the tested languages

Table 21 shows the proportion of training data for each Indic language within each model's total Indic language tokens. From Table 21, we make the following observations:

Balanced vs. Imbalanced Distribution:

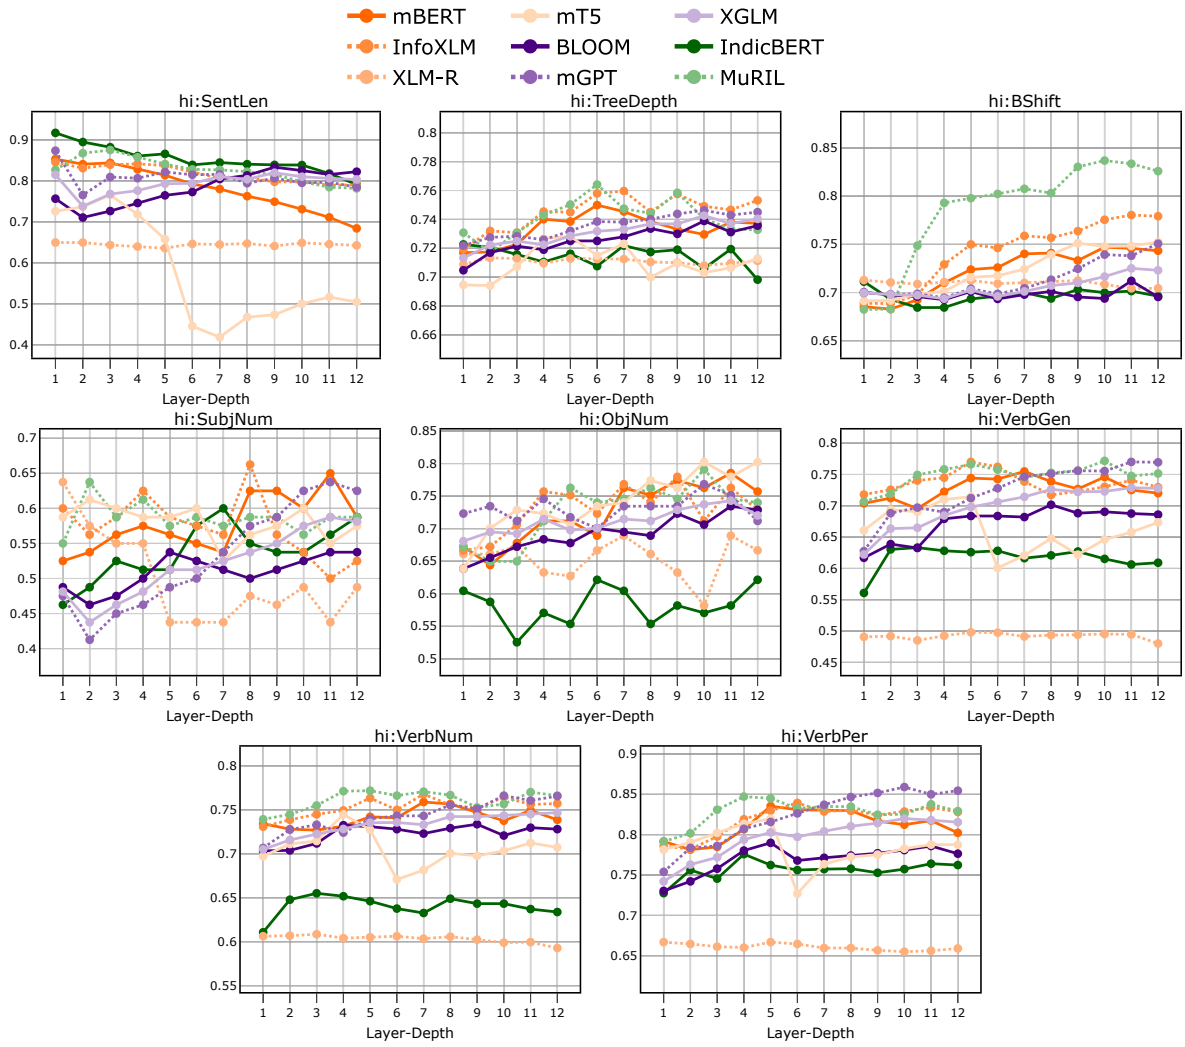

Figure 5: Hindi language probing task results: Layerwise accuracy comparisons between various multilingual representations on 8 probing tasks.

Model	Pretraining objectives	MSL
mBERT-base (Kenton and Toutanova, 2019)	MLM, NSP	512
XLM-R-base (Conneau et al., 2020)	MLM, CLM, TLM	512
InfoXLM-base (Chi et al., 2021)	MLM, TLM, CLM, XLCO	512
BLOOM-base (Scao et al., 2022)	CLM	512
mT5-base (Xue et al., 2021)	MLM, CLM	512
mGPT (Shliazhko et al., 2024)	CLM	512
XGLM (Lin et al., 2022)	CLM	512
IndicBERT-base (Kakwani et al., 2020)	MLM	128
MuRIL-base (Khanuja et al., 2021)	MLM, TLM	512

Table 19: Details of multilingual Transformer-based models used in this study: MLM (masked language modeling), CLM (causal LM), TLM (translation LM), XLCO (cross-lingual contrastive learning), MSL (maximum sequence length).

	hi	kn	ml	mr	te	ur	Total Tokens (for all Indic languages)
mBERT (11)	Detailed information not known publicly						184M
IndicBERT (23)	1.84B	712M	767M	560M	671M	-	7.59B
XLM-R (15)	1.71B	169M	313M	175M	249M	730M	3.99B
InfoXLM (13)	1.17B	95.6M	327M	130M	225M	289M	3.467B
MuRIL(16)	4.8B	2.4B	2.7B	2.6B	2.66B	3.3B	37.76B
BLOOM (13)	Detailed information not known publicly						2.7B
mT5 (11)	24B	1.1B	1.8B	14B	1.3B	2.4B	58.3B
mGPT	1.1B	0.11B	0.11B	0.11B	0.11B	0.2B	2.18B
XGLM	3.45B	446M	458M	935M	689M	1.35B	11.0B

Table 20: Tokens for pretraining multilingual models.

- MuRIL model stands out with the most balanced distribution among the six languages shown (12.7% for Hindi, with other languages between 6-9%).
- In contrast, mGPT shows high Hindi focus (50.5%) with much smaller proportions for other languages.

Hindi Dominance:

- Most models allocate the largest share of their Indic language tokens to Hindi.
- This varies dramatically from 12.7% in MuRIL to 50.5% in mGPT.

Coverage Beyond Major Languages:

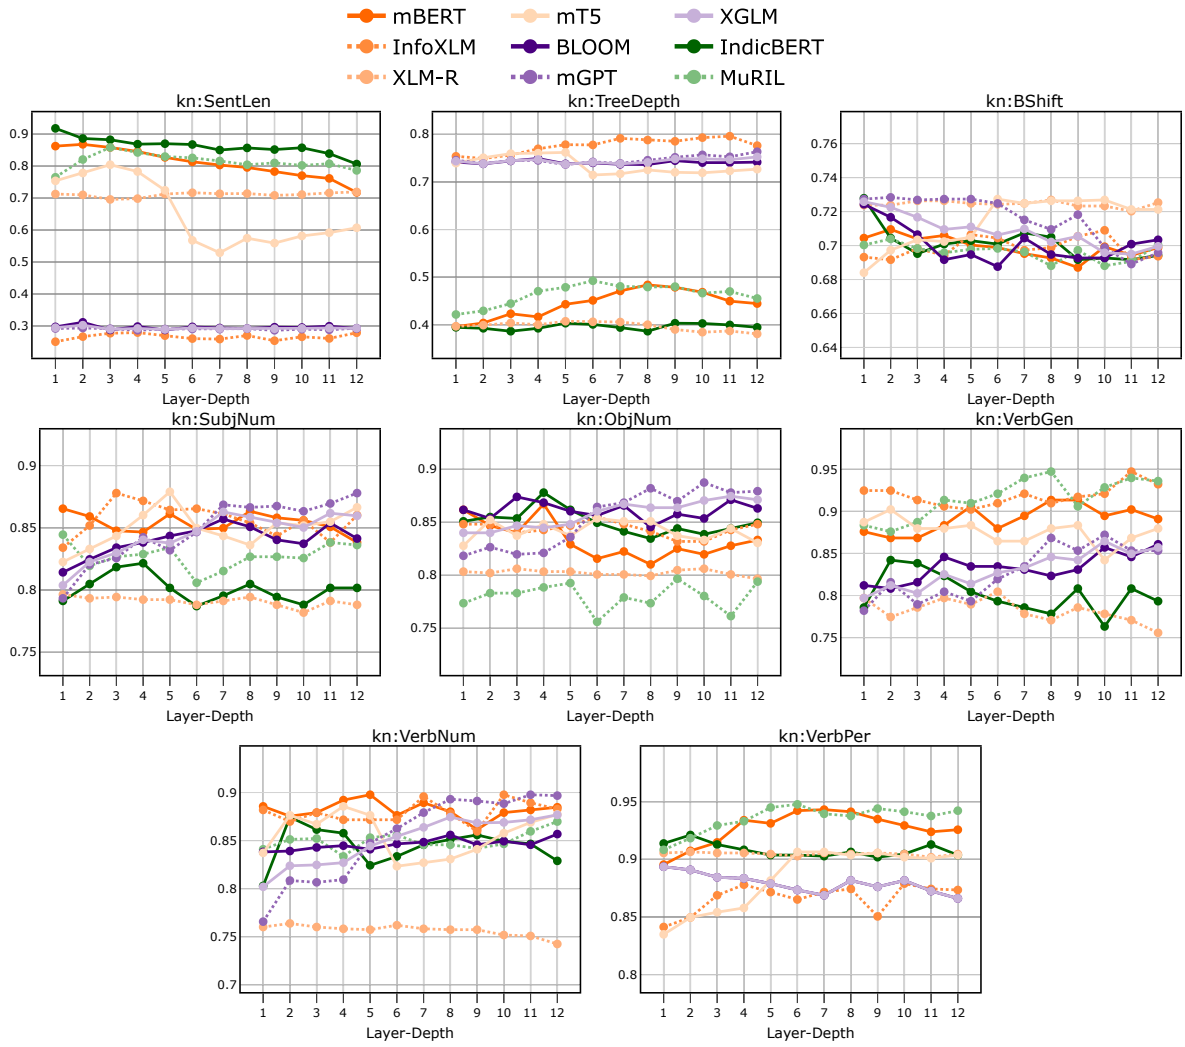

Figure 6: Kannada language probing task results: Layerwise accuracy comparisons between various multilingual representations on 8 probing tasks.

- MuRIL allocates 51.1% of its tokens to "Other Indic" languages beyond the six shown, suggesting much broader coverage.
- This aligns with research showing MuRIL supports 17 Indian languages in total.

Model	hi (Hindi)	kn (Kannada)	ml (Malayalam)	mr (Marathi)	te (Telugu)	ur (Urdu)	Other Indic
IndicBERT	24.2%	9.4%	10.1%	7.4%	8.8%	–	40.1%*
XLM-R	42.9%	4.2%	7.8%	4.4%	6.2%	18.3%	16.2%*
InfoXLM	33.7%	2.8%	9.4%	3.7%	6.5%	8.3%	35.6%*
MuRIL	12.7%	6.4%	7.2%	6.9%	7.0%	8.7%	51.1%*
mT5	41.2%	1.9%	3.1%	24.0%	2.2%	4.1%	23.5%*
mGPT	50.5%	5.0%	5.0%	5.0%	5.0%	9.2%	20.3%*
XGLM	31.4%	4.1%	4.2%	8.5%	6.3%	12.3%	33.2%*

Table 21: Training data proportion of the six Indic languages for both universal and Indic multilingual language models.

Hyper-parameters. We train logistic regression with a regularization parameter C=20 and use a L2 penalty term. For multi-class tasks, we use the "multinomial" setting while training. All experiments were done on a machine with a T4 GPU.

G Probing Results

We report the layerwise probing accuracies for individual multilingual models in Figs. 5 to 10.

Surface-level tasks Analyzing the performance across languages, we observe the following patterns: (i) For universal multilingual models (mBERT, mT5 and InfoXLM) as well as for Indic models (IndicBERT and MuRIL), there is a trend of higher accuracy in the early (or lower) layers, which decreases in the later (or higher) layers. This pattern is expected, as surface-level tasks generally require minimal processing. (ii) Notably, the universal model BLOOM deviates from this trend, showing lower accuracy in the early layers and higher accuracy in the later layers. This unusual pattern in BLOOM could be attributed to its unique autoregressive architectural design, and its approach to representing languages, especially

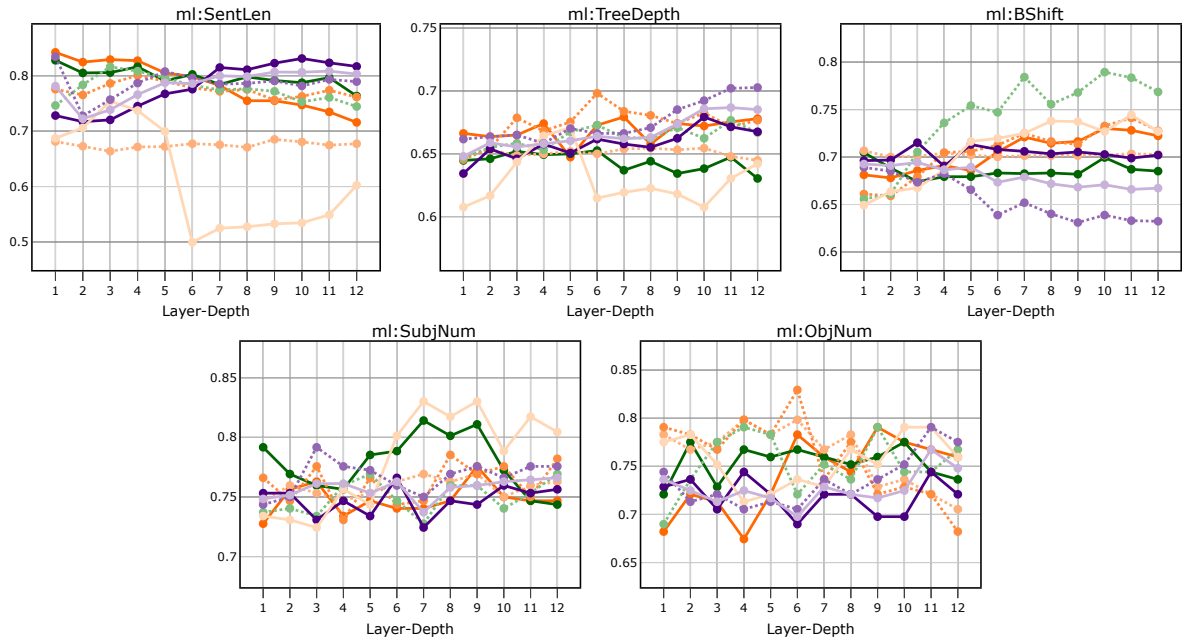

Figure 7: Malayalam language probing task results: Layerwise accuracy comparisons between various multilingual representations on 5 probing tasks.

Table 13: Text perturbation examples for Telugu language.

those less common in the dataset. This suggests that BLOOM may require its deeper layers to effectively grasp the nuances of these languages, even for tasks at the surface level. (iii) Overall, among all the models, IndicBERT reports best accuracy, while XLM-R displays poorer performance. This is likely because IndicBERT is specifically trained on Indic languages, making it more attuned to the nuances and idiosyncrasies of these languages. On the other hand, models like XLM-R, which are designed for universal applicability, might struggle with specific linguistic features unique to Indic languages. These features include script differences, morphological complexity, and visual factors such as orthography and word length.

Syntactic Tasks For TreeDepth, we observe that probing accuracy tends to be higher in the middle layers for various (model, language) combinations. This trend is particularly notable in three universal models, mBERT, mT5 and InfoXLM, and an Indic model, MuRIL. Moreover, this pattern is consistent for three languages: `hi`, `kn` and `ml`. However, other multilingual models do not exhibit any clear layer-wise trend, and the same applies to the other three Indic languages. This suggests a model-specific and language-specific affinity in handling syntactic complexity, where certain models are more adept at processing syntactic information in specific layers, and this proficiency varies across different languages. In contrast to TreeDepth, for BShift task, we generally observe higher probing accuracy in the later layers for four of the models across various

Table 15: Text perturbation examples for Hindi language.

languages. Notably, BLOOM exhibits a decreasing trend in accuracy for kn and te, while showing an increasing trend for ur. This suggests different models' layers may specialize in different types of syntactic processing, with some models better handling tasks like BShift in their later layers. Overall, when comparing performance across models and tasks, InfoXLM and mT5 stand out for their superior accuracy in capturing tree depth information across different languages. Conversely, MuRIL shows notable proficiency in BShift. These distinctions highlight how different models may be better suited for different types of syntactic analyses. These observations contribute to a deeper understanding of how various multilingual models process syntactic information, demonstrating both model-specific and language-specific trends and capabilities in linguistic tasks.

Semantic Tasks These include SubjNum and ObjNum, and VerbGen, VerbNum and VerbPer. We do not have results for ml for VerbGen, VerbNum and VerbPer, since we do not have labeled data for ml for those tasks.

Table 18: Text perturbation examples for Urdu language.

the following observations. For mBERT, InfoXLM, mT5, BLOOM as well as MuRIL, we observe an increasing trend from lower to higher layers for `hi`, `mr` and `te`. This suggests that for these languages, the models become more proficient in handling semantic tasks related to SubjNum and

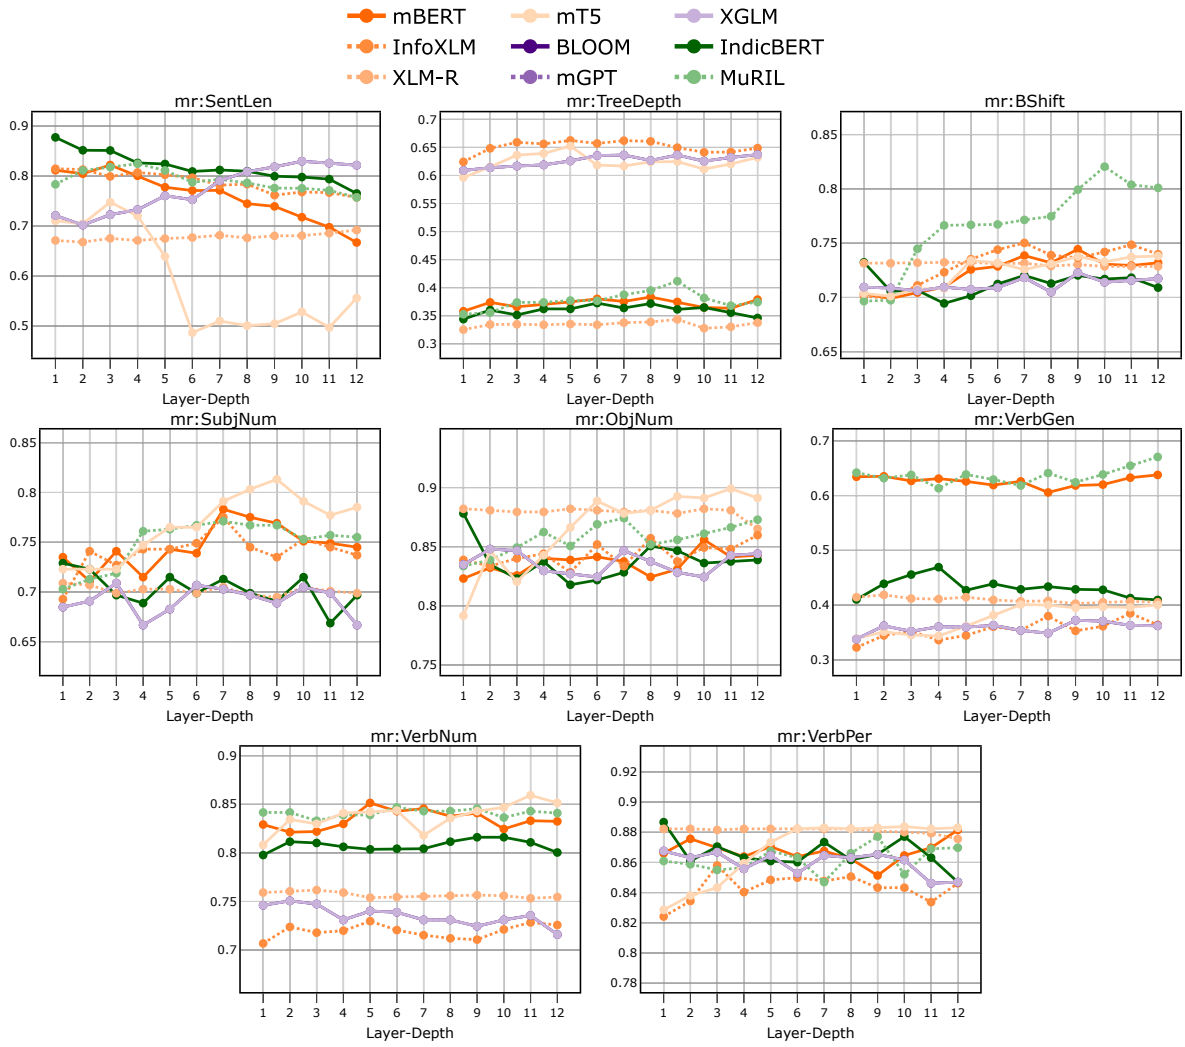

Figure 8: Marathi language probing task results: Layerwise accuracy comparisons between various multilingual representations on 8 probing tasks.

ObjNum as we move to the higher layers. When considering other languages and models, we note that IndicBERT exhibits an increasing trend for the ObjNum task, specifically for ur. This highlights the variability in model performance based on the language. Interestingly, the middle layers of the models show higher probing accuracy for languages such as hi and ml in the SubjNum task. Similar to its performance in surface and syntactic tasks, XLM-R exhibits lower accuracy and lacks a discernible trend when it comes to capturing semantics. MuRIL has the highest probing accuracy although it performs the worst for kn ObjNum task.

For the verb-related tasks, Indic model MuRIL, performs the best for most languages and tasks. Also, in most cases, the last layer is the most predictive, except in te for gender and person detection, where initial layers provide better results. This indicates that gender and person detection in te is straightforward and does not need deep processing. For the universal models, mBERT and BLOOM report an increasing trend across languages and tasks. On the other hand, mT5 showcases an increasing trend for kn and mr languages and decreasing trend for hi, te and ur languages. Models, including, IndicBERT, XLM-R and InfoXLM do not show any trend and have constant performance across layers.

H Extended Discussion

We evaluated 9 multilingual Transformer-based models on 8 probing tasks to understand linguistic structures in 6 Indic languages, using our contributed IndicSentEval dataset. Indic-specific models like MuRIL and IndicBERT excel due to targeted training, while universal models like

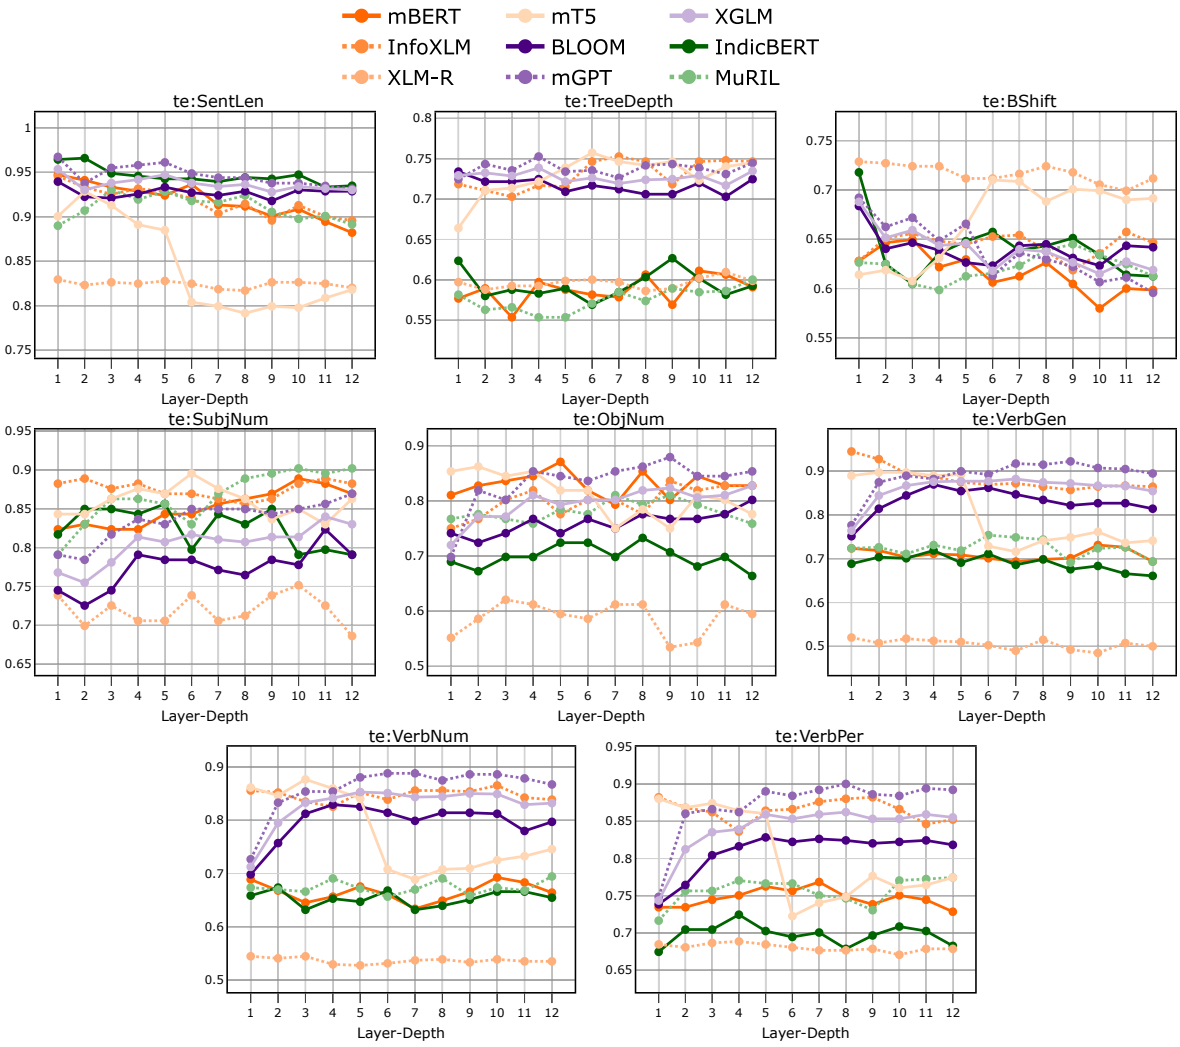

Figure 9: Telugu language probing task results: Layerwise accuracy comparisons between various multilingual representations on 8 probing tasks.

mBERT, InfoXLM, BLOOM, mGPT, and XGLM show mixed results. Perturbation analysis reveals decoder-based models are the most robust, as also noted by Neerudu et al. (2023). Verbs and word order are key signals for encoding linguistic structures. TreeDepth is the most sensitive to perturbations, while SubjNum and ObjNum are the most resilient.

Overall, our study represents the first analysis of the interpretability of both Universal and Indic multilingual language models across six Indic languages where several languages have large training corpora while some have less. Our scientific findings from this model interpretability analysis via both probing and perturbations shed light on how language models capture language hierarchy and how training data influences the language understanding across layers in these models. Surprisingly, universal models show greater resilience to perturbations in at least four Indic languages. In contrast, the universal model (mBERT) and the Indic-specific models (IndicBERT and MuRIL) display a more significant accuracy drop across all the Indic languages. This suggests the necessity for multilingual models that are robust to perturbations and can capture language hierarchy regardless of their training data. Overall, our findings demonstrate significant variability in the ability of current multilingual models to capture surface, syntactic, and semantic structures across different Indic languages. A hierarchy of language proficiency is discernible primarily for languages with more extensive training datasets. This highlights the necessity for innovative approaches in multilingual modeling that can accurately capture language structures, even in low-resource languages.

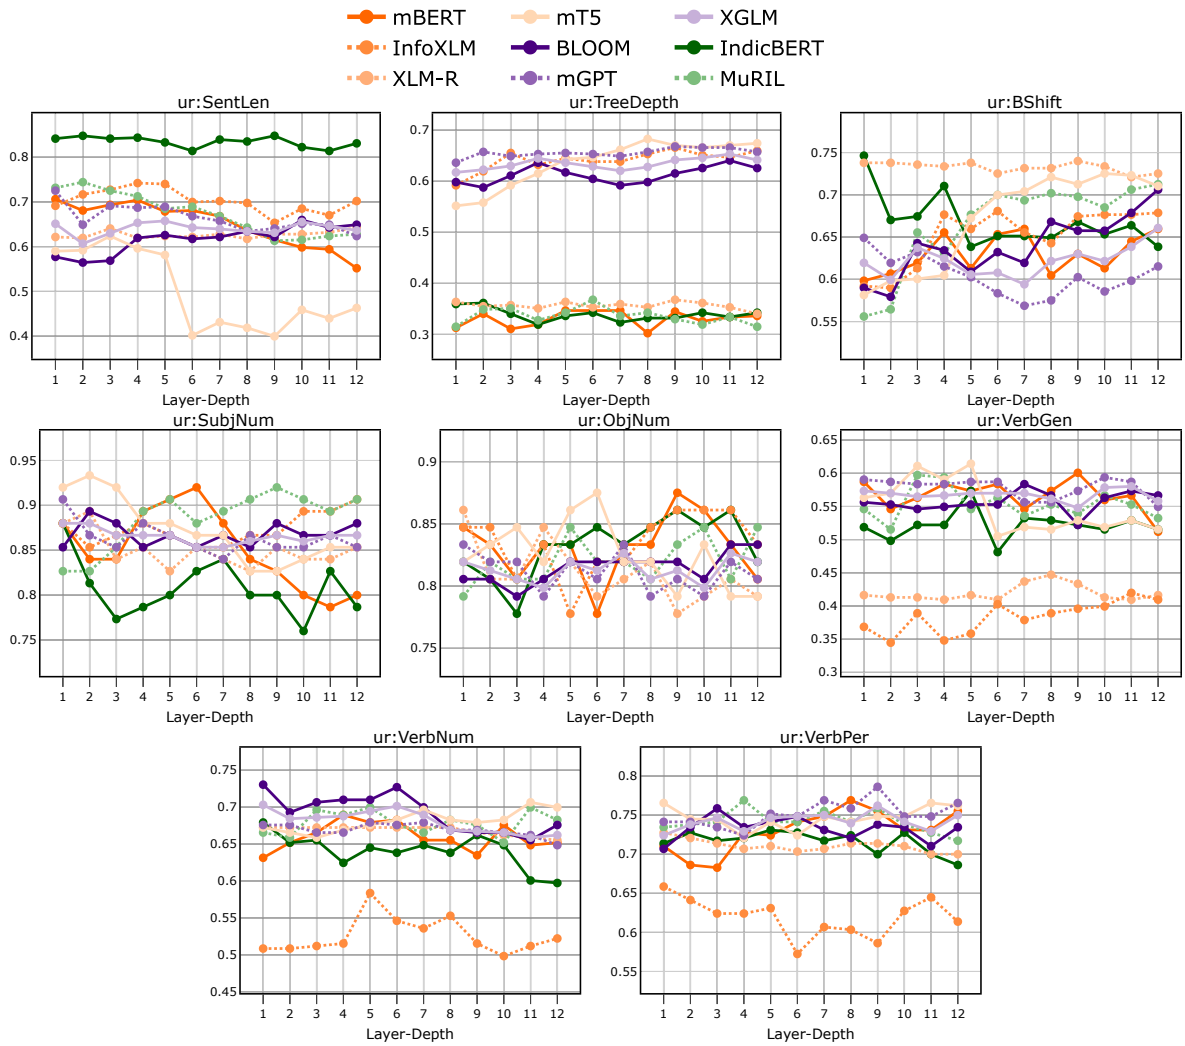

Figure 10: Urdu language probing task results: Layerwise accuracy comparisons between various multilingual representations on 8 probing tasks.

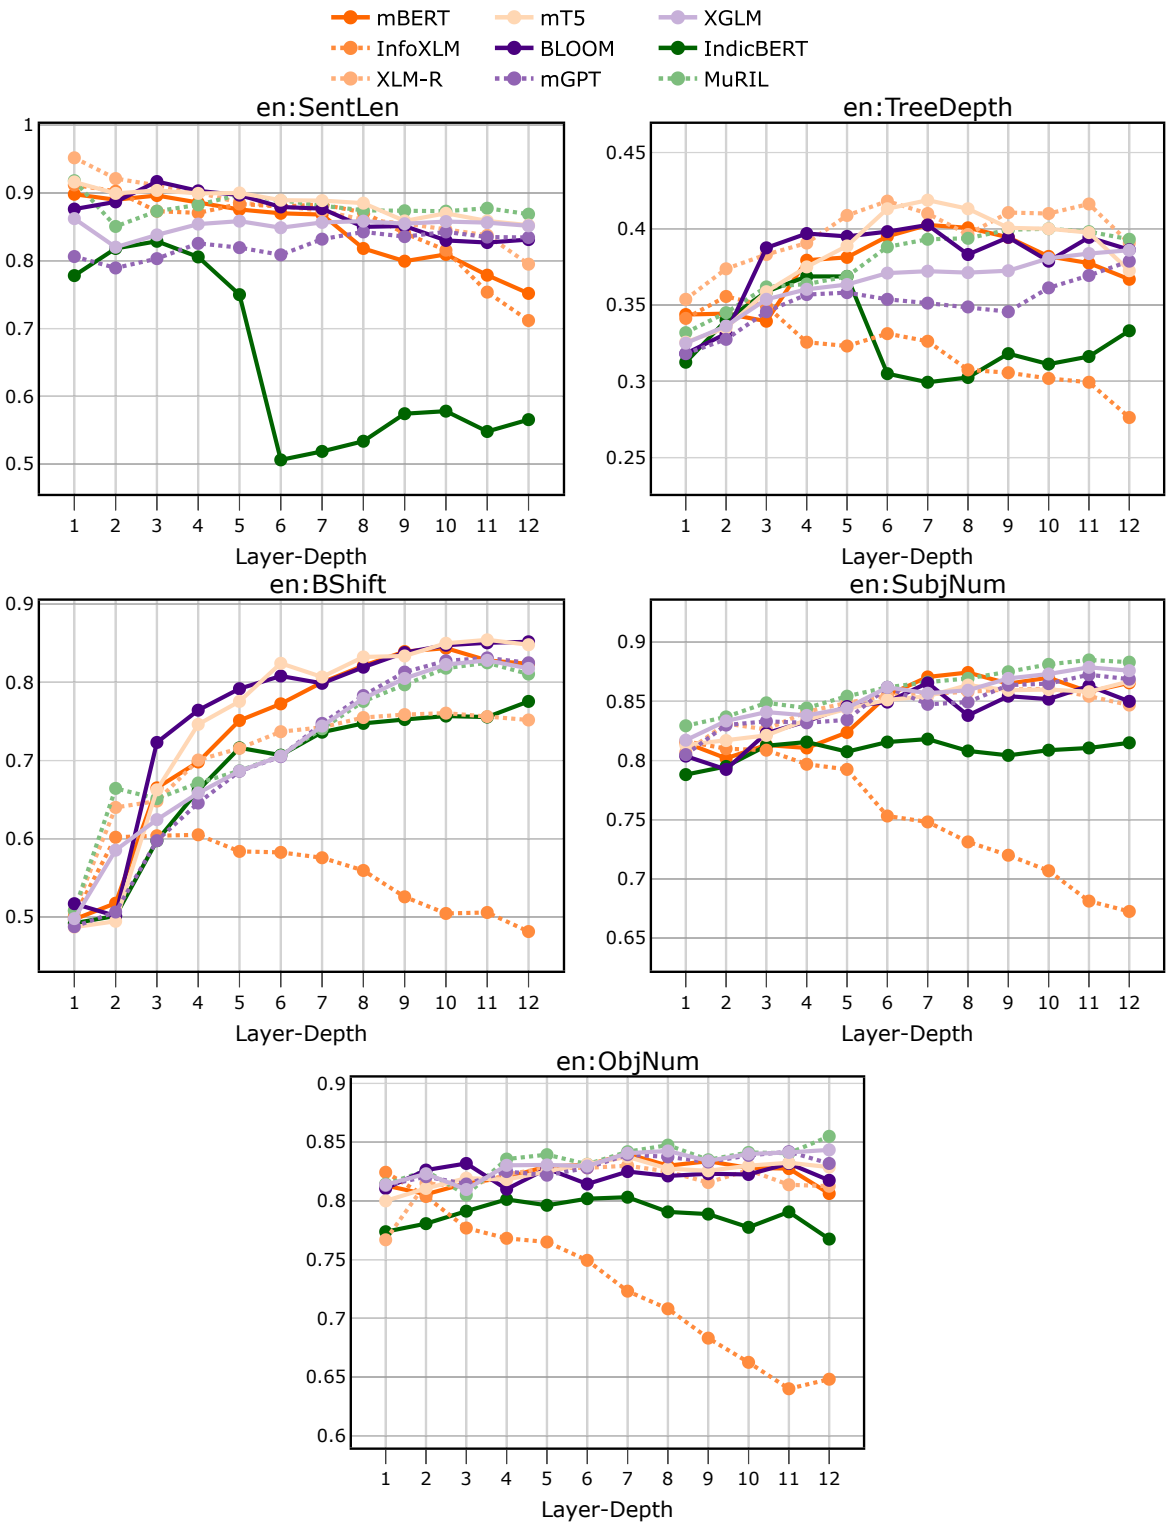

Figure 11: English language probing results: Layerwise accuracy was computed across Universal multilingual (mBERT, XLM-R, InfoXLM, BLOOM, mT5, mGPT and XGLM) and Indic multilingual (IndicBERT, MuRIL) representations on surface-level, syntactic probing and semantic probing tasks.

Consolidating and Developing Benchmarking Datasets for the Nepali Natural Language Understanding Tasks

***Jinu Nyachhyon[1,2], *Mridul Sharma[1,2], Prajwal Thapa[1,2], Bal Krishna Bal[1]**

Abstract

The Nepali language has distinct linguistic features, especially its complex script (Devanagari script), morphology, and various dialects, which pose a unique challenge for Natural Language Understanding (NLU) tasks. While the Nepali Language Understanding Evaluation (Nep-gLUE) benchmark provides a foundation for evaluating models, it remains limited in scope, covering four tasks. This restricts their utility for comprehensive assessments of Natural Language Processing (NLP) models. To address this limitation, we introduce twelve new datasets, creating a new benchmark, the Nepali Language Understanding Evaluation (NLUE) benchmark for evaluating the performance of models across a diverse set of Natural Language Understanding (NLU) tasks. The added tasks include Single-Sentence Classification, Similarity and Paraphrase Tasks, Natural Language Inference (NLI), and General Masked Evaluation Task (GMET). Through extensive experiments, we demonstrate that existing top models struggle with the added complexity of these tasks. We also find that the best multilingual model outperforms the best monolingual models across most tasks, highlighting the need for more robust solutions tailored to the Nepali language. This expanded benchmark sets a new standard for evaluating, comparing, and advancing models, contributing significantly to the broader goal of advancing NLP research for low-resource languages.

1 Introduction

Nepali is written in the Devanagari script and is a highly inflected language. The Nepali language incorporates a complex system of noun, adjective, and verb inflections, including gender, case, and number (Bal, 2004). It has a rich vocabulary and is spoken in different dialects across various regions, and there are variations in vocabulary, grammar, and pronunciation. Developing and establishing robust models for Nepali requires reliable methods to evaluate their quality and effectiveness and it is essential to have tools that can assess how well these models address the language's unique linguistic challenges while identifying their limitations.

Despite Nepali's importance as a primary or secondary language for millions of speakers, research efforts and resources dedicated to its computational processing and evaluation remain relatively sparse. Existing benchmarks, such as Nep-gLUE (Timilsina et al., 2022), have made significant progress in this direction, providing a foundation for evaluating models on fundamental tasks. However, these benchmarks are limited in scope, primarily addressing four basic tasks and overlooking critical aspects of linguistic understanding such as coreference resolution, paraphrase interpretation, and advanced inference capabilities. To address this need, we introduce a new benchmark comprising 12 Natural Language Understanding (NLU) tasks [1] for Nepali. The tasks are grouped into four categories:

Single-Sentence Tasks: Sentiment Analysis (SA), Corpus of Linguistic Acceptability (CoLA), and WinoGrande (WG)

Similarity and Paraphrase Tasks: Quora Question Pairs (QQP), Microsoft Research Paraphrase Corpus (MRPC), Semantic Textual Similarity Benchmark (STS-B), and Query-Ad Matching (QADSM)

Natural Language Inference (NLI) Tasks: Multi-Genre NLI (MNLI), Question Answer NLI (QNLI), Recognizing Textual Entailment (RTE), and Coreference Resolution (CR)

General Masked Evaluation Task (GMET): A diagnostic task for testing factual and contextual understanding.

Table 1: Task descriptions and dataset statistics in the NLUE benchmark.

This suite includes a broader range of linguistic tasks, enabling more comprehensive evaluation of NLU capabilities for Nepali language models (Appendix A). Table 1 provides an overview of tasks, dataset sizes, evaluation metrics, and domains covered in the NLUE Benchmark.

The datasets in the NLUE Benchmark are inspired by the General Language Understanding Evaluation (GLUE) benchmark (Wang et al., 2018) and XGLUE benchmark (Liang et al., 2020), and were developed through a combination of automated and manual processes to ensure high-quality task-specific datasets. Our contributions involved translating datasets with Large Language Models (LLMs), particularly GPT-4o-mini (OpenAI, 2024) and Gemini-2.5-flash (GeminiTeam, 2025), and ensuring the accuracy and contextual relevance of these translations (Appendix B & C). We also conducted a thorough review of the availability of existing Nepali datasets for each task. Where datasets were available, we integrated them with translated data, carefully eliminating duplicates to form a unified and comprehensive dataset. For tasks like Acceptability Judgments and Coreference Resolution, where suitable datasets or high-quality translations were unavailable, we performed manual translations to ensure linguistic accuracy and consistency. These efforts collectively ensure that the final dataset is robust, comprehensive, and reflective of the linguistic diversity in the Nepali language.

To assess the effectiveness of the NLUE benchmark and performance of models, we conducted experiments by fine-tuning both monolingual models trained exclusively on Nepali-language data and multilingual models that include Nepali as one of their supported languages. Each model was fine-tuned on tasks introduced in the NLUE Benchmark and evaluated using metrics provided in Table 1, providing a comprehensive understanding of their performance on various aspects of NLU.

2 Related Works

Benchmarks like GLUE (Wang et al., 2018) and its successor Super General Language Understanding Evaluation (SuperGLUE) benchmark (Wang et al., 2020) have been instrumental in advancing research in Natural Language Understanding (NLU). GLUE introduced a multi-task framework for evaluating diverse NLU capabilities, such as single-sentence classification, sentence-pair similarity, and inference tasks. SuperGLUE extended this with more challenging tasks, including causal reasoning and coreference resolution, addressing GLUE's limitations for state-of-the-art models. These benchmarks set a standard for evaluating

linguistic and semantic understanding in high-resource languages like English, inspiring adaptations in other languages and low-resource settings. Efforts like (Liang et al., 2020) and (Hu et al., 2020) expanded these concepts to multilingual contexts, enabling cross-lingual transfer learning.

Nep-gLUE (Timilsina et al., 2022) is the first comprehensive benchmark for Natural Language Understanding (NLU) tasks in Nepali. It includes four core tasks: Named Entity Recognition (NER), Part-of-Speech Tagging (POS), Content Classification (CC), and Categorical Pair Similarity (CPS). Although Nep-gLUE offers a robust foundation with its multi-task dataset, it falls short in addressing more advanced NLP tasks necessary for comprehensive evaluations of models at the linguistic level. The advanced and complex tasks are crucial for further progress in low-resource languages like Nepali.

Nepali Sentiment Analysis (NepSA) (Singh et al., 2020) is a targeted aspect-based sentiment analysis dataset, with 3,068 comments extracted from 37 YouTube videos across 9 channels. It is annotated using a binary sentiment polarity schema across six aspects: General, Profanity, Violence, Feedback, Sarcasm, and Out-of-scope. Another dataset, Aspect-Based Sentiment Analysis (Tamrakar et al., 2020), contains 1,576 sentences, equally divided between positive and negative sentiments. Additional datasets, such as Nepali Language Sentiment Analysis - Movie Reviews (Ghimire) with 602 data points, and Nepali Sentiment Analysis (Acharya) with 2,161 data points found on Kaggle, are limited in size and domain-specific. For our benchmark, we utilized the Nep-COV19Tweets dataset (Sitaula et al., 2021), which includes ~33.5k sentiments labeled as positive, negative, or neutral. From these, we selected 14.9k positive and 13.5k negative data points for the SA dataset. A more recent dataset, Sentiment of Election-Based Nepali Tweets (Pokharel), contains ~17.8k tweets but includes English characters and numbers, making it less suitable for our benchmarked dataset. To our knowledge, there are no publicly available datasets for coreference resolution, acceptability judgment, paraphrase and similarity detection, commonsense reasoning, pronoun coreference resolution, general masked evaluation, or NLI in the Nepali language. Despite some studies focusing on Nepali grammar, the lack of datasets for these advanced tasks limits the development of comprehensive NLU benchmarks.

3 Model Selection

To evaluate the performance of Natural Language Processing (NLP) models on the Nepali Language Understanding Evaluation (NLUE) benchmark, we selected ten publicly available models that support devanagari script, carefully chosen to represent a diverse range of architectures, parameter sizes, and pretraining strategies including the state-of-the-art encoder model for language understanding and best monolingual models for the Nepali Language. Evaluating these models on the NLUE benchmark serves multiple purposes. First, it provides a comprehensive assessment of their capabilities across a diverse set of tasks. This enables us to identify which architectures and pretraining strategies are best suited for Nepali NLP, particularly for tasks that demand robust handling of the language's morphological complexity and dialectal variations. Second, comparing monolingual and multilingual models highlights the trade-offs between language-specific pretraining and cross-lingual generalization, offering insights into the optimal approach for low-resource languages. By identifying the strengths and weaknesses of existing models, this study informs the development of more robust solutions tailored to Nepali's unique linguistic challenges.

4 Tasks

NLUE is a benchmark designed to evaluate the performance of language understanding models across a diverse set of tasks, addressing the limitations of its predecessor, Nep-gLUE. The objective of NLUE is to provide a robust evaluation metric applicable to a broad range of language understanding challenges. We describe the tasks below and in Table 1.

4.1 Single-Sentence Tasks

Single-sentence tasks in the NLUE benchmark focus on assessing a model's ability to understand and analyze individual sentences. These tasks evaluate a model's ability to understand and interpret the meaning, sentiment, and grammatical structure of individual sentences.

4.1.1 Sentiment Analysis (SA)

The Sentiment Analysis dataset has been added to evaluate models' ability to classify the emotional tone (Positive & Negative) of Nepali text. We created the dataset for sentiment analysis by translat-

Model	Params	SA		CoLA		WG	
		Acc	F1	Acc	F1	Acc	F1
Distilbert-Nepali (Maskey et al., 2022)	67M	86.34	86.33	84.51	80.96	58.20	58.08
NepBERT (Rajan, 2021)	82M	83.34	83.34	80.51	74.80	52.49	52.04
NepaliBERT (Pudasaini et al., 2023)	110M	87.06	87.06	84.51	80.92	54.77	54.75
BERT Nepali (Thapa et al., 2025)	110M	87.73	87.72	84.76	80.65	66.81	66.13
NepBERTa (Timilsina et al., 2022)	110M	86.62	86.62	84.15	80.60	67.12	50.52
RoBERTa Nepali (Thapa et al., 2025)	125M	87.75	87.74	85.44	82.14	**68.07**	**68.07**
DeBERTa-Nepali (Maskey et al., 2022)	139M	87.43	87.42	85.08	81.86	59.76	59.75
Multilingual BERT (Devlin et al., 2019)	172M	86.35	86.34	82.41	78.95	67.12	50.52
XLM-R Base (Conneau et al., 2020)	270M	88.33	88.34	85.64	82.03	50.77	50.52
m-DeBERTa-v3 (He et al., 2023)	276M	**88.94**	**88.93**	**88.31**	**85.64**	67.45	67.44

Table 2: Model Performance across Single-Sentence Tasks

ing Stanford Sentiment Treebank (Socher et al., 2013) from the GLUE Benchmark, which includes ~53k sentence-level data points from movie reviews with human-annotated sentiment labels, using GPT-4o-mini, and manually translating instances that could not be accurately translated (Appendix B & C). We incorporated this dataset with pre-existing sentiment analysis of Nepali COVID-19-related tweets (Sitaula et al., 2021), adding ~28.4k data points. The combined SA dataset totals 81.4k data points, equally distributed between the positive and negative classes. Models are evaluated using Accuracy and Macro F1-score metrics, as reported in Table 1.

4.1.2 Corpus of Linguistic Acceptability (CoLA)

The Acceptability Judgments dataset determines whether a given sentence follows the linguistic rules of Nepali, ensuring the model can assess grammaticality. The dataset was created by translating the Corpus of Linguistic Acceptability (CoLA) (Warstadt et al., 2019) from the GLUE Benchmark, which includes 9.75k data points sourced from books and journal articles on linguistic theory, using GPT-4o-mini. Manual corrections were applied to sections where translations were inaccurate (Appendix B & C). The dataset is divided into correct and incorrect classes in a 70:30 ratio, respectively. Models are evaluated using Accuracy and Macro F1-score metrics, as reported in Table 1.

4.1.3 WinoGrande (WG)

The WinoGrande dataset evaluates a model's ability to perform commonsense reasoning by identifying the correct referent in a sentence with a blank referring to one of two candidate entities. The dataset for this benchmark is converted to Nepali by translating the XGLUE benchmark's WinoGrande dataset (Sakaguchi et al., 2019) using Gemini-2.5-flash, with manual corrections applied to ensure translation accuracy (Appendix B & C). The final dataset contains 40.7k data points, with each instance labeled to indicate the correct referent, and is equally split between both classes. The dataset preserves the original format and balance of the English version. Models are evaluated using Accuracy and Macro F1-score metrics, as reported in Table 1.

4.2 Similarity and Paraphrase Tasks

Similarity and Paraphrase Task in the NLUE benchmark evaluates a model's ability to determine whether two sentences convey the same meaning or are paraphrases of each other. By focusing on this aspect of language comprehension, these tasks provide valuable insights into a model's proficiency in handling diverse expressions of similar ideas.

4.2.1 Quora Question Pairs (QQP)

The QQP dataset tests whether the model can identify if pairs of questions from the community question-and-answer website Quora have similar meanings. The dataset was created by translating the Quora Question Pairs dataset (Iyer et al., 2017) from the GLUE Benchmark into Nepali using GPT-4o-mini and Gemini-2.5-flash, with manual corrections applied (Appendix B & C). The dataset contains 32.5k question pairs, labeled as similar or dissimilar, with a class distribution of 40% similar and 60% dissimilar. Models are assessed using accuracy and Macro F1-score metrics, as reported in Table 1.

Model	Params	QQP		MRPC		STS-B			QADSM	
		Acc	F1	Acc	F1	Sp. corr	Pr. corr	R^2	Acc	F1
Distilbert-Nepali (Maskey et al., 2022)	67M	81.63	81.07	80.52	77.95	84.57	83.13	71.13	65.74	65.63
NepBERT (Rajan, 2021)	82M	71.17	69.61	67.34	56.91	41.44	41.06	12.71	61.03	60.80

Table 3: Model Performance across Similarity and Paraphrase Tasks

4.2.2 Microsoft Paraphrase Research Corpus (MPRC)

We introduced the MRPC dataset, intending to identify whether the sentence pairs extracted from news articles are paraphrases of each other, based on the Microsoft Research Paraphrase Corpus (Dolan and Brockett, 2005). Using GPT-4o-mini, we translated the MRPC dataset into Nepali with manual correction whenever needed (Appendix B & C). The dataset contains 5.23k sentence pairs, with the class distribution of 70-30, with a higher proportion of paraphrase pairs. We report the Accuracy and Macro F1 score, as shown in Table 1.

4.2.3 Semantic Textual Similarity Benchmark (STS-B)

The STS-B dataset measures a model's proficiency in predicting the degree of semantic relatedness between pairs of sentences drawn from sources such as news headlines and video captions. Each pair is annotated with a similarity score on a continuous scale from 0 (no meaning overlap) to 5 (complete semantic equivalence), framing the task as a regression problem. The dataset was created by translating the STS-B dataset (Cer et al., 2017) from the GLUE Benchmark into Nepali using Gemini-2.5-flash, with manual corrections applied to ensure translation accuracy (Appendix B & C). The dataset contains 6.82k sentence pairs. We evaluate the model using Pearson correlation, Spearman correlation, and R^2 metrics, as reported in Table 1.

4.2.4 Query-Ad Matching (QADSM)

The QADSM dataset assesses a model's capability to align the semantic meaning between queries and advertisements. The dataset was created by translating the QADSM dataset from the XGLUE Benchmark (Liang et al., 2020) into Nepali using Gemini-2.5-flash, with manual refinements to ensure linguistic precision (Appendix B & C). The dataset contains 74.3k data points, equally split between relevant and irrelevant classes, based on ad-query relevance. Models are evaluated using accuracy and Macro F1-score metrics, as reported in Table 1.

4.3 Inference Tasks

The NLI tasks in this benchmark assess a model's ability to understand relationships between sentences, such as entailment, contradiction, and neutral alignment. These tasks are crucial because they evaluate a model's comprehension of contextual meaning, logical inference, and its ability to handle complex linguistic structures, making them essential for advancing robust language understanding.

4.3.1 Multi-Genre NLI (MNLI)

The MNLI dataset tests a model's capability to predict the relationship between sentence pairs, determining whether a premise entails, contradicts, or is unrelated to a hypothesis (neutral). The dataset was created by translating the Stanford Natural Language Inference Corpus (Bowman et al., 2015) from the GLUE Benchmark into Nepali using GPT-4o-mini and Gemini-2.5-flash, with manual intervention for precision (Appendix B & C). The dataset contains 51k sentence pairs, equally divided among entailment, contradiction, and neutral classes. We report accuracy and Macro F1-score, as described in Table 1.

4.3.2 Question-Answering NLI (QNLI)

The QNLI dataset evaluates a model's capability to determine whether a context sentence contains the answer to a given question. The dataset has been adapted for Nepali from the GLUE benchmark by translating the original English dataset using GPT-4o-mini and Gemini-2.5-flash, with manual verification for accuracy (Appendix B & C), which originates from the Stanford Question

Model	Params	MNLI		QNLI		RTE		CR	
		Acc	F1	Acc	F1	Acc	F1	Acc	F1
Distilbert-Nepali (Maskey et al., 2022)	67M	68.57	68.61	79.61	79.46	56.06	55.63	52.82	52.63

m-DeBERTa-v3 (He et al., 2023)	276M	**78.76**	**78.84**	**86.65**	**86.65**	57.85	57.80	46.48	32.84

Table 4: Model Performance across Inference Tasks

Answering Dataset (Rajpurkar et al., 2016) that contains question-paragraph pairs sourced from Wikipedia. The dataset contains 35k question-sentence pairs, equally split between entailment and non-entailment pairs, ensuring a balanced class distribution, and evaluated using accuracy and Macro F1-score metrics, as reported in Table 1.

4.3.3 Recognizing Textual Entailment (RTE)

The RTE dataset evaluates a model's ability to predict whether a hypothesis logically follows from a given premise. The dataset for this benchmark is converted to Nepali by translating the GLUE benchmark's RTE dataset, combined from RTE1 (Dagan et al., 2006), RTE2 (Bar-Haim et al., 2006), RTE3 (Giampiccolo et al., 2007), and RTE5 (Bentivogli et al., 2009) using GPT-4o-mini, with manual corrections to maintain translation accuracy (Appendix B & C), containing 2.51k data points, equally distributed between two classes (entailment and non-entailment). We evaluate the model using Accuracy and Macro F1-score, as discussed in Table 1.

4.3.4 Coreference Resolution (CR)

This CR dataset tests the model's ability to resolve coreference relationships within a Nepali text. We developed the coreference resolution dataset by manually translating the Winograd Schema Challenge (Levesque et al., 2011) from the GLUE Benchmark. The dataset has 706 data points, balanced between two classes, evaluated with Accuracy and Macro F1-score, as mentioned in Table 1.

4.4 General Masked Evaluation Task (GMET)

The General Masked Evaluation Task (GMET) dataset evaluates the zero-shot capabilities of language models in recognizing word relationships, understanding contextual nuances, and maintaining grammatical precision without fine-tuning. It serves as a benchmark for assessing logical reasoning and proficiency with complex linguistic constructs, critical for reliable language understanding across diverse scenarios. The GMET dataset comprises 1,500 authentic sentences from real-world contexts, ensuring ecological validity. These sentences are organized into 75 distinct categories, with 20 sentences per category, covering various topics and regional linguistic variations. Each sentence contains a missing word, challenging models to predict the appropriate word based on context, testing their inherent contextual understanding and language comprehension, particularly with nuanced expressions across communities. As the missing word may not always have a single correct answer, native speakers assisted in manual evaluations to ensure accurate and fair assessment.

Model	Params	Acc	C. Acc
Distilbert-Nepali (Maskey et al., 2022)	67M	51.47	42.84
NepBERT (Rajan, 2021)	82M	13.60	12.52
NepaliBERT (Pudasaini et al., 2023)	110M	44.53	37.99
BERT Nepali (Thapa et al., 2025)	110M	49.40	42.63
NepBERTa (Timilsina et al., 2022)	110M	46.40	39.89
RoBERTa Nepali (Thapa et al., 2025)	125M	**57.27**	**48.76**
DeBERTa-Nepali (Maskey et al., 2022)	139M	52.60	44.56
Multilingual BERT (Devlin et al., 2019)	172M	14.13	12.80
XLM-R Base (Conneau et al., 2020)	270M	53.27	44.75
m-DeBERTa-v3 (He et al., 2023)	276M	45.33	42.77

Table 5: Model Performance in GMET

Model performance on the GMET dataset is evaluated using two key metrics: overall accuracy and a combined score. Overall accuracy measures the proportion of correct predictions across all sentences, providing a straightforward performance indicator. The combined score integrates overall accuracy with an equality score, reflecting consistency across categories and penalizing uneven

performance to ensure balanced contextual understanding across diverse topics and linguistic variations. Further details are provided in Appendix F.

5 Experiments

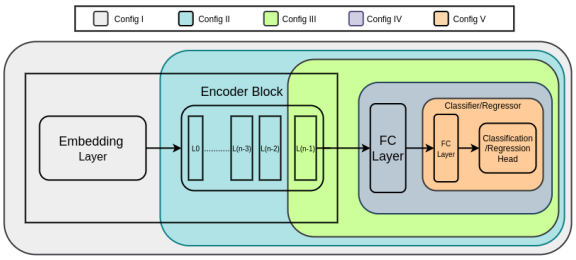

Figure 1: Different training config based on parameters with initial FC Layer

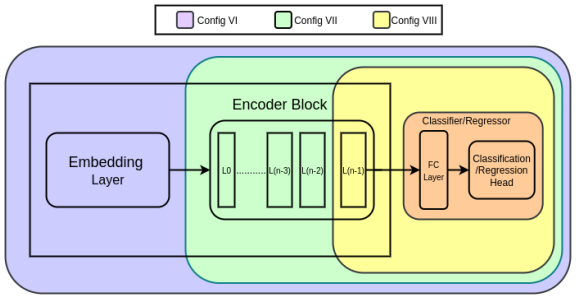

Figure 2: Different training config based on parameters without initial FC Layer

We experimented with eight distinct finetuning configurations (Configs I–VIII), each controlling the subset of model parameters that are updated during training, as illustrated in Figure 1 and Figure 2. These configuration choices were driven by our available datasets to mitigate overfitting risks, which ranged widely from just under 1,000 to 80,000 data points. For larger datasets like QADSM and SA, training only the classification layer was insufficient, while for smaller datasets like CR and RTE, training all layers risked overfitting. Therefore, at least three configurations were tested per dataset to ensure robust performance comparisons and validate generalizability.

As part of our ablation study, we systematically examined how performance was affected by varying the number and type of layers updated during training, ranging from tuning only the top classification layer to progressively unfreezing intermediate and lower transformer layers. This analysis helped isolate the contributions of different layers to downstream performance. Specifically, we also experimented with Config IV both with and without the initial fully connected (FC) layer to assess its specific role in feature transformation.

Hyperparameter Search Space:

- Learning rate: $\{1e-5, 2e-5, 1e-4, 2e-4\}$
- Batch size: $\{8, 16, 32\}$
- Training epochs: Up to 15, with early stopping after three consecutive epochs of non-improving validation loss

For each configuration, we performed 5-fold cross-validation to select optimal hyperparameters and evaluate model performance. For each fold, we trained models with all hyperparameter combinations and selected the configuration that achieved the lowest validation loss. The best average hyperparameters across folds were used for final training. Test evaluation was done only after hyperparameter selection. Optimal hyperparameter settings and configuration for each dataset and model are reported in Appendix E.

6 Result and Analysis

We evaluate 10 language models on the NLUE benchmark across four task categories: Single-Sentence Classification, Similarity and Paraphrase Detection, Inference Tasks, and the GMET. For Classification Tasks, we report accuracy to measure overall correctness and macro-F1 to ensure balanced performance across potentially imbalanced classes. For the Regression Task, we use Spearman and Pearson correlation coefficients to assess monotonic and linear relationships, respectively, between predicted and actual continuous scores, and R^2 to quantify the proportion of variance in actual similarity scores explained by the model's predictions. For GMET, we report a combined score, integrating overall accuracy with an equality score, to evaluate consistency across diverse categories.

Across Single Sentence tasks, m-DeBERTa-v3 achieves the highest overall scores, with an SA Macro-F1 of 88.93, WG Macro-F1 of 67.44, and CoLA Macro-F1 of 85.64. Among Nepali-specific models, RoBERTa-Nepali performs competitively in SA and WG, indicating that moderate-scale models can effectively handle single-sentence understanding in Nepali. Results reported in Table 2.

m-DeBERTa-v3 consistently achieves the highest scores across Similarity and Paraphrase Tasks with top Macro-F1 scores in QQP (83.82), MPRC (81.93), QADSM (66.42), and the highest correlation metrics in STS-B (90.22 Spearman, 89.57 Pearson). Among Nepali-specific models, DeBERTa-Nepali performs strongly on QQP and MRPC, while RoBERTa-Nepali shows better results on STS-B and QADSM. Overall, multilingual models dominate in performance, which suggests that semantic similarity detection in Nepali demands sophisticated representational capabilities beyond what current Nepali-specific models provide. Results reported in Table 3.

In Inference Tasks, m-DeBERTa-v3 achieves the strongest performance on MNLI (78.84 Macro-F1) and QNLI (86.65 Macro-F1), while Multilingual BERT achieves a strong 68 Macro-F1 on RTE, suggesting that multilingual pretraining enhances entailment and contradiction processing capabilities. However, their performance drops notably on the CR task, with no model exceeding 59.15% Accuracy (BERT Nepali), mainly due to its complexity in Nepali and limited dataset size (706 data points), which indicates that all models struggle with generalization from small datasets. Results reported in Table 4.

All evaluated models demonstrated suboptimal performance on the GMET dataset. These results indicate that zero-shot tasks in Nepali present significant challenges for current language models, even when processing straightforward conversational sentences. Notably, multilingual models and those with larger parameter counts failed to achieve superior performance compared to their monolingual counterparts. This performance gap may be attributed to tokenization limitations, as multilingual models typically contain fewer Devanagari tokens in their vocabularies relative to monolingual Nepali models. Results reported in Table 5.

7 Conclusion

The NLUE benchmark reveals distinct performance trends across models and tasks, with model size correlating strongly with performance. Larger models with multilingual pretraining, such as m-deberta-v3 (276M parameters) and XLM-r-base (270M parameters), consistently outperform smaller Nepali-specific models, particularly in tasks requiring nuanced semantic understanding (e.g., STS-B, QNLI). However, RoBERTa-Nepali (125M parameters) achieves competitive results despite its smaller size, suggesting that quality pretraining can outweigh parameter count.

Tasks like RTE and CR remain challenging, due to smaller dataset sizes, highlighting the need for enhanced datasets and improved modeling of Nepali textual entailment and coreference resolution. These results underscore the potential of multilingual models for low-resource languages like Nepali, while also revealing the importance of better Nepali-specific models to address language-specific challenges. Future work should prioritize creating larger, more diverse Nepali datasets and exploring techniques like cross-lingual transfer to enhance model robustness. The NLUE benchmark provides a valuable framework for evaluating and improving language models, paving the way for advancements in Nepali NLP.

8 Limitations

While the Nepali Language Understanding Evaluation (NLUE) benchmark significantly advances the evaluation of Natural Language Processing models for the Nepali Language, several limitations must be acknowledged to contextualize the findings and guide future research.

First, the datasets introduced in the NLUE benchmark were primarily created by translating existing English-language datasets from benchmarks such as GLUE and XGLUE, using automated tools like GPT-4o-mini and Gemini2.5-flash, supplemented by manual corrections. Although efforts were made to ensure translation accuracy, subtle linguistic nuances, cultural contexts, and idiomatic expressions specific to Nepali may not have been fully captured. The small size of certain datasets (e.g., CR and RTE) limits model performance and shows models' lack of generalization on smaller datasets. Second, the study evaluates a range of models with varying parameter sizes (67M to 276M), but resource constraints prevented the inclusion of larger, state-of-the-art models or extensive hyperparameter tuning. Finally, the reliance on specific evaluation metrics (e.g., accuracy, Macro-F1 score, Spearman, and Pearson correlations) may not fully capture the models' performance across all dimensions of language understanding. For example, the GMET task relies on manual evaluations by native speakers, which might introduce subjectivity and potential inconsistencies.

A Dataset Description

A.1 Sentiment Analysis (SA)

To evaluate the sentiment understanding capabilities of language models, we developed a sentiment analysis dataset by combining existing Nepali sentiment datasets and translating several high-quality examples from English to Nepali.

{
'text': 'त्यो दुर्लभ नाटक जसले सबैले अनुभव गरेको वा भविष्यमा अनुभव गर्ने प्रकारको पीडा बारे विचारशील र इनामस्वरूप झलक प्रदान गर्छ।',
'label': 1
}

{
'text': 'कोभिड र घरबन्दी बन्दाबन्दीका कारण नेपालीहरूमा पारेको असरबारे हाम्रो अर्को रिपोर्ट लगातार तीन महिना लामो घरबन्दीका कारण एक तिहाइ नेपालीहरूको आयआर्जन गुमेको र खाद्य संकटमा परेको अध्ययनले देखाएको छ।',
'label': 0
}

Figure 3: SA Positive (1) and Negative (0) Sample

Sentiment analysis requires models to grasp not just the literal meaning of words but also their emotional undertones and contextual implications. It is particularly challenging in Nepali, where sentiment is often conveyed through subtle linguistic cues and cultural context that may not be immediately apparent. Using this, we can better understand whether models truly comprehend the nuanced ways emotions are expressed in Nepali text, rather than simply memorizing surface-level patterns. This evaluation helps us gauge how well these models might perform on real-world applications involving subjective content analysis.

A.2 Corpus of Linguistic Acceptability (CoLA)

The Corpus of Linguistic Acceptability (CoLA) is a dataset originally developed for the GLUE benchmark to assess a model's ability to judge the grammatical acceptability of English sentences. We incorporated CoLA-Nepali into our evaluation suite because understanding grammatical structure is fundamental to language comprehension. Unlike other benchmarks that primarily test semantic understanding or task performance, CoLA directly probes whether models have internalized the syntactic rules that govern sentence formation.

{
'text': 'त्यहाँ एक अग्लो, रातो कपाल भएको र अविश्वसनीय रूपमा राम्रो लुगा लगाएको मानिस आइपुग्यो।',
'label': 1
}

{
'text': 'जति धेरै किताबहरू म सोध्छु कसलाई उसले दिनेछ, त्यति धेरै ऊ पढ्छ।',
'label': 0
}

Figure 4: CoLA Positive (1) and Negative (0) Sample

This evaluation is especially crucial for Nepali, where limited training data often contains grammatical inconsistencies or errors. By testing linguistic acceptability, we can determine whether our models have learned to distinguish well-formed Nepali sentences from those that violate grammatical constraints. This provides valuable insight into how deeply the models understand Nepali's structural patterns, beyond their ability to perform specific NLP tasks.

A.3 WinoGrande (WG)

The WinoGrande dataset is a large-scale collection of Winograd Schema Challenge-style problems designed to evaluate commonsense reasoning and contextual disambiguation in natural language understanding.

{
'sentence': 'हामी गोठको भित्रपट्टि काम गर्नुको सट्टा घरको भित्रपट्टि काम गर्यौं, किनभने _ बस्नयोग्य थिएन।',
'option1': 'घर',
'option2': 'गोठ',
'answer': 2
}

Figure 5: WG Sample

We translated & added the WinoGrande dataset into our evaluation benchmark to assess models' ability to perform commonsense reasoning and resolve linguistic ambiguities. The dataset's adversarial construction reduces reliance on superficial statistical patterns, ensuring models rely on deep semantic and commonsense reasoning, which is essential for real-world applications like dialogue systems or conversational agents in Nepali. Including WinoGrande in the Nepali benchmark allows us to evaluate model strengths and limitations in handling nuanced linguistic structures and cultural contexts specific to Nepali, thereby improving their robustness for practical, context-sensitive applications.

A.4 Quora Question Pairs (QQP)

This dataset consists of pairs of questions that are labeled as either paraphrases (semantically equivalent) or not.

{
'question1': 'स्टार्टअपका लागि ब्रान्डको बारेमा सबैभन्दा राम्रो पुस्तक के हो?',
'question2': 'स्टार्टअप ब्रान्डिङको लागि कुन पुस्तक सर्वोत्तम हो?',
'label': 1
}

{
'question1': 'दैनिक जीवनको मनोविज्ञान: जीवनको बारेमा सिक्न र स्वीकृत गर्न सबैभन्दा कठिन कुरा के हो?',
'question2': 'तपाईंले आफ्नो जीवनमा गरेका सबैभन्दा कठिन कुरा के हो?',
'label': 0
}

Figure 6: QQP Positive (1) and Negative (0) Sample

We incorporated QQP into our benchmark to evaluate paraphrase detection capabilities, which are fundamental for robust language understanding systems. This task is particularly challenging in Nepali due to its morphological richness and limited resources. The dataset allows us to examine whether models can identify semantic equivalence beyond surface-level token matching or basic lexical similarity.

A.5 Microsoft Research Paraphrase Corpus (MRPC)

The MRPC dataset consists of pairs of sentences extracted from news sources, labeled as either paraphrase (semantically equivalent) or not. It is widely used to evaluate a model's ability to detect semantic equivalence between sentence pairs, particularly in formal and factual text domains.

MRPC challenges models to identify nuanced semantic similarities beyond superficial word overlap, requiring a deep understanding of sentence structure and meaning in Nepali. Its inclusion in the Nepali benchmark ensures robust evaluation of models' ability to handle formal news text.

{
'sentence1': 'सुरक्षा विज्ञहरूले चेतावनी दिएका छन् कि एउटा नयाँ मास-मेलिङ वर्म इन्टरनेटभरि व्यापक रूपमा फैलिएको छ, कहिलेकाहीँ माइक्रोसफ्टका संस्थापकको इमेलको रूपमा प्रस्तुत हुँदै।',
'sentence2': 'एक नयाँ वर्म इन्टरनेटभरि तीव्र गतिमा फैलिरहेको छ, कहिलेकाहीँ माइक्रोसफ्टका अध्यक्ष बिल गेट्सको इमेल भएको नाटक गर्दै, एन्टिभाइरस विक्रेताहरूले सोमबार भने।',
'label': 1
}

{
'sentence1': 'तर डेभिसका सल्लाहकार रोजर सालाजारले भने कि राज्यपालको ध्यान आफ्नो काममा छ, न कि फिर्ता बोलाउने निवेदनमा।',
'sentence2': 'तर डेभिसका सल्लाहकार रोजर सालाजारले भने कि राज्यपालको ध्यान उनले पारिश्रमिक पाएको काम गर्नेमा छ।',
'label': 0
}

Figure 7: MRPC Positive (1) and Negative (0) Sample

A.6 Semantic Textual Similarity Benchmark (STS-B)

The STS-B dataset consists of pairs of sentences annotated with a similarity score that reflects their semantic closeness on a continuous scale, typically from 0 (completely dissimilar) to 5 (semantically equivalent).

{
'sentence1': 'होभान बोलेनन्, तर उनका वकिल, जोन स्पेरान्जाले भने कि उनका ग्राहक "त्यो दिन कसैलाई चोट पुर्याउने उद्देश्यले उठेका थिएनन्"।',
'sentence2': 'होभान "त्यो दिन कसैलाई चोट पुर्याउने उद्देश्यले उठेका थिएनन्," प्रतिरक्षा वकिल जोन स्पेरान्जाले भने।',
'label': 4.5
}

{
'sentence1': 'सिरियामा विश्वसनीयता खतरामा',
'sentence2': 'ओबामा: कांग्रेस, विश्वको विश्वसनीयता खतरामा',
'label': 1.4
}

Figure 8: STS-B High (4.5) and Low (1.4) Similarity Sample

Unlike binary paraphrase detection tasks, the Semantic Textual Similarity Benchmark (STS-B) requires models to assess fine-grained semantic similarity between sentence pairs on a continuous scale. This makes STS-B a valuable benchmark for evaluating nuanced language understanding. This task challenges models to understand subtle differences and degrees of meaning overlap, which is essential for many real-world applications such as information retrieval, question answering, and summarization.

A.7 Query-Ad Matching (QADSM)

The QADSM dataset is incorporated into the NLUE benchmark to assess models' ability to align semantic meaning between queries and advertisements in a binary classification task.

{
'query': 'सेतो पखेटा',
'ad_title': 'सेतो पखेटा: सस्तो',
'ad_description': 'सेतो पखेटाका लागि डिलहरू फेला पार्नुहोस्। तपाईंले किन्नु अघि उचित मूल्य हेर्नुहोस्!',
'relevance_label': 1
}

{
'query': 'स्कूल नर्स एड्स भिडियो',
'ad_title': 'स्कूल नर्स शिक्षा',
'ad_description': 'शैक्षिक पाठ्यक्रमहरूको बारेमा जानकारी प्राप्त गर्नुहोस्। स्कूल नर्स डिग्री कार्यक्रमहरू ब्राउज गर्नुहोस्',
'relevance_label': 0
}

Figure 9: QADSM Positive (1) and Negative (0) Sample

QADSM challenges models to discern semantic relevance beyond superficial keyword matching, requiring a detailed understanding of user intent and contextual meaning in Nepali. This is a critical capability for many real-world applications such as targeted advertising, search result optimization, and personalized content delivery in Nepali, where accurate query-ad alignment is critical.

A.8 Multi-Genre Natural Language Inference (MNLI)

The MNLI dataset consists of sentence pairs, each containing a premise and a hypothesis, labeled with one of three classes: entailment, contradiction, or neutral.

We include MNLI in our benchmark to evaluate a model's ability to reason about the relationship between sentences across diverse domains. This task extends beyond surface-level similarity, requiring models to capture subtle semantic distinctions, such as entailment, contradiction, and neutrality, which are essential for applications like question answering, summarization, and dialogue systems.

{
'premise': 'गरिबीका कारण स्वास्थ्य सेवा प्रदायकहरूबाट गर्भपतनसम्बन्धी सेवाहरू प्राप्त गर्नबाट वञ्चित छन्।',
'hypothesis': 'गर्भपतन सेवाहरू गरिबीका कारण निषेधित छन्।',
'label': 0
}

{
'premise': 'उनीहरू यहाँ आउँदैछन्! कादान चिच्याए।',
'hypothesis': 'कादान इङ्गल्याण्डकी रानीको आगमनबारे चिच्याइरहेका थिए।',
'label': 1
}

{
'premise': 'सुपर-मूल्य भोजनको लागि ८० हङकङ डलर र म्याकडोनाल्ड्सले बेच्ने प्रत्येक स्नुपी खेलौनाको लागि ६ हङकङ डलर।',
'hypothesis': 'स्नुपी म्याकडोनाल्ड्सबाट खरिदका लागि उपलब्ध छैन।',
'label': 2
}

Figure 10: MNLI Entailment (0), Neutral (1) and Contradiction (2) Sample

A.9 Question-Answering Natural Language Inference (QNLI)

The QNLI dataset is a sentence pair classification benchmark designed to evaluate a model's ability to perform natural language inference in the context of question answering.

{
'question': '१३ औं शताब्दीको मोजाइक सान सिप्रियानो चर्चबाट कसले किने?',
'sentence': '१९ औं शताब्दीमा चर्च भत्काइएपछि, मोजाइक प्रसियाका फ्रेडरिक विलियम चौथोले किनेका थिए।',
'label': 0
}

{
'question': 'कुन चाडमा मुख्यतया बालबालिकाहरू सहभागी हुन्छन्?',
'sentence': 'तेस्रो र सबैभन्दा ठूलो कार्निवलको अन्तिम दिनमा हुन्छ र यसमा सयौं मानिसहरू शहरको सबैभन्दा लामो मार्गमा पोशाक लगाएर हिंड्छन्।',
'label': 1
}

Figure 11: QNLI Entailment (0) and Non-Entailment (1) Sample

We include the QNLI dataset in our benchmark to evaluate a model's ability to reason over question–answer pairs. This task requires understanding the intent behind a question and determining whether a candidate sentence contains information that answers it, thereby testing the model's grasp of both question semantics and contextual relevance.

A.10 Recognizing Textual Entailment (RTE)

The Recognizing Textual Entailment (RTE) dataset is a benchmark designed to evaluate a model's ability to determine whether the meaning of one text fragment (the hypothesis) can be inferred from another text fragment (the text).

{
'sentence1': 'केसलरको टोलीले १४ देशका वयस्कहरूसँग ६०,६४३ वटा प्रत्यक्ष अन्तर्वार्ता लिएको थियो।',
'sentence2': 'केसलरको टोलीले १४ देशमा ६०,००० भन्दा बढी वयस्कहरूसँग अन्तर्वार्ता लिएको थियो।',
'label': 0
}

{
'sentence1': 'यदि कुनै मेक्सिकन सिमानामा पुग्छ भने, उसले अवैध रूपमा सिमाना पार गर्न खोजिरहेको मानिन्छ।',
'sentence2': 'मेक्सिकनहरूले अवैध रूपमा सिमाना पार गर्न जारी राखेका छन्।',
'label': 1
}

Figure 12: RTE Entailment (0) and Non-Entailment (1) Sample

Including RTE in a Nepali benchmark is important because entailment recognition is a core aspect of natural language understanding, especially in low-resource settings where explicit reasoning and semantic alignment are critical. It helps assess whether models trained on Nepali data can capture subtle logical relationships.

A.11 Co-reference Resolution (CR)

Co-reference resolution is the task of identifying when two or more expressions in a text refer to the same entity. This is essential for understanding the meaning of a passage, as natural language often relies on pronouns and noun phrases that depend on previous context.

We include the co-reference resolution dataset in our evaluation benchmark to assess a model's ability to understand and maintain coherence across sentences. In the context of the Nepali language, this task is particularly challenging due to the flexible and context-sensitive nature of referential expressions shaped by discourse. Evaluating models on this task allows us to probe their understanding of entity continuity, pronoun grounding, and broader contextual reasoning.

{
'sentence1': 'प्रहरीले सबै गिरोहका सदस्यहरूलाई गिरफ्तार गऱ्यो। उनीहरू छिमेकमा लागूऔषध व्यापार रोक्न प्रयास गर्दै थिए।',
'sentence2': 'प्रहरीले छिमेकमा लागूऔषध व्यापार रोक्न प्रयास गर्दै थिए।',
'label': 1
}

{
'sentence1': 'टेबल ढोकाबाट अटाउँदैन किनभने यो धेरै साँघुरो छ।',
'sentence2': 'टेबल धेरै साँघुरो छ।',
'label': 0
}

Figure 13: CR Positive (1) and Negative (0) Sample

A.12 General Masked Evaluation Task (GMET)

We developed the General Masked Evaluation Task (GMET) dataset, and it is designed to test whether a model understands context. As the task is to predict masked tokens, we test our models on this task without fine-tuning. Given a mask, any word or phrase could plausibly fit the blank depending on the context, so the model must deeply understand the meaning and structure of the sentence to make an accurate prediction. Including GMET in the benchmark is important because it evaluates general language modeling capabilities, such as contextual comprehension, lexical choice, and syntactic fluency skills that are essential for strong performance across a wide range of downstream tasks in Nepali.

{
'sentence': 'म भान्सामा चिया पकाउँदै गर्दा अचानक ग्यास [MASK]।'
}

Figure 14: GMET Sample

B Dataset Translation Approach

Given the unfunded nature of this research, we relied on personal resources and utilized the APIs of two large language models, GPT-4o-mini and Gemini2.5-flash, to translate datasets into Nepali[2]. We processed data in batches of 50 to 100 rows, each containing text and its corresponding label, using automated scripts to manage batching, API interactions, and output collection. For tasks requiring nuanced understanding, such as Co-reference Resolution, manual translation and review were employed to ensure accuracy.

[2]Translation Repository

B.1 Translation Problems

During the translation process, we encountered several challenges:

B.1.1 Label Mismatch

Despite instructions to preserve labels, models produced correct Nepali translations that differed in meaning from the English source, resulting in label mismatches. In some cases, models also corrected errors in the original English texts, requiring manual review to ensure consistency. Examples are provided in Figure 15, Figure 16 and Figure 17.

{
"English Sentence": "What did Bill buy potatoes and ?",
"EN Label": 0
"Nepali Sentence": "बिलले आलु र के किन्यो?",
"NE label": 1
}

Figure 15: Incomplete coordination in English becomes a well-formed question in Nepali, causing label mismatch.

{
"English Sentence": "Who do you think that will question Seamus first?",
"EN Label": 0
"Nepali Sentence": "तपाईंलाई के लाग्छ कसले सिमसलाई पहिले प्रश्न गर्नेछ?",
"NE label": 1
}

Figure 16: English ungrammaticality from complementizer-trace is absent in Nepali, leading to label mismatch.

{
"English Sentence": "many evidence was provided.",
"EN Label": 0
"Nepali Sentence": "धेरै प्रमाणहरू प्रदान गरिएको थियो।",
"NE label": 1
}

Figure 17: Plural-subject agreement error in English is resolved in Nepali, resulting in label mismatch.

B.1.2 Literal Translations

Some translations were overly literal, failing to capture contextual nuances. This issue arises when translation models prioritize word-by-word equivalence rather than interpreting the sentence as a whole. As a result, idiomatic expressions, culturally specific phrases, or context-dependent mean-

ings are mistranslated, leading to loss of intended meaning. Examples are provided in Figure 18, Figure 19, Figure 20 and Figure 21.

```
{
 "English Sentence": "on all cylinders",
 "Nepali Sentence": "सबै सिलिन्डरहरूमा",
}
```

Figure 18: English idiom “on all cylinders” meaning “working perfectly or at full capacity” becomes too literal in Nepali translation, losing its sentiment.

```
{
"English Sentence": "hide new secretions from the parental units",
"Nepali Sentence": "आमाबाबुको इकाईहरूबाट नयाँ स्रावहरू लुकाउनुहोस्",
}
```

Figure 19: Teen slang that means hiding new secrets from parents, when translated, talks about bodily fluid, losing the context.

```
{
 "English Sentence": "of saucy",
 "Nepali Sentence": "चटनी को",
}
```

Figure 20: Wordplay lost in translation, English slang becomes nonsensical in Nepali.

```
{
 "English Sentence": "a doa",
 "Nepali Sentence": "एक डीओए",
}
```

Figure 21: English slang phrase transliterated in Nepali, losing its negative sentiment.

B.1.3 Temporal Expression Mismatch

Abbreviated years in English, when translated literally into Nepali numerals, are often misinterpreted as regular numbers rather than references to specific years. This results in a loss of temporal context, which is especially problematic in historical or review texts where accurate time representation is crucial. Such misinterpretations can alter the meaning of the text and reduce the effectiveness of models trained on this data. Careful handling of these expressions is necessary to preserve the intended temporal information in Nepali translations. Examples are provided in Figure 22.

```
{
"English Sentence": “stale retread of the '53 original",
"Nepali Sentence": "५३ मूल संस्करणको बासी पुनरावृत्ति",
}

{
"English Sentence": “(like Saturday morning TV in the '60s)",
"Nepali Sentence": "(६० को शनिवार बिहानको टिभी जस्तै)",
}
```

Figure 22: Examples of temporal expression mismatches due to literal translation of abbreviated years.

B.1.4 Named Entities and Cultural References

Inconsistent translations of named entities and cultural references often disrupted the semantic integrity of the text and required manual corrections to maintain relevance and consistency within the Nepali context. These inconsistencies, if left uncorrected, could mislead models during training or evaluation. Examples are provided in Figure 23, Figure 24 and Figure 25.

```
{
"Premise": "The Old One always comforted Ca'daan, except today.",
"Hypothesis": "Ca'daan knew the Old One very well."
}

{
"Premise": "पुरानो व्यक्तिले सधैं का'दानलाई सान्त्वना दिन्थे, आज बाहेक।",
"Hypothesis": "का'दानले पुरानो व्यक्तिलाई राम्रोसँग चिन्थे।"
}
```

Figure 23: Example of cultural reference mismatch: mythological connotation of "The Old One" is weakened in Nepali translation.

```
{
 "Sentence1": "A plane is taking off.",
 "Sentence2": "An air plane is taking off."
}

{
 "Sentence1": "विमान उडिरहेको छ।",
 "Sentence2": "हवाई जहाज उडिरहेको छ।"
}
```

Figure 24: Example of lexical ambiguity in named entities: English terms like "plane" and "airplane" in Nepali have a subtle semantic distinction.

{
"English Sentence": "Yet another entry in the sentimental oh-those-wacky-Brits genre that was ushered in by The Full Monty and is still straining to produce another smash hit.",
"Nepali Sentence": "फुल मोंटकै द्वारा सुरु गरिएका भावुक ओ-त्यो-पागल-ब्रिटिशहरूको शैलीमा अझ एउटा प्रवेश, र अझै अर्को ठूलो सफलताको उत्पादन गर्न संघर्ष गर्दैछ।",
}

Figure 25: Example of idiomatic mismatch: "oh-those-wacky-Brits" referring to eccentric British cultural traits becomes "oh-those-crazy-British-people," sounding awkward or negative in Nepali.

B.2 Suggestions on Translation

To improve translation quality and accuracy, we recommend the following strategies:

- **Use detailed prompts:** Instruct models to translate into clear, natural Nepali while preserving the original meaning and sentence structure.
- **Handle untranslatable terms:** For words or phrases without direct Nepali equivalents, allow romanization as a fallback strategy.
- **Batch size optimization:** Process **50–100 examples per API request** (assuming each has 80-100 tokens) to balance efficiency with translation quality. Avoid exceeding 100 examples to prevent degradation.
- **Class-wise translation:** Translate examples belonging to the same class in separate requests, and assign labels **after** translation to avoid mismatches due to grammatical differences across languages.
- **Ensure output consistency:** Implement automated checks to verify that the **number of translated outputs matches the input examples**, minimizing the risk of data loss during batch processing.

C Dataset Quality

C.1 Multilingual Content Filtering

We employed automated language detection to identify and remove any English or non-Nepali text remnants from the translated outputs. This filtering process ensures the purity of the translation by flagging code-switching instances, incomplete translations, or processing errors that leave the artifacts of the source language.

C.2 Statistical Quality Sampling with Manual Validation

A random sampling approach was used to select 1% of the translated corpus for manual quality assessment by native Nepali speakers. Each sampled translation was evaluated using standardized rubrics covering adequacy, fluency, and cultural appropriateness. It was decided that if more than 10% of the samples were found to be unacceptable, retranslation would be performed with an updated prompt. However, no such cases were encountered, indicating high confidence in the translation quality achieved using GPT-4o-mini and Gemini-2.5-flash for Nepali language translation.

C.3 Bidirectional Translation Validation (Back-translation)

Back-translation validation was performed on a randomly sampled 1% subset by translating Nepali outputs back to English using a different translation system. Semantic preservation was measured through automated similarity metrics, including BLEU scores between original and back-translated English texts. Some divergences indicated potential quality issues such as semantic drift or ambiguity resolution errors in the forward translations, but no significant concerns were seen.

D Experiment Stats

We utilized 1,200 GPU hours on NVIDIA T4 GPUs for our experiments. This includes fine-tuning 10 distinct model variants on 11 benchmark datasets, on the configurations outlined in the experiments (section 5).

E Hyperparameter Settings

This section details the optimal hyperparameters identified for each model and dataset combination in our benchmark evaluation for reproducibility. Tuning config is written in the following order: Model Config, Learning Rate, Epoch, Batch Size.

For model config, see Figure 1 and Figure 2.

E.1 Single Sentence Tasks

Best hyperparameter settings (model config, learning rate, epochs, batch size) for each model on SA (Sentiment Analysis), CoLA (Corpus of Linguistic Acceptability), and WG (WinoGrande) tasks are reported in Table 6.

Model	Params	SA	CoLA	WG
Distilbert-Nepali (Maskey et al., 2022)	67M	I, 2e-5, 3, 16	I, 2e-5, 5, 16	II, 2e-5, 8, 32

E.2 Similarity and Paraphrase Tasks

Best hyperparameter settings (model config, learning rate, epochs, batch size) for each model on QQP (Quora Question Pairs), MRPC (Microsoft Research Paraphrase Corpus), STS-B (Semantic Textual Similarity Benchmark), and QADSM (Query Ad Matching) tasks are reported in Table 7.

E.3 Inference Tasks

Best hyperparameter settings (model config, learning rate, epochs, batch size) for each model on MNLI (Multi-Genre Natural Language Inference), QNLI (Question-answering Natural Language Inference), RTE (Recognizing Textual Entailment), and CR (Co-reference Resolution) tasks are reported in Table 8.

F More on GMET

F.1 Dataset Categories

The GMET dataset is organized into the following 75 categories, grouped into seven thematic areas, presented here in English:

- **Daily Life & Home:** Family, House, Kitchen, Food, Clothing, Market, Shop, Daily Routine, Furniture, Health, Dream, Cleanliness, Medicine
- **Nature & Environment:** Weather, Animals, Birds, Insects, Fruits, Vegetables, Trees, Flowers, Nature, Water, River, Mountain, Forest, Sky, Earth, Ocean/Sea, Weather Conditions
- **Society & Culture:** School, Village, City, Sports, Festivals, Music, Art, Friendship, Society, Language, Nepali Culture, Movies, Books
- **Concepts & Knowledge:** Colors, Body Parts, Time, Numbers, Days of the Week, Months, Feelings, Shapes, Directions, Senses, Opposites, Geography, Science
- **Work & Activities:** Work, Professions, Agriculture, Learning, Cooking, Hobbies, Communication, Travel
- **Broader World:** Transportation, Money, History, Government, Technology, Space (sun, moon), Tools, Materials (wood, metal)
- **Nepal Specific:** Geography of Nepal, Animals of Nepal, Festivals of Nepal

F.2 Evaluation Metrics for GMET

The General Masked Evaluation Task (GMET) employs two primary metrics to assess language model performance: overall accuracy and a combined score. These metrics are formalized as follows:

F.2.1 Overall Accuracy

The overall accuracy is defined as the proportion of correct predictions across all sentences in the dataset. Given a dataset with N = 1500 sentences, where each prediction is scored as 1 (correct) or 0 (incorrect), let s_i represent the score for the i^{th} sentence. The overall accuracy A is calculated as:

$$A = \frac{1}{N} \sum_{i=1}^{N} s_i$$

F.2.2 Combined Accuracy

The combined score integrates the overall accuracy with an equality score that measures consistency across categories. The dataset is divided into K = 75 categories, with each category containing 20 sentences. For the k^{th} category, the category-wise accuracy A_k is computed as:

$$A_k = \frac{1}{20} \sum_{i=1}^{20} s_{i,k}$$

where $s_{i,k}$ is the score for the i^{th} sentence in the k^{th} category. The standard deviation of the category-wise accuracies, σ, is calculated as:

$$\sigma = \sqrt{\frac{1}{K} \sum_{i=1}^{K} (A_k - \bar{A})^2}$$

where $\bar{A}$ is the mean of the category-wise accuracies:

$$\bar{A} = \frac{1}{K} \sum_{i=1}^{K} A_k$$

The equality score, E, is derived by transforming the standard deviation to map lower deviation values to higher scores, with the score ranging between 0 and 1. The equality score is defined as:

$$E = e^{-\sigma}$$

This function ensures that lower standard deviations (indicating more consistent performance across categories) yield higher equality scores. In the edge case of a single category, where σ is undefined, E is set to 1. The combined score, C, is then

computed as the product of the overall accuracy and the equality score:

$$C = A.E$$

This combined score balances overall performance with consistency, penalizing models that exhibit uneven performance across the diverse linguistic and topical categories of the GMET dataset.

Family helps one another: Dravidian NLP suite for Natural Language Understanding

Abhinav P M, Priyanka Dasari, Nagaraju Vuppala, Parameswari Krishnamurthy
IIIT Hyderabad
{abhinav.pm, dasari.priyanka, nagaraju.vuppala}@research.iiit.ac.in
param.krishna@iiit.ac.in

Abstract

Developing robust Natural Language Understanding (NLU) for morphologically rich Dravidian languages like Kannada, Malayalam, Tamil, and Telugu presents significant challenges due to their agglutinative nature and syntactic complexity. In this work, we present the Dravidian NLP Suite tackling five core tasks: Morphological Analysis (MA), POS Tagging (POS), Named Entity Recognition (NER), Dependency Parsing (DEP), and Coreference Resolution (CR), trained for monolingual models and multilingual models. To facilitate this, we present the *Dravida dataset*, meticulously annotated multilingual corpus for these tasks across all four languages. Our experiments demonstrate that a multilingual model, which utilizes shared linguistic features and cross-lingual patterns inherent to the Dravidian family, consistently outperforms its monolingual counterparts across all tasks. These findings suggest that multilingual learning is an effective approach for enhancing Natural Language Understanding (NLU) capabilities, particularly for languages belonging to the same family. To the best of our knowledge, this is the first work to jointly address all these core tasks on the Dravidian languages.

1 Introduction

The Dravidian language family, one of the world's oldest and most diverse linguistic groups, comprises over 80 languages spoken primarily in South India, Sri Lanka, and parts of Southeast Asia (Amritavalli and Narasimhan). This study focuses on four widely spoken Dravidian languages-Kannada (ka), Malayalam (ml), Tamil (ta), and Telugu (te)-which together account for over 200 million native speakers, based on the 2011 Census of India (Census, 2011).

These languages are typologically complex, featuring agglutinative morphology, free word order, and pro-drop characteristics, where subject pronouns are often omitted and inferred contextually. They lack prefixes and infixes; instead, grammatical relations are expressed solely through suffixation and compounding (Krishnamurti, 2003).

Despite their cultural and demographic significance, computational resources for Dravidian languages remain limited, especially when compared to better-resourced Indo-European languages-posing a major challenge to progress in Natural Language Processing (NLP). Their agglutinative structure requires sophisticated tools to segment words into morphemes (Creutz and Lagus, 2007), while the flexible word order complicates dependency parsing and structural interpretation. To make substantial progress, NLP for these languages must robustly handle these fundamental layers of linguistic analysis-from morphology to discourse-which collectively support comprehensive understanding.

This paper aims to bridge this gap by presenting a systematic effort to develop and evaluate foundational NLU capabilities for these languages. Our primary contributions are:

1. **The Dravidian NLP Suite:** A comprehensive suite of models for five core NLP tasks: MA, POS, NER, DEP, and CR specifically adapted to Kannada, Malayalam, Tamil, and Telugu.

2. **The Dravida Dataset:** A richly annotated corpus meticulously created to support all five tasks for each of the four languages, serving as a crucial resource for model development and comparative evaluation within this work and for future research. The dataset and resources introduced in this work are publicly available at[1].

3. **Systematic Monolingual vs. Multilingual Evaluation:** We conduct a thorough comparison of monolingual models against a multilin-

gual model, including evaluation against the multilingual baseline, demonstrating the significant advantages of cross-lingual learning by leveraging shared linguistic patterns within the Dravidian family.

Our work is guided by the well-established hypothesis that linguistic relatedness enables effective cross-lingual transfer within language families (Pires et al., 2019; Conneau et al., 2019). Training multilingual models across Kannada, Malayalam, Tamil, and Telugu significantly outperforms monolingual models, confirming the benefits of shared learning. This suggests that even in low-resource settings, incorporating rich linguistic representations through shared learning is a powerful strategy (Jurafsky, 2000).

2 Related Work

Natural Language Processing (NLP) for Indian languages has progressed from rule-based and statistical methods to deep learning approaches addressing their rich morphosyntactic diversity and low-resource challenges. This review focuses on five core tasks MA, POS, NER, DEP and CR, tracing developments from finite-state and machine learning models to recent transformer-based and cross-lingual transfer techniques that have advanced NLP for Indian languages.

Morphological Analysis for Indian languages has been explored using both rule-based and neural approaches (Sarveswaran et al., 2021). Early efforts include a Telugu Morphological Analyzer (Rao et al., 2011) organized a linguistic database and employing computing resources effectively. This work is based on the word and paradigm approach (Hockett, 1954; Menaka et al., 2010; Rajendran, 2009). Improvised Tamil morphological analysis using the Apertium platform (Parameshwari, 2011), refining linguistic databases for improved inflectional and derivational analysis. A rule-based finite-state transducer (FST) for Kannada implemented by (Veerappan et al., 2011). For Telugu, (Srinivasu and Manivannan, 2018) developed a morphological analyzer and generator using the Item and Process model with finite-state machines (FSM). More recently, neural-based approaches have been explored. A large annotated Telugu dataset and evaluated it on transformer-based models (Dasari et al., 2023). For multilingual morphological analysis, (Mishra et al., 2024) proposed a multi-task learning framework integrating POS tagging, chunking, and morphological analysis, leveraging fine-tuned contextual embeddings across multiple Indian languages. (Pawar et al., 2023) shows that pretrained multilingual models like mT5 improve root extraction and GNP tagging in low-resource Indian languages through cross-lingual transfer. These approaches complement large-scale cross-lingual morphological databases such as UniMorph (Kirov et al., 2018), which provide universal morphological feature schemas across languages.

Parts of Speech Tagging helps in assigning markers to words in the sentence that give those words some lexical meaning. POS taggers are specially developed for several Indian languages such as Hindi, Bengali, Telugu, etc. (Antony and Soman, 2011) and (Antony and Soman, 2010) developed a POS tagger for Kannada using a Support Vector Machine (SVM)-based approach. Graph-based and cross-lingual techniques are explored to improve POS tagging for low-resource languages. (Imani et al., 2022) proposed a graph-based label propagation method, utilizing multilingual word alignments and graph neural networks to enhance label transfer, and (Kim et al., 2017) introduced cross-lingual transfer learning. Similarly, (Chaudhary et al., 2021) introduced an active learning approach to minimize annotation efforts while reducing conflicts in POS tagging optimization. Recent advancements include active learning approaches by (Chaudhary et al., 2021) and (Kumar et al., 2024) introduced UD-compliant POS tagging datasets for low-resource Indic languages like Angika, Magahi, and Bhojpuri.

Named Entity Recognition research initially focused on English and major languages, with limited work on Indian languages. Multilingual learning enhances NER in low-resource languages by leveraging data from closely related languages through shared neural network layers (Murthy et al., 2018). For Indian languages, (A P et al., 2019) proposed a deep learning-based NER system, utilizing character, word, and affix-level embeddings. More recently, (Bahad et al., 2024) introduced a human-annotated corpus of 40K sentences for four Indian languages and proposed a multilingual NER model tailored for Indian language families.

Dependency Parsing is essential for understanding syntactic relations. Early work by (Kosaraju et al., 2010) evaluated the Malt parser on Hindi, Telugu, and Bangla, experimenting with various parsing strategies. Later, (Nallani et al., 2020) ex-

panded Telugu treebanks by automatically annotating intra-chunk dependencies using a Shift-Reduce parser, resulting in a fully expanded treebank of 3220 sentences. For Malayalam, (Stephen J et al., 2023) developed a Universal Dependencies (UD)-based treebank, ensuring cross-linguistic consistency. Similarly, (Krishnamurthy and Sarveswaran, 2021) created a morphosyntactically annotated Tamil treebank with 534 sentences, introducing language-specific relations for Tamil NLP. These efforts build upon foundational work in multilingual parsing shared tasks (Zeman et al., 2017) and widely-used tools like Stanza (Qi et al., 2020) and UDPipe (Straka and Straková, 2017).

Coreference Resolution research has progressed from rule-based models to deep learning approaches. End-to-end neural models were introduced by (Lee et al., 2017), eliminating explicit mention detection by directly considering all possible spans. This was further refined by (Lee et al., 2018a), who incorporated higher-order coreference resolution with attention-based mechanisms. For Indian languages, (Mishra et al., 2024) introduced TransMuCoRes, a multilingual coreference resolution dataset covering 31 South Asian languages. (Devi et al., 2024) fine-tuned XLM-Roberta for Tamil, Malayalam, and Hindi, showing that linguistic feature integration. To address low-resource challenges, (Rahothvarman et al., 2025) developed mGAP, a multilingual coreference dataset derived from translating the English GAP dataset into South Asian languages.

3 The Dravida Dataset: Creation and Characteristics

This section details the creation and characteristics of the *Dravida dataset*, a multilingual corpus supporting our Dravidian NLP suite. The dataset provides annotations for five core tasks- MA, POS, NER, DEP, and CR- across Kannada, Malayalam, Tamil, and Telugu. All data included met an inter-annotator agreement (IAA) score of at least 0.85. The manual annotation for tasks like NER and CR was carried out by native speakers of the respective languages. Annotation guidelines were developed iteratively, incorporating examples of edge cases. Each document was annotated by two annotators, and disagreements were resolved through discussion with a senior annotator to ensure consistency.

The Dravidian NLP Suite integrates key components; MA captures inflectional and derivational patterns; POS Tagging assigns grammatical roles; NER identifies and classifies proper names (Pillai and Sobha, 2013); DEP models syntactic relations between heads and dependents (Li et al., 2018); and CR links entity mentions across discourse for coherent interpretation. Table 1 presents a detailed linguistic analysis of Telugu sentences, highlighting core tasks in the Dravidian NLP Suite. While the exact annotation format within our Dravida dataset may vary per task, this example highlights the types of linguistic information each core task aims to capture.

Key aspects analyzed include root words, morphological features, UD POS tags (Petrov et al., 2012), named entities (Bahad et al., 2024), and head-dependent relations (yi Lee et al., 2009). Coreference chains are annotated using the mention%chain[2] format (Mujadia et al., 2016), linking referring expressions that refer to the same entity across sentences. In example 1, in the first sentence, i1 (*Kumar*) and i2 (*he*) are linked in coreference chain t1, indicating that '*he*' refers to '*Kumar*'. Similarly, i1 (*New York*) and i2 (*there*) belong to coreference chain t2, denoting the same location. The symbol % separates the mention ID from its coreference chain, ensuring clarity in discourse analysis.

1. **Te:** `kumār nyūyārklō nivasistunnāḍu. atanu aydu saṃvatsarālugā akkaḍa maykrōsāphṭlō panicēstunnāḍu.`
   En: "*Kumar lives in New York. He has been working there at Microsoft for five years.*"

3.1 Data Sources and Preprocessing by Task

Morphological Analysis (MA): The MA data focuses on root and suffix identification and includes features such as lexical category, gender, number, and person. For Kannada and Malayalam, we used (iiit, 2023)-annotated corpus, which is in CoNLL-U format. From this we extracted only the morphological features for our processing.

For Telugu and Tamil, we utilized in-house data, initially processed with a rule-based morphological analyzer and subsequently manually validated and corrected for accuracy. Following (Dasari et al., 2023), we applied noise removal and cleaning, filtering tokens with invalid annotations (e.g., anomalous person values or non-standard gender/number entries). Final dataset statistics are in Table 3.

[2]This format is just used to explain the coreference chains in this paper. In our coreference data annotation, we marked the referring expressions with mention spans

Tkn.no	Word	MA	POS	NER	DEP	CR
	<S>

Table 1: Sample of Telugu sentence analysis of all the Tasks in Dravidian NLP suite.

POS Tagging (POS): We used SSF-formatted data from (Bharati and Sangal, 2007) for all languages. After converting to word-POS pairs and performing preprocessing, BIS format POS tags (of Indian Standards, 2021) were mapped to the Universal Dependencies (UD) scheme (yi Lee et al., 2009). Statistics are in Table 3.

Named Entity Recognition (NER): Given the scarcity of NER-annotated data for Dravidian languages, we combined manually annotated data (Table 2, annotated using a tool detailed in the Appendix) with synthetically generated data. A portion of the manually annotated data, following BIO format, forms our test set. The remaining manually annotated sentences are combined with synthetically generated data to create the training corpus. For synthetic data, we translated Hindi NER data (Bahad et al., 2024) into the four Dravidian languages using Google Translate. High-quality word alignments are then generated using Awesome-Align (Dou and Neubig, 2021), which uses multilingual BERT embeddings (Devlin et al., 2019), a technique proven effective for low-resource scenarios (James and Krishnamurthy, 2025). This allowed accurate projection of BIO tags from Hindi to the Dravidian languages. The process is illustrated in Figure 1.

While large-scale manual validation of the synthetic data was not feasible, we performed a small-scale error analysis to assess its quality. Out of 344 tokens reviewed in Telugu, we identified around 20 annotation issues, while Tamil and Malayalam had approximately 15 and 10 errors, respectively. The most common issues were span boundary mismatches and fragmented entities. For example, Telugu expressions like '*2020 ḍisemḃar 10na*[3]' ('10th December 2020') were incorrectly split across multiple entity tags. These findings inform our analysis of the results in Section 5. Overall NER statistics are in Table 3.

Language	Sentences	Tokens
Kannada	1276	14560
Malayalam	1703	17643
Tamil	2132	38712
Telugu	2016	34179

Table 2: Statistics of the Manually Annotated NER Dataset

Dependency Parsing (DEP): We used in-house CoNLL-U data for Tamil. For Telugu, the limited in-house data was supplemented with the UD Dependency Treebank (Rama and Vajjala, 2017), though Telugu data remains comparatively smaller. Kannada and Malayalam data were sourced from (iiit, 2023) (CoNLL-U format), with Pāṇinian

[3]The Telugu text is transliterated using the ISO 15919 standard.

kāraka relations converted to UD relations as per (Tandon et al., 2016) (tagset in Appendix). Preprocessing involved filtering sentences with multiple root annotations and correcting formatting inconsistencies. Statistics are in Table 3.

Task	Lang.	Train (#Sent, #Tokens)	Test (#Sent, #Tokens)

Table 3: Dataset statistics for MA, POS, NER, and DEP tasks.

Coreference Resolution (CR): Manually annotated data (Table 4, tool in Appendix) was augmented with synthetic data for training. Similar to NER, we translated Hindi coreference data (Mujadia et al., 2016) (275 documents, 3,523 sentences) and used Awesome-Align (Dou and Neubig, 2021) for mention mapping (Figure 1). Ten manually annotated documents per language form the test set. The Tamil test set has fewer sentences due to the nature of the source texts (short stories). The combined CR dataset statistics (manually annotated + synthetic data) are presented in Table 5, including the number of documents and sentences in each split, mentions per document, and the percentage of singleton mentions. To understand the quality of the projected coreference data, we did a manual error analysis on a sample. We found quite a few incomplete or inconsistent coreference chains-especially in Telugu and Tamil, where more than 45% of the sampled spans had annotation issues. These problems, likely due to translation and alignment errors, help explain the relatively modest improvements we report in Section 5.

4 Methodology

This study evaluates the effectiveness of multilingual learning for core NLU tasks in four Dravidian languages: Kannada, Malayalam, Tamil, and Telugu. For each of the five tasks-MA, POS, NER, DEP, and CR- we developed and compared two distinct modeling approaches:

Lang.	Docs	Sent	Mentions	%Sing
Kannada	43	1306	12.6/doc	0.2
Malayalam	15	698	19.2/doc	1.3
Tamil	72	2607	18.1/doc	1.4
Telugu	71	2127	16.2/doc	2.7

Table 4: Statistics of the manually annotated coreference resolution dataset

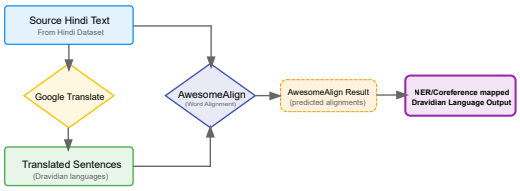

Figure 1: Workflow for Synthetic Data Preparation.

1. **Monolingual Models:** Trained independently on language-specific data for each of the four languages.

2. **Multilingual Baseline:** An additional baseline experiment, conducted using the IndicBERT (Doddapaneni et al., 2023) model, compares its performance with our proposed multilingual setup. For each task, IndicBERT is trained on the combined Dravidian dataset using the same model configuration as our multilingual model.

3. **Multilingual Model:** Trained on a combined dataset comprising data from all four languages for a given task. To ensure a fair comparison, the multilingual model for each task employs the same architecture as its monolingual models.

This comparative setup allows us to assess baseline language-specific performance and quantify the benefits derived from shared linguistic patterns utilized through multilingual training. All models were evaluated on their respective language-specific test sets as detailed in Section 3. The combined multilingual training data for each task was created by simple concatenation of the individual language training sets. The following subsections detail the model architectures and methods for each task.

Language	Train		Test		Avg.Mentions	%Sing
	# Docs	# Sent	# Docs	# Sent		
Kannada	225	3825	10	299	14/doc	5.2
Malayalam	198	3366	10	317	15/doc	7.6
Tamil	336	5712	10	154	12/doc	4.3
Telugu	253	4316	10	332	15/doc	5.3

Table 5: Combined Data Statistics of Coreference Resolution

4.1 Morphological Analysis (MA)

MA in our suite involves two sub-tasks: (1) root word and suffix identification, and (2) prediction of other morphological features lexical category, gender, number, and person.

Root Word and Suffix Identification: As a monolingual model, for this task, we employed a character-level lemmatization model using the Flair framework (Akbik et al., 2019), known for its effective character-level modeling capabilities and adapted specifically for Dravidian languages. To handle the agglutinative nature of Dravidian languages and to operate without pre-trained word embeddings for this sub-task, we developed a custom `FixedLemmatizer`. This involved subclassing Flair's Lemmatizer to handle tensor processing and enable direct character-based sequence generation. A character dictionary is built from the training corpus, encoding words as sequences of characters (including start and end symbols). The model uses a bidirectional RNN with two layers and a hidden size of 256 to predict root and suffix forms at the character level. This architecture served as the basis for both monolingual and multilingual models.

Multi-Task Learning for Morphological Features: For the other four morphological features, we employed a multi-task learning approach. This choice was motivated by the potential for these related features to benefit from shared representations. The architecture features a shared XLM-RoBERTa (Conneau et al., 2019) encoder, selected for its strong performance on multilingual and morphologically rich languages. The encoder captures the contextual meaning of input words, while task-specific classification heads predict individual morphological features. This setup enables the model to utilize shared linguistic patterns through common layers while refining predictions with specialized output layers for each feature. The same architecture is used in both monolingual and multilingual settings.

4.2 POS Tagging (POS)

For POS tagging, we utilize a sequence tagging framework built on Flair (Akbik et al., 2019), leveraging the XLM-RoBERTa (Conneau et al., 2019) model to generate multilingual embeddings pre-trained on a diverse set of languages. The model employs a first-last pooling operation, which combines information from the first and last transformer layers to capture both low-level and high-level linguistic features. These contextualized word representations are then passed to a linear tagging layer to predict UD POS tags for each token.

4.3 Named Entity Recognition (NER)

NER is also implemented as a sequence labeling task within the Flair framework (Akbik et al., 2019), taking advantage of its flexibility for sequence labeling tasks. Our approach employed a transformer-based sequence tagger built on pre-trained multilingual embeddings, fine-tuned specifically for NER. The model uses multilingual BERT (bert-base-multilingual-cased) (Devlin et al., 2019) to generate contextualized token representations, capturing both word-level and contextual information. This model is selected due to its widespread success in multilingual NER tasks. The tagger, configured with a hidden size of 256 and without a CRF layer, directly predicting BIO-formatted NER labels.

4.4 Dependency Parsing (DEP)

We built the parser using a Biaffine Dependency Parser, which relies on biaffine attention (Dozat and Manning, 2016), utilizing the implementation provided by the SuPar toolkit (Zhang et al., 2020). The Biaffine architecture is known for strong performance in dependency parsing. To help the model better understand the structure of Dravidian languages, we used multilingual BERT (bert-base-multilingual-cased) (Devlin et al., 2019) as the encoder. This setup allows the parser to make use of context-aware word representations, which is

especially helpful for handling the complexity of morphologically rich languages. The parser predicts head-dependent arcs and their corresponding labels.

4.5 Coreference Resolution (CR)

For coreference resolution, we extended the transformer-based end-to-end model proposed by Lee et al. (2017), designed to identify and link mentions referring to the same entity. The model uses a span-based architecture, encoding input documents with a multilingual BERT model (bert-base-multilingual-cased) (Devlin et al., 2019) to generate contextualized token representations. For each potential entity span, a representation is created by combining embeddings of boundary tokens, an attention-weighted representation of tokens within the span, and feature embeddings for span width. The model scores candidate spans to identify valid entity mentions, selects the top spans, and computes antecedent scores to link mentions to their references. We applied higher-order refinement using the attended-antecedent strategy (Lee et al., 2018b), where span representations are refined by attending to antecedents based on pairwise scores.

4.6 Training Details

Across all tasks, models were trained using appropriate optimizers (typically AdamW (Loshchilov and Hutter, 2017) or Adam) and learning rates suited to their architectures. For tasks leveraging Transformer-based models (MA-features, POS, NER, DEP, CR), fine-tuning was generally conducted for a number of epochs based on the task and dataset size, often incorporating early stopping where applicable. Common batch sizes ranged from 32 to 128. All experiments were conducted on NVIDIA L40S GPU. Detailed hyperparameters for each task-specific model, including precise learning rates, epoch counts, and optimizer configurations, are provided in Appendix.

5 Results and Analysis

This section presents model performance across all tasks for each language, evaluated using F1 scores (MA, POS, NER, CR) and Unlabeled and Labeled Attachment Scores (UAS and LAS). Results are shown in Table 6 and Table 7.

For Morphological Analysis (Table 6), our primary multilingual model performs better across most languages and features. The root+suffix identification task, being a character-level model, does not have a Transformer-based baseline, hence the empty cells for IndicBERT in the table. In both monolingual and multilingual settings, the root and suffix prediction task for Tamil recorded the highest score among all. For example, the multilingual model improved gender prediction in Tamil by 19.25% and person prediction in Kannada by 3.1%. These improvements show that the multilingual model benefits from shared patterns across the Dravidian languages, leading to better generalization. On the other hand, the lower root+suffix scores for Malayalam, especially the slight dip in the multilingual setting, as noted, potential inconsistencies in the annotation of its root forms which the multilingual model might be more sensitive to if other languages present clearer patterns.

Language	root+suffix	lcat	gender	number	person
Monolingual Model					
Kannada	94.37	69.94	61.66	52.45	67.24
Malayalam	79.31	63.36	40.80	58.32	57.26
Tamil	97.82	70.82	56.27	69.03	66.54
Telugu	96.39	83.36	81.75	72.70	75.29
Multilingual Baseline (IndicBERT)					
Kannada	-	48.23	45.54	52.48	53.08
Malayalam	-	41.47	42.43	49.91	43.57
Tamil	-	58.57	63.63	61.71	62.91
Telugu	-	58.57	63.63	61.71	62.91
Primary Multilingual Model					
Kannada	94.53	72.39	65.43	53.94	70.34
Malayalam	78.53	68.28	52.63	65.97	64.59
Tamil	97.83	75.12	75.52	75.28	76.42
Telugu	96.34	84.96	84.30	74.90	78.43

Table 6: F1 scores of Monolingual, Multilingual Baseline (IndicBERT), and primary Multilingual models on the test set for Morphological features.

The monolingual models perform well in POS tagging, with F1 ranging from 85.65 (Kannada) to 97.14 (Tamil), reflecting a strong understanding of word-level syntax. The multilingual model improves performance, with Kannada F1 rising from 85.65 to 93.88 and Tamil from 97.14 to 97.23.

NER remains challenging, especially for Kannada and Malayalam in the monolingual model (F1: 42.83, 38.65). The multilingual model improves F1 to 49.46 and 46.77, respectively, indicating better entity detection. Tamil also shows a slight gain (76.42 $\rightarrow$ 76.49), while Telugu exhibits a minor drop, possibly due to noise in synthetic data and annotation errors in projected entities (Section 3). These factors, along with underrepresentation in the base BERT model, this suggests the need for further investigation.

Dependency Parsing is evaluated using Unlabeled (UAS) and Labeled Attachment Scores

Language	POS	NER	CR	DEP	
	F1	F1	F1	UAS	LAS
Monolingual Model					
Kannada	85.65	42.83	44.26	91.15	81.11
Malayalam	93.22	38.65	31.89	87.67	72.87
Tamil	97.14	76.42	39.23	82.54	71.58
Telugu	96.71	74.18	25.67	79.87	65.62
Multilingual Baseline (IndicBERT)					
Kannada	89.97	32.57	2.17	84.43	70.97
Malayalam	90.87	42.41	1.77	74.74	59.68
Tamil	90.91	60.38	2.07	80.03	64.60
Telugu	92.72	62.67	0.06	71.65	50.06
Primary Multilingual Model					
Kannada	93.88	49.46	46.32	91.52	81.22
Malayalam	93.28	46.77	33.51	87.97	73.26
Tamil	97.23	76.49	45.31	82.65	71.64
Telugu	97.10	72.94	31.06	82.46	68.18

Table 7: Results of Monolingual, Multilingual Baseline (IndicBERT), and primary Multilingual models on the test set for POS, NER, CR, and DEP tasks.

(LAS). UAS measures correct head assignment, while LAS also checks the dependency label. The monolingual model achieves UAS above 79% (e.g., 91.15 for Kannada) with slightly lower LAS, indicating challenges in labeling relations. The multilingual model offers marginal gains (Kannada UAS: 91.15→91.52; LAS: 81.11→81.22), suggesting limited cross-lingual benefit due to syntactic variation.

For Coreference Resolution, the monolingual Model achieves F1 scores ranging from 25.67 (Telugu) to 44.26 (Kannada). The multilingual model improves these results, with F1 score for Kannada increasing to 46.32 and for Malayalam from 31.89 to 33.51. However, gains are modest, indicating that discourse-level relationships may require further refinement. Here, too, the multilingual model performs better than the monolingual model.

Comparison with IndicBERT Baseline. Our primary multilingual models consistently outperform the IndicBERT multilingual baseline across nearly all tasks and languages (Tables 6 and 7). For instance, in POS tagging, our primary multilingual model surpasses IndicBERT by approximately 3-4 F1 points across languages. The most striking difference appears in Coreference Resolution, where IndicBERT achieves near-zero F1 scores (0.06-2.17) while our model achieves scores from 31.06 to 46.32. This substantial performance gap is likely attributable to differences in model capacity. IndicBERT, based on an ALBERT-base (Lan et al., 2019) architecture with approximately 22 million parameters, is considerably smaller than the 179 million parameters of the mBERT encoder used in our primary CR model. Coreference Resolution is a complex discourse-level task requiring the modeling of intricate, long-distance relationships. The limited capacity of IndicBERT may be insufficient to capture these complex patterns, particularly when combined with the noisy synthetic data used for training.

The consistent outperformance of the multilingual model across all four Dravidian languages strongly validates our central hypothesis: utilizing shared linguistic patterns within this language family significantly enhances NLU capabilities. Notable improvements are observed in MA, POS Tagging, NER, and DEP. However, the gains for Coreference Resolution are more modest. This suggests that further refinements, such as expanding annotated training data, could help the model capture discourse-level relationships more effectively, leading to improved performance in coreference resolution and related tasks.

6 Conclusion and Future work

This paper introduces the Dravidian NLP suite and the corresponding Dravida dataset, providing comprehensive NLU tools for MA, POS, NER, DEP, and CR across Kannada, Malayalam, Tamil, and Telugu. Our key finding is the consistent and significant performance improvement achieved by multilingual models over their monolingual versions, demonstrating the effectiveness of leveraging shared linguistic characteristics within the same language family. This work underscores multilingual learning as an effective strategy for advancing NLU in linguistically related languages with varying degrees of resource availability. As part of our future work, we will increase the size and quality of annotated data for each language and task, and to potentially incorporate additional languages from the Dravidian family to our suite. We explore Large Language Models (LLMs) to develop a unified multilingual multitasking framework that jointly models all core tasks, enabling a single, robust model that can be seamlessly applied to a wide range of downstream applications across multiple Dravidian languages.

Limitations

This study presents several limitations that open avenues for future work in Dravidian NLU. While the Dravida dataset is a significant contribution, its size and diversity-particularly for discourse-level tasks like CR-remain limited compared to high-resource languages. This likely constrained CR performance in the multilingual setup and may hinder generalization to broader discourse phenomena. Synthetic data used for NER and CR helped address annotation scarcity but may introduce errors or miss important language-specific patterns, especially in entity and reference expression. Our MA covers suffixation and predefined features but does not fully address complex phenomena such as compounding or sandhi. The study is restricted to four major Dravidian languages, leaving out others in the family. Moreover, we did not benchmark against widely used multilingual toolkits like Stanza. Such a comparison would help clarify the trade-offs between broad multilingual systems and our targeted, family-specific models. Finally, observed performance fluctuations-such as in Telugu NER under the multilingual setting-highlight the need for a more systematic error analysis beyond the preliminary investigation reported in Section 3.

Acknowledgements

The authors thank the dedicated annotators of the research team for their contributions to the Dravida dataset, and the anonymous reviewers for their valuable feedback. We also acknowledge the use of AI tools for grammar checking.

A Appendix

A.1 Morphological Analysis

A Morphological Analysis involves analyzing tokenized wordforms into their roots, lexical category, and other morphosyntactic information in terms of their constituent morphemes. The six fields include root and suffix, lexical category (lcat), gender (gen), number (num), and person (pers). The field for each attribute feature is fixed, and a comma is

used as a delimiter, as shown in Table 1. In case no value is given for a particular attribute, then the field is left blank. Each feature is associated with one or more values related to it. The values of a feature are called feature values. For Instance, the feature *gender* has three feature values as *male, female* and *neuter*.

The possible features and feature values of a category are given below in Table 8

A.2 POS tagging

The Bureau of Indian Standards (BIS) tagset and the Universal Dependencies (UD) tagset are two different sets of part-of-speech (POS) tags used for annotating text data. While both tagsets serve the same purpose, they have different categorizations and granularities. The BIS tagset is designed explicitly for Indian languages, taking into account their unique linguistic characteristics. On the other hand, the UD tagset is a more universal standard, designed to be applicable across multiple languages. This conversion Table 9 provides a mapping between the BIS tags and the corresponding UD tags, facilitating the transition between the two tagsets.

A.3 Dependency Parsing

The Paninian dependency framework is widely used for annotating Indian languages, especially for syntactic and semantic structure analysis. It offers a rich set of language-specific grammatical relations, etc., which are tailored for Indic linguistic structures. However, with the increasing adoption of Universal Dependencies (UD) as a cross-linguistic syntactic annotation standard, converting Paninian tags to UD tags becomes essential for broader compatibility and multilingual NLP research. Figure 2 shows an example of dependency annotation for a Tamil sentence, and Table 10 presents the mapping between Pāṇinian and Universal Dependency labels.

A.4 NER Tagset

NER is a fundamental task in Natural Language Processing (NLP) that involves identifying and categorizing named entities in unstructured text into predefined categories. Table 11 lists the NER tags used in our annotations, and Figure 3 shows the NER annotation tool.

A.5 Coreference Resolution annotation tool

Coreference resolution is the task of identifying all expressions that refer to the same entity within a discourse. Annotating coreference chains involves marking such referring expressions and linking them to form equivalence chains. The tool shown in Figure 4 shows the chains and their mentions. The right-side column of the tool shows the list of chains with their mention.

A.6 Hyperparameters and Training Details

This subsection provides key hyperparameter details for the models described in Section 4.6.

S.No.	Features	Feature values
1.	**Root**	lemma
	Suffix	Case Markers or Tense, Aspect and Mood markers

Spatial-Aware Visual Program Guided Reasoning for Answering Complex Visual Questions

Haoran Wang **Kai Shu**
Emory University
haoran.wang@emory.edu, kai.shu@emory.edu

Abstract

Visual Question Answering (VQA) often requires complex multi-hop reasoning encompassing both vision and language. Despite the remarkable performance of Large Multimodal Models (LMMs) in vision-language tasks, they encounter difficulties when faced with challenging scenarios that require complex reasoning and may be susceptible to object hallucination. This paper introduces a novel framework named Spatial-aware Visual Program Reasoning (SVPR). The primary goal of SVPR is to enhance the alignment between vision and language within LMMs, fostering their multi-hop reasoning abilities and ultimately strengthening their capacity to address complex visual reasoning tasks. We first utilize the strong visual understanding abilities of LMMs to generate scene graphs, facilitating coordination between vision and language at semantic levels. Then, we leverage the in-context learning ability of LMMs to generate visual programs, which guide the question decomposition process. Finally, we employ a program solver to execute the programs and derive the final answer. This process makes our approach both explanatory and robust, providing clear explanations of its reasoning process while ensuring the faithfulness of the answer to the visual input. We evaluate our framework on two challenging multi-hop multimodal VQA datasets and show its effectiveness under zero-shot settings. Our code is available [1].

1 Introduction

Large Multimodal Models (LMMs) like GPT-4V (Achiam et al., 2023) and Gemini (Team et al., 2023) have demonstrated remarkable zero-shot capabilities in handling various visual-language tasks. Nevertheless, despite their significant advancements, LMMs demonstrate limited performance in answering complex questions that require multi-hop reasoning across various levels of visual information (Yang et al., 2023c; Ossowski et al., 2024; Wu and Xie, 2023; Wang et al., 2025; Xu et al., 2025). For instance, consider the image depicted in Table 1. A straightforward question such as *"What color is the building?"* requires only one-hop (one-step) reasoning to determine the color of the building in the image. In contrast, a more complex question like *"On which side of the walkway leading to the San Francisco Civic Center can the American flag be found?"* requires multi-hop reasoning: (i) visually detecting the walkway leading to the building, (ii) visually locating the American flag, and (iii) determining the spatial relationship between the walkway and the flag, which involves spatial reasoning.

Question: *On which side of the walkway leading to the San Francisco Civic Center can the American flag be found?*

Ground Truth: The flag is located on the left side.

GPT-4V: The American flag is located on the **right side** of the walkway leading to the San Francisco Civic Center in the image provided.

GPT-4V+*SVPR*: The American flag [0.25, 0.3, 0.26, 0.35] is located on the **left side** of the walkway leading to the San Francisco Civic Center [0.3, 0.25, 0.7, 0.75].

Table 1: An example of SVPR in answering a visual question that requires spatial reasoning, with correct textual reasoning illustrated in **green** and incorrect textual reasoning illustrated in **red**. Additionally, SVPR provides bounding boxes (highlighted in blue) as visual evidence to provide grounding.

To facilitate Large Language Models (LLMs) and Large Multimodal models (LMMs) in breaking down the input question into multiple reasoning steps, several techniques have been proposed, such as Chain-of-Thought (Wei et al., 2022), Self-Ask (Press et al., 2023), Least-to-most prompting (Zhou et al., 2022), ReAct (Yao et al., 2022), and others. While these models excel in handling single-hop questions, they encounter challenges when confronted with multimodal multi-hop questions. In such scenarios, the formulation of subsequent questions is influenced by the answers to preceding sub-questions. Moreover, these techniques often do not explicitly facilitate coordination between vision and language and lack spatial awareness. Consequently, there is a discrepancy in semantic granularity between visual and textual information. Unlike textual sentences where each word is distinctly separated, identities within an image lack clear boundaries and aren't isolated in the same explicit manner.

In this paper, we introduce *Spatial-aware Visual Program Reasoning (SVPR)*, a novel framework designed to foster language-vision coordination and enhance the complex reasoning capabilities of LMMs in answering complex visual questions. Specifically, our framework consists of three stages: **(1) Scene graph generation** prompts LMMs to create a structured representation of the image known as a scene graph. This graph encapsulates detailed semantics by explicitly modeling objects, their attributes, and the relationships between pairs of objects; **(2) Visual program generation** decomposes the input question into simpler sub-questions by generating a visual reasoning program. This program is essentially a sequence of sub-tasks aimed at simplifying the overall reasoning process; **(3) Program solver** first answers the formulated sub-questions based on the image using a validator. These sub-questions and their corresponding sub-answers collectively act as rationales for the final reasoning step. Then, LMMs perform reasoning aggregation over the scene graph and rationales to derive the final answer and give justification for their reasoning process.

We evaluate our proposed framework on two challenging datasets that require complex reasoning abilities: WebQA (Chang et al., 2022) and GQA (Hudson and Manning, 2019). Our experiment results demonstrate that SVPR can effectively answer complex questions while providing clear explanations of its reasoning process.

In summary, our contributions are:

- We introduce a new framework to enhance LMMs' vision-language coordination and multi-hop reasoning ability to answer complex visual questions.
- Our framework is designed in a way that each step is transparent and consistent, thus providing both explainable and robust answers.
- We comprehensively evaluate the effectiveness of our method, and the large improvements demonstrate its great potential in complex visual reasoning.

2 Background

Multi-modal Multi-hop Question Answering. Multimodal Multi-hop Question Answering (MMQA) (Chang et al., 2022; Reddy et al., 2022; Talmor et al., 2021) requires answering a question by reasoning over multiple input sources from different modalities. This task often involves multi-step reasoning, wherein one or more intermediate conclusions must be reached before arriving at the final answer (Mavi et al., 2022; Wang et al., 2024). Each intermediate conclusion acts as a necessary premise for the subsequent one. This progression of intermediate and final conclusions is called a reasoning chain. While previous approaches (Chang et al., 2022; Chen et al., 2022; Li et al., 2022; Reddy et al., 2022; Talmor et al., 2021; Yang et al., 2023b; Pan et al., 2024; Heo et al., 2022) utilizing supervised learning have demonstrated promising outcomes, current attention has pivoted towards MMQA under the zero-shot settings. To solve the zero-shot compositional VQA task, VISPROG (Gupta and Kembhavi, 2023) uses a neural-symbolic approach to perform multi-step reasoning using language models. (Rajabzadeh et al., 2023) utilize a tool-interacting divide-and-conquer approach, empowering large language models (LLMs) to address intricate multimodal multi-hop inquiries. More recently, II-MMR (Kil et al., 2024) employs two distinct prompting techniques to determine a reasoning path leading to its solution. Like the prior approaches, our framework also adopts a decomposition strategy for executing multi-step reasoning. However, our emphasis lies in cultivating visual-language coordination and prioritizing visual cues.

Spatial-Aware Prompting Methods. While LMMs have demonstrated remarkable visual reasoning capabilities, they remain vulnerable to hallucination issues, including object, attribute, or relation hallucination. Previous research has indicated that this issue could largely stem from a lack of visual-language coordination or a robust language prior, causing the model to overlook crucial visual cues. To address these challenges, several visual prompting techniques have been proposed to enhance the visual perception of LMMs. For example, RedCircle (Shtedritski et al., 2023) utilized a circle marker to direct the model's attention toward specific regions for fine-grained classification. Meanwhile, FGVP (Yang et al., 2024), SCAFFOLD (Lei et al., 2024), and SOM (Yang et al., 2023a) investigated prompts for spatial reasoning using dot matrices or pre-trained models. Furthermore, (Wu et al., 2024) introduced a prompting paradigm and toolkit aimed at unlocking the zero-shot object detection capability of LMMs. In contrast, given that multi-hop questions often require a clear comprehension of semantic relationships between objects, we leverage scene graphs (Zhu et al., 2022; Samel et al., 2021) to enhance vision-language coordination.

Symbolic-Guided Reasoning. While approaches like Chain-of-Thought (Wei et al., 2022), Self-Ask (Press et al., 2023), and ReAct (Yao et al., 2022) can elicit LLM's step-by-step reasoning capabilities, they perform reasoning directly over natural language, where the intrinsic complexity and ambiguity of natural language could bring undesired issues such as unfaithful reasoning and hallucinations. To address these challenges, several neural-symbolic approaches (Pan et al., 2023b,a; Wang and Shu, 2023; Gupta and Kembhavi, 2023; Xu et al., 2024; Yao et al., 2023) have been proposed to integrate LLMs with symbolic logic. Our work aligns with the symbolic-guided reasoning paradigm. However, unlike previous studies, we explicitly incorporate scene graph information into the textual prompt to offer visual grounding for LMMs' reasoning processes. The inclusion of structural semantic information in the scene graphs enhances our framework's ability to excel in visual reasoning tasks and provide visual evidence with bounding boxes.

3 Method

As depicted in Figure 1, our model takes a natural language question Q and one or multiple images I linked to the question as inputs. Subsequently, our framework conducts spatial-aware visual reasoning through three distinct stages. In the *scene graph generation* stage, we prompt an LMM to identify the objects using bounding boxes as evidence, as well as to discern the attributes of these objects and the relationships between them. In the *visual program-guided reasoning stage*, we instruct the LMMs with a set of in-context examples to translate the question into a symbolic visual program. Subsequently, a program interpreter is employed to convert the visual program into a set of sub-questions. Finally, in the *program-solving* stage, a validator answers the sub-questions, and these, along with their corresponding sub-answers, collectively form rationales. We then aggregate the scene graph and the rationales to conclude the final answer and provide explanations to justify the decision process.

3.1 Scene Graph Generation

Scene Graph (Zhu et al., 2022) is a structural representation that captures detailed semantics. A scene graph comprises relationship triplets represented as <*subject, relation, object*> or <*object, is, attribute*>, which encapsulate the modeling of objects, attributes of objects, and the relationships between paired objects. Given that multi-hop questions usually revolve around attributes and relationships between objects, the first step involves extracting the scene graph to represent the structural information derived from the input images. In light of the strong visual understanding ability and rich world knowledge of LMMs, we prompt an LMM to fulfill this task. First, we overlay the images with a grid and provide a labeling system to assist LMMs in identifying and referring to specific points within the images. Then, we prompt an LMM to generate the scene graph and provide bounding boxes for objects. Specifically, each bounding boxes are represented as a tuple $[x_{min}, y_{min}, x_{max}, y_{max}]$, where x_{min} and y_{min} are coordinates of the top-left corner of the bounding box; x_{max} and y_{max} are coordinates of the bottom-right corner of the bounding box. The prompt for scene graph generation is listed in Section A in the appendix.

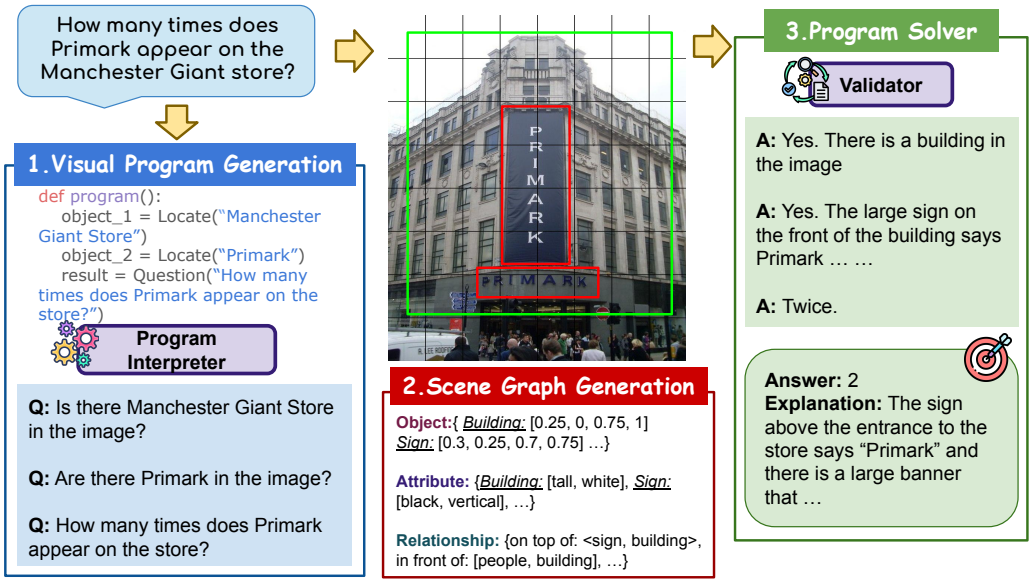

Figure 1: Overview of our *SVPR* framework, which consists of three stages: (i) *SVPR* generates a scene graph and uses it to provide LMMs with structural semantic information of the input images; (ii) *SVPR* then generates symbolic visual programs to represent the multi-step reasoning process and a program interpreter translates the function calls in the program into a set of sub-questions; and (iii) *SVPR* uses a validator to provide answers to the sub-questions and aggregates the reasoning chain to derive the final answer and generate explanations.

3.2 Visual Program-Guided Reasoning

This stage follows a program generation and execution paradigm to translate the natural language question into a symbolic reasoning program.

Program Generation. Given the question and the input images, a planner P generates a reasoning program $P = [S_1, ..., S_n]$ for it, which consists of n sequentially ordered reasoning steps S_i. Each reasoning step $S_i \in P$ is an instruction in controlled natural language that directs S_i to a function that represents a reasoning step. Specifically, we define two functions that the program can invoke during program generation. The `Locate()` function determines the location of objects in the images using bounding boxes, while the `Question()` function poses inquiries regarding the attributes and relationships of objects.

Program Interpreter. The role of the program interpreter is to parse the generated visual programs into a set of sub-questions in natural language. Specifically, each `Locate()` function is translated into *"Is there object in the image? If so, please provide its bounding boxes."* Once we have obtained the list of sub-questions, a program validator answers the sub-questions, utilizing the scene graph as visual grounding.

3.3 Program Solver

During this stage, SVPR consolidates the visual cues provided by the scene graph along with the rationales generated by the program validator, to derive the final answer.

Program Validator. The goal of the program validator is to answer the sub-questions generated by the visual programs. For object-level questions generated by the `Locate()` functions, we employ a pre-trained VQA model (Li et al., 2023a) to answer the question. When compared to LMMs, VQA models typically produce shorter answers with fewer hallucinations, making them a pragmatic option. For attribute-level and relation-level queries generated by the `Question()` functions, we leverage LMMs to provide answers due to their strong visual comprehension capabilities.

Answer Prediction. Guided by the scene graph, along with the sub-questions and their corresponding sub-answers, we employ LMMs as reasoning agents to deduce the final answer. To enhance explainability, we instruct the LMMs to offer justifications for their decisions. Additionally, we prompt them to append bounding boxes directly after expressions referencing objects. This approach facilitates the correspondence between entities men-

tioned in the responses and object instances in the image, thereby providing convenient access to verify the reliability of the output. The prompt for aggregation is included in Section A in the appendix.

4 Experiments

We compare *SVPR* against three baselines on two challenges: Multi-hop Multimodal QA (MMQA) and Compositional QA (CQA). Our experiment settings are described in Section 4.1, 4.2 & 4.3 and we discuss our main results in Section 4.4.

4.1 Dataset

To demonstrate the effectiveness of *SVPR* for MMQA and CQA, we conduct experiments on WebQA and GQA datasets respectively.

WebQA (Chang et al., 2022) is a challenging benchmark for multi-hop multimodal question-answering (MMQA) tasks. This dataset contains questions that are knowledge-seeking and resemble real-world use cases, each question has one or more images as positive evidence associated with it. Each question falls into one of the five categories: color, shape, number (i.e., "how many"), yes/no, and other. To reduce the GPT4-V API costs, we use stratified sampling to select a total of 250 entries from each question category.

GQA (Hudson and Manning, 2019) is a dataset featuring compositional questions over real-world images. Many of the GQA questions involve multiple reasoning skills, spatial understanding, and multi-step inference. We choose the balanced validation set, where the answer distribution for different groups of questions is tightly controlled, in order to prevent educated guess using language and world priors. For the same cost restriction reasons, we sampled 250 entries from the balanced validation set.

4.2 Baselines

We compare our proposed framework against the following three baselines:

Direct This baseline directly prompts LMMs to answer the question based on the input images, establishing a straightforward baseline without any prompt optimization.

Chain-of-Thought (Wei et al., 2022) is a popular approach that guides LMMs to perform step-by-step reasoning before outputting the final answer. This prompting method poses a question to the model and has the model to output a chain of thought before outputting its final answer. The prompt text "Let's think step-by-step" is prepended to the task description.

SCAFFOLD (Lei et al., 2024) is a visual prompting scheme that promotes vision-language coordination in LMMs. Specifically, SCAFFOLD first overlays a dot matrix within the image as visual information anchors and leverages multi-dimensional coordinates as textual positional references. This baseline establishes a scaffold for enhancing vision-language coordination in LMMs and has demonstrated superior performance in spatial and compositional reasoning benchmarks.

4.3 Experiment Settings

LMMs. Our pipeline is training-free and comprises an LMM and a pre-trained VQA model as the validator to answer the sub-questions. Specifically, we choose the following three open-source LMMs: LLaVA-V1.5-13B (Liu et al., 2024), InstructBlip-Vicuna-13B (Dai et al., 2024), and MiniGPT-4 (Zhu et al., 2023). Additionally, we also choose two much larger closed-source LMMs: GPT4-V (Achiam et al., 2023) and Gemini (Team et al., 2023). We utilize Blip2-FlanT5-XXL as the VQA model to answer the sub-questions conditioned on the input image.

Evaluation. Since the answers generated by LMMs are open-ended, traditional metrics such as SQuAD (Rajpurkar et al., 2016) style Exact-Match and F1 do not measure the performance to its fullest. For instance, LLMs excel in generating diverse and contextually relevant responses, which might not always align with exact matches to gold standard answers. Instead, they often provide paraphrases or alternative expressions that convey the same underlying meaning. This highlights the need for more nuanced evaluation strategies that account for semantic equivalence rather than strict verbatim matches. Therefore following (Lin et al., 2022; Li et al., 2023b; Sun et al., 2024; Wang et al., 2023), we use GPT-4 as a judge to check whether the generated answer has the same meaning as the gold answer. The evaluation prompt is included in Section A in the appendix.

	WebQA				GQA			
	Direct	*CoT*	*SCAFFOLD*	*SVPR*	*Direct*	*CoT*	*SCAFFOLD*	*SVPR*
LLaVA	48.6	46.2	51.8	**53.6**	49.6	47.4	50.0	**52.4**
InstructBlip	46.8	45.4	43.6	**52.2**	51.6	50.2	51.4	**55.2**
MiniGPT-4	53.4	58.6	60.0	**64.2**	54.2	56.0	60.0	**62.2**
Gemini	55.2	58.4	61.2	**69.6**	52.4	54.4	56.4	**62.8**
GPT4-V	61.8	62.2	68.4	**71.6**	47.2	51.2	55.4	**65.2**

Table 2: Accuracy of Direct, Chain-of-Thought (CoT), Scaffold, and our method *SVPR* on two challenging visual question answering datasets, WebQA and GQA. We use five unique LMMs for our experiments. The best results within each dataset are highlighted.

4.4 Main Results

We report the overall results of *SVPR* in Table 2. *SVPR* achieves the best performance on both datasets, demonstrating its effectiveness. Based on the experiment results, we have the following major observations:

Scene graphs improve visual reasoning. On the WebQA dataset, SVPR showcases superior performance over Direct, CoT, and Scaffold by margins of 15.86%, 15.11%, and 4.68% on GPT-4V, respectively. This highlights SVPR's effectiveness in answering multi-modal, multi-hop visual questions. Among the baselines, Scaffold proves to be more effective than Direct and CoT. This implies that integrating dot matrices as visual anchors enhances LMMs' spatial reasoning capabilities. However, since many questions demand not only visual comprehension and vision anchors but also a profound semantic understanding of object attributes and relationships within the scene, scene graphs play a crucial role in providing LLMs with deeper semantic visual understanding. They aid LMMs in achieving more comprehensive comprehension. Similar observations are made on the GQA dataset, suggesting that SVPR performs well not only on multi-hop reasoning tasks but also on compositional visual reasoning tasks. In addition to our primary findings, our analysis also highlights discernible performance variations among various LMMs. Notably, our investigation reveals that GPT-4V and Gemini consistently outperform LLaVA and InstructBlip, which are based on the smaller-scale Vicuna-13B model. This observation underscores the significant impact of model architecture and size on overall performance metrics. Furthermore, our comparative analysis demonstrates a slight but consistent advantage held by GPT-4V over Gemini across both datasets evaluated. These findings emphasize the importance of considering model selection criteria tailored to specific task requirements and performance objectives.

Symbolic-guided reasoning can decompose the reasoning chain better. Our *SVPR* method, which uses visual programs to guide the decomposition reasoning approach outperforms CoT and SCAFFOLD baselines on both datasets. This suggests that the visual programs help LMMs to better decompose questions, and result in more accurate reasoning. On both WebQA and GQA, Scaffold exhibits a significant performance boost. Both datasets require intricate reasoning abilities to deconstruct the questions and employ a divide-and-conquer approach to problem-solving. Since Scaffold also actively promotes vision-language coordination, we can infer the performance comes from SVPR's better question decomposition strategy. Overall, SVPR performs better than the Direct baseline across both datasets. This observation indicates the critical role of question decomposition in complex visual question answering, as Direct does not decompose the questions.

	Color	**Shape**	**Number**	**Yes/No**	**Other**
GPT-V	54.2	48.2	46.2	82.4	78.2
GPT-V+Scaffold	52.6	48.4	50.4	76.6	82.6
GPT-V+SVPR	66.4	56.2	64.4	86.2	84.6

Table 3: Ablation Study: Impact of Scene Graphs

4.5 The Impacts of Scene Graphs

To deepen our understanding of the role of scene graphs in the decision-making process of LLMs, we conduct an ablation study on the WebQA dataset using GPT4-V. This study involves comparing the performance of Direct, SCAFFOLD, and SVPR approaches. The Direct approach lacks

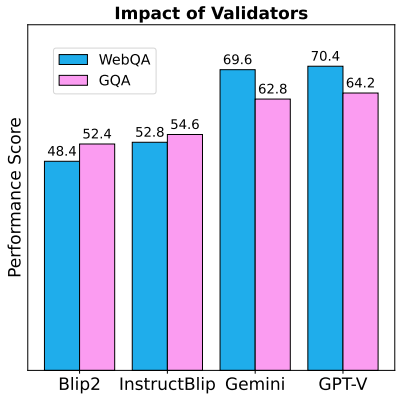

Figure 2: Ablation Study: Impact of Validators

any visual understanding information and solely represents the raw visual understanding capabilities of LMMs. In contrast, SCAFFOLD overlays dot matrices onto the original image and incorporates textual prompts to actively guide LMMs. By utilizing coordinates as vision anchors and reference points, SCAFFOLD promotes coordination between vision and language. In contrast, our SVPR not only incorporates vision anchor points but also integrates deep semantic information from scene graphs. This enables LMMs to engage in structured visual understanding, enhancing their comprehension capabilities. To comprehend the reasoning challenges where scene graphs play the most significant role, we present the performance based on the question category. Table 3 shows the experimental results, indicating that SVPR outperforms both baselines, highlighting its effectiveness. Additionally, we notice that questions categorized as more complex, involving reasoning over relationships between objects such as Yes/No and others, exhibit superior performance on SVPR compared to SCAFFOLD. This underscores the utility of incorporating structured semantic information like scene graphs, particularly in addressing questions necessitating structured reasoning.

4.6 The Impacts of Validators

As discussed in Section 4.4, program-guided reasoning demonstrates superior decomposition of questions compared to CoT-like prompt techniques. However, it's crucial to note that to reach the final correct answer, we must first answer the sub-questions correctly. To evaluate the potential impact of using different validators on the overall performance of SVPR, we conduct the following ablation study. We utilize Gemini to generate the visual programs and employ the following four models as validators: Blip2, InstructBlip, Gemini, and GPT-V. In addition to employing LMMs, we hypothesize that pre-trained VQA models such as (Li et al., 2023a) can mitigate the risk of object hallucination. This refers to the phenomenon where models may generate text describing objects that are not actually present in the image. Given that VQA models typically generate shorter answers compared to LMMs, albeit with fewer instances of hallucinations, they can indeed be considered a viable option for addressing this issue. As shown in Figure 2, our experiment results reveal that despite our assumption that pre-trained VQA models like Blip2 would exhibit superior performance and hallucinate less, they do not perform nearly as well as the larger models. This phenomenon can be attributed to two main factors. Firstly, we observe a significant number of questions that possess inherent ambiguity, leading to misunderstandings by Blip2. Secondly, certain questions necessitate a profound visual understanding of the images. These questions inquire about specific details within the images, demanding a heightened visual comprehension to accurately recognize such details. Furthermore, we notice that Blip2 tends to perform better on the GQA dataset, where the sub-questions are generally more straightforward to answer.

4.7 Taxonomy of Reasons for Failures

As shown in Table 4, upon examining GPT-V's explanations, we identify four primary categories of failure reasons:

Recognition errors occur when the model's visual component misinterprets images, resulting in difficulties in identifying vital details within them. For instance, in subfigure (a), when prompted about the number of distinct railings on the stairs depicted, Gemini failed to detect any railings in the images. Beyond the limited visual comprehension of LMMs regarding image particulars, this could also stem from image-related problems, such as low image quality such as blurriness, or incompleteness, which impairs the model's accuracy in recognizing content.

Reasoning errors emerge when the model misinterprets images due to diverse factors, including unnatural distortions, uncommon perspectives, or logical inaccuracies. For instance, in subfigure (b), the model identifies there is a cross on one of the domes of Saint Peter's Basilica. However, it fails to realize the question asks whether there is a cross

(a) Recognition Error	(b) Reasoning Error	(c) Incorrect Rationales	(d) Conflict Rationales
			
Question: How many different railings are on the stairs at the TAMU Psychology Building?	**Question:** Are there crosses on top of every dome of Saint Peter's Basilica?	**Question:** How many points does each star on the obverse of the 1856 double eagle have?	**Question:** How many flags fly outside the Madison Square Garden?
Answer: Three different railings are on the stairs at the TAMU Psychology Building.	**Answer:** No, there are not crosses on top of every dome on top of Saint Peter's Basilica.	**Answer:** On the obverse of the 1856 double eagle, each star has six points.	**Answer:** One flag flies outside the Madison Square Garden.
Gemini+SVPR: The Scene Graph does not list any railings associated with the stairs or building. ... Despite the third rationale mentioning four railings, this is not supported by the Scene Graph or the other Rationals, so we conclude no railings.	**Gemini+SVPR:** Based on the scene graph, there is a dome on top of Saint Peter's Basilica, and the rationales confirm that there is a cross on top of the dome. Additionally ... Therefore, there are crosses on top of every dome.	**Gemini+SVPR:** Based on the rationale provided, there is an obverse of the 1856 double eagle in the image and it is stated that each star has five points. ... Therefore, we can conclude that each star on the obverse of the coin has five points.	**Gemini+SVPR:** The Scene Graph does not mention any flags outside Madison Square Garden, and the Rationals provide conflicting answers. ... We can conclude that there are no flags flying outside Madison Square Garden.

Table 4: Examples demonstrate why GPT4-V fails to answer the questions. We identify four failure reasons: recognition error, reasoning error, incorrect rationales, and conflict rationales.

on every dome of Saint Peter's Basilica.

Incorrect rationales represent a critical challenge for models like SVPR, as they can significantly impact the accuracy and reliability of the final predictions. Subfigure (c) illustrates this phenomenon, showcasing how a cascade error during the aggregation reasoning phase leads the model to acquire an incorrect rationale—specifically, in this case, each star possesses five points. This erroneous rationale, in turn, undermines the model's ability to generate the correct prediction, highlighting the detrimental effects of error propagation within the SVPR pipeline.

Conflicting rationales present a significant challenge for models like SVPR, particularly when they encounter contradictory factual information from multiple rationales. This phenomenon underscores the complexity inherent in aggregating diverse streams of data and reasoning to arrive at a coherent conclusion. Subfigure (d) illustrates how SVPR grapples with this challenge, highlighting its struggle to determine the ultimate answer when faced with competing lines of reasoning. Therefore, improving the accuracy of the validators is a focus of our future work.

5 Conclusion

In this paper, we propose a novel approach to answer complex visual questions using LLMs by eliciting vision-language coordination and symbolic guided reasoning. We introduce SVPR, a visual reasoning method that enhances LMMs' vision-language coordination and multi-hop reasoning ability to answer complex questions. By explicitly incorporating scene graphs with bounding boxes into the textual prompts, SVPR actively integrates visual cues during reasoning and includes visual evidence as part of its explanations. The visual programs are shown to be effective in decomposing complex visual questions into a series of sub-questions. Our experiment results show that SVPR demonstrates promising performance on two challenging datasets without any additional training. Additionally, we investigate the impact of visual awareness and program-guided reasoning on the performance of SVPR. The results indicate that SVPR can make accurate predictions and generate explanations while providing visual evidence. The limitations and future work are discussed in the subsequent section.

Limitations

We identify two main limitations of SVPR. First, SVPR depends on in-context learning coupled with self-refinement to convert a natural language question into a visual program representation. While this method has proven to be effective, it may face difficulties when dealing with questions with intricate grammar structures and logical structures. This arises from the difficulty in conveying complex grammatical rules to the language model through a limited number of demonstrations within a constrained context size. Second, our aggregation method purely relies on LMMs themselves, which could introduce potential hallucination problems. On the other hand, by using a more robust logic solver could help with the hallucination issues, but there would be a tradeoff between the applicability and the robustness of the model.

Ethical Statement

Biases. We acknowledge the possibility of biases existing within the data used for training the language models, as well as in certain factuality assessments. Unfortunately, these factors are beyond our control.

Intended Use and Misuse Potential. Our models have the potential to answer complex visual questions. However, it is essential to recognize that they may also be susceptible to misuse by malicious individuals. Therefore, we strongly urge researchers to approach their utilization with caution and prudence.

Environmental Impact. We want to highlight the environmental impact of using large language models, which demand substantial computational costs and rely on GPUs/TPUs for training, which contributes to global warming. However, it is worth noting that our approach does not train such models from scratch. Instead, we use few-shot in-context learning. Nevertheless, the large language models we used in this paper are likely running on GPU(s).

A Prompts

Prompt Template: Scene Graph Generation

This labeling system is designed to assist you in identifying and referring to specific points within each image. The image is overlaid with a grid matrix to help you with the task. The bounding boxes, indicating the position of objects in the image, which are represented as [x_{min}, y_{min}, x_{max}, y_{max}] with floating numbers ranging from 0 to 1. Coordinates of a bounding box are encoded with four values in pixels: [x_{min}, y_{min}, x_{max}, y_{max}]. x_{min} and y_{min} are coordinates of the top-left corner of the bounding box. x_{max} and y_{max} are coordinates of bottom-right corner of the bounding box.
Given the image, please generate the scene graph in the following format: First identify the objects and provide the bounding boxes in the form of object: [x_{min}, y_{min}, x_{max}, y_{max}]. Then, identify the attributes of the objects in the form of object: [attribute, attribute]. Then, identify the relationship triplet in the form of Relationship: <object, object>. Here is an example.
Object: object: [x_{min}, y_{min}, x_{max}, y_{max}], object: [x_{min}, y_{min}, x_{max}, y_{max}], ... Attribute: object: [attribute, attribute], object: [attribute, attribute], ... Relationship: Relationship: <object, object>, Relationship: <object, object>, ...

Prompt Template: Visual Program Generation

Given a question, first generate a python-like program that describes the reasoning steps required to answer the question step-by-step. You can call two functions in the program: 1. Question() to answer the question; 2. Locate() to locate an object in the image with bounding boxes; Here are some example.
Question: On which side of the walkway leading to the San Francisco Civic Center can the American Flag be found? def program(): object = Locate("Walkway leading to the San Francisco Civic Center") object = Locate("American Flag") result = Question("Which side of the walkway can the American Flag be found?")
Question: Is the surface of the egg next to the handrail at the Big Egg Hunt in Covent Garden London shiny or dull? def program(): object = Locate("Handrail at the Big Egg Hunt in Covent Garden London") object = Locate("The egg next to the handrail") result = Question("Is the surface of the egg shiny or dull?")
Question:

Prompt Template: Aggregation Prompt

This labeling system is designed to assist you in identifying and referring to specific points within each image. The bounding boxes, indicating the position of objects in the image, which are represented as [x1, y1, x2, y2] with floating numbers ranging from 0 to 1. These values correspond to the bottom left x1, top left y1, bottom right x2, and top right y2.
Your goal is to answer the question based on the following inputs: (1) Question: this is the question you need to answer. (2) Scene Graph: this represents the structural information of the image. (3) Rationals: this is a set of QAs that assist you conclude the final answer.
Please first answer the question based on the inputs, and then provide your explanation.
Question: Scene Graph: Rationals: Your Answer:

Prompt Template: Evaluation Prompt

Given a question and a correct answer. Is the following answer correct? Only reply YES or NO.
Question: Correct Answer: Answer you should evaluate:

Reasoning RAG via System 1 or System 2: A Survey on Reasoning Agentic Retrieval-Augmented Generation for Industry Challenges

Abstract

Retrieval-Augmented Generation (RAG) has emerged as a powerful framework to overcome the knowledge limitations of Large Language Models (LLMs) by integrating external retrieval with language generation. While early RAG systems based on static pipelines have shown effectiveness in well-structured tasks, they struggle in real-world scenarios requiring complex reasoning, dynamic retrieval, and multi-modal integration. To address these challenges, the field has shifted toward *Reasoning Agentic RAG*, a paradigm that embeds decision-making and adaptive tool use directly into the retrieval process. In this paper, we present a comprehensive review of Reasoning Agentic RAG methods, categorizing them into two primary systems: *predefined reasoning*, which follow fixed modular pipelines to boost reasoning, and *agentic reasoning*, where the model autonomously orchestrates tool interaction during inference. We analyze representative techniques under both paradigms, covering architectural design, reasoning strategies, and tool coordination. Finally, we discuss key research challenges and propose future directions to advance the flexibility, robustness, and applicability of reasoning agentic RAG systems. Our collection of the relevant researches has been organized into a GitHub Repository.

1 Introduction

Large Language Models (LLMs) (Singh, 2023; Zhao et al., 2023; Zhu et al., 2024) have demonstrated remarkable capabilities in natural language understanding and generation, enabling a wide array of applications. However, LLMs rely on static training data, making them prone to hallucinations and limiting their ability to provide accurate, up-to-date information in dynamic or knowledge-intensive tasks (Rawte et al., 2023; Zhang et al., 2023; Huang et al., 2025). Retrieval-Augmented Generation (RAG) (Chen et al., 2024; Lewis et al., 2020; Gao et al., 2023) has attracted significant attention as a promising approach to overcome the knowledge limitations of LLMs resulting from static pretraining. By integrating relevant information from external knowledge bases or search engines, RAG enhances factual accuracy and broadens the model's temporal and domain coverage (Zhao et al., 2024; Li et al., 2024a). Traditional RAG methods perform strongly with well-formed queries and readily available necessary information in the retrieved context.

Despite the effectiveness of basic RAG methods, they often struggle when applied to real-world, industrial-scale applications involving complex and heterogeneous data. For example, in multi-document scenarios, relevant information is spread across sources, requiring not just retrieval but also coherent synthesis (Wang et al., 2025, 2024b). Naively concatenating retrieved passages can lead to fragmented or contradictory responses, particularly in domains where multi-hop reasoning is critical. Additionally, most RAG systems are limited to text-only processing and cannot handle multi-modal inputs such as tables, charts, or images (Ma et al., 2024; Yu et al., 2025). This limits their ability in data-rich environments like enterprise intelligence, scientific reporting, or technical support, where visual and structured data play a central role (Lin et al., 2023a; Yu et al., 2024).

To address these limitations of basic RAG in handling complex, real-world tasks, recent research has turned to *Agentic RAG* (Ravuru et al., 2024), a paradigm that tightly integrates retrieval with reasoning and decision-making(see Appendix A.2 for relevant researches). Figure 1 shows the evolution trajectory of Reasoning Agentic RAG. Unlike static pipelines, Agentic RAG treats retrieval as a dynamic, context-sensitive operation guided by the model's reasoning process. This reasoning-centric perspective is crucial for applications demanding

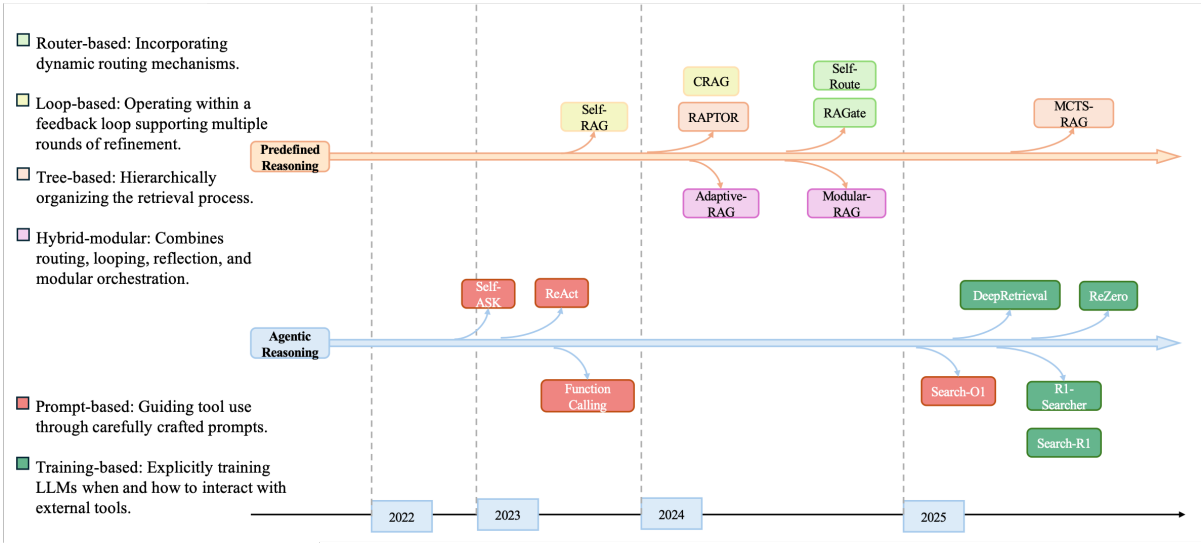

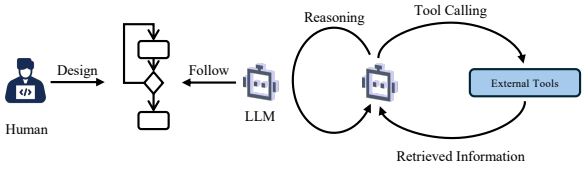

Figure 1: Illustration of the evolution trajectory of Reasoning Agentic RAG.

multi-step problem solving, adaptive information acquisition, and tool-assisted synthesis. Within this paradigm, as shown in Figure 2, two major types of reasoning agentic systems have emerged based on how control and decision-making are handled: *predefined reasoning*, which follow structured, rule-based plans with fixed pipelines to boost reasoning for retrieval and generation; and *agentic reasoning*, where the model actively monitors its reasoning process and determines when and how to retrieve or interact with external tools. These two workflows form the basis of *Reasoning Agentic RAG*, which unifies structured and autonomous approaches for more intelligent, context-aware retrieval-augmented reasoning. Reasoning Agentic RAG can be broadly categorized into two paradigms: *predefined reasoning* and *agentic reasoning*, as shown in Figure 3.

(a) Predefined Reasoning (b) Agentic Reasoning

Figure 2: Two major types of reasoning Agentic Systems.

Predefined reasoning adopts structured and modular RAG pipelines where the retrieval and reasoning steps are explicitly designed. These workflows typically decompose tasks into discrete components such as query reformulation, document retrieval, re-ranking, and answer synthesis, executed in a linear or orchestrated fashion. In general, predefined reasoning spans several architectural variants: *route-based* methods selectively trigger retrieval based on context or model uncertainty, such as low confidence scores or ambiguous intermediate outputs (Wang et al., 2024a); *loop-based* methods enable limited iteration through retrieval-feedback cycles, supporting multiple rounds of refinement (Asai et al., 2023; Yang et al., 2024b); *tree-based* methods organize information hierarchically to support structured exploration (Sarthi et al., 2024; Hu et al., 2025); and *hybrid-modular* frameworks compose specialized modules into a flexible but still rule-driven workflow (Jeong et al., 2024; Gao et al., 2024). These workflows prioritize control and modularity, fitting tasks requiring efficient computation and customization. However, their reasoning remains constrained by predesigned execution paths, limiting flexibility in evolving and open-ended tasks.

Agentic reasoning repositions the LLM as an active decision maker, that autonomously orchestrates retrieval and tool use throughout the reasoning process. Instead of executing a fixed plan, the model identifies knowledge gaps, formulates queries, retrieves external information via tools such as search engines or APIs, and integrates the retrieved contents into an evolving solution. This dynamic interplay of reasoning and tool use enables the system to tackle complex, multi-turn tasks that require iterative refinement and adaptive information synthesis. There are two primary methods for implementing agentic reasoning. The first is *prompt-based* methods, which leverages the in-context reasoning and instruction-following capa-

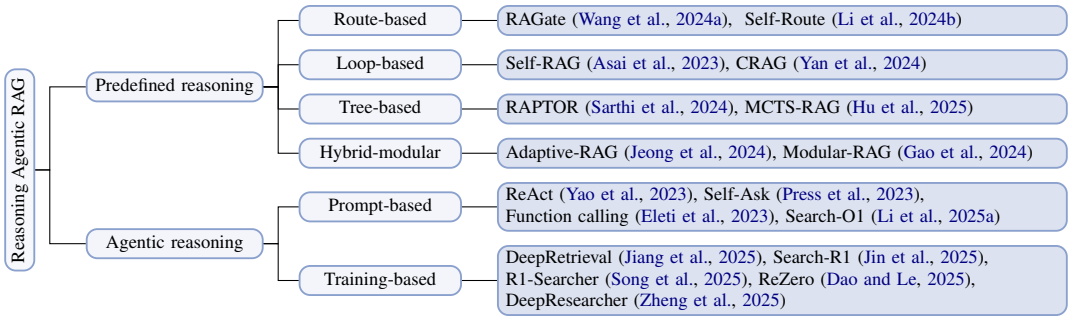

Figure 3: A taxonomy of Reasoning Agentic RAG.

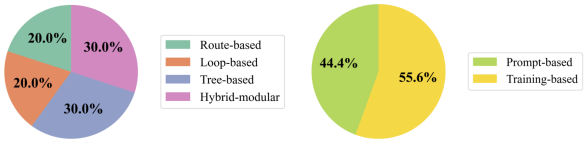
bilities of LLMs (Yao et al., 2023; Press et al., 2023; Li et al., 2025a). In this setting, the model is guided by carefully crafted prompts or embedded control tokens that instruct it when to retrieve, what actions to take, and how to integrate external information. These methods require no additional training, making them lightweight and adaptable across tasks. The second paradigm is *training-based* methods, where models are explicitly optimized through reinforcement learning, to determine when and how to invoke external tools (Jiang et al., 2025; Jin et al., 2025; Zheng et al., 2025). This paradigm enables more fine-grained and strategic tool usage, enabling models to learn long-term planning and develop retrieval policies tailored to complex tasks. Owing to its autonomy and adaptability, agentic reasoning has shown strong performance in open-domain QA, scientific reasoning, and multi-stage decision-making scenarios.



To further contextualize predefined and agentic reasoning within the dual-process theory of cognition, commonly referred to as System 1 and System 2 thinking (Yang et al., 2024a; Li et al., 2025b), we can draw an analogy between these RAG paradigms and human cognitive modes. Table 1 aligns predefined and agentic reasoning with the dual-system theory from cognitive science.

- Predefined reasoning resembles System 1 thinking: fast, structured, and efficient, relying on predefined heuristics and modular workflows that mirror habitual or rule-based cognition. While this enables rapid execution and predictable behavior, it often lacks the flexibility to adapt beyond its design.
- Agentic reasoning aligns more closely with System 2 thinking: slow, deliberative, and adaptive. Here, the LLM actively engages in reasoning, planning, and decision-making, dynamically leveraging external tools and retrieved knowledge to address complex, novel tasks. This reflective mode allows the model to identify gaps, reassess strategies, and adjust its behavior—traits characteristic of conscious, analytical human reasoning.

System Type	Reasoning Workflow	Description
System 1	Predefined Reasoning	Structured, modular, rule-based execution.
System 2	Agentic Reasoning	Autonomous, adaptive, model-driven decision-making.

Table 1: Cognitive system alignment of reasoning workflows.

The paper systematically reviews and analyzes the current research approaches and future development paths of Reasoning Agentic RAG, summarizing them into two primary technical paradigms, among which the distribution of different works is shown in Figure 4. The remainder of the paper is organized as follows: Section 2 and Section 3 dive into the two types of reasoning workflows within Agentic RAG: *Predefined Reasoning* and *Agentic Reasoning*. Section 4 outlines future research directions and Section 5 concludes the paper.

(a) Predefined Reasoning (b) Agentic Reasoning

Figure 4: Distributed Works of Reasoning Agentic RAG.

2 Predefined Reasoning

Agents and RAG are increasingly integrated in advanced AI systems. By augmenting LLMs with external knowledge retrieval, RAG enables agents to ground their reasoning in relevant information. In turn, agent-based reasoning which includes planning, tool use and self-reflection, enhances RAG by guiding the model on what information to retrieve and how to incorporate it into the reasoning process. This synergy supports a predefined reasoning, as illustrated in Figure 5, where the agent iteratively queries external sources (e.g., a local database or

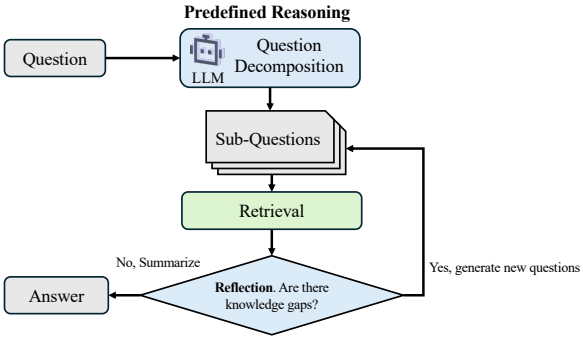


Figure 5: Overview of the Predefined Reasoning. The LLM decomposes a question into sub-questions, retrieves relevant evidence from external sources, and reflects on whether knowledge gaps remain. If gaps are found, new queries are generated; otherwise, the final answer should be summarized.

web search) and refines its reasoning based on the retrieved evidence. We categorize predefined RAG reasoning workflows into four broad types based on their structural and reasoning characteristics.

Route-based Approaches: RAG incorporates dynamic routing mechanisms that direct queries along different retrieval or reasoning paths based on predefined conditions—such as query type, model uncertainty, or confidence estimation—while still operating within a fixed architecture. RAGate (Wang et al., 2024a) uses the conversation context and model confidence to route dialogues truly requiring external knowledge to a RAG process. This ensures the system can bypass retrieval for straightforward prompts while invoking it for knowledge-intensive queries, exemplifying conditional RAG in dialogue. Self-Route (Li et al., 2024b) introduced dynamically routes queries to either RAG or Long-Context (LC) models based on the model's confidence-based routing. This method significantly reduces computation cost while maintaining performance comparable to LC models.

Loop-based Approaches: RAG operates within a feedback loop that supports multiple rounds of refinement. The system can self-reflect, critique intermediate outputs, and iteratively update retrieval inputs to improve generation quality. Self-RAG (Asai et al., 2023) is a foundational example of this controlled reasoning loop. In the Self-RAG workflow, a single LLM agent engages in self-reflection during generation to improve its output. Instead of relying on a fixed retrieved context, the model can decide mid-generation to fetch additional information or to critique its own draft answer. CRAG (Yan et al., 2024) introduced loop-based corrective feedback mechanism into the retrieval process. In the CRAG workflow, a lightweight retrieval evaluator assigning the confidence scores about the quality of the retrieved chunks/documents — categorized as correct, incorrect, or ambiguous. When retrieval quality is deemed suboptimal, the system activates corrective strategies such as query rewriting or external web search to gather better evidence. The system refines the retrieved content into a focused context and iteratively improves retrieval until a satisfactory output is generated.

Tree-based Approaches: RAG organizes the retrieval process hierarchically, using recursive structures such as trees to support multi-hop reasoning or document summarization. RAPTOR (Sarthi et al., 2024) introduces a recursive tree structure from documents, allowing for more efficient and context-aware information retrieval. This approach enhances RAG by creating a summary tree from text chunks, providing deeper insights to overcome limitations of short, contiguous text retrieval. MCTS-RAG (Hu et al., 2025) integrates a Monte Carlo Tree Search loop into the RAG process for complex reasoning tasks. MCTS-RAG dynamically integrates retrieval and reasoning through an iterative decision-making process. Unlike standard RAG, which retrieves information independently from reasoning and thus integrates knowledge suboptimally, or conventional MCTS reasoning, which depends solely on internal model knowledge without external facts, MCTS-RAG combines structured reasoning with adaptive retrieval.

Hybrid-modular Approaches: RAG in its most flexible form combines routing, looping, reflection, and modular orchestration. Tasks are divided among specialized components, coordinated by an agent that can reconfigure the workflow according to the query or reasoning context. Adaptive-RAG (Jeong et al., 2024) extends the Self-RAG framework by introducing routing mechanisms that enable dynamic path selection. In addition to allowing the model to interleave retrieval and generation steps, it equips the agent with a decision-making router that selects appropriate retrieval strategies or reasoning pathways based on the query characteristics or the agent's own uncertainty. Rather than simply determining whether to retrieve more information, the agent can choose which retrieval method to apply, what type of information to prioritize, or which downstream modules to engage. Modular-RAG (Gao et al., 2024) is the most advanced incarnation that transform RAG into a LEGO-like modular framework, breaking the RAG process into an orchestrated pipeline of specialized modules.

Rather than a single agent handling everything, a Modular-RAG architecture compartmentalizes tasks, e.g., one module for query reformulation, one for document retrieval, another for ranking or filtering results, and another for answer synthesis, all chained together in a composable workflow. The pipeline is composed by an agent that coordinates modular components, each of which can be optimized or swapped independently.

This progression of predefined reasoning workflows reflects a broader shift from static retrieval pipelines to dynamic, agent-driven reasoning systems. Modern predefined reasoning increasingly integrates planning, tool use, and decision-making components that allow flexible orchestration of retrieval and reasoning strategies. Rather than predefining rigid retrieval steps, these systems empower agents to determine what information to seek, how to use it, and when to adapt their approach—marking a move toward more autonomous and intelligent knowledge integration. A summary of the representative works and open-source industrial implementations across these predefined RAG workflow types is provided in Table 2.

3 Agentic Reasoning

Beyond the predefined reasoning mentioned above, a more dynamic paradigm has emerged: the *Agentic Reasoning*. In this setting, the LLM serves as an autonomous agent that not only generates text, but also actively manages retrieval. With advances in reasoning and instruction-following capabilities, the model can identify knowledge gaps, determine when and what to retrieve, and interact with external tools such as search engines or APIs. This tight integration of reasoning and tool use enables iterative decision-making, enabling the system to refine its responses based on newly retrieved information. As a result, agentic reasoning supports more flexible and adaptive problem-solving, extending RAG beyond basic QA to complex tasks such as scientific inquiry, multi-step reasoning, and strategic decision-making. Agentic reasoning approaches can be broadly categorized by how the LLM learns to use tools:

- **Prompt-Based Approaches:** These methods leverage the instruction-following, in-context learning and reasoning capabilities of pre-trained LLMs, guiding tool use through carefully crafted prompts or built-in functionalities without additional training.
- **Training-Based Approaches:** These methods involve explicitly training LLMs via reinforcement learning, to learn when and how to interact with external tools effectively.

A summary of representative agentic reasoning approaches and their characteristics is provided in Table 2. The following sections examine representative and techniques within each approach.

3.1 Prompt-Based Approaches

Prompt-based approaches harness the remarkable capabilities already present in pre-trained LLMs to enable agentic behavior. Instead of updating model weights, these methods use advanced prompting, few-shot examples, or built-in tool interfaces to guide LLMs in interacting with external tools such as search engines.

Function-Calling-Based: A core prompt-based method for agentic behavior, and one way to implement function calling, is ReAct (Reason+Act) (Yao et al., 2023). ReAct aims to create a synergy between the reasoning processes and action-taking capabilities within an LLM. Its core mechanism involves prompting the LLM to generate outputs in an interleaved sequence of Thought, Action, and Observation. ReAct employs few-shot prompting, providing the LLM with examples that demonstrate this Thought-Action-Observation trajectory for solving similar tasks. the frozen model learns how to structure its reasoning, invoke tools, and move toward a goal. The framework demonstrated significant advantages in grounding the LLM's reasoning. By allowing the model to actively seek and incorporate external information via actions, ReAct can mitigate the hallucination and error propagation issues observed in purely internal reasoning methods like Chain-of-Thought (Wei et al., 2023). The explicit reasoning traces ("Thoughts") in ReAct enhance the interpretability and transparency of the model's decision-making. Within RAG, ReAct offers a natural agentic reasoning pipeline: the LLM's "Thought" process can identify a knowledge gap, leading to a search "Action," with the retrieved results forming the "Observation" that informs subsequent reasoning. A related method, Self-Ask (Press et al., 2023), encourages step-by-step problem decomposition by prompting LLM to generate and answer simpler follow-up questions. These intermediate steps involve search actions, enabling the model to gather relevant information before attempting to answer the main question.

Table 2: A summary of reasoning agentic rag.

Another prominent prompt-based approach involves leveraging the function calling capabilities that have been explicitly built into or fine-tuned into certain LLMs, such as versions of GPT (Eleti et al., 2023), Llama, and Gemini. This feature allows the LLM to interact reliably with predefined external tools or APIs based on natural language instructions. Function calling significantly expands the capabilities of LLMs beyond text generation, enabling them to access real-time, dynamic information, interact with external systems and databases, automate tasks, and reliably convert natural language requests into structured API calls or database queries. In contrast to the more open-ended "thought-action-observation" cycle of ReAct, function calling often bypasses explicit intermediate reasoning steps. The LLM directly identifies the relevant tool and generates the necessary parameters based on its training to recognize and format specific function calls. This more direct approach relies on the model's pre-existing knowledge of available tools and their required inputs. Furthermore, the format and capabilities of the tools accessible via function calling are typically predefined and have been integrated into the model's training or prompt design. For Agentic RAG, function calling provides a straightforward and structured way for the LLM agent to invoke a search API when its internal analysis determines that external information is required to answer a prompt accurately.

Large Reasoning Model-based: A growing trend in Agentic RAG workflow involves directly utilizing LLMs that possess inherently strong reasoning capabilities, often referred to as Large Reasoning Models (LRMs). These models, sometimes developed through techniques like large-scale reinforcement learning (e.g., models analogous to OpenAI's o1 (OpenAI et al., 2024), DeepSeek-R1 (DeepSeek-AI et al., 2025)), are designed to excel at complex, multi-step reasoning tasks. The underlying premise is that an LLM with superior intrinsic reasoning abilities will be better equipped to manage the complexities of an Agentic RAG workflow, including decomposing challenging queries, planning information-gathering steps, assessing the relevance and utility of retrieved information, and synthesizing knowledge effectively. In essence, leveraging LRMs within RAG represents a prompt-based agentic strategy where the model's powerful inherent reasoning capabilities drive the process, implicitly deciding when and how to retrieve information to support its complex thought processes.

However, effectively managing the retrieved context is another significant challenge. LLMs with extremely long context windows can suffer from a "lost-in-the-middle" problem, where information presented in the middle of a long input receives less attention. Furthermore, retrieved documents, whether in long-context models or standard RAG, often contain verbose, noisy or contradictory content that can disrupt the coherence of the LLM's reasoning process. Mitigating this challenge requires

more precise retrieval strategies and adaptive context management mechanisms. As shown in Figure 6, the Search-o1 framework (Li et al., 2025a) is specifically designed to enhance LRMs by tackling knowledge insufficiency during long, step-by-step reasoning chains. It integrates two core components: an Agentic RAG Mechanism where the LRM dynamically triggers search queries based on self-assessed knowledge gaps, and a Reason-in-Documents Module that processes retrieved content to distill relevant information into a refined format, thereby minimizing noise and maintaining the LRM's reasoning integrity. Search-o1 exemplifies a sophisticated prompt-based agentic approach focused on maintaining reasoning integrity in the face of external information retrieval.

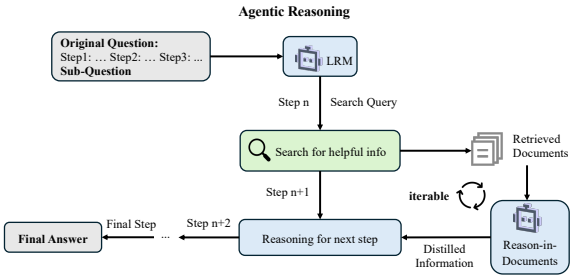

Figure 6: Overview of Agentic Reasoning. The LRM iteratively identifies missing knowledge at each reasoning step, issues targeted search queries, and invokes a Reason-in-Documents module to extract and distill relevant information from retrieved content. The distilled results are incorporated into the next reasoning step until a final answer is derived.

3.2 Training-Based Approaches

While prompt-based methods leverage the inherent capabilities of LLMs, their performance in complex tool-use scenarios can be inconsistent. Achieving highly reliable and optimized behavior, especially in deciding when and how to interact with tools like search engines, often benefits from explicit training. Training-based approaches, particularly those utilizing Reinforcement Learning (RL), enable the LLM agent to learn sophisticated strategies through trial and error, directly optimizing its actions towards specific goals such as maximizing retrieval effectiveness or overall task success. RL enables agents to develop more robust and strategic interaction patterns than prompting alone.

Interacting with local retrieval systems: Search-R1 (Jin et al., 2025) tackles a different aspect of agentic search: training the LLM to autonomously decide when and what to search for during a multi-step reasoning process. It extends RL-based reasoning frameworks (like DeepSeek-R1) by integrating search engine interaction directly into the learning loop. In the Search-R1 framework, the search engine is modeled as part of the RL environment. The LLM agent learns a policy to generate a sequence of tokens that includes both internal reasoning steps (often enclosed in `<think>` tags) and explicit triggers for search actions. These triggers are special tokens, `<search>` and `</search>`, which encapsulate the generated search query. This design allows for flexible, multi-turn interactions where the LLM can interleave reasoning, searching, processing retrieved information (presented within `<information>` tags), and further reasoning or searching as needed. The framework utilizes a simple outcome-based reward function, typically based on the correctness of the final answer generated by the LLM (within `<answer>` tags) compared to a ground truth, avoiding the complexity of designing intermediate process rewards. A crucial technique employed is retrieved token masking. During the calculation of the RL loss (using algorithms like PPO or GRPO (Shao et al., 2024)), the tokens corresponding to the content retrieved from the search engine (i.e., within the `<information>` tags) are ignored or masked out, which stabilizes the training process. Search-R1 has shown significant performance improvements over various RAG baselines on question-answering datasets. Its core contribution is training the LLM to learn an optimal policy for interacting with the search engine as an integrated part of its reasoning flow, enabling dynamic, context-aware search decisions. The related R1-Searcher (Song et al., 2025) framework also proposes a similar two-stage, outcome-based RL approach for enhancing search capabilities.

ReZero (Retry-Zero) (Dao and Le, 2025) introduces another dimension to RL-based agentic search by specifically focusing on incentivizing persistence. It addresses the common scenario where an initial search query might fail to retrieve the necessary information, potentially causing the LLM agent to halt prematurely or generate a suboptimal response. ReZero aims to teach the agent the value of "trying one more time." The framework operates within a standard RL setup (using GRPO is mentioned) where the LLM interacts with a search environment. The novelty lies in its modified reward function, which includes a specific component termed reward retry. This component provides a positive reward signal whenever the LLM issues a `<search>` query after the initial search query within the same reasoning trajectory. Crucially, this reward for retrying is conditional upon the agent

successfully completing the task, indicated by generating a final answer enclosed in <answer> tags. This conditionality prevents the agent from accumulating rewards simply by retrying indefinitely without making progress. By directly rewarding the act of persistence (when productive), ReZero encourages the LLM to explore alternative queries or search strategies if the first attempt proves insufficient. This contrasts with methods that might only implicitly reward persistence through eventual task success. ReZero positions itself as complementary to frameworks like DeepRetrieval; while DeepRetrieval focuses on optimizing a single refined query, ReZero emphasizes the value of making multiple retrieval attempts when needed.

Interacting with real-world search engines: DeepRetrieval (Jiang et al., 2025) focuses specifically on improving the quality of the search queries generated by the LLM agent. It frames the task of query generation or rewriting as an RL problem, training the LLM to transform an initial user query into a more effective query for downstream retrieval systems. The core mechanism involves the LLM generating an augmented or rewritten query based on the input query. DeepRetrieval employs RL algorithms like Proximal Policy Optimization (PPO) (Schulman et al., 2017) to train this query generation process. A key innovation lies in its reward signal: instead of relying on supervised data (e.g., pairs of original and "gold" rewritten queries), DeepRetrieval uses the performance of the generated query in the actual retrieval system as the reward. Metrics such as recall@k, Normalized Discounted Cumulative Gain (NDCG), or evidence-seeking retrieval accuracy (Hits@N) obtained from executing the generated query against a restricted real search engine (like PubMed) or document collection are used to provide feedback to the LLM. The model learns, through trial and error, to generate queries that maximize these retrieval metrics. To structure the generation, the model often produces reasoning steps within <think> tags before outputting the final query in an <answer> tag. This approach offers significant advantages. By directly optimizing for the end goal (retrieval performance), it bypasses the need for expensive and potentially suboptimal supervised query datasets. Compared to other RL methods, DeepRetrieval's primary focus is on optimizing the content and formulation of the search query itself.

DeepResearcher (Zheng et al., 2025) pushes the boundaries of training-based Agentic RAG by moving beyond controlled environments or static corpora to perform end-to-end RL training directly within real-world web. It aims to equip LLM agents with the capabilities for complex research tasks that require navigating the noisy, unstructured and dynamic nature of the open web. This addresses a key limitation of many existing agents, whether prompt-engineered or trained in simulated/static RAG settings, which struggle with the complexities of real-world web interaction. The framework employs RL (specifically GRPO with an F1 score-based reward for answer accuracy) to train agents that interact with web search APIs and browse actual webpages. DeepResearcher utilizes a specialized multi-agent architecture to handle the complexities of web interaction. This includes a reasoning module for invoking web search, and dedicated "browsing agents" responsible for extracting relevant information from the diverse structures of webpages encountered. Training in this realistic setting was found to foster several emergent cognitive behaviors not typically observed in agents trained under more constrained conditions. These include the ability to formulate initial plans and dynamically adjust them during research process, cross-validate information retrieved from multiple web sources, engage in self-reflection when retrieved information seems contradictory or insufficient leading to refined search strategies, and exhibit honesty by declining to provide an answer when definitive information cannot be found. DeepResearcher demonstrated substantial performance improvements over prompt-engineering baselines and RAG-based RL agents trained on static corpora, particularly on open-domain research tasks. The results suggest that end-to-end training in realistic web environments is crucial for developing capable research agents, moving closer to the capabilities hinted at by proprietary systems like OpenAI's Deep Research (OpenAI, 2025) or Grok's DeeperSearch.

The progression for the training-based methods, from optimizing the decision process of when and what to query (Search-R1), to fostering persistence (ReZero), optimizing query formulation (DeepRetrieval), and managing real-world research workflows (DeepResearcher) reflects the growing sophistication of RL in agentic search. It reflects a growing appreciation that effective information seeking by an agent involves a confluence of factors: query quality, strategic timing, resilience to failure, and adeptness in navigating realistic information environments and so on. Future advance-

ments in RL-based Agentic RAG will likely need to integrate these facets more holistically, perhaps through more complex reward structures, multi-objective optimization, or architectures that explicitly model these different dimensions of the search process, to achieve truly human-like research and problem-solving capabilities.

4 Future Research Directions

Enhancing tool interaction through advanced configuration. Current agentic reasoning often utilizes search tools with relatively basic interfaces, primarily focused on generating text queries. Future work should enable agents to exploit more advanced configurations offered by external APIs and tools. This could involve training agents to understand and utilize options like result filtering (e.g., by date, source type), sorting criteria, specifying search domains, or interacting with structured databases via complex queries. Granting finer control would support more targeted, efficient, and strategic retrieval aligned with task demands.

Developing finer-Grained and process-oriented reward functions. Simple outcome-based rewards like exact match may not offer adequate guidance for complex RAG tasks that require multi-step reasoning or detailed responses. Future research should develop fine-grained reward functions that assess both final answer correctness and intermediate steps such as document relevance, reasoning coherence, information cross-validation, and effective problem decomposition. These signals are vital for training agents to handle queries requiring more than short factual answers.

Improving Efficiency in Retrieval. The approaches mentioned above primarily focus on the accuracy of the final answer, but enhancing the efficiency of the retrieval process itself is also critical. Agents trained to interact with potentially vast information sources, must learn to perform retrievals strategically. Future research should focus on techniques that help agents avoid excessive or unnecessary search queries, select the most promising sources, and know when sufficient information has been gathered. Developing strategies to prevent agents from getting stuck in loops of unproductive searching or performing redundant retrievals is vital for practical and scalable Agentic RAG.

Enhancing Generalization and Robustness in Dynamic Environments. Robust generalization to new queries, unseen tools (e.g., sparse or dense retrieval), and changing environments remains a major challenge. While training in realistic conditions (as in DeepResearcher) improves resilience, agents still struggle with tool failures and shifting knowledge availability. Future work should explore adaptive training methodologies and architectures that ensure robust performance in unfamiliar or dynamic settings.

By addressing key areas such as improving agent control over tools, designing more sophisticated reward signals, increasing efficiency, and enhancing generalization, the field can move toward building more capable, reliable, and widely applicable Agentic RAG systems. These advancements are essential for transitioning agentic AI from research prototypes to practical systems that can effectively support humans in complex information tasks.

5 Conclusions

As language models are increasingly deployed in complex, knowledge-intensive applications, the limitations of static RAG pipelines have become apparent. Reasoning Agentic RAG offers a promising path forward by integrating retrieval with model-driven planning, self-reflection, and tool use. This paper surveyed the landscape of reasoning workflows within Agentic RAG, distinguishing between predefined reasoning with fixed orchestration, and agentic reasoning that enables dynamic, autonomous decision-making. We reviewed key methods across both paradigms, highlighting their strengths, limitations, and use-case applicability. To advance the field, we identify several crucial directions for future research, including fine-grained reward design, enhanced tool control, automated data synthesis, and robust training in dynamic environments. These innovations will be essential for realizing intelligent, context-aware RAG systems capable of addressing real-world challenges with greater adaptability, transparency, and reliability.

Limitations

While this paper provides a comprehensive review of Reasoning Agentic RAG methods, it still has limitations in terms of resource coverage. The study mainly focuses on representative published literature and open-source projects in recent years, excluding closed-source solutions from the analysis scope. This may lead to an incomplete understanding of the practical application landscape of Reasoning Agentic RAG.

A Related Work

A.1 Basic RAG

Retrieval-Augmented Generation (RAG) was introduced to overcome the static knowledge limitations of LLMs by integrating external retrieval mechanisms during inference (Chen et al., 2024; Gao et al., 2023). Naive RAG methods represent the earliest implementations, typically using sparse retrieval techniques like BM25 (Robertson et al., 2009) to fetch documents based on keyword overlap (Ma et al., 2023). While efficient for simple factoid queries, these approaches offered limited semantic understanding, thus often retrieving noisy or redundant content and failing to reason across multiple sources.

The emergence of Advanced RAG and Modular RAG was aimed at addressing key limitations of the Naive RAG, particularly in terms of retrieval precision, information integration, and system flexibility (Gao et al., 2023). Advanced RAG improves retrieval quality through techniques such as dense semantic matching, re-ranking, and multi-hop querying, while also introducing refined indexing strategies like fine-grained chunking and metadata-aware retrieval. Modular RAG rethinks the Naive RAG by breaking down the end-to-end process of indexing, retrieval, and generation into discrete, configurable modules. This design allows for greater architectural flexibility and enables system developers to incorporate diverse techniques into specific stages, such as enhancing retrieval with fine-tuned search modules (Lin et al., 2023b). In response to specific task demands, various restructured and iterative module designs have also emerged. As a result, modular RAG has increasingly become a dominant paradigm in the field, supporting both serialized pipeline execution and end-to-end learning across modular components.

Despite their effectiveness, basic RAG workflows are limited by static control logic and lack the ability to reflect, adapt, or assess the sufficiency of retrieved information. These constraints reduce their suitability for tasks requiring iterative reasoning, tool use, or multi-modal integration. Thus, Agentic RAG has proposed to embed reasoning and decision-making into the retrieval process. This work focuses on reasoning Agentic RAG approaches that enable more autonomous and context-aware information processing.

A.2 Reasoning Agentic RAG

The year 2025 is marked as the year of agentic AI, with applications emerging such as agentic LLMs and so on (Ruan et al., 2023; Kong et al., 2024; Zhang et al.). Recent advances in RAG have seen a shift from static, rule-driven retrieval pipelines toward dynamic, reasoning-driven architectures, collectively referred to as *Reasoning Agentic RAG*. Figure 1 illustrates the evolution trajectory of Reasoning Agentic RAG. These systems embed decision-making into the retrieval process, enabling models to actively determine when, what, and how to retrieve based on their internal reasoning trajectory. As shown in Figure 3, Reasoning Agentic RAG approaches can be broadly categorized into two paradigms: *predefined reasoning* and *agentic reasoning*.

Predefined reasoning depends on structured, rule-based pipelines where the retrieval and reasoning stages are modularized and fixed in advance. These workflows often include components for query reformulation, document retrieval, re-ranking, and response generation, coordinated by static control logic. RAGate (Wang et al., 2024a) exemplifies route-based designs, where retrieval is conditionally triggered based on the context or model con-

fidence, enabling the system to skip unnecessary operations and focus on knowledge-intensive inputs. Self-RAG (Asai et al., 2023) introduces loop-based reasoning by enabling the model to self-reflect and iteratively refine its responses, while RAPTOR (Sarthi et al., 2024) leverages a recursive tree structure to hierarchically summarize and organize retrieved content, supporting multi-hop and abstractive reasoning. Building on these foundations, more advanced frameworks like Adaptive-RAG (Jeong et al., 2024) combine dynamic routing and retrieval adaptation, enabling models to select optimal reasoning paths. Modular-RAG (Gao et al., 2024) extends this idea by dividing the RAG pipeline into interoperable modules like retrievers, rerankers and generators, which can be flexibly composed into hybrid workflows. These designs enabling more flexible orchestration while still operating under predefined execution paths.

Agentic reasoning empowers the LLM to act as an autonomous agent, dynamically deciding how to interact with external tools based on its current reasoning state. These workflows tightly couple reasoning with tool use, enabling the model to issue retrieval queries, assess results, and iteratively adapt its actions. Two main implementation strategies have emerged: *prompt-based* and *training-based* approaches. Prompt-based methods leverage the instruction-following abilities of pretrained LLMs to drive agentic behavior without additional training. For example, ReAct (Yao et al., 2023) interleaves reasoning steps with tool use to guide retrieval based on emerging knowledge gaps. Other methods like Self-Ask (Press et al., 2023) and Search-o1 (Li et al., 2025a) support decomposition into sub-questions or trigger retrieval mid-generation. Additionally, function calling mechanisms (Eleti et al., 2023) built into commercial LLMs such as GPT and Gemini offer structured interfaces for tool use, further enabling prompt-based agentic control. In parallel, training-based approaches aim to explicitly teach LLMs to reason and retrieve in a unified, goal-driven manner by leveraging reinforcement learning (RL) to optimize tool-use behavior. DeepRetrieval (Jiang et al., 2025) trains models to reformulate queries by maximizing retrieval metrics. Search-R1 (Jin et al., 2025) and R1-Searcher (Song et al., 2025) both adopt a two-stage, outcome-driven RL framework that enables LLMs to learn when and what to search within a reasoning trajectory. ReZero (Dao and Le, 2025)incentivizes persistence, rewarding effective retry strategies. DeepResearcher (Zheng et al., 2025) pushes further by training agents in open web environments, enabling robust search and synthesis across diverse, unstructured sources.

Extracting Numeric Assertions from Text

Amar Parajuli[1] **and Koninika Pal**[2]

[1] amarparajuli45@gmail.com [2] kpal@iitpkd.ac.in

Abstract

Open-domain Information Extraction (IE) plays an essential role in constructing large-scale knowledge bases and supports downstream applications such as Question Answering, Text Summarization, etc. While most prior research in IE has centered around extracting categorical relational tuples (e.g., president of, located in), the extraction of numerical relations (e.g., literacy rate, area, molecular weight), that link quantitative mentions to corresponding entities, remains relatively underexplored. This work addresses this gap by targeting the extraction of open-domain numeric assertions, which require identifying both the relevant entity and the appropriate measuring attribute associated with a quantity in natural language text. We begin by refining an existing OpenIE system through a rule-based approach where retrieving implicit measuring attributes for a quantity mention becomes the main challenge. To overcome this, we propose a neural framework that jointly identifies the relevant entity for a numeric mention and infers the measuring attribute to relate them, using contextual cues in the sentence. Experimental evaluation shows that our proposed model outperforms the baseline and a general-purpose large language model with a significantly large margin.

1 Introduction

Quantitative information is a fundamental aspect of factual knowledge and plays a crucial role in enabling downstream NLP tasks (Mausam, 2016), such as question answering, summarization, recommendation, and fact verification. Numeric assertions, which link entities and quantities with appropriate measuring attributes, provide valuable insights into numerical properties, ranging from population sizes and distances to prices and percentages. Such assertions also enrich knowledge bases and support reasoning over quantitative facts.

Despite the prevalence of numerical content in text, existing OpenIE frameworks (Saha et al., 2017; Cui et al., 2018; Pei et al., 2023) often fail to capture such numeric assertions, specifically extracting the measuring attributes of an entity as a relational phrase. For example, in the sentence "With an estimated spread of 1,774.53 square kilometers, an estimated 111.8 people live per square kilometer in Sinanana Dinsho", existing systems fail to infer that the first quantity refers to the area of Sinanana Dinsho, while the second refers to its population density. While one can consider a simple rule to use units to identify the measuring attribute, no such dictionary is present that covers an exhaustive list of units. Moreover, quantity may be dimensionless, such as the capacity of a playground or the number of habitat. Large Language Models (LLMs), like BERT (Devlin et al., 2019), GPT4 (OpenAI, 2023), Gemini (Anil et al., 2023), etc. are very effective in capturing contextual cues, which allows them to generate semantically related measuring attributes from sentences, but they still struggle when cues are implicit or ambiguous. For instance, given the sentence "Hyundai owns 33.88% of Kia", GPT-4 often fails to generate the precise measuring attribute share, instead producing semantically broader terms like ownership. However, very few systems extract numerical information, but model them for the information retrieval task (Ho et al., 2019; Alonso and Sellam, 2018), and therefore focus on retrieving the context rather than specific measuring attributes.

This work focuses on extracting numerical assertions from sentences, specifically extracting a measuring attribute as a relational tuple, where the object is a quantity. Here, we aim to extract triples ⟨E, M, Q⟩ from a sentence, where E is an subject entity, M is the associated measuring attribute, and Q is the corresponding numerical value with the unit if available. For example, from a sentence "Arlescote is fairly remote, with the nearest village being 2 miles away", the valid extraction is ⟨**E**: 'Arlescote', **M**: 'distance from nearest village',

Proceedings of the 14th International Joint Conference on Natural Language Processing and the 4th Conference of the Asia-Pacific Chapter of the Association for Computational Linguistics, pages 1967–1977
December 20-24, 2025 ©2025 Association for Computational Linguistics

Q: '2 miles'⟩. To extract the numerical assertions from sentences, we propose a neural framework that jointly identify the entity and the measuring attribute for a given quantity in a sentence. As there is no annotated dataset for numerical triples available in literature for training the proposed network, we first generate a large-scale pseudo-labeled dataset from Wikipedia using a rule-based approach that converts triples extracted from an existing OpenIE system to acquire labeled triples. We summarize our contributions as follows.

- We develop a rule-based approach to generate numerical triples from Wikipedia on top of an existing OpenIE system.
- We introduce a neural framework to extract numerical assertions, trained on the dataset generated by the proposed rule-based pipeline.
- A comparative evaluation of the proposed models against a few baselines is reported.
- The codes and data generated from the rule-based model are made public here and the neural models are available here.

2 Related Works

Open Information Extraction. Early OpenIE systems, such as KnowItAll (Etzioni et al., 2004), TEXTRUNNER (Yates et al., 2007), REVERB (Etzioni et al., 2011), use human-defined patterns and sentence structure to generate facts from web data. OLLIE (Mausam et al., 2012) overcomes the drawbacks of REVERB and takes advantage of the pattern learning approach using bootstrapping. While REVERB is a verb-mediated extractor, RELNOUN 2.0 (Pal and Mausam, 2016) is a noun-mediated extractor for complex noun phrases and uses linguistic processing for extraction. Open IE 4.2 [1] combines SRLIE (Christensen et al., 2011) and RELNOUN (Pal and Mausam, 2016).

Recently, encoder-decoder architecture is explored to model the open IE task (Cui et al., 2018). OpenIE6 (Kolluru et al., 2020a) exploits the BERT-based encoder to design an iterative grid-level architecture that imposes constraint rules and conjunction rules to improve the earlier system. DetIE (Vasilkovsky et al., 2022) trains a model using BERT (Devlin et al., 2019) and transformer encoder architecture with order-agnostic loss to improve efficiency of the OpenIE task. A recent survey (Pei et al., 2023) categorizes OpenIE systems and datasets by application. However, all these systems are generic and do not target numeric relations or implicit measuring attributes.

Relation Extraction Models. Relation extraction (RE) is typically framed as a classification task over predefined relations. State-of-the-art RE models leverage pre-trained language models like BERT (Devlin et al., 2019) to capture entity and context representations (Wu and He, 2019; Tian et al., 2021; Li et al., 2019). Aman et al. (Madaan et al., 2016) propose a rule-based relation scoping and probabilistic graphical model to extract numerical relations, like inflation rate, atomic number, etc. While RE models perform well on curated datasets such as TACRED(Zhang et al., 2017) and KB-37 (Zhang and Wang, 2015), they are limited to closed schemas and do not generalize to open-domain numeric assertions. A recent survey (Zhao et al., 2024) presents a range of relation extraction methods, however, none of them specifically target numerical relations.

Extraction of Numerical Assertions. BONIE (Saha et al., 2017) introduces the first numerical assertion extractor, built using the Bootstrapping method. It extracts triples in the form ⟨Arg1, relation phrase, Arg2⟩ where Arg2 captures quantity phrase. While it improves precision over OpenIE 4.2, it struggles with conjunctions and implicit measuring attributes. Many works formulate the information extraction task as a sequence tagging problem (Ho et al., 2019; Kolluru et al., 2020b; Almasian et al., 2024a) where input tokens are tagged according to the required output forms. There are NLP pipelines (Roy et al., 2015) that specifically aim to identify quantities in text. FiNER (Loukas et al., 2022) specifically focuses on extracting quantities from financial documents. However, they do not retrieve the associated entity or context that describes the quantities. Addressing this problem, some works explored the task of retrieving related information for a quantity mentioned in text (Alonso and Sellam, 2018; Ho et al., 2019; Almasian et al., 2024b). However, as the target application is considered open-domain question-answering, they accept noisy or partial extraction. A few recent works (Zhang, 2022; Liu et al., 2021) targets the extraction of numerical assertions from Chinese text by fine-tuning BERT

[1] https://github.com/allenai/openie-standalone

and other neural models on question-answering datasets, where they inquire about the entity and the attribute for a target quantity in a sentence.

3 Rule-Based Approach for Training Data Generation

We introduce an extraction pipeline to construct a large-scale dataset of numerical triples, in the form of ⟨ E, M, Q ⟩ from natural language text, which we use to train neural models. Our extraction pipeline consists of two steps–1) filtering OpenIE outputs and 2) converting filtered triples to ⟨ E, M, Q ⟩.

3.1 Filtering OpenIE Generated Triples

OpenIE systems are effective in extracting general purpose relational tuples, typically in the form ⟨subject(S), predicate(P), object(O)⟩, but they are not optimized to identify numerical information or associate it with appropriate measuring attributes. Here, we adopt one of the existing OpenIE systems BONIE (Saha et al., 2017) as it aims at retrieving triples containing numerical mention in any of the three arguments in ⟨S, P, O⟩ extracted from a sentence. Hence, we filter the triples extracted by BONIE using the following rules to find potential candidate ⟨S, P, O⟩ triples that are later transformed into numerical assertions.

- We discard triples that do not include any quantity in the object phrase and have a confidence score less than 0.9.
- We eliminate all ⟨S, P, O⟩ triples that specify any temporal tags (e.g., date, seconds, etc.) or geolocation in the subject or object phrase.
- We filter ⟨S, P, O⟩ with multiple quantities in the object phrase as such triples can introduce noisy ⟨E, M, Q⟩ during conversion.

3.2 Rule-based method for converting OpenIE Triples to Numerical Assertions

The retrieved triples may capture the measuring attribute within the subject or predicate phrase. Additionally, measuring attributes (e.g., distance, duration, area) are often implicit or embedded in nominal phrases, and thus are missed out by the extractor. Therefore, we devised a rule-based approach to convert the extracted triples ⟨S, P, O⟩ into numerical assertions ⟨E, M, Q⟩ by identifying the quantity Q and measuring the attributes M from the subject, predicate, or object phrase of extracted triples by BONIE.

To facilitate effective conversion, we first determine whether the sentence associated with a given ⟨S, P, O⟩ triple matches one of the following patterns, defined below.

Sentence Pattern 1: It captures the sentences for which the predicate (P) extracted by BONIE contains the verb that is also the syntactic root. Additionally, the subject phrase (S) must contain at least one named entity, and the noun phrase in S or P (identified by a PROPN or NOUN) is linked via 'nsubj' or 'dobj' to root, respectively.

Sentence Pattern 2: It considers all sentences that do not follow the syntactic structure of pattern 1, but the extracted S, P, and O contain a noun phrase, only a verb, and a quantity without any noun phrase, respectively.

For both sentence patterns, we extract the quantity (Q) from the object phrase (O) using the QUANTULUM3 parser (Mündler, 2022). It identifies the numerical expressions and their associated units from the extracted object phrase in ⟨S, P, O⟩ by BONIE. Finally, we apply a set of pattern-specific rules to retrieve the entity and the measurement attribute.

3.2.1 Extraction Rules for Sentence Pattern 1

We apply the following set of rules to extract the subject entity (E) and the measuring attribute (M) from the ⟨S, P, O⟩ and the source sentence that matches pattern 1.

Extraction of Entity(E): We identify the subject entity using the syntactic structure of the source sentences and the entities named in the subject phrase (S) in ⟨S, P, O⟩ triples. For this, we exploit the following three heuristic cases.

- **case 1:** If a named entity is detected in the subject phrase S using SpaCy NER library, we retrieve all connected noun phrases linked to the entity from the dependency parse tree of the source sentence, and consider them together as entity phrase (E). For example, we extract 'Montreal and the southern Quebec region' as entity phrase E from "Montreal and the southern Quebec region receive slightly over 2,000 hours of sunshine annually, with summer being the sunniest", whereas the BONIE extracts only 'Montreal' as the subject S.
- **case 2:** If the subject contains a single named

entity that is a proper noun and there are no linked noun phrases, it is extracted as E.

- **case 3:** If there are no named entities detected by SpaCy in subject phrase S, we identify the proper noun from it as the entity E. If multiple such noun phrases exist, we choose the last one as the entity E.

Extraction of Measuring Attribute (M): Considering the position of the noun phrase in predicates and objects in ⟨S, P, O⟩ triples, we devise the following rules to identify measuring attributes M.

- **Case 1:** If the predicate has one noun phrase, it is extracted as the measuring attribute M; otherwise, the noun phrase nearest to quantity Q is chosen.

- **Case 2:** When predicate P does not contain any noun phrases, we find all noun phrases in the object O. If there is only one, we consider it as the measuring attribute M. Otherwise, we consider the one closest to the quantity Q as the measuring attribute. For example, we extract 'surface elevation' as the measuring attribute from triple ⟨ Lake Baikal, has, surface elevation of 455.5 meters⟩ extracted by BONIE from the sentence "Lake Baikal has surface elevation of 455.5 meters".

In both cases, if the noun phrase includes the immediate preposition 'of', we consider the linked phrase with 'of' as part of the measuring attribute. For example, the extracted predicate 'poverty ratio' from "the country had a poverty ratio of 46.86% of the households in 2005." is modified to 'poverty ratio of the households'.

3.2.2 Extraction Rules for Sentence Pattern 2

Sentences that match with pattern 2, we first apply the same entity extraction rule as in Sentence Pattern 1 (Case 1) and extract linked noun phrases with the entity. Next, we use the following rules to retrieve the entity phrase E and the attribute M jointly from the extracted phrase.

- **Case 1:** If multiple noun phrases exist and one of them is possessive, it's taken as the entity E. From the rest, the first noun becomes the measuring attribute M. For example, in "The average age of the Politburo's members was 58 years", the phrase 'Politburo's members' becomes E, and 'average age' is considered as measuring attribute M. Otherwise, the first noun phrase recognized by NER is considered as the entity E. The next noun phrase in the order is selected as the attribute M.

- **Case 2:** If there is a single noun phrase containing a named entity, the detected entity is considered E and rest of the phrase becomes attribute M. For example, in "Chicago's overall sales tax is 9.75% ", we identify Chicago and overall sale tax as the entity E and the measuring attribute M, respectively. Otherwise, that noun phrase is considered as E and the measuring attribute is retrieved by converting the adjective present within a window of two words from the quantity Q to the nominal phrase. If no such adjective exists, the attribute is considered as a null string.

Using these rule-based extractor, we generate a corpus of over 90,000 numerical assertions from Wikipedia sentences, which is employed to train our proposed LLM-based neural extractors, proposed in the next section.

4 LLM-based Extraction of Numerical Assertions

Identifying patterns and creating the corresponding rules for extracting ⟨E,M,Q⟩ triples for different types of sentences are labor-intensive and inefficient for diverse unseen sentence patterns. Furthermore, measuring attributes are often indirectly referenced in the sentence. Although BONIE uses a unit-based dictionary to infer implicit measuring attributes, its effectiveness is limited based on the unit coverage of the dictionary. Even when units are present, they can ambiguously refer to multiple properties (e.g., monetary units may correspond to profit, loss, asset, or net worth). In case of dimensionless quantity, dictionary-based measuring attribute inference is not even applicable. These challenges highlight the importance of contextual reasoning in identifying the measuring attribute. To overcome these limitations, we propose an end-to-end transformer-based neural framework to find numerical assertions from sentences.

We design a multi-tasking learning framework by combining a sequence tagging module built on top of a BERT-based encoder and a generative transformer decoder. Motivation comes from the observation that while entities E are usually mentioned explicitly in sentences and can be effectively

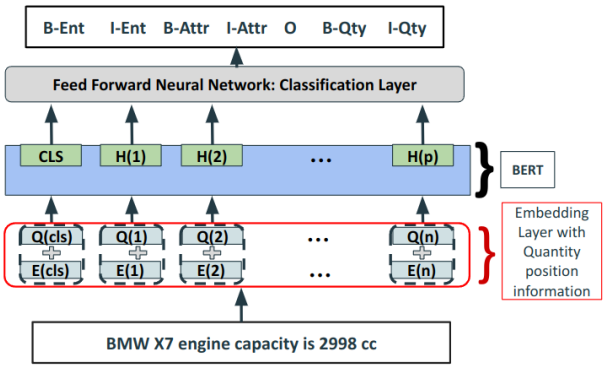

Figure 1: Quantity-pivoted Sequence Tagging Module

extracted through token classification, measuring attributes M often require generation based on implicit contextual cues from sentences.

Quantity-pivoted encoder module. We design this module to identify the entity phrase and to capture the cues for generating measuring attribute for a given quantity. Similarly to the sequence tagging task, the input sentence is fed to the BERT encoder along with the position of a quantity mention as a pivot, and each token from the input is classified into three types of tags – Entity, Attribute, and Others, depicted in Figure 1. We use BIO encoding to represent the tags. The quantity embedding layer provides extra information about the position of pivot quantity by using a vector of 1's. Other tokens are encoded with vectors of 0's. Then the average of quantity and token embeddings is passed to the BERT encoder. The model considers cross-entropy as the loss function ($\mathcal{L}_{enc}$) to measure the disparity between the actual tags (annotations) and the predicted tags generated by the encoder.

Generative Module. While the entity phrase is always explicitly present in the input sentence, measuring attribute can be implicit or inferred from context, as discussed in earlier sections. Hence, we introduce a decoder for generating measuring attributes considering the contextual cues provided by the encoder. Finally, the output from decoder and encoder can be combined to extract the final assertion. For example, consider the sentence 'Hyundai owns 33.88% of KIA'. The encoder predicts the tag sequence [B-ent, O, B-qty, I-qty, O, I-attr] for the input tokens, identifying 'Hyundai' as the entity and 'KIA' as the attribute. And the decoder generates 'shares of' based on the contextual cues from encoder, resulting in the final assertions ⟨Hyundai, shares of KIA, 33.88%⟩. For training the decoder, we consider the cross-entropy loss between the generated tokens and the target tokens as the decoder loss $\mathcal{L}_{dec}$.

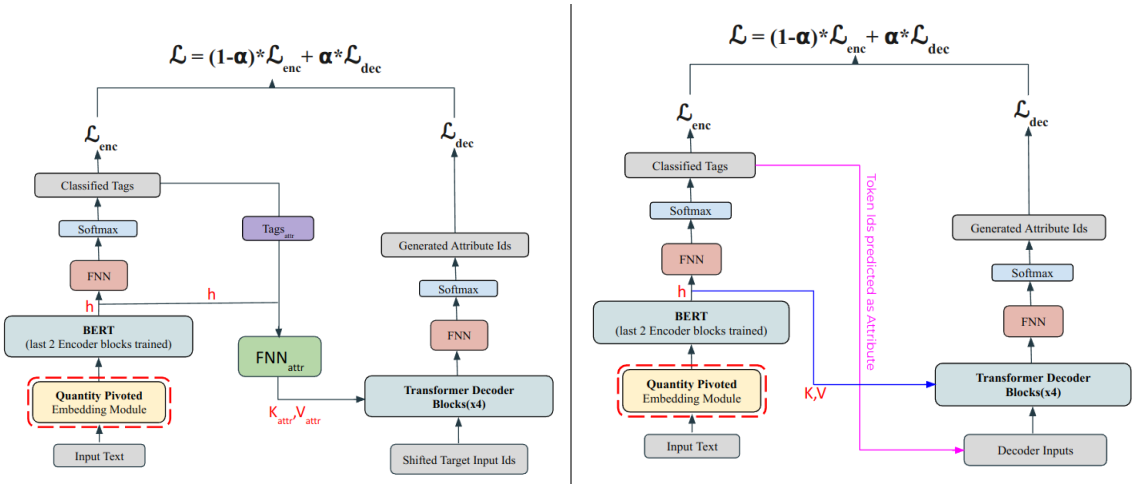
As encoder and decoder modules are performing two different but related tasks, we propose a joint training strategy, allowing the encoder and decoder to be optimized simultaneously. This way the model leverage the information contained in the gradients from the encoder to guide the weight updates on the decoder and vice versa.

We define a unified loss function $\mathcal{L}$, given in Equation 1, as a weighted linear combination of the encoder loss ($\mathcal{L}_{enc}$) and the decoder loss ($\mathcal{L}_{dec}$) mentioned earlier.

$$\mathcal{L} = (1 - \alpha) * \mathcal{L}_{enc} + (\alpha) * \mathcal{L}_{dec} \quad (1)$$

Here, we propose two joint learning frameworks that consider different information flows to share the information between the encoder and decoder.

4.1 Tag-aware Joint Extraction



In this approach, we enrich the information flow from encoder to decoder by providing token positions predicted as attributes by the encoder with the cross-attention mechanism. The process involves concatenating the last hidden state embeddings of the encoder with a vector representing the token positions predicted as attributes. This concatenated tensor is then passed through a Linear layer with a rectified linear unit (ReLU) activation function, generating a final embedding of a token. The modified hidden representation is defined as follows:

$$K_{attr} = ReLU(W_{attr}.[h, Pos_{attr}]) \quad (2)$$

Here, K_{attr} represents the Key and Value passed to the Decoder's cross-attention mechanism, h denotes the last hidden state embeddings of the Encoder, and Pos_{attr} is a binary vector, where ones indicate the positions predicted as attribute tag in the sequence tagging module. The framework is illustrated in Figure 2 (a). This enhancement allows the decoder to more effectively attend to semantically relevant regions of the input when inferring measuring attributes.

4.2 Attribute-aware Joint Extraction:

In this variant depicted in Figure 2 (b), we make the decoder explicitly aware of the measuring attribute tokens predicted by the encoder. Unlike the conventional Transformer decoder that typically receives shifted target token IDs as input, we fed the token

(a) Tag-aware Joint method

(b) Attribute-aware Joint method

Figure 2: LLM-based extraction models for numerical assertions

IDs corresponding to the predicted attribute spans as the query into the decoder. This modification helps the decoder to capture better contextual cues and anticipate relevant measuring attribute. Additionally, the encoder's final hidden state representations are passed to the decoder via cross-attention as in the standard Transformer architecture. This setup allows the decoder to condition its generation on both: (i) the structural cues derived from attribute predictions, and (ii) the full contextual information encoded in the source sentence.

5 Experimental Results

Datasets. We constructed a total of 93,769 numeric assertions using our rule-based extractor from Wikipedia sentences which is made public. The dataset statistics are given in Table 1. Since existing OpenIE benchmark dataset do not focus on numerical assertions where the measuring attribute serves as the predicate, we use our dataset generated using the rule-based method as training data. To evaluate the quality of this dataset, we randomly sampled 100 generated triples and assessed how precise the extraction was with precision, reported in Table 2. The results indicate that the rule-based extractor performs more reliably for shorter sentences. Based on this observation, we curated a cleaner subset of 10,000 high-quality triples extracted from sentences of length fewer than 15, which we use to train our LLM-based extraction models. For evaluation of all baselines and the proposed models, we created a test dataset by manually annotated 100 Wikipedia sentences with gold

Table 1: Statistics of rule-based dataset

Length of sentences	Complete	Test
< 11	5745	25
$11 \leq$sen. len < 21	26985	25
$21 \leq$ sen len < 31	36830	25
≥ 31	24209	25

⟨E, M, Q⟩ triples.

Evaluation Metrics. We primarily use precision, recall and F1 measure to evaluate the quality of the extracted entity and measuring attribute for triples. As these metrics do not consider the word order, we consider BLEU score as well for the evaluation.

Experimental Setup The hyperparameters for each model were determined through a 5-fold cross-validation. We set the best value for α that tunes the combined loss to 0.5. The batch size and the learning rate are set to 8 and $1 \times e^{-5}$ respectively. The dropout value for the FNN in the encoder block is set to 0.1 and the dropout for the FNN in the Tag-aware Joint method is set to 0.3. We use 4 decoder blocks from transformer library.

Baselines We employ BONIE as our underline extractor for rule-based model. Therefore, we consider our rule-based approach as the primary baseline, instead of BONIE itself. Furthermore, we use the encoder-decoder architecture (Cui et al., 2018) and GPT-4 in Zero-shot set up as competitors. The following prompt was used for the Zero-shot generation of the entity and the measuring attribute from a sentence using GPT 4.

Table 2: Evaluation of rule-based model using Precision

Sentence Length	E	M	Q
≤ 15	0.96	0.76	0.94
> 15	0.86	0.62	0.82

> "Given the sentence: what is the measuring attribute for the numeric mention, Quantity (number and the unit), and what is the associated entity?"

Additionally, a fine-tuned GPT 3.5 turbo is considered another baseline. We observed that the GPT fine-tuning process is very sensitive to noise and also costly. Therefore, we finetune GPT-3.5 turbo with 200 manually annotated samples, instead of using the automatically generated noisy training data. We also consider the latest Qwen3 (Yang et al., 2025) 8 billions model with the same prompt as used for GPT 4 in a Zero shot setup.

5.1 Evaluation of the Models on Extracting Measuring Attributes

Table 3 provides a comprehensive evaluation of the extraction methods for measuring attributes. From the results presented in Table 3, we can see that the proposed joint extraction methods significantly outperform all baselines w.r.t. all metrics. Qwen3 8 billion model reaches only 0.21 F1-score in extracting measuring attributes. Hence, Qwen performance is not included in Table 3. We can also observe that tag-aware and attribute-aware extraction methods perform better in extracting measuring attributes from the smaller sentences (length ≤ 15) compared to the longer ones. This is consistent with the statistic of the training dataset. Additionally, we observe the same characteristic for all baselines, reflecting the difficulty of the task for longer sentences.Comparing the performance of the proposed models with the encoder-decoder architecture, we can ensure that the availability of additional task-specific information to the decoder from the encoder stack significantly contributed to train a better model for extracting measuring attributes.

We can also observe from the results that the rule-base models perform more steadily across different sentence lengths compared to the proposed neural models. This characteristic reflects that we are able to cover sentences with different lengths with the two patterns mentioned in Section 3. However, the overall performance of the rule-based model in extracting measuring attributes is inferior. As the rule-based model mainly rearranges the extracted BONIE triples ⟨S, P, O⟩ to numerical assertions ⟨E, M, Q⟩, its performance is is affected by the limitation of BONIE in extracting measuring attributes.

5.1.1 Analysis of the Performance on Different Measuring Dimensions

As we target the open-domain extraction of measuring attributes, we analyze the distribution of different measuring dimensions in our testset. Table 4 presents the statistics of the dominating dimensions along with a miscellaneous category that includes area, money, mass, speed, angle, etc.
Table 5 presents the effectiveness of the proposed models in extracting measuring attributes on different measuring dimensions. We can observe that both models perform slightly inferior for the miscellaneous category compared to others, as this slice incorporates many tail measuring dimensions.

5.2 Evaluation of the Models on Extracting the Entity Phrases

Table 2 has shown that the precision in retrieving the entity phrase using the proposed rule-based model is efficient, reaching 96% precision for shorter sentences, specifically due to the precise extraction of entity phrases by BONIE. Overall, we achieve 91% precision for entity extraction using the rule-based model. It is important to note here that the rule-based model is able to detect conjugated entities where BONIE fails.

From the evaluation, we can also see that the performance of the proposed neural models is comparable with the performance of the rule-based model for extracting entity phrase from shorter sentences (less than length 15). However, their performance deteriorates for longer sentences. This result fits the characteristics of the training data. As they are trained with shorter sentences, they are unable to generalize the learning patterns for extracting entity phrases from longer sentences. While the best performing LLM-based model achieves an overall 77% F1 score, the rule-based model reaches 81% F1 score. The similar pattern is also reflected for the BLEU score. From the results, we can see that only the fine-tuned GPT-3.5 is able to outperform the rule-based model in entity extraction. This is attributed to its exposure to vast underlying data. However, GPT with zero-shot setup is significantly under-performing for entity extraction as well. Although Qwen3 performance was not acceptable for

Table 3: Performance of the models on extraction of measuring attributes

Performance (Sentence Length $\leq$ 15)				
Models	**Precision**	**Recall**	**F1 Score**	**BLEU Score**

miscellaneous	29

identifying the measuring entity, it performs well in the subject extraction task.

5.3 Discussion

Here, we can observe from the results presented in Table 3 and Table 6 that the proposed models perform comparable to each other. Overall, they outperform baselines for extracting numerical assertions from shorter sentences. However, the rule-based model outperforms the entity extraction task for longer sentences, although overall performance remains inferior to the neural models. We also observe from the results that fine-tuned GPT model significantly outperforms the GPT 4 with zero-shot set up. While fine-tuned GPT 3.5 built on a LLM with $\approx$ 175 billion parameters, we consider a comparatively smaller LLM with 108 million parameters only. Our proposed models are trained with only $\approx$ 280 million parameters on a relatively small data set with 10K samples. With these smaller models, we outperform fine-tuned GPT in most cases.

Table 7 shows anecdotal examples for extracting numerical triples from different models. We can see that GPT 4 generates out-of-context tokens as measuring attributes for the first example, which is contributed to its poor performance, reflected in the BLEU and F1 score in Table 3. Fine-tuning GPT brings improvement in this aspect. For the example with longer sentence, none of the methods generates appropriate measuring attribute. Consequently, the performance of entity extraction is affected. Our proposed model able to understand that 35% is about poll voter in Florida, which is partially correct. Here, GPT models tends to capture factual content rather than the measuring attribute. As reflected in the performance scores, all models perform well in extracting entity correctly for shorter sentences.

6 Conclusion

Extracting numerical assertions in the form of $\langle$ entity, measurement attribute, quantity$\rangle$ can enhance the coverage of quantitative facts in knowledge graphs, as well as the understanding of quantity in text. This work presents a rule-based extraction pipeline built on BONIE to generate numerical triples from text. While the extractor demonstrates high precision in identifying entities and quantities, its performance in extracting implicit or context-dependent measuring attributes remains limited. Addressing this limitation, we propose two LLM-based neural models Attribute-aware and Tag-aware Joint extractor that are trained using the dataset generated by the rule-based model. We consider BERT as the underlying LLM, which allows us to create a smaller model with $\approx$ 280 million parameters, compared to the dominant general purpose LLMs. From the evaluation, we observe that the integration of additional information flow from the encoder to the decoder stack helps to learn better generative models for the measuring attribute extraction task, and the proposed models outperform all the baselines with a significant margin.

Limitations

Measuring attribute extraction in open-domain settings remains underexplored, and no benchmark

Rule-based	The Same Poll	non-cuban hispanics supporting	35%
Attribute-aware	Florida	Poll voters	35%

datasets exist for numerical assertions. To address this, we leveraged BONIE and designed a rule-based approach to generate a pseudo-labeled dataset for numerical assertions. However, the limitation of BONIE in extracting measuring attribute from longer sentences adversely impacted the quality of measuring attribute annotations, reducing overall extraction quality. This, in turn, restricted the proposed neural model's exposure to various syntactic patterns, limiting its ability to generalize to longer or more complex inputs. Consequently, models often capture only partial measuring attributes and may fail to correctly associate the corresponding entity for longer sentences.

Another limitation of our work stems from the architectural choices in our neural model. We observed that the rule-based approach achieved high precision in extracting the entity phrase. And therefore, we prioritized learning robust models that can capture the representation of measuring attributes efficiently. Although we investigated the joint extraction of entity and measuring attribute, our design choice remains simple for entity extraction, using sequence tagging over fine-tuned pre-trained language models. This design, combined with training primarily on shorter sentences, restricts generalzibility of the model and affects performance of entity extraction for longer sentences. This further affects the extraction of measuring attribute as both tasks are linked. However, a combined approach that leverages the strengths of both methods remains a promising direction for future work.

Abstract

Multimodal models play a key role in empathy detection, but their performance can suffer when modalities provide conflicting cues. To understand these failures, we examine cases where unimodal and multimodal predictions diverge. Using fine-tuned models for text, audio, and video, along with a gated fusion model, we find that such disagreements often reflect underlying ambiguity, as evidenced by annotator uncertainty. Our analysis shows that dominant signals in one modality can mislead fusion when unsupported by others. We also observe that humans, like models, do not consistently benefit from multimodal input. These insights position disagreement as a useful diagnostic signal for identifying challenging examples and improving the robustness of empathy systems.

1 Introduction

Empathy recognition in human communication is a nuanced and multifaceted task and a core component of socially intelligent systems (Fung et al., 2016). Commonly defined as the capacity to understand others and share their emotional experiences, empathy encompasses both cognitive perspective-taking and affective resonance (Baumeister and Vohs, 2007). In human interactions, language, speech, and visual cues jointly convey emotional intent (Holler and Levinson, 2019). For example, a speaker's verbal message may appear neutral, yet their vocal prosody or facial expressions may signal warmth or concern. It is then the listener's responsibility to draw inferences about meaning based on a *combination* of these signals.

For AI systems, effectively interpreting these multimodal signals requires not only accurate unimodal representations but also robust integration of potentially conflicting information across modalities. Despite recent advances in multimodal emotion recognition (Jabeen et al., 2021), empathy recognition remains particularly complex, as unlike discrete emotions such as anger or joy, empathy often arises from subtle contextual cues that may not align across modalities (Hasan et al., 2023). For example, a neutral utterance might be perceived as warm or concerned when accompanied by a sympathetic tone or expression.

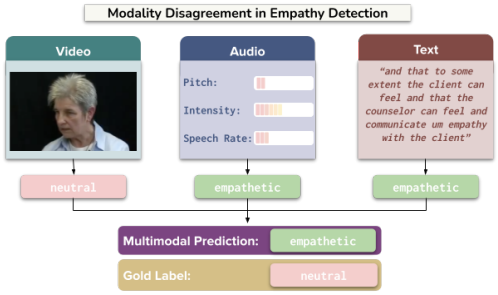

Figure 1: Given classifications provided by a single modality, we identify cases where integrating additional modalities leads to a different prediction. We analyze these differences to understand when and why they occur.

Our work investigates some of the complexities of multimodal empathy detection by examining instances of disagreement between multimodal models and their unimodal counterparts. In parallel, humans annotate unimodal and multimodal examples in our dataset for the presence of empathy. Our analyses reveal that instances of multimodal and unimodal model disagreement often correspond to examples that are difficult for human annotators as well, highlighting examples that are particularly challenging, ambiguous, or nuanced. By linking multimodal and unimodal *model* disagreement to *human* disagreement, we offer new insight into the limitations of current empathy modeling and highlight the value of disagreement-based analysis in socially grounded language tasks.

relevant textual responses (Rashkin et al., 2019; Li et al., 2019), but these approaches are inherently limited by the absence of non-verbal cues, which are critical to empathic understanding. Recent datasets such as EMPATHICSTORIES++ (Shen et al., 2024), MEDIC (Zhu et al., 2023), EMMI (Galland et al., 2024) and Chen et al. (2024b) address this limitation by incorporating context, speech, and facial expressions, enabling more comprehensive modeling of empathy. These resources have motivated frameworks such as PEGS (Zhang et al., 2024), EMOKNOB (Chen et al., 2024a) and SYNTHEMPATHY (Chen et al., 2025), which further extend multimodal empathetic generation by leveraging large language models (LLMs) and large audio-language models. Despite these advances, empathy still remains difficult to model due to its reliance on subtle, often conflicting signals across modalities. Prior work has largely focused on improving multimodal fusion strategies under the assumption that modalities are complementary (Zadeh et al., 2017; Tsai et al., 2019), but has paid less attention to when fusion may fail or introduce noise.

Dataset Difficulty. Complementary lines of work have investigated data difficulty and model disagreement as tools for understanding model behavior. Swayamdipta et al. (2020) propose *dataset cartography*, a method to identify hard or ambiguous training samples, showing how difficulty-aware instance selection improves benchmarking and reveals mislabeled or trivial examples. Saha et al. (2022) demonstrate that difficult instances are also harder for both humans and models to explain, and Wang et al. (2023)'s Learning-From-Disagreement (LFD) framework underscores the importance of examining disagreements between models to gain deeper, actionable insights into their behaviors. Although ambiguity is intrinsic to empathy modeling, disagreement-based diagnostics do remain underexplored. As such, we leverage modality disagreement to flag difficult examples that both mislead fusion models and elicit annotator uncertainty.

3 Experiment 1: Identifying Complex Examples from Modality Disagreement

Disagreement between models trained on different modalities can reveal challenging, nuanced, or ambiguous examples. Here, we identify and analyze such cases of disagreement in binary empathy detection using a multimodal English empathy speech dataset collected from Youtube (Chen et al., 2024b) (referred to as EMPSPEECH) consisting of 1,718 manually annotated English speech segments labeled as empathetic or neutral (Appendix A).

Modality	Model	Accuracy	F1
Text	**RoBERTa**	**0.75±0.02**	**0.73 ±0.02**
	DeBERTa	0.69±0.02	0.68±0.02
Audio	**HuBERT**	**0.72±0.01**	**0.71±0.01**
	Wav2Vec2	0.68±0.01	0.63±0.02
Video	**VideoMAE**	**0.77±0.02**	**0.77±0.02**
	TimesFormer	0.64±0.02	0.62±0.02
Fusion (All Modalities)		**0.76±0.02**	**0.72±0.02**

Table 1: Fine-tuned model performance by modality on empathy classification (mean ± std over five runs).

Experimental Setup. Examples in EMPSPEECH include video segments spanning three modalities: text (transcript), audio (speech), and video. The task is to predict whether the input contains empathetic (1) or neutral (0) speech.

We finetune two models per modality on the training set from EMPSPEECH: ROBERTA (Liu et al., 2019) and DEBERTA (He et al., 2021) for text, HUBERT (Hsu et al., 2021) and WAV2VEC2 (Baevski et al., 2020) for audio, and VIDEOMAE (Tong et al., 2022) and TIMESFORMER (Bertasius et al., 2021) for video (Appendix B.1).[1] Then, we extract 768-dimensional embeddings from each best-performing unimodal model (ROBERTA, HUBERT, and VIDEOMAE; Table 1) to train a multimodal fusion model that projects all three modalities into a shared latent space (Appendix B.2). Each modality embedding passes through an independent sigmoid gate that adaptively scales its contribution before fusion. The gated embeddings are then passed through an additive attention layer: each is projected into a shared attention space and scored against a learned attention vector. These scores are normalized across modalities to compute a weighted sum that forms the fused representation.

Results. We evaluate all models (unimodal and multimodal) on the test split of EMPSPEECH to identify *disagreements*, or examples where two models with varying input modalities assign *different* labels, highlighting those cases where different modalities may carry ambiguous, conflicting, or modality-specific signals.

Text shows the highest disagreement with audio and video (Table 2), while audio and video align

[1]The hidden layer dimensions of all models we consider are similar.

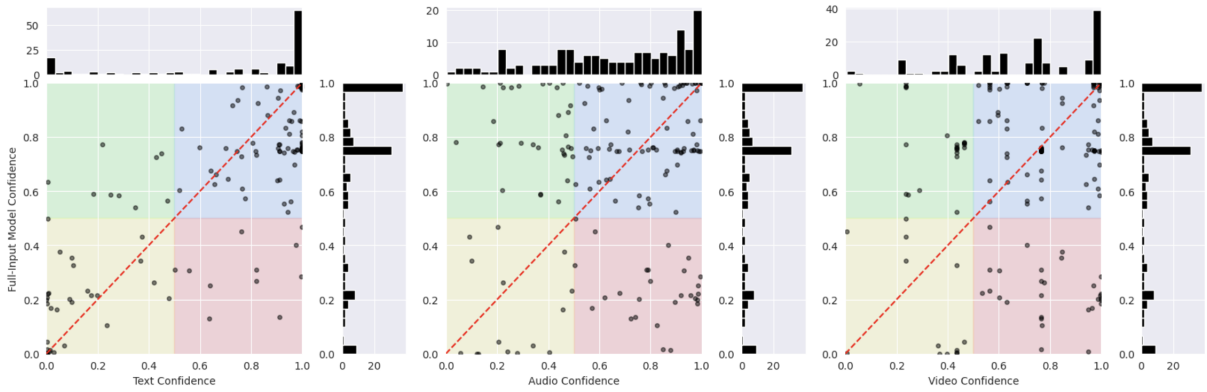

Figure 2: Comparing predictions between unimodal (text, audio, video) and multimodal models. We highlight regions where model predictions *agree* (blue and yellow quadrants) and disagree (red and green quadrants).

Modality	Text	Audio	Video
Text	–	0.338	0.318
Audio	0.338	–	0.253
Video	0.318	0.253	–
Full	0.214	0.383	0.331

Table 2: Pairwise disagreement rates among unimodal models and the fusion model, computed as the fraction of test examples with differing predictions.

Feature	Red vs. Blue		Green vs. Blue	
	p-value	Direction	p-value	Direction
valence	**0.0047**	$\mu_{\textbf{blue}} > \mu_{\textbf{red}}$	0.5166	$\mu_{\text{green}} > \mu_{\text{blue}}$
arousal	**0.0065**	$\mu_{\textbf{blue}} > \mu_{\textbf{red}}$	**0.0136**	$\mu_{\textbf{blue}} > \mu_{\textbf{green}}$
Mean Pitch	**0.0100**	$\mu_{\textbf{blue}} > \mu_{\textbf{red}}$	**0.0001**	$\mu_{\textbf{blue}} > \mu_{\textbf{green}}$
dominance	**0.0108**	$\mu_{\textbf{blue}} > \mu_{\textbf{red}}$	0.0667	$\mu_{\text{blue}} > \mu_{\text{green}}$
Min Pitch	**0.0333**	$\mu_{\textbf{blue}} > \mu_{\textbf{red}}$	**0.0001**	$\mu_{\textbf{blue}} > \mu_{\textbf{green}}$
Jitter	**0.0347**	$\mu_{\textbf{red}} > \mu_{\textbf{blue}}$	0.0667	$\mu_{\text{green}} > \mu_{\text{blue}}$
Max Intensity	0.1260	$\mu_{\text{red}} > \mu_{\text{blue}}$	**0.0023**	$\mu_{\textbf{green}} > \mu_{\textbf{blue}}$

Table 3: T-test results comparing red vs. blue and green vs. blue examples for audio features with $\alpha = 0.05$. Statistically significant results are bolded. See Appendix D for full table.

more closely. This difference likely reflects shared nonverbal cues such as prosody and facial expression. The fusion model's minimal disagreement with text suggests a bias toward verbal content, possibly mirroring the annotators' own reliance on textual signals.

Figure 2 visualizes disagreement regions between each unimodal model and the fusion model. We plot unimodal confidence (x-axis) against fusion confidence (y-axis) in the correct label; hence confidence greater than 0.5 results in a correct prediction. This yields four quadrants: green (multimodal correct, unimodal incorrect), red (multimodal incorrect, unimodal correct), blue (both correct), and yellow (both incorrect). Red and green quadrants are disagreement regions which we explore to identify complex examples.

AU	p (R vs B)	Dir	p (G vs B)	Direction
AU04	**0.0106**	**red > blue**	0.3682	green > blue
AU12	**0.0174**	**blue > red**	0.8977	green > blue
AU05	0.1837	blue > red	**<0.0001**	**blue > green**

Table 4: T-test results comparing AU activation rates between red vs. blue and green vs. blue with $\alpha = 0.05$. Statistically significant results are bolded. See Appendix D for full table

3.1 Modality-Based Feature Analysis

To better understand examples in disagreement regions, we extract and analyze modality-based human interpretable features.

Audio. We extract twelve prosodic and paralinguistic features from audio signals: nine low-level acoustic features using PRAAT (Boersma and Weenink, 1992–2022) and PARSELMOUTH (Jadoul et al., 2018), and three high-level affective dimensions: valence, arousal, and dominance using a finetuned WAV2VEC2 (Wagner et al., 2023) model. We compare feature distributions using t-tests for examples in disagreement quadrants (red and green) compared to those in the blue quadrant, signifying non-ambiguous, easy examples. Blue examples have several significantly elevated pitch-related values than red examples (Table 3), suggesting that stronger prosodic fluctuations are frequently corroborated by other modalities. Examples in the green quadrant show significantly higher *Max Intensity* than in blue, potentially reflecting the role of volume-based emphasis in aiding unimodal predictions. Both red and green examples exhibit significantly lower arousal than blue examples, suggesting that these less-aroused, subtler examples lack sufficient affective intensity, which misleads both unimodal and multimodal models.

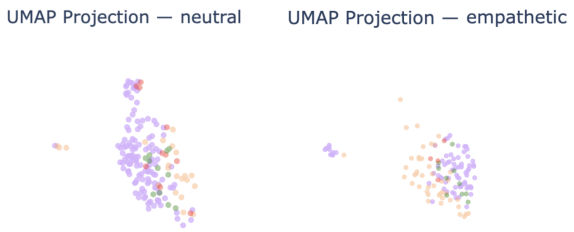

Figure 3: UMAP of text-only embeddings for empathetic (left) vs. neutral (right) examples, colored by modality disagreement; red and green points cluster near the decision boundary, marking ambiguous cases.

Quadrant	Mean Entropy	St. Dev
Red	0.670	0.017
Blue	0.259	0.222
Yellow	0.347	0.196
Green	0.565	0.192

Table 5: Mean entropy of the fusion model grouped by quadrant

Video. We examine facial action unit (AU) activations (Baltrušaitis et al., 2016) from video. AU04 (Brow Lowerer), AU12 (Lip Corner Puller), and AU05 (Upper Lid Raiser) show significant differences across example types, revealing how specific facial expressions contribute to perceptual ambiguity (Table 4). AU04 is more active in red examples than blue, indicating that, despite its visually strong presence, its signal conflicts with other modalities. In contrast, AU12, which is associated with positive affect, and AU05, which is linked to attentiveness (Friesen and Ekman, 1978), both show greater activation in blue examples than in red and green, respectively, suggesting that these expressions may serve as clearer cues that are more consistently interpreted across modalities. Our findings indicate that fine-grained facial signals may contribute to perceptual complexity in the visual stream.

Text. Visualizing UMAP (Sainburg et al., 2021) projections of text embeddings (Figure 3) reveals that examples in disagreement regions (red and green) cluster along the boundary between consistently correct (blue) and consistently incorrect (yellow) examples. Rather than forming isolated clusters, disagreement examples occupy transition zones in the embedding space: areas where semantic cues are weak. This underscores our finding that red and green examples are ambiguous and confirms modality disagreement as a reliable marker of challenging examples in empathy detection.

Quadrant	Unimodal Judgment	Multimodal Judgment	Δ
Red	0.301	0.164	-0.137
Blue	0.379	0.646	0.267
Yellow	0.225	0.329	0.104
Green	0.482	0.218	-0.264

Table 6: Cohen's Kappa between internal and external annotators, computed separately for each quadrant and prediction round.

3.2 Uncertainty Analysis

To ensure that the patterns observed in the disagreement quadrants are not simply a byproduct of model uncertainty, we compute the mean predictive entropy from the fusion model's posterior for examples of each quadrant (Table 5).

We observe a pronounced divergence in uncertainty: the disagreement quadrants (red and green) have a substantially higher mean predictive entropy than those of the combined agreement quadrants (blue and yellow). Independent-samples t-tests at $\alpha = 0.05$ confirm that the difference is statistically significant, with disagreement quadrants showing a higher mean predictive entropy than agreement quadrants ($p = 0.001$). This disparity indicates that model disagreement often co-occurs with high uncertainty, suggesting that examples in the red and green quadrants are both challenging and inherently ambiguous due to conflicting modality signals.

4 Experiment 2: Characterizing Complex Examples

We further assess whether model disagreements stem from data ambiguity using a human annotation study that tests whether examples from the two disagreement regions (red and green quadrants) are equally challenging for annotators.

Annotation Setup. We sample 204 examples evenly split across the four quadrants of each Figure 2 modality plot. For each example, annotators provide a binary judgment (empathetic or neutral) from a unimodal signal, then a judgment from the full multimodal version (instructions in Appendix C), allowing us to track how human predictions shift with additional modality signals and to understand the cognitive burden of multimodal integration. All examples were annotated by one author and one external annotator. Table 13 in the Appendix showcases frames and transcripts for four examples, along with annotator judgments.

Results. Annotator *disagreement*, measured with Cohen's Kappa (Cohen, 1960), can signal complex

Quadrant	Unimodal Judgment	Multimodal Judgment	Δ
Red	0.347	0.143	-0.204
Blue	0.364	0.533	0.169
Yellow	0.304	0.548	0.244
Green	0.573	0.329	-0.244

Table 7: Cohen's Kappa between internal and external annotators for examples of at least six tokens (the dataset median), computed separately for each quadrant and prediction round.

phenomena in examples (Jiang and de Marneffe, 2022; Pavlick and Kwiatkowski, 2019) such as uncertainty in meaning leading to discrepancies in reasoning. In disagreement regions (red and green), we see a *decrease* in annotator agreement between unimodal and multimodal judgments (Table 6), indicating that humans diverge when weighing signals across modalities. In contrast, annotator agreement *improves* upon examples where unimodal and multimodal model predictions are in agreement, supporting our hypothesis that these examples are relatively unambiguous and can be reliably interpreted once the full context is available (Table 6).

We repeat the analysis on the subset of clips containing at least six tokens (the median utterance length in EMPSPEECH). Examples below the median often include short phrases and backchannels, while examples above the median are often complete sentences with richer lexical and syntactic structure. As shown in Table 7, the red and green quadrant utterances continue to exhibit a substantial drop in Cohen's κ compared to blue and yellow quadrant utterances, which exhibit substantial gains with additional information. These results collectively corroborate our hypothesis that modality disagreement can serve as a valuable signal for identifying ambiguous, challenging, or complex instances that are also difficult for human annotators.

5 Discussion and Conclusion

We have demonstrated how disagreement, both between modalities and between humans and models, can serve as a diagnostic lens to understand the complexity of multimodal empathy detection, challenging the assumption that more signals from other modalities reliably yields better performance. Our analysis reveals that disagreement between unimodal and multimodal models is often not arbitrary, but instead marks the presence of subtle, ambiguous, or context-sensitive cues that challenge fusion models and human annotators alike.

While our study focuses on speaker-centric empathy (evaluating speakers' empathic expression), our diagnostic can be generalized to listener-centric tasks, which dominate existing empathy datasets and capture listeners' emotional responses to each utterance (Appendix A.2). These findings emphasize the necessity for high-quality annotation in socially complex tasks like empathy detection, where model errors may reflect genuine human uncertainty or disagreement. This framework provides a scalable method for identifying ambiguity and enhancing model reliability, especially in recognizing complex emotional states.

Beyond diagnosis, disagreement offers a foundation for improving multimodal learning. Cross-modal conflict can guide labeling efforts toward informative and ambiguous examples, making annotation more efficient when resources are limited. Patterns of disagreement can also inform curriculum design (Qian et al., 2025), where models first learn from consistent, low-disagreement examples before tackling more ambiguous ones to build nuanced reasoning and robustness. Furthermore, insights from disagreement can inspire more adaptive fusion approaches that dynamically re-weight or downplay misleading modalities when they conflict (Huang et al., 2023), reducing over-reliance on a single signal. High-disagreement examples can also serve as realistic adversarial test cases that expose systematic vulnerabilities and strengthen fusion strategies under genuine multimodal conflict (Yang et al., 2022). Finally, this diagnostic perspective extends beyond empathy detection to other socially complex tasks such as persuasion (Bai et al., 2021), rapport (Baihaqi et al., 2024), or sarcasm (Zhou et al., 2024), where multimodal cues and subjective judgments often diverge. In such settings, disagreement between unimodal and fusion models highlights genuinely ambiguous cases that can guide targeted annotation, evaluation, and model refinement.

Ultimately, treating disagreement as a meaningful signal rather than an error reframes how we evaluate and improve multimodal models. By revealing when and why models diverge, this perspective lays the foundation for building systems that reason more like humans do. Beyond empathy detection, this framework also opens broader pathways toward socially intelligent multimodal systems that can recognize uncertainty, resolve conflicting evidence, and adapt their reasoning to the inherent ambiguity of human affective communication.

Limitations

We acknowledge several limitations in our study. Our analyses are based on a limited dataset and a small number of human annotators. Given that empathy is inherently subjective, annotations may vary due to individual interpretations, potentially introducing biases rather than reflecting universal properties of the data. Additionally, we rely upon a single dataset, and future work should investigate whether the patterns we observe hold across other datasets and domains.

Our data is also derived from U.S.-based, English-language television and interview content. As such, the generalizability of our findings to multilingual or culturally diverse settings may be limited. Future research should investigate these patterns in varied cultural and linguistic environments to better assess the broader applicability of our conclusions.

Ethics Statement

We used a publicly available dataset and strictly use open-source models for analysis.

All annotations were conducted by an author and an individual affiliated with the research team. No participants were recruited via crowdsourcing or external platforms, and no monetary compensation was provided, as the annotators were contributing in a research capacity. We provided detailed information on what we asked the annotators to annotate and how we planned to use the data. The annotators willingly agreed to participate with full knowledge of the task. No sensitive or identifying information was collected from annotators.

We note that empathy expression may vary across cultures, and our findings may not generalize to non-English or non-Western contexts. We encourage future work to explore these questions in more diverse settings.

We will release all code and experimental resources at https://github.com/mayasrikm/multimodal-empathy-disagreement to support reproducibility.

A Dataset

A.1 Dataset Specifications

We use a multimodal empathy dataset (Chen et al., 2024b) consisting of 346 English-language videos totaling approximately 53 hours, collected from YouTube between 2020 and 2022 using keywords like "empathy" and "empathetic training." The dataset includes empathy training sessions, therapy roleplays, interviews, TED Talks, and TV/movie scenes, comprising both acted (62%) and spontaneous (38%) speech. Each video was labeled by at least three expert annotators as either empathetic or neutral, with final labels determined by majority vote. Metadata such as speaker gender, topic, and emotional context was manually annotated, covering themes like therapy, parenting, workplace dynamics, and social relationships. From this collection, a subset of 65 videos was transcribed, diarized, and manually re-aligned using Praat to ensure accurate speaker segmentation and time alignment. This process resulted in 1,718 annotated segments with speaker labels, timestamps, transcripts, and empathy stage annotations, enabling fine-grained analysis of empathy in naturalistic and semi-scripted settings. The median utterance length of the dataset is six tokens. Table 8 shows example utterances below and above the median; examples below the median often include short phrases and backchannels, while examples above the median are often complete sentences with richer lexical and syntactic structure.

A.2 Dataset Comparison

To the best of our knowledge, our work is the first to evaluate multimodal disagreement on speaker-centric empathy detection datasets. Most publicly available empathy datasets (such as EMPATHICSTORIES++ (Shen et al., 2024) and OMG-EMPATHY (Barros et al., 2019)) are fundamentally structured around listener response, not speaker expression. In these datasets, the task is to predict how empathetic a listener feels after hearing a story, rather than to assess whether the speaker themselves is expressing empathy. For instance, in EMPATHICSTORIES++, participants record personal stories and then rate their own emotional responses, framing empathy as a *reaction* to the content rather than as a property of the speaker's delivery. Similarly, OMG-EMPATHY evaluates listener self-reported affective states following brief monologues, again focusing on perceived empathy rather than expressed empathy. This distinction matters because listener-focused tasks inherently entangle speaker behavior with listener subjectivity, making it difficult to isolate which cues (textual, audial, or visual) are directly responsible for empathy expression. In contrast, the dataset we use in this study (Chen et al., 2024b) is one of the only accessible resources that explicitly asks annotators to evaluate the *speaker's* empathy, based solely on the speech segment itself, across modalities. This framing allows us to analyze how empathy is expressed in real time by the speaker, independent of listener interpretation, and enables direct comparisons between modalities on their ability to convey empathetic intent. Our current dataset offers a uniquely valuable lens into the structure of empathy as a speaker-side communicative behavior: something that remains underexplored in the literature. In future work, our modality-disagreement diagnostic could be used to flag nuanced, high-ambiguity segments that challenge *listener* empathy models. They could serve as an effective proxy for identifying segments that elicit high listener variance in empathy judgments, enabling targeted annotation and model refinement on exactly those ambiguous utterances where listener-centric prediction systems struggle most.

B Model Training Details

Data was split into train, test and validation sets using random sampling, with an 80-10-10 split. We run fine-tuning and inference for all open-source models on an A100 GPU in Google Colab.

B.1 Unimodal Model Training Details

Each model is trained on a binary empathy classification task using precomputed 768-dimensional embeddings. We freeze all but the final two transformer layers and train for fifteen epochs with a learning rate of 5e-6 and batch size of eight.

B.2 Fusion Model Details

Each unimodal model representation is independently gated and passed through an additive attention mechanism that computes modality-specific weights. The weighted embeddings are aggregated and classified using a three-layer feedforward network with max pooling. The fusion model is trained for ten epochs using a learning rate of 1e-4 and includes modality dropout during training. To characterize how the model balances each of the three modalities at inference time, we computed the

< 6 Tokens	≥ 6 Tokens
"there's no way" (3 tokens)	*"No, no he's a good guy go easy on him he's lost his son, Fabio"* (15 tokens)
"You lost it?" (3 tokens)	*"You kids have the biggest hearts I've ever seen."* (9 tokens)
"I can understand that." (4 tokens)	*"congrats my dude, on everything man"* (6 tokens)

Table 8: Example utterances with fewer than six tokens (left) versus at least six tokens (right).

per-modality gate-weight distributions over the full test set (Table 9). The mean gate weights indicate that our model allocates substantial importance to each modality, with only a slight preference toward audio and video. The high variance also shows that the model dynamically adapts its reliance on each modality on a per-sample basis. Thus, our fusion model draws substantially on all three streams; no single modality is systematically favored.

Modality	Mean	Standard Deviation
Text	0.430	0.297
Audio	0.502	0.227
Video	0.476	0.315

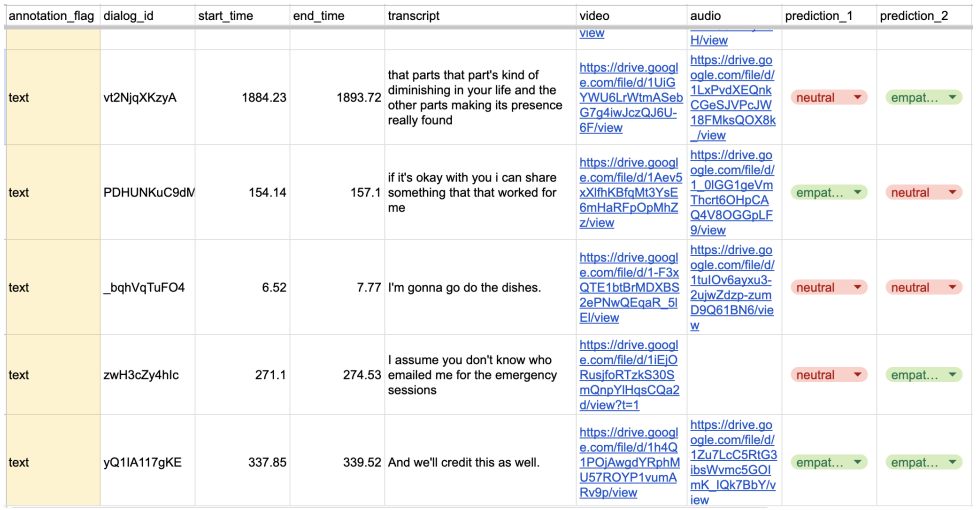
Table 9: Per-modality gate-weight distributions over the full test set.

C Annotation Instructions

We employed two annotators, one of the paper's authors and an non-author, both fluent English speakers based in the United States. No additional demographic information was collected, as the annotation was conducted internally for research purposes.

Annotators were asked to provide two judgments per example, labeling each as either empathetic or neutral (Figure 4). A excerpt describing empathy (drawn from the Encyclopedia of Social Psychology, Volume 1, (Baumeister and Vohs, 2007)) was provided to ensure a consistent conceptual foundation for annotation:

> Empathy is often defined as understanding another person's experience by imagining oneself in that other person's situation: One understands the other person's experience as if it were being experienced by the self, but without the self actually experiencing it. There are three commonly studied components of emotional empathy. The first is feeling the same emotion as another person (sometimes attributed to emotional contagion, e.g., unconsciously "catching" someone else's tears and feeling sad oneself). The second component, personal distress, refers to one's own feelings of distress in response to perceiving another's plight. The third emotional component, feeling compassion for another person, is the one most frequently associated with the study of empathy. Cognitive empathy refers to the extent to which we perceive or have evidence that we have successfully guessed someone else's thoughts and feelings.



Annotators were given an annotation flag indicating which modality to use for the first pass; for instance, if the flag was text, only the transcript was to be used to make the first prediction. After submitting the first judgment, annotators were then given access to the full video, including all available audio, visual, and textual information. They were then asked to provide a second prediction.

D Full Feature Comparisons

Tables 10, 11 and 12 provide additional results from the t-tests comparing examples across different confidence quadrants. Table 10 provides an internal comparison between the disagreement quadrants. Table 11 presents the full version of the audio feature comparisons summarized in Table 3. Table 12 expands on the facial feature comparisons shown in Table 4.

E Feature Distributions

Figures 5 and 6 visualize the distributions of key features across confidence quadrants. Figure 5 presents the distribution of selected audio features (e.g., pitch, intensity) for red, green, and blue examples, highlighting acoustic patterns associated with model disagreement. Figure 6 shows activation rates for facial Action Units (AUs) in red, green, and blue examples, illustrating how specific facial expressions vary across agreement conditions. These visualizations complement the statistical comparisons reported in Tables 11 and 12, providing a more interpretable view of the underlying feature dynamics.

Abstract

We introduce **PHLoRA**[1] (Post-hoc LoRA), a simple yet powerful method to extract low-rank adapters from full-rank fine-tuned models without requiring access to training data or gradients. By computing the low-rank decomposition of weight differences between a base model and its fine-tuned counterpart, our method reconstructs adapter modules that can be merged, dynamically routed at inference time via S-LoRA, or served in scalable industry settings using platforms like NVIDIA NIM. This approach amortizes latency overhead across requests and yields substantial cost savings. Unlike prior work that trains each adapter explicitly, our approach decouples fine-tuning from adapter generation, allowing adapter extraction from existing full-rank models or third-party checkpoints. Experiments on text, image, and video benchmarks using the Amazon Nova model family demonstrate that extracted adapters preserve high energy from the full weight delta, can be pruned safely, and yield negligible degradation in downstream task performance when re-merged. Overall, PHLoRA provides a practical path for making all existing full-rank checkpoints adapter-ready, democratizing scalable inference for all models.

1 Introduction

The Low-Rank Adapters (LoRA) technique [Hu et al., 2022] is a popular way to reduce memory during training, and it offers an additional advantage at inference: it allows a single server to host adapters for hundreds or thousands of users in a shared inference API, as in S-LoRA [Sheng et al., 2024]. Modern industry platforms such as NVIDIA NIM support scalable, low-latency serving of LoRA-based adapters in production. However, many practitioners have existing models trained with full-rank fine-tuning, including through the use of other training methods beyond standard fine-tuning like DPO [Rafailov et al., 2024] or PPO [Schulman et al., 2017]. To serve these users, we introduce and evaluate a method for compressing full-rank updates into low-rank adapters compatible with dynamic serving frameworks, called **Post-hoc Low-Rank Adapter Extraction** (PHLoRA). Our contributions include the following:

- **Post-hoc LoRA formulation:** We pose adapter extraction as a low-rank decomposition solved with truncated SVD over the checkpoint's weight delta; it does not require any gradients or data.
- **LoRA Rank compression:** PHLoRA can also be used to compress rank of existing LoRA adapters (e.g., convert LoRA trained with rank 128 to rank 32)
- **Flexible deployment and fast start-up:** Compact adapters cut model-load latency by over 10× compared to full-rank checkpoints and can be merged for static inference or dynamically routed via shared-adapter execution (e.g., S-LoRA), and are compatible with scalable industry platforms such as NVIDIA NIM, to minimize run-time cost.
- **Multimodal results:** We evaluate on three text, one image, and one video understanding benchmark, showing that PHLoRA preserves performance while reducing inference cost by up to 4×.

2 Background and Related Work

PHLoRA uniquely provides constant-cost, post-hoc adapter generation that is fully LoRA-inference-compatible for both text and multimodal settings [Sung et al., 2022], with further comparisons in Table 1.

LoRA inserts rank-r matrices in parallel with linear layers and trains only these additions, reducing memory and compute [Hu et al., 2022]. LoRA+ further re-balances the optimizer by raising the learning rate on the B matrix [Hayou et al., 2024]. Other variants explore dynamic rank schedules (AdaLoRA [Zhang et al., 2023]), quantized training (QLoRA [Dettmers et al., 2023]), and selective layer targeting. Soft prompt-tuning [Lester et al., 2021], BitFit [Zaken et al., 2021], AdapterFusion [Pfeiffer et al., 2021], and VL-Adapter [Sung et al., 2022] trade different portions of trainable parameters for efficiency, but all require task-specific optimization. Recent methods extend parameter-efficient transfer to vision-language models [Sung et al., 2022]. PiSSA initializes LoRA adapters with principal singular vectors *before* adapter training, accelerating convergence but not eliminating the need for training [Meng et al., 2025]. SLiM [Mozaffari et al., 2025], SVD-LLM [Wang et al., 2025b], and SVDQuant [Li et al., 2025] apply low-rank decomposition (often combined with quantization) directly to pretrained weights W for inference compression and acceleration. GPTQ [Frantar et al., 2023] is another widely-used post-hoc quantization approach. However, these methods do not expose LoRA-compatible factors nor leverage the fine-tuning delta. Dobi-SVD [Wang et al., 2025a] makes SVD differentiable and tunes the factors with task supervision, achieving lower reconstruction error at the cost of additional gradient steps. SORSA [Cao, 2024] proposes a structured low-rank adaptation that replaces dense LoRA matrices but still requires full adapter training.

While prior works have explored low-rank approximation techniques for fine-tuning (e.g., Hu et al., 2022, Zhang et al., 2023), we also found a recent GitHub implementation, LoRD [Gauthier-Caron, 2024], that performs similar post-hoc low-rank extraction, though without an associated peer-reviewed manuscript.

3 Methodology

3.1 Problem Setup

Given a pretrained model and a fine-tuned model, each consisting of weights, we define the weight delta as

$$\Delta W = W_{\text{ft}} - W_{\text{base}}, \text{ where } W \in \mathbb{R}^{d\times k} \quad (1)$$

Our objective is to approximate each ΔW with a rank-r factorization in the LoRA form:

$$\Delta W \approx BA, \text{where } A \in \mathbb{R}^{r\times k}, B \in \mathbb{R}^{d\times r} \quad (2)$$

Once A and B are obtained, they can be deployed as standard LoRA adapters (for dynamic or conditional routing) or merged back into the backbone via $W_{\text{base}} \leftarrow W_{\text{base}} + BA$. This process is repeated for all target components (typically attention and MLP submodules).

3.2 Post-hoc LoRA Extraction

We perform a truncated singular value decomposition (SVD) on ΔW:

$$\begin{gathered} U\Sigma V^\top = \text{SVD}(\Delta W), \text{where} \\ U \in \mathbb{R}^{d\times d}, \quad \Sigma \in \mathbb{R}^{d\times k}, \quad V \in \mathbb{R}^{k\times k} \end{gathered} \quad (3)$$

The low-rank LoRA factorization is then:

$$\begin{aligned} B &= U_{[:,:r]}\Sigma^{\frac{1}{2}}_{[:r,:r]} \\ A &= \Sigma^{\frac{1}{2}}_{[:r,:r]}V^\top_{[:r,:]} \end{aligned} \quad (4)$$

where the first r columns of U, the first r rows of V, and the first r rows and columns of Σ are taken, and the $\frac{1}{2}$ exponent represents the element-wise square root. This SVD-based decomposition ensures that BA is the best rank-r approximation of ΔW [Eckart and Young, 1936]. All computations are performed independently for each target weight matrix (e.g., q_{proj}, k_{proj}, mlp_{fc1}).

Merged inference computes $W_{\text{base}} + BA$ once, fully restoring the original fine-tuned model up to

Dataset	Metric(s)

Table 2: Primary evaluation metrics and citations for each benchmark.

truncation error (no runtime adapter overhead). Dynamic routing, as in S-LoRA [Sheng et al., 2024], loads A and B as lightweight adapters and activates them on demand, enabling low-cost serving of multiple adapters in a single process.

PHLoRA is compatible with the HuggingFace PEFT library [Hugging Face, 2023], PyTorch LoRA implementations, and multi-adapter serving frameworks. No access to gradients or training data is needed, but only the base and fine-tuned checkpoints.

3.3 Energy-Based Analysis

In low-rank matrix approximation, the *energy* of a matrix refers to the sum of the squares of its singular values, quantifying the total information content or signal present in the matrix. For a weight delta ΔW with singular values $\sigma_1, \sigma_2, \ldots \sigma_d$, we define the preserved energy at rank r as

$$E_r = \frac{\sum_{i=1}^{r} \sigma_i^2}{\sum_{i=1}^{d} \sigma_i^2}. \tag{5}$$

Intuitively, E_r measures what fraction of the "important" weight update is retained by the top-r singular directions. High preserved energy typically correlates with the adapter's ability to recover full-rank performance.

In Figure 1, we present the values of E_r as the rank parameter varies across three modalities and three Nova model sizes. We observe a consistent pattern: energy preservation improves with higher rank values, independent of modality or model size. Instead of exploring all possible ranks, this paper focuses on three representative settings, 32, 64, and 512, which correspond to low, medium, and high energy levels, respectively. This selection enables us to analyze the approach's performance under different energy conditions.

4 Experiments

4.1 Experimental Setup

We benchmark **PHLoRA** on three text only datasets, *TAT-QA* [Zhu et al., 2021], *Medical Knowledge from Extracts (MKFE)* [Owkin, 2024], *MedMCQA* [Pal et al., 2022]; one image and text dataset, *VQA-RAD* [Lau et al., 2018]; and one video and text dataset, *CaptionGen* [Chen and Dolan, 2011]. We sub-sample and reformat the datasets. See Table 2 for primary metrics, and Appendix A for detailed statistics. All experiments use the Nova model family.

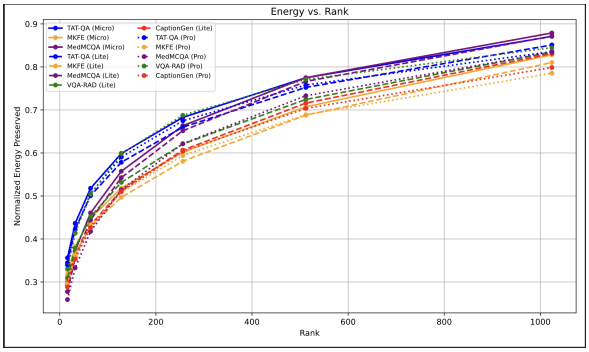

Figure 1: Preserved energy vs rank.

We compare: (i) the base model, (ii) the full-rank fine-tuned model, (iii) LoRA+ with rank 32, and (iv) PHLoRA with rank 32 (default) and 64 (see Section 4.3 for larger r). We use an evaluation prompt that does not specify formatting, which results in many formatting errors in the base model. Though the base model could be improved substantially with prompt optimization, our choice of prompts accentuates the effect of fine-tuning.

4.2 Results and Analysis

Table 3 reports test-set performance across all model sizes and benchmarks. For each task, we include one or two evaluation metrics (e.g., Accuracy / Exact Match), with the best score for each metric shown in **bold**. PHLoRA demonstrates consistency with full-rank fine-tuning across the Nova Micro, Lite, and Pro model families, often coming within 1% performance while occasionally even surpassing full-rank results.

On Nova Micro, full-rank leads on TAT-QA, but PHLoRA remains close and even surpasses it on MedMCQA, with only minor gaps on MKFE. On

Table 3: Test set results for Nova Micro (text-only), Lite, and Pro. Where two metrics are shown, the best per metric is **bolded**. The evaluation prompts do not provide formatting instructions, substantially increasing the difficulty of the task for the base model prior to fine-tuning.

Dataset (Metric)	Base Model	Full-Rank	LoRA+ (r32)	PHLoRA (r32)	PHLoRA (r64)
Nova Micro					
TAT–QA (Acc / Exact Match)	0 / 0	**84.95 / 51.68**	82.47 / 48.49	83.54 / 48.14	84.07 / 49.02
MKFE (Key Overlap / Val Overlap)	50.0 / 22.0	**100.0 / 28.0**	**100.0** / 26.75	99.0 / 27.75	99.0 / **28.0**

Nova Lite, PHLoRA (r64) delivers the best scores on TAT-QA, MedMCQA, VQA-RAD, and CaptionGen, which highlights its strength in reasoning and multimodal tasks. Nova Pro further demonstrates scalability: PHLoRA nearly matches full-rank on TAT-QA and outperforms it on MedMCQA and VQA-RAD, while it also remains competitive on CaptionGen. Overall, the margin between PHLoRA and full-rank shrinks as the Nova model scales, with PHLoRA often taking the lead.

Inference Cost and Latency. PHLoRA, when merged into the backbone ("m-packed" as in S-LoRA [Sheng et al., 2024]), is computationally equivalent to full-rank and merged LoRA inference for a single adapter or task. All three approaches require only a single matrix multiplication per layer. For scalable multi-adapter deployment, we estimate cost and throughput improvements using S-LoRA-like dynamic routing [Sheng et al., 2024], which achieves up to 4× higher throughput and cost efficiency than naive dynamic LoRA serving (e.g., PEFT or vLLM) in multi-tenant settings, as shown in Table 3 and Figure 4 of S-LoRA. These reference results provide a strong indication that PHLoRA, when paired with S-LoRA-like serving, is highly cost-effective for scalable, multi-user inference scenarios.[2]

4.3 Ablation: Rank and Energy Preservation

We vary the PHLoRA rank (from 32 to 512) and report preserved energy E_r (as defined in Equation 5). The results across all three Nova model sizes (Micro, Lite, Pro) are presented in Tables 4, 5, and 6, where each table reports test-set scores alongside preserved energy (E_r, %) for different PHLoRA ranks and the full-rank reference.

Across all three Nova model scales (Micro, Lite, Pro), PHLoRA rank shows a clear correlation between preserved energy (E_r) and downstream task performance. Higher ranks consistently recover full-rank accuracy, while lower ranks maintain strong results with considerable efficiency gains. For Nova Micro (text-only), performance is stable across ranks, with r512 closely matching or slightly exceeding full-rank metrics on MedMCQA. In Nova Lite (multimodal), intermediate ranks such as r64 achieve performance comparable to or better than full-rank on tasks like VQA-RAD and CaptionGen. Similarly, in Nova Pro, r32 and r64 occasionally surpass full-rank scores, particularly in multimodal settings, though MKFE value overlap metrics appear more sensitive to rank and do not always improve with higher E_r. Overall, higher PHLoRA ranks reliably recover accuracy, while intermediate ranks can offer a strong balance between efficiency and performance across different model sizes and tasks.

5 Conclusion

We presented PHLoRA, a practical post-hoc method for deriving LoRA-compatible adapters directly from fully fine-tuned models, without requiring access to training data or gradients. Our experiments focused on three modalities—text, image,

[2]We use "S-LoRA-like" to refer to any scalable, dynamic multi-adapter LoRA serving implementation; S-LoRA [Sheng et al., 2024] is used as a reference.

Table 4: Ablation study for Nova Micro (text-only). We show one or two evaluation metrics, with the best score for each metric shown in **bold** and E_r (preserved energy, %) for PHLoRA in parentheses.

Dataset (Metric)	Full-Rank	PHLoRA (r32)	PHLoRA (r64)	PHLoRA (r512)
TAT–QA (Accuracy / EM)	**84.96 / 51.68**	83.54 / 48.14 (44)	84.07 / 49.03 (52)	**84.96** / 51.15 (77)
MKFE (Key Overlap / Value Overlap)	**100.0** / 28.0	99.0 / 27.75 (38)	99.0 / 28.0 (45)	**100.0 / 28.75** (71)
MedMCQA (Accuracy / F1)	60.49 / 60.52	60.79 / 60.85 (37)	60.60 / 60.63 (46)	**60.93 / 60.94** (78)

Table 5: Ablation study for Nova Lite (text, image, video). We show one or two evaluation metrics, with the best score for each metric shown in **bold** and E_r (preserved energy, %) for PHLoRA in parentheses.

Dataset (Metric)	Full-Rank	PHLoRA (r32)	PHLoRA (r64)	PHLoRA (r512)
TAT–QA (Accuracy / EM)	83.89 / 48.45	85.84 / 52.39 (42)	86.02 / 53.45 (49)	**86.90 / 55.58** (74)
MKFE (Key Overlap / Value Overlap)	**99.50** / 22.75	**99.50 / 26.50** (36)	**99.50** / 26.00 (42)	99.0 / 24.75 (68)
MedMCQA (Accuracy / F1)	63.40 / 63.33	64.11 / 64.07 (35)	**64.30 / 64.25** (44)	63.83 / 63.77 (76)
VQA–RAD (Similarity)	54.87	58.57 (37)	**57.56** (45)	55.01 (71)
CaptionGen (ROUGE_L / CIDEr)	49.40 / 1.43	49.19 / **1.51** (36)	49.43 / 1.50 (43)	**49.84** / 1.50 (71)

and video—using three Amazon Nova [AGI, 2024] models and five moderate-sized benchmarks, all in the supervised fine-tuning (SFT) setting. PHLoRA maintains competitive task accuracy while reducing inference GPU-hour costs by up to 4-fold compared to merged adapter inference, and by a similar or greater margin compared to full-rank model inference, in dynamic multi-adapter routing scenarios such as S-LoRA. This cost reduction reflects improvements in inference throughput, i.e., the number of tokens or requests processed per unit time, as demonstrated in S-LoRA [Sheng et al., 2024].

PHLoRA provides a practical path for making all existing full-rank checkpoints adapter-ready, democratizing scalable inference for legacy models.

6 Future Work

Several avenues remain for future research:

- **Scaling to Larger and More Diverse Tasks:** Our current experiments are limited to moderate-sized SFT datasets. Future work should evaluate PHLoRA on larger-scale, more challenging benchmarks and additional modalities.
- **Advanced Tuning Strategies:** Extending PHLoRA to support advanced fine-tuning techniques such as DPO, PPO, or reward-based learning.
- **Extending Beyond Linear Layers:** While LoRA has been generalized to convolutions [Zhong et al., 2024], post-hoc SVD-based extraction for higher-order tensors requires further research, potentially leveraging advanced tensor decompositions [Kolda and Bader, 2009] or alternative adapter parametrizations [Chen et al., 2023].
- **Rank Selection and Usability:** Further developing practical methods for adaptive, data-free, or black-box rank selection, and enabling adapter extraction even when the base model is unavailable.
- **Empirical data displaying inference efficiency improvements:** Our current experiments are limited to generation of LoRA adapters. Future work should evaluate the empirical data displaying inference efficiency improvement with the generated adapters.

Limitations

While **PHLoRA** offers a simple and effective post-hoc mechanism for adapter extraction, it comes with several important limitations.

PHLoRA is currently designed for standard linear (matrix-shaped) layers, as it relies on singular value decomposition (SVD) to extract low-rank adapters from weight differences. While LoRA and similar adapters have been extended to convolutional layers — either via kernel reshaping or structured convolutional approximations (e.g., [Zhong et al., 2024]), post-hoc SVD extraction for convolutions or other higher-order tensors is non-trivial and depends on the decomposition or flattening strategy, which may lose spatial structure or interpretability. More generally, advanced tensor decompositions [Kolda and Bader, 2009] or alternative adapter parametrizations [Chen et al., 2023] would be required for such modules, which we leave to future work. Note also that attention

Table 6: Ablation study for Nova Pro (text, image, video). We show one or two evaluation metrics, with the best score for each metric shown in **bold** and E_r (preserved energy, %) for PHLoRA in parentheses.

Dataset (Metric)	Full-Rank	PHLoRA (r32)	PHLoRA (r64)	PHLoRA (r512)
TAT–QA (Accuracy / EM)	**89.38** / **62.48**	87.96 / 55.22 (42)	89.0 / 58.0 (50)	89.0 / 61.0 (75)
MKFE (Key Overlap / Value Overlap)	99.50 / 24.75	**100.0** / 24.00 (36)	**100.0** / **25.0** (43)	50.0 / 23.0 (68)
MedMCQA (Accuracy / F1)	69.4 / 69.42	**70.0** / **70.0** (35)	**70.0** / **70.0** (41)	**70.0** / 69.70 (73)
VQA–RAD (Similarity)	56.20	**57.58** (41)	56.92 (50)	57.07 (77)
CaptionGen (ROUGE_L / CIDEr)	**48.94** / 1.37	48.55 / 1.45 (35)	48.85 / **1.48** (42)	48.87 / 1.39 (70)

"caches" refer to runtime data, not persistent parameters, and so are out of scope for PHLoRA.

In this paper, we fix the adapter rank r globally for all layers. Although we analyze energy-based rank selection, adaptive or per-layer rank scheduling—which could further improve the efficiency/accuracy tradeoff—remains for future work. Furthermore, while the preserved energy metric (E_r) is a useful indicator of information retention at a given rank, model quality on the target task does not always correlate perfectly with energy preservation. Thus, optimal adapter rank cannot be reliably selected solely from energy curves; empirical evaluation remains necessary.

PHLoRA assumes access to both base and fully fine-tuned weights. In settings where only the fine-tuned model is available (e.g., closed-source vendors), post-hoc adapter extraction is not directly possible.

The principal benefits of PHLoRA are realized in dynamic inference scenarios (e.g., S-LoRA or multi-adapter routing), where multiple adapters are loaded or swapped at runtime. In conventional merged-inference pipelines—where a single adapter is fused into the model for all requests—the practical advantage of post-hoc extraction is diminished, as cost and latency resemble standard LoRA or full-rank fine-tuning.

Our evaluation is limited to a set of public text, image, and video benchmarks. Results may differ for larger, more diverse real-world applications. While PHLoRA enables substantial inference cost reductions with dynamic adapter routing, there remains a modest runtime latency penalty versus full-rank merging; practical savings will depend on system-level batch sizes and workload characteristics.

We encourage future work to address these limitations by extending PHLoRA to non-linear modules, developing robust energy-aware or data-free rank selection strategies, enabling black-box or partial-weight extraction, and improving dynamic adapter composition schemes.

A Dataset Descriptions

We provide summary statistics and descriptions for each benchmark used in this study.

- **TAT-QA** [Zhu et al., 2021]: A table-augmented question answering dataset in the financial domain, requiring models to reason over both natural language and tabular data. *Train:* 2,830; *Test:* 565. License: MIT. Evaluated using Accuracy and Exact Match.
- **MKFE** [Owkin, 2024]: Medical Knowledge from Extracts. Evaluates the ability to extract structured key-value medical facts from unstructured text. *Key Overlap* measures the proportion of gold-standard keys correctly predicted; *Value Overlap* measures the fraction of correct values among matched keys. *Train:* 1,000; *Test:* 200. License: Apache 2.0.

- **MedMCQA** [Pal et al., 2022]: A large-scale medical multiple-choice question answering dataset. *Train:* 20,000; *Test:* 3,683. License: MIT. Evaluated using Accuracy and F1.
- **VQA-RAD** [Lau et al., 2018]: Visual question answering over radiology images, requiring both visual and textual understanding. *Train:* 1,793; *Test:* 451. License: CC0 1.0 Universal. Evaluated by average normalized similarity.
- **CaptionGen**: A video captioning benchmark with 2,000 training and 500 test examples. Videos are sourced from MSVD [Chen and Dolan, 2011]; captions are from the Multi-Source Video Captioning dataset [DAMO-NLP-SG]. License: MIT. Evaluated using ROUGE_L and CIDEr.

B Implementation Details

Hardware. All experiments were performed on AWS P5.48xlarge instances, each equipped with 8×NVIDIA H100 80GB GPUs. Post-hoc LoRA adapter extraction and energy analysis steps were also executed on the same hardware.

Fine-tuning Hyperparameters. We used the AdamW optimizer (β_1=0.9, β_2=0.999), a learning rate of 1×10^{-5}, batch size 32, and trained for 2 epochs.

LoRA+ Training Hyperparameters.

- **Nova Micro:** Learning rate 1×10^{-5}, `loraplus_lr_ratio` 16.0, rank $r = 32$, $\alpha = 128$, `lora_dropout` 0.01, `target_modules = [attention_qkv, attention_dense, mlp_fc1, mlp_fc2]`.
- **Nova Lite/Pro:** Learning rate 1×10^{-5}, `loraplus_lr_ratio` 8.0, rank $r = 32$, $\alpha = 32$, `lora_dropout` 0.01, `target_modules = [attention_qkv, attention_dense, mlp_fc1, mlp_fc2]`.

PHLoRA Extraction. SVD was performed per linear layer using PyTorch's `torch.linalg.svd`. The default low-rank approximation used rank $r = 32$, with ablations at ranks $r = 64$ and $r = 512$.

Energy Plots. Energy preserved at rank r, E_r, was calculated as in Equation 5.

C Reproducibility Checklist

- **Random seeds:** Fixed to 42.

D Optimality of SVD for Low-Rank Adapter Extraction

Given any real matrix $\Delta W \in \mathbb{R}^{m \times n}$, the Eckart–Young–Mirsky theorem [Eckart and Young, 1936] states that the rank-r matrix $\hat{W}_r = U_r \Sigma_r V_r^\top$ (where U_r, Σ_r, V_r are the top r components from the SVD of ΔW) uniquely minimizes the Frobenius norm $\|\Delta W - \hat{W}_r\|_F$ over all matrices of rank at most r.

To see this, let $\Delta W = U \Sigma V^\top$ be the full SVD, with singular values $\sigma_1 \geq \sigma_2 \geq \cdots \geq \sigma_{\min(m,n)}$. The truncated approximation is

$$\hat{W}_r = \sum_{i=1}^{r} \sigma_i u_i v_i^\top,$$

and satisfies

$$\|\Delta W - \hat{W}_r\|_F^2 = \sum_{i=r+1}^{\min(m,n)} \sigma_i^2.$$

Therefore, by setting $A = U_r \operatorname{diag}(\sqrt{\Sigma_r})$ and $B = \operatorname{diag}(\sqrt{\Sigma_r}) V_r^\top$, as in PHLoRA, $AB = \hat{W}_r$ is the best rank-r LoRA update (minimizing Frobenius error).

For more details, see [Eckart and Young, 1936, Golub and Loan, 2013].

Harmonious Minds: Benchmarking Intertwined Reasoning of Human Personality and Musical Preference

Sayantan Pal, Souvik Das[†], Rohini K. Srihari

Department of Computer Science and Engineering,
State University of New York at Buffalo
[†]JPMorgan Chase & Co.[*]

Abstract

Understanding how large language models (LLMs) reason across semantically distinct domains remains an open challenge. In this work, we investigate whether LLMs can connect personality traits to musical preferences, specifically chord progressions. Drawing on psychological theory and symbolic music structure, we introduce a novel benchmark that evaluates two interdependent tasks: (1) inferring personality traits from a textual context and (2) selecting a musically appropriate chord progression aligned with the inferred trait. We release a synthetic, expert-guided dataset grounded in Cattell's 16 Personality Factors (PF16), genre-conditioned chord structures, and diverse situational contexts. We explore multiple learning strategies, including fine-tuning task-specific corpora, model merging with LoRA adapters, and advanced prompt-based reasoning techniques such as verbalization. Additionally, we propose a teacher-student framework to evaluate the quality of model-generated explanations using a five-dimensional rubric. Our findings show that verbalization outperforms standard reasoning methods, achieving up to 11% improvement over zero-shot baselines.

1 Introduction

Music is more than just entertainment; it is often an emotional extension of the self, subtly reflecting our moods, values, and personalities (Juslin, 2010; Flannery and Woolhouse, 2021; Chamorro-Premuzic and Furnham, 2007; Ferwerda et al., 2017). Across cultures, the music people enjoy and create provides a window into who they are, offering insights into their internal worlds. In recent years, conversational AI has seen a surge of interest in simulating human-like personas using datasets such as Persona Chat (PC) (Zhang et al., 2018) and Blended Skill Talk (BST) (Smith et al., 2020). These efforts have been further extended by creating a Synthetic Persona Chat (SPC) (Jandaghi et al., 2024) dataset, which generates artificial profiles to diversify persona-driven dialogue. Parallel to this, newer datasets like Journal Intensive Conversations (JIC) (Pal et al., 2025) aim to capture more intrinsic personality traits by grounding conversations in long-form, autobiographical texts. While such datasets have improved the personalization capabilities of large language models (LLMs) (Kasahara et al., 2022), they are primarily confined to understanding personality within the dialogue domain. What remains underexplored is whether LLMs can reason across domains (Simon et al., 2022; Akyürek et al., 2023), particularly in capturing the connection between personality traits (Mazaré et al., 2018; Lee et al., 2025) and musical preferences. *We hypothesize that the music individuals resonate with is not a random choice but a psychologically grounded expression*

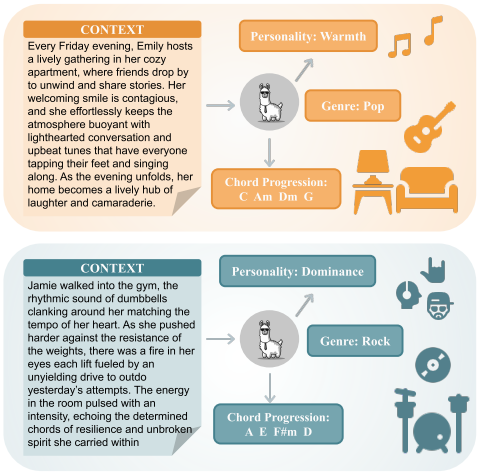

Figure 1: Illustrating our benchmark's core idea: *Can language models link personality traits to musical structures?* Given a context, the model infers personality and selects a matching genre and chord progression, reflecting distinct creative preferences.

[*]This work is independent research and does not involve JPMorgan Chase & Co.

of who they are. For instance, highly extroverted individuals may gravitate toward energetic genres like rock or hip-hop, while more introspective personalities may find alignment with genres such as jazz or pop. This connection is intuitive and supported by decades of psychological literature (Chamorro-Premuzic and Furnham, 2007; Ferwerda et al., 2017), yet remains largely untested in computational models. This raises important questions about whether LLMs can reason consistently when connecting personality traits to other domains like music, a low-resource domain with symbolic structure and limited textual data (Huang and Yang, 2020).

Personality refers to the characteristic patterns of thoughts, emotions, and behaviors that define how individuals perceive and interact with the world (Mairesse et al., 2007; McCrae and Costa Jr., 1999; Sanchez-Roige et al., 2018). In psychology, several models have been proposed to represent personality traits, including the Big Five (OCEAN (Hurtz and Donovan, 2000; Azucar et al., 2018)), the Myers-Briggs Type Indicator (MBTI)(Cohen et al., 2013), and Raymond Cattell's 16 Personality Factors (PF16) (Cattell and P. Cattell, 1995). On the other hand, chord progression in music theory refers to a sequence of chords that forms the harmonic foundation of a musical piece (Cho et al., 2016; Kawase, 2024). Different progressions evoke distinct emotional tones and are often linked to particular genres, moods, or artistic styles (Bakker and Martin, 2015). Music theory and chord reasoning are relatively low-resource and underrepresented in mainstream LLM training corpora, making it difficult for models to generalize across these modalities (Yuan et al., 2024). Understanding how LLMs interpret the relationship between personality traits and musical inclinations can open new possibilities for personalized content generation (Wang et al., 2024), human-centered creative tools (Spangher et al., 2025), and emotionally aware recommendation systems (Lyu et al., 2024). Addressing this cross-domain reasoning challenge is a step forward in improving LLM capabilities and is crucial for building AI that reflects the interconnectedness of human cognition, creativity, and identity.

The relationship between personality and music is not just theoretical; it is often explicitly articulated by artists when reflecting on their creative process. For example, Taylor Swift breaks down "Blank Space"[1], she explains how the song responds to the media's exaggerated portrayal of her dating life, crafting a fictionalized character based on public perception. Similarly, Charlie Puth breaks down "Attention"[2], describing how it evolved from a piano ballad into a layered pop track reflecting his emotional state and artistic confidence. He emphasizes his production choices, such as using acoustic guitar rhythms, vinyl textures, and deliberate drops as extensions of his personal identity and emotional landscape. Billie Eilish and Finneas, in their deconstruction of "Bad Guy"[3], highlight their spontaneous, personal approach to sound design, incorporating chaotic sonic quirks that mirror their creative personalities. These examples suggest that musical composition often encodes deeper personality traits and emotional intentions. This motivates our central question as shown in Figure 1: Can large language models, which perform well in dialogue personalization, also reason across domains to connect personality with musical structure?

In this work, (1) we release a **novel benchmark** that evaluates whether large language models can **reason across domains** by aligning personality traits with musical structure. (2) Our benchmark is designed with a **modular construction methodology**, allowing extensibility to more challenging variants. (3) We explore two key training strategies: **personality-grounded fine-tuning** and **joint adaptation across both tasks**. (4) To improve performance without training, we propose a **verbalization-based inference pipeline** that dynamically guides chord selection, yielding a consistent **11% improvement** over zero-shot baselines. (5) Finally, we introduce a **thinking evaluation protocol** to assess reasoning quality through **teacher-rated justifications**, enabling evaluation beyond output correctness. Our code and data is publicly available.[4]

2 Related Work

Personality Grounding in Conversational LLMs. Understanding and generating persona-consistent responses has been a long-standing goal in dialogue systems (Liu et al., 2016; Caron and Srivastava, 2023; Saha et al., 2022). Early approaches (Yamashita et al., 2023; Zhang et al., 2018) such

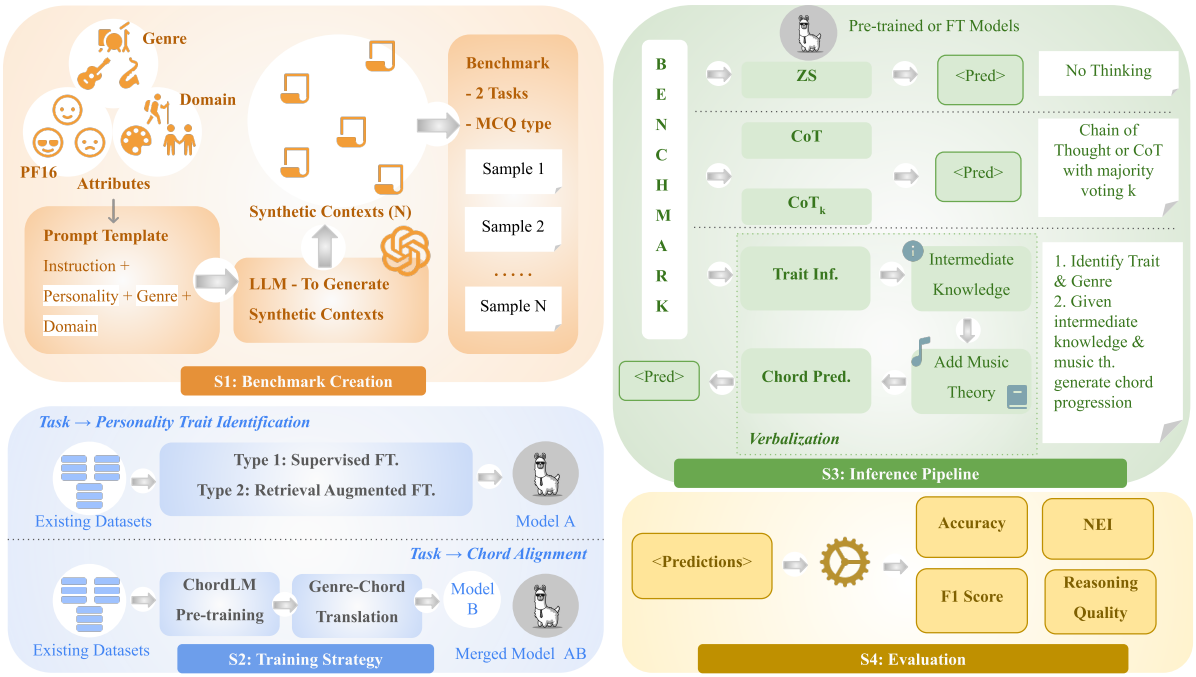

Figure 2: Overview of our benchmark design and methodology. **S1: Benchmark Creation**- We generate synthetic contexts using PF16 traits, genres, and domains as prompts, forming two multiple-choice tasks per sample. **S2: Training Strategy**- Task 1 models are trained on existing dialogue datasets, while Task 2 uses chord pretraining and genre-conditioned generation. **S3: Inference Pipeline**- We evaluate models under zero-shot, CoT, and verbalized prompting strategies. Verbalization chains trait inference and music theory to guide chord generation. **S4: Evaluation**- Outputs are assessed using Accuracy, F1, NEI, and reasoning quality.

as PersonaChat (Zhang et al., 2018) and Blended-SkillTalk (Smith et al., 2020) used manually authored or template-based persona attributes to drive more faithful conversations (Dušek and Jurčíček, 2016). Synthetic extensions like SPC (Jandaghi et al., 2024) diversified persona representation, while Journal Intensive Conversations (JIC) (Pal et al., 2025) introduced free-form autobiographical grounding to capture more nuanced traits. Beyond static attributes, recent research has explored integrating psychological theories such as the Big Five (OCEAN) (Azucar et al., 2018; Hurtz and Donovan, 2000) and PF16 (Cattell and P. Cattell, 1995) to enrich modeling of personality in LLMs. While fine-tuning LLMs on personalized data has led to more trait-aligned generations (Labruna et al., 2024; Pal et al., 2024), most work focuses exclusively on dialogue settings, without examining if such personalization can extend to semantically distant domains like music.

Language Models for Symbolic Music Understanding. Recent works (Copet et al., 2023) have explored LLM capabilities in music composition and understanding, primarily through symbolic representations such as chord labels or textual scores. ChatMusician (Yuan et al., 2024) introduced a large-scale dataset and training framework for music-related dialogue tasks, while Chordonomicon (Kantarelis et al., 2024) compiled a genre-specific chord progression database aimed at symbolic pattern learning. Models like MusicTransformer (Huang et al., 2018) and MusicNet (Thickstun et al., 2017) have focused on sequence modeling in music but often rely on specialized musical representations or piano-roll formats. In contrast, our work focuses on the textual reasoning behind chord choices, leveraging symbolic descriptors grounded in genre and personality. Unlike prior approaches that focus on chord generation or genre classification, we pose chord selection as a cross-domain reasoning task, situated at the intersection of psychological and creative semantics.

3 Personality-Music Alignment Bench (PMAB)

3.1 Motivation and Novelty

Recent advances in personalized dialogue and creative language generation have treated these domains separately. Yet, real-world reasoning is rarely so isolated. Our benchmark takes a first

step toward evaluating whether LLMs can connect personality traits expressed through language with corresponding musical choices like chord progressions. It challenges models to carry intent across symbolically and semantically distinct domains without training, supervision, or domain-specific fine-tuning. Designed purely for evaluation, this two-stage task tests how well LLMs generalize and align outputs across contexts that demand interpretation and creativity. Figure 2 outlines the overview of our benchmark design and methodology.

3.2 PMAB Design: Annotation, Terminology, and Mapping Strategy

Personality Trait Framework. We adopt Cattell's 16 Personality Factor (PF16) model[5] to represent fine-grained human traits across both ends of a bipolar scale. Each trait includes a high and low pole, capturing variations in behavior and emotional disposition. For instance, the trait *Warmth* spans from descriptors like "outgoing" and "participating" to "reserved" and "aloof."

Genre Alignment via Expert-Led Mapping. To connect personality traits to musical preferences, we curated a genre inventory consisting of 19 categories (Apdx. Table 8). Using GPT-4o under the guidance of psychology and music experts, we annotated each PF16 trait with *alike genres* (those resonating with the trait) and *different genres* (those misaligned). For example, high scorers on *Warmth* were mapped to genres like *Pop*, *Country*, and *Gospel*, reflecting expressive and socially oriented aesthetics. Conversely, low scorers were aligned with introspective or emotionally distant genres like *Rock*, *Electronic*, and *Metal*. These mappings form the backbone of our benchmark's trait-to-genre reasoning tasks and are detailed in Apdx. Table 9.

Chord Progression Design. To support musically grounded inference, we sourced chord progressions from the Chordonomicon dataset (Kantarelis et al., 2024), a structured repository of genre-labeled chord progression patterns. For each genre, we selected 10 most representative progressions based on the frequency and stylistic fit. These were then reviewed by musicians to ensure genre authenticity. A subset of 5 genres with 4 representative progressions each is presented in Apdx. Table 10, along with associated danceability and mood characteristics. This mapping enables precise chord inference aligned with inferred personality and genre labels.

Algorithm 1 Synthetic Context Generation for Personality-Music Benchmark

Input: PF16 trait key t, trait-to-genre mapping $\mathcal{G}$, domain set $\mathcal{D}$ with subdomains, descriptor set $\mathcal{H}_t$ (high polarity), sampling parameter K
Initialize: GPT-4o as context generator $\mathcal{M}$
Create two descriptor subsets: $\mathcal{H}_1, \mathcal{H}_2$ from $\mathcal{H}_t$ with $|\mathcal{H}_i| = 3$
for each domain $d \in \mathcal{D}$ **do**
  for each subdomain $s \in d$ **do**
    for each genre $g \in \mathcal{G}(t)$ **do**
      for each descriptor set $\mathcal{H}_i \in \{\mathcal{H}_1, \mathcal{H}_2\}$ **do**
        Generate K candidate contexts $\{c_1, c_2, \ldots, c_K\}$ using GPT-4o given prompt $(\mathcal{H}_i, g, d, s)$
        Use GPT-4o to select the most diverse and representative context $c^* = \arg\max_{c_k} \texttt{representativeness}(c_k)$
        Append context c^* to dataset $\mathcal{C}$
      end for
    end for
  end for
end for
Output: Synthetic context set $\mathcal{C}$ grounded in PF16 traits, musical genres, and domain diversity

Synthetic Domain and Subdomain Construction. To ensure wide topical coverage and contextual variability, we constructed 10 high-level domains (e.g., *Personal Development*, *Creative Expression*), each with 3 coherent subdomains. These were generated using GPT-4o with prompt templates encouraging socio-cognitive realism, emotional nuance, and stylistic diversity (Apdx. Table 11). Our method is inspired by the prompt diversification approach of the TÜLU dataset[6] from AllenAI, which showed that structured instruction generation improves coverage and generalization. This design simulates real-world contexts where personality traits manifest through narrative, behavior, and preference.

3.3 Synthetic Context and PMAB Construction

Context Generation. We generate compact, fictional scenarios that implicitly reflect specific personality traits and musical preferences. Each scenario is conditioned on: (i) a PF16 trait t, (ii) a descriptor subset $\mathcal{H}_t$, (iii) a genre g aligned with the trait, and (iv) a domain-subdomain pair (d, s). A generation model $\mathcal{M}$ (GPT-4o) receives the prompt:

$$\mathcal{P} = \texttt{prompt}(\mathcal{H}_t, g, d, s),$$

and generates K narrative candidates $\{c_1, \ldots, c_K\} = \mathcal{M}(\mathcal{P})$. The final context c^* is selected as:

$$c^* = \arg\max_{c_k} \texttt{representativeness}(c_k),$$

[5] Wiki-16PF-Questionnaire

[6] Tulu-v2-sft-mixture

Algorithm 2 Final Benchmark Construction for Personality-Music Alignment

Input: Generated contexts $\mathcal{C}$, PF16 types $\mathcal{T}$, chord progression map $\mathcal{M}$, embedding model $\mathcal{E}$
Output: Flat benchmark dataset $\mathcal{B}$ with dual-task annotations
Compute context embeddings $\mathcal{E}(\mathcal{C})$
Build descriptor pool $\mathcal{D}$ from all PF16 trait descriptors (high + low)
Compute descriptor embeddings $\mathcal{E}(\mathcal{D})$
for each context $c \in \mathcal{C}$ **do**
  // Task 1: Personality Identification
  Select correct descriptor $d_{gt} \in c[\texttt{high}]$
  Exclude descriptors belonging to the same PF16 type
  Select 3 distractors d_i with lowest cosine similarity to $\mathcal{E}(c)$
  Shuffle correct option with distractors to form Task 1 choices
  // Task 2: Chord Progression Matching
  Select genre $g = c[\texttt{alike_genre}]$
  Choose one correct progression from $\mathcal{M}[g]$
  Choose 3 distractors from other genres in $\mathcal{M}$
  Shuffle correct option with distractors to form Task 2 choices
  Append entry to benchmark $\mathcal{B}$ with:
  context, domain, subdomain, PF16 type, genre,
  Task 1: question, options, correct label
  Task 2: question, options, correct label
end for
Return benchmark dataset $\mathcal{B}$

ensuring trait expressivity and musical alignment. Further details are provided in Algorithm 1 and Appendix A.1.

Benchmark Tasks. Each context is converted into two multiple-choice tasks: *(1) Personality Trait Identification* and *(2) Chord Progression Matching*. Both follow a 1-correct, 3-distractor format. Distractors for Task 1 are selected based on semantic distance in embedding space, while Task 2 distractors are sampled from genres unrelated to the aligned one. Algorithm 2 provides the full construction pipeline.

Modularity and Extensibility. The benchmark is designed to support harder variants: distractors can be made more semantically similar, genre-chord mappings can be made noisier, or new context types can be added. This modular design allows the benchmark to scale in complexity, enabling a more nuanced evaluation of cross-domain reasoning.

3.4 Quality Control and Evaluation Attributes

Automated Filtering during Context Generation. As part of the generation process, we sample $K = 1$ to 3 candidate contexts per configuration and retain the most representative sample, as selected by GPT-4o based on a diversity and relevance prompt. This initial filtering ensures each retained scenario reflects its intended personality-musical alignment.

Human and Model-Based Evaluation. To further verify quality, we randomly select 20 contexts per PF16 trait and 3 human judges and GPT-4o evaluate them across five qualitative dimensions: *personality alignment*, *musical coherence*, *naturalness*, *implicitness*, and *specificity*. Each context is rated independently by three expert annotators and GPT-4o. Appendix A.3 defines each evaluation dimension, and Table 12 has the mean and SD of the evaluation.

Reliability and Qualitative Evidence. Inter-rater reliability is assessed using Intraclass Correlation Coefficients (ICC), reported in Apdx. Table 13. Qualitative examples are included in Appendix A.2.

4 Benchmark Statistics

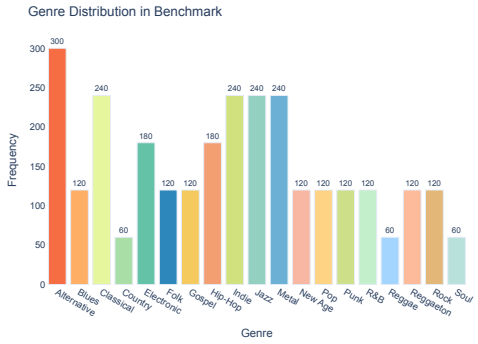

Figure 3: Genre distribution across the 2,880 benchmark contexts. Each bar represents the frequency of a genre used in the dataset. The genres are alphabetically sorted, and the distribution is designed to maintain stylistic and semantic diversity across personality-aligned contexts.

Our benchmark consists of a total of 2,880 context–question pairs. For each trait, we generate exactly 180 unique contexts, resulting in a balanced distribution across personality categories. The benchmark spans 10 high-level domains, each further subdivided into 3 subdomains. This leads to 288 data points per domain and 96 samples per subdomain, ensuring uniform representation across the entire context space.

In total, the benchmark covers 19 unique musical genres, with personality-genre mappings grounded in trait semantics and verified through expert feedback. We measure the diversity of the dataset using the number of unique categories and Shannon entropy for both personality traits and genres, summarized in Table 1. Genre distribution across the benchmark is visualized in the bar chart in Figure 3.

5 Experimentation

5.1 Training Strategy

We fine-tune both benchmark tasks using parameter-efficient fine-tuning (PEFT) with Low-Rank Adaptation (LoRA) (Hu et al., 2022) on

Table 1: Benchmark Composition and Diversity Statistics

Attribute	Unique Values	Entropy
Total contexts	2,880	–
Personality traits	16	2.773
Musical genres	19	2.844
Domains	10	–
Subdomains per domain	3	–

LLaMA 3 8B (AI@Meta, 2024) and Mistral 7B v0.3 (Jiang et al., 2023). Only the projection layers (W_q, W_k, W_v, W_o) are updated while all other weights remain frozen.

Let $\mathcal{D}^{(1)}_{\text{train}}$ and $\mathcal{D}^{(2)}_{\text{train}}$ denote the training sets for Task 1 (T1) and Task 2 (T2), respectively. The general training objective is to minimize the negative log-likelihood (NLL) loss:

$$\mathcal{L}_{\text{task}}(\theta) = -\frac{1}{|\mathcal{D}|} \sum_{(x,y)\in\mathcal{D}} \log p(y|x;\theta),$$

where x is the input (e.g., context, genre, or chord prefix) and y is the target label.

LoRA Optimization. Each attention projection matrix is updated using low-rank decomposition:

$$W'_q = W_q + A_q B_q, \quad A_q \in \mathbb{R}^{d\times r}, \quad B_q \in \mathbb{R}^{r\times d},$$

with r as the rank hyperparameter. The same applies to W_k, W_v, and W_o.

T1: Personality Trait Identification. We fine-tune both models using multiple dialogue-style datasets annotated with personality traits: PC, BST, SPC, and JIC following the strategy by (Pal et al., 2025). These datasets help models capture a wide range of personality-grounded linguistic cues. See Appendix B.1.1 for dataset statistics.

T2: Chord Alignment and Adapter Merging. For Task 2, we first pre-train a chord-focused language model on sequences from Chordonomicon, followed by genre-conditioned chord generation. We additionally perform inverse modeling to predict genre from chord sequences. Finally, we merge the personality and chord adapters using SVD-based LoRA merging from the PEFT library, enabling joint reasoning over dialogue and symbolic music. Detailed strategy, implementation, and training configurations are provided in Appendix B.1.

5.2 Inference Pipeline

We evaluate models under three setups: **(1) Zero-shot prompting**, and **(2) Guided prompting strategies**.

(1) Zero-shot Prompting. Given a context x, we prepend a task description and present four candidate options. The model selects the most probable output without training. This serves as our baseline. Additionally, we use the fine-tuned adapter $\mathcal{M}_{\text{JIC}}$ for Task 1 and a merged model $\mathcal{M}_{\text{SVD}}$ for Task 2. Outputs are compared to gold labels using classification metrics.

(2) Guided Prompting. To improve reasoning, we use structured prompting methods inspired by chain-of-thought (CoT) and staged inference.

(A) CoT Prompting. The model is encouraged to reason step by step using a modified prompt to think step by step.

(B) Ensemble CoT. We sample $k = 5$ completions $\{y_1, ..., y_k\}$ and take the majority vote:

$$\hat{y} = \texttt{mode}\{y_1, y_2, ..., y_k\}.$$

(C) Verbalization Pipeline (Task 2). This is our key reasoning enhancement method. We introduce a two-step prompt chaining approach to align personality traits with genres and then map those genres to suitable chords using music theory.

Step 1: Trait → Genre Reasoning. Given a context x, we prompt the model to infer the dominant trait and its associated genres using a structured prompt $\mathcal{P}_{\text{genre}}$:

$$\hat{g} = \mathcal{M}_{\text{verbal}}(\mathcal{P}_{\text{genre}}(x))$$

Step 2: Genre → Chord Reasoning with Music Theory. The next prompt $\mathcal{P}_{\text{chord}}$ is conditioned on the context x, predicted genre $\hat{g}$, and corresponding music theory explanation $\mu(\hat{g})$. The model generates a rationale and selects a suitable chord progression:

$$\hat{y} = \mathcal{M}_{\text{verbal}}(\mathcal{P}_{\text{chord}}(x, \hat{g}, \mu(\hat{g})))$$

The final prediction is extracted from the generated response using answer tags. Prompt formats are detailed in Appendix B.2.1.

5.3 Evaluation Strategy

Task-Level Performance Metrics. We evaluate both benchmark tasks using standard classification metrics: accuracy (Acc) and macro-averaged F1 score (F1). In addition, we report the *Not Enough Information* (NEI) count, which reflects model responses that are vague, contradictory, or insufficiently grounded in context. NEI is triggered when the model fails to select a valid option.

Reasoning Quality Assessment. To assess deeper model understanding, we evaluate reasoning quality for Task 2 on randomly selected 500 samples. For each model, we prompt a teacher model (GPT-4o) to generate ideal responses based on the correct chord label. The student model's explanation is then rated on a 1–5 Likert scale across five dimensions: *Personality-Musical Alignment (PMA)*, *Chordal Appropriateness (CA)*, *Causal Justification (CJ)*, *Specificity (S)*, and *Fluency and Clarity (F)*. Definitions of these dimensions and the full scoring rubric are provided in Appendix C.1. We report both the mean score and the percentage of high-quality responses (score ≥ 4) for each dimension.

Benchmark Validity. To validate Task 1, we compare model performance against the LM Evaluation Harness[7] OCEAN benchmark.

6 Results and Discussion

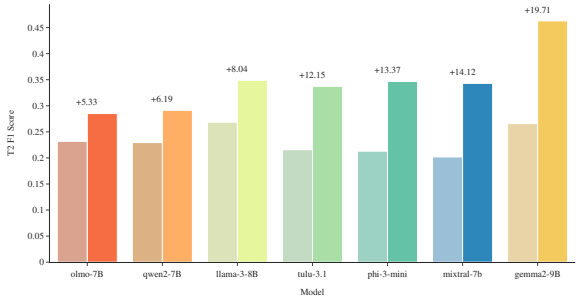

Figure 4: Task 2 F1 scores for baseline and verbalized setups across models, sorted by improvement.

Model	T2 F1 (B)	T2 F1 (V)	%Imp.
phi-3-mini	0.2129	0.3466	13.37
mixtral-7b	0.2018	0.3430	14.12
llama3-8B	0.2685	0.3489	8.04
tulu3.1-8B	0.2157	0.3372	12.15
qwen2-7B	0.2294	0.2913	6.19
olmo2-7B	0.2318	0.2851	5.33
gemma2-9B	0.2657	0.4628	**19.71**

Table 2: Comparison of Task 2 F1 scores between zero-shot baseline (B) and verbalized prompting (V) for open-source models. Verbalization consistently improves performance, with largest gains seen in `gemma2-9B`. Detailed results of all tasks in Table 14

[7] https://github.com/EleutherAI/lm-evaluation-harness

6.1 Inference-Only Evaluation

We begin by analyzing model performance under inference-only settings, which include zero-shot prompting, chain-of-thought (CoT), majority-vote ensembles (CoT$_k$), and our verbalization pipeline. Table 2 reports performance across second task. Detailed results in Apdx. Table 14

Task 1 (Personality Trait Identification). Zero-shot prompting yields strong performance across models, with F1 scores consistently above 0.81. Surprisingly, CoT reasoning does not always help: models like `mistral`, `llama3` and `gemma2` see degraded F1 with CoT$_k$, indicating overthinking or drift in trait inference. The best-performing model in Task 1 is `gemma2-9b-it` (F1: 0.8988), followed by `llama-3-8Bb` (F1: 0.8620).

Task 2 (Chord Progression Alignment). In contrast to Task 1, the baseline F1 scores for Task 2 are significantly lower (ranging from 0.18–0.27), highlighting the inherent difficulty of musical reasoning. Here, CoT strategies offer only marginal improvements (1–3%) in most models. However, our **verbalization pipeline** consistently provides the largest gains, improving F1 by over **13%** on `phi-3`, `mixtral`, and `Tulu-3.1`, and over **19%** on `gemma2-9b-it`. This validates the importance of modular reasoning and staged prompt design in music-theoretic alignment tasks. Additional insights in Appendix D.1

Commercial Models. Closed-source models like `GPT-4.1` and `GPT-4o` outperform open models, with `GPT-4.1-mini` scoring highest on Task 1. For Task 2, performance improves with newer and larger models. Due to API cost, we report only zero-shot results for these systems.

Overall Insights. Verbalization consistently outperforms unguided reasoning strategies such as CoT and CoT$_k$ by explicitly chaining personality inference to genre selection and symbolic chord prediction. This structured, staged inference enables better control and alignment than generic prompting methods. Notably, `deepseek-llama3.1`, a model pretrained to "think" by design, outperforms its supervised counterpart (`Tulu-3.1`) in Task 2, highlighting that models trained for reflective reasoning inherently generalize better than those forced into such behavior via prompts alone.

Further, the pretrained capabilities of open-source models reveal strong variance. As shown

in Figure 4 and Table 2, base performance on Task 2 varies significantly. `Llama3` and `gemma2` start strong, whereas `phi-3` and `mistral` begin weaker. However, the gains from guided prompting are also uneven: models like `phi-3` and `mistral` achieve large improvements post-verbalization, sometimes even surpassing stronger baselines like `llama3`. Meanwhile, `gemma2` maintains top performance throughout, demonstrating both high base capability and strong responsiveness to verbalized guidance.

6.2 Impact of Fine-Tuning and Merged Models.

Among all supervised setups, fine-tuning on JIC provides the largest gains for Task 1, improving F1 scores by 1.4% (Mixtral) and 2.4% (LLaMA-3), consistent with trends from the LM Harness benchmark (Pal et al., 2025). However, merged models fail to yield meaningful improvements on Task 2, likely due to the dataset gap: symbolic chord alignment may require dialogue-style data where musical preferences are explicitly discussed (e.g., artist interviews). Notably, the verbalized inference variant (`Merged (V)`) still delivers the best Task 2 performance without fine-tuning, reaffirming the strength of prompt chaining. Detailed results in Table 15.

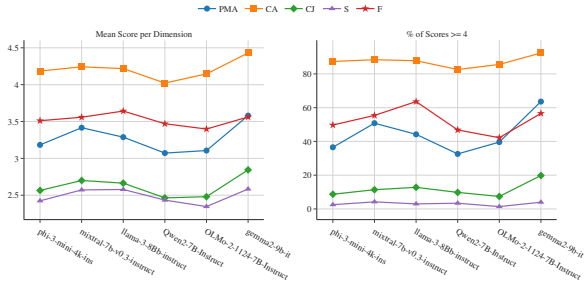

Figure 5: Reasoning quality across models on five dimensions: PMA, CA, CJ, S, and F. Left: mean Likert scores (1–5). Right: percentage of high-quality responses (≥ 4).

6.3 Reasoning Quality Across Models.

Figure 5 illustrates the reasoning quality of models along five dimensions. The left plot shows the mean Likert scores (1–5), while the right plot reports the percentage of responses rated ≥ 4. We observe in Table 3 that `gemma2-9b-it` achieves the highest scores across most dimensions, especially in PMA, CA, and CJ, indicating consistent alignment between personality and musical reasoning.

Model	PMA	CA	CJ	S	F
phi-3	3.18 / 36.5	4.19 / 87.4	2.57 / 8.7	2.42 / 2.5	3.51 / 49.7
mixtral	3.42 / 50.8	4.24 / 88.4	2.70 / 11.4	2.57 / 4.2	3.56 / 55.4
llama3	3.29 / 44.2	4.22 / 87.8	2.66 / 12.8	2.58 / 3.0	**3.64 / 63.6**
qwen2	3.07 / 32.6	4.02 / 82.6	2.46 / 9.8	2.43 / 3.4	3.47 / 46.8
olmo2	3.11 / 39.6	4.15 / 85.6	2.48 / 7.4	2.35 / 1.4	3.40 / 42.2
gemma2	**3.58 / 63.6**	**4.43 / 92.4**	**2.84 / 19.8**	**2.58 / 4.0**	3.56 / 56.6

Table 3: Mean (M) and % of high-quality (**%H**) teacher ratings (≥ 4) across five reasoning dimensions (Reported M/%H): PMA, CA, CJ, Specificity, and Fluency. Full table in Table 16.

`llama-3-8B` excels in Fluency, and `mixtral-7b` leads in Specificity. These trends reaffirm that larger models are generally more capable of producing coherent, human-aligned justifications, even when overall accuracy differences are moderate.

6.4 Ablation Study

Variant	Acc	F1	%Imp
Verbalized	**0.3521**	**0.3489**	**8.04**
CoT (Maj. Vote)	0.2874	0.2755	0.70
CoT	0.2872	0.2752	0.67
Baseline	0.2721	0.2685	–
Mis-verbalized	0.2282	0.2287	-3.98

Table 4: Inference-time ablation on `LLaMA-3-8B` for Task 2 (Chord Matching). Verbalized prompting shows the highest gains. See full results in Appendix 17.

We conduct an ablation to assess the impact of different reasoning strategies and training configurations on benchmark performance. Table 17 separates results into two blocks: *inference-only* and *trained model* settings, using the LLaMA-3-8B and Mistral-7B architectures. In inference mode, we vary prompting strategies (baseline, CoT, verbalization, etc.), while in training mode, we isolate the effect of verbalization by toggling it in merged models.

7 Conclusion

This work bridges a novel intersection between personality modeling and symbolic music reasoning by evaluating whether LLMs can align personality traits with musical preferences through a modular cross-domain benchmark. We evaluate fine-tuning and inference-time strategies, finding that while trait-specific training aids identification, verbalization-based prompting significantly improves chord alignment without supervision. Our reasoning evaluation further shows that larger models generate fluent, personality-consistent justifications. These findings open a new direction in evaluating LLMs' capacity to reason about identity

through language and music.

Limitations

While our benchmark and methods demonstrate promising results in aligning personality traits with musical structure, several limitations remain:

1. Limited Real-World Data. Our benchmark relies on synthetic contexts rather than real-world conversations or interviews about music preferences. While we mitigate this through careful prompt engineering and sampling, grounded datasets involving real individuals would provide more robust evaluation.

2. Symbolic Music Bias. Chord progression alignment captures only one facet of musical structure. Other dimensions such as rhythm, melody, or production aesthetics are not modeled, potentially underrepresenting a user's full musical identity.

3. Model Pretraining Bias. Open-source models vary widely in pretraining corpora and musical exposure, affecting baseline performance on symbolic reasoning tasks. Some gains may be due to prior exposure to musical texts or specific chord forms.

4. Limited Generalization to Other Domains. While our focus is on personality-music reasoning, it remains to be seen whether similar verbalization or alignment techniques generalize well to other symbolic or creative domains (e.g., art, literature).

Ethical Considerations

Our benchmark relies on synthetic data generated by GPT-4o, which may carry subtle biases from its pretraining. While personality and genre cues are indirectly embedded, unintended stereotypes could emerge. The benchmark is for research use only and is not intended for sensitive applications like diagnosis or profiling. All annotations were model-generated or anonymized, and no personal data was used. The dataset will be released under the CC BY-NC 4.0 license for non-commercial research use.

Acknowledgements

We thank the anonymous reviewers for their valuable feedback on our manuscript. We are also grateful to the human judges who participated in evaluating the LLM-generated synthetic data. The human evaluation team was led by Anushka Tiwari (PhD student, Computational and Data-Enabled Sciences, University at Buffalo), and a small team of graduate students within the University at Buffalo research group. We had external contributions from Anisha Gupta and Shruti Kumar.

A PMA Bench Details

A.1 Context Generation Prompt

The following prompt was used with GPT-4o to generate realistic personality-conditioned musical scenarios. Each instance was conditioned on a PF16 descriptor set $\mathcal{H}_t$, an aligned genre g, and a domain-subdomain pair (d, s). No trait or genre was explicitly named in the output.

> You specialize in crafting realistic, engaging scenarios that subtly reflect individuals' personality traits and musical preferences without explicitly mentioning them.
>
> Generate a short, structured context (50–70 words) that describes an individual's character and preferred music style in a natural, real-world scenario. Do not explicitly mention the personality trait or the music genre.
>
> **Instructions:**
> 1. The individual exhibits qualities such as: {descriptor list}.
> 2. Their musical preference subtly aligns with a style reminiscent of {genre}.
> 3. Incorporate contextual details from the domain "{domain}" and subdomain "{subdomain}".
>
> Please produce a plain text description.

A.2 Qualitative Analysis of Personality-Musical Alignment

We present illustrative examples from our benchmark to highlight how personality traits and musical preferences are naturally encoded in context and whether models can reason through this mapping. GPT-4o rated each example below along five dimensions: Personality Alignment, Musical Coherence, Naturalness, Implicitness, and Specificity. Scores range from 1–5.

Example 1: Joyful Domesticity (Pop – Liveliness)

> *Sophie twirled into the living room, her laughter echoing through the house as she playfully swung her younger brother around in a dance. The sound of catchy, upbeat tunes streamed from the kitchen, where her mom clapped along while preparing dinner. Sophie loved these impromptu moments, turning everyday routines into lively celebrations, her energy infectious, setting a joyful rhythm in their home.*

This context captures a high-liveliness personality through spontaneous, energetic behavior and social warmth. The selected trait, *animated*, and the genre-aligned chord progression (`C G Am F`, common in uplifting pop music) match the tone and rhythm of the narrative. GPT-4o rated this scenario with perfect scores across Personality Alignment, Musical Coherence, and Naturalness, noting slightly lower scores (4) for Implicitness and Specificity, indicating the cues were vivid but somewhat overt.

Example 2: Reflective Absorption (Jazz – Abstractedness)

> *At the monthly community art exhibit, Ella wandered, her eyes lingering on abstract canvases. Lost in thought, she barely noticed the faint strains of saxophone drifting from the corner stage. As locals gathered, swapping stories of the night, she found herself nodding in rhythm to the seamless improvisation, her fingers unconsciously sketching patterns on the program in hand.*

This example showcases introspective, imaginative tendencies associated with high Abstractedness. The trait *absentminded* aligns with the narrative's detached tone, while the chosen genre (Jazz) and progression (`Dm7 Em7 A7 Dm7`) reinforce the reflective, improvisational mood. All five reasoning dimensions received top scores, validating both the subtle personality encoding and genre integration.

A.3 Evaluation Dimensions for Context Quality

Human judges evaluated a randomly sampled subset of synthetic contexts to assess their quality and faithfulness to intended personality-music mappings. Each context was independently rated on a 5-point Likert scale (1 = poor, 5 = excellent) across five qualitative dimensions listed in Table 5. Annotators were instructed to read each context carefully and assign scores reflecting how well it satisfied each criterion.

Instruction to Human Annotators:

For each given context, please rate it from **1 (poor)** to **5 (excellent)** on the following five aspects:

1. Personality Alignment: Does the context express the intended PF16 trait?
2. Musical Coherence: Is the implied musical preference plausible for that trait?
3. Naturalness: Is the text fluent and realistic in everyday language?
4. Implicitness: Are the cues subtle rather than explicit?
5. Specificity: Does the description include concrete, non-generic detail?

Provide your numeric ratings only; no written explanations are required.

Dimension	Explanation
Personality Alignment (PA)	Measures how well the context reflects the high-polarity descriptors of the intended PF16 trait.
Musical Coherence (MC)	Evaluates whether the scenario plausibly implies a genre preference aligned with the given trait.
Naturalness (N)	Assesses the realism and fluency of the scenario in everyday language.
Implicitness (I)	Captures whether personality and genre cues are subtly embedded rather than explicitly stated.
Specificity (S)	Judges the level of concrete detail and avoidance of generic phrasing.

Table 5: Qualitative dimensions used to evaluate sampled contexts across traits.

B Experiments

B.1 Training Strategy Detailed

T2: Chord Progression Alignment. This task involves symbolic reasoning over music theory, conditioned on inferred personality traits. We approach it in two steps:

(i) Chord-LM Pre-training (Unsupervised): We first train a causal decoder-only model on 30K+ chord sequences from the Chordonomicon corpus.

Attrib	PC	SPC	BST	JIC
# of Conversations	18,878	10,905	6,808	418,476
Tot. # of Turns	120,361	152,945	44,959	3,347,808
Avg. # of Turns	6.38	14.03	6.60	8.00
Tot. # of Utterances	259,600	310,874	89,918	6,695,616
Avg. Utt. (conv)	13.75	28.51	13.21	16.00
Avg. Words (u)	11.24	8.75	13.46	15.48
Avg. Conv. Length (w)	154.56	249.53	177.83	247.61
Longest Conv. (u)	49	117	28	16
Shortest Conv. (u)	11	6	4	16
Longest Conv. (w)	477	637	422	581
Shortest Conv. (w)	41	60	24	16
Avg. Topic Consistency (u)	0.50	0.57	0.55	0.53
Avg. Semantic Similarity (u)	0.31	0.39	0.36	0.36

Table 6: Comparison of various datasets across several attributes. Here PC is Persona Chat, SPC is Synthetic Persona Chat, BST is Blended Skill Talk, (u) means per utterance, and (w) means per word.

Given a sequence $C = (c_1, c_2, \ldots, c_n)$, the model is trained to maximize the likelihood of predicting the next chord:

$$\mathcal{L}_{\text{chord}}(\theta) = -\sum_{i=2}^{n} \log p(c_i | c_{1:i-1}; \theta).$$

(ii) Genre-Chord Translation (Supervised): We treat genre-chord reasoning as a translation task. The model is trained in both directions: (a) generate chords $c_{1:n}$ from a genre label g and related attributes (e.g., subgenre, era), (b) generate the most likely genre label g given a chord progression. This bidirectional fine-tuning improves both generation and reverse classification:

$$\mathcal{L}_{\text{genre}}(\theta) = -\sum_{i=1}^{n} \log p(c_i | c_{1:i-1}, g; \theta)$$

$$\mathcal{L}_{\text{genre-inv}}(\theta) = -\log p(g | c_{1:n}; \theta)$$

This formulation allows the model to learn the genre-conditioned musical structure and improves generalization to unseen chord forms and personality mappings.

Model Merging via SVD. To combine the personality and chord reasoning capabilities, we merged the adapters trained on T1 and T2 using SVD-based adapter merging from the PEFT library. This method approximates a shared low-rank subspace across LoRA modules, allowing efficient integration.

B.1.1 Personality Trait Identification - Dataset stats.

Table 6 shows the dataset statistics.

B.1.2 Training Arguments and GPU

All the models were trained on a single A100 80 GB. Table 7 shows the Training Args used to train

all the Models. The batch size default was set to 4 but was reduced to 2 when A100 80GB was unavailable (used A100 40 GB). LoRA hyper parameters (r = 64, $alpha$ = 16, dropout = 0.1) were most significant.

Argument	Value
lora_r	64
lora_alpha	16
lora_dropout	0.1

Table 7: Trainer Arguments

B.2 Inference Pipeline

B.2.1 Verbalization Prompt

Prompt Templates for Verbalization Pipeline

Step 1: Personality-to-Genre Prompt

> You are a music expert and songwriter who knows how personality drives musical taste.
>
> Below is a mapping of personality traits to genres:
> - Warmth: Pop, Country, Gospel
> - Reasoning: Jazz, Alternative, Classical ...
>
> Context: {context}
>
> Task: In no more than 30 words, identify the dominant personality traits from the context and recommend 2–3 genres they are most likely to enjoy, based on the mapping above.

Step 2: Genre-to-Chord Prompt

> You are a music expert and songwriter who knows how personality influences musical preferences and harmonic structure.
>
> Below is a mapping of genres to music theory knowledge:
> - Pop: Uses the I–V–vi–IV major-key cycle with simple triads. Uplifting, highly danceable.
> - Rock: Drives on I–IV–V or I–V–vi–IV power chords. Bold, energetic tone.
> - Jazz: Rich in 7th chords and ii–V–I cadences. Complex, smooth. ...
>
> Context: {context}
>
> Personality and Genre Knowledge: {predicted trait and genre rationale from Step 1}
>
> Question: Which chord progression best matches the user's music preference?
>
> Options: A: {prog1} B: {prog2} C: {prog3} D: {prog4}
>
> Please analyze how the context, predicted genre, and music theory knowledge align to justify your selection.
>
> Limit your answer to 100 words. Conclude with ONLY the letter of your choice inside <answer> tags. Example: <answer>C</answer>.

C Evaluation Strategy

C.1 Reasoning Evaluation Dimensions

To evaluate the quality of model-generated reasoning in Task 2 (chord progression alignment), we define five key dimensions, each rated on a 1–5 Likert scale. These dimensions are adapted from prior work on explanation quality, natural language generation, and interpretability in NLP models.

1. **Personality-Musical Alignment:** Measures how well the explanation connects the inferred personality trait to the selected chord progression or genre. Inspired by trait-grounded reasoning evaluation in personality modeling (Mairesse et al., 2007) and controllable generation (Keskar et al., 2019).

2. **Chordal Appropriateness:** Assesses whether the described chord progression is musically coherent with the inferred genre or emotional tone. Draws from music theory alignment evaluation and symbolic music generation benchmarks (Krumhansl, 1995).

3. **Causal Justification:** Evaluates whether the explanation includes a clear, logical cause-effect rationale for why the chosen progression fits the described personality or mood. Builds on explanation plausibility and justification work in NLI and commonsense reasoning (Camburu et al., 2018; Rajani et al., 2019).

4. **Specificity:** Measures the level of detail in the reasoning, including references to actual chord functions, emotional textures, or subtraits. Inspired by dialogue specificity metrics (See et al., 2019).

5. **Fluency and Clarity:** Captures the grammatical correctness, coherence, and readability of the explanation.

Each reasoning sample is first evaluated by a teacher model (GPT-4o) that generates a gold explanation from the context and ground-truth label. It then scores the student model's explanation on each dimension, optionally providing a short justification.

D Results and Discussions

D.1 Verbalization Success and NEI Trends

Verbalized prompting substantially reduces NEI rates for most models, notably dropping from 187 to 1 for `OLMo`, indicating improved grounding. While `mixtral` shows a minor NEI increase, which indicates the model is overthinking, models like `phi-3`, `llama3`, and `gemma2` remain consistently low, reflecting better alignment and control.

E Miscellaneous

Contains tables and extra information

Genre	Description
Alternative	A broad genre encompassing experimental and non-mainstream rock/pop styles.
Blues	A soulful genre rooted in African American history, emphasizing emotion and improvisation.
Classical	Western art music tradition featuring orchestral, chamber, and solo compositions.
Country	Narrative-driven music with acoustic instrumentation and Southern U.S. cultural roots.
Electronic	Synthesized, beat-driven music spanning ambient, techno, and dance substyles.
Folk	Acoustic storytelling music rooted in cultural traditions and social commentary.
Gospel	Spiritually expressive music grounded in Christian themes and vocal harmony.
Hip-Hop	Rhythm-centric genre combining rap, beats, and urban cultural expression.
Indie	Independent music often characterized by artistic freedom, introspection, and lo-fi sounds.
Jazz	Improvisational and harmonic genre blending swing, blues, and complex instrumentation.
Metal	High-intensity genre marked by distorted guitars, aggression, and darker themes.
New Age	Meditative, atmospheric music focused on relaxation, spirituality, and soundscapes.
Pop	Mainstream music emphasizing catchy melodies and broad appeal across demographics.
Punk	Raw, fast-paced genre with rebellious lyrics and stripped-down instrumentation.
R&B	Rhythm and blues style blending soulful vocals with groovy and romantic instrumentation.
Reggae	Jamaican-born genre known for offbeat rhythms and themes of resistance and peace.
Reggaeton	Latin fusion of reggae, hip-hop, and dancehall with rhythmic Spanish vocals.
Rock	Guitar-driven genre ranging from classic rock to modern subgenres like alt-rock.
Soul	Emotionally rich music emphasizing vocal power and themes of love and struggle.

Table 8: Descriptions of the 19 musical genres used in the benchmark. These span a range of emotional, structural, and cultural attributes relevant to personality alignment.

Trait	High Descriptors	Low Descriptors	Alike Genres	Different Genres
Warmth	Warm, outgoing, attentive to others, kindly, easygoing	Impersonal, distant, cool, detached, aloof	Pop, Country, Gospel	Rock, Electronic, Metal
Reasoning	Abstract-thinking, intelligent, bright, fast-learner	Concrete-thinking, less intelligent, unable to abstract	Jazz, Alternative, Classical	Pop, Country, Hip-Hop
Emotional Stability	Emotionally stable, adaptive, mature	Reactive, changeable, easily upset	New Age, Reggae, Folk	Metal, Punk, Rock
Dominance	Dominant, assertive, competitive, bossy	Deferential, cooperative, submissive	Rock, Metal, Punk	Pop, Country, Gospel
Liveliness	Lively, animated, spontaneous, cheerful	Serious, restrained, taciturn	Pop, Hip-Hop, Electronic	Jazz, Blues, Folk
Rule-Consciousness	Rule-bound, dutiful, moralistic	Expedient, nonconforming, self-indulgent	Classical, Jazz, R&B	Hip-Hop, Punk, Electronic
Social Boldness	Socially bold, venturesome, uninhibited	Shy, timid, hesitant	Hip-Hop, Electronic, Reggaeton	Jazz, Classical, New Age
Sensitivity	Sensitive, sentimental, refined	Tough-minded, objective, rough	Soul, Gospel, Blues	Metal, Punk, Rock
Vigilance	Vigilant, skeptical, oppositional	Trusting, unsuspecting, accepting	Alternative, Metal, Punk	Pop, Country, Reggae
Abstractedness	Imaginative, absentminded, absorbed in ideas	Grounded, practical, conventional	Jazz, New Age, Indie	Country, Hip-Hop, Reggae
Privateness	Discreet, shrewd, diplomatic	Forthright, genuine, open	Classical, Indie, Folk	Pop, Hip-Hop, Electronic
Apprehension	Apprehensive, insecure, self-blaming	Self-assured, secure, confident	Blues, Alternative, Indie	Pop, Country, Gospel
Openness to Change	Experimental, analytical, freethinking	Traditional, conservative	Electronic, Alternative, Reggaeton	Country, Blues, Gospel
Self-Reliance	Self-reliant, solitary, individualistic	Group-oriented, dependent	Indie, Alternative, Metal	Pop, Country, Reggae
Perfectionism	Perfectionistic, organized, self-disciplined	Tolerates disorder, lax, impulsive	Classical, Jazz, R&B	Hip-Hop, Punk, Electronic
Tension	Tense, driven, frustrated	Relaxed, tranquil, composed	Rock, Hip-Hop, Metal	New Age, Folk, Reggae

Table 9: PF16 traits, their descriptors (high and low range), and genre associations.

Genre	Chord Progressions	Dancability	Mood
Pop	C Am F G C G Am F Am F C G C Am Dm G	8	Uplifting
Rock	G D Em C D A Bm G E B C#m A A E F#m D	7	Energetic
Jazz	Dm7 G7 Cmaj7 Am7 Dm7 G7 Cmaj7 Dm7 Em7 A7 Dm7 Gm7 C7 Fmaj7	6	Sophisticated
Hip-Hop	Am7 Dm7 G7 Cmaj7 Am F C G Em Am Dm G Am7 Em7 Dm7 G7	9	Groovy
Metal	Em C Am B Em G D A Em D C B Em C B A	4	Intense

Table 10: Representative chord progressions for five popular genres, along with dancability scores (1–10) and associated mood labels. These examples demonstrate genre-specific harmonic structures used in our benchmark.

Domain	Subdomains
Social Dynamics	Friendships, Romantic Relationships, Community Engagement
Personal Development	Self-Improvement, Emotional Resilience, Identity Exploration
Lifestyle & Routine	Daily Routines, Leisure & Recreation, Health & Wellness
Professional Environment	Workplace Culture, Career Growth, Leadership Dynamics
Creative Expression	Artistic Pursuits, Music Exploration, Literary Interests
Cultural Engagement	Heritage & Tradition, Global Influences, Local Community
Urban Living	City Life, Public Transit, Neighborhood Vibes
Technology & Media	Digital Connectivity, Social Media Trends, Innovative Consumption
Family & Home	Domestic Life, Family Bonds, Home Environment
Adventure & Exploration	Travel Experiences, Outdoor Activities, Culinary Journeys

Abstract

Multiple Choice Question (MCQ) answering is a widely used method for evaluating the performance of Large Language Models (LLMs). However, LLMs often exhibit selection bias in MCQ tasks, where their choices are influenced by factors like answer position or option symbols rather than the content. This bias undermines the reliability of MCQ as an evaluation framework. Most existing selection bias metrics require answer labels and measure divergences between prediction and answer distributions, but do not fully capture the consistency of a model's predictions across different orderings of answer choices. Existing selection bias mitigation strategies have notable limitations: majority voting, though effective, is computationally prohibitive; calibration-based methods require validation sets and often fail to generalize across datasets. To address these gaps, we propose three key contributions: (1) a new unsupervised label-free **Permutation Bias Metric (PBM)** that directly quantifies inconsistencies in model predictions across answer permutations, providing a more precise measure of selection bias, (2) an efficient majority voting approach called Batch Question-Context KV caching (BaQCKV), to significantly reduce computational costs while preserving bias mitigation effectiveness, and (3) an unsupervised Low-Rank Adaptation (LoRA)-1 fine-tuning strategy based on our proposed metric and the BaQCKV that mitigates selection bias, providing a computationally efficient alternative that maintains model generalizability. Experiments across multiple MCQ benchmarks demonstrate that our approaches reduce bias, increasing consistency in accuracy while minimizing computational costs.

1 Introduction

Selection bias in Large Language Models (LLMs) has been increasingly recognized as a significant challenge, particularly in multiple-choice question (MCQ) answering tasks (Wei et al., 2024a; Zheng et al., 2024; Zong et al., 2023). This bias occurs when models exhibit a preference for certain answer choices based on factors like their position or symbolic representation, rather than the option content (Wei et al., 2024a). For instance, LLMs may disproportionately favor the last option or option "A" across different questions. Such biases are especially problematic in evaluation settings, where multiple-choice formats are widely used for example, in standardized testing, professional certification exams, and educational assessments. These biases undermine the fairness and reliability of model evaluations, as they can lead to inconsistent answers across equivalent permutations, eroding trust in LLM-based decision systems.

The presence of selection bias in LLMs was highlighted by (Zheng et al., 2024), demonstrating how factors like answer position and symbolic representation can lead to systematic errors in MCQ answering. Effectively addressing selection bias requires a well-defined metric for bias quantification. Several metrics have been proposed to measure the selection bias such as the Choice Kullback-Leibler Divergence (CKLD) (Choi et al., 2024), Standard Deviation of Recalls (RStd) (Zheng et al., 2024), and Relative Standard Deviation (RSD) (Croce et al., 2021; Reif and Schwartz, 2024), which primarily evaluate bias in terms of divergence from ground truth distributions (i.e., CKLD) or variability in class-wise performance (i.e., RStd and RSD). However, they do not adequately capture the bias exhibited by models to option permutations. Also, the Fluctuation Rate proposed by (Wei et al., 2024b) only considers two permutations of the options, which may not capture the full permutation bias. We therefore introduce a new permutation bias metric (PBM) that evaluates selection bias in LLM without requiring ground truth distributions while considering all possible option permutations. The primary intuition behind our metric is that *logically,*

Proceedings of the 14th International Joint Conference on Natural Language Processing and the 4th Conference of the Asia-Pacific Chapter of the Association for Computational Linguistics, pages 2019–2038
December 20-24, 2025 ©2025 Association for Computational Linguistics

an answer's correctness does not change based on its position in a list of options and we therefore want language models to possess this behaviour.

Addressing the problem of bias requires not just quantifying but also mitigating bias. Prior mitigation strategies like majority voting (Zong et al., 2023) that aggregates predictions across all permutations of answer choices - has been shown to reduce bias. However, its computational cost increases factorially with the number of choices, making it impractical for real-time inference. Thus, a key challenge is to develop an efficient method for bias quantification and bias mitigation that can be integrated into real-world systems. We therefore propose **Batch Question-Context KV caching** (BaQCKV), an efficient implementation of majority voting that reduces computational cost considering all permutations. Additionally, we introduce an unsupervised Low-Rank Adaptation (Hu et al., 2021) finetuning strategy that optimizes the model on our proposed metric.
Our contributions can be summarized as follows:

- We propose a novel, unsupervised, and label-free Permutation Bias metric (PBM) that captures inconsistencies in model predictions across all permutations of answer choices. Unlike prior metrics, it requires no access to ground-truth labels and directly measures permutation sensitivity.
- We introduce **BaQCKV (Batch Question-Context KV caching)**, a computationally efficient variant of majority voting that significantly reduces the overhead associated with evaluating all permutations of multiple-choice questions.
- We develop a LoRA-based fine-tuning strategy that leverages our proposed bias metric as a differentiable objective, enabling parameter-efficient debiasing without the need for labeled data or full model retraining.

Our efficient BaQCKV method achieves token savings of up to **54.4%**, while our lightweight unsupervised LoRA-1 (LoRA Rank = 1) fine-tuning reduces the PBM bias by an average of **58%** and improves standard deviation of accuracy by **27%**, outperforming existing approaches. BaQCKV is particularly well-suited for evaluation or deployment scenarios where deterministic and fully permutation-invariant responses are required, as it can achieve 0 bias but with additional compute and latency. In contrast, LoRA-1 fine-tuning offers a lightweight, one-pass inference alternative for practical large-scale LLM deployments or latency-sensitive settings. Together, these contributions can lead to a unified framework for quantifying and mitigating selection bias in LLMs, particularly in the context of multiple-choice question answering.

2 Related Work

Large Language Models (LLMs) exhibit systematic selection biases in multiple-choice question answering (MCQA), favoring options by position (e.g., last choice) or by identifier (e.g., option "A") rather than semantic content. In this review, we focus on existing approaches for bias quantification and mitigation.

2.1 Bias Evaluation in LLMs

Bias quantification typically measures divergence between predicted and ground-truth answer distributions. Choice Kullback–Leibler Divergence (CKLD) (Choi et al., 2024) measures the KL divergence between the model's predicted answer frequency and the ground-truth (i.e, how often the correct answer is A, B., etc.). Other metrics focus on variability in per-option accuracy and recall. The Relative Standard Deviation (RSD) (Reif and Schwartz, 2024) and the Standard Deviation of Recall (RStd) (Zheng et al., 2024) assess variability in per-option accuracy or recall, respectively, revealing positional preference, but ignore how predictions change under option reordering. While useful, such label-dependent metrics fail to capture *inconsistency across permutations* They do not consider if a model would answer the same question differently when choices are presented in a different option permutation, since they only evaluate against the single correct label in the original ordering.

To capture such inconsistency, Wei et al. (2024a) introduced Fluctuation Rate (FR), a label-free metric that measures answer changes when options are reversed. While FR highlights instability, it is limited to two permutations and only detects discrete flips, ignoring confidence shifts and being non-differentiable, which limits its use in fine-tuning.

In summary, current metrics are either label-dependent (CKLD, RSD/RStd) or permutation-limited (FR), offering incomplete views of bias. To

address this, we propose a ***permutation-sensitive, label-agnostic metric*** that captures prediction consistency across all answer orderings. Our approach enables broad applicability on unlabeled datasets and introduces a ***differentiable objective for debiasing during fine-tuning*** (section 3.3.2).

2.2 Bias Mitigation Strategies

Several research works have explored various strategies to mitigate selection bias in LLMs, ranging from calibration, voting, to finetuning-based approaches.

Calibration-based methods aim to adjust the model's output probabilities to compensate for the skewed bias distributions. Most of these methods target recalibration to improve accuracy and not directly to reduce bias. CalibraEval (Li et al., 2024) reweights predictions to reduce positional bias during evaluation, while label bias calibration (Reif and Schwartz, 2024) improves accuracy using known statistics. PriDe (Zheng et al., 2024) estimates prior probabilities over option IDs to normalize predictions, effectively reducing RStd. These methods, however, typically need labeled data and apply the same calibration across permutations, thus failing to ensure consistency under reordering. Prompt-based fixes like Auxiliary Option Injection (AOI) (Choi et al., 2024) are simple and model-agnostic but offer limited and prompt-sensitive improvements.

Majority voting aggregates predictions over option permutations to reduce bias (Zong et al., 2023; Wei et al., 2024b). Though effective, it scales poorly to $k!$ permutations for k options making it impractical. Efficient variants include batch prompting (Zhou et al., 2024) and random subset voting (Guda et al., 2024). Self-consistency (Wang et al., 2024; Kim et al., 2024) improves stability by sampling varied reasoning paths, akin to voting. However, all such methods incur significant inference-time cost. Our BaQCKV approach reduces this by reusing computation across permutations.

Instead of repeatedly querying a biased model at inference time, another strategy is to adjust the parameters that induce bias within the model itself. Teacher–student distillation (Liusie et al., 2024) transfers debiased behavior from a teacher model into compact models. Bias Node Pruning (BNP) (Choi et al., 2024) identifies a bias vector in the final decoder layer and prunes parameters in the LLM's final linear head projection matrix based on their interactions with this vector. While such methods reduce metrics like FR, they may negatively impact the model's performance on other tasks due to irreversible weight pruning or overfitting to specific bias patterns.

In summary, training-time debiasing techniques including knowledge distillation, fine-tuning, and structural pruning aim to internalize bias mitigation and reduce the need for repeated inference-time interventions. However, these often require labeled datasets and can compromise generalization. In contrast, our approach introduces a fully differentiable, label-free bias objective that enables debias fine-tuning to reduce permutation sensitivity. This allows for unsupervised debiasing that generalizes across datasets.

3 Methodology

In this section, we define our bias quantification metric, which accounts for all option permutations and also describe the mitigation strategies - BaQCKV and LoRA-1 fine-tuning.

3.1 Permutation Bias Metric (PBM)

PBM is based on the intuition that, logically, a model's confidence in an option should be invariant to the permutation of the options. Also, we argue that this quantification should be label-free because the confidence for each option content across all permutations should be constant regardless of option correctness. Let Q represent a question, and $O = \{o_1, o_2, \ldots, o_n\}$ represent a set of n options for the question. A model processes the sequence $S_\pi = Q \oplus O_\pi$ for a permutation π of the options O, where $\oplus$ denotes the concatenation operator. Passing a permutation of the options S_π through the model assigns probabilities $P(o_{\pi(i)} \mid Q, O_\pi)$ to each option content o_i. Similarly, for a different permutation $\pi^{'}$ it assigns $P(o_{\pi^{'}(i)} \mid Q, O_{\pi^{'}})$. We define our selection bias metric mathematically for a model in Equation (1) as the variance of the probabilities for each option content across all permutations. This will capture how much the model's confidence fluctuates due to reordering.

Definition 1 (Permutation Bias Metric – PBM)**.** Given a question Q and a set of answer options $O = \{o_1, o_2, \ldots, o_n\}$, the selection bias $B(Q, O)$ is defined as:

$$B(Q,O) = \frac{1}{n}\sum_{i=1}^{n} \mathrm{Var}_\pi \left(P(o_{\pi(i)} \mid Q, O_\pi)\right), \quad (1)$$

We refer to this selection bias score as the **Permutation Bias Metric (PBM)**, where:

$$\begin{aligned}&\text{Var}_\pi\left(P(o_{\pi(i)} \mid Q, O_\pi)\right) = \\ &\frac{1}{n!}\sum_\pi\Bigg(P(o_{\pi(i)} \mid Q, O_\pi) \\ &-\mathbb{E}_\pi\left[P(o_{\pi(i)} \mid Q, O_\pi)\right]\Bigg)^2,\end{aligned} \tag{2}$$

and the expectation over all permutations π is:

$$\mathbb{E}_\pi[P(o_{\pi(i)} \mid Q, O_\pi)] = \frac{1}{n!}\sum_\pi P(o_{\pi(i)} \mid Q, O_\pi).$$

By defining the **PBM** to be proportional to the variance of a model's prediction across all permutations, the metric captures the inconsistency in the predictions. A lower variance indicates more stable and consistent predictions across permutations. Therefore, lower values of the **PBM** are preferred. **PBM** is label-free compared to previously proposed metrics like RStd (equation (4)), FR (equation (3)) and CKLD (equation (5)) which capture some form of divergence from the answer distribution, requiring the ground truth answers. The RStd and CKLD do not capture any information about the option permutations because they only use the original permutations of the options. This assumes the original permutation corresponds to the fixed answer order provided in the dataset, which is often arbitrary (i.e, randomly assigned during test construction). Also, while **PBM** goes into the granular confidence level by considering option probabilities, the FR does not capture granular information of the changes in confidence but only checks if the chosen answer (argmax) is the same in the forward and reverse permutations. By considering only 2 permutations, it does not capture information from other permutations. The Fluctuation Rate (FR) is expressed as:

$$\begin{aligned}FR = \frac{1}{N}\sum^{N}\Big(&\underset{i}{\text{argmax}}\big(P(O \mid Q, O_\pi)\big) \\ &\neq \underset{i}{\text{argmax}}\big(P(O \mid Q, reverse(O_\pi))\big)\Big)\end{aligned} \tag{3}$$

where the $reverse(O_\pi)$ function is the reverse permutation of O_π and N is the total number of questions.

RStd (R_σ) is expressed as:

$$R_\sigma = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(r_i - \mu_r)^2} \tag{4}$$

where n represents the number of option classes, r_i is the recall for the i-th option symbol (e.g. recall for option A, B....), and μ_r denotes the average recall across all option symbols.

$$CKLD = \sum_i^n p_i \log\frac{p_i}{q_i} \tag{5}$$

where p_i is the ratio of ground truth choice label for option ID i and q_i is the ratio for predictions.

3.2 Investigation into the cause of Selection Bias in LLMs

In the decoder-only transformer architecture, which is prevalent in most large language models (LLMs), each token is generated based on causal attention. This causal attention mechanism ensures that predictions are conditioned only on previously generated tokens. To preserve the sequential structure of the input, positional encodings are applied during attention computation. When a question and its permuted-option variant are provided as input, the set of unique tokens remains unchanged. However, the reordering alters the positional encodings assigned to each option token. Since positional encodings influence attention scores, this modification can lead to differences in the model's output, even if the semantic token content remains the same (see Appendix A.1 and Appendix A.2).

3.3 Bias Mitigation Methodology

In the following sections, we explain our efficient BaQCKV approach and the unsupervised LoRA-1 debiasing. BaQCKV, an efficient majority voting variant that enforces permutation invariance (zero bias) with reduced compute via batched inference, ideal for critical evaluations requiring strict consistency; and LoRA-1, a lightweight adaptation method trained using our unsupervised bias metric to debias models for single-pass inference, suitable for large-scale deployments. BaQCKV trades computational overhead for robustness, while LoRA-1 prioritises scalability with minimal latency. This can enable users to balance bias mitigation against operational constraints.

3.3.1 Efficient Majority Voting with BaQCKV

The majority voting is an effective mitigation strategy for selection bias (Zong et al., 2023). It passes

all option permutations of a question through the model and chooses the option with the highest average score across the permutations. This scheme enforces permutation invariance (0 bias on our metric) by ensuring that an option has the same confidence across all permutations, making it an ideal selection bias mitigation strategy. Mathematically, majority voting calculates

$$i^* = \underset{i \in O}{\operatorname{argmax}} \, \mathbb{E}_\pi \left[P(o_{\pi(i)} \mid Q, O_\pi) \right], \quad (6)$$

where $O = \{o_1, \ldots, o_n\}$ is the set of answer options, π denotes a permutation of the options, and $\mathbb{E}_\pi$ represents the average over all $n!$ permutations (as defined in Section 3.1).

In spite of its effectiveness in mitigating bias, the majority voting has not been widely adopted, as the computational complexity of making predictions on all possible permutations is $n!$ for an MCQ with n options. This can be easily reduced by defining a fixed number k and considering only k permutations instead of $n!$, reducing the computational cost (Guda et al., 2024). Thus, $p_i = \frac{1}{k} \sum_{j=1}^{k} p_{ji}$. However, this scheme can be made even more efficient, without a corresponding loss in bias, by employing a KV cache. To do so, we leverage the insight that while an MCQ consists of a question Q (with or without a context), and a set of options, O, *the question, Q, remains the same across all possible option permutations.*

For k permutations of the options, the original formulation of majority voting (Guda et al., 2024) requires k passes through the LLM, resulting in an additional overhead of $(k-1) \times |\text{Questions} \oplus \text{Context} \oplus \text{Options}|$ tokens per question. We however, note that the set of $Questions \oplus Context$ tokens remains constant across all k passes for each question in a batch. To eliminate the redundant computation of these tokens across the batch, we are motivated by the KV cache in (Pope et al., 2023) to introduce the BaQCKV, which caches and reuses the KV states of the Questions $\oplus$ Context tokens for a set of k permutations. This cached KV state is prepended to the KV states of the k permuted options. The attention mask of the permuted options is then expanded based on the length of the $Questions \oplus Context$ tokens to ensure that the LLM's attention is correctly computed. We show in Appendix A.3 that the percentage of tokens saved by using the BaQCKV is defined by Equation (7), where C is the optional set of context tokens for the Question Q.

Algorithm 1 Efficient Majority Inference with BaQCKV

procedure BAQCKVINFERENCE($Q_C, O_k, \mathcal{M}$)
  Input: Q_C - Question $\oplus$ Context tokens, O_k - k permutations of options, $\mathcal{M}$ - Language Model, **Output:** $\mathcal{Y}_k$ - Model outputs

  Step 1: Cache Question-Context KV States
  $\texttt{KV}_{Q_C} \leftarrow \mathcal{M}.\text{encode}(Q_C)$
  Step 2: Compute KV States for Permuted Options
  for $i = 1$ to k **do**
    $\texttt{KV}_{O_i}, \texttt{mask}_i \leftarrow \mathcal{M}.\text{encode}(O_i)$
  end for
  Step 3: Merge and Adjust KV States
  for $i = 1$ to k **do**
    $\texttt{KV}_i \leftarrow \texttt{KV}_{Q_C} \oplus \texttt{KV}_{O_i}, \quad \texttt{mask}_i \leftarrow \mathbf{1}_{|Q_C|} \oplus \texttt{mask}_i$
  end for
  Step 4: Compute Batch Outputs
  $\mathcal{Y}_k \leftarrow \{\mathcal{M}.\text{decode}(\texttt{KV}_i, \texttt{mask}_i) \mid i = 1, 2, \ldots, k\}$
  return $\mathcal{Y}_k$
end procedure

$$\text{Token savings (\%)} = \frac{(k-1) \times |Q \oplus C|}{k \times |Q \oplus C \oplus O|} \times 100 \quad (7)$$

In Equation (7), the savings are maximized when $|C|$ is large, as in Retrieval-Augmented Generation (RAG), where redundant computation is minimized. Even when $|C| = 0$, savings persist due to the shared $|Q|$ tokens. Larger permutation sizes k further amplify savings because of the increased redundancy in $|Q \oplus C|$ across permutations. Thus, BaQCKV is most effective in tasks with substantial shared context, multiple options, and large permutation sizes.

3.3.2 Unsupervised LoRA-1 Bias Mitigation

We introduce an unsupervised fine-tuning of **PBM**, our permutation-based bias metric, to mitigate the selection bias. This is because PBM is fully differentiable unlike the Fluctuation Rate (FR) and the Standard Deviation of Recalls (RStd). In addition, it is also label-free, unlike all the other metrics including the CKLD. We make two adjustments to the metric when using it as a loss for fine-tuning (equation (8)). Firstly, to ensure that there is an adequate flow of information from the gradients we take the variance of the log of the probabilities (Equation (9)). When obtaining the option probabilities from the model, we only consider the logits that correspond to the option IDs instead of logits for the entire vocabulary. Secondly, we observe that a model can learn to minimize the bias by simply predicting a uniform probability for all options IDs across all permutations. In that case, the mean probability for all option IDs would be the same as the uniform probabilities assigned to all option IDs

for all permutations. To prevent this, we regularize the bias with the entropy across the option IDs (Equation (10)). This helps in making the model maintain its confidence in the chosen answer while also minimizing the bias across different permutations. λ is a hyper-parameter that balances the model's confidence in an answer and minimizing the bias. Computing the loss defined in Equation (8) can be computationally expensive, since each example must be expanded to all possible permutations. To reduce this cost, first, we apply the BaQCKV to compute the loss and only sample a maximum of 24 permutations for questions with more than 4 options.

$$\text{Loss} = B(Q,O)_{log} + \lambda H(Q,O) \tag{8}$$

where

$$B(Q,O)_{\log} = \sum_{\pi} \Big(\log\left(P(o_{\pi(i)} \mid Q, O_\pi)\right) - \log\left(\mathbb{E}_\pi\left[P(o_{\pi(i)} \mid Q, O_\pi)\right]\right) \Big)^2 \tag{9}$$

$$H(Q,O) = -\sum_{\pi}\sum_{i} (P(o_{\pi(i)} \log(P(o_{\pi(i)})) \tag{10}$$

As LLMs are desired to be used for a wide variety of tasks and not just answering MCQs, we adopt the LoRA fine-tuning (Hu et al., 2021) to preserve the original performance of the LLM on non-MCQ tasks while avoiding expensive training. The LoRA debiasing weight adapters can be connected when the model is used for MCQ.

3.3.3 Complexity Analysis

We present a comparison of the computational requirements of various bias metrics in Table 1, focusing on the number of permutations each metric considers and the effective token cost passed through the model. Existing metrics such as RStd, CKLD, and FR operate over one or two fixed permutations and require ground-truth labels, limiting both their expressiveness and flexibility. In contrast, our proposed PBM evaluates how model confidence varies across different permutations of answer options, offering a more comprehensive and label-free assessment of positional bias. While full PBM evaluation over all $n!$ permutations is computationally expensive, we use both two permutation sampling and BaQCKV to make PBM scalable. Sampling allows us to approximate the metric using only $m \ll n$ permutations, and BaQCKV further reduces cost by reusing the shared context $Q \oplus C$, resulting in a total complexity of $\mathcal{O}(|Q \oplus C| + m|O|)$ tokens per query. This approach strikes an effective balance between computational efficiency and expressive power.

Metric	Labels?	Perms	$\mathcal{O}(\cdot)$
RStd	Yes	1	$\lvert Q \oplus C \oplus O\rvert$
CKLD	Yes	1	$\lvert Q \oplus C \oplus O\rvert$
FR	No	2	$2\lvert Q \oplus C \oplus O\rvert$
PBM (full)	No	$n!$	$n!\lvert Q \oplus C \oplus O\rvert$
+ sampling	No	$m \ll n!$	$m(\lvert Q \oplus C \oplus O\rvert)$
+ BaQCKV	No	$m \ll n!$	$\lvert Q \oplus C\rvert + m\lvert O\rvert$

Table 1: Computational comparison of bias metrics.

4 Results

Datasets and Models : For our experiments, we employed three small language models of comparable size: Qwen2.5-3B-Instruct (Bai et al., 2023), Phi-2 (Javaheripi et al., 2023), and Llama3.2-3B (Grattafiori et al., 2024). We experiment with these models on four diverse datasets across different domains: TeleQnA (Maatouk et al., 2023), MedMCQA (Pal et al., 2022), QASC(Khot et al., 2020) and ARC Challenge(Clark et al., 2018). ARC Challenge and MedMCQA have 4 options and TeleQnA has 2-5 options, while QASC has 8. A full description of these datasets and their statistics can be found in Appendix C.4

Experiments: We conduct experiments to evaluate both the accuracy and bias of various models across all datasets, and to assess the effectiveness of different selection bias mitigation strategies. First, we demonstrate that *majority voting not only reduces or eliminates selection bias (quantified by PBM) but also improves model accuracy*. Furthermore, by introducing BaQCKV, we show that *majority voting can be made significantly more efficient*, yielding substantial savings in both computation time and token usage. In addition, we assess the impact of our proposed **LoRA-1 fine-tuning method**, which, on average, reduces the variation of accuracy, PBM and Fluctuation Rate and increases accuracy across all datasets/models and exhibits strong transferability across datasets.

We compare our approach against three alternative bias mitigation methods: (1)

GRAY (Wei et al., 2024b), a gray-box technique that leverages both forward and backward predictions to reduce bias; (2) **BNP (Bias Node Pruning)** (Choi et al., 2024), which prunes parameters in the final projection layer that contribute to bias; and (3) **PRIDE** (Zheng et al., 2024), which normalizes model predictions using prior probabilities estimated from the dataset.

However, these prior methods do not achieve the consistency of majority voting, a technique well-established for mitigating selection bias (Zong et al., 2023; Wang et al., 2024). The prompt templates and hyperparameter configurations used in our experiments are documented in Appendix C.

Our unsupervised bias metric (PBM) correlates with the difficulty of the MCQ: The results in Table 2 show that all models exhibit varying degrees of bias, correlating with the difficulty of the problem. Across all models, the bias is seen to be highest with the MedMCQA benchmark due to its difficulty (having the lowest accuracy). This confirms that selection bias is present and measurable using our proposed metric (PBM). This also means that PBM may be used to compare the difficulty of different MCQ datasets without having access to the labels. Notably, after applying majority voting (MV) with the help of BaQCKV, the PBM value consistently drops to 0.00. Additionally, applying majority voting shows substantial improvements in accuracy, particularly in QASC, where scores increase significantly (e.g., from 0.630 to 0.9329 for Phi-2 and 0.4892 to 0.837 for Llama), validating the effectiveness of our metric in capturing and mitigating bias.

Efficiency of the BaQCKV: Beyond bias reduction, the BaQCKV enhances real-world applicability by significantly reducing the computational costs of applying majority voting. As shown in Table 2, our efficient BaQCKV approach for the majority voting results in significant time savings of up to 84% (Qwen on QASC) and 89% (Phi on TeleQnA) and over 90% across token savings across all models and datasets. This efficiency gain is crucial for deploying bias-mitigation strategies at scale during inference, making our approach feasible for real-world applications where computational cost is a limiting factor.

The unsupervised LoRA-1 Bias Mitigation demonstrates the best performance in maintaining consistency:

The scatter plot in Figure 1a illustrates that, overall, the LoRA-1 fine-tuning approach exhibits greater consistency in accuracy, characterised by a smaller standard deviation and lower selection bias **(PBM)** compared to other mitigation strategies. Ideally, an effective model should have its corresponding points converge near the origin of the plot, indicating minimal variability and bias. Moreover, as shown in Table 3, when evaluating the percentage change relative to the undebiased models, LoRA-1 fine-tuning achieves the greatest average reduction in both standard deviation of accuracy (-27%), PBM bias (-58%) and FR (-52%) across all evaluated models and datasets. These results highlight the effectiveness of LoRA-1 in mitigating variability and bias simultaneously. It also, on average, improves the accuracy of the models by 20% even though this is not up to the 41.92% demonstrated by PriDe. Also, PriDe shows the highest reduction in the RStd (-24%) and the smallest increase in CKLD (43.2%). However, PriDe is not helpful in reducing the PBM bias, it rather increases PBM bias (180%). It also hardly offers any improvements in the standard deviation of accuracy (-0.4%). We show a training graph of the unsupervised finetuning for the TeleQnA dataset process in Figure 1b.

The transferability of the unsupervised LoRA-1 Bias Mitigation: We investigate the transferability of the unsupervised LoRA-1 fine-tuning approach by training a model on a single dataset and evaluating the resulting checkpoint on all other datasets. The average performance across each model/dataset pair is reported in Table 4, with complete results provided in Appendix B.2. As shown in Table 4, the unsupervised fine-tuning generally transfers well: it consistently reduces our permutation bias metric (PBM), fluctuation rate, and the standard deviation of accuracy across option permutations. In many cases, it also yields modest improvements in accuracy. However, similar to the non-transfer setting, this approach does not improve the CKLD metric. Notably, for the Qwen-MEDCQ model, CKLD actually increases significantly, accompanied by a more than 200% rise in RStd. This may be due to the model shifting toward greater consistency across permutations, which can lead to more uniform confidence distributions that diverge from dataset-specific label frequencies. Importantly, this behavior aligns with our objective of reducing positional sensitivity. However, future studies will need to be done to properly analyse

and understand this behaviour.

We compare the computational efficiency of the different bias mitigation strategies in Appendix D.

5 Conclusion

In this work, we address a critical yet underexplored challenge in Multiple-Choice (MCQ) Question Answering—selection bias in Large Language Models (LLMs). We introduced a novel unsupervised, label-free bias metric (PBM) that directly quantifies inconsistencies in predictions across permuted answer choices, offering a more faithful measure of selection bias than existing methods. To mitigate this bias without incurring prohibitive computational costs, we proposed BaQCKV, an efficient majority voting strategy, and LoRA-1, a lightweight fine-tuning method grounded in our bias metric. Our experiments across diverse MCQ datasets and models demonstrate that these techniques not only reduce bias and improve accuracy but also significantly cut down inference time and token usage, making them scalable and practical for real-world deployment. Ultimately, our work provides both a theoretical and practical framework for more reliable and efficient MCQ with LLMs.

6 Limitations

This work only focuses on decoder only transformer language models and did not investigate bias in other language models such as encoder-decoder models. Also, we only investigate MCQs where the model has to choose one option and do not consider other types of MCQs.

In practice, multiple-choice questions typically

have only 2–5 options. Thus, we fix the maximum at 24 permutations, which we believe balances computational costs with practical applicability. MCQs with more options are rarer. This ensures that the metric remains both meaningful and efficient in real-world MCQ settings. Also, we show that using these 24 permutations is sufficient, because it does well on the QASC dataset that has 8 options and the TeleQnA that has 2-5 options. However, future works may consider more permutations and larger LLM models.

A Appendix

A.1 Positional Encoding and Sensitivity of Transformers to Option Permutations

In decoder-only transformers, token generation is conditioned on causal self-attention, where each token attends to prior tokens using both content-based embeddings and positional encodings. When a question Q and its associated options $O = \{o_1, o_2, \ldots, o_n\}$ are presented, the model processes the sequence:

$$S = Q \oplus O.$$

For a permutation π of the options, the modified sequence becomes:

$$S_\pi = Q \oplus O_\pi.$$

While the token set remains unchanged, the reordering affects positional encodings, altering attention computations. The self-attention mechanism computes attention scores between tokens at positions i and j as:

$$\text{Attention}_{i,j} = \frac{Q(o_i + p_i) \cdot (K(o_j + p_j))^T}{\sqrt{d}}.$$

For the permuted sequence S_π, the updated scores are:

$$\text{Attention}^{\pi}_{i,j} = \frac{Q(o_i + p_{\pi(i)}) \cdot (K(o_j + p_{\pi(j)}))^T}{\sqrt{d}}.$$

Since $p_i \neq p_{\pi(i)}$, the attention patterns for S and S_π differ, resulting in distinct contextual representations for the same token set.

As attention weights directly influence token representations, these changes propagate through the network, modifying the sequence representation and ultimately affecting the model's output distribution. Let $P(y \mid S)$ and $P(y \mid S_\pi)$ denote the probability distributions over possible answers. Then,

$$P(y \mid S) \neq P(y \mid S_\pi).$$

A.2 Impact of option permutations on attention scores

The impact of the permutations owing to the positional encoding on the attention scores is illustrated in Figure 2. The figure shows that there are more fluctuations in the attention scores on the option tokens (later parts of the x-axis) compared to the question tokens (earlier tokens on the x-axis).

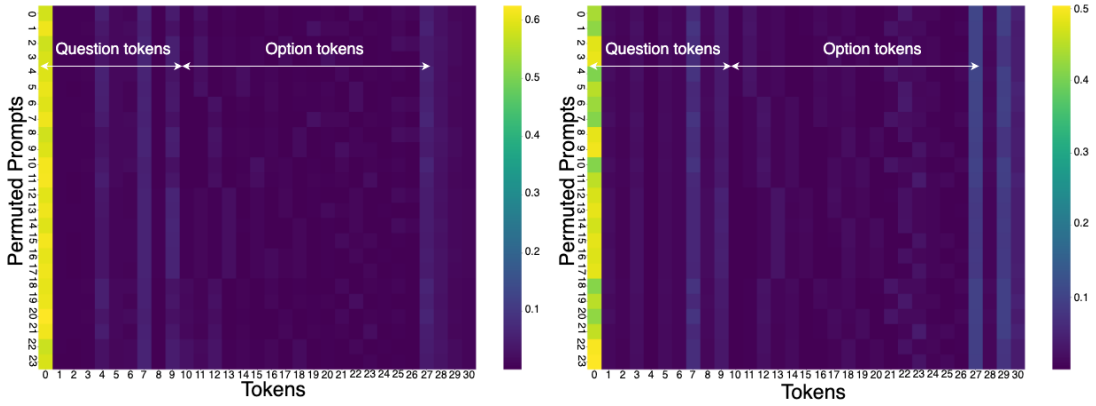

Figure 2: Attention scores for the last token in the last layer of the Llama model across different prompt permutations, shown for two transformer heads.

A.3 Proof of Token Savings in BaQCKV

In the original Majority Voting (MV) framework, each question undergoes k passes through the LLM, processing the full sequence of $Q \oplus C \oplus O$ each time. The total token cost per question is:

$$\text{Cost}_{\text{MV}} = k \times |Q \oplus C \oplus O| \tag{11}$$

In BaQCK, the shared $Q \oplus C$ tokens are processed only once, while the O tokens are processed k times. Thus, the total token cost per question is:

$$\text{Cost}_{\text{MV}} = |Q \oplus C| + k \times |O| \tag{12}$$

The token savings is computed as:

$$\begin{aligned}
\text{Savings} &= \text{Cost}_{\text{MV}} - \text{Cost}_{\text{BaQCK}} && (13)\\
&= k \times |Q \oplus C \oplus O| - (|Q \oplus C| + k \times |O|) && (14)\\
&= k \times |Q \oplus C| + k \times |O| - |Q \oplus C| - k \times |O| && (15)\\
&= (k-1) \times |Q \oplus C| && (16)
\end{aligned}$$

Expressing this as a percentage of the original cost:

$$\text{Token savings (\%)} = \frac{(k-1) \times |Q \oplus C|}{k \times |Q \oplus C \oplus O|} \times 100 \tag{17}$$

This result shows that BaQCK significantly reduces token computations, particularly when $|C|$ is large (e.g., in Retrieval-Augmented Generation). Even for small or zero-context cases ($|C| = 0$), savings persist due to shared $|Q|$ tokens. Increasing k further amplifies efficiency by reducing redundant recomputation across shuffled options.

C Prompt Templates and Hyperparameter Configurations

C.1 Prompt Templates Used in All Experiments

This appendix provides the exact prompt templates used during evaluation of transferability experiments across datasets and models.

MedMCQA Dataset (All Models)

```
Instruct = Youre a Medical Question Answering Expert, answer the following question.
Please generate only answer choice (1, 2, 3 or 4)
{question}
```

```
{options}
Output: option
```

TeleQnA Dataset (Qwen & Llama)

```
Instruct: Answer the following question using the context provided.
Your answer must start with the correct option letter (1, 2, 3, 4, or 5):
{question}
{options}
Output: option
```

TeleQnA or ARC Dataset (Phi-2)

```
Instruct: Answer the following question.
Your answer must start with the correct option letter (1, 2, 3, 4, or 5) followed by the
text of the answer:
{question}
{options}
Output: option
```

ARC Dataset (All Models Except Phi)

```
Instruct: {question}
{options}
Output: option
```

QASC Dataset (Qwen, Phi-2)

```
Instruct: Answer the following question using the context provided, reason over it.
Please generate only answer choice (1, 2, 3, 4, 5, 6, 7 or 8) without any explanations

{question}
context: {context}

{options}
{question}
Output: option
```

QASC Dataset (Llama)

```
Instruct: Answer the following question using the context provided, reason over it.
Please generate only answer choice (1, 2, 3, 4, 5, 6, 7 or 8) without any explanations

{question}
context: {context}

{options}
Output:
```

C.2 Hyper-Parameter Configurations

Unsupervised LoRA Finetuning: During each iteration we randomly sample 64 samples every epoch from the train split of the dataset and use it for training. For the LoRA adapters, we target the attention QKV and Output projection weights, with a dropout of 0.05 and LoRA alpha of 16. We used an AdamW optimizer with learning rate of $1e^{-4}$ and weight decay of 0.001 for all experiments. In computing the loss, we find the use of α of 0.1 to weight the entropy as yielding good performance. However, further experiments on the balance of this hyper-parameter choice can be further studied in more details.

C.3 Model Size And Budget

We evaluated our methods on a set of compact yet capable LLMs, including Qwen2.5–3B, Phi-2, and LLaMA3.2–3B, each with approximately 3 billion parameters. All experiments were conducted on NVIDIA L40 GPUs (48 GB VRAM). Using AWS g5.12xlarge instances (approximate L40 equivalent) priced at $3.06/hour on-demand, the cost per fine-tuning run is $6–$9, and BaQCKV inference costs are $1–$2 per dataset. This keeps the total cost for running all experiments within a practical research budget, demonstrating that our methods are efficient and deployable even on mid-sized mod.

Bias Metric Computation: To compute the PBM, we do not use the raw probabilities over the vocab size. We rather use the logits for only the option IDs to compute the probabilities. Also, we limit the number of permutations to a maximum of 24 (4!). This is due to our GPU memory budget and our considerations that most MCQs would have around 4 options.

C.4 Dataset Description

We evaluate our methods on four publicly-available multiple-choice QA benchmarks: TeleQnA (Maatouk et al., 2023), MedMCQA(Pal et al., 2022), QASC(Khot et al., 2020) and ARC Challenge(Clark et al., 2018). Table 20 summarizes their key statistics.

Dataset	Domain	# Choices	Splits (Train/Test)	License
TeleQnA	Telecom knowledge	2–5	1461 / 366	MIT
MedMCQA	Medical exam	4	5000/ 4183	MIT
QASC	Grade-school science	8	8134 /926	CC BY 4.0
ARC Challenge	Grade-school science (hard)	4	1119 /1172	CC BY-SA 4.0

Table 20: Overview of QA benchmarks used in our experiments.

TeleQnA is a telecommunications-domain multiple-choice QA dataset consisting of 10,000 English questions extracted from 3GPP standards and research articles. Each question has between 2 and 5 answer options. We use the publicly released splits for the Zindi subset of the data (Zindi). TeleQnA is distributed under the MIT license.

MedMCQA comprises 194,000 medical-entrance exam questions across 21 subjects and over 2,400 topics. Each item has 4 answer choices. We used the validation set as our test set in order to have access to the answers. It is available under the MIT license.

QASC is a multi-hop commonsense reasoning dataset containing 9,980 grade-school science questions designed for sentence composition. Each question has 8 choices. We follow the official splits of 8,134 training, 926 validation, and 920 test examples. We also used the validation set as our test, similar to the MedMCQA. It is released under a CC BY 4.0 license.

The ARC Challenge set contains 2,590 “hard” grade-school science questions that simple IR baselines fail to answer correctly. All questions have 4 answer options. We adopt the official splits: 1,119 train and 1,172 test examples. We use the actual test split as our test split since it contains the answers. The dataset is provided under CC BY-SA 4.0.

D Computational Efficiency Comparison of the Bias Mitigation Strategies

Mitigation Method	ARC Dataset		MEDMCQ Dataset		QASC Dataset	
	Debiasing Time (s)	Inference Time (s)	Debiasing Time (s)	Inference Time (s)	Debiasing Time (s)	Inference Time (s)
LoRA-1	143.30	0.042	91.33	0.059	100.03	0.058
Gray	-	0.049	-	0.061	-	0.0796
BNP	182.87	0.037	74.87	0.036	242.48	0.036
PriDe	52.54	0.042	248.27	0.037	87.20	0.037

Table 21: Comparison of the computational time for the different mitigation methods on the ARC, MEDMCQ, and QASC datasets. The debiasing time refers to the time required to compute calibration parameters or fine-tune the model before inference. The average inference time indicates the time to compute the final answer logits per example.

From Table 21, it can be seen that BNP consistently incurs the longest debiasing time across datasets. This is due to the overhead of computing the bias vector, which in the worst case requires a forward pass over all permutations of the dataset. In contrast, our proposed method, LoRA-1, offers a more efficient trade-off between debiasing time and inference speed. Specifically, LoRA-1 finetuning takes an average of 28.6 seconds per epoch using the BaQKCV loss function, resulting in approximately 143 seconds for five epochs on the ARC dataset. For MEDMCQ and QASC, LoRA-1 required only 91.3s and 100.0s, respectively, which are both lower than BNP and PriDe in those settings.While PriDe required just 52.5s on ARC, its debiasing time rose significantly on the MEDMCQ dataset (248.3s), highlighting its sensitivity to dataset size as it calibrates using 10% of the data, and so its cost scales with dataset volume. On the QASC dataset, its time (87.2s) was also slightly lower than LoRA-1. However, as dataset sizes grow, LoRA-1 remains more stable and predictable, making it more suitable for scalable deployment. Additionally, LoRA-1 maintains competitive inference times, showing only minor overhead compared to GrayBox and BNP.

MINDS: A Cross-cultural Dialogue Corpus for Social Norm Classification and Adherence Detection

Pritish Sahu*, **Anirudh Som***, **Dimitra Vergyri, Ajay Divakaran**
SRI International
{pritish.sahu, contact.anirudh.som}@gmail.com, {dimitra.vergyri, ajay.divakaran}@sri.com

Abstract

Social norms are implicit, culturally grounded expectations that guide interpersonal communication. Unlike factual commonsense, norm reasoning is subjective, context-dependent, and varies across cultures, posing challenges for computational models. Prior works provide valuable normative annotations but mostly target isolated utterances or synthetic dialogues, limiting their ability to capture the fluid, multi-turn nature of real-world conversations. In this work, we present **Norm-RAG**, a retrieval-augmented, agentic framework for nuanced social norm inference in multi-turn dialogues. Norm-RAG models utterance-level attributes including communicative intent, speaker roles, interpersonal framing, and linguistic cues and grounds them in structured normative documentation retrieved via a novel Semantic Chunking approach. This enables interpretable and context-aware reasoning about norm adherence and violation across multilingual dialogues. We further introduce **MINDS** (Multilingual Interactions with Norm-Driven Speech), a bilingual dataset comprising 31 multi-turn Mandarin-English and Spanish-English conversations. Each turn is annotated for norm category and adherence status using multi-annotator consensus, reflecting cross-cultural and realistic norm expression. Our experiments show that Norm-RAG improves norm detection and generalization, demonstrates improved performance for culturally adaptive and socially intelligent dialogue systems. The MINDS dataset is available at https://github.com/anirudhsom/MINDS-Dataset.

1 Introduction

Social norms are culturally embedded, often implicit expectations that shape how individuals interact in society, especially in interpersonal dialogues. These norms whether, behavioral conventions, moral obligations, or expectations of politeness guide acceptable conduct and influence both verbal and non-verbal communication (Sherif, 1936; Haidt, 2012; Schwartz et al., 2012). As norms can vary significantly across cultures (Triandis, 1994; Arieli, 1964), modeling them in computational systems demands reasoning beyond the literal meaning of utterances. Unlike factual commonsense, social norm reasoning involves subjectivity, context, and cultural nuances, making it significantly more ambiguous and under-determined.

Recent works, however, have made strides in codifying normative knowledge through structured resources such as SocialChem (Forbes et al., 2020), NormSage (Fung et al., 2022), NormDial (Li et al., 2023), SocialDial (Zhan et al., 2023) and RENOVI (Zhan et al., 2024), which annotate social norms in descriptive scenarios or conversations. These datasets highlight the importance of understanding values, intents, justifications, and social expectations. However, they fall short in modeling the dynamic, multi-turn nature of conversations where shifts in intent, emotional alignment, or interpersonal sensitivity can dramatically affect norm interpretation. For example, identifying whether a speaker's disagreement is socially acceptable may depend on factors such as power dynamics, tone, or context established across earlier turns. Existing resources often lack fine-grained annotations for cues, interpersonal relationships, or latent intentions which are critical signals for robust social norm understanding.

To address these limitations we propose **Norm-RAG**, a retrieval-augmented generation based agentic framework for social norm inference in dialogue. It models utterance-level features such as intent, cue, interest, and role interplay, enabling a more nuanced detection of implicit and culturally sensitive social norms in natural conversation. Furthermore, it decomposes norm behavior into the following pragmatically grounded attributes to enhance the interpretability and accuracy of norm

*Equal contribution

Proceedings of the 14th International Joint Conference on Natural Language Processing and the 4th Conference of the Asia-Pacific Chapter of the Association for Computational Linguistics, pages 2039–2052

detection - *Communicative Intent*, *Interpersonal Framing*, *Linguistic Features*, and *Contextual Triggers and Constraints*. By integrating these structured representations with LLM-based reasoning and dynamic retrieval of relevant norm documentation, we support both norm classification and norm adherence/violation assessment in multilingual conversation settings.

We also release **MINDS**, short for **M**ultilingual **I**nteractions with **N**orm-**D**riven **S**peech, a novel bilingual dataset consisting of 31 annotated multi-turn dialogue sessions across Mandarin-English and Spanish-English pairs. Each turn is labeled for norm category and adherence/violation status labels, with multi-annotator consensus to ensure quality and consistency. Unlike prior datasets that rely on static prompts or synthetic conversations, ours captures natural, two-party interactions, enabling more realistic modeling of culturally embedded norm violations and their detection.

Our key contributions are summarized as follows:

- We developed **Norm-RAG**, a novel agentic architecture that models social norms through retrieval-augmented generation, leveraging feedback from prior utterances and structured dialog context for turn-level inference.
- We introduce the **MINDS corpus**, a bilingual, multi-annotated dialogue dataset covering Spanish-English and Mandarin-English conversations, annotated for social norm type and adherence/violation status, reflecting cross-cultural, real-world interactions.
- We formulate norm classification using four interpretable, latent dimensions: *Intent*, *Framing*, *Linguistic Features*, and *Constraints*, moving beyond surface-level cue detection.
- We present a novel **Semantic Chunking** technique for norm document retrieval, replacing heuristic keyword matching with context-aware semantic segmentation to accurately extract applicable normative guidance.
- We benchmark and analyze retrieval-based and generative approaches across various configurations, demonstrating improved norm detection performance and generalizability.

2 Related Work

Early efforts in modeling social norms computationally have centered around static textual contexts (Ziems et al., 2023; Sap et al., 2019; Rashkin et al., 2018; Emelin et al., 2020; Jiang et al., 2021; Kim et al., 2022; Gu et al., 2021; Ziems et al., 2022; CH-Wang et al., 2023). Social Chemistry 101 (Forbes et al., 2020) introduced Rules-of-Thumb (RoTs) which are defined as free-text normative statements tied to situational prompts annotated with categorical labels capturing legality, moral foundations, and cultural expectations. While this large-scale resource enabled pretraining norm-aware language models, its static, monologic format restricts application to real-time dialogic settings. To overcome the lack of interactive context, NormSage (Fung et al., 2022) proposed a zero-shot prompting method for extracting culture-specific norms from dialogues across languages using GPT-3, creating the NormsKB knowledge base. Though NormSage allows dynamic norm discovery and cross-cultural applicability, it lacks annotations for turn-level adherence or violation, thereby limiting its utility in norm-tracking tasks.

NormDial (Li et al., 2023) advanced the field by annotating each dialogue turn with adherence, violation, or irrelevance labels, using human-in-the-loop generation of synthetic conversations grounded in American and Chinese norms. However, its reliance on synthetic data and predefined norm templates limits its coverage of spontaneous and organically evolving dialogues. SocialDial (Zhan et al., 2023) is a large-scale, monocultural resource centered on a Chinese ontology of social norms (5 categories, 14 subcategories). Its evaluation tasks involve predicting dialogue-level social factors (*e.g.*, distance, relation, location, formality, topic) and detecting norm violations within Chinese cultural contexts. In contrast, our work introduces a cross-cultural, bilingual dataset spanning Mandarin–English and Spanish–English conversations derived from real conversational data, annotated not only for norm adherence but also for underlying speaker-level features such as intent, cue, and interpersonal alignment. Furthermore, we propose a dual-task framework that performs latent norm discovery alongside turn-level adherence classification, without assuming access to predefined norm statements. This approach offers a more holistic and dynamic modeling of social norms in conversation, addressing key limitations in prior datasets and moving closer to deployable, socially intelligent dialog systems.

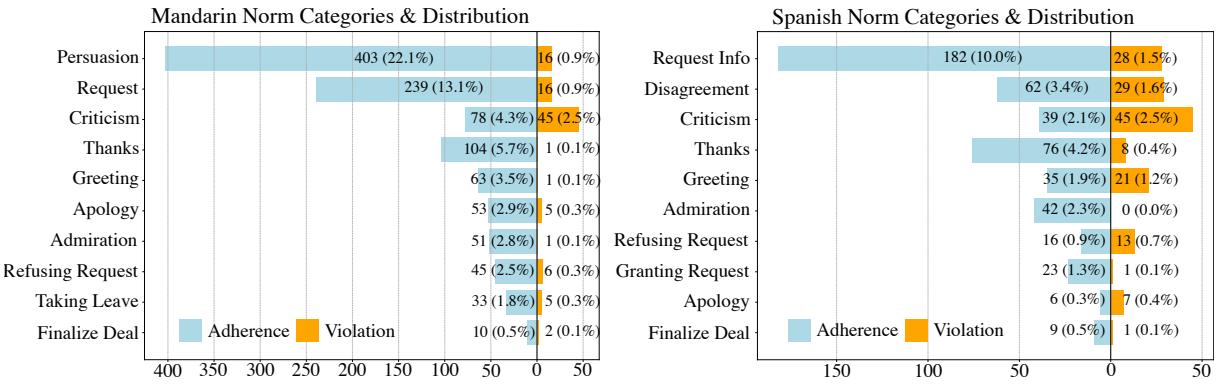

Figure 1: Distribution of annotated social norms across languages, norm categories and status (adherence/violation) labels. Numbers in parenthesis indicate sample percentage contribution in the database.

3 MINDS Corpus

Unlike static rule-sets, norms are context-sensitive, adaptive, and frequently nuanced by linguistic, interpersonal, and situational cues. Existing datasets have made significant strides in curating large-scale corpora for norm recognition and classification. However, each of these datasets presents notable limitations as described in Section 2. In contrast, the proposed MINDS corpus is curated from real bilingual conversational sessions with rich cultural and linguistic grounding. Below we outline the data collection and annotation methodology.

3.1 Data Collection

Each of the 31 sessions features a two-person, multi-turn dialogue between a foreign language expert and an English language expert. During the interaction, the foreign language expert communicates solely in the foreign language (either Mandarin or Spanish), while the English expert responds entirely in English. This structure was designed to simulate real-world bilingual communication scenarios such as interpreter training, second-language learning environments, or multilingual human-computer interactions.

The dataset is evenly balanced between the two language groups, where 16 sessions involve Mandarin speakers and 15 involve Spanish speakers. The Mandarin subset includes 12 unique speakers, with each unique speaker pair appearing only once. Similarly, 22 unique Spanish speakers were recruited with the same one-time unique pair participation constraint. This design ensures speaker diversity and eliminates redundancy, which is critical for fair evaluation in speaker-independent modeling tasks. The dialogues reflect a wide range of interpersonal dynamics, accents, and conversational styles. By enforcing the one-language-per-speaker rule, the setup captures code-switching boundaries, implicit translation patterns, and culturally specific communication strategies, making this dataset well-suited for multilingual NLP tasks.

3.2 Annotation Protocol

Each session in the dataset was independently annotated by multiple human raters. The annotators were tasked with labeling individual utterances within the dialogue, assigning a social norm and a status (e.g., adherence or violation of the social norm). These judgments reflect the pragmatic and sociolinguistic interpretation of the utterances in context, requiring annotators to consider intent, tone, and interpersonal dynamics. The annotation process was structured such that no single annotator was responsible for all sessions in a given language group. Instead, annotators were selectively assigned to sessions, resulting in partial coverage across sessions and users. For instance, within the Mandarin subset, 5 unique annotators participated, with each annotating a subset of the 16 sessions. Similarly, 6 annotators contributed to the Spanish subset, with varied levels of session coverage. No annotator covered all sessions, a deliberate design choice to maintain annotator diversity and avoid individual annotator bias dominating the evaluation outcomes.

Each turn in a session was labeled by at least one annotator, and many were reviewed by two or more annotators, enabling inter-rater reliability (IRR) analysis. In cases where multiple annotators reviewed the same turn, the agreement was quantified using Cohen's Kappa across combinations of norm and status annotations. Several sessions show high IRR, with only minor annotation discrepancies in labeling across turns, indicating high consistency where overlap existed. This further

supports the reliability of the annotations in modeling and evaluation tasks. By leveraging a multi-rater framework and ensuring speaker-annotator diversity, this annotation protocol supports robust downstream applications such as norm adherence classification, multilingual dialogue modeling, and socially intelligent agent development. The combination of linguistic variation, dialogue realism, and reliable annotation makes this dataset a valuable benchmark for cross-cultural and multilingual AI systems.

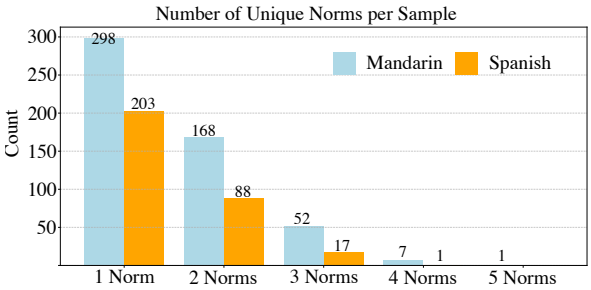

Figure 2: Frequency of norm categories per conversation sample.

3.3 Insights

As illustrated in Figure 1, Mandarin-English dialogues show a strong skew toward Persuasion and Request categories, suggesting a focus on negotiation and directive strategies. In contrast, Spanish-English interactions are dominated by Request for Information and Thanks, reflecting a more transactional or expressive discourse style. These trends highlight language-specific tendencies in conversational norms. The relative frequency of Disagreement and Criticism in Spanish, compared to Persuasion in Mandarin, points to cultural differences in how interpersonal boundaries and assertiveness are navigated. Such patterns underscore the need for culturally adaptive modeling of normative behavior. Violations are infrequent overall but consistently concentrated in sensitive categories like Criticism and Disagreement across both languages. These acts, though less common, are more likely to deviate from normative expectations, indicating higher pragmatic risk.

Most utterances reflect norm adherence, suggesting it is the default mode of interaction. However, norm-sensitive acts such as refusals or criticisms, even when rare, carry higher likelihoods of violation highlighting the asymmetry in norm observance across speech acts. The dataset captures a broad spectrum of social norms with balanced coverage of adherence and violation, across two linguistically and culturally distinct bilingual contexts. This makes it well-suited for cross-cultural norm modeling and the development of socially aware dialogue systems. Figure 2 illustrates the distribution of the number of unique norm categories annotated per conversation sample, comparing Mandarin-English and Spanish-English dialogues. Most samples exhibit a single norm type, with 298 Mandarin and 203 Spanish samples falling into this category. As the number of distinct norms per sample increases, the counts drop sharply, indicating that multi-norm interactions are less common. Nevertheless, a notable portion of conversations particularly in Mandarin contain two or more co-occurring norms, highlighting the normative complexity present in real-world dialogue. This distribution supports the need for models capable of handling multi-label norm classification in conversational contexts.

4 Approach

Here, we describe our Retrieval-Augmented Generation framework, **Norm-RAG**, designed for social norm classification and adherence detection in dialogues. Unlike prior works that either retrieve from static corpora (Forbes et al., 2020) or synthesize templated dialogue (Li et al., 2023), our method targets real-time, evolving conversational data. The central insight of **Norm-RAG** is to represent norms through pragmatic, multidimensional structures, enabling semantic and social interpretability beyond surface-level content. Our framework consists of four stages as illustrated in Figure 3: (1) *Semantic Clustering for Norm Chunking*, (2) *Structured Norm Attribute Extraction*, (3) *Semantic Norm Retrieval and Re-ranking*, (4) *Dialogue-Aware Norm Classification*. Refer to Appendix A for details about the different prompt templates used throughout the entire process.

4.1 Semantic Clustering for Norm Chunking

To structure the norm corpus for retrieval and alignment, we adopt a block-diagonal clustering approach guided by semantic similarity between norm sentences. Inspired by prior work on block-diagonal clustering structures (Xing and Zhao, 2024), we utilize a similarity-based heuristic grounded in the observation that semantically coherent norm definitions exhibit localized similarity in embedding space.

Let the norm document consist of n sequential

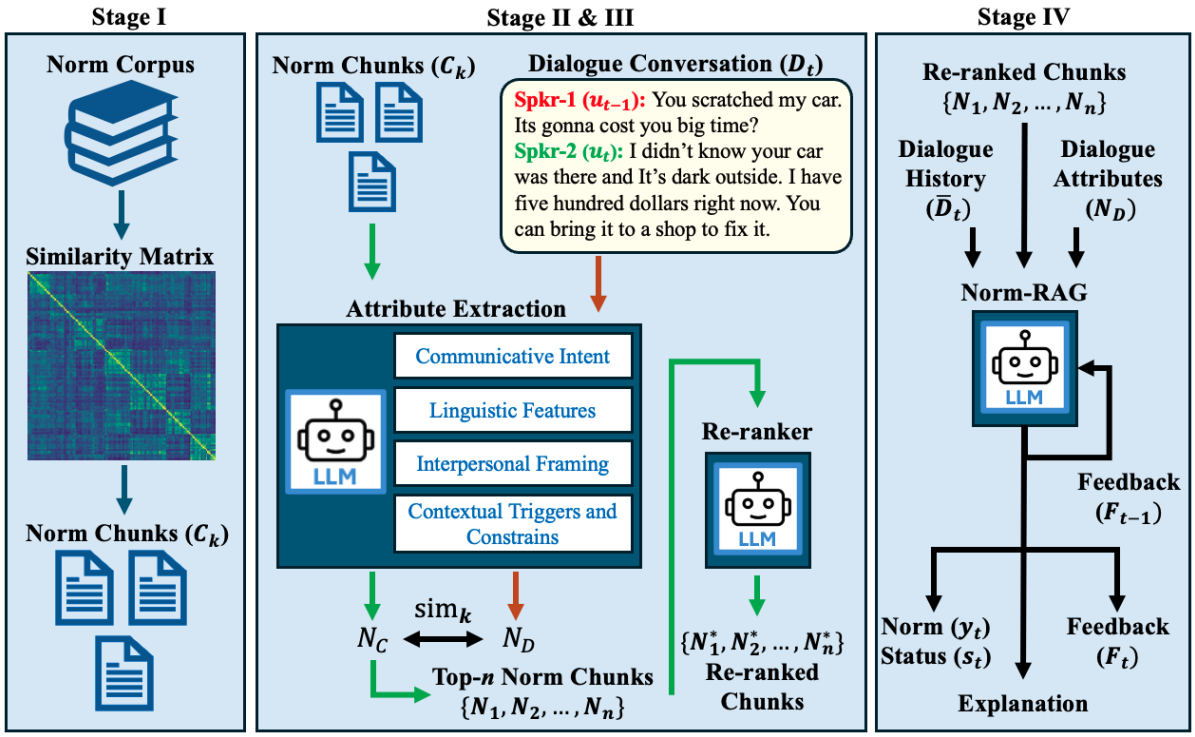

Figure 3: Illustration of the different stages of our proposed framework. Stage I represents semantic clustering for norm chunking. Stage II & III illustrates the structured norm attribute extraction, semantic norm retrieval and re-ranking modules. Finally, Stage IV shows the dialogue-aware norm classifier within the **Norm-RAG** system.

sentences $\{x_1, x_2, ..., x_n\}$. Each sentence x_i is encoded using a pre-trained sentence transformer, $s_i \in \mathbb{R}^d$. We define the pairwise cosine similarity matrix $\mathbf{S} \in \mathbb{R}^{n \times n}$:

$$\mathbf{S}_{i,j} = \frac{s_i \cdot s_j}{\|s_i\| \|s_j\|} \tag{1}$$

When visualized as a heatmap, $\mathbf{S}$ reveals a clear block-diagonal structure, clusters of high similarity corresponding to contiguous segments of norm-related sentences. These blocks emerge naturally because norm definitions and their illustrative examples tend to form coherent segments within the text. To segment these into preliminary clusters, we use a greedy line-wise algorithm. We begin with sentence x_1 and append subsequent sentences until the similarity with the previous line falls below a segmentation threshold ϵ_{seg}. Formally, for each i, we assign x_i to the current cluster if

$$\cos(s_{i-1}, s_i) \geq \epsilon_{\text{seg}} \tag{2}$$

Otherwise, a new cluster is initiated. We find that each cluster closely represents a candidate *norm chunk* C_k, a semantically consistent unit of norm information. Initial segmentation often leads to over-fragmentation due to outlier examples or edge-case scenarios within the same norm description. To address this, we apply a refinement stage: adjacent clusters C_k and C_{k+1} are merged if the cosine similarity between their mean embeddings μ_k and μ_{k+1} exceeds a merging threshold ϵ_{merge}:

$$\cos(\mu_k, \mu_{k+1}) > \epsilon_{\text{merge}} \tag{3}$$

Note, in experimentation we used grid search to find the optimal value for ϵ_{seg} and ϵ_{merge}. This two-phase process ensures that each norm chunk captures a semantically cohesive unit while minimizing cross-norm contamination. In practice, we observe that a single norm may be split across two clusters, however, it is rare for a single cluster to span multiple norms, thereby validating the precision of our clustering approach. These discovered norm chunks form the foundational retrieval units for semantic alignment with dialogue, enabling fine-grained context-aware norm reasoning in the subsequent stages of our framework.

4.2 Structured Norm Attribute Extraction

Real-world dialogue often evolves dynamically, with shifting intents, roles, and relationship framings. Different from general pipelines, the core insight driving our **Norm-RAG** is that normative behavior in conversation is multi-dimensional, governed not just by surface-level semantics. We repre-

sent these multidimensional structures around four foundational attributes of normative behavior:

> **1. Communicative Intent (*CI*):** What is the pragmatic goal conveyed (e.g., apologize, warn, inquire)?
> **2. Interpersonal Framing (*IF*):** What social relationship or power dynamic is implied (e.g., elder-junior, peer-peer)?
> **3. Linguistic Features (*LF*):** Which discourse cues or syntactic patterns characterize the norm (e.g., hedging, imperative verbs)?
> **4. Contextual Triggers and Constraints (*CTC*):** What environmental, cultural, or situational conditions activate or constrain the norm?

These dimensions capture latent communicative goals, social relationships, stylistic strategies, and situational factors that are essential to identifying and interpreting normative behavior. Next, we describe how these attributes are extracted for both the extracted norm chunks and dialogues during inference.

Once the norm chunks $\{C_k\}$ are identified, we extract their attributes via prompting a LLM, *e.g.,* gpt-4o-mini (Hurst et al., 2024). The goal is to extract the four underlying components (CI, IF, LF, CTC) from each norm chunk C_k in a normalized format:

$$C_k \xrightarrow{\mathcal{P}_{\text{GPT}}} N_{C_k} : \{CI_{C_k}, IF_{C_k}, LF_{C_k}, CTC_{C_k}\} \tag{4}$$

The prompt is designed to be culturally sensitive and context-aware, mirroring the structure of the norm examples provided in the documentation. The LLM returns a structured JSON-like response with textual content or canonical tags corresponding to each attribute. This extraction process not only supports semantic alignment in downstream retrieval, but also introduces interpretability and modularity in norm representation. By decoupling normative knowledge into interpretable attributes, our method enables precise matching between dialogue utterances and applicable social norms, supporting both generalization and cultural specificity in norm understanding.

4.3 Attribute-based Semantic Retrieval and Re-ranking

For a dialogue segment D_t up-to time t, our goal is to retrieve semantically aligned norm definitions based on shared pragmatic structure. We begin by extracting a normative attribute vector from D_t using the same four-part schema introduced earlier:

$$D_t \xrightarrow{\mathcal{P}_{\text{GPT}}} N_{D_t} : \{CI_{D_t}, IF_{D_t}, LF_{D_t}, CTC_{D_t}\} \tag{5}$$

Each attribute $a^i_{D_t}$ is compared independently against its corresponding attribute $a^i_{C_k}$ from all norm chunks in the index. Let ϕ denote the cosine similarity between embeddings. We define the aggregated similarity score between N_{D_t} and N_{C_k} as:

$$\text{sim}_k = \frac{1}{4}\sum_{i=1}^{4} \phi(a^i_{D_t}, a^i_{C_k}) \tag{6}$$

We retrieve top-n candidate norm chunks with the highest sim_k values, filtered to exceed a global threshold μ_{sim} (average across all sim_k scores), to ensure semantic proximity. These candidates serve as context for grounding downstream prompt generation.

Dialogue Window Design: To prevent topic drift from full-dialogue embeddings, we adopt a recency-focused strategy. Let u_t be the utterance at time t and D_t the entire dialogue segment up till time t. We construct a focused context window:

$$\bar{D}_t = \text{Concat}(u_{t-l}, \ldots, u_t) \tag{7}$$

This structure only considers the current utterance and previous l dialogue turns, thereby helping preserve critical dependencies while emphasizing recency. Here, l is determined via LLM given the dialogue history and the latest utterance. We optionally apply weighted averaging of embeddings with positional bias toward u_t to capture moment-level intent without any prior contextual noise.

Re-ranking Module: The retrieved candidates are further evaluated using a LLM-based re-ranker. Given extracted query attributes $\{a^i_{D_t}\}$ and each norm chunk N_n, the reranker $\mathcal{R}$ evaluates contextual alignment and re-ranks the retrieved norm candidates. The top-ranked norm is accompanied by a natural language explanation generated by the reranker, which justifies its contextual relevance to the dialogue. This attribute-disentangled retrieval mechanism mirrors the interpretive reasoning humans apply when aligning utterances with social norms. It also provides a semantically grounded context that enhances prompt-based inference in the final classification stage.

4.4 Dialogue-Aware Norm Detection Agent

In the final stage of the **Norm-RAG** pipeline, our objective is to identify at each time step t, the relevant social norm category and status for

each turn within the dialogue session. Additionally, we are also interested in generating explanations for the predicted result and relevant feedback to help at the next turn in the dialogue. To do this our RAG-based agentic framework incrementally processes each dialogue turn, one utterance at a time. At step t, the agent receives the focused context window $\bar{D}_t$; re-ranked retrieved norm chunks $\{N_1^*, \ldots, N_n^*\}$; and dialogue attributes $N_{D_t} : \{CI_{D_t}, IF_{D_t}, LF_{D_t}, CTC_{D_t}\}$. These along with the dynamic feedback variable F_{t-1} from the previous turn is embedded as a structured prompt and presented to the LLM for classification. Note, the feedback encodes high-level observations (e.g., tone, contradiction, escalation) that can influence future norm adherence. For the first utterance ($t = 1$), we set $F_0 = \emptyset$.

LLM Query and Output: The different LLM query inputs and outputs are illustrated as follows:

LLM Inference at Each Step

At each utterance step t, the LLM is prompted with:

- Focused Dialogue History: $\bar{D}_t$
- Retrieved Chunk Attributes: $CI_{D_t}, IF_{D_t}, LF_{D_t}, CTC_{D_t}$
- Retrieved Norm Context: $\{N_1^*, \ldots, N_n^*\}$
- Prior Feedback: F_{t-1}

The model produces:

- Norm Category: y_t
- Norm Status: $s_t \in \{\text{adhered}, \text{violated}\}$
- Explanation for y_t and s_t
- Updated Feedback Signal: F_t

Formally, the model performs:

$$(y_t, s_t, F_t) = \mathcal{L}(\bar{D}_t, CI_t, IF_t, LF_t, CTC_t, \{N_i^*\}_{i=1}^k, F_{t-1}) \quad (8)$$

where $\mathcal{L}$ denotes the LLM invoked with a custom instruction-tuned prompt. This agentic setup enables feedback-driven norm reasoning over the course of an entire conversation.

Agentic Loop: This structure forms a dynamic reasoning loop over the session:

Agentic Reasoning Loop

For a given session with utterances $\{u_1, \ldots, u_T\}$:

1. Initialize $F_0 = \emptyset$
2. For $t = 1$ to T:
   - Extract $\bar{D}_t = \{u_1, ..., u_{t-1}\}$
   - Retrieved Chunk Attributes: $CI_{D_t}, IF_{D_t}, LF_{D_t}, CTC_{D_t}$
   - Prompt Construction: $\bar{D}_t$, N_{D_t}, and F_{t-1}
   - Query LLM to obtain (y_t, s_t, F_t)
3. Repeat until end of session

By iteratively grounding each utterance in structured context, retrieved norms, and conversational dynamics, the **Norm-RAG** agent enables robust and explainable norm classification throughout multi-turn interactions. This agentic structure also supports temporal coherence, capturing how normative behavior evolves within a session.

5 Experiments

We conduct a comprehensive evaluation of our proposed approach on norm discovery and adherence/violation classification for conversations that include multi-lingual and cross-culture scenarios.

There has been no baselines or proposed model for Norm Discovery and Adherence discovery excluding NormSage (Fung et al., 2022) and NormDial (Li et al., 2023). However, these works do not compare to our proposed dataset and metric. Hence, we include the latest state-of-the-art LLMs both proprietary (GPT-4o (Hurst et al., 2024)) and open-sourced (LLaMA (Dubey et al., 2024), QWEN (Yang et al., 2025), Phi (Abdin et al., 2024)) baselines for comparison. For each utterance

5.1 Norm Classification and Adherence Detection Accuracy

Given a conversation, the task is to classify which social norm categories are invoked by the *latest utterance*, and determine whether the utterance adheres to or violates them. We evaluate this across two subtasks: norm classification and adherence status detection.

We benchmark our **Norm-RAG** framework against a range of zero-shot LLM baselines both closed-source (GPT-4o-mini) and open-source (LLaMA 3.1 8B, Qwen-3 32B, Phi-4 14B), across two key input configurations: 1. **Hist.**: Whether the model is provided with only the *latest utterance*

Model	Hist.	Docs	Norm Acc.	Adh./Viol. Acc.
GPT-4o-mini	✗	✗	64.6	57.2
Ours w/ GPT-4o	✓	✓	**70.4**	**63.6**
LLaMA 3.1 (8B)	✗	✗	56.4	44.7
LLaMA 3.1 (8B)	✓	✗	57.4	45.4
Ours w/ LLaMA	✓	✓	**64.4**	**54.4**
Qwen-3 (32B)	✗	✗	61.1	54.9
Qwen-3 (32B)	✓	✗	62.3	57.1
Ours w/ Qwen	✓	✓	**67.9**	**60.2**
Phi-4 (14B)	✗	✗	66.4	58.6
Phi-4 (14B)	✓	✗	67.8	**61.6**
Ours w/ Phi	✓	✓	**69.1**	60.2

Table 1: Accuracy for norm classification and adherence/violation detection on the MINDS corpus. **Hist.**: dialogue history used (✓) vs. only last utterance (✗). **Docs**: retrieved documentation used (✓) or not (✗).

Model	Hist.	Docs	Norm Acc.
GPT-4o-mini	✓	✗	58.0
Ours w/ GPT-4o	✓	✓	**62.0**
LLaMA 3.1 (8B)	✓	✗	57.2
Ours w/ LLaMA	✓	✓	**62.0**
Qwen-3 (32B)	✓	✗	52.4
Ours w/ Qwen	✓	✓	**55.0**

Table 2: Accuracy for norm classification and adherence/violation detection on the SocialDial corpus. **Hist.**: dialogue history used (✓) vs. only last utterance (✗). **Docs**: retrieved documentation used (✓) or not (✗).

Ablation Variant	Qwen-3	GPT-4o
Fixed text split	63.2 / 58.7	66.1 / 61.2
Cluster w/o attr.	65.1 / 59.0	67.4 / 61.9
w/o feedback	67.0 / 60.1	69.2 / 62.9
Full pipeline	**67.9 / 60.2**	**70.4 / 63.6**

Table 3: Ablation study of the **Norm-RAG** pipeline. "Fixed text split" uses uniform segmentation; "Cluster w/o attr." excludes attribute extraction; "w/o feedback" disables conversational feedback. We report norm classification and status accuracy as Norm/Status.

or with the *entire conversation history + latest utterance*, 2. **Docs.**: Whether the model receives *no external context* or is given *retrieved documentation* containing culture-specific norm definitions and examples. Each baseline is evaluated under these combinations, while our **Norm-RAG** method additionally integrates context i.e., structured attributes and feedback-driven reasoning.

As shown in Table 1 and Table 2, our approach consistently outperforms all baseline configurations across both norm classification and adherence detection tasks. Within each model family, the addition of historical context and external normative knowledge leads to meaningful gains. **Norm-RAG** further amplifies this by grounding LLM inference in retrieved, semantically-aligned norm definitions. **Norm-RAG** achieves an improvement of $+14.1\%$, $+21.7$ improvement for LLaMA 3.1 in norm classification and adherence detection accuracy respectively and lowest for Phi-4 with $+4.\%$ in norm classification while a drop in -2% in adherence accuracy. The modest gains with Phi-4 suggest that its performance benefits less from additional context, likely due to its reliance on internal knowledge and preference for concise instructions—larger retrieved prompts may disrupt its reasoning compared to models like Qwen and LLaMA that better utilize external context. Overall our results confirms that retrieval-augmented structure-aware prompting yields stronger generalization across dialog settings.

5.2 Ablation Study

To better understand the contribution of different components in the **Norm-RAG** framework, we conduct an ablation study summarized in Table 3. Starting with a fixed-size text splitter chunking mechanism (row 1), we observe significantly lower performance across both models, suggesting that arbitrary chunking limits semantic cohesion in the retrieved context. When switching to semantically clustered chunks without extracting norm attributes (row 2), we see consistent improvements (+1.9 in Qwen and +1.3 in GPT for norm accuracy), indicating the value of topically coherent segmentation. Turning off feedback (row 3) yields additional gains, showing that conversational grounding plays a role in cumulative norm reasoning. Finally, the full **Norm-RAG** pipeline (row 4) achieves the best performance across both models, confirming that attribute-guided context and feedback-driven prompting are complementary. Notably, GPT shows a larger gain from feedback than Qwen, likely due to its stronger adaptation to turn-level dialog intent modeling.

5.3 Qualitative Analysis

In challenging cases involving overlapping intents, such as: “I want the junior surgeon who performed the operation to be fired." **Norm-RAG** correctly

identifies the `doing request` as an act of adherence, while also detecting the embedded `doing criticism` as a norm violation—matching the human-labeled ground truth. By leveraging structured dialog attributes and semantically retrieved normative context, Norm-RAG disentangles multi-intent utterances and reasons about their distinct normative implications with high fidelity, even when cues are emotionally charged or culturally sensitive.

6 Conclusion

We presented **Norm-RAG**, a retrieval-augmented, agentic framework for modeling social norm adherence in multilingual dialogue. By combining semantically clustered norm documentation with structured dialog attributes—such as communicative intent, framing, and linguistic features—our approach enables interpretable and culturally sensitive norm reasoning. We introduced **MINDS**, a novel bilingual dataset of Mandarin-English and Spanish-English conversations annotated for norm categories and adherence status. Empirical results across multiple LLMs demonstrate significant gains in both norm classification and adherence detection. Through ablation studies, we show the importance of semantic chunking, structured attribute modeling, and feedback-based prompting. Together, these components move beyond static, template-based inference toward dynamic, socially grounded interaction. Future work will explore higher-order norm dynamics such as escalation, social repair, and longitudinal alignment in multilingual, multi-agent settings.

Acknowledgments

This material is based upon work supported by the Defense Advanced Research Projects Agency (DARPA) under Contract No. HR001122C0032. Any opinions, findings, and conclusions, or recommendations expressed in this material are those of the author(s) and do not necessarily reflect the views or policies of DARPA, the Department of Defense or the U.S. Government. We would like to thank the Applied Research Laboratory for Intelligence and Security (ARLIS) for their contributions to the data collection and annotation effort. Finally, we acknowledge the use of GPT-based models during the development of this work for research assistance and code prototyping.

Limitations and Ethical Considerations

While our work aims to improve norm understanding in multilingual dialogues, it has several limitations. First, our dataset covers only two non-English languages (Mandarin and Spanish), which limits generalization to other linguistic and cultural contexts. Second, although we employ LLMs for attribute extraction and classification, these models can inherit social and cultural biases from their training data, which may affect norm interpretation. We also acknowledge the limitations of using simulated or partially controlled bilingual dialogues, which may differ from spontaneous in-the-wild interactions.

Ethically, we ensured speaker anonymization in our dataset and limited language use to non-sensitive topics. We encourage future work to expand linguistic coverage and explore real-world deployment risks in downstream applications.

Computational Resources We conducted all experiments using 2× NVIDIA A6000 GPUs (each with 48GB VRAM). The classification pipeline used three open-source LLMs: LLaMA 3.1 (8B), Qwen (32B), and Phi-3 (14B), applied to a dataset of 835 utterances. For each utterance, the agent performed structured prompting and reranking per model. The total compute time across all models was approximately 30 GPU hours on the A6000 infrastructure.

A Prompts Used in Norm-RAG

Norm Attribute Extraction Prompt

System Prompt

```
"""You are a social interaction analyst specializing in pragmatics and social
norm recognition in conversation.

Given the dialogue below, extract a structured representation of the
**speaker's behavior in the final utterance**, focusing on how it performs or
aligns with one or more socially recognizable norms such as persuasion,
request, refusal, apology, etc.

The extracted structure will be used to retrieve similar conversational
behaviors, so it must **accurately reflect the speech act's social function,
nuance, and framing**, in a way that can **disambiguate between multiple norm
categories**.

=> If the utterance aligns with **more than one norm** (e.g., 'doing request'
+ 'doing thanks'), your attributes should reflect that layered action.

Return the following 4 **pragmatic attributes**:

```json
{{
  ``CommunicativeIntent": ``<Describe *all communicative goals* the speaker
  is pursuing -- both primary and secondary. Use norm language if applicable
  (e.g., persuading, requesting info, refusing, finalizing). Prioritize
  intent differentiation across norms.>",
  ``InterpersonalFraming": ``<How the speaker *relates to the listener*:
  formality, power dynamics, face-work (saving/threatening), emotional
  stance, or alignment. Make distinctions like deferential vs. assertive,
  affiliative vs. distancing -- as they cue norm categories.>",
  ``LinguisticFeatures": ``<Detail rhetorical strategies used to *signal or
  mitigate norm performance*: hedges, indirectness, modality (e.g., 'might',
  'should'), discourse markers, politeness formulas, etc. Capture evidence
  that helps distinguish one norm from another.>",
  ``ContextualTriggersAndConstraints": ``<What about the broader dialogue or
  situation shapes how this norm is performed? Include role relations,
  timing, known stakes, prior acts, social rules or expectations that
  constrain the speaker's behavior.>"
}}
```
"""
```

User Prompt

```
### Dialogue Context:
{dialog_context}
```

Figure 4: Prompt Template to extract the four key attributes that describe the dialog.

Dialog Window Design Prompt

System Prompt

```
You are an expert in pragmatics and social norms.
Given the dialogue history below, analyze the communicative function and
social dynamic of the most recent turn.
Please return your response in the following JSON format:
```
{{
    "CommunicativeIntent": "<short summary of what the speaker is trying to
    achieve>",
    "InterpersonalTension": "<comment on any social tension, repair,
    dominance, submission, etc.>",
    "LikelyNormCategory": "<the most likely norm involved, e.g., 'doing
    apology', 'doing greeting', etc.>",
    "ContextDependenceScore": <float between 0.0 and 1.0, where higher means
    more dependent on prior context>
}}
```
```

User Prompt

```
### Dialogue History:
{dialog_history}
```

Figure 5: Analyzing the latest utterance to determine dialog window.

Re-ranking Retrieved Norm Chunks Prompt

```
You are a pragmatics and discourse analysis expert.
You are given:
-- A brief snippet of dialogue (usually the last 1-2 turns of a conversation),
-- A structured interpretation of that snippet, for attribute
{attribute_name},
-- A list of candidate norm definitions retrieved from a semantic search
system.
Your task is to rerank the candidates from most to least relevant, based on
how well each one aligns with the communicative behavior expressed in the
dialogue as represented by the extracted attributes.

### Dialogue Context:
"{dialog_context}"

### Extracted Norm Attributes:
{attributes}

### Retrieved Candidate Norm Descriptions:
{doc_entries}

### Instructions:
-- Compare the overall meaning and function of each candidate to the
extracted attributes.
-- Pay special attention to the Communicative Intent, but also consider
whether the interpersonal stance, language choices, and situational framing
match.
-- Your goal is to rank which candidate best captures the type of norm being
enacted in the given dialogue.

### Output Format:
{{
  "Ranking": [3, 1, 2, 4, 5],
  "TopJustification": "..."
}}
Only return the JSON object.
```

Figure 6: Prompt used to re-rank the retrieved norm chunks.

Feedback Prompt

System Prompt

```
You are a pragmatic analyst helping to generate interpretive context for
understanding turn-by-turn norms in conversation.
Given the most recent utterance in a dialogue, along with its predicted
norm(s) and surrounding dialogue context, your task is to produce **feedback
that captures the communicative force and social trajectory** of the current
moment.
This feedback will be used to inform the interpretation of the *next*
utterance -- by helping identify what norms or responses are socially
relevant or expected, and what social constraints are already in play.

### INPUT:
- `DialogueHistory`: The full dialogue history leading up to the latest
utterance (short or long).
- `LastUtterance`: The final utterance by the most recent speaker.
- `PredictedNorms`: One or more social norms inferred from the last
utterance. One or more of:
  ['Doing persuasion', 'Doing request', 'Doing requesting information',
  'Doing criticism', 'Doing thanks', 'Doing greeting', 'Doing admiration',
  'Doing disagreement', 'Doing refusing a request', 'Doing apology', 'Doing
  taking leave', 'Doing granting a request', 'Doing finalizing
  negotiation/deal', 'No Norm']

### OUTPUT FORMAT:
{
  ``SituatedSummary": ``<Explain what is being socially performed in the last
  utterance, and how it connects to the unfolding dialogue -- including tone,
  intentions, relational shifts, or embedded expectations.>",
  ``NormImplications": ``<What social norm(s) are being enacted or invoked?
  Why? Include cues from wording, context, or sequencing.>",
  ``NextTurnExpectation": ``<What types of responses -- in terms of social
  action or stance -- are made relevant by this utterance? What does it
  *invite*, *pressure*, or *allow* the next speaker to do (or not do)?
  Mention if there's a power dynamic, politeness constraint, emotional
  charge, etc.>"
}
```

User Prompt

```
### Dialogue History
{dialoghistory}

### Last Utterance
{lastutterance}

### Predicted Norms
{predictednorms}
```

Figure 7: System and user prompts used to extract the feedback from latest utterance shown to Dialog Aware Agent which will become context for the next incoming utterance.

Norm Detection and Adherence Detection Prompt

System Prompt

```
You are an expert in analyzing conversations to identify underlying social
norms. Your task is to classify all applicable social norm categories
(minimum 2, maximum upto 5) reflected in the **latest utterance** of a given
dialogue using both **explicit and implicit cues** of social interaction.
### Norm Categories: {norm_categories}
### Task Instructions:
1. Use the **entire dialogue history** and the **retrieved context from RAG**
to interpret the **social intent** behind the **latest utterance**.
   - Consider both **explicit speech acts** (e.g., asking, refusing) and
   **implicit or indirect signals** (e.g., persuading by justification,
   criticizing through description).
   - Understand the progression and structure of the dialogue to reveal the
   **pragmatic function** of the utterance.
2. Identify **all relevant norm categories** the latest utterance satisfies
from the list (maximum 3).
   - Choose norms based on **intent**, **emotion**, **relational context**,
   **dialogue progression**, and **linguistic cues**, even when **indirectly
   expressed**.
   - Include **weak or moderate instances** of norms (e.g., subtle persuasion
   or soft disagreement), not just overt ones.
3. For each norm category:
   - Assess whether the utterance reflects **Adherence** or **Violation** of
   that norm.
4. Evaluate whether the **retriever context** is relevant to the **overall
set of predicted norms**:
   - If **Relevant**, use it to support a more confident classification.
   - If **Not Relevant**, ignore the retriever context and use your own
   reasoning about social norms.
5. If **no identifiable norm** is present in the utterance:
   - Return only one entry:
     - Norm Category: `No Norm`
     - Status: `Violation`
6. Provide a **natural language confidence level** for your prediction:
   - Choose from: `High`, `Medium`, or `Low`
   - Justify your confidence based on clarity of social intent, surface and
   hidden patterns, and context fit.

### Output Format in JSON:
```json
{{
  "latest_utterance": "<copy of the utterance>",
  "predicted_norms": [
    {{"norm_category": "<norm category 1>", "status": "<Adherence or
    Violation>"}},
    {{"norm_category": "<norm category 2>", "status": "<Adherence or
    Violation>"}}
  ],
  "retriever_context_relevance": "<Relevant / Not Relevant>",
  "confidence_level": "<High / Medium / Low>",
  "explanation": "<Justify the norm predictions, referencing how context and
  implicit cues shaped the interpretation>"
}}
```
```

User Prompt with (or without) Context

```
{% if context %}
### Relevant Context from RAG on 4 key attributes that are used to capture
the underlying norm:
{{ context }}
{% endif %}
### Dialog:
{{ dialog }}

Abstract

Large language models (LLMs), despite their remarkable text generation capabilities, often hallucinate and generate text that is factually incorrect and not grounded in real-world knowledge. This poses serious risks in domains like healthcare, finance, and customer support. A typical way to use LLMs is via the APIs provided by LLM vendors where there is no access to model weights or options to fine-tune the model. Existing methods to detect hallucinations in such settings where the model access is restricted or constrained by resources typically require making multiple LLM API calls, increasing latency and API cost. We introduce CONFACTCHECK, an efficient hallucination detection approach that does not leverage any external knowledge base and works on the simple intuition that responses to factual probes within the generated text should be consistent within a single LLM and across different LLMs. Rigorous empirical evaluation on multiple datasets that cover both the generation of factual texts and the open generation shows that CONFACTCHECK can detect hallucinated facts efficiently using fewer resources and achieves higher accuracy scores compared to existing baselines that operate under similar conditions. Our code is available here.

1 Introduction

Large Language Models (LLMs) are the go-to tools for NLP applications given their excellent text generation capabilities (Zhao et al., 2023). However, despite recent developments in model architecture and training, even state-of-the-art models such as GPT-4 (Achiam et al., 2023) and PALM-540B (Chowdhery et al., 2023) often generate text that appears plausible, but is factually incorrect or non-sensical – a phenomenon termed *hallucination* (Huang et al., 2023). A formal analysis by Xu et al. (2024) shows that LLMs cannot learn all possible computational functions, and hence, by design, will always hallucinate, albeit to different degrees. Consequently, detecting when the LLM hallucinates is imperative to take corrective action and minimize misinformation from reaching users.

Such model hallucinations can be either *intrinsic* or *extrinsic* (Ji et al., 2023). Intrinsic hallucinations arise when model outputs contradict the input or in-context instructions and can often be detected by checking input-output consistency (Huang et al., 2023). Extrinsic hallucinations, on the other hand, occur when the model output is factually incorrect and is not grounded on the pre-training data (Huang et al., 2023). Given the volume of pre-training data and that it is typically inaccessible by the users, extrinsic hallucinations pose a greater challenge due to their unverifiable nature (Ji et al., 2023).

Hallucinations in LLMs are typically addressed by either *(i)* improving factual accuracy via training or fine-tuning (Tian et al., 2023; Azaria and Mitchell, 2023a; Chuang et al., 2023), or *(ii)* verifying model outputs using external knowledge sources (Cheng et al., 2024). However, in many practical cases, end-users or developers lack access to model weights or external verification sources. Recent approaches circumvent this by repeatedly querying the LLM (Manakul et al., 2023; Zhang et al., 2023a; Liu et al., 2022) to thoroughly verify responses or sample large number of outputs to estimate output probability distributions, leading to significantly increased cost and latency. To address these limitations, we propose CONFACTCHECK, a lightweight method for hallucination detection that relies solely on the LLM's internal knowledge. CONFACTCHECK is based on a simple idea: an LLM's understanding of a topic can be evaluated by asking related questions and measuring consistency. This recursive probing strategy has also been used in testing question-answering systems (Chen et al., 2021). As illustrated in Figure 1, CONFACTCHECK identifies key entities/tags

*Equal contribution.

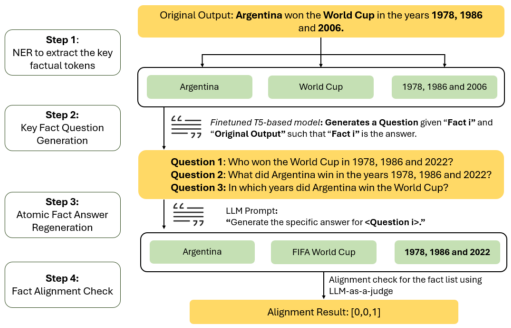

Figure 1: Key fact-based hallucination detection through the Fact Alignment check of our ConFactCheck pipeline. Each fact is used to generate a question, and the fact is regenerated by prompting the question to the LLM. The regenerated facts are compared with the original extracted key facts to check for their consistency.

(using NER/POS tagging) in the generated output and then formulates contextually relevant questions around these entities. We term these entities/tags as 'key facts', as these contain essential factual information in sentences. The LLM's answers to these questions are checked for consistency with the original response, with high consistency indicating that the output is grounded in the model's pre-training data (reflective of the world knowledge).

We evaluate ConFactCheck on four different datasets spanning question-answering (NQ_Open (Kwiatkowski et al., 2019), HotpotQA (Yang et al., 2018), WebQA (Berant et al., 2013)) and open-ended generation tasks where inputs to the LLM lack any additional context (WikiBio (Manakul et al., 2023)). ConFactCheck outperforms recent state-of-the-art self-check or self-consistency-based baselines (Manakul et al., 2023; Zhang et al., 2023a; Liu et al., 2022) along with baselines relying on the internal states of models (Chen et al., 2024) for LLMs of different model families. ConFactCheck achieves this outperformance while being significantly faster and requiring a lower number of LLM calls (*c.f.*, Table 2). We also report the results of various ablation studies guiding our design choices and conclude by discussing the strengths and limitations of ConFactCheck.

2 Related Work

LLMs are inherently prone to hallucinations (Xu et al., 2024; Ji et al., 2023), a phenomenon also observed in visual and multi-modal models (Bai et al., 2024; Liu et al., 2024). This has led to extensive research on hallucination detection and mitigation (Huang et al., 2023; Zhang et al., 2023b; Tonmoy et al., 2024). Existing methods fall broadly into two categories: *self-checking, prompt-based* approaches and those that require access to model weights or external knowledge sources.

Methods Requiring Access to Model Weights and External Sources: Tian et al. (2023) demonstrate that fine-tuning with factuality preferences improves output correctness. Azaria and Mitchell (2023b) use internal LLM activations passed through a classifier to estimate truthfulness. INSIDE (Chen et al., 2024) uses internal sentence embeddings and analyzes their covariance eigenvalues to detect hallucinations. Various decoding strategies (Chuang et al., 2023; Shi et al., 2024) have also been developed that utilize token probabilites at various layers to detect and mitigate hallucinations. Some approaches such as HaluAgent (Cheng et al., 2024) use additional tools such as web search engines, code interpreters etc for text and code-based detection of hallucinations respectively.

Self-Checking and Prompt-Based Methods: Zhang et al. (2023a) propose Semantic-Aware Cross-Check Consistency (SAC^3), a sampling-based method that checks for self-consistency across multiple generations. Similarly, SelfCheckGPT (Manakul et al., 2023) samples diverse outputs and scores their similarity to the original to estimate confidence. InterrogateLLM (Yehuda et al., 2024), focuses on regenerating the original query for a generated answer by reversing few-shot QA pairs to few-shot AQ pairs to self-check for model confidence during regeneration. These self-refining approaches often rely on the target LMs themselves, which is also demonstrated in Self-Refine (Madaan et al., 2023), an iterative mitigation-based approach for hallucinations. Mündler et al. (2023) explore self-contradictions using two LLMs – one for generation and one for contradiction analysis. TRUE (Honovich et al., 2022) evaluates factual consistency using a range of metrics (n-gram, NLI, model-based) on the FEVER dataset (Thorne et al., 2018). Liu et al. (2022) propose a reference-free, token-level method for detecting hallucinations and also present the Hallucination Detection dataset (HaDes), with raw web text being perturbed and then annotated by humans to design it for hallucination detection as a classification task. Cohen et al. (2023) present a cross-checking prompt-based method with 2 LLMs in a dialogue setting for

evaluating hallucinations. Yang et al. (2023) employ a reverse validation method for self-checking via "databases" (i.e the same LLMs), by prompting specific fact-based information to the models. FactScore (Min et al., 2023) breaks outputs into atomic facts, and verifies them using reliable *external* knowledge sources. We also utilize the notion of atomic facts in CONFACTCHECK , however, instead of leveraging external sources, we check for consistency in LLM outputs about the atomic facts.

3 The CONFACTCHECK Approach

Figure 2 summarizes our proposed hallucination detection approach comprising of two main steps – *(i)* a *fact alignment* check where key facts in the output are compared with facts obtained by targeted probing of the LLM; and *(ii)* a *uniform distribution check* that filters out the low confidence predictions. We now describe the overall pipeline in detail.

3.1 Fact Alignment Check

Extracting Key Facts: To check whether a piece of text, $\mathcal{A}$, generated by an LLM $\mathcal{M}$ is hallucinated, we start with the assumption that the generated text is correct. We then generate questions targeting each key fact in $\mathcal{A}$, such that they can be answered solely using the content of $\mathcal{A}$. Subsequently, we employ the LLM to answer the questions and see if the answers match the information in $\mathcal{A}$, a mismatch indicating hallucinations. The initial step is to identify the factual components within a sentence. According to Kai et al. (2024), factual information in a sentence is typically conveyed through specific parts of speech, *viz.*, nouns, pronouns, cardinal numbers, and adjectives. We highlight tags with such information as key facts that are to be extracted. Min et al. (2023) use a similar concept, where they classify short sentences in text (obtained by InstructGPT generation and human annotation) as atomic facts. However, the key facts we discuss are extracted NER/POS tags containing factual information, and hence are different. Key facts can be extracted by performing part-of-speech (POS) tagging or Named Entity Recognition (NER) on the sentence. Given an LLM output $\mathcal{A}$, we perform coreferencing and decompose $\mathcal{A}$ into sentences $S_1, S_2, \ldots, S_N$, where N is the total number of sentences, such that $\mathcal{A} = \{S_1, S_2 \ldots, S_N\}$. Each sentence is tagged to extract key facts a_{ij}, where $i \in \{1, \ldots, N\}$, and j depends on the number of tagged entities in a sentence. The tagging can be either POS-based or NER-based, as discussed in Section 5.4.3. For example, given the original sentence "*Argentina won the World Cup in the years, 1978, 1986 and 2006.*", in Figure 1, the key facts consist of $a = [a_{11} = \textit{Argentina}, a_{12} = \textit{World Cup}, a_{13} = \textit{1978, 1986 and 2006}]$.

Targeted Question Generation: After identifying key facts, the next step involves verifying whether each fact is hallucinated within the context of the sentence. Unlike previous methodologies that assign a hallucination score to each sentence, CONFACTCHECK focuses on key facts, thereby enhancing explainability by pinpointing the exact parts of a sentence that are hallucinated and providing reasons for this determination, as detailed in Section 5.5. Specifically, for each key fact a_{ij} given sentence S_i, a corresponding question q_{ij} is generated (using a T5-based model that is specifically finetuned for this task of question regeneration), with a_{ij} as the target answer and S_i as the context, expressed as $q_{ij} = \mathcal{Q}(a_{ij}|S_i)$, where $\mathcal{Q}$ represents the question generation module. In Figure 1, each key fact provides one question $q = [q_{11} = \text{Question 1}, q_{12} = \text{Question 2}, q_{13} = \text{Question 3}]$. LLM $\mathcal{M}'$ is then used to evaluate these questions at a low temperature to ensure response consistency, as it enables the LLM to generate high-quality and deterministic outputs. Each individual key fact-based question is answered by the LLM with greater precision and therefore helps to better identify whether the fact is correct or incorrect (Dhuliawala et al., 2024). Note that $\mathcal{M}'$ may or may not be the same as $\mathcal{M}$, as another LLM can be used to evaluate the responses of LLM $\mathcal{M}$.

Consistency Checking The responses from $\mathcal{M}'$ yield regenerated facts f_{ij}, which are subsequently checked for consistency with a_{ij}. To check for the similarity between f_{ij} and a_{ij}, we follow the LLM-as-a-judge paradigm (Zheng et al., 2023), by querying GPT4.1-mini using few-shot prompting to assess whether each pair is aligned or not. For instance, the set f for Figure 1 being $f = [f_{11} = \textit{Argentina}, f_{12} = \textit{FIFA World Cup}, f_{13} = \textit{1978, 1986 and 2022.}]$, and original key facts being a = [a_{11} = *Argentina*, a_{12} = *World Cup*, a_{13} = *1978, 1986 and 2006*]. In this case, facts f_{13} and a_{13} are non-aligned; whereas, the pairs $< f_{11}, a_{11} >$ and $< f_{12}, a_{12} >$ are aligned as per the judge's output. For each aligned and non-aligned pairs, we assign the score of 0 and 1 respectively. Note that since the number of extracted *facts* varies based on the sentence, the number of

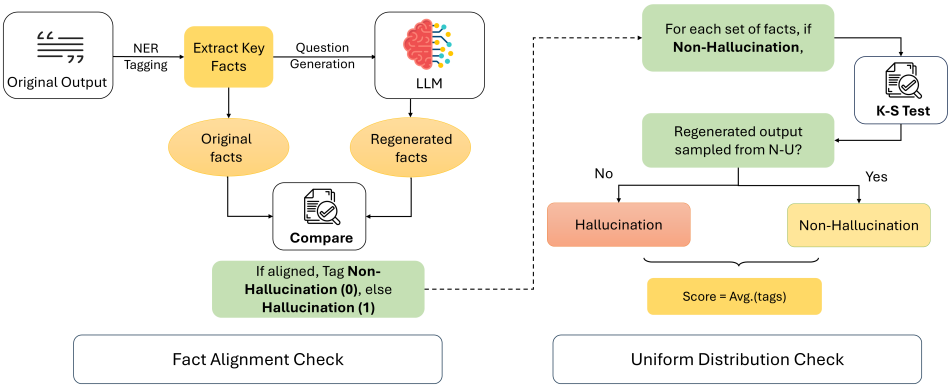

Figure 2: Pipeline of the CONFACTCHECK approach, with NER tagging of outputs followed by the first comparison-based check (Fact Alignment Check) and the secondary KS test-based probability check (Uniform Distribution Check) for rechecking the classfied non-hallucinations, result in the final tagging of hallucinations.

questions generated per sentence also varies. The consistency checking step, thus, enables the decomposition of sentence-level information into discrete factual elements and leverages and operates under the assumption that the LLM's responses will remain consistent for factual information when sampled at a low temperature.

3.2 Uniform Distribution Check

After the fact-alignment step, we perform a subsequent step to check if the facts were regenerated with high confidence. The underlying intuition behind this step is that if the LLM is confident in regenerating a fact correctly, the probability distribution of the generated tokens will be skewed, with the selected tokens having significantly higher probabilities than the other possible tokens. This results in a non-uniform distribution of token probabilities. Conversely, if the LLM is uncertain, even though the generated tokens may have the highest relative probability, their values will be closer to those of alternative tokens (closer to a uniform distribution) and indicating less confidence in LLM prediction. To quantify this effect, we apply the Kolmogorov–Smirnov (K–S) test to the top five tokens associated with each regenerated fact f_{ij}. The test is conducted using a standard significance level of 0.05. A p-value below this threshold leads to the rejection of the null hypothesis (i.e., the top tokens are drawn from a uniform distribution) implying that the LLM exhibits confidence in its generation. If the test indicates a non-uniform distribution, the LLM is deemed confident in regeneration, and original fact a_{ij} is classified as non-hallucinated. However, if the token probabilities follow a uniform distribution, it is concluded that the particular fact is hallucinated, reflecting the LLM's lack of confidence. The final hallucination score for a sentence S_i is calculated by averaging the individual scores of a_{ij} present in it to give a probability of how likely a sentence has been hallucinated.

4 Experimental Protocol

4.1 Task and Datasets

We consider two common task settings – question answering (QA) and text summarization. In the QA setting, LLMs are particularly susceptible to factual hallucinations, especially when no external context or information is provided with the input questions. The summarization task is a representative of the long-form text generation tasks where the output is not limited to be a short answer (a phrase or a sentence), and hence enables us to evaluate the ability of various methods to detect hallucinations in longer pieces of text. Further, this setting also tests the ability of the LLM to generate text that is *faithful* to the input context (text to be summarized).

We use the following datasets for evaluation, (with the validation/test sets for QA):

1. Natural Questions (NQ)-open (Kwiatkowski et al., 2019) is an open-domain QA benchmark derived from the Natural Questions dataset (Lee et al., 2019). The validation split of this dataset consists of 3,610 open-domain question-answer pairs covering a wide range of topics..

2. HotpotQA (Yang et al., 2018) is a QA dataset that features complex questions requiring multi-hop reasoning.

3. WebQA (Berant et al., 2013) dataset is a factoid

QA dataset where the questions are derived from the Freebase knowledge base.

4. WikiBio (Manakul et al., 2023) is a hallucination detection dataset derived from Wikipedia biographies. It consists of 238 randomly selected articles from among the longest 20% Wikipedia articles. It also provides synthetic text generated by GPT-3 for each of the original articles, along with labels for factual correctness of the sentences.

4.2 Baselines

We use following four representative self-check and self-consistency based hallucination detection methods as baselines.

HaDes (Liu et al., 2022) is an external reference-free method that leverages various token-level features such as POS tags, average word probability, mutual information, and TF-IDF scores to identify if a token is hallucinated or not.

SelfCheckGPT (Manakul et al., 2023) is a sampling based approach built upon the intuition that for hallucinated responses, stochastically sampled responses for the same input are likely to diverge.

SAC^3 (Zhang et al., 2023a), another sampling-based approach that generates responses to multiple semantically similar inputs to the original input and checks for consistency in the generated outputs.

INSIDE (Chen et al., 2024) detects hallucinations using the EigenScore metric, calculated using the eigenvalues of the covariance matrix of the responses to measure the semantic consistency/diversity in the dense embedding space of the generated outputs.

4.3 Implementation details

Models Used. We use `LLaMA3.1-8B-Instruct` and `Qwen2.5-7B-Instruct` as the base LLMs for comparing CONFACTCHECK and various baselines. For the QA task, initial responses are also generated using these base LLMs, with a temperature of 1. Further, we use different models of Phi-3 family to study how well CONFACTCHECK performs with LLMs of varying scale (Section 5.3). We present ablations that guided our design choices in Sections 5.4.2 and 5.4.3. We use the official implementation of HaDes[1] for our experiments. For SAC^3 (Zhang et al., 2023a), we compute the question-level consistency SAC^3-Q score and employ predetermined thresholds to discern the presence of hallucinated outputs.

[1] https://github.com/microsoft/HaDes

Metrics for Analysis: We consider hallucination detection as a binary classification task where the text generated by the LLM is either hallucinated or not. For QA datasets, we assign labels of 1 for hallucination and 0 for non-hallucination to the original outputs by comparing them with the golden answers in the QA datasets using GPT4.1-mini as a judge LLM. For WikiBio, each sentence-level golden label is provided in the dataset itself. We compare the baselines with our approach (see Table 1) and report the AUC-PR scores on the 3 open-domain QA datasets, as well as the WikiBio summarization dataset. Note that the SelfCheck-GPT baseline is applicable on the WikiBio dataset, as the others deal with only the QA task and require questions as part of their input.

5 Empirical Results

5.1 CONFACTCHECK for Hallucination Detection

Table 1 summarizes the results of different methods for the four datasets and across two LLM backbones (`LLaMA3.1-8b` and `Qwen2.5-7B`). We observe that CONFACTCHECK outperforms most baselines on the QA datasets and the two LM backbones. Only the Selfcheck-Prompt baseline outdoes our approach in few settings, and even in all such cases, CONFACTCHECK is the second-best performing method (the second-best approach in each column is underlined). Selfcheck-Prompt achieves the second-best performance on three other QA settings, while SAC^3 and INSIDE achieve the second-best performance in 2 different settings. Thereby, CONFACTCHECK demonstrates consistency by either being the best or second-best performing method in all settings. Further, only SelfCheckGPT can be used for detecting hallucinations in free-form text (WikiBio dataset), as the other baselines are designed for detecting hallucinations in QA tasks and need questions as part of their input. CONFACTCHECK, on the other hand, can detect hallucinations in QA as well as free-form text settings and achieves strong performance across all settings. Such strong performance of CONFACTCHECK can be attributed to the fact that it identifies the key factual tokens in the generated text and probes the LLM regarding its knowledge around these tokens.

Model	NQ Open		HotpotQA		WebQA		WikiBio	
	LLaMA3.1	Qwen2.5	LLaMA3.1	Qwen2.5	LLaMA3.1	Qwen2.5	LLaMA3.1	Qwen2.5
HaDes (Liu et al., 2022)	0.54	0.67	0.68	0.69	0.46	0.48	N/A	N/A
SAC^3 (Zhang et al., 2023a)	0.59	0.71	0.68	0.59	0.63	0.55	N/A	N/A
SelfCheck-MQAG (Manakul et al., 2023)	0.58	0.75	0.76	0.78	0.50	0.62	0.83	0.83
SelfCheck-Prompt (Manakul et al., 2023)	**0.76**	0.80	**0.86**	0.82	0.54	0.68	**0.92**	**0.90**
INSIDE (Chen et al., 2024)	0.61	0.54	0.56	0.60	0.58	0.68	N/A	N/A
ConFactCheck	0.73	**0.80**	0.83	**0.84**	**0.66**	**0.71**	0.86	0.85

Table 1: AUC-PR scores for NQ Open, HotpotQA, WebQA, and WikiBio datasets. We compare ConFactCheck in the same settings as the baselines, using LLaMA3.1-8B-Inst and Qwen2.5-7B-Inst as the base models. Settings for ConFactCheck results use beam decoding on the whole pipeline (this yields best possible scores). The best performing method in a given column is in **bold** and the second best performing model is underlined.

5.2 Computational Efficiency of Different Methods

Recall from discussions in Section 1 that self-check or self-refinement style methods suffer from high latencies due to the need to query the LLM repeatedly to estimate the output probability distributions or for a thorough verification of the generated output. ConFactCheck, on the other hand, identifies key facts in the generated output and generates targeted questions around these facts, thereby greatly reducing the number of LLM calls. Further, ConFactCheck relies on lightweight comparisons and statistical operations (Section 3) to check if the answers to targeted questions align with the original output. Table 2 presents the average number of LLM calls made and the average inference time for different methods. We note from the table that ConFactCheck achieves fast inference times for both the `LLaMA3.1` and `Qwen2.5` backbones. INSIDE is slightly faster than ConFactCheck, however our pipeline offers up to ≈1.4x speedup compared to SelfCheck-Prompt (Manakul et al., 2023) (9.51s vs. 13.35s for `LLaMA3.1`) and ≈1.5x and ≈3x when compared to SAC^3 (on the 2 LLMs respectively). Note also that in the case of ConFactCheck the number of calls being made to the LLM is equivalent to the average number of key facts extracted per input in the dataset plus one additional call to the judge-LLM for Fact Alignment. In Table 2), we report the latency numbers for SelfCheckGPT and SAC^3 with 20 and 5 LLM samples per question, and INSIDE with 10 LLM samples as recommended by the respective papers. Also note that the performance numbers for SelfCheckGPT and SAC^3 in Table 1 are with these optimal number of LLM calls (20 and 5 respectively, while they can be lower) to exhibit their best performance with efficiency. All experiments on ConFactCheck and the baselines as reported were run using NVIDIA A6000 GPUs, using the mentioned open-source LLMs for querying and execution.

Method	# LLM calls/samples	LLaMA3.1	Qwen2.5
SelfCheck-MQAG	20	58.9 s	47.94 s
SelfCheck-Prompt	20	13.35 s	12.16 s
SAC^3	5	15.46 s	29.37 s
INSIDE	10	4.89 s	5.68 s
ConFactCheck	3.8	9.51 s	9.03 s

Table 2: Average inference time (in seconds) for ConFactCheck and the baselines (which have configurable amount of LLM calls) over the samples of the NQ_Open dataset while using `LLaMA3.1` and `Qwen2.5` models. ConFactCheck offers significant speedups over the self-checking baselines.

5.3 ConFactCheck with LLMs of Varying Scale

We now study how the performance of ConFactCheck varies with the scale of the underlying LLM. We use the `Phi-3-Instruct` family (Abdin et al., 2024) of models for this purpose and chose models of 3 sizes – 3.8B, 7B, and 13B. Table 3 summarizes the results for the three Phi-3 models on the three QA datasets. In addition to the AUC-PR of hallucination detection, we also report the percentage of hallucinated outputs in each setting to understand the severity of hallucinations at different model scales. We note from the table that for these datasets, there is a decent amount of hallucinated outputs, which wavers from the 3.8B to 13B models. This shows that just increasing the model size may not eliminate hallucinations. We also note that the ability of ConFactCheck to detect hallucinations is similar and consistent across different model sizes. While the Phi3-7B slightly

outperforms on NQ-open, the increasing model sizes show moderate gains for the HotpotQA and WebQA datasets.

Model	NQ Open		HotpotQA		WebQA	
	AUC	%Hall.	AUC	%Hall.	AUC	%Hall.
Phi-3-4b	0.69	0.65	0.74	0.69	0.63	0.49
Phi-3-7b	**0.73**	0.58	0.74	0.60	0.62	0.46
Phi-3-13b	0.71	0.54	**0.76**	0.64	**0.65**	0.50

Table 3: Performance of CONFACTCHECK for different size models of the Phi-3 family. We report AUC-PR of hallucination detection and percentage of hallucinated outputs (Hall.) for the 3.8B, 7b, and 13B models for the three QA datasets.

5.4 Ablation Studies

We now describe different ablation studies that guided different design choices for CONFACTCHECK. We report the impact of *fact-alignment* and *uniform distribution check* steps in the pipeline (Section 3). We also describe the effects of different decoding strategies and methods for detecting key facts in the input.

5.4.1 Role of Different Components in CONFACTCHECK

Recall that there are two main steps in CONFACTCHECK – *fact alignment* and *uniform distribution check*. The fact alignment step attempts to regenerate the key facts in the generated output by querying the LLM with targeted questions. The regenerated facts are then compared with the original output for consistency. The subsequent uniform distribution check acts as another verification layer by relying on the model's confidence in the generation of regenerated key facts. Table 4 summarizes the hallucination detection scores achieved by just the fact-alignment step along with the improvements achieved by performing the subsequent uniform distribution check (the complete pipeline). We note from the table that the uniform distribution step plays a crucial role in the overall performance of CONFACTCHECK with maximum gains of up to 18%.

5.4.2 Effect of Decoding Strategies

Regardless of how the original response, subject to hallucination assessment, was generated, we examine the variations in regenerated factual responses when decoding strategies are varied. The following decoding strategies were utilized:

Component	LLM	NQ Open	HotpotQA	WebQA
Fact Alignment	LLaMA3.1	0.66	0.79	0.56
+ Distribution Check	LLaMA3.1	**0.73**	**0.83**	**0.66**
% gain		11%	5%	18%
Fact Alignment	Qwen2.5	0.79	0.82	0.68
+ Distribution Check	Qwen2.5	**0.8**	**0.84**	**0.71**
% gain		1%	2%	5%

Table 4: AUC-PR scores achieved by the two major components of CONFACTCHECK. A uniform distribution check after the fact alignment step leads to significant performance gains.

- **Greedy Decoding**: Greedy decoding involves selecting the token from the vocabulary V with the highest conditional probability. This suggests prioritizing key facts for which the model has the highest immediate confidence.
- **Beam Decoding**: Beam decoding represents an enhancement over greedy decoding. In Beam decoding, a parameter known as beam_size determines the number of tokens with the highest conditional probabilities considered at each time step t. For our experiments, we considered the beam size to be 5.

Model	NQ Open	HotpotQA	WebQA	WikiBio
LLaMA3.1 (Greedy)	0.70	0.81	0.62	0.86
LLaMA3.1 (Beam)	**0.73**	**0.83**	**0.66**	0.86
Qwen2.5 (Greedy)	0.79	0.82	0.66	0.85
Qwen2.5 (Beam)	**0.80**	**0.84**	**0.71**	0.85

Table 5: The AUC-PR scores of CONFACTCHECK with `LLaMA3.1-8B-Inst` and `Qwen2.5-7b-Inst` models using different decoding strategies for fact regeneration on the QA datasets. Beam decoding (beam size = 5) outperforms Greedy Decoding in most of the settings.

Beam decoding improves the detection of hallucinations during fact regeneration compared to greedy search. This advantage likely arises because beam decoding explores multiple possible answer paths before selecting the most likely one. Beam decoding also implicitly mitigates hallucinations by preferring sequences with higher cumulative confidence, which are more likely to reflect consistent factual patterns across generations. As a result, when regenerating key facts, beam decoding ensures a more informed selection of entities, and the results in Table 5 show its improvements. Chen et al. (2018) further corroborate this by indicating that beam decoding generally outperforms greedy decoding. By maintaining multiple candidate generations, beam decoding reduces the likelihood of

factual errors, ensuring the correct regeneration of facts. However, this decoding strategy does involve a trade-off with computational efficiency compared to greedy decoding.

5.4.3 Tagging of key-facts

Identifying of key facts in the generated text is a crucial step in CONFACTCHECK as they are used to probe the LLM in a targeted fashion. Hence, the choice of method used for identifying key facts in the generated text can have significant impact on the overall performance. Kai et al. (2024) suggests that factual information in a sentence can be identified using POS tagging, specifically 'NNP' or 'NNPS'. Building on this, we selected the tags 'NNP', 'NNPS', 'CD', and 'RB' to be considered key facts. As an alternative, we also evaluated using NER tagging and considering identified named entities as key facts. We used Stanford's Stanza (Qi et al., 2020) library for NER and POS tagging. Additionally, we also sampled random tokens from the sentence and used them as key facts, ensuring that the number of sampled tokens equaled the number of NER tags present. Table 6 summarizes the results for the three strategies and reveals that though the results are similar, NER outperforms both POS tagging and random token sampling in more settings to identify which tokens contribute to the factuality of a sentence or paragraph.

Tagging	NQ Open		HotpotQA		WebQA	
	LLaMA3.1	Qwen2.5	LLaMA3.1	Qwen2.5	LLaMA3.1	Qwen2.5
Random	0.72	0.78	0.82	0.83	**0.68**	0.69
POS	0.71	**0.81**	0.82	0.83	0.66	0.7
NER	**0.73**	0.8	**0.83**	**0.84**	0.66	**0.71**

Table 6: The AUC-PR scores while using different tagging strategies on LLaMA3.1-8B-Inst and Qwen2.5-7B-Inst for identifying key facts in the sentence. NER is observed to perform slightly better in more cases over these three QA datasets.

5.5 Key Strengths of CONFACTCHECK

We now discuss the major strengths of CONFACTCHECK which are summarized as follows.

Training-Free Operation: Our generic approach requires only the LLM-generated output for fact-alignment check stage of the pipeline and does not necessitate dataset- or task-specific training. The number of generated questions is determined by the factual content within the generated sentence, avoiding heuristic selection. During fact regeneration, CONFACTCHECK leverages the output token probabilities for the probability check, which is provided by most open-source LLMs. However, in few cases of LLMs accessed via APIs it is possible that the access to output probabilities is not available (see Limitations). Even in cases where such API-based LLMs are used for generation, their outputs can be passed through open-source LLMs to perform both checks with token probabilities.

Ease of Implementation: CONFACTCHECK does not require access to model weights or underlying training data. Requiring only the model's output and the LLM used for response generation, our method can be deployed on the same device as the response generation process, whether through a web interface, API, or a locally executed model. Even for the use of KS test, we require only the output token probabilities of the top-5 generations, which can be directly stored during LLM generation.

Consistent Sample Scoring: Unlike stochastic hallucination detection methods such as SelfCheck-GPT (Manakul et al., 2023), CONFACTCHECK operates deterministically by probing factual tokens at temperature 0. While similar consistency can be achieved in other methods using fixed seeds, CONFACTCHECK offers this behavior by default, resulting in stable sample scoring without additional tuning. This also modestly reduces computational overhead by avoiding multiple generations per query.

Interpretability: CONFACTCHECK provides key-fact-level scoring, enabling users to identify specific hallucinated facts. For instance, in the running example of Figure 1, in addition to classifying the output text as hallucinated, CONFACTCHECK explicitly identifies that the *fact* $a_{21} = \{1978, 1986 \text{ and } 2006\}$ is hallucinated (non-aligned). Operating on fine-grained facts rather than entire sentences, our pipeline offers a greater degree of explainability than previous approaches like SAC (Zhang et al., 2023a), clarifying the rationale behind a hallucination classification.

6 Conclusions

We presented CONFACTCHECK, a novel fact-based hallucination detection pipeline evaluated it using four factuality measurement datasets and compared with multiple strong baselines. Our findings reveal that despite being less computationally expensive and not requiring any training, CONFACTCHECK performs on par with other ap-

proaches while being significantly faster.

7 Limitations

Despite the high performance, ease of use, and efficiency offered by CONFACTCHECK, it is not without limitations. We analyze and present representative examples of failure cases to highlight its shortcomings and possible future areas of improvement.

Effect of incorrect tags on correct outputs:
Consider the following example from HotpotQA: *Which of the office buildings used to staff the White House used to be known as the State, War, and Navy Building?* For this question, the answer provided by an LLM is the following. *The office building used to staff the White House that was once known as the State, War, and Navy Building is now known as the* ***Eisenhower Executive Office Building****. This building was constructed in 1952 and was named after President Dwight D. Eisenhower.*
Although Eisenhower Executive Office Building is factually correct, our pipeline categorizes the paragraph as hallucinated. This discrepancy arises because our model identifies the fact '1952' as hallucinated because of the building's actual construction period between 1871 and 1888. This contrasts with the golden output from HotpotQA, which does not flag the answer as hallucinated (when the judge LLM is used on the original output and golden answer to get the golden label). However, due to the presence of other hallucinated facts, our pipeline assigns a hallucinated tag to the paragraph. Similarly, while the model correctly identifies the building as the Eisenhower Executive Office Building, it erroneously states the construction year as 1952 (actual: 1871–1888). As a result, CONFACTCHECK tags this factual mismatch, leading to a hallucination score for the entire paragraph.

Inefficiency in question generation:
The generated questions extracted key facts are done by the T5-based finetuned model. While it is efficient in generating pinpointing questions with the extracted fact as answer with original output as context, some ambigious questions such as "Who was the building named after?" can be generated. This ambiguity can result in inaccuracies when regenerating facts. For this, using a much larger LLM can be useful, however it would be computationally expensive and time-inefficient while not providing significant improvements.

Language-based limited usecases:
In addition, we also note that the proposed CONFACTCHECK has only been tested for English language and LLMs trained mostly on English data. Although the framework is theoretically language-agnostic, its reliance on NER/POS tools constrains applicability in low-resource languages lacking robust NLP pipelines. Further, the performance of CONFACTCHECK depends crucially on intermediate steps requiring NER and POS tagging, which may not always be available for low-resource languages.

Unavailability of output token probabilities in API-based LLMs:
While using CONFACTCHECK, fact regeneration is performed and subsequently the output token probabilities of the regenerated facts are required for the Uniform Distribution check to gauge the LLM's confidence in generation. However, it is possible that for multiple API-based LLMs or closed source models, output generation probabilities cannot be stored or utilized. Hence, CONFACTCHECK cannot be accessed by such LLMs and specifically requires open-source LLMs for the two checks in the pipeline.

A Models and Implementations

A.1 SelfCheckGPT (Manakul et al., 2023)

One of the first papers to counter zero-resource hallucination detection, we compare the SelfCheck-Prompt variant using `LLaMA3.1-8B-Instruct` and `Qwen2.5-7B-Instruct` which is the best performing approach in their paper. Additionally we compute the SelfCheck-MQAG scores as well (which is the QA-based variant). These are presented in Table 1. We set the number of stochastic samples to be generated as 20 (as mentioned in the original paper). The scoring method for SelfCheck-MQAG selected was Bayes with Alpha. Both β_1 and β_2 were set to 0.95.

A.2 SAC3 (Zhang et al., 2023a)

As discussed above, for using SAC^3 as one of the baselines, we evaluate it using the instruction finetuned model version of `LLaMA3.1-8B` and `Qwen2.5-7B`. We calculate the question-level consistency score (SAC^3-Q) which is highlighted in the original study as a score describing the cross-check consistency between 2 types of QA pairs, i) the original question and generated answer as a pair and ii) a number of semantically similar generated questions along with their answers as pairs. For feasibility in accordance with our available computational resources, we experimented with 2 generated perturbated QA pairs. This number can be increased or varied to check for different comparisons, but Zhang et al. (2023a) suggest that using between 2 to 5 perturbed questions per data sample yields similar quantitative results.

A.3 HaDes (Liu et al., 2022)

HaDeS is a novel token-free hallucination detection dataset for free-form text generation. For the dataset creation, raw text from web data is perturbed with out-of-box BERT model. Human annotators are then employed to assess whether the perturbed text spans are hallucinations given the original text. The final model is a binary classifier for detecting hallucinated/non-hallucinated text.

A.4 INSIDE

(Chen et al., 2024) INSIDE is a hallucination detection method which deals with the interal states of LLMs during generation to detect for hallucinations in outputs. Their approach utilizes the layer of sentence embedding outputs and exploits the eigenvalues of the covariance matrix of outputs to measure consistency in the dense embedding space. The define a particular score known as EigenScore, which is the logarithmic determinant of the covariance matrix between a certain K number of outputs' sentence embeddings (to check for the consistency in the relationship of those K outputs' embeddings). Using it as a baseline, we implement it with our settings with `LLaMA3.1-8B` and `Qwen2.5-7B` as the LLMs on the 3 QA datasets and calculate the AUC-PR scores.

B Usage of ConFactCheck on datasets

B.1 Open-Domain Question Answering

Three datasets are used for this particular task, as shown above. We use ConFactCheck on the originally generated outputs for each of the questions in the datasets, to check for whether the LLMs generating the original answers have hallucinated or not. ConFactCheck is applied on a sentence-level basis, where the outputs are split into sentences, following which key facts are extracted and ConFactCheck begins the checking mechanism.

B.2 Text-based Summarization

For this particular task, we use the WikiBio dataset which contains summaries of individuals collected from Wikipedia, along with synthetic GPT3 generated summaries of the same. ConFactCheck is applied as a sentence-level detector on the respective sentences of each of the provided synthetic summaries, which have be annotated with their hallucination labels at the said sentence-level as part of the dataset. We obtain sentence level hallucination scores and compare those with the golden annotate labels per sentence, and for passage-level hallucinations, we average over the sentence-level scores to get overall scores for passages.

C F1-Score based Matching

In our primary pipeline, factual alignment is determined using an LLM-as-a-judge approach. Specifically, we query OpenAI's `GPT-4.1-mini` via the API to compare extracted and regenerated facts and assign binary alignment labels. While this method yields strong performance, it requires reliable access to the OpenAI API and incurs associated computational and cost overheads.

To support use cases where API access is restricted or an external LLM judge is unavailable, we also explore an alternative matching strategy based on simple lexical overlap using F1-score. In this variant, alignment between fact pairs is determined by computing the F1-score of their token overlap, and pairs exceeding a predefined threshold are marked as aligned. The table below presents the AUC-PR scores across three datasets using this heuristic method at various F1-score thresholds, where the $\mathcal{M}'$ is `LLaMA3.1-8B-Instruct` (used for the fact regeneration). For this scoring, we split the extract and regenerated facts into lists of individual words, and compute the F1-scores on these lists. Different thresholds are used (as shown in Table 7 below) to assign 0/1 labels for similar/dissimilar facts.

Although this approach is less semantically robust than LLM-based judgment, it offers a lightweight, fully offline alternative that still provides reasonable scores that are close to the main scores in our pipeline, especially in resource-constrained settings.

F1-score	LLaMA3-NQopen	LLaMA3-Hotpot	LLaMA3-WebQA
0.4	0.640	0.791	0.550
0.5	0.648	0.795	0.556
0.6	0.659	0.796	0.556
0.7	0.662	0.798	0.562
0.8	0.664	0.800	0.570

Table 7: F1-score based matching with different thresholds in fact alignment (ranging from 0.4 to 0.8)

D Prompting Format

Prompt Templates Used in the Pipeline

1. Fact Regeneration Prompt (Manually Constructed Chat Format):

This prompt is used to generate fact-based questions from the given sentence. The prompt follows a constructed chat format, to be manually customized for the model in use (e.g., LLaMA3.1, Qwen2.5). It is used for each of the questions generated by the T5-finetuned model on the extract key facts.

i) Example format for `LLaMA3-8B-Instruct`:

```
'''<|begin_of_text|><|
    start_header_id|>system<|
    end_header_id|>
You are a Question-answering
    assistant, only answer the
    question.
<|eot_id|><|start_header_id|>user<|
    end_header_id|>
Question: <insert question here>
<|eot_id|><|start_header_id|>
    assistant<|end_of_header_id|>'''
```

2. Fact Alignment Prompt (used with the judge LLM):

Few-Shot prompt used to check for alignment between extract and regenerated facts using LLM-as-a-judge. This prompt is well-structured to give the judge LLM complete understanding of how to generate the alignment output for the pairs of facts that it is applied on.

```
"'You are a fact comparison expert. Your task
is to determine whether pairs of extracted and
regenerated facts refer to the same real-world
entity, concept, or meaning.
For each pair:
- Return '0' if the two facts refer to the
same thing, even if the wording, specificity,
or structure is different.
- Return '1' if the two facts do not refer to
the same thing, or if their meanings conflict.
Guidelines:
- Minor differences in wording, grammar, or
capitalization should be ignored.
- Partial vs full names (e.g., "Vancouver" vs
"Vancouver, British Columbia") should match
if they refer to the same entity.
- Aliases and synonyms (e.g., "Roger Pirates"
vs "Roger crew") should count as a match.
- Abbreviations (e.g., "UCLA" vs "University
of California, Los Angeles") are also matches.
- Return '1' only if clearly unrelated or
ambiguous.
Format:
Return a Python-style list of exactly {n}
binary values (0 or 1), corresponding to each
fact pair in order.
Do not output anything else. If unsure, still
return a complete list.
Examples:
```

- "President Donald J. Trump" vs "Donald Trump" → 0
- "Vancouver, British Columbia" vs "Vancouver" → 0
- "five" vs "5 seasons" → 0

```
    • "UCLA" vs "University of California, Los

E Annotation Performance of LLM-as-a-judge

To demonstrate the reliability of our LLM-based judging, we conducted a small-scale human evaluation. We engaged two human annotators to label 150 samples each across the three QA datasets. When comparing these human annotations with the GPT-4o labels, we observed overlap scores (between GPT and Human annotators) ranging from 82.6% to 93%, indicating that the LLM is capable of reliably generating accurate labels.

Furthermore, we've calculated inter-annotator agreement metrics among the human annotators as well. The Cohen's Kappa scores range from 0.76 to 0.91, which highlights substantial agreement and further corroborates the quality of our labels. We will be adding these details in the appendix of the submitted paper.

Dataset	Metric	Value
NQOpen	GPT Overlap (with Annotator 1)	84%
	GPT Overlap (with Annotator 2)	82.60%
	Inter-Annotator Overlap	96%
	Inter-Annotator Cohen's Kappa	91.17%
HotpotQA	GPT Overlap (with Annotator 1)	93%
	GPT Overlap (with Annotator 2)	91%
	Inter-Annotator Overlap	91%
	Inter-Annotator Cohen's Kappa	78%
WebQ	GPT Overlap (with Annotator 1)	89%
	GPT Overlap (with Annotator 2)	84%
	Inter-Annotator Overlap	88%
	Inter-Annotator Cohen's Kappa	76%

Table 8: GPT-human and inter-annotator overlap scores for three QA datasets (150 samples).

F Cross-evaluation with different LLMs

CONFACTCHECK provides additional flexibility when it comes to the usage of LLMs for detection in the pipeline. The original LLM used to generate the initial output can be used for the Fact Alignment check in a self-check-based setting. However, while using CONFACTCHECK on the outputs of a particular base LLM (eg. `LLaMA3.1-8b-Instruct`), we can employ usage of another LLM for cross-evaluation during fact regeneration (eg: using `Qwen2.5-7b-Instruct` on the initial LLaMA-3.1 outputs). We provide experimental results to demonstrate the efficacy of cross-evaluation while using the 2 LLMs `Qwen2.5-7b-Instruct` and `LLaMA3.1-8b-Instruct` on two of the QA datasets.

Method	NQOpen	WebQ
Qwen on LLaMA3 Outputs	0.71	0.63
LLaMA3 as Self-Evaluator	**0.73**	**0.66**
LLaMA3 on Qwen Outputs	**0.81**	0.70
Qwen as Self-Evaluator	0.80	**0.71**

Table 9: AUC-PR scores comparing evaluator setups on NQOpen and WebQ datasets.

G Comparison of Selfcheck with varying number of samples

The SelfCheckGPT baseline methods provide configurable flexibility in terms of the number of stochastic samples that are generated to provide their final scores. The authors suggest that the samples' count can vary from 5 samples to 20 and provide similarly comparable results. We have used 20 samples for generation using Selfcheck in the Table 1 of our paper. Here, we provide a demonstration of results on the WebQA dataset with `LLaMA3.1-8b-Instruct` as the base LLM, when samples are varied between 5 and 20 for the Selfcheck methods, and compare their AUC-PR scores and computational time metrics with each other and CONFACTCHECK.

H Judge LLM vs Human evaluation in Fact Alignment

We evaluate the reliability of LLM-based comparison in the Fact Alignment Check of the pipeline

Approach	Sample Size	Time (s)	AUC-PR
SelfCheck-MQAG	5 samples	29.15	0.51
	20 samples	61.59	0.50
SelfCheck-Prompt	5 samples	8.4	0.54
	20 samples	14.1	0.54
ConFactCheck	2.8 avg facts + 1 API call	8.77	0.66

Table 10: Performance comparison of Selfcheck methods with 5 and 20 samples each, along with latency comparisons of these approaches with ConFactCheck.

using GPT-4.1-mini as the judge LLM. Each extracted and regenerated fact pair is scored (0 for aligned, 1 for not aligned) by the LLM. To validate its accuracy, we randomly sampled 25 instances from each of three QA datasets (75 in total) and obtained equivalent 0/1 judgments from a human evaluator for each individual facts within each of the instances. Comparing the two sets of scores revealed strong agreement, with accuracy between 89.7%–93.2% and Cohen's $\kappa > 0.79$. These results offer strong evidence of the efficacy of the LLM-based comparison in our use case.

Dataset	Agreement (%)	Cohen's Kappa
NQ-Open	89.7	0.783
HotpotQA	93.2	0.845
WebQA	89.9	0.799

Table 11: Model (LLaMA-3) vs. human agreement scores on the evaluation of Fact Alignment samples across three datasets.

I Step-by-Step ConFactCheck Example

Example: Question and Answer Processing Step-by-Step

Input:

```
Question: Who won the FIFA World
    Cup in 2022?
Answer: The FIFA World Cup in 2022
    was won by Argentina.
```

Step 1: Extract sentences from the original answer

- The sentence splitter extracts: `"The FIFA World Cup in 2022 was won by Argentina."`

Step 2: Extract Key facts using NER

- Named entities detected: "`FIFA World Cup`", "`Argentina`", "`2022`".
- Generated questions using T5-finetuned model for each key fact:
  - **`FIFA World Cup`** → Q1: Which tournament did Argentina win in 2022?
  - **`Argentina`** → Q2: Who won the FIFA World Cup in 2022?
  - **`2022`** → Q3: When did Argentina win the FIFA World Cup?

Step 3: Generate pinpointed answers

- Using the LM to answer the generated questions: Answers = ["`FIFA World Cup`", "`Argentina`", "`1978, 1986 and 2022`"]

Step 4: Compare original and regenerated answers

- `Use Huggingface QA pipeline to extract shortened pinpointed answers from original and regenerated contexts.`
- Judge if answers match (0 = match, 1 = hallucination):
  `Initial hallucination flags = [0, 0, 1]`

Step 5: Final hallucination check with probability

- `Use token-level probabilities and KS-test to confirm hallucination.`
- `Final hallucination flags remain: [0, 1, 1]`

Figure 4: Hypothetical step-by-step example explaining the methodology of ConFactCheck

J Pseudocode for the algorithm proposed

The hallucination detection algorithm is designed as a two-step process applied at the sentence level for a generated answer. Given a generated answer $\mathcal{A}$ and a model $\mathcal{M}'$, the goal is to produce a score for each sentence indicating the likelihood of hallucination.

In the first step as highlighted in **Algorithm 1**, the generated answer is split into sentences, and each

sentence is analyzed to extract atomic facts using Named Entity Recognition (NER). For each key fact a_{ij} in sentence S_i, a corresponding question q_{ij} is generated. The model $\mathcal{M}'$ then provides an answer f_{ij} to this question. A separate **Align** function (which uses a judge LLM for fact pair comparison) evaluates whether the fact a_{ij} is consistent with the answer f_{ij}. If aligned, the fact is marked as consistent (score 0), otherwise as hallucinated (score 1). This step yields an initial binary score list for all facts.

In **Algorithm 2**, for each fact marked as consistent (score 0) in Step 1, we compute the logit scores of the top k tokens in the model's answer f_{ij}. These scores are converted into a probability distribution. We then perform a Kolmogorov–Smirnov (KS) test to statistically compare this empirical distribution against a uniform distribution. If the KS test yields a p-value less than a significance threshold (typically 0.05), the null hypothesis — that the two distributions are the same — is rejected. This indicates that the distribution is significantly different from uniform, and the fact remains marked as consistent (score 0). However, if the p-value is greater than or equal to 0.05, the distribution is considered close to uniform, signaling high uncertainty in the model's response, and in such case the fact is reclassified as hallucinated (score 1).

Algorithm 1 : Fact Alignment Check

Input: Generated Answer $\mathcal{A}$, Model $\mathcal{M}'$
Output: Initial Score List $[s_{ij}]$ for all facts a_{ij}
`// Step 1: Sentence splitting and fact extraction`
Perform coreference resolution on $\mathcal{A}$ and split into sentences $\{S_1, S_2, \ldots, S_N\}$
for all sentence S_i in $\mathcal{A}$ **do**
    Extract atomic facts $\{a_{ij}\}$ from S_i using NER
    for all fact a_{ij} **do**
        Generate question $q_{ij} \leftarrow Q(a_{ij} \mid S_i)$
        Get answer $f_{ij} \leftarrow \mathcal{M}'(q_{ij})$
        if Align(f_{ij}, a_{ij}) **then**
            Set $s_{ij} \leftarrow 0$ ▷ Fact is consistent
        else
            Set $s_{ij} \leftarrow 1$ ▷ Fact is hallucinated
        end if
    end for
end for
return $[s_{ij}]$

Algorithm 2 : Uniformity Check Phase (via KS Test)

Input: Initial Score List $[s_{ij}]$, Corresponding Answer Logits s_{ijk}
Output: Final Sentence Scores $[Score(S_1), \ldots, Score(S_N)]$
for all sentence S_i **do**
    Initialize $Score(S_i) \leftarrow 0$
    for all fact a_{ij} in S_i **do**
        if $s_{ij} == 0$ **then**
            Compute normalized probabilities:

$$p(w_{ijk}) = \frac{e^{s_{ijk}}}{\sum_{m=1}^{k} e^{s_{ijm}}}$$

            `// Compare with uniform distribution`
            Perform KS test between $p(w_{ijk})$ and uniform distribution
            if p-value ≥ 0.05 **then**
                Set $s_{ij} \leftarrow 1$ ▷ Mark as hallucinated
            end if
        end if
        Add s_{ij} to $Score(S_i)$
    end for
    Normalize: $Score(S_i) \leftarrow \frac{Score(S_i)}{\text{\#facts in } S_i}$
end for
return $[Score(S_1), \ldots, Score(S_N)]$

Feather-SQL: A Lightweight NL2SQL Framework with Dual-Model Collaboration Paradigm for Small Language Models

Wenqi Pei[1], Hailing Xu[1], Henry Hengyuan Zhao[1], Shizheng Hou[1], Han Chen[1], Zining Zhang[1], Pingyi Luo[2], Bingsheng He[1,*]

Abstract

Natural Language to SQL (NL2SQL) has seen significant advancements with large language models (LLMs). However, these models often depend on closed-source methods and high computational resources, posing challenges in data privacy and deployment. In contrast, small language models (SLMs) struggle with NL2SQL tasks, exhibiting poor performance and incompatibility with existing frameworks. To address these issues, we introduce **Feather-SQL**, a new lightweight framework tailored for SLMs. Feather-SQL improves SQL executability and accuracy through: (i) schema pruning and linking, (ii) multi-path and multi-candidate generation. Additionally, we introduce **1+1 Model Collaboration Paradigm**, which pairs a strong general-purpose chat model with a fine-tuned SQL model, combining strong analytical reasoning with high-precision SQL generation. Experimental results on BIRD demonstrate that Feather-SQL improves NL2SQL performance on SLMs, with around 10% boost for models without fine-tuning. The proposed paradigm raises the accuracy ceiling of SLMs to 54.76%, highlighting its effectiveness. Our implementation is available at https://github.com/CedricPei/Feather-SQL.

1 Introduction

Natural Language to SQL (NL2SQL) is the task of converting natural language questions into corresponding SQL queries, allowing users to retrieve structured data from databases without requiring proficiency in SQL. In recent years, the field has seen significant advancements with the emergence of large language models (LLMs) such as GPT-4 (OpenAI et al., 2024), enabling frameworks like CHASE-SQL (Pourreza et al., 2024) and XiYan-SQL (Gao et al., 2025b) to achieve state-of-the-art (SOTA) performance. However, two limitations hinder their practical adoption. First, mainstream methods depend on closed-source models, and their reliance on external APIs introduces data privacy risks in sensitive domains like healthcare and finance (Liu et al., 2024). Second, most open-source research focuses on models with 7B–30B parameters, leaving small language models (SLMs) with 4B or fewer parameters relatively underexplored. Meanwhile, many relational databases are deployed on high-performance systems with limited GPU resources.

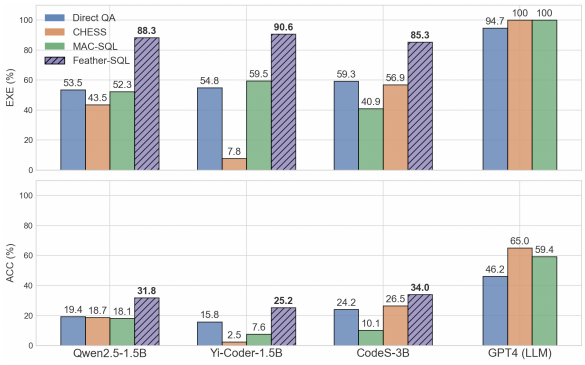

Figure 1: NL2SQL performance on the BIRD DEV dataset. EXE (Executability) measures successful query executions, while ACC (Accuracy) measures correct result matches.

In this paper, we focus on enhancing NL2SQL performance using SLMs. As shown in Figure 1, SLMs face two key challenges: (i) one critical issue is their sharp decline in executability. Unlike LLMs, which can effectively handle long-context dependencies, SLMs struggle with complex database schema and verbose prompts, often leading to hallucinated outputs (Nguyen et al., 2024; Qu et al., 2024) (Figure 2); (ii) existing frameworks for NL2SQL with LLMs are incompatible with SLMs, as they rely on strong instruction-following capabilities to produce intermediate results, which SLMs lack. As illustrated in Figure 3, SLMs' outputs frequently violate imposed requirements: they often fail to conform to JSON or array specifications and do not meet predefined constraints. Directly

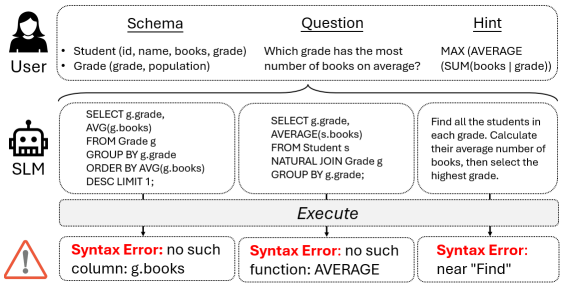

Figure 2: Examples of typical syntax errors produced by small language models (SLMs) in an NL2SQL scenario.

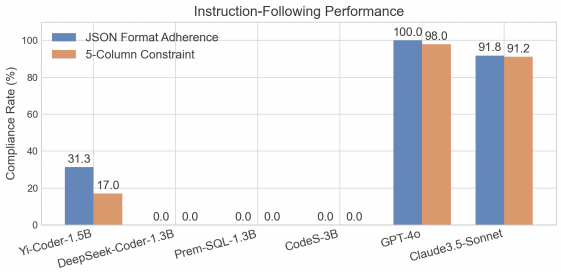

Figure 3: Experiments on CHESS-provided BIRD subset for schema linking. Models are required to output a JSON-formatted response containing no more than five relevant columns related to the question.

applying these frameworks to SLMs may further degrade executability.

To address these challenges, we propose **Feather-SQL**, a lightweight framework tailored for SLMs to enhance both executability and accuracy. It consists of six key components: schema pruning, schema linking, multi-path generation, multi-candidate generation, correction, and selection. Designed for SLMs, schema pruning discards irrelevant tables, allowing models to concentrate on essential database elements. Schema linking improves alignment between questions and database schema, ensuring accurate column selection. To mitigate errors from linking and pruning, multi-path generation explores diverse query formulation strategies, enhancing robustness. Multi-candidate generation further improves the model's executability and accuracy by enhancing the variety of generated SQL queries, thereby increasing the likelihood of producing correct candidates. The best candidate is then selected through execution validation and ranking. Complementing these components, we introduce extraction and simplification prompting strategies. Extraction selectively retrieves key information, while simplification removes extraneous prompt details to lower computational overhead. By integrating these techniques, Feather-SQL enables SLMs to generate SQL queries more reliably despite their inherent limitations.

A common approach to enhancing SLMs is fine-tuning. However, while fine-tuned SLMs for SQL generation tasks (e.g., Prem-SQL (Anindyadeep, 2024), CodeS (Li et al., 2024)) outperform general-purpose chat models on SQL generation, they suffer from catastrophic forgetting (Luo et al., 2025; Kotha et al., 2024) on auxiliary tasks—where task-specific fine-tuning erodes their foundational reasoning abilities. To counter this, we propose **1+1 Model Collaboration Paradigm**, in which a general-purpose chat model handles reasoning-intensive auxiliary tasks (e.g., schema linking and candidate selection), while a fine-tuned SQL model focuses on SQL generation. This collaboration leverages both models' strengths: the chat model provides broad reasoning ability, while the SQL model delivers domain-specific precision. Experiments confirm that the paradigm improves overall performance. Our main contributions are as follows:

- We introduce Feather-SQL, an NL2SQL framework for SLMs to address their unique challenges of low executability and incompatibility with existing LLM-based frameworks.
- We propose a novel 1+1 Model Collaboration paradigm that mitigates catastrophic forgetting in fine-tuned SLMs by delegating reasoning-intensive tasks to a general-purpose chat model.
- Experiments on Spider and BIRD demonstrate that Feather-SQL consistently achieves strong performance with various SLMs and yields SOTA results on BIRD within the scope of SLMs when paired with the paradigm.

2 Related Work

2.1 Conventional Methods

Early NL2SQL methods were rule-based or template-based (Zelle and Mooney, 1996; Li and Jagadish, 2014; Saha et al., 2016). Although effective on small datasets, these approaches demanded extensive manual engineering and did not generalise well. The arrival of sequence-to-sequence (Seq2Seq) models marked a shift to data-driven methods. Models such as Seq2SQL (Zhong et al., 2017), SQLNet (Xu et al., 2017), IRNet (Guo et al., 2019), RyanSQL (Choi et al., 2021), and RESDSQL (Li et al., 2023a) jointly encode the

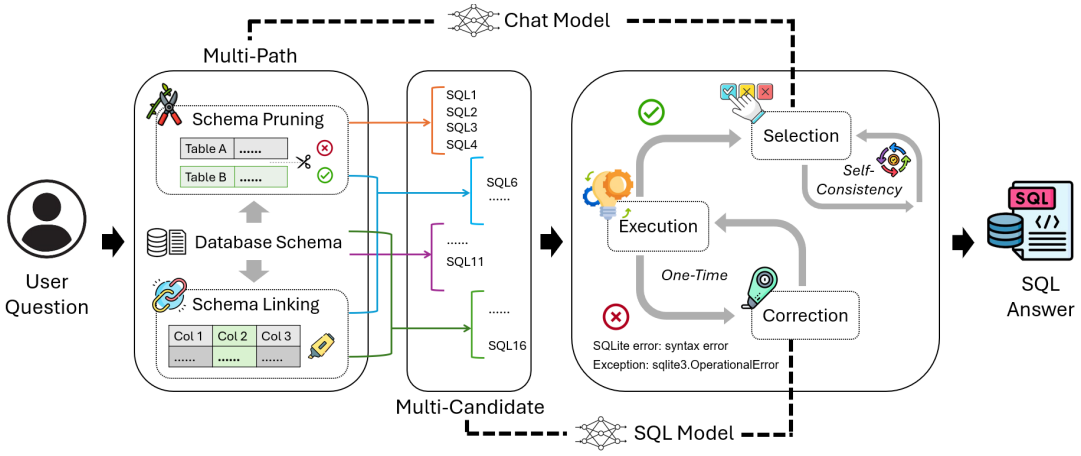

Figure 4: An overview of **Feather-SQL** for small language models (SLMs) in NL2SQL. The **1+1 Model Collaboration Paradigm** pairs a general-purpose chat model with a SQL fine-tuned model: the chat model conducts the multi-path and selection stages (upper dashed links), while the SQL model performs the multi-candidate and correction stages (lower dashed links).

natural-language question and database schema before decoding the corresponding SQL query. Fine-tuning pretrained language models (PLMs) including BERT (Devlin et al., 2019) and T5 (Raffel et al., 2020) further improves robustness, yet still requires substantial annotated data and struggles with highly complex schemas.

2.2 LLM and SLM Approaches

Instruction-tuned large language models (LLMs) now achieve state-of-the-art performance by decomposing NL2SQL into subtasks. Methods such as DIN-SQL (Pourreza and Rafiei, 2023), TASQL (Qu et al., 2024), MAC-SQL (Wang et al., 2024), and CHESS (Talaei et al., 2024) exceed earlier accuracy, but their multi-stage prompting incurs significant computation, and potential privacy risks when queries leave the user's environment.

To alleviate these drawbacks, researchers have turned to small language models (SLMs). Approaches such as CodeS (Li et al., 2024), DTS-SQL (Pourreza and Rafiei, 2024), Prem-SQL (Anindyadeep, 2024), and SQLCoder (Defog) fine-tune SLMs on NL-to-SQL datasets. However, training makes them susceptible to catastrophic forgetting, diminishing their compositional-reasoning ability. MSc-SQL (Gorti et al., 2025) trains separate around 10B models for different subtasks to preserve capabilities, but at the expense of extra memory and storage, limiting practical deployment. Therefore, a lightweight framework that empowers SLMs to perform NL2SQL effectively remains an open and important research goal.

3 Methodology

3.1 Feather-SQL

As shown in Figure 4, we propose Feather-SQL to enhance the performance of SLMs in NL2SQL. We will elaborate on its six components in the following sections.

Schema Pruning. This step reduces schema complexity by filtering out tables irrelevant to the question. Only the Data Definition Language (DDL) statements of tables judged pertinent advance to later stages, preventing SLMs from being overwhelmed by lengthy inputs while preserving essential information. Although it was previously explored by Jose and Cozman (2023) who applied it as a training-time preprocessing driven by statistical analysis, our approach performs it at inference-time using one SLM.

Schema Linking. This step aligns the question with the database schema by identifying relevant columns (Guo et al., 2019). As a commonly adopted practice, schema linking extracts pertinent columns from complete schema (Wang et al., 2020; Talaei et al., 2024). By establishing precise mappings between questions and database elements, this process significantly enhances SQL generation accuracy.

Multi-Path Generation. This step employs four distinct prompt types: (1) with both schema linking and pruning, (2) linking only, (3) pruning only, and (4) without either operation. The multi-path design mitigates the risk of information loss caused by pruning errors and reduces potential misunder-

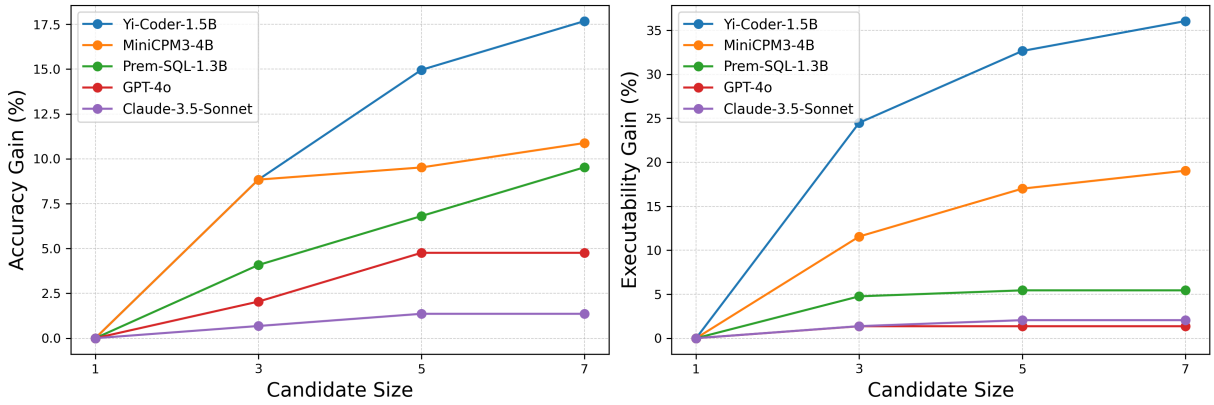

Figure 5: Accuracy gain and executability gain by candidate size. Gains are measured as the percentage-point difference from each model's performance with a single candidate. For both metrics, a set of candidates is counted as correct or executable if at least one candidate in the set meets the criterion.

standings arising from linking inaccuracies.

Multi-Candidate Generation. This step generates multiple SQL queries in parallel to increase the likelihood of producing a correct result (Pourreza et al., 2024; Gorti et al., 2025). To ensure diversity, beam search is employed alongside carefully tuned temperature and top-p parameters. Each path consistently generates a fixed number of candidate queries, maintaining a balanced exploration of possible solutions.

As shown in Figure 5, increasing candidate size yields consistent improvements in both accuracy and executability for SLMs, with notably larger gains compared to LLMs. Larger models are already robust with a single candidate and show only marginal improvements when more candidates are provided. (Details in Appendix B.)

Correction. This step executes each generated query and handles it based on the outcome (Wang et al., 2024; Pourreza and Rafiei, 2023). If a query executes successfully, it is directly added to the array of executable SQL queries. For failed queries, error feedback is used to revise the query through a self-correction approach, generating two new candidate queries. If any of these revised queries are executable, they are also stored in the set of executable SQL queries.

Selection. This step applies a selection-ranking method to assess all executable queries according to their alignment with the expected answers (Pourreza et al., 2024; Gao et al., 2025b; Talaei et al., 2024). If a query yields a limited number of results, the evaluation considers both the query and its execution outcome. In contrast, the evaluation focuses solely on the query itself. The selection process is repeated three times, and the mode of the rankings is returned as the final result.

Method	Stage	Words

	Generation	190
	Correction	106
	Selection	271

Table 1: Prompt length comparison.

3.2 Prompting Strategies

Extraction. We propose an extraction strategy to avoid rigid structural outputs by allowing SLMs to freely generate responses. We have two methods to achieve that: (i) Lexical Matching: identify schema elements by matching table/column names in the response. For instance, when the SLM outputs "required tables include customer and orders", the framework extracts customer/orders if they exist in the schema. (ii) Pattern Matching: extract the final answer by identifying predefined patterns in the model's output, such as "answer is" or "Answer:". For example, if the model generates "The answer is 128", the framework extracts "128" as the final result.

Table 2: Comparison of EX (Execution Accuracy) and EP (Execution Proportion) across different methods on the BIRD DEV dataset. The best and second-best results are highlighted by **bold** and underline, respectively. * denotes results with the extraction strategy.

Simplification. We reduce computational overhead by minimizing prompt verbosity while keeping the task unambiguous. In Feather-SQL, we achieve this by removing superfluous details and using concise instructions with the fewest effective examples. This approach refines the input by eliminating unnecessary complexity, avoiding the need for SLMs to process lengthy inputs while maintaining the clarity of the task.

As shown in Table 1, CHESS uses instruction-heavy prompts, and MAC-SQL also exceeds 500 words in 2 stages. Only Feather-SQL stays concise across all stages, balancing context and complexity without burdening SLMs with lengthy inputs.

3.3 1+1 Model Collaboration Paradigm

Our paradigm categorizes NL2SQL pipeline tasks into two types: reasoning-intensive tasks and SQL generation tasks. Reasoning tasks require contextual understanding and adaptability, while SQL generation demands precision in query synthesis. We employ two specialized models to leverage complementary strengths: the general-purpose chat model for reasoning tasks and the SQL fine-tuned model for SQL generation.

General-purpose Chat Model. This model leverages broad linguistic and contextual comprehension without domain-specific fine-tuning, which helps prevent catastrophic forgetting. Compared to the SQL fine-tuned model, it is more effective in schema linking and candidate evaluation, ensuring that the generation process is guided by accurate and well-structured contextual information.

SQL Fine-tuned Model. Optimized exclusively for SQL generation, this model is extensively trained on large-scale NL2SQL datasets, allowing it to achieve superior performance on SQL-specific tasks. Its focused training reduces hallucinations and enhances both query executability and accuracy.

4 Experiments

4.1 Settings

4.1.1 Datasets

BIRD (Li et al., 2023b) encompasses databases over 37 professional domains. Due to the proprietary nature of the BIRD TEST dataset, we conduct our experiments using the publicly accessible BIRD DEV subset, which contains 1,534 unique question-SQL pairs.

Spider (Yu et al., 2019) is another large-scale benchmark dataset for cross-domain SQL generation, covering 138 different domains. Our experiments utilize the Spider TEST set, comprising 2,147 question-SQL pairs.

4.1.2 Evaluation Metrics

Execution Accuracy (EX) (Li et al., 2023b) is a widely adopted metric in NL2SQL evaluations, measuring whether the result of executing the generated query matches the result of the ground-truth query. This metric allows for different query formulations that yield the same result. It is calculated as:

$$\text{EX} = \frac{|\{n \in N \mid \text{E}(Q_{gen}) = \text{E}(Q_{\text{gt}})\}|}{N} \times 100\%$$

Method	Qwen2.5-0.5B		Yi-Coder-1.5B		DeepSeek-Coder-1.3B

where N denotes the number of questions. Q_{gen} represents the SQL query generated by the model, while Q_{gt} is the ground-truth query. E is the execution function.

Execution Proportion (EP) is an auxiliary metric we proposed, evaluating the proportion of generated SQL queries that can be executed on the corresponding database without syntax errors. This metric reflects the model's upper-bound capability by assuming that any executable query is potentially correct. It is defined as:

$$\text{EP} = \frac{|\{n \in N \mid \text{E}(Q_{\text{gen}}) \neq \text{error}\}|}{N} \times 100\%$$

4.1.3 Baselines

Direct Response (DR) directly generates an SQL query from the natural language question without applying any refinement techniques. The process follows a single-turn interaction.

First Executable Query (FEQ) leverages the model's ability to generate multiple SQL candidates. Among candidates, the first executable query is selected without any refinement. This approach simulates multi-turn query generation.

MAC-SQL (Wang et al., 2024) is an LLM-based multi-stage framework, featuring a core Decomposer agent for SQL generation supported by auxiliary agents for sub-database acquisition and query refinement. It also utilizes few-shot chain-of-thought reasoning to enhance generation processes.

CHESS (Talaei et al., 2024) comprises four specialized agents: Information Retriever, Schema Selector, Candidate Generator, and Unit Tester. Notably, it employs locality-sensitive hashing and vector databases to efficiently retrieve relevant data from extensive database values and catalogs.

4.1.4 Implementation Details

Backbone Models. Our implementation leverages both general-purpose chat models and SQL fine-tuned models. The chat models include Qwen2.5-0.5B, Qwen2.5-1.5B, Qwen2.5-Coder-1.5B (Hui et al., 2024), Yi-Coder-1.5B (Young et al., 2025), DeepSeek-Coder-1.5B (DeepSeek-AI, 2024) and MiniCPM3-4B (Hu et al., 2024), while the SQL models consist of Prem-SQL-1.3B (Anindyadeep, 2024) and CodeS-3B (Li et al., 2024).

Candidate Size. In the multi-candidate generation stage, we generate 4 candidates per path, resulting in a total candidate pool of 16. During the correction stage, the candidate size is reduced to 2.

Selection Rounds. During the selection stage, we perform 3 rounds for each selection. The final choice is the majority vote across the three rounds, ensuring consistency of the selected candidate.

4.2 Main Results

4.2.1 Feather-SQL

To validate the general effectiveness of Feather-SQL for SLMs, we conducted experiments on two datasets across a range of models (all results here were obtained using a unified model without adopting the collaboration paradigm).

BIRD Results. As shown in Table 2, Feather-

Chat Model	SQL Model	EX (%)	EP (%)
–	Prem-SQL	49.28	98.04
Qwen	Prem-SQL	52.44 ↑	94.08
Qwen Coder	Prem-SQL	52.83 ↑	98.31
Yi Coder	Prem-SQL	54.76 ↑	93.94
–	CodeS	33.96	83.31
Qwen	CodeS	35.79 ↑	80.05
Qwen Coder	CodeS	37.03 ↑	81.10
Yi Coder	CodeS	39.43 ↑	80.44

(a) Feather-SQL

Chat Model	SQL Model	EX (%)	EP (%)
–	Prem-SQL	24.64	43.22
Qwen	Prem-SQL	49.28 ↑	82.07
Qwen Coder	Prem-SQL	49.61 ↑	79.60
Yi Coder	Prem-SQL	47.65 ↑	79.79
–	CodeS	26.53	56.91
Qwen	CodeS	28.55 ↑	56.19
Qwen Coder	CodeS	28.88 ↑	63.04
Yi Coder	CodeS	27.44 ↑	55.22

(b) CHESS

Table 4: Paradigm performance on the BIRD DEV dataset. When no chat model is specified, the SQL model is used as the chat model. Qwen refers to Qwen2.5-1.5B, Qwen Coder refers to Qwen2.5-Coder-1.5B, Yi Coder refers to Yi-Coder-1.5B, Prem-SQL refers to Prem-SQL-1.3B, and CodeS refers to CodeS-3B.

SQL demonstrates superior performance across all general-purpose chat models, achieving the highest scores in both EX and EP, with EX showing an average increase of approximately 10% and EP exceeding a 20% improvement compared to FEQ. For SQL fine-tuned models, Feather-SQL combined with CodeS achieves substantial gains in both EX and EP, while Prem-SQL shows notable improvements specifically in EP, with an average increase of around 5% compared to FEQ. Besides, we explored the upper bound of Feather-SQL on this dataset (Appendix C).

Moreover, we observe that CHESS and MAC-SQL do not perform effectively on SLMs, with their results on Qwen2.5 and Yi-Coder showing even lower EX and EP scores compared to DR. Their performance also falls behind that of FEQ.

Spider Results. Table 3 highlights the results on Spider TEST. Although MAC-SQL and CHESS show inconsistent performance across models, MAC-SQL generally performs well. Notably, for SQL fine-tuned models, MAC-SQL could achieve the best EX if extraction is applied, highlighting the necessity of this step. This may be attributed to MAC-SQL's Selector mechanism, which also employs schema pruning. Unlike our table pruning approach, MAC-SQL adopts column pruning, which may be more effective for Spider's relatively simple schema structures.

4.2.2 1+1 Model Collaboration Paradigm

As observed in Table 2, although Feather-SQL improves the EP of Prem-SQL, its EX shows a 2% decrease compared to FEQ. This decline is primarily due to Prem-SQL's inability to handle auxiliary reasoning tasks. To address this limitation, we propose a division of tasks where the general-purpose chat model handles auxiliary reasoning, while the SQL fine-tuned model focuses on SQL generation.

As shown in Table 4a, our 1+1 collaboration paradigm under Feather-SQL achieves a 3–6% improvement in EX for both Prem-SQL and CodeS. However, we observe a decline in EP when paired with a chat model. This is because when the SQL model is also used as the chat model during schema pruning, it returns a query instead of the expected answer. But our extraction strategy still retrieves table names from the output, often resulting in an overly pruned schema containing only one or two tables. While a simplified schema can occasionally boost EP, it frequently leads to lower overall EX.

Additionally, Table 4b shows that our paradigm improves both Prem-SQL and CodeS in CHESS, with EX increasing by ~20% and EP by over ~35% for Prem-SQL, while CodeS sees a smaller but consistent EX gain with no clear trend in EP.

However, the two models benefit differently due to their handling of auxiliary tasks. Prem-SQL attempts to answer linking questions but often does so incorrectly, whereas CodeS, due to severe catastrophic forgetting, fails to provide valid responses. As a result, CHESS defaults to using the original schema with CodeS, reducing linking errors.

Furthermore, since CHESS constructs long prompts without schema pruning, introducing a chat model increases input length and complexity. While this improves reasoning, it does not fully offset CodeS's limitations in processing extended inputs, restricting its EX improvement.

SOTA within SLMs. To contextualize our re-

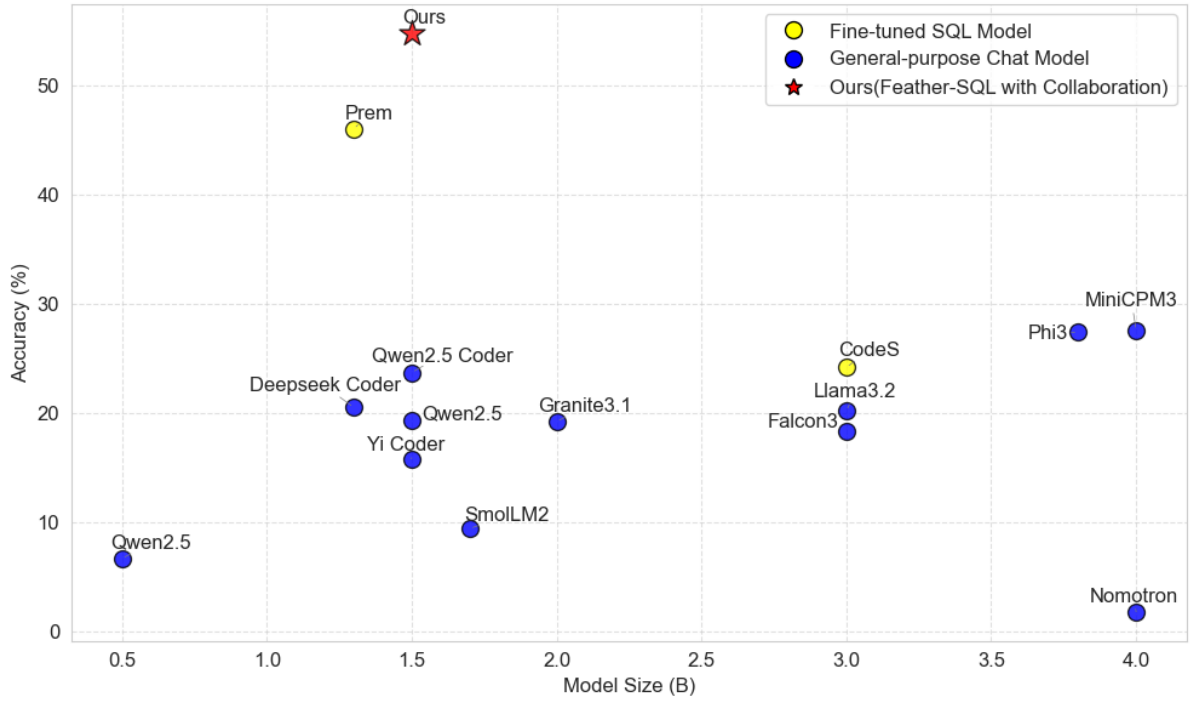

Figure 6: Accuracy (%) versus model size (billions of parameters) on BIRD DEV for small language models. Fine-tuned SQL models are shown in yellow, general-purpose chat models in blue, and ours (Feather-SQL + 1+1 Model Collaboration) is marked with a red star.

sults, we further compare against widely used open-source SLMs beyond our backbones—namely Granite-3.1B (Mishra et al., 2024), SmolLM2-1.7B, Llama3.2-3B (Dubey et al., 2024), Falcon-3B (Gao et al., 2025a), and Nemotron-4B (Nvidia et al., 2024). Figure 6 shows that combining Feather-SQL with the 1+1 Model Collaboration paradigm yields state-of-the-art accuracy among small language models.

4.3 Ablation Studies

4.3.1 Component Contribution

Framework	EX (%)	EP (%)
Full Model	31.81	88.33
–w/o Schema Pruning	-4.63 ↓	-20.34 ↓
–w/o Schema Linking	-3.45 ↓	-20.92 ↓
–w/o Multi-Candidate	-2.47 ↓	-17.99 ↓
–w/o Correction	-0.20 ↓	-12.58 ↓
–w/o Selection	-2.21 ↓	-10.36 ↓

Table 5: Ablation Study on Framework Components.

We conducted an ablation study to quantify the impact of each framework component by removing them one at a time and measuring changes in EX and EP on the BIRD DEV dataset, using Qwen2.5-1.5B (Table 5).

We can see from the ablation results that removing any of the components causes a drop in both EX and EP. This underscores that each step in our pipeline contributes to overall performance, and omitting even one module leads to noticeably reduced accuracy or executability.
