## Abstract

This paper describes a multi-site project to annotate six sizable bilingual parallel corpora for interlingual content. After presenting the background and objectives of the effort, we describe the data set that is being annotated, the interlingua representation language used, an interface environment that supports the annotation task and the annotation process itself. We will then present a preliminary version of our evaluation methodology and conclude with a summary of the current status of the project along with a number of issues which have arisen.

lation (MT) and a range of other Natural Language Processing (NLP) applications. The project participants include the Computing Research Laboratory at NMSU, the Language Technologies Institute at CMU, the Information Science Institute at USC, UMIACS at the University of Maryland, the MITRE Corporation and Columbia University. In the remainder of the paper, we first present the background and objectives of the project. We then describe the data set that is being annotated, the interlingual representation language being used, an interface environment that is designed to support the annotation task, and the process of annotation itself. We will then outline a preliminary version of our evaluation methodology and conclude with a summary of the current status of the project along with a set of issues that have arisen since the project began.

## 1 Introduction

This paper describes a multi-site National Science Foundation project focusing on the annotation of six sizable bilingual parallel corpora for interlingual content with the goal of providing a significant data set for improving knowledge-based approaches to machine trans-

## 2 Project Goals and Expected Outcomes

The central goals of the project are:

- to produce a practical, commonly-shared system for representing the information conveyed by a text, or “interlingua”,

- to develop a methodology for accurately and consistently assigning such representations to texts across languages and across annotators,
- to annotate a sizable multilingual parallel corpus of source language texts and translations for IL content.

This corpus is expected to serve as a basis for improving meaning-based approaches to MT and a range of other natural language technologies. The tools and annotation standards will serve to facilitate more rapid annotation of texts in the future.

### 3 Corpus

The target data set is modeled on and an extension of the DARPA MT Evaluation data set (White and O'Connell 1994) and includes data from the Linguistic Data Consortium (LDC) Multiple Translation Arabic, Part 1 (Walker et al., 2003). The data set consists of 6 bilingual parallel corpora. Each corpus is made up of 125 source language news articles along with three translations into English, each produced independently by different human translators. However, the source news articles for each individual language corpus are different from the source articles in the other language corpora. Thus, the 6 corpora themselves are comparable to each other rather than parallel. The source languages are Japanese, Korean, Hindi, Arabic, French and Spanish. Typically, each article is between 300 and 400 words long (or the equivalent) and thus each corpus has between 150,00 and 200,000 words. Consequently, the size of the entire data set is around 1,000,000 words.

Thus, for any given corpus, the annotation effort is to assign interlingual content to a set of 4 parallel texts, 3 of which are in the same language, English, and all of which theoretically communicate the same information. The following is an example set from the Spanish corpus:

**S:** Atribuyó esto en gran parte a una política que durante muchos años tuvo un "sesgo concentrador" y representó desventajas para las clases menos favorecidas.

**T1:** He attributed this in great part to a type of politics that throughout many years possessed a "concentrated bias" and represented disadvantages for the less favored classes.

**T2:** To a large extent, he attributed that fact to a policy which had for many years had a "bias toward

concentration" and represented disadvantages for the less favored classes.

**T3:** He attributed this in great part to a policy that had a "centrist slant" for many years and represented disadvantages for the less-favored classes.

The annotation process involves identifying the variations between the translations and then assessing whether these differences are significant. In this case, the translations are, for the most part, the same although there are a few interesting variations.

For instance, where *this* appears as the translation of *esto* in the first and third translations, *that fact* appears in the second. The translator choice potentially represents an elaboration of the semantic content of the source expression and the question arises as to whether the annotation of the variation in expressions should be different or the same.

More striking perhaps is the variation between concentrated bias, bias toward concentration and centrist slant as the translation for *sesgo concentrador*. Here, the third translation offers a clear interpretation of the source text author's intent. The first two attempt to carry over the vagueness of the source expression assuming that the target text reader will be able to figure it out. But even here, the two translators appear to differ as to what the source language text author's intent actually was, the former referring to bias of a certain degree of strength and the second to a bias in a certain direction. Seemingly, then, the annotation of each of these expressions should differ.

Furthermore, each source language has different methods of encoding meaning linguistically. The resultant differing types of translation mismatch with English should provide insight into the appropriate structure and content for an interlingual representation.

The point is that a multilingual parallel data set of source language texts and English translations offers a unique perspective and unique problem for annotating texts for meaning.

### 4 Interlingua

Due to the complexity of an interlingual annotation as indicated by the differences described in the previous section, the representation has developed through three levels and incorporates knowledge from sources such as the Omega ontology and theta grids. Since this is an evolving standard, the three levels will be presented in order as building on one another. Then the additional data components will be described.

## 4.1 Three Levels of Representation

We now describe three levels of representation, referred to as *ILO*, *ILI* and *IL2*. The aim is to perform the annotation process incrementally, with each level of representation incorporating additional semantic features and removing existing syntactic ones. *IL2* is intended as the interlingua, that abstracts away from (most) syntactic idiosyncrasies of the source language. *ILO* and *ILI* are intermediate representations that are useful starting points for annotating at the next level.

### 4.1.1 ILO

*ILO* is a deep syntactic dependency representation. It includes part-of-speech tags for words and a parse tree that makes explicit the syntactic predicate-argument structure of verbs. The parse tree is labeled with syntactic categories such as *Subject* or *Object*, which refer to deep-syntactic grammatical function (normalized for voice alternations). *ILO* does not contain function words (determiners, auxiliaries, and the like): their contribution is represented as features. Furthermore, semantically void punctuation has been removed. While this representation is purely syntactic, many disambiguation decisions, relative clause and PP attachment for example, have been made, and the presentation abstracts as much as possible from surface-syntactic phenomena. Thus, our *ILO* is intermediate between the analytical and tectogrammatical levels of the Prague School (Hajič et al 2001). *ILO* is constructed by hand-correcting the output of a dependency parser (details in section 6) and is a useful starting point for semantic annotation at *ILI*, since it allows annotators to see how textual units relate syntactically when making semantic judgments.

### 4.1.2 ILI

*ILI* is an intermediate semantic representation. It associates semantic concepts with lexical units like nouns, adjectives, adverbs and verbs (details of the ontology in section 4.2). It also replaces the syntactic relations in *ILO*, like *subject* and *object*, with thematic roles, like *agent*, *theme* and *goal* (details in section 4.3). Thus, like PropBank (Kingsbury et al 2002), *ILI* neutralizes different alternations for argument realization. However, *ILI* is not an interlingua; it does not normalize over all linguistic realizations of the same semantics. In particular, it does not address how the meanings of individual lexical units combine to form the meaning of a phrase or clause. It also does not address idioms, metaphors and other non-literal uses of language. Further, *ILI* does not assign semantic features to prepositions; these continue to be encoded as syntactic heads of their phrases, although these might have been annotated with thematic roles such as *location* or *time*.

### 4.1.3 IL2

*IL2* is intended to be an interlingua, a representation of meaning that is reasonably independent of language. *IL2* is intended to capture similarities in meaning across languages and across different lexical/syntactic realizations within a language. For example, *IL2* is expected to normalize over conversives (e.g. *X bought a book from Y* vs. *Y sold a book to X*) (as does FrameNet (Baker et al 1998)) and non-literal language usage (e.g. *X started its business* vs. *X opened its doors to customers*). The exact definition of *IL2* will be the major research contribution of this project.

## 4.2 The Omega Ontology

In progressing from *IL0* to *IL1*, annotators have to select semantic terms (concepts) to represent the nouns, verbs, adjectives, and adverbs present in each sentence. These terms are represented in the 110,000-node ontology Omega (Philpot et al., 2003), under construction at ISI. Omega has been built semi-automatically from a variety of sources, including Princeton's WordNet (Fellbaum, 1998), NMSU's Mikrokosmos (Mahesh and Nirenburg, 1995), ISI's Upper Model (Bateman et al., 1989) and ISI's SENSUS (Knight and Luk, 1994). After the uppermost region of Omega was created by hand, these various resources' contents were incorporated and, to some extent, reconciled. After that, several million instances of people, locations, and other facts were added (Fleischman et al., 2003). The ontology, which has been used in several projects in recent years (Hovy et al., 2001), can be browsed using the DINO browser at <http://blombos.isi.edu:8000/dino>; this browser forms a part of the annotation environment. Omega remains under continued development and extension.

## 4.3 The Theta Grids

Each verb in Omega is assigned one or more theta grids specifying the arguments associated with a verb and their theta roles (or thematic role). Theta roles are abstractions of deep semantic relations that generalize over verb classes. They are by far the most common approach in the field to represent predicate-argument structure. However, there are numerous variations with little agreement even on terminology (Fillmore, 1968; Stowell, 1981; Jackendoff, 1972; Levin and Rappaport-Hovav, 1998).

The theta grids used in our project were extracted from the Lexical Conceptual Structure Verb Database (LVD) (Dorr, 2001). The WordNet senses assigned to each entry in the LVD were then used to link the theta grids to the verbs in the Omega ontology. In addition to the theta roles, the theta grids specify the mapping between theta roles and their syntactic realization in arguments, such as Subject, Object or Prepositional Phrase, and the Obligatory/Optional nature of the argument,

thus facilitating *IL1* annotation. For example, one of the theta grids for the verb “load” is listed in Table 1 (at the end of the paper).

Although based on research in LCS-based MT (Dorr, 1993; Habash et al, 2002), the set of theta roles used has been simplified for this project. This list (see Table 2 at the end of the paper), was used in the Interlingua Annotation Experiment 2002 (Habash and Dorr).<sup>1</sup>

#### 4.4 Incremental Annotation

As described earlier, the development and annotation of the interlingual notation is incremental in nature. This necessitates constraining the types and categories of attributes included in the annotation during the beginning phases. Other topics not addressed here, but considered for future work include time, aspect, location, modality, type of reference, types of speech act, causality, etc.

Thus, *IL2* itself is not a final interlingual representation, but one step along the way. *IL0* and *IL1* are also intermediate representations, and as such are an occasionally awkward mixture of syntactic and semantic information. The decisions as to what to annotate, what to normalize, what to represent as features at each level are semantically and syntactically principled, but also governed by expectations about reasonable annotator tasks. What is important is that at each stage of transformation, no information is lost, and the original language recoverable in principle from the representation.

## 5 Annotation Tool

We have assembled a suite of tools to be used in the annotation process. Some of these tools are previously existing resources that were gathered for use in the project, and others have been developed specifically with the annotation goals of this project in mind. Since we are gathering our corpora from disparate sources, we need to standardize the text before presenting it to automated procedures. For English, this involves sentence boundary detection, but for other languages, it may involve segmentation, chunking of text, or other “text ecology” operations. The text is then processed with a dependency parser, the output of which is viewed and corrected in TrED (Hajič, et al., 2001), a graphically-based tree editing program, written in Perl/Tk<sup>2</sup>. The revised deep dependency structure produced by this process is the *IL0* representation for that sentence.

In order to derive *IL1* from the *IL0* representation, annotators use Tiamat, a tool developed specifically for

this project. This tool enables viewing of the *IL0* tree with easy reference to all of the *IL* resources described in section 4 (the current *IL* representation, the ontology, and the theta grids). This tool provides the ability to annotate text via simple point-and-click selections of words, concepts, and theta-roles. The *IL0* is displayed in the top left pane, ontological concepts and their associated theta grids, if applicable, are located in the top right, and the sentence itself is located in the bottom right pane. An annotator may select a lexical item (leaf node) to be annotated in the sentence view; this word is highlighted, and the relevant portion of the Omega ontology is displayed in the pane on the left. In addition, if this word has dependents, they are automatically underlined in red in the sentence view. Annotators can view all information pertinent to the process of deciding on appropriate ontological concepts in this view. Following the procedures described in section 6, selection of concepts, theta grids and roles appropriate to that lexical item can then be made in the appropriate panes.

Evaluation of the annotators’ output would be daunting based solely on a visual inspection of the annotated *IL1* files. Thus, a tool was also developed to compare the output and to generate the evaluation measures that are described in section 7. The reports generated by the evaluation tool allow the researchers to look at both gross-level phenomena, such as inter-annotator agreement, and at more detailed points of interest, such as lexical items on which agreement was particularly low, possibly indicating gaps or other inconsistencies in the ontology being used.

## 6 Annotation Task

To describe the annotation task, we first present the annotation process and tools used with it as well as the annotation manuals. Finally, setup issues relating to negotiating multi-site annotations are discussed.

### 6.1 Annotation process

The annotation process was identical for each text. For the initial testing period, only English texts were annotated, and the process described here is for English text. The process for non-English texts will be, *mutatis mutandis*, the same.

Each sentence of the text is parsed into a dependency tree structure. For English texts, these trees were first provided by the Connexor parser at UMIACS (Tapanainen and Jarvinen, 1997), and then corrected by one of the team PIs. For the initial testing period, annotators were not permitted to alter these structures. Already at this stage, some of the lexical items are replaced by features (e.g., tense), morphological forms are replaced by features on the citation form, and certain constructions are regularized (e.g., passive) and empty arguments inserted. It is this dependency structure that

---

<sup>1</sup> Other contributors to this list are Dan Gildea and Karin Kipper Schuler.

<sup>2</sup> [http://quest.ms.mff.cuni.cz/pdt/Tools/Tree\\_Editors/Tree\\_d/](http://quest.ms.mff.cuni.cz/pdt/Tools/Tree_Editors/Tree_d/)

is loaded into the annotation tool and which each annotator then marks up.

The annotator was instructed to annotate all nouns, verbs, adjectives, and adverbs. This involves annotating each word twice – once with a concept from Wordnet SYNSET and once with a Mikrokosmos concept; these two units of information are merged, or at least intertwined in Omega. One of the goals and results of this annotation process will be a simultaneous coding of concepts in both ontologies, facilitating a closer union between them.

In addition, users were instructed to provide a semantic case role for each dependent of a verb. In many cases this was “NONE” since adverbs and conjunctions were dependents of verbs in the dependency tree. LCS verbs were identified with Wordnet classes and the LCS case frames supplied where possible. The user, however, was often required to determine the set of roles or alter them to suit the text. In both cases, the revised or new set of case roles was noted and sent to a guru for evaluation and possible permanent inclusion. Thus the set of event concepts in the ontology supplied with roles will grow through the course of the project.

## 6.2 The annotation manuals

Markup instructions are contained in three manuals: a users guide for Tiamat (including procedural instructions), a definitional guide to semantic roles, and a manual for creating a dependency structure (IL0). Together these manuals allow the annotator to (1) understand the intention behind aspects of the dependency structure; (2) how to use Tiamat to mark up texts; and (3) how to determine appropriate semantic roles and ontological concepts. In choosing a set of appropriate ontological concepts, annotators were encouraged to look at the name of the concept and its definition, the name and definition of the parent node, example sentences, lexical synonyms attached to the same node, and sub- and super-classes of the node. All these manuals are available on the IAMTC website<sup>3</sup>.

## 6.3 The multi-site set up

For the initial testing phase of the project, all annotators at all sites worked on the same texts. Two texts were provided by each site as were two translations of the same source language (non-English) text. To test for the effects of coding two texts that are semantically close, since they are both translations of the same source document, the order in which the texts were annotated differed from site to site, with half the sites marking one translation first, and the other half of the sites marking the second translation first. Another variant tested was

to interleave the two translations, so that two similar sentences were coded consecutively.

During the later production phase, a more complex schedule will be followed, making sure that many texts are annotated by two annotators, often from different sites, and that regularly all annotators will mark the same text. This will help ensure continued inter-coder reliability.

In the period leading up to the initial test phase, weekly conversations were held at each site by the annotators, going over the texts coded. This was followed by a weekly conference call among all the annotators. During the test phase, no discussion was permitted.

One of the issues that arose in discussion was how certain constructions should be displayed and whether each word should have a separate node or whether certain words should be combined into a single node. In view of the fact that the goal was not to tag individual words, but entities and relations, in many cases words were combined into single nodes to facilitate this process. For instance, verb-particle constructions were combined into a single node. In a sentence like “He threw it up”, “throw” and “up” were combined into a single node “throw up” since one action is described by the combined words. Similarly, proper nouns, compound nouns and copular constructions required specialized handling. In addition, issues arose about whether annotators should change dependency trees; and in instructing the annotators on how best to determine an appropriate ontology node.

## 7 Evaluation

The evaluation criteria and metrics continue to evolve and are in the early stages of formation and implementation. Several possible courses for evaluating the annotations and resulting structures exist. In the first of these, the annotations are measured according to inter-annotator agreement. For this purpose, data is collected reflecting the annotations selected, the Omega nodes selected and the theta roles assigned. Then, inter-coder agreement is measured by a straightforward match, with agreement calculated by a Kappa measure (Carletta, 1993) and a Wood standard similarity (Habash and Dorr, 2002). This is done for three agreement points: annotations, Omega selection and theta role selection. At this time, the Kappa statistic’s expected agreement is defined as  $1/(N+1)$  where N is the number of choices at a given data point. In the case of Omega nodes, this means the number of matched Omega nodes (by string match) plus one for the possibility of the annotator traversing up or down the hierarchy. Multiple measures are used because it is important to have a mechanism for evaluating inter-coder consistency in the use of the IL representation language which does not depend on the assumption that there is a single correct annotation of a

---

<sup>3</sup> [http://sparky.umiacs.umd.edu:8000/IAMTC/annotation\\_manual.wiki?cmd=get&anchor=Annotation+Manual](http://sparky.umiacs.umd.edu:8000/IAMTC/annotation_manual.wiki?cmd=get&anchor=Annotation+Manual)

given text. The tools for evaluation have been modified from previous use (Habash and Dorr, 2002).

Second, the accuracy of the annotation is measured. Here accuracy is defined as correspondence to a predefined baseline. In the initial development phase, all sites annotated the same texts and many of the variations were discussed at that time, permitting the development of a baseline annotation. While not a useful long-term strategy, this produced a consensus baseline for the purpose of measuring the annotators' task and the solidity of the annotation standard.

The final measurement technique derives from the ultimate goal of using the IL representation for MT, therefore, we are measuring the ability to generate accurate surface texts from the IL representation as annotated. At this stage, we are using an available generator, Halogen (Knight and Langkilde, 2000). A tool to convert the representation to meet Halogen requirements is being built. Following the conversion, surface forms will be generated and then compared with the originals through a variety of standard MT metrics (ISLE, 2003).

## 8 Accomplishments and Issues

In a short amount of time, we have identified languages and collected corpora with translations. We have selected representation elements, from parser outputs to ontologies, and have developed an understanding of how their component elements fit together. A core markup vocabulary (e.g., entity-types, event-types and participant relations) was selected. An initial version of the annotator's toolkit (Tiamat) has been developed and has gone through alpha testing. The multi-layered approach to annotation decided upon reduces the burden on the annotators for any given text as annotations build upon one another. In addition to developing individual tools, an infrastructure exists for carrying out a multi-site annotation project.

In the coming months we will be fleshing out the current procedures for evaluating the accuracy of an annotation and measuring inter-coder consistency. From this, a multi-site evaluation will be produced and results reported. Regression testing, from the intermediate stages and representations will be able to be carried out. Finally, a growing corpus of annotated texts will become available.

In addition to the issues discussed throughout the paper, a few others have not yet been identified. From a content standpoint, looking at IL systems for time and location should utilize work in personal name, temporal and spatial annotation (e.g., Ferro et al., 2001). Also, an ideal IL representation would also account for causality, co-reference, aspectual content, modality, speech acts, etc. At the same time, while incorporating these items, vagueness and redundancy must be eliminated from the annotation language. Many inter-event relations would

need to be captured such as entity reference, time reference, place reference, causal relationships, associative relationships, etc. Finally, to incorporate these, cross-sentence phenomena remain a challenge.

From an MT perspective, issues include evaluating the consistency in the use of an annotation language given that any source text can result in multiple, different, legitimate translations (see Farwell and Helmreich, 2003) for discussion of evaluation in this light. Along these lines, there is the problem of annotating texts for translation without including in the annotations inferences from the source text.

## 9 Conclusions

This is a radically different annotation project from those that have focused on morphology, syntax or even certain types of semantic content (e.g., for word sense disambiguation competitions). It is most similar to PropBank (Kingsbury et al 2002) and FrameNet (Baker et al 1998). However, it is novel in its emphasis on: (1) a more abstract level of mark-up (interpretation); (2) the assignment of a well-defined meaning representation to concrete texts; and (3) issues of a community-wide consistent and accurate annotation of meaning.

By providing an essential, and heretofore non-existent, data set for training and evaluating natural language processing systems, the resultant annotated multilingual corpus of translations is expected to lead to significant research and development opportunities for Machine Translation and a host of other Natural Language Processing technologies including Question-Answering and Information Extraction.

<b>Agent</b>	The entity that does the action	<b>Agent:</b> <i>load</i> <b>Theme</b> with possessed	SUBJ	OBLIGATORY
<b>Theme</b>	The entity that is worked on	<b>Agent:</b> <i>load</i> <b>Theme</b> with possessed	OBJ	OBLIGATORY
<b>Possessed</b>	The entity controlled or owned	<b>Agent:</b> <i>load</i> <b>Theme</b> with possessed	PP	OPTIONAL

**Table 1 : A theta grid for the verb "load"**

Role and Definition	Examples
<b>Agent:</b> Agents have the features of volition, sentience, causation and independent exist	<ul style="list-style-type: none"> <li>• <b>Henry</b> <i>pushed/broke</i> the vase.</li> </ul>
<b>Instrument:</b> An instrument should have causation but no volition. Its sentience and existence are not relevant.	<ul style="list-style-type: none"> <li>• <b>The Hammer</b> <i>broke</i> the vase.</li> <li>• She <i>hit him with a baseball bat</i></li> </ul>
<b>Experiencer:</b> An experiencer has no causation but is sentient and exists independently. Typically an experiencer is the subject of verbs like feel, hear, see, sense, smell, notice, detect, etc.	<ul style="list-style-type: none"> <li>• <b>John</b> <i>heard</i> the vase shatter.</li> <li>• <b>John</b> <i>shivered</i>.</li> </ul>
<b>Theme:</b> The theme is typically causally affected or experiences a movement and/or change in state. The theme can appear as the information in verbs like acquire, learn, memorize, read, study, etc. It can also be a thing, event or state (clausal complement).	<ul style="list-style-type: none"> <li>• <b>John</b> <i>went</i> to school.</li> <li>• John <i>broke</i> <b>the vase</b>.</li> <li>• John <i>memorized</i> <b>his lines</b>.</li> <li>• She <i>buttered</i> the bread <b>with margarine</b>.</li> </ul>
<b>Perceived:</b> Refers to a perceived entity that isn't required by the verb but further characterizes the situation. The perceived is neither causally affected nor causative. It doesn't experience a movement or change in state. Its volition and sentience are irrelevant. Its existence is independent of an experiencer.	<ul style="list-style-type: none"> <li>• He <i>saw</i> <b>the play</b>.</li> <li>• He <i>looked into</i> <b>the room</b>.</li> <li>• The cat's fur <i>feels</i> good <b>to John</b>.</li> <li>• She <i>imagined</i> <b>the movie to be loud</b>.</li> </ul>
<b>Predicate:</b> Indicates new modifying information about other thematic roles.	<ul style="list-style-type: none"> <li>• We <i>considered</i> him a <b>fool</b>.</li> <li>• She <i>acted</i> <b>happy</b>.</li> </ul>
<b>Source:</b> Indicates where/when the theme started in its motion, or what its original state was, or where its original (possibly abstract) location/time was.	<ul style="list-style-type: none"> <li>• John left <b>the house</b>.</li> </ul>
<b>Goal:</b> Indicates where the theme ends up in its motion, or what its final state is, or where/when its final (possibly abstract) location/time is. It also can indicate the thing/event resulting from the verb's occurrence (the result).	<ul style="list-style-type: none"> <li>• John <i>ran</i> <b>home</b>.</li> <li>• John <i>ran</i> <b>to the store</b>.</li> <li>• John <i>gave</i> a book <b>to Mary</b>.</li> <li>• John <i>gave</i> <b>Mary</b> a book.</li> </ul>
<b>Location:</b> Indicates static locations---as opposed to a source or goal, i.e., the (possibly abstract) location of the theme or event.	<ul style="list-style-type: none"> <li>• He <i>lived</i> <b>in France</b>.</li> <li>• The water <i>fills</i> <b>the box</b>.</li> <li>• <b>This cabin</b> <i>sleeps</i> five people</li> </ul>
<b>Time</b> Indicates time.	<ul style="list-style-type: none"> <li>• John <i>sleeps</i> <b>for five hours</b>.</li> <li>• Mary <i>ate</i> <b>during the meeting</b>.</li> </ul>
<b>Beneficiary:</b> Indicates the thing that receives the benefit/result of the event/state.	<ul style="list-style-type: none"> <li>• John <i>baked</i> the cake <b>for Mary</b>.</li> <li>• John <i>baked</i> <b>Mary</b> a cake.</li> <li>• An accident <i>happened</i> <b>to him</b>.</li> </ul>
<b>Purpose:</b> Indicates the purpose/reason behind an event/state	<ul style="list-style-type: none"> <li>• He <i>studied</i> <b>for the exam</b>.</li> <li>• He <i>searched</i> <b>for rabbits</b>.</li> </ul>
<b>Possessed:</b> Indicates the possessed entity in verbs such as own, have, possess, fit, buy, and carry.	<ul style="list-style-type: none"> <li>• John <i>has</i> <b>five bucks</b>.</li> <li>• He <i>loaded</i> the cart <b>with hay</b>.</li> <li>• He <i>bought</i> it <b>for five dollars</b></li> </ul>
<b>Proposition:</b> Indicates the secondary event/state	<ul style="list-style-type: none"> <li>• He <i>wanted</i> <b>to study for the exam</b>.</li> </ul>
<b>Modifier:</b> Indicates a property of a thing such as color, taste, size, etc.	<ul style="list-style-type: none"> <li>• The <b>red</b> book <i>sitting on the table</i> is old.</li> </ul>
<b>Null</b> Indicates no thematic contribution. Typical examples are impersonal <i>it</i> and <i>there</i> .	<ul style="list-style-type: none"> <li>• <b>It</b> was raining all morning in Miami.</li> </ul>
